Results: There are 357 patients suffered from severe preeclampsia among all obstetric 1588 patients at Dr. Soetomo Hospital. In 2017, 77 patients (21.57%) were treated conservatively while the remaining 280 patients (78.43%) were terminated directly or postpartum patients. Of the 280 patients, 258 (92.14%) were referred patients and 22 patients (7.86%) are self-referred patients. More than 50% of referred patients had been given some intervention such as O₂ installation, urinary catheter insertion, and iv line administration. In this study, 151 patients (58.53%) were given MgSO₄ while those according to administration were only 78.15%. The number of maternal deaths in severe preeclampsia/eclampsia patients were 18 patients and fetal complications that often occur are IUFD 29 babies and 25 babies born with IUGR.

Conclusion: More than 50% of severe preeclampsia/eclampsia referred patients in Dr. Soetomo Hospital had done a referral preparations but only 58.53% of referred patients given MgSO₄ as a form of pre-referral intervention.

Keywords: Preeclampsia, Pre-referral intervention

Introduction

One of the indicators of success in the health sector is the maternal mortality rate (MMR). Indonesia’s MMR in 2007 was 228 people and increased to 359 in 2012. This number is still far from the Sustainable Development Goals (SDGs) target which is 70 per 100,000 people in 2030. Preeclampsia is an obstetric problem in the world especially in developing countries that it’s increasing morbidity and mortality in both mother and fetus. The rate of preeclampsia in the world is 2% to 8% of all pregnancies. Preeclampsia-eclampsia is one of the causes of maternal death in Indonesia, which is around 12%. In 2007, 117 of 414 maternal deaths at East Java was caused by preeclampsia while in Dr. Soetomo Surabaya Hospital there was an increasing number of maternal deaths due to preeclampsia from 57% in 1999 to 60% in 2007. Pre-referral intervention...
is expected to reduce maternal and infant mortality rate due to preeclampsia-eclampsia. In Surabaya, especially in Dr. Soetomo Surabaya Hospital, there are no data regarding the pre-referral stabilization in patients with severe preeclampsia/eclampsia referred to the Dr. Soetomo Surabaya Hospital. This study tried to provide an overview of pre-referral intervention on referred patients with severe preeclampsia/eclampsia in Dr. Soetomo Surabaya Hospital and how the maternal and neonatal outcome was.

**Method**

This is a retrospective descriptive observational study by using medical records conducted at Dr. Soetomo Surabaya Hospital from January to December 2017. The population of this study were total pregnant or postpartum patients referred to Dr. Soetomo Surabaya Hospital in 2017 with severe preeclampsia/eclampsia.

During 2017, the total number of patients who came to the Dr. Soetomo Hospital was 1588 patients with 357 cases with severe preeclampsia/eclampsia both pregnant and postpartum. There were 77 patients (21.57%) were treated conservatively (giving fetal lung maturation, waiting until 34 weeks gestational age by monitoring fetal and maternal well being), while the remaining 280 patients (78.43%) were terminated directly (due to poor fetal condition, maternal condition and time to deliver) or postpartum patients. From all of the patients who directly terminated or postpartum, 258 patients (92.14%) were referred patients and 22 patients (7.86%) came by themselves to Dr. Soetomo Hospital.

The average age of these patients was 30.43 years old with the highest number in 17-34 group, which was on 176 patients (68.22%). Multigravida patients is more than primigravida with 177 (68.60%) compare to 81 (31.40%).

About the BMI, the highest BMI group was 25.0-29.9 (overweight). Almost all of the referred patient underwent antenatal care during pregnancy, only 7 patients (2.71%) did not undergo antenatal care. Mostly, the referred patients who did antenatal care were examined by an obstetrician and 208 patients (82.87%) did the antenatal care more than 4 times.

Most of the patients came from Surabaya (51.55%) and referred by secondary health facilities (72.48%) and 72.48% patients were treated only in one facility before reaching Dr. Soetomo Hospital. Twelve patients came by themselves to Dr. Soetomo Hospital, and never had been diagnosed with preeclampsia before. The transport time ranged from 8 to 443 minutes (mean: 70.07 minutes) and the distance ranged from 2.8 km to 274 km (mean: 45.25 km).

**Pre-referral interventions**

The patients had some interventions before getting referred. There is a standard procedure of prereferral management in Indonesia which every health care providers should follow which are providing oxygenation, urinary catheter insertion, infusion insertion, MgSO<sub>4</sub> administration as eclampsia prophylaxis including loading dose and maintenance dose.

There were 107 patients (41.47%) not given MgSO<sub>4</sub> before getting referred. Patients who were not given MgSO<sub>4</sub> included patients who were referred without transporter, patients with complications such as lung edema and patients not given MgSO<sub>4</sub> without information. Two patients were given a loading dose but did not match the procedure because the dose given only 2 grams intravenously. Patients who were not given maintenance doses including patients who came by themselves bringing referral note, patients with complication such as lung edema and patients who were not given according to procedure and level of health facilities.

There were 102 patients (39.53%) need ICU facilities. Most patients treated in ICU using a ventilator are patients with complications such as lung edema and eclampsia. Patients with length of stay more than 1 week are complicated patients such as eclampsia and acute kidney injury, HELLP syndrome, and DIC and all of these patients were died.

It was found that the number of maternal deaths in severe preeclampsia/eclampsia patients were 18 patients. From these patients, only 7 patients received MgSO₄ injection with appropriate procedure, 3 patients were given MgSO₄ but the method was not appropriate, and 8 patients were not given MgSO₄ that had complication such as of lung edema, 1 patient with suspected cardiac abnormalities, 1 patient came by herself, and 1 patient with post cesarean section 25 days ago.

The heaviest birth weight was more than 3000 grams which was 62 patients (22.88%). This data illustrates that referred patient with severe preeclampsia/eclampsia with a gestational age more than 34 weeks or late onset is more than early onset preeclampsia. The most common complication in severe preeclampsia/eclampsia patients is IUFD as many as 29 infants.

Discussion

During 2017, there were 357 cases of severe preeclampsia/eclampsia cases at Dr. Soetomo Hospital, both pregnant and postpartum. Study in Dr. Kariadi Semarang Province Hospital there were 1030 cases of preeclampsia/eclampsia during the 2013-2016, while in Dr. Soetomo Hospital in 2013-2014, Wardhana (2018) found that there were 1106 cases of preeclampsia/eclampsia (21%) from 5266 deliveries.³⁴

Based on the age, 31.01% patient with advanced maternal age. Too young or too old is a risk factor for preeclampsia. Maternal age more than 35 years old has risk of 1.5 times greater to be preeclampsia. At this age, women are more susceptible to systemic diseases such as hypertension, diabetes mellitus, and others.⁵

From the number of pregnancies, most of severe preeclampsia/eclampsia patients were multigravida compared to primigravida. Study by Erliana (2016) obtained more cases of severe preeclampsia happened in multigravida compared with primigravida. It is because many maternal factors influence such as maternal age, comorbidities, history of hypertension, etc.⁶ However,
ametanalysis study by Bartsch et al (2016), 25 studies showed nullipara was a risk factor to increased preeclampsia and found 32.2% in the preeclampsia population.7

Obesity is one of the factors that can increase preeclampsia incidence. In this study, the total number of obese patients was more than overweight and normal. One of the mechanism that links obesity with preeclampsia is inflammation. Adipose tissue produces several inflammatory mediators that can alter endothelial function.8

From the antenatal care, 7 patients did not undergo antenatal care during their pregnancy and all of them came from outside Surabaya. This was probably due to the public health centre is far from patient’s house or the patient’s awareness was low to get antenatal care. Antenatal care is an attempt to prevent preeclampsia. Initial information on antenatal care such as blood pressure before pregnancy can be used to distinguish between chronic hypertension and preeclampsia. Karima’s study at Padang Public Hospital found that there was no significant relationship between the number of antenatal care and the incidence of severe preeclampsia.9

The gestational age when admitted will affect the outcome of the baby and affect the decision that will be taken in severe preeclampsia/eclampsia patients. In this study, most of gestational age of the referred patients with severe preeclampsia/eclampsia was more than 34 weeks. This shows that most of the referral cases of severe preeclampsia/eclampsia in Dr. Soetomo Hospital are late onset. This is consistent with the theory that the incidence of late onset of preeclampsia is 75% of all numbers.10 Late onset of preeclampsia is associated with abnormalities in the maternal side such as obesity or gestational diabetes and according to the results of this study where the number of severe preeclampsia/eclampsia patients with obesity and overweight is more than normal BMI.

Dr. Soetomo Hospital as a tertiary hospital receives referrals from various health centers. The most frequent health facilities that made referrals were 2nd level of health facilities. This condition is in accordance with the referral pathway that if the patient requires further treatment which 2nd level of health facilities cannot handle, so the patient must be referred to the 3rd level of health facility immediately to get better services. However, if the case is too difficult to handle in 2nd level of health facilities, direct referrals to higher health facilities are carried out. This is expected to reduce the referral time so that patients get proper treatment immediately.

Almost 50% patients referred to Dr. Soetomo Hospital were not oxygenated. Catheter insertion is needed to determine the patient’s urine because in severe preeclampsia/eclampsia patients, the amount of fluid must be arranged so that there will be not overload condition causing further complications such as lung edema. From those who did not have a urine catheter, they included patients who came by herself and only given a referral note because they did not diagnosed with severe preeclampsia/eclampsia before.

The administration of MgSO4 is a kind of pre-referral stabilization in patients with severe preeclampsia/eclampsia. MgSO4 is drug of choice to prevent eclampsia. This drug is superior to diazepam and phentoin. Compared with placebo or without anti-seizures, MgSO4 can reduce 59% of the risk of eclampsia, 36% reduce placental abruption.11 The main purpose of giving MgSO4 in severe eclampsia patients is to prevent eclampsia. In addition, MgSO4 can also reduce maternal and perinatal mortality and morbidity even in severe eclampsia patients who do not experience seizures. Some studies found that administration of MgSO4 prophylaxis given to severe eclampsia patients was associated with a significant reduction in the incidence of eclampsia.12

The most common maternal complications that occurred in referred patients with severe preeclampsia/eclampsia in Dr. Soetomo Hospital in 2017 was lung edema and 39.53% of patients had to undergo treatment in the ICU and needed a ventilator in their care. Lung edema is one indication of ventilator used in these patients. As in Wardhana’s study, there were 50 cases (81%) of lung edema needed ICU and 37 cases (60%) needed a ventilator.4 In preeclamptic patients, endothelial dysfunction causes increasing in systemic vascular resistance and the proteinuria and systemic inflammation also cause decreasing in plasma oncotic pressure. This condition will make fluid extravasation into the surrounding tissue and lung edema can be happened easily. Acute Kidney Injury is one of the complications that can occur during the conservative treatment in severe preeclampsia patients. In this patients, the glomerulus becomes large and swollen. This event, together with the presence of overall vasoconstriction that occurs in
preeclamptic patients, cause 25-30% reduction in plasma flow and glomerular filtration compared to normal pregnancies. This condition will usually improve after labor.\textsuperscript{13}

**Conclusion**

More than 50% of referred patients with severe eclampsia/eklampsia during 2017 have been prepared properly by the referrer but not all patients are given MgSO\textsubscript{4} as a form of pre-referral interventions. Mismanagement about the administration procedure of MgSO\textsubscript{4} is still found.

Effect of Children’s Stunted Growth on Adult’s Obesity in Indonesia: A Longitudinal Study

Winda Mulia Ningsih1, Ratu Ayu Dewi Sartika1, Dodi Izwardi2

1Department of Nutrition, Faculty of Public Health, Universitas Indonesia.
2Directorate Community of Nutrition, Ministry of Health, Indonesia.

Abstract

Indonesia has been facing serious nutritional problems for many decades. Undernutrition has not been resolved, but overnutrition problems occur in all stages of life. This study was conducted to determine the effect of children’s stunted growth on adult obesity in Indonesia. The research design was a longitudinal study using secondary data from the Indonesian Family Life Survey (IFLS) 1 in 1993, IFLS 2 in 1997, IFLS 3 in 2000, IFLS 4 in 2007 and IFLS 4 in 2014. The population of this study was comprised of children who were observed until they became adults. Total eligible sample was 927 subjects. Our results showed the proportion of stunting in children aged 1–5 years to be 50.2% decreased at the age of 15–19 years old (25.1%). This contrasts with the proportion of obesity that increased when subjects were aged 5–9 years (1.6%) at the age 22–26 years old (14.4%). The analysis suggest that children’s stunted growth does not affect adult obesity. Father’s obesity status, living in urban areas, and low consumption of fruits and vegetables can affect adult obesity.

Keywords: Stunted growth, Obesity, Adult, Body Mass Index

Introduction

The prenatal period is the fastest growth phase and the growth rate will decrease during infancy period. In the period before puberty, growth will stabilise and will stop when entering adulthood.1,2 However, there are still many children that fail to achieve optimal growth due to health conditions and inadequate nutrient intake.3 This can be seen from the stunting prevalence of children in the world, with 23.8% of children under 5 years of age showing stunted growth.4

Indonesia was ranked the 25th in 2015 among 132 countries with a high prevalence of stunting and was classified as country with only a few advances in stunting improvement.5 Moreover, the 2007, 2010 and 2013 National Basic Health Study results indicate that Indonesia is categorised with heavy stunting.6,7,8 If this stunting problem is not immediately address, children will bear the consequences in the future.9

Several studies show that stunted children are at greater risk of obesity.10,11,12 Obesity does not only occur in adults, but also in children and adolescents.13 Beside that, being overweight and obese during childhood and the adolescent period can cause premature death and morbidity in adulthood.14 Therefore, the aim of this study was to determine the effect of stunting in infants on adult obesity (IFLS data in 1993 - 2014).

Material & Method

A longitudinal study of a fixed cohort population by periodic monitoring of subjects at the age of 1 – 5 years to 22 – 26 years. This study used a linked patient population from The Indonesian Family Life Survey (IFLS).

The sample in this study was stunted children who were in infants in 1993 and met the inclusion criteria as follows: 1) Children aged 1 – 5 years, 2) Biological
children and live births, 3) Children who were alive until at least 22 – 26 years, 4) Having complete information of sex, age, weight and height from 1993 to 2014. In total, 927 children were eligible for the study.

Bivariate analysis used chi-squared test and multivariate analysis with General Estimation of Equation Test (GEE).

Findings
The results showed the proportion of stunting in children aged 1–5 years to be 50.2% and which decreased at the age of 15–19 years old to be 25.1%. This contrasts with the proportion of obesity that increased when subjects were aged 5–9 years to be 1.6% and at age of 22–26 years old to be 14.4%. (Table 1).

Beside that the rate of obesity in all stunted children aged 1–5 years decreased after being followed for 14 years. However, there was an increase in the obese proportion when subjects were aged 22–26 years.

Table 1. Distribution frequency of stunted and obesity based on IFLS data in 1993, 1997, 2000, 2007, and 2014

Of the 927 respondents, only 449 respondents were able to be analysed in the final stage of observation. Based on the results of bivariate analysis, there were six variables significantly affecting obesity that is stunted, sex, father’s obesity, mother’s obesity, birth weight, and living area. From the latest modelling for GGE analysis, there were only three variables significantly affecting obesity at the age of 5–26 years (p< 0.05) (Table 2).

Discussion
During the 21 years study period, policies in Indonesia have only managed to prevent 2 out of 3 children from being stunted. According to IFLS data (1993), 1 in 2 subjects had stunted growth during infancy. Other data show that 1 in 3 children under five is stunted.7,8,15 Indeed, this achievement is not satisfactory as the reduction in stunting appears to be insignificant as many children still experience growth failure in prenatal and infancy periods. These factors were caused by unmodifiable risk factors (such as, age and sex), protective factors (i.e. household income and maternal education), and non-linear factors (i.e. maternal BMI and maternal age).16
As in other developing countries, the nutrition problem in Indonesia is quite serious. The ‘undernutrition’ problem has not been overcome properly, but there is now an ‘overnutrition’ problem emerging. Results of studies between 1997 – 2014 indicated an increase in the prevalence of obesity and a decrease in stunting prevalence as age increases. According to the WHO, a double burden is caused by the occurrence of nutritional, epidemiological and demographic transitions. These three types of transitions occur relatively quickly over the course of a few decades.  

The results of our study suggest that the prevalence of obesity in young adult aged 22 – 26 years (2014) was at 14.4%. Meanwhile, the results of National Basic Health Study indicated that the prevalence of obesity in the adult population (> 18 years) was 21.8 in 2018, 14.8% in 2013, and 10.5% in 2007. According to studies, boys have a higher likelihood to be overweight to obese than girls. The result same with our study, boys aged 5–9 years had a greater likelihood of obesity compared to girls of the same age and female subjects aged 22–26 years had a likelihood of obesity greater compared to males of the same age. However, the cause of obesity in children is not completely understood. In line with age, women are greater risk of obesity than men. Studies conducted in low- and middle-income countries indicate that women are more likely to be obese when they are aged 22 or older. Moreover, a study towards women aged ≥ 18 years had a risk of 9.88 - 27.80 times for obesity. The oestrogen hormone plays an important role in obesity in women. In addition, obesity in women is also caused by high intake of fat and fast food, less physical activity, eating when not hungry, coming from rich families, highly education, easy access to food, living in urban area, unemployed, living with a partner (married), using hormonal contraception and parity more than two.

There are also reports of a significant association between living in urban areas and obesity in children, adolescents, and adults. Similarly in our study, obesity observed in subjects aged 5 – 12 years and 22 – 26 years was influenced by living in urban areas. In fact, the age group of 30 years living in urban areas have an increased risk of obesity by 8 – 9.5 times higher compared to the rural areas. However, the relationship between residence and obesity in developing and developed countries are different due to cultural, socio-economic and environmental differences.

At the age of 8 – 19 years subject also influenced by birth weight ≥ 3500 grams. The results of a meta-analysis of 66 studies from 26 countries showed that the ‘high’ birth weight was associated with childhood and adult obesity. The children living in low- and middle-income countries will be obese if they have birth weight of > 3.5 kg. The parental obesity had increased risk factors of obesity at age 8–26 years. Genetic factors have an influence of 25 – 40% on the incidence of obesity and accordingly, parental obesity is a strong predictive factor for obesity in children and adolescents. Genetic influences on obesity are also due to the presence of concomitant factors. While parents are not solely responsible for gene structure, behaviour, attitudes, lifestyle and socio-economic can also affect risk of obesity.

Many studies have observed that stunting is a related to obesity. A study by Popkin et al. in Russia, Brazil, South Africa and China showed a significant association between stunting and overweight. However, our findings suggest that promotion of balanced nutrition programme needs to be expanded through the use of the latest types of social media, such as Facebook, Instagram, telegram and WhatsApp, in order to open insight and concern for society at large.

**Conclusion**

However, our findings suggest that promotion of balanced nutrition programme needs to be expanded through the use of the latest types of social media, such as Facebook, Instagram, telegram and WhatsApp, in order to open insight and concern for society at large.

Abstract

In Indonesia, Open Defecation Behaviour can be found in all age groups starting from children to the elderly, both male and female. Community Based Total Sanitation Data (2018) recorded that the number of families who still practiced Open Defecation in Pekalongan Regency were as many as 51,537 with open defecation access of 21.38%. The research aims to assess the median and trend of The Open Defecation Behaviour cases based on age groups. This research uses the nonreactive approach by referring to the secondary data from the result of Environmental Health Risk Assessment (EHRA) of Pekalongan District in 2017. The sampling unit is the households, in which respondents of 11,400 were taken by multistage random sampling, spread across 19 sub-districts. Based on the calculation of Chi-Square Test for Trend for Binomial Proportions (Cochran-Armitage), the value of $T_1 = 323.41798 > \text{table of Chi-Square } \chi^2 = 3.84 \text{ (} \alpha = 5\%)$, there were 91,200 individuals with a minimum number of Open Defecation Behaviour cases of 1,943, a maximum number of 20,857, and a median $= 11,400 \text{ (SD } = 9,242.844\text{) which was estimated to be at the age of 50 years. The findings are that there is a trend in cases of Open Defecation Behaviour according to age groups. The trend is increasing among the adults.}$

Keywords: Behaviour, Open Defecation, Age

Introduction

Behavioural development starts from infancy, children, adolescent, adult, to elderly.[1] The behaviour of an individual is influenced by several factors, one of which is age. In Indonesia, Open Defecation Behaviour can be found in all age group, from the children to the elderly.[2,3,4] In rural areas, many children defecate in the yard, gardens, and sewers.[3] Adolescents also seem to behave this way. The adult is the stage in which people should cognitively understand the disadvantages of Open Defecation Behaviour. However, many adults consider an urgent situation and a culture that is ingrained becomes a strong impetus for Open Defecation Behaviour. The elderly group of age is quite difficult to educate regarding the behaviour of defecating in healthy lavatories.[2] Open Defecation Behaviour means that the human practice of defecating outside in any open places, instead of in a healthy lavatory with a septic tank.[5] Healthy lavatories can be built as simple.[6] In other words, sanitation conditions are still relatively poor in the era of Sustainable Development Goals (SDGs) due to behavioural factors.[4] Especially in coastal areas, large riverside, rural or inland areas and areas with low economic conditions.[2,7] The main disadvantage of Open Defecation Behaviour is water sources are contaminated by Escherichia coli. The polluted water will enter the human body causing diarrheal disease. So it is not surprising that diarrheal diseases are increasing, especially among children under five and children.[8] In addition, the long-term effect will occurs that it will lead to the disorder in children’s growth, such as abnormalities in the body, known as stunting.[9] Stunting threatens children’s intelligence, children will be more susceptible to various degenerative diseases such as coronary heart disease, diabetes mellitus and obesity. Besides that, in the next few years we will find many dwarf generations. The Open Defecation case will also worsen the environment.
In Indonesia, there is no data providing the trend of Open Defecation Behaviour based on age groups. These data can actually support the planning of ‘Stop Open Defecation’ strategy according to age groups. Innovation in intervention is needed to reach the area of ‘Stop Open Defecation’ so that the strategy can be executed effectively. Research in India showed that mothers are the decision makers to provide toilet facilities in the households, however the reality showed that it really depended on the behaviour of the whole family members. Based on the data from Community Based Total Sanitation (2018), the number of families who still practiced Open Defecation in Indonesia were as many as 13,434,080, in Central Java Province as many as 1,177,564, and in Pekalongan Regency as many as 51,537. At present, Pekalongan Regency achieves sanitation access of 78.61%; Permanent Healthy Latrine access of 53.06%; Semi Permanent Healthy Latrine access of 9.66%; sharing access of 15.9%; and Open Defecation access of 21.38%. Therefore, the study aims to examine the median and trend of Open Defecation Behaviour cases based on age groups.

### Material and Method

Nonreactive approach is employed by using the secondary data in 2017 from the results of the Environmental Health Risk Assessment (EHRA) study in Pekalongan Regency, Central Java, Indonesia. The population and research sample according to the sampling technique in the EHRA study were multistage random sampling. The main sampling unit is households, the study area is all villages in Pekalongan Regency with total 285 villages with 40 respondents as the minimum sample of each village, so a sample of 40 respondents x 285 villages = 11,400 respondents in total, spread over 19 sub-districts. Respondents are mothers or daughters who are married and aged between 18-60 years. This research was limited to Open Defecation based on age. The data were indichotomic type. The Statistical Package for the Social Sciences (SPSS) software version 21.0 and Epi Info version 7.2.2.6 were used to process the data. The Median Test was used to analyse the data in order to determine the value of cut off and Chi-Square Test for Trend for Binomial Proportions (Cochran-Armitage). The results of the value of cut off and Chi-Square Test were then used to determine the trend of cases of Open Defecation Behaviour based on age groups.

### Findings

Pekalongan Regency is in the western coastal region, one of the 35 districts / cities in Central Java, Indonesia. The capital is Kajen. The area of Pekalongan Regency is around 836.1 km². According to the Pekalongan Regency Central Bureau of Statistics, in 2016 there were 880,092 people in Pekalongan Regency. Pekalongan Regency has 19 Subdistricts namely Kandang Serang, Palinggaran, LebakBarang, Petung Kriyono, Talun, Doro, Karanganyar, Kajen, Kesesi, Sragi, Bojong, Wonopringgo, Kedungwuni, Buaran, Tirto, Wiradesa, Siwalan, Karangdadap and Wonokerto. Geographically, Pekalongan Regency is a basically lowland and its southern regions are mountainous and rural areas or inland. In addition, the major rivers in Pekalongan are Sragi River and Sengkarang River and their watercourses leading to the Java Sea.

The study involved 91,200 individuals consisting of children, adolescents, adults and the elderly. The minimum number of Open Defecation Behaviour cases were 1,943, while the maximum amount were 20,857 (SD = 9,242.844), resulting Median value of 11,400 that was estimated involving individuals aged 50 years. The Median is the middle value of the Open Defecation Behaviour cases. The median is the limit or cut off to determine whether an individual is in the category of those who practice Open Defecation or those who stop practicing the Open Defecation. There were 11,155 individuals practicing the Open Defecation while 80,045 others stopped the practice. Each age group has n = 22,800 so that the total is 91,200 individuals. The proportion between the number of individuals practicing Open Defecation (x) with n in the age group of children = 0.1006; adolescents = 0.0852; adults = 0.1743 and elderly = 0.1290.

### Table 1. Cross Tables of Open Defecation Behaviour Cases by Age Groups

</tbody>
</table>
The conformity test with Chi-Square Test ($\chi^2$) showed that 0 cells (0%) has an expected less than 5. The minimum expected count is 2,788.75 with P value = 0.0000 indicating that there were differences between age groups practicing Open Defecation Behaviour ($\alpha = 5\%$). Chi-Square Test Value of Trend for Binomial Proportions (Cochran-Armitage) ($T_1$) = 323.41798. The value in the Chi-Square table with the degree of freedom (n-1) = 2-1 = 1, $\alpha = 5\%$ at 3.84. $T_1 = 323.41798 > (\chi^2) = 3.84$, so that the trend of Open Defecation Behaviour according to age group was obtained. Based on table 1, we can calculate the Prevalence Risk value for each age group. The adolescents is a reference group, in which the value of 0.0852 becomes the denominator of all proportions in the age groups, so that the Prevalence Risk value for the adolescent group = 1.000 was obtained. Prevalence Risk for children, adults and elderly groups was 1.1807, 2.0457, and 1.5140.

**Discussion**

In Indonesia the data on Open Defecation cases is not very accurate. Generally, the data presented is about the percentage of sanitation access, Open Defecation access, the number of families who are practice Open Defecation Behaviour and the number of villages that trigger the practice, starting from the national, provincial, district or city, sub-district to village or urban village levels. The presentation is usually presented globally and the data is not distinguished by gender or age groups. One example is the data on Community Based Total Sanitation which is managed by the Ministry of Health of the Republic of Indonesia and can be accessed online by anyone. So far, sanitation intervention has not been effective in changing Open Defecation Behaviour. The category of individuals practicing Open Defecation Behaviour is located between the range of 1 to 11,400 or below 11,400. The estimation between the median test and cross tabulation shows almost the same value. Meanwhile, the total number of individuals who stop practicing Open Defecation in all age groups is 80,045, this value is in the range of values between 11,401 to 91,200. The number of individuals practicing Open Defecation from the highest to the lowest is the adult age group with 3,975 individuals, the old age group with 2,943, the age group of children with 2,294 and the adolescents age group with 1,943. The adult age group dominates those who practice Open Defecation Behaviour. Thus, the proportion of individuals practicing Open Defecation from the highest to the lowest is as follows: the adult age group = 0.1743; old age group = 0.1290; the age group of children = 0.1006 and the teen age group = 0.0852.

The trend increased within the adults from 1,943 to 3,975. In the old age group the trend declined, but not significantly. The practice of Open Defecation in children depended on the attitudes and behaviour of parents, especially mothers.$^{[1]}$ In a family, the role of a mother is very important so that toddlers or children aged between 5-12 years have the habit of defecating in a latrine. Habits from an early age will affect their behaviour when they grow up. In India, Ghana and Kenya, Open Defecation Behaviour is still dominated by the age groups of children and adults.$^{[3,9]}$ The adolescents had a lower probability in practicing Open Defecation. They had some perceptions and attitudes towards the advantages and disadvantages of Open Defecation Behaviour. Aversion as well as to defecate inside the lavatory are some factors related to self-efficacy. Different from the adolescents, the elderly changed in attitudes and behaviours into a child-like and this factor becomes a challenge.$^{[15]}$ The habit of the elderly to defecate in the river or garden seems difficult to overcome. This is due to the reducing cognitive and motoric functions so that it is difficult to be given directions in how to defecate in healthy lavatories even though latrine access is available.
Prevalence Risk in adolescents had the smallest value, meaning that the adolescent age group was a protective factor of Open Defecation Behaviour. The elderly group was at risk of practicing the Open Defecation Behaviour by 1.5140 times that of the adolescent age group. The adult age group is at risk for Open Defecation Behaviour by 2.0457 times that of the adolescent age group. The adult age group with the highest number of risk of practicing Open Defecation Behaviour. The fundamental factor of the adult age group dominates Open Defecation Behaviour was due to urgent factors, low awareness, unhealthy habits that have been ingrained for such a long time. They also chose to defecate outside because they would feel more relieved whenever they defecated in the river than in the lavatory. This phenomenon was a habitual culture so that the adult age group didn’t like to be given some instructions and they basically didn’t feel shy to defecate openly. Therefore, the habit of practicing Open Defecation have been rooted to the conscience of individuals in the adult age group. Meanwhile, adolescents can be role models and need to be involved in sanitation activities such as Community Led Total Sanitation with religious leaders, community leaders and all village officials.[7] The elderly group in the countryside listened more carefully to the instructions from religious leaders during the religious gathering. The conversation about the Open Defecation Behaviour that is related to religious law by reading the related verses from Al Quran and Al Hadith is considered to be more effective.

Conclusion

Cut off in the number of Open Defecation cases and the increasing trend within the adult group were still quite high. This proved a serious challenge in facing 100% of ‘Stop Open Defecation’ area.

Abstract

This study aims to determine the relationship of the Body Mass Index (BMI) to the incidence of Tuberculosis. This is a cross-sectional study. The subjects in this study were people aged ≥18 years who were interviewed and had complete data. We investigated Tuberculosis-related factors in Indonesia associated with body mass index by controlling other confounding variables. Statistical analysis with p value <0.05 was considered significant. The prevalence of tuberculosis in respondents is 1%. Chi square test showed a significant relationship between body mass index and tuberculosis (p <0.001). Multivariate analysis showed that people with thin BMI were 2.54 times at risk of tuberculosis compared to people with normal BMI. Active discovery of Tuberculosis cases must be carried out to increase the number of case finding by involving the participation of the community and across sectors.

Keywords: Body mass index, Tuberculosis, Cross-sectional, Indonesia

Introduction

Pulmonary tuberculosis is still a public health problem globally. Since the adoption of the strategy directly observed treatment short (DOTS) in 1995, Indonesia has made rapid progress. Case finding rates are 71% and treatment success rates are 88.44%. This figure has met the global target, namely the case discovery rate of 70% and 85% treatment success.\textsuperscript{1}

Based on data from the Global Tuberculosis Report (2017), in 2016 the estimated burden of TB problems in Indonesia has not decreased significantly with the number of incidents of 1,020,000 people with TB and a rate of 391 per 100,000 population. In 2016 pulmonary TB mortality in Indonesia was 110,000 people with TB and 42 rates per 100,000 populations in groups outside of HIV + TB, 13,000 people with TB and a rate of 5.1 per 100,000 populations.\textsuperscript{2}

One of the risk factors for TB is a low body mass index (BMI). Low BMI can affect immune system function which acts as the body’s defense against various infectious diseases. Cellular immunity is part of the immune system which is the body’s defense system against TB.\textsuperscript{3} Nutritional status parameters that are very useful for following the development of acute and chronic diseases in a person are measurements of body weight and references to normal body weight referring to BMI, i.e. weight in kilograms divided by height in square meters.\textsuperscript{4}

A study states that the level of energy sufficiency affects nutritional status.\textsuperscript{5} Nutritional disorders can increase the risk of pulmonary tuberculosis.\textsuperscript{6} The relationship between malnutrition and pulmonary tuberculosis has been demonstrated by trials in the US in the 1960s and it has been estimated that malnourished children have twice the risk of pulmonary tuberculosis.\textsuperscript{7}

In addition to BMI factors, pulmonary tuberculosis is influenced by other factors such as diabetes mellitus, ventilation, occupancy density, and lighting,\textsuperscript{8} education level, history of BCG, history of contact with TB patients, water sources, and smoking,\textsuperscript{9} temperature, humidity, floor type,\textsuperscript{10} phlegm removal behavior,
coughing behavior, length of stay in detention, history of roommates\textsuperscript{11}, age, gender\textsuperscript{12}. Irawan et al study in 2017 proved that low nutrient intake is a risk factor for contracting tuberculosis. Body mass index can be said to be a risk factor for pulmonary tuberculosis\textsuperscript{13}. This study was conducted to determine the relationship of BMI with pulmonary tuberculosis.

**Method**

This study used a cross-sectional design using data from Indonesian Family Life Survey-5 in 2014.\textsuperscript{14} The survey collects information data on individuals, households and community levels using multistage stratified random sampling. The IFLS is a survey of longitudinal households using questionnaires and anthropometric measurements. The sampling framework was based on 13 households from 27 provinces in Indonesia selected to maximize the representation of the research population and which represented around 83\% of Indonesia’s population in 1993.\textsuperscript{15} The fifth wave of IFLS included 50,148 people of all ages. IFLS-5 was conducted in 13 provinces.\textsuperscript{16} The study population was the population who were the subjects of the IFLS-5 research in 2014. While the sample was the age group ≥18 years who took the interview and had complete questionnaire data. other confounding variables. Sampling is done by means of the total population because it meets the minimum sample requirements. So the sample analyzed in this study was 10,722 respondents.

We include demographic information, individual characteristics and behavioral factors as confounding. We categorize the level of education completed by respondents to low and high education levels, gender, while marital status is classified as unmarried and married. We included smoking behavior categorized as not smoking and smoking. We also included the characteristics of housing between ventilation that was categorized as sufficient and not, type of floor that was categorized as healthy (ceramics, tiles, cement) and unhealthy (plywood, bamboo, soil), roofs that were categorized as healthy (concrete, wood, metal plates, roof tiles) and unhealthy (asbestos, bamboo and leaves).

Body mass index (BMI <20 kg / m\textsuperscript{2}: thin; BMI 20 kg / m\textsuperscript{2}: normal) originating from height and weight measured during a physical examination, these criteria are determined based on the Republic of Indonesia Ministry of Health RI in 2013.\textsuperscript{17} Height was measured by the Shorr measurement board and the weight is measured using the Seca floor-scale model developed in collaboration with UNICEF. The floor-scale model has digital readings and is accurate to the nearest 0.1 kg. In this study measurements of body weight and height were carried out by interviewers or enumerators who were competent in their fields and had received prior training. Whereas Tuberculosis was known through the question of whether suffering from tuberculosis diagnosed by a doctor or paramedic and / or taking Tuberculosis drugs. Data analysis in this study was conducted to see the risk of BMI with the incidence of tuberculosis after controlled by covariate variables using logistic regression test with 95\% confidence level.\textsuperscript{18}

**Results**

Based on the incidence of tuberculosis, it was seen that 46.73\% of respondents had a thin BMI of the size, whereas in people who did not have tuberculosis only 31.69\% had a thin BMI (table 1).

Note: BMI: Body Mass Index

Based on the incidence of Tuberculosis, only 53.27% had a normal BMI while those who were not tuberculosis were 68.31% higher. In people who have tuberculosis, only 57.94% have adequate ventilation while those who are not tuberculosis are 85% higher. In people who have Tuberculosis 24.30% have an unhealthy roof while those who do not have less tuberculosis are unhealthy, 9.93%. In people who have Tuberculosis 32.71% have unhealthy floors while those who do not have less Tuberculosis are unhealthy which is 14.32%.

Stratification analysis has been done which shows that there is no interaction in the relationship between BMI and tuberculosis. Six confounding variables were obtained with ΔOR more than 10%, namely marital status, smoking status, history of DM, ventilation, roof and floor. In addition, it can be seen if there are 3 non-confounding variables in the relationship between BMI and Tuberculosis with ΔOR of less than 10%, namely age, sex, and education level so that it is not included in the final model below.

Discussion

In this study, the proportion of Tuberculosis in Indonesia in 2014 was 1% or 107 people out of 10722 respondents. Based on the results of the study it was also found that the proportion of normal BMI in Tuberculosis was 53.27% whereas in non-Tuberculosis people it was 68.31%, while the proportion of thin BMI in Tuberculosis was higher at 46.73% whereas in people not Tuberculosis was lower namely 31.69%.

The results of this study also showed that BMI had a significant relationship with the incidence of Tuberculosis in Indonesia in 2014. The results of the bivariate analysis showed that BMI of respondents had a relationship with the incidence of Tuberculosis. After multivariate analysis, it was found that the relationship between skinny BMI and Tuberculosis was 2.54 times (95% CI: 1.69-3.79), meaning that respondents with thin BMI had a risk of 2.54 times to experience Tuberculosis compared to normal after controlling for variable marital status, smoking status, history of DM, ventilation, roof and floor.

Globally, risk factors for the prevalence of TB infections have been found to vary across regions. A low body mass index (BMI) has been shown to be associated with a risk for the development of active TB. In addition, obesity (IMT≥30 kg / m²) and overweight (25 kg / m²≤IMT <25 kg / m²) were significantly lower risk of developing tuberculosis than individuals with normal weight (BMI, 18.5 to <25 kg / m²).

The correlation between body mass index and TB was first recognized by Hippocrates. Basically it is always assumed that there is a clear relationship between nutrition and TB. TB is also associated with poverty, which can cause malnutrition. TB causes children to miss school, and in adults causes increased costs of care, lack of productivity and the stigma of this disease causing social disturbances.

But does a low BMI predispose to TB or occur after TB infection? To answer this, it is necessary to look at the long-term effects of cohort studies that measure BMI before TB infection occurs. Palmer studied 68,754 members of the US Navy, a study conducted by Edwards to more than 823,000 members of the Navy found that TB developed 3 times more in young men (10%) or more under ideal body weight.

The strong association between TB and low BMI occurred in various TB incidents in various countries and in all BMI categories. If you see a 95% CI value: 1.69-3.79, it looks tight or quite narrow. This shows the results of the research obtained have good precision. In addition, based on the power of study calculation using the Lameshow formula, a strong power of study is obtained at 90%. So the results of the study might be generalized in the target population, namely the entire population of Indonesia and the population that has the same characteristics as the sample of this study. But the study used a cross-sectional design so that the relationship of the temporality of the variables in this study could not be ascertained.

Conclusions

Based on the study showed the proportion of Tuberculosis is 1%. In the bivariate analysis a significant association of BMI was found with the incidence of tuberculosis. Besides that, it was also known that the relationship between thin BMI and incidence of Tuberculosis was 2.54 (95% CI: 1.69-3.79) after controlled confounding variables which were previously bivariate analysis were only 1.89. In this study, it was
found that most TB patients had a thin BMI so that patients and non-TB patients were expected to keep their BMI normal to prevent the occurrence of TB and recurrence of TB disease. In addition, given the low prevalence of reported Tuberculosis cases, optimization of the search for Tuberculosis cases is needed so that transmission does not continue.

Determining Benzene Concentration Safe Level at Gas Stations in Pancoranmas Depok, Indonesia

Nurhayati Saridewi, Abdul Rohim Tualeka

Department of Occupational Health and Safety, Public Health Faculty, Airlangga University, Surabaya

Abstract

Benzene is a dangerous chemical compound contained in Gas Station product. It is one of components in gasoline containing carcinogens. Gas station workers are prone to the risk of benzene due to continuous exposure, which can endanger their health and safety. This study was aimed to determine benzene concentration safe level at gas stations in Pancoranmas, Depok. The design of this study was article review based on reviews of previous studies that were then analyzed.

The result of the study showed that benzene concentration safe level limit at gas stations in Pancoranmas, Depok, based on the calculation done was 0.3 ppm. This value was different from the values set by international and national institutions such as OSHA, NIOSH, ACGIH, ATSDR, the Indonesian National Standardization Agency and the Ministry of Manpower and Transmigration of the Republic of Indonesia. Therefore, reviews are needed to provide health and safety guarantees for the gas stations’ workers. The control recommendation for the gas stations’ workers exposed to benzene was the provision of Personal Protective Equipment (PPE) in the form of respirator organic vapor to minimize benzene exposure and green open space by planting a number of ornamental plants to absorb and reduce benzene exposure such as Spider Plant, Boston Fern, Peace Lily, Dutch Beteland Golden Pothos.

Keywords: Benzene, safe concentration, gas station worker.

Introduction

Benzene is a colorless liquid aromatic hydrocarbon compound with the characteristics of having fresh odor, evaporating quickly, is dissolved in water and easy to burn\(^1\). Cigarette smoke, gasoline burning and evaporation containing benzene (more than 5%), petrochemical industries, and combustion process are sources of benzene in the air. The higher levels of indoor and outdoor benzene are found around emission sources such as in gas stations\(^2\).

Gas Stations are public infrastructure provided for the community to meet their fuel needs. In general, gas stations sell fuel in the form of gasoline such as premium, pertalite, pertamax and pertamax plus. Gas station workers are prone to the risk of benzene due to continuous exposure, especially through inhalation. Gas station workers are constantly exposed to benzene because they are in the environment that emits benzene from the fuel pump engine when they help customers to do refueling, when refilling fuel at the storage warehouse, as well as when they inhale the exhaust from the vehicles during the refueling process. The benzene exposures endanger their health because it can increase the risk of cancer\(^3\). ATSDR (2007)\(^1\) also stated that benzene enters bodies through inhalation, oral and skin contact. Long-term exposure to benzene can cause cancer in blood-forming organs. This condition is called as leukemia. Benzene exposure is associated with the development of a type of leukemia called as Acute Myeloid Leukemia (AML).

An effort that can be taken to protect the workers against the hazard risks of benzene exposure by various institutions is through determining the Threshold Limit
Value (TLV) as the standard hazard factor in workplaces or Time Weighted Average (TWA) that is safe to workers without causing illness or health problems in their daily working time exceeding 8 hours or 40 hours per week. In Indonesia, several standards have been set TLV for benzene. In 2005, Indonesian National Standard stated that benzene was classified in group A2 (chemical that is estimated to be a carcinogen for humans) that has a TLV of 10 ppm. Moreover, the based on the Regulation of the Minister of Manpower and Transmigration of the Republic of Indonesia Number PER.13/MEN/X/2011 on Threshold Value of Physical and Chemical Factors in Workplace stated that benzene is classified in group A1 (chemical proven to be a carcinogen for humans) and has a TLV of 0.5 ppm. Some international institutions also set benzene exposure threshold. The Occupational Safety and Health Administration (OSHA) set benzene exposure threshold (PEL/Permissible Exposure Limit) at 1 ppm. The National Institute for Occupational Safety and Health (NIOSH) set benzene exposure limit in TWA of 0.1 ppm. The American Conference of Governmental Industrial Hygienists (ACGIH) of threshold limit value (TLV) set benzene exposure limit in TWA at 0.5 ppm. The Agency for Toxic Substance and Disease Registry (ATSDR) set the Minimum Risk Levels (MRLs) of benzene at 0.009 ppm for acute exposure, 0.006 ppm for moderate exposure and 0.003 ppm for chronic exposure.

This study was an article review study based on reviews of several studies that have been carried out previously and then were analyzed. Salim (2012) conducted a research on the analysis of the risk of benzene exposure in gas station workers which the sample data used was 15 workers consisted of 13 workers as pump engine operators and 2 administrative workers with an average body weight of 57.73 kg, the average respiratory rate was 0.6 m3/hour, and the average working time was 8 hours/day. The study found out that the result of benzene concentration measurement in the air from 15 points in the gas station service areas and administration areas in gas stations in Pancoranmas, Depok, showed the same value of 0.02 ppm. The data benzene concentration was obtained by using Coconut shell charcoal that was then analyzed by Gas Chromatography (GC). Although the benzene concentration was below the TLV set by the Republic of Indonesia Ministry of Labor, the fuel pump operators are prone to the carcinogenic effects in lifetime exposure. The next review was according to the research done by Tualeka (2013) about the safe limit of ammonia gas concentration in working environment. The average body weight of the data of 6 experimental white rats was 0.1405 kg with the average respiratory rate was 0.0013 m3/hour and the duration of exposure to ammonia gas was 8 hours every day. The data was used to determine the ammonia concentration safe limit as a reference to determine the ammonia threshold value in workplace.

According to the previous researches and differences in the determination of benzene TLV in working environment, and there has been no research on benzene concentration safe level in the Indonesian working environment, it is necessary to study the determination of concentration safe level (C safe) in working environment with benzene exposure. Gas station areas as working environment that have high benzene exposure should have benzene concentration with safe limit to prevent health and safety problems for workers. Therefore, based on the explanation above, the researcher conducted a study on determining the benzene concentration safe level at gas stations in Pancoranmas, Depok. According to William (1985), the safe limit of toxin in the air for workers can be used to predict the safe toxin concentration in working environment if there is no TLV determination and it also can be used as a comparison with the TLV set by some institutions.

The purpose of this study was to determine the benzene concentration safe level (C safe) in gas stations in Pancoranmas, Depok, which was preceded by calculating the body surface area (BSA) of the workers, the body surface area (BSA) of white rats as the experimental animal, the highest dose of toxin without effects on the Experimental Animals (NOAEL), the Km factors in animals (Animal Km), the Km factors in workers (Human Km), and the safe limit for toxin dosages for workers (SHD/Safe Human Dose).

**Findings:**

A. **The Characteristics and Body Surface Area of the Experimental Animals (White Rats):** Compounds can be used to determine the potential of chemicals that cause damage when entering the human body. Toxicity test usually used experimental animals, white rats, as the object. In general, human response to toxicity is qualitatively similar to the animals'. Therefore, this fact forms the basis of extrapolation from animal to human data.

Tualeka (2013) found out the characteristic data from 6 experimental white rats in the forms of weight
(W/Weight), respiration rate (BR/Breathing Rate) and exposure time (t/Time) according to the data in Table 1.

Furthermore, based on the body weight data of the experimental animals, the Body Surface Area (BSA) can be calculated by using the following formula\(^{11}\).

\[
\text{Animal BSA} = 0.09 W^{0.67}
\]

**Description:** BSA: Body Surface Area (m\(^2\)), W: Weight (kg)

Table 1. The Distribution of Characteristics and Body Surface Area of the Experimental Animals (White Rats)

</tr>
</tbody>
</table>

According to Table I, the results of the calculation analysis showed that the average Body Surface Area (BSA) of white rats was 0.024165 m\(^2\).

B. The Characteristics and Body Surface Area of the Workers: The characteristics data of gas station workers were obtained from the research conducted by Salim (2012)\(^8\) which included weight (W), worker breathing rate (BR) and length of working time (t/Time), according to the data in Table 2, whereas height (h) uses the average value of adult male height in Indonesia which is 159 cm.

Based on the data of the workers’ weight and height, the Body Surface Area (BSA) can be calculated by using the following formula\(^{11}\).

\[
\text{BSA} = \sqrt{W.h/3600}
\]

**Description:** BSA: Body Surface Area (m\(^2\)), W: Weight (kg), h: Height (cm)

Table 2. The Distribution of Characteristics and Body Surface Area of Gas Station Workers

<td></td>
<td></td>
<td>1.39</td>
</tr>
</tbody>
</table>

According to Table 2, the result of the calculation analysis showed that the average body surface area (BSA) of workers was 1.59 m\(^2\).

C. Animal Km and Human Km: The determination of safe dosage of toxin for workers is firstly done by calculating Animal Km and Human Km by using the following formula\(^{11}\).

1. Animal Km

\[
\text{Animal Km} = \frac{W \text{ animal}}{\text{BSA animal}}
\]

**Description:** Animal Km: Km factor in animals, W: Weight of the experimental animals (white rats), BSA: Body Surface Area of the experimental animals (white rats)

The calculation result for Animal Km can be seen in Table 3. The average Animal Km of white rats was 5.81.

Table 3. The Result of Animal Km Calculation of the Experimental Animals (White Rats)

D. Noael (No Observed Adverse Effect Level): One of the objectives of the research in toxicology field is to evaluate substances’ safety. To determine chemical concentration safe level, toxicity test is done to determine the highest dose without causing effects on the experimental animals or No Observed Adverse Effect Level (NOAEL).

Swaen et al. (2010)\(^{12,13}\) stated that the NOAEL of benzene was 3.0 mg/m\(^3\) or equivalent to 0.22 mg/kg obtained from the calculation of the average respiratory rate, average length of exposure and average body weight of white rats as follows.

$$\text{NOAEL benzene (mg/m}^3\text{)} = \frac{3 \times 0.0013 \times 8}{0.1405} = 0.22 \text{ mg/kg}$$

E. Safe Human Dose: The benzene safe level for workers exposed to benzene or Safe Human Dose (SHD) was determined by using the following formula\(^{11}\).

$$\text{SHD} = \frac{\text{Animal Km}}{\text{Human Km}}$$

Description: SHD: Safe Human Dose (mg/kg), Animal Km: Km factor in animals, Human Km: Km factor in humans/workers

Based on the formula, the result of SHD calculation obtained from the NOAEL value, the average animal Km, and the average human Km was:

$$\text{SHD} = \frac{(0.22 \times 5.81)}{35.96} = 0.04 \text{ mg/kg}$$

F. Benzene Concentration Safe Level: Benzene concentration safe level in working environment (gas station) was calculated by using the following formula\(^{11}\).

$$\text{C safe} = \frac{(\text{SHD})(W)}{(\alpha)(\text{BR})(t)} \text{ mg/m}^3$$

To convert mg/m\(^3\) to ppm, the following formula was used.

$$\text{C safe} = \frac{\# \text{ mg/m}^3}{(\text{MW})} \times 24.45 \text{ ppm}$$

Description: C safe: Concentration of toxin in the air that is safe for workers (mg/m\(^3\)), SHD: Safe Human Dose (mg/kg), W: Weight (kg), \(\alpha\): % of substances absorbed by the lungs, BR: Human breathing rate (m\(^3\)/hour), t: Working time (hours), MW: Molecular Weight

Based on the above formula, the results of the benzene concentration safe level calculation obtained from the SHD value, the average body weight, the percentage of absorption of substances, the average breathing rate of workers and the average length of working time was:

$$\text{C safe (mg/m}^3\text{)} = \frac{(0.04)(57.73)}{(50\%)(0.6)(8)} = 0.96 \text{ mg/m}^3$$

$$\text{C safe (ppm)} = \frac{\# \text{ mg/m}^3 \times 24.45 \text{ ppm}}{\text{BM}} = \frac{0.96 \times 24.45}{78.11} = 0.3 \text{ ppm}$$

Thus, it can be determined that the benzene concentration safe level (C safe) in gas stations (working environment) in Pancoranmas, Depok, was 0.96 mg/m\(^3\) or 0.3 ppm.

Conclusion

The benzene concentration safe level (C safe) in gas stations (working environment) in Pancoranmas, Depok, based on the calculations done in this study was 0.3 ppm. This value is different from the TLV determined by some international institutions such as OSHA, NIOSH, ACGIH and ATSDR. This value is also different from
the value set by some institutions in Indonesia such as the National Standardization Agency and the Ministry of Manpower and Transmigration of the Republic of Indonesia. Therefore, reviews are needed to provide health and safety guarantees for workers exposed to benzene, especially in Indonesia.

Workers at gas stations who are prone to benzene exposure need control efforts. The recommended control is the provision of Personal Protective Equipment (PPE) in the form of respirator organic vapor to minimize benzene exposure\textsuperscript{14} and green open space by planting a number of ornamental plants to absorb and reduce benzene exposure such as Spider Plant, Boston Fern, Peace Lily, Dutch Beteland Golden Pothos\textsuperscript{15,16,17}.

Relationship Patterns of Rest with Blood Chromium Levels of Workers at Leather Industry Magetan

Pipid Ari Wibowo¹, Abdul Rohim Tualeka², Noeroel Widajati³

¹Student at Department of Occupational Health and Safety, ²Department of Occupational Health and Safety, ³Department of Occupational Health and Safety, Faculty of Public Health, Airlangga University, Surabaya, East Java, Indonesia

Abstract

Operational processes in the leather industry use chemicals. One of them uses chromium sulfate as a tanner. Various studies have shown that there are health problems in tanning workers if exposed to chromium. The purpose of this study is to find out the relationship between resting patterns and levels of chromium in the blood of workers. Using a cross sectional design, there were 10 workers studied specifically handling the tanner’s process with a minimum ten-year tenure. The results showed that all respondents had chromium levels exceeding the standard according to Jantzen namely 1.6 µg/L-5.1 µg/L. The pattern of rest includes staying up late has a weak correlation with the levels of chromium in the blood, total rest also has a weak correlation with the levels of chromium in the blood, as well as rest at night. The metabolic process in the body plays a role in removing chromium toxins as long as workers carry out adequate resting activities. In conclusion, exposure to chromium during the tanning process causes high levels of chromium in the blood. The existence of a weak correlation between the break pattern variables shows that these variables do not affect significantly. Suggestions that workers use personal protective equipment so as to minimize exposure to chromium and take advantage of rest periods optimally.

Keywords: Chromium Sulfate, Rest Pattern, Chromium Levels In Blood.

Introduction

The leather industry or leather tanning is one of the community commodities that can support the economy in several regions in Indonesia. The leather industry produces finished leather that can be made into sandals, shoes, bags, jackets, and other fashion accessories. One process in the leather industry is the tanning process. In this process it aims to change the raw skin that is prone to damage due to the activity of microorganisms into tanned skin which is more resistant to these destructive factors using chemicals.

One of the chemicals used in the tanning process is using chromium sulfate. This is because chromium is able to react and form bonds with amino acids, collagen proteins¹. In addition, leather that is tanned using chrome has several advantages, including being suitable for the production of a variety of leather goods and having better compatibility with chemicals for the process of retanning and fatliquoring².

According to research Bregnbaket al (2014)³, as many as 80 (66%) allergic patients have a positive history of contact dermatitis caused by exposure to chromium through skin products. In addition, based on research Julander et al (2010)⁴ which examined skin deposition of workers in gas turbine production companies and space propulsion, it was found that although workers wash their hands several times after work, they will still be exposed to chromium exposure on the skin can contribute to deposition and risk of allergies.

Sleep or rest habits are very important factors in maintaining a healthy body. Because with enough sleep,
our focus and concentration will be maintained as long as we carry out activities. In addition, with enough rest, the natural processes that occur in the body also work optimally. The time, duration, and quality of sleep can affect endocrine, metabolic, and neurohormonal functions related to health. Sleep is an active time in which different brain wave patterns with unique physiological functions act in a progressive sequence. Sleep follows a pattern of rapid eye movement (REM), known as stage R, and non-REM (NREM) sleep throughout the night in a repetitive cycle itself approximately every 90 minutes. We spend 75% a night on NREM sleep and 25% on REM sleep. Enough sleep can regenerate damaged body cells to be new, expedite the body’s growth hormone, rest the tired body due to all day activities, increase the body’s immunity from disease attacks, increase concentration and physical ability, and improve the body’s metabolism.

Epidemiological and experimental studies have pointed to the relationship between lack of sleep behavior and the development of serious metabolic and endocrine consequences, especially diabetes mellitus. An interesting study was conducted on a group of 11 young men who underwent periods of sleep deprived of experimental sleep and extended periods of sleep after a normal initial six-night sleep duration. Glucose tolerance and acute insulin response to glucose are significantly altered during periods of lack of sleep.

The purpose of this study was to look at the relationship of rest patterns with chromium content in the blood of respondents in the Magetan leather industry.

**Material and Method**

Type of research is a descriptive study using quantitative analysis method. The design of this study is cross sectional where sampling of chromium levels in water resources and blood workers is done at one time in order to determine the level of risk of exposure to worker chromium in the tanning process. This research was conducted on leather tanning workers in 10 UKM in the area of UPT Leather Industry and Magetan Leather Products in East Java which was held in February 2018. The number of samples in this study were 10 workers using the total population method taken from 10 SMEs in the Leather Industry UPT area and Magetan Leather Products that work on the tanning process using chromium.

**Findings:** Chromium Levels in Skin Tanning Workers Blood: Results of examination of chromium (Cr) in the blood of workers tanning process:

![Figure 1. Testing Results of Chromium Levels in Worker’s Blood](image)

Figure 1 shows that the average levels of chromium in the blood of tanned workers is 36.1 µg/L with a minimum chromium level in the blood of 23.6 µg/L and a maximum of 48.3 µg/L. Based on Jantzen (2013), the chromium content in blood plasma is 1.6-5.1 µg/L so that the levels of chromium in the blood of tanned workers are all above the standard value according to Jantzen.
Resting Pattern

1. Stay Up at Night: Results correlation between the variables stay up all night with the chromium levels in the blood of respondents can be seen in Table 1 as follows:

<table>
<thead>
<tr>
<th>Variable</th>
<th>$R$</th>
<th>$N$</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chromium Value</td>
<td>-0.190</td>
<td>10</td>
</tr>
<tr>
<td>Stay Up at Night</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The results of the correlation test between the habit of staying up at night and the levels of chromium in the blood of workers showed that the correlation coefficient showed a correlation value of -0.190 with a very low negative relationship direction. The correlation value is negative, meaning that the more frequent tanned workers stay up at night, the lower the chromium level in the blood.

2. Total Rest: The results of the variable correlation between total rest or sleep at night with chromium levels in the blood of respondents can be seen in table 2, as follows:

<table>
<thead>
<tr>
<th>Variable</th>
<th>$R$</th>
<th>$N$</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chromium Value</td>
<td>-0.355</td>
<td>10</td>
</tr>
<tr>
<td>Total Rest</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Table 2 shows the test results of the correlation between the total number of workers who tanned tanners with chromium in blood. The correlation coefficient shows a value of -0.355 with a negative relationship direction and is in the area of a low relationship. This means that the more frequent the rest, the lower the level of chromium in the blood of tanning workers.

3. Sleeping at Midnight: The results of the variable correlation between sleeping at midnight and the levels of chromium in the blood of skin tanning workers can be seen in table 3, as follows:

<table>
<thead>
<tr>
<th>Variable</th>
<th>$R$</th>
<th>$N$</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chromium Value</td>
<td>-0.348</td>
<td>10</td>
</tr>
<tr>
<td>Sleep at Midnight</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Table 3 shows the results of the correlation between the habits of workers sleeping at midnight with levels of chromium in the blood. Correlation results showed a correlation coefficient of -0.348 with a low negative relationship and relationship strength. This means that the more often leather tanning workers sleep at midnight (sleeping between 23.00 WIB-01.00 WIB), the lower the chromium content in the body of the worker.

One reliable indicator to find out the exposure of chromium to workers in the tanning industry is blood serum. This is because the toxic material that enters the body will be distributed by the blood so that the blood of workers exposed to chemicals or toxic substances can be seen clearly and validly. Based on the research, the average value of chromium in the blood of tanners is 36.1 µg/L. According to the research conducted by Jantzen et al. (2013), the chromium content in the blood is 1.6 µg/L-5.1 µg/L so that the chromium content in the worker’s blood exceeds the standard value proposed by Jantzen\textsuperscript{7}.

Workers in the leather industry are accustomed to being exposed to chemicals used during the tanning process. One of them is exposed to chromium sulfate as the most used tanner in the leather industry. Chromium material can enter the body through the respiratory system. This is because chromium sulfate is in the form of powder which has the potential to spread into the air if it is not done carefully. In addition, exposure to chromium sulfate is the most risky, namely through contact with workers’ skin. This is because chromium sulfate is mixed with water in the tanning process so that exposure to chromium through the medium of water becomes very possible and has great potential to enter the body of the worker through the skin.

The content of chromium in the blood of workers that exceeds the standard value will potentially cause health problems in the body. According to research conducted by Ateeq et al. (2016)\textsuperscript{8}, that the use of chromium in the tanneries industry results in reproductive abnormalities, respiratory problems and stomach. However, skin disorders are a dominant problem due to direct contact with workers’ skin. Chromium sulfate has the potential to bind proteins to the skin and produce complex antigens that lead to hypersensitivity and dermatitis. During the tanning process, occupational exposure to toxic chemicals and microbial agents, namely mycotoxins and endotoxins, is one of the main reasons for health hazards. These findings indicate that exposure to chromium work...
can cause reproductive abnormalities, skin dermatitis and asthma-related problems in tanning workers.

This research is in line with research Danadevi et al (2004)\textsuperscript{9} which shows that DNA damage is positively correlated with blood chromium concentration. The mechanism of Cr poisoning has been linked to oxidative stress. Excessive reactive oxygen production causes lipid peroxidation, which adversely affects cell structure, nucleic acids and lipids. Other studies have shown that the high content of chromium in the blood correlates with increased oxidative stress and DNA damage. This study also shows that long-term exposure to chromium will be absorbed by the body and distributed to various tissues of the body and exposed organs of workers. DNA damage and levels of blood chromium in the blood can be an efficient biomarker for tanners who are exposed to chromium\textsuperscript{10}.

Based on the results of statistical tests show that the correlation coefficient indicates a very low strength of the relationship between staying up variables, while the variable total rest and sleep at midnight has a low relationship strength. Variables staying up late, total rest and sleep at midnight have a correlation coefficient that has a negative sign so that the higher the variable value, the lower the chromium level in the blood of the respondent.

Sleep or rest habits are very important factors in maintaining a healthy body. Because with enough sleep, our focus and concentration will be maintained as long as we carry out activities. In addition, with enough rest, the natural processes that occur in the body also work optimally. Sleep is a condition that is repetitive, changes in state of state that occur during a certain period\textsuperscript{11}.

Sleep or rest at night has an important role in the body’s metabolic processes. By having adequate rest, workers can concentrate on the work that will be done tomorrow so that it can reduce the number of workplace accidents in the workplace. According to Patricia et al (2005)\textsuperscript{11}, sleep also has a role to restore disease, control pain, reduce fatigue, increase blood circulation to the brain, increase protein synthesis, balance the mechanisms against diseases of the immune system, help the body detoxify and remove toxins in body, increases cell repair and growth, improves healing and decreases tension.

Lack of sleep or disturbed sleep is clearly detrimental to our health and performance during the day. Starting from lack of motivation, decreased ability to concentrate and memory, to bad moods. Condition of sleep deprivation also decreases a person’s immune system. The most obvious effect of sleep deprivation is on skin that looks dull and not fresh\textsuperscript{12}. The impact of sleepiness/overslept during the day can threaten work safety, including driving a vehicle, and a bad night’s sleep, can reduce the ability to fulfill daily tasks and not enjoy life activities\textsuperscript{13}. Insomnia is also a sleep disorder that can interfere with other body functions. Insomnia can result in decreased production of the hormone melatonin so that the process of repairing damaged body cells does not work perfectly, memory disorders, mood disorders, loss of enthusiasm and motivation so that daily activities can be disturbed and easily emotional. Insomnia can also lead to diseases such as muscle pain and hypertension\textsuperscript{14}.

**Conclusion**

The content of chromium in the blood of tanners of all respondents exceeds the normal level of chromium in the blood. The results of the analysis of the relationship between rest patterns with chromium content in blood indicate a weak relationship so that further research is needed regarding other variables that are more likely. Suggestions for SME entrepreneurs to provide personal protective equipment to reduce the impact of chromium exposure In addition, it is expected that workers do not carry out activities at night which can interfere with rest periods.

The Behavior of Adolescent Mosque toward Earlier Introduction Tuberculosis Diseases in Kekait Village West Lombok

Agus Supinganto¹,², Irwan Budiana³, Ni Ketut Metri⁴

¹Doctoral Student, Department of Medical Science, Faculty of Medical, Udayana University, Bali, ²Lecturer at High School of Health Science Yarsi Mataram, West Nusa Tenggara, ³Lecturer of Health Ministry Polytechnic Kupang, East Nusa Tenggara, ⁴Nurses Health Center Gunungsari, West Nusa Tenggara, Indonesia

Abstract

Background: Tuberculosis incidence rate is still quite high in Indonesia. Behavioral knowledge, attitudes, and skills of mosque adolescent about early recognition of tuberculosis disease is very important to know in order to be able to support government programs in prevention of transmission and increase the findings of new suspects in the community. The purpose of this research is to know the knowledge, attitudes, and skills of an adolescent mosque in the early introduction of tuberculosis disease.

Method: The type of research used was descriptive with the Household Survey approach of all adolescent mosques with a total sample of 40 people with sampling using the Purposive Sampling method. Data collection is done using a questionnaire that has been tested by validity and reliability and the data obtained are presented in the form of a frequency distribution table. While the data analysis used in this study is univariate analysis.

Results: An overview of the knowledge of adolescent mosques about the introduction of Tuberculosis is still lacking as many as 16 respondents (40.0%). While the attitudes of adolescent mosques about the early introduction of tuberculosis are sufficient, namely as many as 17 respondents (53%). Awareness of respondents who are still minimal also influences adolescent behavior in recognizing various health problems, one of which is tuberculosis.

Conclusion: The lack of knowledge and attitudes of adolescent mosques in the early introduction of tuberculosis has an impact on skills in recognizing the signs and symptoms of tuberculosis.

Keywords: Behavior, youth mosque, early recognition, tuberculosis.

Introduction

Tuberculosis disease prevention efforts have been done through various health programs, but the results are still not quite as expected and the tuberculosis incidence rate is still quite high in Indonesia. Based on data from West Nusa Tenggara Province Health Office in West Lombok regency in the number of smear positive tuberculosis patients is 560 people. The achievement of Case Detection Rate (CDR) of 42.98% which is still far from the target of 70% of CDR. The result of the hearing with the Tuberculosis officers at the Gunung Sari health care center obtained information on the occurrence of dropout treatment (Tuberculosis defaulters) because the patient felt healed, and there are still some events Multi-Drug Resistant (MDR). There is still a shortage of officers handling Tuberculosis programs, as well as a wide range of areas and weak community participation and awareness in supporting Tuberculosis control programs.

DOI Number: 10.37506/v10/i12/2019/ijphrd/192182
The stigma that is not good in the community against Tuberculosis sufferers is still there so people do not want to come to check their health. Coughing complaints experienced are considered a normal cough. And still, there is a presumption of sickness experienced because it is handled so there are still people who come to the shaman medication. The low level of public knowledge so that ignorance about the signs and symptoms of tuberculosis itself, as well as feel the old treatment. Early introduction of tuberculosis disease in West Lombok regency has never involved adolescent mosques, whereas adolescent mosques have strategic value to be empowered.

The potential of adolescents to improve their knowledge, attitude, and skill directly in the community is very good because the level of curiosity of adolescents is very high. This is certainly in line with government programs to increase community participation in efforts to improve health status. This strategy can exploit adolescents potential to increase the coverage of Tuberculosis patients. From the description on the background of the problem can be asked the formulation of the problem of how the behavior of knowledge, attitudes, and skills of an adolescent mosque in the early recognition of tuberculosis disease. While the purpose of this paper is to know the knowledge, attitudes, and skills of an adolescent mosque in the early introduction of tuberculosis disease.

**Material and Method**

This study is descriptive survey research with a household survey approach. Primary data was obtained directly from the adolescent mosque by using questionnaires as an instrument of data retrieval research and from interview and observation of researcher directly, meanwhile secondary data obtained from the district health office of West Lombok. The population in this study are all adolescent mosques in Kekait village Gunungsari District West Lombok regency, which amounts to 40 adolescent mosques. The sample in this research is 40 adolescent mosque using the purposive sampling method. Data obtained from the questionnaires.

From table 5 shows that the majority of mosque adolescent skills about early recognition of tuberculosis disease is enough that 17 respondents (42.5%) and the lowest is good category as many as 11 respondents (27.5%).

Discussion

The Knowledge of Youth Mosques in Early Introduction of Tuberculosis Disease: In the knowledge variables in this study, data were collected through questionnaire instruments. The interview is a method used to collect data, where researchers get information from a target research. Interviews can also be helpful in observation. The purpose of the interview is not just to get an oral number but also to get a direct impression of the respondent, assess the truth of the respondent, read the respondent’s expression, explain the question if not understood and provoke a jammed answer.

From the result of research, the knowledge of adolescent mosque in early recognition of Tuberculosis disease is the least category which is 16 respondents (40.0%), and the smallest is the knowledge of good category respondent is 11 respondents (27.5%). The knowledge of youth of the mosque in early recognition of Tuberculosis disease is needed as an effort to prevent the spread of disease in society. Level of knowledge of adolescent mosque in early recognition of Tuberculosis disease influenced by several factors one of education and training.

Knowledge can be the basis for a person before the person adopts the behavior. So knowledge is one important part that needs to be known in the analysis of one’s behavior. Knowledge can be influenced by factors such as formal education. Knowledge is closely related to education, which is expected that with a high education then someone will be more knowledgeable. If seen from the distribution of education, education most of the respondents can be classified as being heading low because of more graduates of junior high school and elementary school.

Respondents in this study have wrong answers in answering certain questions. This shows that the level of knowledge of some new respondents to the level of know. Though the know stage is the lowest level of knowledge, because the respondent can only mention, describe a little, define, and ask. Respondents have not reached the level of conclusion and level of problem solving.

The knowledge is also the result of human sensing of certain objects influenced by intensity, especially influenced by the sense of hearing and sight. Based on it can be concluded that high knowledge is not absolutely influenced by formal education but can also be caused by the sensing process with the exposure of respondents on health-related information. The results showed that the majority of respondents age ≥20 years with the same percentage of 20.0%. With the age of a person, there will be changes in physical and psychological aspects. Growth on the physical aspects matures the development of organs while the psychological or mental aspects affect the level of thinking a person so that more mature and mature. However, with increasing age, the brain’s ability to capture knowledge will decrease. These results indicate that the age of respondents has maturity so that it can affect the level of thinking, but its ability to capture or absorb knowledge can decrease.
The Attitude of Youth Mosque In Early Treatment of Tuberculosis Disease

Attitude is a variable that needs to be observed because attitude can be the basis for behavior formation. Based on the scale of Likert opinion assessment attitude is divided into 5 categories namely: strongly agree, agree, doubtful, disagree and strongly disagree. In this questionnaire, attitude is measured using Likert scale with the gradation of questions from very positive to the very negative. A positive attitude means good behavior in accordance with the values and norms of life prevailing in society. While the negative attitude is an attitude that is not proper with values and norms of life prevailing in society or even contradictory.

The results showed that the majority of mosque adolescent attitude about early recognition of tuberculosis disease was enough that 17 respondents (53%) and the lowest was a good category as many as 10 respondents (6.7%). Attitudes according, is a closed response to a stimulus but involves the factors of opinion and emotions concerned (happy-not happy, agree-disagree, positive-negative, etc.). The difference between attitudes and behavior of respondents can be caused by a closed reaction of respondents to the researcher so that the information obtained may not be able to describe the actual situation. When viewed from the item statement of a certain attitude, will be illustrated statements which are actually still unknown respondents.

In accordance with the theory attitude is a closed reaction to an object that is a tendency to behave (behave) with certain patternsto the object. Attitude is a response in an abstract form that cannot be seen, so it is still possible for respondents to lie.

Mosque Teens Skills In Early Treatment Of Tuberculosis Disease: In this variable, interviewed by using a questionnaire to find indications of youth behavior of the mosque. According, behavioral measurement can be done by measuring behavior indirectly. Indirect behavior measurement can be done by interviewing activities that have been done several hours, days, or months ago. The results of this study indicate that the majority of adolescent youth skills about early recognition of tuberculosis disease is enough that 17 respondents (42.5%) and the lowest is a good category as many as 11 respondents (27.5%).

According to, basically a form of behavior can be observed through attitudes and actions. But it does not mean that behavior can only be seen from attitudes and actions alone. Behavior may be potential ie from the form of research, motivation and perception. With the perception of the individual is aware to understand the circumstances surrounding the environment as well as about things that exist within the individual concerned. There are three main components in the perception process: the selection component, the interpretive component (interpretation), and the component are translated to the behavioral. In addition, awareness also has an effect on adolescent behavior in recognizing various health problems one of them tuberculosis disease. Awareness is the stage where a person realizes or knows first about the stimulus.

Conflict of Interest: The author(s) declared no potential conflicts of interest with respect to the research, authorship,and/or publication of this article.

Acknowledgment: The authors thank all students participating in this study. Special thanks to LPDP for its contribution regarding financial support.

Health Information Systems (HIS) as a Tool for
Transformative Learning of Health Care Practitioners
in Resource Constraint Environment

Alfred Coleman
Associate Professor and Chair of Department School of Computing, University of South Africa

Abstract

The increase in the quantity of medical research output do not translate into the improvement of patient care and treatment. This is because healthcare professional in resource constraint environment do not learn and implement these new research outcomes. These studies investigated how transformative learning could be incorporated as a tool on existing Health Information system (HIS) to assist healthcare professionals. The study employed a case study approach in collecting data. Data was collected using semi-structured open-ended interviews. It was revealed that structured learning programs or tools were necessary but not available to facilitate the implementation of learning new research outcomes despite the hospitals having some standalone HIS in place. Based on the findings the researcher proposed an Integrated Health Information System framework (IHISF) which was underpinned by transformative teaching and learning theory and tool. This is to assist physicians in remote hospitals to learn and implement newly published research findings in their practices. The IHISF did not only meant to assist doctors to learn but to help them share new ideas with their counterparts in other remote regions.

Keywords: Health Information System, Physicians, Transformative learning, self-reflection, ICT.

Introduction

The proliferation of recent medical devices and the speedy healthcare research, regularly produces giant amounts of results and revised ways of treatment and care for patients, which, if enforced in practice, will potentially save lives and improve the standard of life of patients. Nevertheless, the increase in new research output do not mechanically translate into improved patient care and treatment. There is a broad proof that there is a considerable gap between the health care that patients receive and the new practice that researchers suggest. This is also referred to as “research and practice gap”, evidence and practice-gap or knowing and doing gap. This is because of physicians’ failure to learn the outcomes of those health care research innovations in other to translate them into their practices. The failure to translate new research findings into practice is exacerbated in cases where freshly trained physicians from university are deployed to rural communities were health care facilities are restricted and overladen with high number of patients. The physicians are unable to reflect on what they learned from university and to adopt new innovative research into their practices. Reflection on previous practices in order to unlearn these practices and learn new practices is termed transformative learning. A range of things are projected to account for the problem of “unlearning so as to learn”. Though physicians have difficult time adopting new practices, they appear to own a good harder time which is “unlearning” old-fashioned ones. Unlearning “old-fashioned” health care practices in order to learn new health care research based practices may be improved through Information and communication Technology (ICT). These new technologies play a significant role for instructional directions, information sharing of different tasks. Coleman contends that there is a great potential in using information system(IS) as one of the supportive systems within the health care system to handle pressing challenges facing health care systems in developing countries. However, Ehealth initiative group resolutely maintains that the recognition of health information system and its associated technologies not an end unto itself but a means to an end.
The objective of this paper is to investigate the level of HIS usage and its potential as a transformative learning tool for physicians in resource constraint environment. Based on the findings, an Integrated Health System HIS framework is compiled to help physicians learn and implement newly research findings in their practices.

The proceeding sections of this paper are presented as follows: related work, method, results and discussion, proposed Integrated Health care system Framework (IHISF) and finally the conclusion of the paper.

Transformative learning of healthcare professional's quandary

Disorienting Dilemma: Transformational learning involves ever-changing existing beliefs and thought patterns through the employment of discourse and demanding reflection. Ideally, the learner develops an open and accommodating idea of the subject or world. Beyond subject content, transformative learning develops skills for progressive autonomous thinking. According to Mezirow, transformative learning will involve any combination of religious, political, emancipatory, or developmental elements. Transformational learning happens in formal or informal learning environments and is expedited by educators or self-reliant. Transformational education seeks to transmit new information, skills, and ways of thinking, but beyond transmission of information, it serves to awaken the learner to a brand new manner of viewing and examining the world. Transformative learning permits participants to interact in knowledge construction, acting with the facilitators to use new information and broaden existing schemes of meaning. Mezirow further reiterates that this can be accomplished through an eleven-phase process which are; a disorienting dilemma, self-examination, critical assessment of assumptions, recognition of discontent and identification with similar others, exploration of recent choices, planning, getting knowledge for plans, experimenting with new roles, building confidence, reintegration, and renegotiation of relationships. Throughout these stages, the learner uses critical reflection and discourse to judge information, skills, roles, and views. Key elements of Mezirow’s theories, including the disorienting dilemma, essential reflection, discourse and action, All of Mezirow’s transformative learning method is related to healthcare-sparked transformation.

The next paragraph will elaborate on Health Information System (HIS) as a transformative learning tool.

Health Information System (HIS) as a transformative learning tool: Sound and reliable data is the foundation of decision-making across all health system building blocks, and is crucial for health system policy development and implementation, governance and regulation, health research, human resources development, health education and training, service delivery and funding. Health Information System (HIS) according to WHO is a system, which provides the foundation for the generation of good-quality data, and is a major building block of a health system. It integrates collection, processing, reporting and use of information essential for improving effectiveness and efficiency of health services through improvement of management at all levels within the health system. (HIS) is classify into two major halves: a clinical half and administrative/statistical part.

The distinction between these two is the means data is used. In clinical work, they are connected to a true patient name or a novel personal identifier. Decisions regarding this patient are created based on this information. Therefore, there is a high demand for data accuracy and correctness. Within the administrative or statistical part of the system, data are separated from the patient and are not any longer utilized in decision making regarding individual patients. Therefore, the demand for absolute correctness in every individual case is not therefore high. Instead, the usefulness of the information at this level is extremely dependent on definitions, comparable use of codes etc. The information from an administrative or statistical system might not in any case be copied back to the patient once more.

The next section will elaborate on the methodology applied in this research.

Methodology: The aim of the study was to investigate the level of HIS usage and its potential as a transformative learning tool for physicians in resource constraint setting to learn new ideas emanating from current health research. In order to achieve these objective six hospitals (3 district hospitals and 3 regional hospitals) were selected from North West province in South Africa. Secondly, hospitals were purposefully selected based on their geographical locations, which is situated across North West province of South Africa.
For confidentiality that was requested by the hospital directors, the names of the hospitals are anonymized in this research paper. Given the character of the study, a case study approach provided the most effective technique for data collection. Participants for the study were drawn from the whole population doctors and nurses. Two doctors and two nurses were selected for participation. A composite number of twelve doctors and twelve nurses voluntarily took part in the research (N=24).

Data was collected using semi-structured, open-ended interviews. The interviewees were asked to respond to the subsequent questions in their own words:

1. What form of Health information system do you have in your hospital?
2. What’s this Health information system used for (if there’s any)?
3. Is there any part of the HIS that assists you as a doctor or nurse to learn new procedures?
4. How do you as a doctor learn new research findings, and technology that have been recently discovered?
5. How do peer-to-peer information shared to boost your practice?
6. What part of HIS will you recommend to the hospital management to include in helping your daily routine job?

The interviews lasted for one hour with every respondent and were audio-recorded and transcribed by the researcher. Another independent researcher checked integrity of data entry from the study. Content analysis techniques was used to transcribe the code as prescribed by Fraenkel. After the initial coding, the independent researcher and the main researcher met to check the consistency of their various interpretation of the transcripts and then coded them. The main themes were identified. The various broad categories that were noted and discussed below.

Findings and Discussion

1. Availability of HIS and usage in resource constraint environment: The respondents indicated that there is a limited functionality of HIS in their hospitals. Some of the functionalities support administrative duties in the hospital while others support clinical duties. The administrative duties as indicated by the physicians were as follows;

Patient administration systems which helps them to admit, discharge and transfer patients. This system keeps track of patient’s movement of care in an inpatient setting. The respondents further indicated that the patient administration systems help them to register patients demographics, and date of visit by patients. One physician stated, “We have Patients administration and Billing system (PAAB) in our hospitals”. This system is used to submit claims and monitor submission and reimbursement status of the patients. There were other administrative systems, which were also found in the hospitals like Personnel management system, which manages human resource information for staff, including salaries and benefits. Moreover, there was Staff scheduling and time management system, which assists in scheduling and monitoring staffing needs, tracks employee work schedules and employee attendance.

The interviewees further stated that there were other systems for clinical duties. There was Laboratory information system for supporting collection, verification, and reporting of laboratory tests. In addition, was Pharmacy information system for supporting medication ordering, dispensing, and inventory control for drug compatibility checks and allergy screening. One very important system which the respondents made mention of was Electronic medical record (EMR) facilitates capturing and reporting of patient’s health history, problem lists, treatment and outcomes which allows clinicians to document clinical findings, progress notes, and other patient information. However, this system is not fully utilized because of lack of ICT skills of the physicians. Another system, which was available but underutilized, was Telemedicine and telehealth system, which supports remote delivery of care.

The usage of HIS as a tool for transformative learning of new research finding and improved practice: The respondents indicated that the HIS in their facilities do not give them any special function to be able to learn and improve on their practices. Health professionals only get to know of any new practices and procedures through monthly face-to-face briefing or workshops organized by the department of health in their respective regions. There is little or no reflection on what the physicians already know which can be brought into his practice because of little time at the disposal of physicians. Physicians treat high number of patients per day, which gives them no time to reflect. Mezirow, indicates that critical reflection is very important and forms an integral a part of shaping physicians behaviours.
towards new assumptions\textsuperscript{17}. There is no concept of HIS as an adult learning tool for interaction between doctors, and researcher using the web. Liaw and others\textsuperscript{20}, state that electronic learning using network technologies to provide and facilitate transformative learning is crucial to assist doctors. Mezirow\textsuperscript{17} additionally states that it is a dialogue involving the assessment of beliefs, feelings, and values. He further states that, “discourse is learner-centered, participatory, and interactive. It involves group deliberation and group problem solving\textsuperscript{15}. This implies that doctor’s action, which is exhibited in their daily routine, can be improved through accessing materials, and sharing ideas at their work.

The need of Integrated Health Information System framework (IHISF): Based on the findings stated above a transformative teaching and learning tool, which forms part of HIS is proposed to assist physicians learn, and implement newly research findings in their practices. A set of applications and processes, which use available electronic media to deliver electronic learning to physicians, will be designed as an Integrated Health Information System framework (IHISF).

The IHISF to be built will be based on transformative learning ideas. Transformational learning involves ever-changing existing beliefs and thought patterns through the employment of discourse and demanding reflection\textsuperscript{9}.

For transformative learning to occur ICT systems are involved and ICT needs to be seamlessly integrated and grounded in the context of the learner. The ICT system evolves around networked-delivered interactive multimedia courses and network-based tutoring which constitute the main learning features.

The Integrated Health Information System framework (IHISF) consists of different elements, the Learning Management System (LMS), the Visual Authoring Tool, the doctor’s Interactive e-learning setting and Key-guided Search Tool. The elements declared above are described within the following paragraphs:

- The Learning Management System (LMS): this is often a complex administrative system that is employed to deliver electronic content in a form of lessons and to prepare the physicians who participate in the teaching activities.
- The Visual Authoring Tool: this is often custom developed software system facilitating the efficient creation of lessons. Experience authors construct straightforward lessons with this tool.
- The doctor’s Interactive e-learning environment: this is often at the presentation tier where user interaction is concentrated. It focus is on efficient user interface (UI) style and accessibility.
- The Keyword Search Tool: The database holds all he accessible content together with their corresponding description. The keyword search tool permits exploring through keyword with the aim to permit users find content.

Conclusion

This research article investigated how physicians in resource constraint environment learn and incorporate new research finding emanating from medical research field into their daily routine practices. It was revealed that many hospitals in resource constraint environment have HIS for supportive and administrative functions instead of clinical functions. It was further learnt that new research findings and ideas generated in the field of medicine are not easily learned and integrated into practice by the doctors.

Based on the findings the researcher proposed an Integrated Health Information System framework (IHISF) which was underpinned by transformative teaching and learning theory and tool to assist healthcare physicians in remote hospitals to learn and implement newly research findings in their practices. The IHISF did not only meant to assist doctors to learn but to help them share new ideas with their counterparts in other remote regions. The IHIS will also serve as framework for the government in these deploy resources to these areas equitably.

ABSTRACT

The purpose of this study is to evaluate and compare the root proximity of maxillary and mandibular interradicular sites using orthopantomogram (OPG) and cone beam computed tomograph (CBCT) for the primary stability of mini implants. The cone beam computed tomographic images and orthopantomographic images of 70 subjects were taken. The interdental sites from distal of canine to mesial of second molar are examined for root proximity. The root proximity was measured at four levels from cementoenamel junction in 70 CBCT and OPG images. The results showed a statistically significant difference between the values obtained from CBCT and OPG images; the root proximity was least 6mm above the cementoenamel junction in maxilla and mandible in the range of 1.09-3.62mm, 1.45-4.17 mm respectively. The study concluded that CBCT images are more accurate and reliable. At 5mm from CEJ in the region between the first molar and second premolar in maxilla and in the area between first molar to first premolar in mandible the root proximity is least and adequate for mini implant placement.

Keywords: Orthopantomogram, CBCT, Implants

Introduction

The expanding demand on orthodontic treatment procedures with minimal patient compliance and maximal anchorage consideration had caused the popularity of using temporary anchorage devices mainly miniscrews or mini implants during active treatment. The mini implants can be used for anchorage control in all three planes namely sagittal, vertical, transverse planes. The stability of the mini implant plays a role in providing the absolute anchorage required and it requires an optimal site for placement which should provide increased contact with the underlying cortical bone without any interference to the adjacent vital structures. Pantomographic and cephalometric skull radiographs have limited views of the dentition and surrounding structures, and may not truly depict the anatomical relationship of structures, in as much as they only provide two-dimensional views.¹ The introduction of Cone Beam Computed Tomography (CBCT) in orthodontics provides a three dimensional view of oral and craniofacial structures aiding as an eminent diagnostic tool. Due to the reduced radiation exposure when compared to conventional CT, CBCT plays its main role in diagnosis and treatment planning in orthodontics.² ³ Poggio et al looked at the mandibles and maxillae of 25 patients to determine “safe zones” for mini-implant placement using cone
Another study by Motoyoshi et al. evaluated specifically the correlation between cortical bone thickness and success rates of mini-implants. A minimum thickness of 1mm of cortical bone was shown to be necessary for increasing success rates. This study showed that knowledge of the thicknesses of cortical bone throughout the jaws is directly linked to the success of mini-implants. In the present study, we are comparing the accuracy in assessment of root proximity of the teeth to the implant site using Orthopantomograph and Cone Beam Computed Tomography for the purpose of placement of mini implant in an ideal site without interfering the roots of the adjacent teeth and to provide an absolute anchorage for orthodontic treatment. So in this study the root proximity at the interradicular sites mesial to second molar and distal to canine is evaluated and compared using Orthopantomograph and Cone Beam Computed Tomography.

Material and Method

In this study, cone beam computed tomographic images and orthopantomographic images of 70 subjects in the age group of 18 to 45 years who never underwent orthodontic treatment were selected.

The patients selected for the study were without facial asymmetry, missing permanent teeth, cleft lip/ cleft palate, without any systemic diseases, without periodontal diseases and periapical pathology. Patients who never had orthodontic treatment, without any prosthetic implants in the measuring sites, without any pathology like cyst/tumors/fractures of maxilla and mandible. The Kodak CS 9300 3D system (figure 1) is the CBCT device used with voxel size between 0.15mm and 0.30mm. The image reconstruction time was approximately 4.5 minutes. The 120 images acquired are analysed using Kodak CS 3D imaging software version 3.5.7 and the images are oriented in three planes of space so that the measurement errors produced from non standardized head postures could be minimized. The horizontal axis of the software is aligned parallel to the anatomic occlusal plane in the sagittal view and is adjusted to pass through the buccal cusps of maxillary first molars in the coronal and axial view. Interdental sites from the distal aspect of the maxillary canine to the mesial aspect of the maxillary second molar are examined. The regions were between

1. Canine and first premolar (3–4),
2. First and second premolars (4–5),
3. Second premolar and first molar (5–6), and
4. First and second molars (6–7).

Root proximity is the term used when the roots of adjacent teeth are 1.0mm or less apart, as measured radiographically. To measure the root proximity at the four interradicular sites (3-4 to 6–7), transverse planes are prepared along a line parallel to the occlusal plane(figure 2) Next, the interdental sites were equally divided into four sectors of 2 mm intervals from cementoenamel junction and were labeled L1 to L4 from bottom to top.

In the CBCT images, at each transverse planes (L1 to L4), root proximity is defined as the shortest distance between tangent lines to the proximal root surfaces(figure 3). In the panoramic radiographs of 70 subjects, the hardcopies are made and the values are measured manually on the radiograph using aerospace digital caliper when viewed on a x-ray viewer by a single operator. (figure 4) The interdental areas (3-4 to 6–7), are divided into four levels from the cementoenamel junction towards the apex and the four levels are separated by a distance of 2mm and the root proximity is measured.
deviation was obtained and in the groups showing normal distribution, one-way analysis of variance was used for intergroup comparisons. For the comparison of the independent set of data, an independent t test was performed. The results were evaluated at the $P<0.05$ significance level.

**Results**

The measured data of root proximity obtained on evaluating 70 images of CBCT and OPG of maxilla and mandible at the inter radicular sites mesial to second molar and distal to canine at four levels from CEJ. The data obtained for root proximity using OPG and CBCT are compared.

**Graph 1: Comparison of Mean Values for Root Proximity in the Interdental Spaces from Mesial to Second Molar and Distal to Canine of Maxilla in OPG and CBCT.**

**Statistical Analysis**

The measured data obtained from both OPG and CBCT were tabulated separately and are evaluated statistically. Statistical calculations were carried out using SPSS (Statistical Package for Social Sciences) 16.0 software. The descriptive statistical mean, standard
Discussion

The success of orthodontic treatment greatly depends upon the anchorage control. Numerous techniques have been advocated in orthodontics to reinforce anchorage. Evolution of skeletal anchorage system has made the orthodontist to achieve absolute anchorage. Primary stability of mini implants due to mechanical interdigitation plays a major role in its success rates which in turn are influenced by 3 factors, placement technique (operator factor), bone quality (host factor) and implant design (material factor). Under operator factor, precise placement technique of the implant is essential to preserve the integrity of the cortical bone without damaging the roots of the adjacent teeth. Assessment of interradicular distance is important as it relates to both safety and stability of microimplants. Kuroda et al reported that the proximity of the miniscrews to the root is a major risk factor for miniscrews. Root proximity is the term used when the roots of the adjacent teeth are 1 mm or less apart, as measured radiographically. The clinical evaluation of root proximity is based on routine radiographic procedures. The orthopantomograph provides distorted two dimensional views of the three dimensional maxilla and mandible whereas cone beam computed tomography provides three dimensional images of maxilla and mandible. However, cone beam computed tomography cannot be taken in all patients due to cost and radiation factor, but orthopantomographs are routinely taken in orthodontic profession. The form of maxilla and mandible specifically the density and thickness of the cortical bone is determined by the masticatory muscle force. The thickness of the cortical bone is closely related to the facial vertical dimensions.

Under material factor, primary stability of mini implants is determined by various implant designs like diameter, length, thread pitch width, thread design, thread sharpness and surface characteristics. Numerous studies have already evaluated about the material factor determinants for the primary stability of mini implants.

The diameter of the mini implants used in clinical practice varies from 1.2-2 mm. So, to place the mini implants without contacting the adjacent root structures, it has been considered that a minimum of 3-4 mm of bone is required in the interradicular region, with approximately one mm of bone between mini implant and the adjacent root structures. The results of the study on evaluating the root proximity of maxilla and mandible in the region between first and second molar, first molar and second premolar, second premolar and first premolar, first premolar and canine using OPG and CBCT suggests that the root proximity decreases gradually from cementoenamel junction to apex which is from level 1 to 4. The root proximity is least at level 4 in both maxilla and mandible which is consistent with the study done by Sawada et al who concluded that the distance between the roots increases in the direction of the root apex and it is necessary to assure root proximity of at least 2.5 mm for implant placement.

The root proximity is in the range of 1.09-3.62 mm in maxilla and 1.45-4.17 mm in mandible at 4 mm from the cementoenamel junction. These results were also in accordance with study done by Joorok Park et al who concluded that the interdental space increases from cementoenamel junction to apex with average of 1.62-3.35 mm in maxilla and 1.99-4.00 mm in mandible and also Sebastian Baumgaertel et al in their study on buccal cortical thickness in maxilla and mandible concluded that the placement of mini implants more
than 4mm apical to the alveolar crest is required. The root proximity is less in mandible when compared with maxilla. The root proximity is minimum and acceptable at levels 3 and 4 which is 4mm and 6mm from CEJ, but the attached gingiva also should be considered. Placing implants in movable mucosa is known to cause tissue irritation and inflammation of gingival tissue, resulting in loss of the implant. According to Lim WH et al the height of the attached gingiva upto 6mm from alveolar crest is considered to be adequate for mini implant placement. Based on the results of the present study, the cortical bone thickness is significantly less mesial to maxillary second molar when compared with the other areas. This is consistent with the study by Schnelle et al who concluded that adequate bone existed mesial to the maxillary first molar than the distal of maxillary first molar. According to Dalstra et al, a micro implant (outer diameter, 2.0 mm; inner diameter, 1.2) should have cortical bone thickness of more than 1mm in the peri-implant bone tissue for initial stability of the mini implant. The amount of bone seen in between maxillary first molar and second premolar at 5mm above the CEJ (i.e.) level 6 is 1.11 ± 0.06mm where as in mandible region mesial to second molar to distal canine in maxilla and mandible, the area between first molar to first premolar in maxilla and in the area between first molar to first premolar in mandible, where the root proximity is less and adequate bone support can be achieved for miniscrew stability.

Conclusion

The study evaluated the accuracy of measurements of root proximity between OPG and CBCT in the maxillary and mandibular interradicular sites at four levels from CEJ in the region mesial to second molar and distal to canine in maxilla and mandible. CBCT is more accurate and reliable in evaluating the root proximity of the maxillary and mandibular interradicular sites and the adequate root proximity for mini implant placement is 5mm from CEJ in the region between the first molar and second premolar in maxilla and in the area between first molar to first premolar in mandible.

Effects of Breast Feeding and its Impact on Oral Health—A Review

Hariharan R.1, Aravinda Babu N.2, L. Malathi3, K. M. K. Masthan4

ABSTRACT

During infancy and early childhood, breastfeeding is one of the most important activities. For the first six months of life, the only source of nutrition for a healthy infant is breast milk as specified in the policy statement of the AAP section. It is beneficial to both mother and the child. To infants it offers ideal nutrition, resistance to infectious diseases, enhanced immune system since it contains secretory immunoglobulins (IgA, IgG), reduced risk of chronic diseases and allergy, physical and developmental growth benefits. The most common infection encountered during childhood is Acute otitis media (AOM), commonly referred to as middle ear infection. In US, children aged through 0 to 4 years, the health care visits with AOM as primary diagnosis was 575 per 1000 visits in 2007. AOM begins as an upper respiratory tract infection that can lead to Eustachian tube dysfunction which can eventually result in hearing loss in children[1,3]. To mother, the benefits of breast feeding include increased physiologic postpartum recovery and reduced long term risk of obesity, osteoporosis and breast and ovarian cancers[1]. As recommended by HHS Healthy people 2010 goals, one of the consequences of continued breastfeeding beyond six months is compromised dental health. However there is no valid link has been made between breastfeeding and dental cavities[1,4].

Keywords: Breastfeeding, Nutrition, Oral microbiome.

Introduction

Dental Caries: The two primary elements required to form a dental caries are:

1. Cariogenic bacteria
2. Simple carbohydrates (in the form of free sugars)

Cariogenic bacteria are microbes (Streptococcus mutans, Lactobacillus species) that can cause caries in tooth by digesting carbohydrates (sugars) and releasing acids in turn. These acids can demineralise the tooth enamel causing caries. However the tooth enamel can be remineralised (effectively regrown) by the components of saliva, therefore the demineralisation process is not necessarily irreversible. When the process of demineralisation exceeds the process of remineralisation, caries begins[3,4].

Early Childhood Caries/Baby Bottle Tooth Decay: Early childhood caries (ECC) refers to decay in deciduous teeth (milk teeth). The deciduous teeth erupt around 6 to 12 months of age in infants. Tooth decay in milk teeth can be caused by cavity causing bacteria which is transferred from mother (or primary caregiver) to the infant. This can happen when the mother puts the baby’s feeding spoon in her mouth or cleans a pacifier in her mouth.

Prenatally, the baby’s mouth is more like a sterile gut. Soon after birth, the baby’s mouth get colonised with bacteria which result in formation of oral microbiome. The appearance of ECC is partly related to the age at...
which a child’s oral microbiome is colonised with cariogenic bacteria. More earlier this occurs, more likely the child develops ECC\cite{3,5}.

Apart from breast feeding, the condition which more likely can cause ECC is enamel hypoplasia (less/thinner enamel). The factors that can cause hypoplasia include genetic/systemic conditions, malnutrition, vitamin D deficiency, traumatic and premature birth etc. and hence, ECC\cite{3}.

Caries in early childhood can significantly affect the overall quality of life in infants.

**Does Breastfeeding Cause Ecc??**

This is an ongoing debate whether breastfeeding causes early caries in infants. A combination of sugars, low amounts of saliva and a low pH in saliva is required for caries causing bacteria namely S. mutans. Breastmilk in fact contains lactoferrin that actually kills S. mutans\cite{3,4}.

Breastmilk contains immunomodulatory factors that can establish normal intestinal flora. In additional to this breast milk components also establish a healthy oral microbiome which can change with time with eruption of new teeth.

However, breast feeding duration, frequency of breastfeeding and nocturnal breastfeeding during sleep are more often correlated with the development of ECC. During nocturnal breastfeeding, the tongue fills the mouth and holds the nipple against the teeth surface, thereby prolonging the exposure of cariogenic bacteria over the substrate resulting in caries\cite{6}.

Per Brian Palmer stated "Human milk alone does not cause dental caries. Infants exclusively breastfed are not immune to decay due to other factors the impact the infant’s risk for tooth decay. Decay causing bacteria (S. mutans) is transmitted to the infant by way of parents, caregivers and others (2002)"

A study by Erickson 1999, concluded that breast milk is more identical to water and does not cause tooth decay and another study of his inferred that immersing teeth in breastmilk can make it stronger. According to the review done by Lavigne 2013, there is no evidence that prolonged breastfeeding can increase the risk of ECC.

Despite all these researches, a study done by systemic review and meta-analysis conclude that breastfeeding up to 12 months of age is not associated with an increased risk of dental caries and it also renders some protection. Breastfeeding beyond 12 months of age (during eruption of deciduous teeth) may increase the risk of dental caries. This can also be due to the introduction of carbohydrate rich diet during weaning period in infants\cite{6}.

**Role of Mothers in Prevention of Dental Caries:**
Mothers play an important role in the prevention of caries in infants. They should be properly educated regarding transmission of infection from mothers having dental caries to children, breastfeeding, weaning, brushing techniques and routine dental visits of child.

As recommended by World Health Organisation, healthy diet and proper feeding habit is essential for prevention of oral diseases which includes ECC, dental erosion, defects in development, diseases of oral mucosa and periodontal diseases\cite{7}.

Mothers should take the following points into note in order to prevent ECC in infants

- Do not share saliva with the baby through feeding spoons or pacifiers.
- Wipe the gums of the child after each meal with clean wet gauze or cloth.
- Do not encourage nocturnal bottle/breast feeding
- Place only plain milk/breast milk in bottle. Avoid adding sugars, juice or soft drinks.
- Do not dip the pacifier in honey or milk, use clean and plain pacifier.
- When the first tooth erupts, brush them gently with child tooth brush and a smear of fluoride toothpaste (size of rice grain) until the age of 3
- Between the age of 3 to 6 years, brush the teeth with fluoride tooth paste (size of a pea)
- Supervise brushing until your child can be counted on to spit and not swallow toothpaste.
- Right from his/her first birthday encourage to drink from a cup.
- Encourage healthy eating habit\cite{5}.
- Visit dentist so that they recommend an antibacterial mouthwash or chewing gums that contains xylitol which can reduce the amount of bacteria in mouth\cite{8}.
Conclusion

An anthropologist’s quoted “If breastmilk caused decay-evolution would have selected against it. It would be evolutionary suicide for breastmilk to cause decay” [9]. According to the guidance provided by Public Health England (December 2018), breastfeeding upto 12 months of age is associated with decreased risk of tooth decay. They also provide links between dental damage and breastfeeding beyond 12 months[9]. The result of one of the cohort studies done on breastfeeding and dental health(july 2017) conclude that breastfeeding≥24 months increases the risk of having ECC. Adopting early preventive measures to dental caries is essential to provide the whole beneficial effects of breastfeeding to infants.[10]

Institute of Higher Education and Research

ABSTRACT

Epithelial dysplasia, a term becoming increasingly referred to as intraepithelial neoplasia, is the sum of
various disturbances of epithelial proliferation and differentiation as seen microscopically. Individual
cellular feature of dysplasia are called epithelial atypia. Studying on individual dysplastic feature in
microscope is a little difficult during the early period on viewing neoplastic tissue when comparing to the
normal structure. This article briefly views on each dysplastic features along with referral hand drawn images
for easy understanding.

Keywords: Dysplasia, Pleomorphism, Nucleus, Atypia.

Introduction

The histological epithelial alterations were divided
as in previous publications into dysplasia (slight,
moderate and severe) or carcinoma in situ. As reported
elsewhere 1,2 the thickness of the squamous epithelium
of the cervix was divided into three equal parts: BP
(basal-parabasal zone), IM (intermediate zone), and S
(superficial zone bordering the lumen). This division was
achieved by the aid of a translucent ocular grid. The grid
measured 10 mm in length (having 10 divisions) and 5
mm in width. The occurrence of mitotic figures in each
part of the epithelium was recorded. The classification
of dysplasia and carcinoma in situ is in accordance with
the one proposed by the WHO International Reference
Center. 3,4 The criteria for the histological classification
are as follows:

Slight Dysplasia: The full thickness of the epithelium
is composed of cytologically atypical cells, i.e. cells
with abnormal, irregular nuclei. Undifferentiated cells
are present in the BP compartment (the nuclei being
rounded or elongated with a maximum nuclear diameter
perpendicular to the epithelial border). The nuclear
density is higher in the BP compartment and decreases
markedly towards the surface. The cytoplasm in the cells
in the IM zone and in the S zone is abundant, suggesting
cell maturation. Cells with basal cell hyperplasia, but
without atypical nuclei in the IM and S compartment,
are not included in the group of mild dysplasia.

Moderate Dysplasia: Undifferentiated cells are present
both in the BP compartment and in part of or throughout
the IM compartment with a similar nuclear density in
these zones. The rest of the epithelium contains atypical
cells with abundant cytoplasm and has a lower nuclear
density.

Severe Dysplasia: Undifferentiated cells are present in
the BP, IM and deeper half of the S compartments. The
nuclear density is similar in these zones. The superficial
half of the S compartment contains atypical cells with
abundant cytoplasm, and has a lower nuclear density.
Carcinoma in situ: Undifferentiated cells occupy the
whole thickness of the epithelium and the nuclear density
is similar in all three compartments. The uppermost cell

DOI Number: 10.37506/v10/i12/2019/ijphrd/192306
layers covering the luminal border of the epithelium, however, could be flattened (up to three layers in thick epithelium), 23 with irregular, pyknotic nuclei arranged parallel to the luminal border.

The neoplastic cell is characterised by morphologic and functional alterations, the most significant of which are ‘differentiation’ and ‘anaplasia’.

**Differentiation**: Differentiation is defined as the extent of morphological and functional resemblance of parenchymal tumour cells to corresponding normal cells. If the deviation of neoplastic cell in structure and function is minimal as compared to normal cell, the tumour is described as ‘well-differentiated’ such as most benign and low-grade malignant tumours. ‘Poorly differentiated’, ‘undifferentiated’ or ‘dedifferentiated’ are synonymous terms for poor structural and functional resemblance to corresponding normal cell.

**Anaplasia**: Anaplasia is lack of differentiation and is a characteristic feature of most malignant tumours. Depending upon the degree of differentiation, the extent of anaplasia is also variable i.e. poorly differentiated malignant tumours have high degree of anaplasia. As a result of anaplasia, noticeable morphological and functional alterations in the neoplastic cells are observed.[1-4]

As a result of anaplasia, noticeable morphological and functional alterations in the neoplastic cells are observed. Histopathological features of epithelial dysplasia (Krammer et al., 1978) are:[3]

1. Loss of polarity of the basal cells
2. Presence of more than one layer of cells having a basaloid appearance
3. Increased nuclear cytoplasmic ratio
4. Drop-shaped rete processes
5. Irregular epithelial stratification
6. Increased number of mitotic figures (a few abnormal mitoses may be present)
7. Presence of mitotic figures in the superficial half of the epithelium
8. Cellular pleomorphism
9. Nuclear hyperchromatism
10. Enlarged nucleoli
11. Reduction of cellular cohesion
12. Keratinization of single cells or cell groups in the prickle layer

**Loss of Polarity of the Basal Cells**: Normally, the nuclei of epithelial cells are oriented along the basement membrane which is termed as basal polarity. This property is based on cell adhesion molecules, particularly selectins.

Early in malignancy, tumour cells lose their basal polarity so that the nuclei tend to lie away from the basement membrane. Cell polarity refers to the intrinsic asymmetry observed in cells, either in their shape, structure or organization of cellular structure or organization of cellular components.[1-4]

**Presence of More Than One Layer of Cells Having a Basaloid Appearance**: A cell, usually of epidemis, resembling a basal cell, basal cell hyperplasia- the development of basal cells that are several layer thick.[1-4]

**Increased Nuclear Cytoplasmic Ratio**: Generally, the nuclei of malignant tumour cells show more conspicuous changes. Nuclei are enlarged disproportionate to the cell size so that the nucleocytoplasmatic ratio is increased from normal 1:4 to 1:1.[1-4]

**Drop-Shaped Rete Processes**: Rete pegs that are wider in the deeper portion than they are superficially. Nodular, bulbous or tear rete ridge and extremely elongated rete processes (drop shaped) in one of the classical identification in tumor cells. This is due to increased proliferation of cell and loss of architecture of the rete process.

**Irregular Epithelial Stratification**: A Stratified squamous epithelium consists of squamous (flattened) epithelial cells arranged in layers upon a basal membrane. Only one layer is in contact with the basement membrane; the other layers adhere to one another to maintain structural integrity. In case of tumor, this architecture of cell arrangement is lost which is called as irregular epithelial stratification. This is because of increased and atypical proliferation of cells.

**Mild Dysplasia**: Slight nuclear abnormalities, most marked in the basal third of the epithelial thickness and minimal in the upper layers, where the cells show maturation and stratification. A few, but no abnormal mitoses may be present, usually accompanied by keratosis and chronic inflammation.

**Moderate Dysplasia**: More marked nuclear abnormalities and nucleoli tend to be present with changes most marked in the basal twothird of the epithelium, nuclear abnormalities may persist up to the surface, but cell maturation and stratification are evident in the upper layers. Mitoses are present in the parabasal and intermediate layers, but none is abnormal.
Severe Dysplasia: Marked nuclear abnormalities and loss of maturation involve more than two-third of the epithelium with some stratification of the most superficial layers. Mitoses some of which are abnormal may be present in the upper layers.[1-4]

Increased Number of Mitotic Figures: The parenchymal cells of poorly differentiated tumours often show large number of mitoses as compared with benign tumours and well-differentiated malignant tumours. During the mitosis (M phase) of the cell cycle, the dividing cell undergoes a series of events.

During the prophase portion of mitosis, the chromosomes become visible as extended double structures and the chromosome pairs become shorter and thicker. In metaphase, the chromosomes become aligned on the equator of the cell. During anaphase, chromosome pairs split and move toward opposite poles of the cell. In telophase the chromosomes reach their respective poles and soon after, the cell divides into 2 daughter cells, each with a complete set of chromosomes.

Mitosis counts have long been the gold standard by which we have routinely evaluated cell proliferation in neoplasms. The identification of abnormal mitotic figures is generally acknowledged to be a feature of malignancy, and in certain tumors, their identification may provide prognostic information. Abnormal or atypical mitotic figures are more important in malignant tumours and are identified as tripolar, quadripolar and multipolar spindles in malignant tumour cells[1-4]

Presence of Mitotic Figure in Superficial Half of Epithelium: It is apparent that despite cytoplasmic maturation the abnormal nuclei of some superficial cells retain some of the properties of immature cells, namely the capacity to undergo mitosis or to replicate its DNA. It is conceivable that this phenomenon occurring in mature cells in slight and moderate dysplasia may antedate the arrest of cytoplasmic maturation present in the superficial cells of more severe lesions.

The study of the lateral distribution of mitosis in the atypical epithelium demonstrated the occurrence of foci of dividing cells alternating with foci of non-dividing cells. This finding was similar to that reported for DNA syntheizing cells in cases with cerebral epithelium containing epithelial atypias, and suggest the existence of proliferating and non-proliferating (i.e. resting) compartments. The existence of such compartments has earlier been reported in experimental solid tumors[1-4]

Cellular Pleomorphism: The term pleomorphism means variation in size and shape of the tumour cells. The extent of cellular pleomorphism generally correlates with the degree of anaplasia. Tumour cells are often bigger than normal but in some tumours they can be of normal size or smaller than normal[1-4]

Nuclear Hyperchromatism: Characteristically, the nuclear chromatin of malignant cell is increased and coarsely clumped. This is due to increase in the amount of nucleoprotein resulting in dark-staining nuclei, referred to as hyperchromatism. Nuclear shape may vary, nuclear membrane may be irregular and nuclear chromatin is clumped along the nuclear membrane[1-4]

Enlarged Nucleoli: Malignant cells frequently have a prominent nucleolus or nucleoli in the nucleus reflecting increased nucleoprotein synthesis. This may be demonstrated as Nucleolar Organiser Region (NOR) by silver (Ag) staining called AgNOR material.[1-4]

Reduction of Cellura Cohesion: The cells lose their attachment to the neighboring cells, because of the faulty or reduced attachment of their desmosomes.[1-4]

Keratinization of Single Cells: Pre-mature production of keratin within the cytoplasm of individual cells or a group of cells.

Keratins are associated filaments provide a scaffold for epithelial cells and tissues to sustain mechanical stress, maintain their structural integrity, ensure mechanical resilience, protect against variations in hydrostatic pressure and establish cell polarity. Keratin and its filaments are involved in cell signaling, cell transport, cell compartmentalization and cell differentiation. Keratin proteins regulate the response to pro-apoptotic signals and have the ability to modulate protein synthesis and cell size in epithelial cells. Keratins also participate in wound healing.

Most epithelial cells, migrating cells and developing cells require some form of cell polarity for their function. Epithelial cell establish an apical –basal polarity which results from the differential distribution of phospholipids, protein complexes and cytoskeletal components between the various plasma membrane.

The oral epithelium is stratified squamous type consisting of cells called keratinocytes. These cells undergo a process of maturation during which the cells produced by the mitotic division in the basal layer migrate to the surface where they are shed off and are replaced by the maturing cell population.

In case of tumor, these group of malignant epithelial cells in the form of islands invades to the underlying connective tissue and on maturation produce keratin in whorl pattern called individual cell keratinization (keratin pearls). These keratin pearls are well appreciated in well differentiated squamous cell carcinoma and less seen in moderately differentiated squamous cell carcinoma.[1-4]
1. In case of loss of polarity of the basal cells there is disorganization and excessive cell growth.

2. The architecture of cell arrangement is lost which is called as irregular epithelial stratification. This is because of increased and atypical proliferation of cells.

1. More than one layer of basaloid (basal cell-like) appearance is seen, this is due to increased...
Conclusion

Histologically differentiating between normal and dysplastic features under the microscope is of utmost importance. Proper identification and the art of reading a slide under a microscope holds the strength in producing accurate histopathological diagnosis, thereby providing the right treatment outcome. Therefore clear knowledge on each dysplastic feature and the alteration is a key factor in histopathological diagnosis and reporting.

ABSTRACT

Purpose: To study a series of cases where vascularised fibula flap was used in mandibular defect.

Patients and Method: The investigators designed a retrospective study composed of patients with any pathology or defect who underwent reconstruction of mandible with vascularised fibula free flap from 2014 to 2018. All patients were evaluated for age, gender, location and type of defect, incorporation of adjoining skin paddle and muscle, number of fibula osteotomies, ischaemia time, anticoagulant regimen, length of hospital stay, flap failure rate, dental implant rehabilitation. All patients with a minimum follow-up of 6 months post-operatively, were included in this study.

Results: The study sample composed of 8 patients with average age of 40 years. Immediate reconstruction done in all patients. In two patients, the fibula was double barrelled. Skin island was included with the fibula in all patients. Two patients underwent dental rehabilitation using implants with double barrel reconstructions. Hematoma at the recipient site was the commonest post-operative complication, although its frequency was low. A low donor site morbidity was seen. Average stay in hospital was about 10 days. Post-operatively all patients ambulated normally and none used assisted devices. A reconstruction plate was used to achieve the ideal contour of the jaw in most cases. Aesthetic results were usually good, especially in young patients. The overall success rate was good. Conclusion: The fibula has many assets which make it the ideal choice for bony reconstruction of mandible skeleton and adjoining soft tissue with predictable results.

Keywords: Mandible Reconstruction, Fibula free flap.

Introduction

Partial or complete resection of mandible can be unaesthetic and at the same time cause functional difficulties. Large defects involving the mandibular region due to destruction of bony segments and soft tissues have long been the consequences of extensive surgical ablations.

Immediate reconstruction of mandible and adjoining soft tissues has been performed using fibula tissue transfer from past 3 to 4 decades and has proved to be a reliable morphofunctional reconstruction technique. Fibula free flap was first described by Taylor and colleagues in 1975 [1], and Hidalgo [2] introduced it for mandibular reconstruction in 1989.

Fibula free flap (FFF) provides several advantages over other donor sites. These include ample bone length, ease of flap dissection and shaping with less blood loss, a possibility of 2 team approach, long pedicles with large calibre vessels and minimal donor site morbidity. Its vascular supply is recipient independent, making it favourable for reconstruction in irradiated or poorly vascularized tissues. The fibula is nourished by its periosteal blood supply. Hence, multiple osteotomies of the fibula to confirm the mandible are feasible without devascularising individual segments. Moreover FFF offers tremendous bicortical bone stock for dental implant placement and a versatile cutaneous unit for concomitant soft tissue reconstruction. Also FFF based on separate septocutaneous perforators is of benefit to extensive substitution to externally cutaneous and internally oral linings [10].
The aim of this study is to report a case series with our experience in using vascularized fibula flap in various combinations of bone, muscle and skin for reconstruction of mandible.

**Patients and Method**

A retrospective analysis of 8 patients who had undergone reconstruction for mandibular defects operated on between 2014 to 2018 in Department of Maxillofacial Surgery, Sree Balaji Dental Hospital, Chennai, India was done and informed consent was obtained from all the patients involved in this study. Inclusion criteria included patients with any pathology or defect demanding reconstruction, with a minimum follow-up of 6 months. Exclusion criteria included only unwilling patients.

All patients underwent fibula free flap transfer via a midlateral incision over the fibula with a modification if skin paddle was included. Pre-operatively the extent of defect was determined using panoramic radiograph and/or computed tomography (CT). Jewer et al.’s [11] HCL classification (Fig. 1) for mandible was used in this study. Hand Doppler and Duplex colour Doppler [12], was performed to detect any anatomical variation or pathology of the peroneal circulation, patency of the anterior and posterior tibial vessels and identification of skin perforators. No arteriograms were used. Allen’s test of arterial occlusion of the foot was also done routinely for all patients.

![HCL classification of mandibular defects](image)

**Fig. 1: HCL classification of mandibular defects. C - central segment, L - lateral segment excluding condyle, H - lateral segment including condyle**

A lateral approach [13] under tourniquet was used for flap harvesting. Proximal and distal ends of at least 6 cm of fibula were left in situ to maintain ankle and knee joint stability. The skin island was centred at the middle and/or lower thirds of the leg. Recipient needs dictated the size of the fibula and its cutaneous paddle. A two-team approach was used in all patients. The cephalic team prepared the recipient site and neck vessels, while the other team harvested the flap and reconstructed the defect.

Data collected through the chart reviews included age at reconstruction, gender, diagnosis, defect location and size, flap ischaemia time, fibula bone length, skin paddle, use of soleus and/or flexor hallucis muscle, number of fibula osteotomies, anticoagulant regimen, length of hospital stay, duration of follow-up, esthetic satisfaction, post-operative complications (flap problems, fistula formation, bone exposure, miniplate complications, infection, donor site disabilities), dental rehabilitation.

**Results**

Eight consecutive patients with various etiologies, underwent reconstruction of mandible with FFF (Table 1). There were 2 males and 6 females, with average age of 40 years. Immediate reconstruction was done in all patient.

According to the classification proposed by Jewer et al., for mandibular defects, 1 patients were of H-category, 5 L-category, 1 LC-category, and 1 of C-category (Fig. 2).

A lip-split incision with skin crease extension in the neck was used for mandibular reconstruction (Fig. 3). Anastomosis to the facial vessels was commonly done to the facial or lingual or superior thyroid branch of ECA and a branch/trunk of IJV was done for mandibular reconstructions.
Skin paddles were harvested in all patients, with all the cutaneous units placed as intraoral linings (Fig. 4). Donor sites were closed primarily in 7 patients with harvested skin paddles and one required split thickness skin graft (Fig. 5). A suction drainage was inserted before wound closure, and an elastic bandage was used as dressing.

The number of osteotomies of the fibula to recreate the mandibular shape was two (range 0–3) (Fig. 6), depending on the location and extent of the defect. A reconstruction plate was prebent intraoperatively (Fig. 7) to be symmetrical with the contralateral jaw and was used to attach the fibula segments to it. 2 of patients were reconstructed with a ‘double-barrel’ technique (Fig. 8). Titanium miniplates and screws were used to fix the osteotomy segments.

The flap artery and vein were anastomosed to the recipient vessels. No autogenous vein graft was used. All the donor and recipient vessels were topically irrigated with heparinized saline solution before microanastomosis. Return of flap circulation was judged by bleeding of periosteum, bone and skin paddle. The total ischaemic time was 2-3 hours. Post-operatively pharmacologic regime was a low molecular weight heparin during the first few days for thrombosis prophylaxis. All patients were ambulated within 3–5 days and none of them used any assisted devices. Hospital stay was approximately 10 days in all cases.

Fig. 3: Midline lip – split with skin crease extension in neck, Visor incision
No Venous stasis was reported in our patients. Following 2 veins were anastomosed for all our FFF patients as a protocol. A significant donor site morbidity was seen in one of our patients but none had any permanent disability. Two patients reported back for dental implant rehabilitation in double-barrel technique reconstructions. An overall success rate was good with our study.

Discussion

The vascularized fibula flap in combination with skin and muscle has become a flap of choice for mandibular reconstruction. Eight consecutive patients were evaluated with a minimum follow-up of 6 months following reconstruction. Irrespective of the etiology of the defect, FFF was preferred for reconstruction. The ease of harvesting, use of two-team approach, availability of good bone length, feasibility of obtaining a skin paddle, muscle or both, perform multiple osteotomies, ability to double barrel the flap, presence of good caliber vessels
including two veins, minimal donor site morbidity, make it the flap of choice for most mandible reconstructions.

The most important finding from our series is the functional and aesthetic rehabilitation that all the patients have received. The FFF provides a better base for oral rehabilitation than that offered by other kinds of reconstruction.

Soft tissue flaps like latissimus dorsi free flap or rectus abdominis free flap, achieve good bulk to fill the defect, however they do not address the bony skeleton particularly the mandible, alveolus. The scapula osteocutaneous free flap offers the potential to address these needs but it may not always be suitable for placement of osseointegrated implants [14, 15]. Further disadvantages include inability to harvest the flap simultaneously with the extirpative procedures, difficulty in orienting the bone to provide mandiblereconstruction and the relatively short pedicle length. The disadvantages of iliac crest myo-osseous flap are its potentially excessive bulk, limited soft tissue mobility in relationship to the bone and short pedicle length [16, 17].

The composite radial forearm flap is not adequate for the quantity and quality of bone it can supply [18]. The FFF provided the best bone source for functional reconstruction of mandible in terms of quality and esthetic contouring of the face. This flap has an added advantage of providing sufficient height of bone using ‘double-barrel technique’. Use of stereolithographic models for pre-operative planning of the osteotomy cuts and the shape of the jaw, should be considered to achieve better and quicker results. Long term studies of a larger population is required to further support the data provided in this article. Considering the advantages and versatility with less complications and limitations, FFF should be considered as gold standard in reconstruction of mandible defects.

**Conclusion**

The various advantages of fibula free flap with minimal complications and limitations make it the most versatile flap for reconstruction of mandible defects. Hence, fibula microvascular free flap should be considered as the, ‘gold standard in reconstruction of mandibledefects’. However, long term studies with a larger population is needed.

**ABSTRACT**

Biocompatibility of dental implants is affected by corrosion, and their functional ability and useful lifetime. It can cause a lot of problems or even failure of the implant. The oral environment is affected by the electrolytes and oxygen compositions that are produced differ from that of tissue fluids. This is a review and update of the interaction of dental implants with the environment, and effects of secretion contamination on the load of implant prostheses.

**Keywords:** saliva milieu, materials of dental implants, pH of saliva, systemic diseases.

**Introduction**

Biocompatibility of dental implants is affected by corrosion, and their functional ability and useful lifetime. It can cause a lot of problems or even failure of the implant. Corrosion is defined as reaction of a metal within its environment so as to result in destruction. The environment of interest in this case is the maxillary and mandibular bone, soft tissues, and saliva. The electrolytes and oxygen compositions that are produced differ from that of tissue fluids. The pH of saliva can vary in areas around dental implants. There are 2 electrochemical reactions that occur in corrosion of metals. An oxidation reaction occurs at the anode, and a reduction reaction occurs at the cathode. Cathodic reactions consist of reduction of the dissolved oxygen in the electrolyte.

The above reactions will occur simultaneously on a metal surface exposed to body tissue and fluids. The anodic reaction consists of dissolution of the metal according to kinetic equation. When the implant components are under the tissue, metal ions may migrate into the tissue, causing possible irritation or systemic effects. Soft tissues (fibers and cells) are interposed between dental implants and bone. Corrosion reactions may occur on a metal surface exposed to body tissue and fluids.

Most metallic dental prosthesis components (overdentures, crowns) attached to titanium implants, initiate corrosion events that involve the metallic prosthesis part (overdenture), as anode and the implant inside the bone as cathode. Several types of corrosion, including general, galvanic, pitting, crevice, fretting, and stress, will be discussed. Mechanical and chemical effects may cause generalized corrosion. The mechanical breakdown of the film, which surrounds the metal, may occur when the film is stressed and ruptures. The chemical breakdown occurs when the film is removed or penetrated chemically (e.g., by chloride ions, which are present in body tissues and saliva). These pits may nucleate at the site of a metallurgical defect, inclusion, or scratch on the surface of an implant. Nucleation of pits is not completely understood, but tests [ASTM F-746] have been designed to assess the susceptibility of specific implant metals into pitting. Another problem of local- ized corrosion in implants materials is crevice corrosion. Many examples of crevice corrosion have been found in dental implants. Chloride ions from saliva move into the crevice and cause more damage.
Infiltration of saliva between implants and implant-supported structures creates galvanic cells between the dental alloys, which are responsible for crevice corrosion. The major electrolytes in salivary secretions are sodium, potassium, chloride, calcium, phosphate, and bicarbonate. Minor electrolytes include fluoride, thiocyanate, magnesium, sulfate, and iodide. The length of time of secretion largely causes the effect of flow rate on the electrolyte composition of parotid and submandibular saliva.

By contrast, sodium and chloride concentrations are high in the early hours of the morning, while potassium is high in the early afternoon. While calcium and phosphate concentrations appear to remain stable during the day, the calcium concentrations increase at night. Several factors can change the pH of saliva. Infection can change the values of pH of saliva, making the values more acidic. Sulfur and the sulfur-bearing ions, which come from certain foods, can contribute to corrosion of dental implants. The above mentioned factors, pH of saliva, and chloride concentrations can provide ions in saliva milieu.

**Discussion**

Environmental effects on dental implants. The infiltration of saliva between the elements of prosthetic appliance brings different types of dental alloys into permanent contact. The dental alloys, which have been brought into contact, form a galvanic cell. An electric current resulting from their potential difference is generated in the cell.

The in vitro study by Reclaru and Meyer measured galvanic currents between samples in saliva milieu at temperature 37°C and pH 5. The samples were made of Ti/gold based alloys, Ti/palladium, and Ti/non precious alloys. They concluded that Ti/gold and Ti/palladium alloy were more resistant to crevice corrosion. These alloys caused negligible galvanism. Titanium is used as a metal for biocompatible materials. However, the corrosion of Ti is cased in the prophylactic fluoride-containing environment. The commercial dental gels and rinses containing fluoride from 1000 to 10,000 ppm with a pH of saliva ranging from 3.5 to neutral may be harmful to titanium implants. Therefore, the corrosion of dental implants seems to depend not only on fluoride concentration but also on pH of saliva.

Several investigations tried to explain this phenomenon. Jaarda et al concluded that interchanging implant prosthetic retaining screws could affect the long-term survival of implant fixtures or implant prostheses. Many problems associated with screw-retained implant restorations and chemical reactions caused by galvanic corrosion are faced by using a grade I pure titanium metal.

Many factors determine the failure of osseointegrated implants. They are systemic conditions, such as alteration in bone metabolism, hormone balance, smoking habits, and local conditions. These conditions are quality and quality of bone, traumatic surgi cal technique, occlusal conditions, composition of dental implants, and corrosion of the metal of implants.

Nowadays in the United States, there is a common procedure to put endosseous titanium implants into fluoride solution before they are placed into the bone cavity. This treatment results in a blue discoloration of the titanium surface. It has not been found in further references in the relevant literature review.

The Effects of Salivary Contamination on the Preload of Implant Prosthetic Screws: It is known that uneven occlusal loads cause repeated compression and then tension of implant components. The manner in which forces are applied to implant restorations within the oral environment dictates the likelihood of system failure. If a force is applied a ways far away from a weak link in an implant or restorative, bending or torsional failure might result from moment masses. Excessively long cantilever bridge or bar sections may result in interface breakdown, bone re- sorption, prosthetic screw loosening, and bar/bridge fracture. This imposed moment load may be destructive to implant systems.

The tensile force needed to keep the parts tightly together during all static and functional conditions is called “preload.” Screw loosening is a common problem with implant-retained prostheses.

Several investigations tried to explain this phenomenon. Jaarda et al concluded that interchanging implant prosthetic retaining screws could affect the long-term survival of implant fixtures or implant prostheses. Many problems associated with screw-retained implant restorations and chemical reactions caused by galvanic corrosion are faced by using a grade I pure titanium metal.

Many factors determine the failure of osseointegrated implants. They are systemic conditions, such as alteration in bone metabolism, hormone balance, smoking habits, and local conditions. These conditions are quality and quality of bone, traumatic surgical technique, occlusal conditions, composition of dental implants, and corrosion of the metal of implants.

In this study, the major role of saliva on...
the dental implants was examined. Many studies in animal models and human beings showed that metal ions were released from implant surfaces. These ions contribute to osteolysis.26,27 Macrophages participate in the elimination of metals ions. They may remain free in the intercellular spaces. Metal ions can be titanium particles and associated with a corrosion process.28,29 Numerous investigators30–32 have reported the presence of macrophages of failed orthopedic and dental implants.

In general, it is known that pure titanium metal has a high reactivity with oxygen. A surface oxide spontaneously covers metal if it is exposed in air at room temperature. This oxide layer determines the corrosion resistance and interface chemistry of the metal.33 It has been reported that the surface oxide layer of titanium plays an adhesive role in determining the biocompatibility. However, some reports showed that this layer might not be sufficiently protective in the saliva environment.33,34

Sawase et al studied the application of oxygen ions to titanium surfaces (i.e., in vitro and in vivo in rabbits models). A plasma source ion implantation method was used to increase the thickness of the surface oxide layer. Their results indicated an improved corrosion resistance in vitro, and this layer did not influence the bone formation around titanium implants in vivo.34

Duffo et al concluded that the pH of saliva plays an important role in the corrosion of a titanium implant. A high corrosion was observed when the samples of implants were immersed in a lower pH (5.2) as in chronic inflammatory processes. The following diseases affect the pH of saliva: (i.e., acid value of pH):

1. Neurologic disorders. Parkinson disease and other extrapyramidal disorders, Alzheimer disease and other primary dementias, common disorders of the cranial nerves36
2. Disturbances of renal function.37
3. Hormone dysfunction. Diabetes mellitus, diseases of the parathyroid (hypercalcemia and hypocalcemia disorders), thyroiditis, adrenocortical diseases.36
4. Hypertension, hyperlipidemia, malnutrition (gastrointestinal system).38 Peptic ulcer disease, inflammatory bowel disease, diseases of the gall bladder, and bile ducts.36
5. Disturbances of respiratory tract.39 Sarcoidosis, Sjögren’s syndrome, and rheumatoid disease.38

Denture stomatitis, squamous cell carcinoma, and immunopathologic mucosal lesions.11,40

Cortada et al41 performed measurements of the ion release in artificial saliva using the titanium implant. They concluded that the titanium oral implant coupled with a chromium-nickel alloy releases a high quantity of ions. Whereas the implant coupled with the titanium superstructure presented a low value of ion release.41 The effects of electrolytes such as sulfuric acid, acetic acid, and phosphoric acid cause dissolution of the material of dental implants.42

Ravnhol43 measured the pH values when corrosion occurred around titanium implants and found it about 10. The researcher concluded that if the buffer systems of adjacent tissues in vivo are not able to cope with the high pH generated around the titanium, local tissue damage may ensue. Taher and Jabab44 observed that the titanium alloys showed high corrosion resistance when the pH of saliva was adjusted to 7.2.

Conclusions

After much study of the previous studies, the following conclusions can be drawn:

1. It is clear that the corrosion of titanium implants is affected not only by the concentration of electrolytes but also by the pH of saliva,
2. The salivary contamination affects the preload of implant prosthetic screws, and
3. We do not know the effects of corrosion products on the soft tissues.

Buffered Local Anesthesia in Dentistry—A Review

Joseph Changankary Pia, Suresh Mitthra, Balasubramanian Anuradha, Arunajetasan Subbiya

1Third Year PG Student, 2Reader, 3Professor and Head, Department of Conservative Dentistry and Endodontics, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research, Narayananapuram, Pallikaranai, Chennai, Tamilnadu, India

ABSTRACT

Local anesthetics (LA) are one among the safest drugs used in dentistry. The disadvantages include burning sensation upon injection, slow onset of action etc., Buffering of local anesthetics is introduced to counteract these undesirable qualities. The advantages of buffering of local anesthetics include quicker onset, more reliable and comfortable for the patient. This article provides an overview on buffering of local anesthetics.

Keywords: Buffering, Local Anesthesia, Ph

Introduction

An unpleasant sensory and emotional experience associated with actual or potential tissue damage is defined as pain (1). The management of pain is a crucial factor in dentistry since it dictates the behavior of patient during the present appointment, as well as ensures compliance for future visits. In dentistry, the employment of LA as a means of pain control has been one of the medical marvels of the twentieth century. Lignocaine hydrochloride is the most commonly used anesthetic agent since its clinical availability in 1941. Hence, it is considered as the “gold standard” to which all new LAs are compared (2). However, the method employed to reduce pain, may be a source of both pain and anxiety. Anxiety can increase pain perception and may create a barrier to receiving optimal and necessary dental care (2). Various factors such as the speed of injection, pressure during administration, injection site, pH, volume and temperature of the anesthetic solution have been attributed to the degree of pain associated with LA administration (3). Buffering the drug to a neutral pH can make the injection more comfortable to the patient.

Alkalisation of Local Anesthetic Solutions: To raise the pH of LA solution a basic solution can be added. Sodium bicarbonate is the most commonly used basic solution. This process of adding a basic solution to the LA solution is termed as buffering. However currently this terminology is not acceptable. Hence alkalisation is a described as a more accurate term.

A buffer is defined as a solution that tends to resist a change in its pH whether acid or a base is added to it. When a basic solution is added to the LA solution there is an increase in the pH. The tissues will function as buffers as they tend to minimize the change in pH, when an acidic LA solution is injected. When too much of basic solution is added, the rapid increase in pH causes the precipitation of non-charged basic ions from the solution. This will be detected as a white clouding of the solution. Provided precipitation does not occur, alkalisation does not adversely affect the efficacy of the LA solution. As precipitation increases with time, alkalized LA solutions should generally be freshly prepared and used promptly.

Mechanism of Action: The LA contains spontaneously uncharged molecules (the base) and positively charged molecules (the cation) (2). The uncharged free base form of the solution is responsible to diffuse through
the nerve sheath, revert to the charged form within the axoplasm, and block the sodium channels to induce non-depolarizing nerve block (2). The relative proportion of the base and the cation varies with the pH of the solution or the targeting tissues (2). The higher the pH of the solution, more the free base form of the solution exists. The dissociation constant (pKa) also determines the relative proportion of ionic form (2). When the pH of the solution equals the pKa of the LA there exist equal amounts of base and cation in the solution.

Epinephrine is often used as an addition to LA agents to achieve prolonged anesthetic effects. However, a lower pH is required for LA to prolong the shelf life of epinephrine. The pH of LA without epinephrine is about 5.5 (2). When epinephrine is added to lidocaine, to maintain a lower pH value, sodium bisulfite or hydrochloric acid are commonly used in the solution. Thus, the mean pH (± standard deviation, SD) of the solution of 1% lidocaine with 1:1,00,000 epinephrine is 4.24 (± 0.42), and 2% lidocaine with 1:1,00,000 epinephrine is 3.93 (± 0.43) (4). The acidity of lidocaine increases the hydrogen ions in the local tissue environment and thus results in injection pain and increases onset time (2,5), which causes discomfort for patients during the injection.

The alkalinisation of the lidocaine with sodium bicarbonate can increase the pH value of the solution thereby reducing the pain during anesthetic administration (3). When it interacts with the hydrochloride acid in LA, sodium bicarbonate creates water and carbon dioxide (CO2). Catchlove (6) concluded that CO2 could potentiate the action of LA by serving as a direct depressant on the axon, concentrating LA inside the nerve trunk, and converting LA to active cations through its effect on pH at the site of action inside the nerve. CO2 potentiates the action of LA by 1) a direct depressant effect of CO2 on the axon, 2) concentrating LA inside the nerve trunk (diffusion trapping) and 3) will convert the LA to the active cation through its effect on pH at the site of action inside the nerve (6).

The alkalinisation of lidocaine has been widely evaluated in the medical field. In a systematic review, Davies (7) included 22 randomized clinical trials (RCTs) in humans and concluded that buffering LA with sodium bicarbonate could reduce injection pain while not affecting efficacy. A more rapid onset can be achieved by increasing the number of uncharged base molecules in the solution (5). An approach of the addition of sodium bicarbonate immediately before anesthetic administration to increase the pH value of the solution in dentistry was reported by Malamed in 1992 (8). CO2 also has independent anesthetic effects that enhance the anesthetic solutions action sevenfold.

**Advantages of Buffered Local Anesthetics:**
Alkalinisation has potential advantages like the higher pH of the solution may result in less stinging pain being experienced by the patient. The pH of the injected solution may quickly approach that of the normal tissue pH after injection. The faster formation of a mixture with charged and uncharged forms will result in more rapid drug diffusion and a quicker onset of nerve blocking. Buffering is particularly useful in body sites with low tissue buffering capacity where there can be a delay in the rise of pH after injection.

Buffered lignocaine was revealed as the most efficacious anesthetic agent; however, articaine and lignocaine were found to be equally effective (9). DiFazio et al (10) Zahl et al (11) Benson et al (12) and Sinnott et al (13) found that anesthetic formulations with higher pH values had a faster onset. It would seem that the higher pH adjusted anesthetic formulations have more uncharged base available initially. Therefore, a faster onset would theoretically result. However, a statistically faster onset with the lidocaine sodium bicarbonate formulation was not reported in some studies (14). Galindo et al (15) and Christoph et (16) also did not find pH-adjusted agents to have a faster onset. In the infiltration anesthesia, the onset of the block is generally rapid so there is minimal time to be gained. Alkalinisation of LA to reduce the onset time of regional anesthesia or major nerve blocks is not useful.

There is decreased tissue irritation from the more physiologic pH of the buffered solution (9). Buffering increases the concentration of uncharged lignocaine particles the faster onset of nerve blockade may help explain the decreased sensation of pain (17). Alkalinised LA solution will reduce pain on injection and will result in a quicker onset of anesthesia (16). Malamed et al (19) and Kashyap et al (18) both reported more comfortable injections with alkalized 2% lignocaine when used for the inferior alveolar nerve block; The reduction of stinging pain due to infiltration anesthesia and the block of small peripheral nerves is the major advantage of alkalinisation of LA solutions. A study by Chopra R et al reported that there was no difference in the pain perception between lignocaine and buffered lignocaine (20).

**Conclusion**

The induction of LA is dependent upon the patient’s physiologic process of converting the cationic...
to the anionic form, and back to the active form. This dissociation process is dependent upon the patient’s tissue pH and the pH of the administered drug and is responsible for delayed onset of action, and overall inconsistency of anesthesia. Buffering of LA before injection takes the physiology out of the process and provides an alternative to the in vivo process. The recent introduction of the sodium bi-carbonate and delivery devices developed to accommodate the dental anesthetic cartridges has offered the dental profession an easy way to accomplish chairside anesthetic buffering.

Evaluation of Intensity of LED Curing Light on the Depth of Cure of Composite- An in Vitro Study

Lakshmisree A G1, Arumugam Karthick2, Nagarajan Geethapriya3, Arunajatesan Subbiya4
1Third Year PG Student, 2Professor, 3Reader, 4Professor & Head, Department of Conservative Dentistry and Endodontics, Sree Balaji Dental College And Hospital, Bharath Institute of Higher Education and Research, Narayananapuram, Pallikaranai, Chennai, Tamilnadu, India

ABSTRACT

Aim: To evaluate the effect of intensity of curing light on depth of cure of resin based composite material and also to bring about the awareness to the dentists community regarding the maintenance of intensity of curing light unit.

Materials and Method: The resin based composite material of A2 shade was tightly packed into a plastic mould (fig1D) of diameter 6mm and depth 5mm. The sample size for each group was 10 in numbers, which was irradiated from the top, for each varying intensity, with light tip in nearest contact. An LED Light Curing unit was used throughout this study; the input voltage to the curing light was controlled by a regulated dc power supply. Four different settings of voltage 2.9V , 3.0V , 3.1V and 3.2V which yielded the light intensity as 200mW/cm2, 250mW/cm2, 300 mW/cm2 and 375 mW/cm2, the power supply to the curing light then was set to this voltage level i.e. 5V and the intensity was verified according to the ISO test method to determine the depth of cure of the resin-based composites.

Results: Statistical difference between the groups and among the groups were calculated using Students ‘t’ test. Results clearly shows a statistically significant difference in depth of cure with varying intensity of light used.

Conclusion: Depth of cure is comparatively low when intensity of curing light is low. These measurements provide valuable baseline information about the specific depth of cure for different intensities of curing light on resin-based composite materials used by dentists.

Keywords: Intensity of light, depth of cure, composite

Introduction

Due to increased aesthetic demands, fear of mercury toxicity and government regulations, the use of amalgam has declined significantly over the past decade. Resin based composites have largely replaced dental amalgam as the direct material of choice for restoring posterior teeth. In addition to being light-polymerized, tooth-colored and repairable, the cavity preparations for composite restorations are also more conservative when compared to amalgam due to the use of micro-mechanical and chemical retention. Direct composite is today the material of choice to restore small-to-medium sized occlusal and proximal cavities in posterior teeth on the condition that the bonding and filling procedures can be adequately performed (1). To fill posterior cavities,
an incremental filling or layering technique, generally involving the placement and curing of composite in layers with a maximum thickness of 2 mm, has been favored over a bulk-fill technique or the filling of the entire cavity with a single composite portion. The main advantages of the layering technique includes more optimal cure throughout the depth of composite and lower polymerization shrinkage with the associated reduced shrinkage stress. On the other hand, layering is more time-consuming and technique-sensitive than bulk-fill placement with the additional risk of void entrapment between layers as well as operative field contamination due to the prolonged working time. There is a constant need to simplify the clinical procedure for direct posterior composite restorations. Several factors affect light curing of a resin based composite: the material’s composition (including opacity), the choice of photoinitiators and the concentration of the initiators. The peak wavelengths and bandwidth of the curing light, the intensity of the light and the irradiation time also have profound effects on the depth of cure. Discoloration, pulpal irritation, post-operative sensitivity and eventual failure of restoration are the main problems resulting from inadequate polymerization. Different variables affecting light energy absorption by the composite have been examined for their effect on the polymerization contraction. Since the polymerization contraction is closely associated to the degree of cure of the restoration in a very complex way, this parameter is designated as an important indicator for the extent of polymerization. It is important to determine the factors that affect light curing and how these factors influence the depth of cure of resin based composites. Knowing the depth of cure of a particular shade of material would guide a dentist in regard to the thickness of a composite layer that could be adequately cured clinically. There is a substantial lack of awareness among dentists of the need for maintenance and regular checking of the light intensity of the light curing units. A numerous number of methods, such as hardness tests, interaction with color dyes, translucency changes, double-bond conversion, nuclear magnetic resonance microimaging, tactile tests, penetration tests and scraping tests have been used to measure the depth of cure of resin-based composites.

There are many studies in literature that have examined the types of curing light used in composites, but provide no information about the light intensity or wavelength characteristics. Therefore the aim of this study was to evaluate the effect of intensity of curing light on depth of cure of resin based composite material and also to bring about the awareness to the dentists community regarding the maintenance of intensity of curing light unit.

**Materials and Method**

We used a curing light [LY – A 180, classic rechargeable LED Light Curing unit] throughout this study; the input voltage to the curing light was controlled by a REGULATED DC POWER SUPPLY [ATTEST, Maharashtra, India] (fig1B) and intensity was measured with a LED light meter [Radiometer, LM – 1, Woodpecker]. The positive and negative nodes in the curing unit circuit was connected to the positive and negative nodes of the Regulated Power Supply and the input voltage was adjusted to produce different intensities of light. Those intensities were measured using a specialized light meter (fig1A) which contains a photosensitive diode that quantifies the blue light output.

With the apparatus set up (fig1c), we were able to calibrate the light intensity as desired. We had four different settings of voltage 2.9V, 3.0V, 3.1V and 3.2V which yielded the light intensity as 200mW/cm², 250mW/cm², 300 mW/cm² and 375 mW/cm². After extrapolated the input voltage needed to deliver a curing-light intensity of 300 mW/cm² for 400- to 515nm wavelength bandwidth, the power supply to the curing light then was set to this voltage level i.e. 5V and the intensity was verified according to the ISO test method to determine the depth of cure of the resin-based composites.

The resin based composite material of A2 shade was tightly packed into a plastic mould (fig1D) of diameter 6mm and depth 5mm. The sample size for each group was 10 in numbers. Each sample was irradiated from the top, for each varying intensity, with light tip in nearest contact (fig1E). Each sample was irradiated for 20 seconds. After irradiation, sample was removed from the mould. Then from the bottom of the sample, the uncured material was scraped out with a plastic spatula. Using a digital Vernier caliper (fig1F), an instrument which measures 1/100th of a millimeter, the remaining length of the sample after scraping out was measured. The depth of cure was recorded as 50 percent of the remaining measured length as required by the ISO (International Organization for Standardization. ISO 4049:2000).

Discussion

In general practice, assessment of the effectiveness of a curing unit is presumably based on whether the surface of a light-cured resin is hard. The surface hardness of the restoration is not a reliable index, because even an inferior curing unit was able to polymerize the surface as well as an effective unit\(^{(7)}\). Adequate curing of a resin-based composite is paramount to its clinical performance. In composite resins, camphorquinone is the light-sensitive component, which responds to irradiation by creating free radicals and initiates the polymerization process.\(^{(14)}\) The photoinitiator used in most composites is activated by light in 400- to 515-nm wavelength, with 470 nm being the wavelength of peak absorption for the most commonly used photoinitiator\(^{(8)}\).

To be effective, a curing light must have sufficient energy in the 400- to 515-nm range to effectively activate the mass or increment of composite being irradiated\(^{(8)}\). The light also must be capable of generating sufficient energy density, or intensity, to cure through the entire thickness of the mass or increment. This study evaluated the effect of intensity of curing light on resin based composites. The ISO technical specification 10650 was based on commercial curing lights available at the time the specification was developed. It has been reported that the minimum QTH light intensity required to adequately cure most resin composites is between 300 and 400 mW/cm\(^2\). The suggested minimum intensity of 300 mW/cm\(^2\) could be achieved by most curing lights available in the global market at that time\(^{(9)}\). It is well known that numerous factors influence the light output of curing units, including line voltage\(^{(10)}\), deterioration of the bulb and filter, contamination of the light tip end, and breakage of photoconductive fibers. Lower than optimal light intensity may lead to impaired polymerization of the light-cured resins, even though curing times recommended by manufacturers are followed, and adversely affect the resin’s physical properties\(^{(8,10)}\). When the light intensity of a curing unit decreases below an adequate level as determined by a radiometer, dentists should inspect the unit for deterioration of the parts such as lamps, filters, and fiber optic bundles. The results of this study showed that 33 (82.5 percentage) of the 40 tested samples met the ISO depth-of-cure requirement of 1.5 mm when cured according to the ISO methods and 7 (17.5 percentage) did not. Marginal decrease in the intensity from the recommended intensity of 300mW/cm\(^2\) to 250 mW/cm\(^2\) and 200mW/cm\(^2\) has a significant negative effect on depth of cure of resin based composite.

The ISO scraping test used to determine depth of cure requires minimal instrumentation and can be performed easily in a dental office\(^{(3)}\). The ISO defines depth of cure as 50 percentage of the length of the composite specimen after the uncured material is removed with a plastic spatula\(^{(11)}\). Curing lights must provide sufficient energy to the composite to produce acceptable polymerization and hardness in the composite resin. It has been reported by Fan et al\(^{(3)}\) that an energy density of 6 to 12 J/cm\(^2\) was sufficient to cure most resin composites to a depth of 1.5 mm. Knowing the depth of cure of a particular shade of material would guide a dentist in regard to the thickness of a composite layer that could be adequately cured clinically\(^{(12)}\). It may be that the absolute values of depth of cure found are material specific, but we believe that the relationships found between curing units, between exposure times, and between light guide distances are universal.\(^{(13)}\) Another observation was that the light intensity of LEDs is significantly higher than that of QTHs, which may be due to the difference in the output light spectrum and clinical age of devices. This finding is consistent with a study by Hegde et al.\(^{(14)}\) There is a substantial lack of awareness among dentists of the need for maintenance and regular checking of the light intensity of the light curing units.
Application to Dental Offices: Using the curing lights in their offices, dentists can readily adopt the ISO method to establish the depth of cure of various composite materials used in their practices. Knowing the depth of cure of a particular shade of material would guide them in regard to the thickness of a composite layer that could be adequately cured clinically. Clinicians often experience difficulty in placing the light tip close to the resin surface when curing resin composites. While both intensity and DOC decrease with increasing distance, the relationship between these factors and distance may not be similar for all lights and may depend on the characteristics of individual lights.

Conclusion

The results of this study show that varying curing-light intensity of 200, 250, 300 and 375 mW/cm² has a significant effect on depth of cure. Depth of cure is comparatively low when intensity of curing light is low. These measurements provide valuable baseline information about the specific depth of cure for different intensities of curing light on resin-based composite materials used by dentists.

Micro Flora—A Challenge in Endodontic Management: A Review

New Begin Selvakumar Gold Pearlin Mary1, Alagarsamy Venkatesh2, Dhakshinamoorthy Malarvzhi2, Loganathan Saatwika3

1Reader, 2Professor, 3First Year PG Student, Department of Conservative Dentistry and Endodontics, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research, Narayananpuram, Pallikaranai, Chennai, Tamilnadu, India

ABSTRACT

Microorganisms are major source of infection of the root canal system. A wide range of microbial flora are isolated from the root canals. A proper understanding of the root canal microorganisms are very important for the success of root canal treatment. This review highlights the microbial flora involved in endodontic pathology and its role in our treatment procedure.

Keywords: Micro-organisms, Retreatment, Endodontic flare up, Endodontic infections.

Introduction

Endodontic infection is the major etiologic agent of apical periodontitis [1]. Physical and chemical factors can also induce periradicular inflammation but scientific evidence clearly states that progression and perpetuation of apical periodontitis are mainly caused by microorganisms[2]. The ultimate aim of endodontics is to completely eradicate the microorganisms from the root canal system thereby preventing the progression of apical periodontitis [3]. Thorough understanding of the root canal anatomy, biomechanics of the root canal preparation and three dimensional hermetic obturation are very essential for the success and long term outcome of the endodontic treatment[4]. This article gives an insight of the microbiology of root canals and its importance for endodontic success.

The Endodontic Microflora: The development in the field of microbiology has led to the recognition of various types of microorganisms which causes root canal pathology.

Bacteria are broadly classified into Gram positive and Gram negative. Most of the apical periodontitis are caused by multifunctional causes. Some of the microorganisms like Actinomyces, Spirochetes and Fusobacterium are responsible for primary endodontic infections. The residual microflora of the oral cavity typically contains $10^{10}$ bacteria[5].

Gram negative bacteria
1. Treponema
2. Fusobacterium
3. Porphyromonas
4. Prevotella
5. Tannerella

Gram positive bacteria
1. Streptococcus sp
2. Camphylobacter sp
3. Neisseria
4. Corynebacterium
5. Anaerobic lactobacilli
Along with the microbial flora some of the viruses are also isolated from the root canal system especially herpes species, cytomegalovirus and Epstein barr virus are also found to be causes of infection in primary endodontic and also the failure of root canal endodontics[6].

**Features of the Microorganisms**

a. Can exist with and without oxygen  
b. Can thrive well in nutrition  
c. Can be antibiotic resistant  
d. Can damage the adjacent viable tissues[7].

**Biofilms:** Biofilm is a group of bacteria where interacting sessile cells are irreversibly attached to the solid substratum and also between microorganisms. They are three dimensional structured community with fluid channels for transportation of nutrition and waste products[8]. Caldwell et all stated that, they have the tendency to self organise (autopoiesis), they can result in environmental perturbations (homeostasis), they are more effective when associated than in isolate(synergy) and respond to environmental changes as unit rather than single individual (communality) [9].

**Importance of Understanding Microbiology for the Success of Non-Surgical and Surgical Endodontic Treatment:** The presence of microorganisms in the dental pulp is directly proportional to the development of periapical disease. There is a favorable outcome when chemomechanical preparation of the infected root canal using antimicrobial agents, followed by obturation and coronal restoration is performed. Due to persistent or secondary intraradicular infection failure of root canal treatment occurs [10].

Microorganisms found in failed endodontically treated teeth have either remained in the root canal from previous treatment or have entered during or after treatment via leakage. It is difficult to differentiate between the microorganisms remaining from primary infections and new microorganisms contributing to the secondary infection. The remaining microorganisms from primary infection should have maintained the viability throughout the treatment procedure. This might occur as a result of an inability of chemomechanical instrumentation and because of inaccessible locations of bacteria in isthmuses, accessory canal and apical regions of canals[11].

**Conclusion**

Microorganisms are the major cause of failure in endodontics. Proper understanding of the pathophysiology of the causative agents is very essential for long term success of root canal treatment.

Hemisection of Mandibular First Molar: Clinical Management—A Case Report

Parthasarathy Rajasekar¹, Suresh Mitthra², Dhakshinamoorthy Malarvizhi³, Arunajetasan Subbiya⁴

¹Final Year PG Student, ²Reader, ³Professor, ⁴Professor and Head, Department of Conservative Dentistry and Endodontics, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research, Narayananpuram, Pallikaranai, Chennai, Tamilnadu, India

ABSTRACT

Hemisection refers to the surgical separation of a multi-rooted tooth with the extraction of one root along with the overhanging crown. It is performed to retain the original tooth structure and attain the fixed prosthodontic prosthesis. Loss of the posterior teeth leads to teeth drifting, loss of masticatory function and loss of arch length, which requires prevention and maintenance measures. Management of periodontally involved molars with extensive decay is challenging and is limited to dental extraction and replacement with implants.

Keywords: Hemisection, prosthesis, implant, periodontally compromised.

Introduction

The term tooth resection denotes the excision and removal of any segment of the tooth or root with or without its accompanying crown portion. Various resection procedures are Root amputation, Hemisection, Radisection and Bisection. Hemisection refers to the surgical separation of a multi-rooted tooth with the extraction of one root along with the overhanging crown. It is performed to retain the original tooth structure and attain the fixed prosthodontic prosthesis. Hemisection is defined as the removal of half of a tooth performed by sectioning the tooth and removing one root (1). Advances in dentistry have provided an opportunity to maintain a functional dentition for a lifetime (2). Loss of the posterior teeth leads to teeth drifting, loss of masticatory function and loss of arch length, which requires prevention and maintenance measures (3). Management of periodontally involved molars with extensive decay is challenging and is limited to dental extraction and replacement with implants (4). Nevertheless, treatment strategy to retain such teeth involves periodontal, prosthodontic and endodontic assessment to allow for stronger survival.

Selected root removal allows improved accessibility and plaque control which leads to bone formation and reduced pocket depth. Continued periodontal breakdown may lead to a total loss of tooth structure. Unless these defects are repaired or eliminated, the health of the tissues cannot be restored to normal form and function. Thus post-treatment these teeth can be used as an individual unit or as an abutment for placement of prosthesis which can restore the masticatory function (5).

Periodontal indications for root resection are: a tooth with a severe vertical bone loss involving only one root of multi-rooted teeth; through and through furcation destruction; unfavourable proximity of roots of adjacent teeth preventing adequate hygiene maintenance in proximal areas and severe root exposure due to dehiscence (6).
Endodontic indications for the prosthesis failure of an abutment within a fixed partial denture: If a single or multi-rooted tooth is periodontally involved within a fixed prosthesis, instead of removing the entire fixed partial denture, if the remaining abutment support is sufficient, the root of the involved tooth is extracted (6).

Endodontic failure: Hemisection is useful when there is furcal perforation or the root canal of one of the roots cannot be instrumented (6) due to calcific obstruction, perforation or ledging.

Vertical fracture of one root: The poor prognosis is seen in vertical root fracture. If vertical fracture traverses one root while the other roots are unaffected, the offending root may be removed (6).

Severe destructive process: This may occur as a result of furcation or subgingival caries, traumatic injury and large root perforation during endodontic therapy (6).

Indications for hemisection include:

- the tooth affected by caries
- vertical root fracture
- periodontal disease
- iatrogenic root perforation where only one root of a multirooted tooth is affected, the surviving root is easily accessible and treatable by endodontic treatment,
- the surviving root is capable of supporting a dowel and core restoration
- the surviving root is aligned as to provide proper retention for the resulting fixed prosthesis.

Contraindications to using a tooth root as an abutment can include:

- poorly shaped roots or fused roots
- poor endodontic candidates or inoperable endodontic roots
- patient not willing to undergo surgical and endodontic treatments and undertake the care for the final restoration.

Risks of this treatment modality include increased risk of caries in the area of the resection due to increased difficulty in cleansing the area. Wide span fixed prosthesis causes increased stress on abutment teeth and leads to periodontal mobility.

The treatment modality that is chosen depends on the grade of furcation, amount of attachment loss present, remaining bone level in relation to the roots and the furcation region, morphology of the roots and long-term prognosis of the involved tooth.

Case Report: A 69 year old female patient reported to the Department of Conservative Dentistry and Endodontics, Sree Balaji Dental College and Hospital, Chennai presenting with a chief complaint of pain and swelling in right mandibular first molar since 2 weeks. The pain was intermittent, aggravated on chewing food and relieved on medication. The patient also complained of food lodgment in the inter-dental area between right first and second molar teeth. His medical history was non-contributory to the condition.

Clinical Examination: On examination, the tooth was sensitive to percussion with respect to 46, and probing pocket depth measured 10mm in the distal aspect of 46 fig1(a) and there was grade 2 mobility, periodontal abscess in 46 on examination. And 3mm pocket depth in the mesial root of 46 was found clinically.

Radiographic Examination: On radiographic examination, severe vertical bone loss was evident surrounding the distal root and involving the furcation area. The bony support of the mesial root was completely intact Figure 2(A).

Endodontic Procedure: Vitality test was done by gutta-percha stick method and showed negative results. Considering the clinical and radiographic evaluation, primary endodontic therapy was performed by resection of the distal portion of the tooth along with the root. The canals of the roots were biomechanically prepared using the step-back technique. The canals were obturated by lateral condensation method using gutta-percha. To obtain good seal and strength for the tooth glass ionomer cement was used Figure 2B.

Hemisection: After adequate local anesthesia, a crevicular incision was given from the first premolar to the second molar. Full thickness flap was reflected to expose the furcation area. Then granulation tissue was removed by curettes to expose the bone. The vertical cut was made in the bifurcation area using tapered fissure carbide bur. The adequate cut was given to ensure the separation of the resected tooth portion. The distal root was removed and the socket was irrigated adequately.
with sterile saline to remove bony chips and debris Figure 1(C). The furcation area was rounded off to avoid further periodontal irritation. The flap was then repositioned and suturing was done with single interrupted 3/0 black silk sutures to obtain primary closure Figure 1(B). Forces acting along the long axis of the mesial root was redirected by reducing the occlusal table. The patient was recalled after one week for suture removal. The case was followed up for 6 months for the survival of the resected molar Figure 2D. A fixed bridge was fabricated using adjacent 2nd molar and the resected molar as abutments to replace the edentulous area Figure 1D&E.

Figure 1: Intra-oral clinical photographs of Hemisection of 46 : A) 10mm probing depth in distal root of 46 ; B) Suture placed after hemisection ; C) Hemisected distal portion of 46 ; D) Tooth preparation done in 46 and 47 ; E) FPD luted in 46 and 47

Discussion

Root-resection therapy is technique sensitive and complex, proper case selection is essential \(^7\). Root resection is a treatment option for molars with periodontal, endodontic, restorative or prosthetic problems. Therapeutic measures performed to ensure retention of teeth varies in complexity. Management of mandibular molar that has lost its bone support surrounding the root or that has a Class II furcation involvement often is a disappointing process for both clinicians as well as patients. The treatment, management and long-term retention of mandibular molar teeth exhibiting such invasions have always been a challenge to the clinician.

One of the methods to treat these type of cases is hemisection. The hemisection is a useful alternative treatment to extraction to save the multi-rooted teeth by endodontic approach, which includes the root canal treatment of the remaining roots and restoring them with suitable restorative material and splinting it with the adjacent tooth to decrease the risk of displacement followed by a fixed prosthodontic prosthesis to maintain the occlusal balance.

Hemisection is one of the option to be considered before the extraction of posterior teeth especially in the patients with severe vertical bone loss, furcation destruction, unfavorable proximity of roots of adjacent teeth, preventing adequate hygiene in maintenance of proximal areas and severe root exposure \(^9\).

Endodontic/restorative conditions which require hemisection are the prosthetic failure of abutments within a splint, endodontic failures, vertical fracture of one root, the non-restorable portion of a multi-rooted tooth \(^6\). The retained root is endodontically treated and the furcations area is made self-cleansable by removing the lip of root carefully. Since hemisected teeth fail by root fractures, it is important to restore them adequately by an extra-coronal restoration \(^10\).

Buhler (1988) observed 32% failure rate in hemisection cases attributed to endodontic pathology and root fracture while other authors (0-9%) have shown greater success in hemisection cases in the long term studies \(^4,6,9\). In the present case, the good prognosis was observed with proper occlusion, absence of mobility and healthy periodontal condition up to 4 months of follow-up. Concurring with previous reports, hemisection is a valid treatment option for the molar teeth, which otherwise have to be extracted due to the extensive lesion \(^10\). Thus, conservative management of molar teeth can not only preserve the tooth but also reduce the financial burden, psychological trauma and occlusal dysfunction.

Conclusion

Hemisection is an alternative, conservative and effective treatment over conventional treatment or extraction of periodontally and endodontic affected teeth. Hemisection should be discussed with patients during consideration of treatment options. The prognosis of hemisected teeth is similar to that of endodontic treatment provided that case should be selected properly and the restoration should be of acceptable design based on the occlusal and periodontal needs of the patient. A guiding principle of conservative treatment should be to try and maintain what is present.

ABSTRACT

Metagenomics using next generation sequencing technologies has produced bacterial profiles and genomic profiles to study the relationships between microbial diversity, genetic variation, and oral diseases. Several oral metagenomic studies have examined the oral microbiome of periodontal disease and caries. Gene annotations in these studies support the association of specific genes or metabolic pathways with oral health and with specific diseases. The roles of pathogenic species and functions of specific genes in oral disease development have been recognized by metagenomic analysis. This review gives an overview on the interaction between oral microbiomes that determine a state of health or disease.

Keywords: Metagenomics, PCR, bacteria, dental caries.

Introduction

Dental caries is the most prevalent oral disease and the primary causes of tooth loss in the western world. At present, periodontitis and dental caries are mostly diagnosed at late stages of disease, often leading to costly and invasive dental treatment. Therefore, new diagnostic approaches capable of identifying periodontitis and dental caries at preclinical stages, favouring preventive treatment strategies, are urgently needed.

As development of DNA sequencing technologies have progressed, metagenomics has become a popular approach to microbial analysis. Metagenomics is a DNA sequencing approach in which a large amount of genomic DNA is randomly sheared, and shotgun sequenced. Several recent studies have used a metagenomic approach to examine microbial roles in oral diseases.

The oral cavity harbours a diverse microbiota comprising more than 700 unique bacterial species. The microbiota plays a pivotal role in maintenance of oral homeostasis, as various oral habitats are colonized by characteristic bacterial community profiles organized in local biofilms. However, ecological changes, for example in relation to increased sugar intake, insufficiently performed oral hygiene or fluctuations in the immune response can induce structural and functional alterations of local oral biofilms. Such alterations may in turn change the relation between the host and the resident microbiota from symbiosis to dysbiosis, thereby fuelling initiation and progression of periodontitis and dental caries.

Meta genomics in Studying Oral Microorganisms:
Metagenomics is another DNA sequencing approach that is used to study uncultivated oral microbial communities. In this approach, whole genome shotgun (WGS) sequencing is used. Entire DNA samples are randomly sheared by a “shotgun” method and sequenced by either classical Sanger sequencing or NGS. The comprehensive sequences can then be analysed to obtain
either bacterial profiles based on 16S rRNA genes or
 genomics profiles based on whole genomes.(1)

For obtaining bacterial profiles by metagenomics,
the DNA sequences are grouped (binned) by conserved
 gene sequences (such as 16S rRNA) that are represented
in individual genomes of different microorganisms.
 Metagenomics requires less PCR amplification than 16S
rRNA sequence analysis, and therefore, more accurately
quantifies individual bacterial species in samples.
For obtaining genomic profiles by metagenomics, the
 shotgun sequence reads are filtered for high-quality
sequences, and contaminating human sequences are
removed. The filtered sequences are then assembled,
based on sequence overlaps, to form longer genomic
sequence contigs. Coding sequences in the contigs
are identified by computational algorithms. Whole-
genome information in the bacterial samples is collected
including protein coding regions, RNA genes, repeats,
 mobile elements, and plasmids. Genes are annotated
via data mining and database searches using different
algorithms.(2)

Abnormal genetic segments that are associated
with health or disease conditions, such as pathogenicity
islands, plasmids, and genes acquired from HGT can be
identified.

Although most current studies employ 16S rRNA
sequence analysis because of its low cost and lesser
computational requirements, 16S rRNA sequence
analysis only provides information on microbial
taxa. Metagenomics provides more comprehensive
information on the oral microbiome. Metagenomic
analysis will become more common in oral microbiology
research as improvements in sequencing technologies
occur and new algorithms are developed for high-speed
computational analysis. New sequencing technologies
will produce longer sequence reads, high accuracy,
shorter processing times, and significantly reduced
costs. Many new computational algorithms will help
speed the handling of sequence metadata, allow for rapid
searching of multiple databases, efficient data mining,
and the integration of different genomic information.

Microorganisms in Carious Lesions: Carious lesion of
the oral cavity is one of the most common disease among
the primary, mixed dentition and adult age groups.
Carcinogenesis itself is the outcome of multifactorial
events that includes plaque microflora, susceptibility of
host immune system, dietary habits, and most importantly
maintenance of oral hygiene. Plaque formation per
se is conceived as a physiologically normal event,
which otherwise is disrupted and removed by effective
brushing techniques. However, when maintenance of
oral hygiene suffers the bacterial flora within the plaque
begins to mature with early and late colonizers which in
the availability of carbohydrate rich substrates becomes
preferentially populated by acidogenic and acid-tolerant
species.

Higher prevalence of Streptococcus mutants has
frequently been associated with carcinogenesis though
not all caries patients test positive for S. mutans. While
S. mutans is known to occur at higher prevalence, several
other acidogenic species have also been reported to co-
prevail within the niche areas such as supra- and sub-
gingival plaque substance and dentinal caries. Some of the
most commonly reported bacteria include Lactobacillus,
Granulicatella, Gemella, Haemophilus, Veillonella,
Actinomycetes, Rothia, Selenomonas, Atopobium,
Neisseria, Eikenella, Fusobacterium, Leptotrichia, and
Enterococcus(3,4,5,6)Several studies have indicated co-
existence of above bacteria in various combinations,
though the detection depended on the source of sample
saliva, mature plaque or dentinal caries from primary,
secondary or mixed dentition age groups.(7,8)

Recent Studies of Oral Microbiome Using
Metagenomics:

- Belda-Ferre and colleagues employed a
metagenomic approach to compare bacterial
profiles in 6 supragingival dental plaque samples
(from six subjects—two healthy, two with a low
number of active caries, and two with a high
number of active caries) and in two cavity samples
from which sufficient DNA for sequencing was
obtained. They found that the array of bacterial
species in the caries samples differed from the array
of bacteria found in healthy individuals. Bacilli
and Gammaproteobacteria were more common
in the healthy samples—whereas, some typically
anaerobic taxa like Clostridiales and Bacteroidetes
were more common in the caries samples. It is
interesting that higher levels of Streptococcus
sanguinis and Aggregatibacter sp. were found in
the healthy samples—whereas, higher levels of
Streptococcus gordonii and Leptotrichia buccalis
were found in the caries samples. They also found
that strains of *Veillonella parvula* were present in all samples but were more abundant in the caries samples. The bacterial profile analysis indicated that tooth cavities were almost complete absent of *S. mutans*, the originally identified etiological agent, but by a complex community formed of numerous bacterial species including the most common genera, *Veillonella*, *Corynebacterium*, or *Leptotrichia*. They proposed that *S. mutans* might initiate caries and interact with other bacterial species and other species could colonize the niche leading to disease development. For example, it was previously reported the synergistic effect of *S. mutans* and *Veillonella alcalescens* in which the mixture of both species produced more acid than either one of them separately. The analysis also found that diversity of the bacterial community diminished as caries advanced. Individuals who have never suffered from dental caries do not have *mutans* streptococci but have high recruitment of other species such as *S. sanguinis*. This finding is consistent with a previously reported analysis showing reduced bacterial diversity concomitant with caries development. The reduction in bacterial diversity in caries development may result not only from the harsh acidic environmental but may also be caused by antagonistic factors, such as the mutacins produced by acid tolerant *S. mutans*.\(^9\)

- **One well-known example in the oral cavity is the competition between *S. sanguinis* and *S. mutans* in which *S. sanguinis* produces H2O2, which inhibits *S. mutans*, while *S. mutans* produces mutacins, which inhibit *S. sanguinis* leading to Competition and coexistence between *Streptococcus mutans* and *Streptococcus sanguinis* in the dental biofilm.\(^10\)**

- **Advantage of Metagenomics in Dental Caries:**

  The prospects for important contributions from oral metagenomics toward understanding oral carious lesions are many. First, metagenomics promises to provide reliable bacterial profiles unencumbered by the biases inherent in culture-dependent microbiologic methods or PCR-dependent molecular biologic methods. Bacterial profiles will help to identify “keystone” microorganisms in dental caries. The healthy bacterial profile may be used to build new therapeutic treatments or to manipulate the oral microbiome by introducing probiotic microorganisms or by selectively inhibiting “keystone” pathogens. Second, many reference genomes will be assembled or completed. Multiple genomes can be compared with study microbial genome evolution. The reference genomes of new oral microorganisms will provide chances to study the roles of these microorganisms precisely in the oral cavity. Third, metagenomics will identify new genes or genetic variations (e.g., pathogenicity islands, HGT) that may be associated with oral diseases. Disease-related genetic variations may be used to develop new diagnostic markers for clinical applications. Finally, bacterial profiles can be associated with genomic profiles through
metagenomics to understand which microorganism(s) and which genes or metabolic pathways play keystone functions in dysbiosis of dental caries.

**Conclusion**

Metagenomics is in an early stage of application to the oral microbiome. However, both bacterial profiles and genomic profiles can be examined and compared in metagenomics to study relationships between microbial diversity, genetic variations, and oral diseases. Current data suggest deep complexity of the oral microbiome. Various studies provide a model in which three levels of interactions are involved in the oral community and, consequently, determine oral health or disease. The first level includes the molecular interactions among biological molecules, such as DNA, RNA, protein, and metabolites. These molecules interact with each other intra-cellularly or inter-cellularly in bacterial cells, and determine microbial growth. The second level includes biological interactions between microbes and microbes and host, such as neutralism, amensalism, antagonism, mutualism, commensalism, or parasitism. The different biological interactions shape the composition of the oral microbiome. The third level includes the relationship of microorganisms with the oral environment. For example, oral environmental changes, such as high-sugar diet, low-pH, smoking, and fluoride use, may affect oral microbial diversity. These three levels of interactions work together to determine the microbiome and to affect pathogen capacities. Dental caries are a consequence of the effects of the microbiome on the host. A systems biology approach is required to explain the complex interactions of microbiome and host. The advances in metagenomics will lead the way for understanding oral disease.

Need for Evidence Based Dentistry in Clinical Practice—A Review

Nagarajan Geethapriya¹, Arumugam Karthick², Dhakshinamoorthy Malarvizhi², Ramu Shobhana³

¹Reader, ²Professor, ³First Year Postgraduate Student, Department of Conservative Dentistry and Endodontics, Sree Balaji Dental College & Hospital, Bharath Institute of Higher Education & Research, Narayananapuram, Pallikaranai, Chennai, Tamilnadu, India

ABSTRACT

Evidence based dentistry is an effort towards oral health care and is a process to systematically collect and analyze scientific evidence to answer a particular clinical situation. It is a logical, common sense, patient-oriented approach which is not different from the regular treatment except that it takes into consideration the uniqueness of each patient. Evidence-based dentistry (EBD) forms an important asset to practice modern dentistry and to educate upcoming dental care professionals. It is important for dentists to be able to keep up with developments in diagnosis, prevention and treatment of oral disease, as well as newly discovered causes of diseases, especially in regards to patient safety. For everyday practice, EBD offers increased personal satisfaction in the knowledge that the patient’s healthcare requirements are met by a treatment that is based on scientific evidence.

Keywords: Evidence based research, Evidence based approach, Systematic review, Dentistry.

Introduction

To make clinical decisions, dentists rely on various factors which includes clinical experience, textbooks, journal articles and previous educational experience. Therefore, for practicing modern dentistry and to educate upcoming dental care professionals, evidence-based dentistry becomes a valuable asset. Research evidence has become a need for dentistry in 21st century. The aim of evidence-based dentistry is to help practitioners provide their patients with optimal care. Often doubts arise in practitioners mind if the new innovations are better than our present clinical approach. EBD requires compilation of the best available evidence with clinical expertise and patient preferences but it cannot replace the clinical judgment [1]. It focuses on answering clinical questions using a critical appraisal of research, assessing the dental literature, finding the relevant and valid scientific studies and applying such results of such investigations to improve clinical care [2]. Hence, helps to solve any clinical problems faced by dentists in their day to day practice.

Evidence based approach is well suited for the present scenario as it will incorporate the best Available scientific evidence for decision making in order to maximize the potential for successful clinical outcome and in turn providing the best patient care [3]. Proper application of the available literature for a clinical situation and if inculcated properly in our practice can make huge difference in our approach and so in the outcome of the treatment. This article is a review from the available literature and using it for better results.

History: Though Dentistry came much after medicine but has adopted the same language and conversations. So, the definition given for evidence based medicine
Evidence based dentistry is defined as an approach to oral health care that includes integration of systematic assessments of clinically relevant scientific evidence, relating to patient’s oral and medical condition and history, the dentist’s clinical expertise, and the patient’s treatment needs and preferences [11].

The establishment of journal on evidence based dentistry 1st appeared as a supplement to the BDJ in 1998 and later it became a stand-alone journal in 2000. The 1st center for evidence based dentistry established in the year 2000 in Davangere (India). In the year 2001 the journal of evidence based dental practice was first established in United States [12]. The DSM-Forsyth center for evidence based dental research was established in Boston in 2003 [6].

**EBD Process:** EBD is a conscious process to identify the best and most up-to-date research that addresses a patient’s clinical problem. The research is based on conjunction with patient’s values, aspirations and preferences, combined with the practitioner’s own clinical proficiency and judgment, to offer more effective ways of managing clinical problems [13, 14].

Evidence-based dentistry has two main goals:
1. Best evidence/research and
2. The transfer of this in practical use.

This involves four basic phases:
1. Asking evidence-based queries (framing an answerable query from a clinical scenario)
2. Searching for the best evidence
3. Reviewing and critically appraising the evidence
4. Applying this data in a way to help the clinical practice.

Carr and McGivney [15] have suggested an additional phase that is the
5. Evaluation of performance of the techniques, procedures or materials.

There are two types of researches that are of considerable importance in dentistry: Qualitative and evidence-based. EBD is based on evaluation of research as opposed to qualitative facts derived from research. Qualitative based research lacks regular appraisal of clinical interventions, which is the very basis of
EBD. EBD has its roots in the discipline of clinical epidemiology, whereas qualitative methods have their foundations in the social sciences [16].

In contrast to traditional dental care which used knowledge and experience from books, adherence to accepted standards, and the opinion of experts and peers, Evidence based practice is based on using current evidence to solve clinical questions [17].

Glover et al. refined the hierarchy by characterizing literature as filtered information and unfiltered information. Filtered information is considered the higher level of evidence. It generates three categories of studies: Systematic reviews, critically appraised topics, and critically appraised individual articles [18].

Only the websites which have been certified over the years for their genuine content should be preferred. Following are the websites which can be assessed for literature review: [19]

- Websites related to EBD are as follows:
  - American Dental Association
  - A-Z systematic reviews.
  - www.ada.org/prof/resources/ebd/reviews/index.asp
    - Cochrane Collaboration. www.cochrane.org
    - Cochrane Oral Health Group. www.ohg.cochrane.org
    - EBD (Journal).
  - www.nature.com/ebd/index.html

The Cochrane Collaboration is a worldwide effort to establish an online resource of pre-appraised bio-medical evidence, which is continuously expanded and updated [20, 21]. Specifically, the collaboration is an international organization whose goal is to prepare, maintain, and provide systematic reviews of the effects of healthcare interventions. The overall aim is to produce periodically updated systematic reviews of randomized controlled trials in specific health areas. The main work of the collaboration is done by fifty Collaborative Review Groups, within which Cochrane Systematic Reviews are prepared and maintained. It has been called “an enterprise that rivals the Human Genome Project in its potential implications for modern medicine” [22] and has also been described as being one of the most significant clinical advances since the creation of the National Institutes of Health (NLM) in the US [23].

PubMed is a free medical database provided by the US National Library of Medicine and the NLM. Highly authoritative and up-to-date, PubMed gives us access to MEDLINE, NLM’s database of citations and abstracts in the fields of medicine, nursing, dentistry, veterinary medicine, health care systems, and preclinical sciences [23]. Articles can be searched by keywords, specific phrases, and Medical Subject Headings or MeSH terms, which are standardized headings used by the National Library of Medicine for cataloging articles in PubMed central [24].

Advantages of Evidence-Based Approach [25, 26]
1. Better use of research evidence in clinical practice
2. Uses resources more effectively
3. More attention on evidence rather than authority for clinical decision-making
4. Monitors and develops clinical performance

**Conclusion**

EBD is an approach which is logical, common sense, patient-oriented and is not different from the regular treatment except that it takes into consideration the uniqueness of each patient. EBD approach empowers clinicians to question and consider the use of current best evidence in decision-making on the management of individual patients. But the question regarding the authenticity of it remains unclear. Thus, well-trusted sites such as Cochrane Library or the PubMed should be trusted. This information is an adjunct, but not a substitute for our clinical judgment and patient preferences. For the clinician in everyday practice, EBD offers solutions to many greater faced in daily practice. Hence, efforts should be made to introduce more trusted websites and other sources which can help practitioners to inculcate evidence based approach in their practice.

Bleaching Lights—A Review

Dhakshinamooorthy Malarvizhi1, Arumugam Karthick1, Nagarajan Geethapriya2, Hannah Christmin3

1Professor, 2Reader, 3Under Graduate Student, Department of Conservative Dentistry and Endodontics, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research

ABSTRACT

Vital bleaching is one of the most common cosmetic dental procedures done in dental office. This procedure consists of carbamide or hydrogen peroxide gel applications that can be applied in-office or by the patient (at-home/overnight bleaching system). In-office treatments utilise light to speed up the process. The objective of this article is to review the effect of light-activation sources on in-office tooth bleaching.

Keywords: In-office bleaching, Carbamide peroxide, Hydrogen peroxide, Whitening

Introduction

Tooth discolouration are of multifactorial etiology. They have been classified as extrinsic, intrinsic and internalised discoloration.1 The extrinsic discoloration is associated with the use of tea, coffee, tobacco.2 Intrinsic stains occurs due to various systemic diseases, medications (e.g., minocycline, tetracycline), childhood diseases, infection or trauma to a primary tooth while the underlying tooth is developing, natural aging changes and the accumulation of stain that has entered the teeth.3 There is an increase in patient awareness of the ability to improve the appearance of their discoloured teeth. Tooth bleaching is a conservative and non-invasive technique which has been well accepted to be safe and effective.3

Hydrogen peroxide releases oxygen that breaks down conjugated bonds in protein chains associated with stain into a single bond. This will result in more absorption of colour wavelengths and resulting in the reflection of little colour (i.e., a whitening effect).2 Various treatment modalities are available which include over-the-counter bleaching (self-administered), in-office bleaching (professionally administered) and dentist supervised take-home bleaching (professionally dispensed).7

Nonvital Tooth Bleaching: When the discolouration is from within the pulp chamber, from necrotic pulp tissue or from staining agents that are present in the pulp chamber, the bleaching treatment need to take place within the pulp chamber. The various techniques are thermolytic technique, walking bleaching and inside-outside bleaching. Recommendations are sodium perborate mixed with water or 10% carbamide peroxide.

Home Bleaching: Home bleaching is considered to be safe and effective treatment.8,9,10 This technique is performed with low concentration hydrogen peroxide (4%-8%) or carbamide peroxide (10%-22%) formulations, which are inserted into trays. These trays are placed in the mouth for 2-8 hours per day, over the course of 2-6 weeks.11

Over-the-counter Bleaching: The patient applies two strips per day for 30 minutes each. 6.5% hydrogen peroxide-coated strip is available. Clinical studies comparing the whitening efficacy of 10% carbamide peroxide with the efficacy of the hydrogen peroxide-coated strips have demonstrated that the polyethylene strips may be an acceptable alternative to the night guard method of at-home whitening.12
**In-office Bleaching:** Although in-office bleaching is performed using high concentration hydrogen peroxide (15%-40%) it is widely used because of these advantages: Minimally invasive, immediate visible results and no need of patient cooperation.\textsuperscript{13}

Since the introduction of in-office bleaching treatments, the use of curing lights (including halogen curing lights, plasma arches, LED, LED plus lasers, lasers) has been recommended to accelerate the action of the bleaching gel.\textsuperscript{14} It is believed that most light sources decompose peroxide faster (by increasing the temperature) to form free radicals which whiten teeth.\textsuperscript{15,16,17}

**The effect of light-activation sources on in-office tooth bleaching:** Strong controversy surrounds the success of light sources has been detected. Some researchers believe that it is effective in the bleaching process, while others believe only certain lights are effective and others reported no effect.

Luk et al., 2004\textsuperscript{18} reported that colour change were significantly affected by inter action of the bleaching and light variables, and the application of light significantly improved the whitening efficacy of same bleaching materials.

Hein et al., 2003\textsuperscript{19} reported no difference in the whitening effect of bleaching gels They concluded that the proprietary chemicals added to the bleaching gels acted as catalysts in the whitening process and were solely responsible for activation, where as the lights had no influence.

Lima et al., 2009\textsuperscript{20} summarised that non-activated whitening did not differ from activated whitening. Where, approximately 35% HP was used with different light sources (LED/diode laser, a halogen lamp, plasma arc lamp, argon laser).

Bernardon et al., 2010\textsuperscript{21} reported that similar results were observed when teeth bleached using the in-office technique and light irradiation were compared to teeth bleached without light irradiation.

Torres et al., 2011\textsuperscript{22} reported that bleaching is more effective with a hybrid light-emitting diode (LED) and a low-intensity infrared diode laser than the control group.

Kossatz et al., 2011\textsuperscript{23} reported a larger difference in bleaching with a LED/laser than without it on 35% HP gel after the first session of bleaching, but after two sessions, the use of LED/laser light activation did not improve bleaching speed.

Hahn et al., 2013\textsuperscript{24} could not find an improvement in tooth whitening as a result of LED or laser light treatments, when evaluating the colour stability of bleaching with Opalescence Xtra Boost (38% hydrogen peroxide) using four different methods: activation with halogen, LED, laser or chemical activation.

Liang et al., 2013\textsuperscript{25} concluded that halogen light and chemically activated in-office bleaching systems were both effective for tooth whitening; however, halogen light activation could improve the immediate tooth whitening.

Nuttera et al., 2013\textsuperscript{26} reported that there was no significant difference in shade change between in-office bleaching with light activated 25% hydrogen peroxide gel followed by 2 weeks at home, night-time bleaching with 10% carbamide peroxide gel in a customised bleaching tray and in-office bleaching with 25% hydrogen peroxide without light activation followed by 2 weeks at home, night time bleaching with 10% carbamide peroxide gel in a customised bleaching tray.

Henry et al., 2013\textsuperscript{27} reported that on a split-mouth design study, the use of a sodium arc bulb lamp with 25% hydrogen peroxide for in-office whitening produces better results on maxillary teeth up to 1 week after whitening is completed.

**Discussion**

This review summarises the effect of light-activation sources on in-office tooth bleaching. Bleaching has been accepted as the least aggressive method for treating discoloured teeth. The application of light significantly improved the whitening efficacy of bleaching materials. This may be attributed to tooth dehydration that presumably is greater with increased tooth heating on using light activation source. However, some researchers have stated that no acceleration or increase in efficacy occurs when using light sources. Light-activated whitening systems add cost, occupy operatory space, can cause burning of the soft tissue, and can increase operatory temperature. The use of a light for in-office whitening may not be justified due to the risks involved. The controversial results which are reported
with different tooth bleaching systems can be attributed to various factors such as: Base-line colour of the teeth of the chosen subjects, the type and concentration of the bleaching product, the time period for the in-chair treatment as well as the treatment period.

**Conclusion**

The use of light source in bleaching show improvement with the use of light activator sources accelerating the process of the bleaching gel and achieving better results.

Veneers—Diagnostic and Clinical Considerations: A Review

Suresh Mitthra¹, Balasubramaniam Anuradha¹, Joseph Changankary Pia², Arunajatesan Subbiya³

¹Reader, ²Third Year PG Student, ³Professor & Head, Department of Conservative Dentistry and Endodontics, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research, Narayanapuram, Pallikaranai, Chennai, Tamilnadu, India

ABSTRACT

Comprehensive oral care that combines both art and science to optimally improve dental health, aesthetics and function is termed as cosmetic dentistry. The objective of Cosmetic Dentistry is to provide maximum improvements in aesthetics with the minimum trauma to the dentition. Veneer is a layer of tooth colored material that is applied to a tooth to restore localized or generalized defects and intrinsic discoloration. Veneer are made up of chairside composite, processed composite, porcelain and compressed ceramic materials. This evolution of material sciences, ceramics, and adhesive system permits improvements of the aesthetic smile design of patients. The current manuscript is a review that highlights the diagnostic considerations; repair and maintenance; and recent advances in veneers.

Keywords: Aesthetic dentistry, Smile design, Repair of veneers, Lumineers.

Introduction

All human desires are in some way related to beauty. The term “esthetics” is borrowed from the Greek word “aesthesia” meaning sensation or sensibility. It can be defined as belonging to the appreciation of the beautiful. Pilkington in 1936 defined dental esthetics as the science of copying or harmonizing our work with that of nature, making our art inconspicuous. “cosmetic” means “kosmos” or adornment in Greek. Veneer is a layer of tooth colored material that is applied to a tooth to restore localized or generalized defects and intrinsic discoloration. Veneers are made up of chairside composite, processed composite, porcelain and compressed ceramic materials. The process of applying a thin veneer of preformed porcelain, composite resin or plastic material to a tooth is called laminating. With the successful use of laminates smiles can be transformed painlessly, conservatively and quickly with long lasting results.¹

Recently people seek dental care mainly for esthetic reasons. The objective of Cosmetic Dentistry must be to provide maximum improvements in aesthetics with the minimum trauma to the dentition. One of the greatest assets of a person is a perfect smile that shows beautiful natural teeth. Rendering or restoration of the smile is one of the most appreciated treatment provided by the dentist. Correction of discoloured, malformed or crooked teeth can produce dramatic changes in appearance, which often results in improved confidence, personality and social life. Veneer is considered one of the most conservative operative treatment procedures because the tooth preparation involves the removal of less than half the thickness of the enamel, leaving the remaining portion intact before veneer placement (2). Number of clinical studies have concluded that bonded laminate veneer restorations delivered good results over a period of 10 years and more (3). The modern improvement of composite cements, adhesive systems and simplified cementation procedures enable the promotion of using veneers among the dentists (4,5).
Classification of Veneers

I. Based on method of fabrication:
   i. Direct technique
   ii. Indirect technique

II. Based on extent of coverage:
   i. Partial veneers - used for localized defects or areas of intrinsic discoloration that involve only a portion of the clinical crown.
   ii. Full veneers - when majority of the facial surface or whole crown of the tooth is discoloured or restoration of generalized defects.

III. Based on tooth preparation – full veneer:
   i. Full veneer with incisal lapping.
   ii. Full veneer with window preparation.

IV. Based upon the materials & techniques used:
   i. Directly fabricated composite resin veneers.
      a. Direct partial veneers
      b. Direct full veneers
   ii. Indirectly fabricated veneers
      a. Etched porcelain veneers
      b. Processed composite veneers
      c. Castable ceramic veneers
   iii. Veneers for metal restorations.

Indications

1. Teeth with intrinsic/extrinsic discoloration - single/multiple: Extrinsic – Plaque, chromogenic bacteria, chlorhexidine mouthrinse, beverages (tea, coffee, red wine), iron supplements.
   Intrinsic – tetracycline stains, fluorosis, haematological diseases, devitalization, smoking, caries and dental restorative materials.

2. Enamel defects - gross enamel hypoplasia of the anterior teeth, amelogenesis imperfecta.

4. Teeth with abnormal shape and form.

5. Improper surface texture.

6. Mal-aligned teeth - For developing the esthetic illusion of straight teeth where orthodontic treatment is not sought or indicated.

7. Malocclusion - The configuration of lingual surface of anterior teeth can be changed to develop incisal guidance or centric contacts in malocclusion or periodontally compromised teeth.

8. Multiple carious lesions and decalcifications.

10. Stained or defective restorations that appear unesthetic on labial surfaces of teeth.

11. Trauma/fracture of multiple anterior teeth.

12. Aging - For discoloured teeth or attrited teeth due to aging, improvement can be done by bleaching or bleaching with subsequent veneering.

13. Wear patterns - Porcelain laminates are useful in teeth with slow progressive wear patterns. If sufficient enamel remains and the desired increased in length is not excessive, porcelain veneers can be bonded to remaining tooth structure to change shape, color or function.

Contra-indications

- Teeth having insufficient enamel.
- Young permanent teeth.
- Teeth exhibiting severe occlusal wear patterns, due to para-functional habits.
- Severe periodontal involvement with severe crowding.
- Poor oral hygiene.
- Inability to etch the enamel in excessively fluoridated teeth.
- Patients with high caries rate.

Ideal requirements of a veneer

1. Biological compatibility, especially with gingival tissues and periodontium.

2. Chemical durability of both the veneer material and its bond to enamel.

3. To be wear resistant.

4. Good aesthetics, which depends on: Color of veneer, Translucency, Color of the luting agent, Resistance to both staining and discoloration.
5. Replicate tooth contour, with a minimum thickness (not thicker than 0.5mm)

6. Smooth surface and margins, capable of retaining high lustre.

7. To be able to mask all sorts of discoloration without the need of an excessive increase in thickness.

8. To be able to copy well, natural colours of tooth both at cervical and at its middle portion and incisal.

9. To be easy to prepare.

10. When in service, to resist fracture and be easily repaired or substituted when fracture occurs.

11. To be of a low cost.

Diagnostic considerations:

1. **Assessment of the Face:** It is important to assess the shape of the face, skin color, symmetry, maxillary and mandibular lip lines. Patients with a narrow face may desire veneers with long and narrow teeth to emphasize the facial shape or round and short teeth to soften the narrowness of the face. Veneers appear brighter and high in value – dark skin and appear yellow and low in value as the skin tone becomes lighter.

2. **Assessment of the Smile:** It is important to assess the shape, form, color of the teeth. The clinician should note the maxillary incisal edge position in relation to the lower lip, the amount of gingival display during smiling and speaking and the overall quality of the smile. In an ideal tooth arrangement, the smile line should coincide or follow the curvature of the lower lip while smiling.

   The space that includes the teeth and tissues (inferior border of the upper lip, superior border of the lower lip) that is revealed when smiling is called the smile zone. Smile zones can be classified into the following types namely - straight, curved, ellipse, bow, rectangular and inverted. This is helpful in assessment of the smile. (6)

3. **Photographs:** The pre-operative photographs documents the pre-operative condition and aids the technician for the veneer fabrication. This should include- a full face smile, retracted frontal view with the shade tab held beneath the incisal edges of the maxillary incisors, a close-up view of the teeth to be veneered and a post-preparation view with the shade tab.

4. **Computer Imaging and Diagnostic Mock Ups:** Computer imaging of the patient’s smile and making the desired changes on the screen – provides the patient and the dentist a realistic preview of the expected result. Preparation and waxing on the diagnostic cast is necessary when veneers are required to lengthen teeth, close spaces or correct mal-aligned teeth.

**Maintenance of veneers:**

- Devices such as ultrasonic cleaner and air- abrasive polisher must be avoided.
- Surface stains on porcelain veneers can be removed with Al₂O₃ or diamond polishing paste on a felt wheel or a rubber cup.
- Proximal stains can be removed with composite proximal polishing strips.
- When scaling is performed around veneers care must be taken not to chip off the margins.
- If topical fluoride application is required by the patient it should have neutral pH- stannous fluoride, acidulated phosphate fluoride should not be used.

**Instructions for the patient:**

1. Patient should be advised that foods & liquids with a high potential for staining such as tea and coffee, increase the potential for marginal staining.

2. Patient must also be aware of the potential of porcelain to fracture.

3. Activities like ice-chewing and finger nail biting should be avoided.

4. Patients with parafunctional habits or in cases when porcelain veneer oppose the natural teeth – a protective appliance or occlusal guard is fabricated and worn by the patient to protect both the veneers and the opposing teeth. (7)

5. Patient should be recalled after 6 months for clinical evaluation. Kihn & Barnes recall method, which was also modified from Ryge criteria are used to evaluate the restoration (9) given in Table 1.

Repair of veneers:

1. Repair of direct/indirect composite veneers:
   Direct laminate veneer restorations have been developed for advanced esthetic problems of anterior teeth. Tooth discolorations, rotated teeth, coronal fractures, congenital or acquired malformations, diastemas, discolored restorations, palatally positioned teeth, absence of lateral incisors, abrasions and erosions are the main indications for direct laminate veneer restorations.

   Small chipped areas can be corrected by recontouring and polishing. When a sizable area is broken -the area is cleaned and shade selection is done. The operator roughens the damaged surface of the veneer with a coarse round ended diamond instrument to form a chamfered cavosurface margin. Roughening can also be done by sandblasting. For additional retention-undercuts or mechanical locks are placed in the remaining composite with a small ¼ round bur. A 45° bevel (2mm in width) is placed at the junction of the remaining composite and fractured portion. Acid etchant is applied and rinsed. Bonding agent is applied on the remaining composite and exposed tooth surface and cured. Composite is then added, cured, finished and polished.

2. Repair of porcelain veneers: PLVs have become the aesthetic alternative to ceramic crowns and the traditional porcelain fused-to metal. These restorations exhibit reduced plaque build-up and its easy removal due to their smoothly glazed surface. The union of etched enamel and porcelain, combined with the bonding composite resin-luting agent with a silane coupling agent provides a long lasting restoration. The patients acceptance of the porcelain laminate veneer technique now-a-days seems to be high. Goldstein and Lancaster in their study showed that patients would readily accept shorter restoration life expectancy (five to eight years) if enamel could be saved by not reducing the tooth for a full crown. Due to the delicate nature of porcelain veneers, a possible post-operative complication is cracking. If the veneer is been well bonded to the underlying enamel and is not an aesthetic concern, the patient should be informed and the veneer should be left in place. When the patient presented with a fracture of the mesio-incisal portion of porcelain veneer, isolation is done with an oral retractor. Initial shade selection is done. A quick mock-up of the repair with the selected resin composite can verify the shade selection. A 2mm wide bevel is placed on the porcelain surrounding the fracture. To protect the adjacent soft tissue and the restoration surface- EtchArrest – sodium bicarbonate gel is applied. 10% of hydrofluoric acid gel is applied for 1 min. To prevent the potentially harmful acid splatter and to neutralize the effect of HF acid-
Etch Arrest is again applied. Next the porcelain surface is rinsed and dried. The silane primer is applied and allowed to dry for 60 sec. This silane treatment of the exposed silica surface results in the formation of siloxane bond with the methacrylate groups of the composite. Bonding agent is applied and cured. The resin composite is applied to the fractured site, cured, finished and polished. Large fractures are treated by replacing the entire porcelain veneer.

Recent advances in veneers

1. Porcelain veneer with Inman aligner: The Inman aligner was invented by Dr. Don Inman in 2001 at the Inman Orthodontic Laboratory at Kent in U.K. Indicated in patients with severe anterior crowding, where extensive tooth preparation is required for porcelain veneers. The aligner worn for 4-12 weeks, prevents excessive tooth reduction by pre-alignment of teeth. Minimum tooth preparation is done and porcelain veneers are fabricated.

2. MAC Veneer: The MAC (Micro Advanced Cosmetic division) veneer was introduced by the Micro Dental laboratory at Dublin in 2005. They are made from pressed ceramic. When compared to porcelain veneers, they are stronger, thicker (0.8-1 mm), fit more tightly and securely over teeth. These custom-made veneers are long lasting, stain resistant and not easily dislodged.

3. Da Vinci Veneers: They were introduced by Dr. Joel D. Gould in 2008 at the Da Vinci laboratory at California. They are ultrathin shells of tooth coloured ceramic that are resistant to permanent staining. The thickness is 0.2 – 0.3 mm. This requires no anesthesia with minimum or no tooth preparation. The teeth are lightly buffed to removed 0.5 mm thickness of enamel, an impression is made and sent to the lab. No temporization is required. Depending on the colour of the luting cement the shade of the veneer can be adjusted.

4. Lumineers: They were introduced by Dr. Mat Carty in 1990 and manufactured by the Den Mat corporation. They are the most popular no preparation veneers. This exceptionally thin veneer (0.3 – 0.5 mm) can maintain its durability due to the high strength – Cerinate porcelain. Cerinate porcelain is a translucent leucite based feldspathic porcelain, available as stackable or pressable porcelain. A study conducted by Strassler et al. evaluated the colour stability, marginal integrity, discoloration and secondary caries for 10 years revealed that 94% out of 167 Cerinate Lumineers placed with ultrabond were successful.

5. E- max veneers: Introduced by Microstar Corporation to the U.S. market in September 1998. Available either as ingots for pressing or as blocks that can be milled by CAD/CAM milling machines. Made from IPS Empress 2 ceramic – lithium disilicate veneers. Mostly used for crowns and bridges. Indicated for veneers when combined with adjacent IPS e max bridges or crowns. They are very thin (0.3 mm), can be used to increase the vertical dimension of the concerned teeth. High bond strength, most popular for the last 15 years, cemented with dual cure resin cement variolink II.

Conclusion

A beautiful smile is like a green light at an intersection. The ultimate goal of veneers is to enhance the aesthetics with a beautiful smile. Veneers are a useful adjunct to the armamentarium of the dentist for management of aesthetic problems in both young and elderly patients. Care needs to be taken during tooth preparation and the luting phase to ensure maximum results. With the combined advancements in acid etch, resin bonding techniques and material properties, veneers have become a more conservative and a highly aesthetic alternative to full coverage restorations.

Diagnosis of Vertical Root Fracture: A Review

Alagarsamy Venkatesh¹, Arunajatesan Subbiya², Suresh Mitthra³, Venkatachalam Prakash¹

¹Professor, ²Professor & Head, ³Reader, Department of Conservative Dentistry & Endodontics, Sree Balaji Dental College & Hospital, Bharath Institute of Higher Education and Research, Narayananapuram, Pallikaranai, Chennai, Tamil Nadu, India

ABSTRACT

Vertical root fracture in teeth can be a barrier in diagnosis. There are other clinical and radiographic findings which can be vigilant to the clinician to the existence of fracture. Knowledge of the diagnostic aspects and the correct correlation and interpretation of radiograph was enough to establish the diagnostic hypothesis of vertical root fracture.

Keywords: Endodontics, Diagnosis, Vertical Root Fracture, Three dimensional imaging.

Introduction

A vertical root fracture (VRF) is defined as a complete or incomplete, longitudinally oriented fracture of the root, which is usually directed in the buccolingual plane. This fracture usually initiates in the tooth root and may extend coronally (1). VRF are most commonly associated with endodontically treated teeth (2). Pain and swelling, the presence of an isolated deep periodontal pocket and a combination of periapical and lateral radiolucency associated with the root are considered pathognomic for VRFs (3). However, the clinical signs, symptoms and radiographic appearance of VRFs frequently resemble endodontic failure to distinguish VRFs from non-VRFs (4).

The fracture is usually diagnosed years after all endodontic and prosthetic procedures have been completed (5).

The final diagnosis of VRF is, at times, challenging because of either shortage of specific signs and symptoms and/or of conventional radiographic features. Therefore, the differential diagnosis from other pathologic existence can be a challenging task (6-9).

Several etiologic factors may be involved (5, 8, 10). The affected root or tooth has an unfavourable prognosis and extraction is usually the only treatment option (4, 11).

Clinical features: Clinical signs and symptoms as well as radiographic representations often resemble to those associated with non-healing root canal treatments and with certain phenomenon of periodontal disease. Although, a quick determination is mandatory to prevent undesirable bone loss, that can result in difficulty in reconstructing the area, in which the treatment of choice for replacement is dental implant. Yet, the diagnostic information may be insufficient or the patient may be reluctant to undergo a diagnostic surgical procedure, thus forcing postponement of a conclusive decision on the diagnosis.

Frequently occurring were bone loss, tolerable mild pain, sinus tract opening, and aggravation of a chronic lesion and pain during mastication.

One of the presenting signs of VRF is resorption along the fracture line (12, 21). In the apical region, this resorption may progress apically where it creates a V-shaped nick, or along the whole length of the fracture,
giving the appearance of an irregular long resorptive osseous defect running longitudinally along the gutta percha root canal filling. Defragmentation of root canal sealer, silver points and gutta percha in conjunction with considerable resorption of the root has been recorded as being a component of vertically root fractured teeth (21).

A definitive diagnosis of VRF is best attained by an exploratory flap (9,12,13). If dehiscence, fenestration, and/or a clear sign of fracture are not found during a surgical procedure, an apicoectomy may be attempted. Yet, the tooth may still have a questionable prognosis, as an undiagnosed incomplete fracture may be present at the lingual aspect of the tooth.

Radiographic features: A final diagnosis of VRF identified on radiographs can be made in two illustrates. First one is the appearance of a fracture as hair line radiolucency in the dentin body. The other sign of fracture is the radiographic appearance of root segment separation (7, 14), usually accompanied by large bone losses surrounding the tooth or root.

It may be difficult to detect the fracture line as root fractures almost generate in a bucco-lingual pathway, and only the bone facing the fracture resors at the early stage, which shows associated radiolucencies producing root superimposition. Anyhow, as the bone resorption extends laterally, it may be potential to detect. When a VRF is suspected in a specific tooth, two periapical radiographs taken from different horizontal angulations are mandatory. Other radiographic signs include diffused V-shaped bone loss radiolucent halo around the entire tooth surface (15). [Figure 1,2,3]

![Figure 1: Endodontic treated tooth with halo type radiolucency-suggestive of VRF in 36](image1)

![Figure 2: Diagnostic radiograph-mesial shift – VRF not appreciated in 36](image2)

![Figure 3: Diagnostic Radiograph–Distal shift – VRF seen in the coronal third of mesial root of 36](image3)

Discussion

VRFs are considered to have severe complication and differential diagnosis which unavoidably leads to tooth extraction. The differential diagnosis includes failed endodontic treatment and periodontal diseases. Clinical examination, history and various investigation rules out the differential diagnosis of VRF. Advanced imaging examinations like conventional computed tomography (16, 17) and coherence optical tomography(18). Till date, coherence optical tomography is not available for dental use; it is a diagnostic unit for arteriosclerotic plaques present in cardiac catheter laboratories and could be a important tool for the diagnosis of VRFs (18). Unfortunately, conventional computed tomography and cone-beam or digital volume computer assisted tomography are not feasible to most of the community since they are expensive. The conventional periapical radiograph is still the most implied method, in spite of its low sensitivity, and this is likely due to the credibility of low cost of X-ray machines. Furthermore, the diagnosis of a VRF is only conclusive when the affected tooth is surgically explored to visualize the fracture line (6, 19, 20)
Advanced imaging techniques are good alternate methods for enhancing the diagnosis of VRFs (16,17) because periapical radiographs are unable to detect the fracture line.

**Conclusion**

In conclusion, any lesions due to VRFs will not have a similar appearance on CBCT images in relation with those which appear due to non-VRFs. Hence, three-dimensional CBCT images can be used to differentiate the VRF with a high degree of accuracy. However, clinical and radiographic signs suggests that a root fracture is present, direct inspection of the fracture is the most assertive way to confirm the presence of VRF. Location of the fracture can be assisted by passing a sharp probe lightly over the tooth surface. A ‘clicking’ sound can be heard as the probe is passed over the fracture line (12). Where this is contra-indicated, elevation of a small flap is recommended in order to view the root and confirm the presence of a fracture. At the time of surgery, the appearance of the fracture may vary. When the fracture is stained, visualization is simple. A fibro-optic light is a useful diagnostic tool, particularly where the fracture is not stained, or where separation of fragments has not occurred.

ABSTRACT

Handpieces are one of the most important instruments used in dentistry today. With the advancement in technology, handpieces are fast developing and playing a major role in many of the procedures in dentistry today. This review is about the handpieces used in dentistry, their recent advances and speed, which is an important factor which is closely associated with handpieces.

Keywords: handpieces, dentistry, speed, cutting, efficiency

Introduction

A handpiece is a device for holding rotating instruments, powering them, and for positioning them inside the oral cavity. Some of the requirements of a handpiece are (1) safe and effective, minimizes dental trauma, gross hard tissue removal, enables preparation refinement, offers sufficient power and torque, enables or enhances visualization, light weight, good grip and handle configuration, ergonomically designed, no noise or vibration, easy to sterilize.

History: In 1778, a near-mechanical drill was invented. It was powered by a simple hand-crank attached to a gear. Though it was hardly any technology, it was the first to remove bits of tooth structure. In 1864, the clockwork dental drill was invented by a British dentist named George Fellows Harrington. In 1868, the pneumatic dental drill was introduced by George Green. In 1914, electric drills of speeds 3000rpm were introduced. In 1949, John Patrick Walsh from New Zealand patented air turbine handpiece(2). In 1957, Bordon introduced aeroter air turbine handpiece(3) which was manufactured by Densply. And today we have handpieces of advanced technology with multiple ports for water spray(4) and also fibre-optic bundle for illumination.

Anatomy of a Handpiece: An air driven handpiece has two main components namely the body or the shell and the turbine. The body has two parts. They are the head that houses the turbine and an outer sheath. Air and water are delivered through the body to the handpiece head. This includes the main drive air, coolant water (balances the heat generated), and chip air (often used to atomize the water spray). After the drive air passes through the turbine, it is sent off through the hollow body of the handpiece and down the handpiece tubing.

Various materials are used for the body. Of them, brass and stainless steel have been the commonest. Stainless steel is heavier and stronger than brass and also costlier. The material being used recently is Titanium. It is newer, stronger and resistant to repeated cycles of sterilization.

Coming to the turbine, a high speed turbine contains two components; A chucking mechanism to hold the cutting instrument and a rotary system that turns the bur at speeds of approximately 6,000 times for every second when air pressure is supplied.
The rotary system is made of an impeller, or rotor, which “catches” drive air, mounted on a spindle. The spindle rotates clockwise at high speeds, supported by two precision bearings and two suspension O-rings. The miniature bearings are the heart of the turbine. The most critical element of these bearings is the retainer, or cage, that secures the ball bearings within the raceways. This becomes brittle as it is subjected to harsh sterilization environments; upon failure, the bearing cage disintegrates and the turbine will no longer rotate or generate power\(^5\). Some symptoms of bearing failure include the bur no longer spinning concentrically, unacceptable vibration when the handpiece is activated, or unusually loud sounds emanating from the turbine\(^6\).

**Recent Improvements**

**Air Driven Handpieces:** Air driven hand pieces are available in different head sizes. They are full-size, mid-size and miniature head. Small head size improves visibility and access. Large head sizes have higher power and therefore takes less time for the procedure. Coming to angulation, a typical handpiece is angled back at 22.5° so that the cutting instrument lies in line with operator’s line of sight, however this can sometimes restrict access to posterior teeth by causing the handpiece to come in contact with maxillary teeth. Newer designs are featured with a unique head angle to overcome this.

Newer handpieces are with lower noise levels of 58-71 decibels\(^4\). The ergonomic design of the handpiece is also improved with wider flared body shape towards the rear of the handpiece which reduces the pinching force required to grip the handpiece, thereby reducing hand and wrist fatigue\(^6\).

Innovations in turbine design include turbine impeller improvements which help handpieces to maintain a constant speed even under load and reduce stalling. Another new feature that addresses torque and stalling issues in the inclusion of sensors that tell the unit’s electronic ‘brain’ when additional power is required to maintain constant speed. Modern microsized components allow additions like high tech sensors to be integrated into the handpiece without increasing size or weight.

The newer antisuck technology is the integration of air compartments that store air, and then release it to counteract the Venturi effect making a difference.

**Electrical Handpieces:** Earlier small carbon brushes were used which wore against the rotors. Many of the new motors are brushless requiring lesser maintenance. Shorter and lighter weight motors maintain balance between motor and attachment. Newer electrical handpieces are with fewer attachments\(^7\). The fiber optics and multiport water spray are delivered through the attachments\(^8\).

**Maintainence and Sterilization:** Handpieces are semicritical instrumentation requiring sterilization. The current CDC guidelines recommend autoclaving of dental handpieces after use for a single patient\(^9\). The United States Air Force Dental Investigative Service concluded that the clinician can expect a handpiece to survive approximately 500 sterilization cycles without significantly reduced performance, if the handpiece is properly maintained\(^10\). Five hundred cycles for a handpiece used and sterilized twice a day, five days per week, would translate into approximately one year of clinical service\(^11\).

Autoclave sterilization is the most rapid methods of sterilization. Fibreoptics dim with repeated heat sterilization, apparently owing to oil residue and debris baked on the ends of the optical fibre. Cleaning with detergent solution and wiping ends of the optics with alcohol or other suitable organic solvents may prolong the use before factory servicing. The handpieces should be bagged, sheathed and autoclaved. Manufacturers directions have to be followed. Using chemicals that would damage the internal parts should be avoided.

Other methods of sterilization of handpieces are chemical vapour pressure sterilization or chemiclaving recommended for ceramic bearing handpieces. When autoclaving or chemiclaving, temperature should not exceed 275°F or 135°C. Another method is ETOX Gas. This is a gentlest method. The oil left can impair the sterilization. One must confirm with the manufacturer that the sterilizer has pre-marketed review and approval from FDA. Further research is needed on ETOX sterilization for handpieces.

**Speed:** According to Sturdevant, Speed is number of times a rotary instrument such as a bur, will make a full turn during a minute\(^12\). According to Marzouk, Speed is the surface feet per unit time of contact that the tool has with the work to be cut\(^13\). The rotational speed of an instrument is calculated as revolutions per minute (RPM).
Since the surface feet per minute is controlled mainly by RPM and the size of the revolving tool, it is important to consider the size of the working tool in relation to speed of operation. A rotary tool should be large in diameter when used with low speeds to approach the optimum surface feet per unit time. In the ultra high speed range, the diameter of a cutting tool should be reduced to approximate the limits of maximum cutting efficiency.

**Classification**

According to Sturdevant are:

1. Low or slow speeds (<12000 rpm)
2. Medium or intermediate speeds (12000-200,000 rpm)
3. High or ultrahigh speeds (>200,000 rpm)

According to Marzouk:

1. Ultra low speed (300-3000 rpm)
2. Low speed (3000-6000 rpm)
3. Medium high speed (20000-45000 rpm)
4. High speed (45000-100,000 rpm)
5. Ultra high speed (> 100,000 rpm)

According to Vimal Sikri:

1. Conventional or low speed (<6000 rpm)
2. Intermediate or high speed (6000-100,000 rpm)
3. Ultra or super speeds (>100,000 rpm)

The crucial factor is the surface speed of the instrument, the velocity at which the edges of the cutting instrument pass across the surface being cut. The speed is proportional to the rotary speed and the diameter of the instrument, with large instruments having higher surface speeds at any given rate of rotation.

**Slow Speed:** Although intact tooth surface can be removed by an instrument rotating at low speed, it has many disadvantages of being ineffective, time consuming, requiring heavy force application (results in heat and vibrations of low frequency and high amplitude which causes patient discomfort), burs having a tendency to roll out of the tooth preparation and mar the proximal margin or tooth surface and the brittle blades of the carbide bur are easily broken at slow speeds. The advantages of slow speed are better tactile sensation and less chance for overheating cut surfaces.

**High Speed:** At high speed, the surface speed needed for good cutting can be achieved by more smaller and versatile cutting instruments.

The advantages of high speed are removal of tooth structure faster with less pressure, vibration and heat generation, the number of rotary cutting instruments being reduced because smaller sizes are more versatile in application, having better control and greater ease of operation. The instruments last longer. Patients are less apprehensive and several teeth in the same arch can be treated at the same appointment.

The disadvantages are loss of control and tactile sensation, breakage of instruments proceeded by flute distortion and change in anatomical curvature of the canal.

The air driven high speed handpieces rotate at a speed of 2-8 lakh rpm. The actual speed and the rotational speed are two different aspects of high speed turbine/airrotor hand piece. The cutting speed is 30% less than the rotating speed. It is also called as free speed and active speed. Free speed is the true rotating speed while active speed is the cutting speed. Their is a safety mechanism in high speed hand piece i.e. the bur stalls when pressure is applied more than what is required for cutting. This is because as resistance builds during cutting the air pressure is insufficient to maintain the speed of the turbine’s rotation. So air-driven handpiece should not be selected based on top speed as it is not the actual speed during tooth preparation.

There is a basic difference in conventional micromotor bur rotation and high speed handpiece. With high speed instruments bur continues to rotate even after clinician removes his foot from the pedal controlling the air-water spray. This is called coast speed. Most of the high speed handpieces have two holes called Borden’s two hole handpieces. In 1950, Dr. John Borden invented air driven high speed handpiece. Eventually coast speed was substantially reduced and bur comes to a halt at the earliest. Today we have 4 and 6 hole handpieces.

The international standards specifications allow up to 0.03 mm of eccentricity commonly referred to as run out or bur wobble. However concentricity is defined as ability of a handpiece to produce a cutline consistent with the diameter of the bur.
**Speed in Electric Handpieces:** Electric handpieces have been found to be more efficient than air-driven high speed handpieces\(^{(18)}\). Electric systems alternatively offer smooth, constant torque that does not vary as the bur meets resistance. Because the speed and torque are constant, removing difficult crowns, bridges, and restorations become easier\(^{(19)}\). Electric motors give end users an advantage of setting precise speeds for procedures, rather than the conventional ‘feathering’ of the rheostat. When considering an electric hand piece you will need a 1:5 gear ratio for tooth preparation. Low-speed hand pieces are also available for other dental treatments procedures.

**Relation of Speed with Different Factors**

**Pressure\(^{(13)}\):** Pressure is force per surface area. Using same force, smaller tools apply more pressure to the point of contact than larger tools. To have both the tools cut at same pressure, force applied with smaller ones should be reduced. If so, then larger tools will remove more tooth structure since there is more surface contact. To make smaller tools remove more tooth structure it is necessary to increase the speed i.e. revolutions per minute. It has been observed clinically that low speed requires 2-5 pounds force, high speed requires 1 pound and ultra high speed requires still less force i.e. 1-4 ounces.

**Vibrations\(^{(13)}\):** A wave of vibration consists of frequency and amplitude. At low speed, large amplitude and small frequency vibrations are produced. At higher speeds, it is reverse. The greatest harm is caused by amplitude (patient apprehension, destructive reaction in tooth and dentist’s fatigue). By increasing operating speed, amplitude and its effects are decreased. It has been shown that rotation of approximately 6000RPM sets up a fundamental vibrational wave of approximately 100 cycles/sec. Higher speeds produce less amplitude and high frequency and hence perception will be lost in ultra high speed ranges of 100,000 RPM or more.

A study reported that average measurement of the frequency of sounds emitted by high-speed dental air turbines was 6860 Hz\(^{(20)}\). It indicated that under any working conditions, high-speed dental air turbines emit frequencies which can cause hearing loss.

**Cutting Efficiency\(^{(13)}\):** The rate of cutting increases with the rotational speed but this increase is not in direct proportion. It has been found that at very high speeds 150,000 and above, the time required for the removal of the same weight of tooth structure is very nearly the same as at still higher speeds. There is however a minimum rotation speed for a given load below which the tool will not cut. Greater the load, lower is this minimum speed. The correlation between the speed and the load depends upon whether enamel or dentin is being cut, design and composition of bur.

**Conclusion**

We cannot imagine dentistry without a handpiece. It is like going back in time by more than a hundred years. Today practitioners are extremely dependent on handpieces. The dental handpiece is a vital part of clinical procedures in every dental operatory. As the scope and need of procedures increases, advancements in handpiece technologies will continue to play a critical role in the practice of dentistry.

Management of Maxillary First Molar with Six Canals—A Case Report

Lakshmisree A G¹, Arumugam Karthick², Nagarajan Geethapriya³, Arunajatesan Subbiya⁴
¹Third Year PG Student, ²Professor, ³Reader, ⁴Head and Professor, Department of Conservative Dentistry And Endodontics, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research, Narayananapuram, Pallikaranai, Chennai, Tamilnadu, India

ABSTRACT

Generally permanent maxillary first molar has three roots and four canals. While there is usually a single canal in each of the distobuccal and palatal roots, the broad buccolingual dimension of the mesiobuccal root and associated concavities on its mesial and distal surface is consistent with the majority of the mesiobuccal roots having two canals. In the literature with respect to frequency of occurrence of the number of canals in each root, there is a wide range of variation with regards to the number of roots and incidence of fusion. The root canal morphology of teeth is often extremely complex and highly variable. Variations may result because of ethnic background, age and gender of the population studied. The following manuscript is a case report that describes the management of maxillary first molar with 6 canals.

Keywords: six canals, maxillary first molar, anatomical variations

Introduction

One of the essential prerequisite for successful endodontic diagnosis and treatment, is the recognition of variations in root canal anatomy. The complexities of internal anatomy are often masked by the external surfaces, which have a relatively simple and uniform anatomy.(1) Successful root canal therapy requires a thorough knowledge of root and root canal morphology. Generally permanent maxillary first molar has three roots and four canals.(2) While there is usually a single canal in each of the distobuccal and palatal roots, the broad buccolingual dimension of the mesiobuccal root and associated concavities on its mesial and distal surface is consistent with the majority of the mesiobuccal roots having two canals.(2,3) In the literature with respect to frequency of occurrence of the number of canals in each root, there is a wide range of variation with regards to the number of roots and incidence of fusion.

The root canal morphology of teeth is often extremely complex and highly variable. Variations may result because of ethnic background, age and gender of the population studied. In some studies, a separate canal is defined as a separate orifice found on the floor of the pulp chamber(10), two instruments placed into two MB canals simultaneously to a minimum depth of 16 mm from the cusp of an intact tooth (11), one that can be instrumented to a depth of 3 to 4 mm (12) or a treatable canal in retrospective clinical studies(8). Weine et al. in 1969 (5), gave the first clinical classification of more than one canal system in a single root, and used the mesiobuccal root of the maxillary first molar as the type specimen. A system was further developed for root canal anatomy classification for any tooth that has a broad buccolingual diameter(7,13).

Case Report: A 52 year old male patient came to Department of Conservative dentistry and Endodontics,
Sree Balaji Dental College and Hospital, with a chief complaint of pain in right upper back tooth region for past 1 month. Pain was aggravating during mastication and relieved under medication with an onset of lingering response to hot and cold stimulus for 1 month before the initiation of the treatment. Patient had no relevant medical history. On extra oral examination, there were No palpable lymph nodes. On intra oral examination no abnormality was detected in relation to soft tissue and a deep class II caries was present in relation to right maxillary first molar which was tender on percussion. Radiographic examination revealed radiolucency involving enamel, dentin and pulp and widening of periodontal space and loss of lamina dura in 16 with ill defined radiolucency in the periapical region (fig.1A). Based on clinical and radiographic examination, case was diagnosed to be symptomatic irreversible pulpitis with symptomatic apical periodontitis in relation to 16. The treatment plan opted was root canal treatment, followed by full coverage crown in 16.

Treatment was initiated with anesthetizing the tooth with 1.8 mL 2% lignocaine containing 1:80,000 epinephrine (Lignox 2% A, Indoco Remedies Ltd., Navi Mumbai, India) and relieving it from occlusion. The access cavity was prepared under rubber dam isolation (fig1c), and the chamber was irrigated with 3% sodium hypochlorite [NaOCl] (Neelkanth Health Care (P) Ltd.). MB1, MB2, MB3, DB1, and (palatal) P1,P2 canal orifices were located using DG 16 explorer and coronal flaring was done with gates-glidden drills size no. 2 and 3 to improve the straight-line access. The canals were negotiated for patency using K-flex files and working length was determined using RootZX Mini [JMoria] and initial hand filing till #20 K-file was done in all the canals. The working length (fig1B) was later confirmed by radiograph. Also CBCT image of the particular small field of vision in relation to 16 was taken. The canals MB1, MB2, MB3 and DB were instrumented with #25 4% NeoEndo instruments and #25 6% and #20 6% for palatal canal respectively. Master-cone radiograph was taken(fig1D). Final irrigation was done with EDTA (Endoprep-RC, Anabond Stedman Pharma research ltd.) and the canals were completely dried with paper points and obturated (fig1E) with gutta-percha (Dentsply Maillefer) and AH plus resin sealer (Maillefer, Dentsply, Konstanz, Germany). The patient was asymptomatic on follow-up (fig1G) and was posted for full coverage crown for the tooth.

Endodontic management of maxillary first molars is a constant challenge, due to the anatomical complexities of their roots and root canals. One of the major causes of root canal to fail is the inability to identify, locate, and manage the entire root canal system. Anatomical aberrations are commonly observed in maxillary first molar ranging from one to seven canals.\(^{(14)}\) It is generally accepted that maxillary first molar has three roots and three canals with a fourth canal (MB2) seen in 50.4–91% of cases.\(^{(14–16)}\) The occurrence of double root canal system in all roots of a maxillary molar simultaneously is an unusual finding.\(^{(8)}\) Diagnostic measures such as multiple preoperative radiographs, examination of the pulp floor with a sharp explorer, troughing of grooves with ultrasonic tips, staining the chamber floor with 1% methylene blue dye, visualising canal bleeding points and performing the hypochlorite champagne bubble test, are important aids in locating root orifices.\(^{(17)}\)

Different methods to decrease the occurrence of missed Canals include steps such as sufficient tooth structure removal to allow instruments to be placed easily into the orifice of each canal during root canal preparation without interfering with overhanging walls. Each canal orifice must be visible and easily accessible for placement of the instrument. If extra roots and/or canals are suspected at the diagnosis stage, modification of the access cavity outline form should be done.\(^{(18)}\) The anatomical laws of Krasner and Rankow\(^{(19)}\) highlight some useful general anatomical landmarks (independent of the crown anatomy). Degree of canal curvature, the position of the canal apex relative to its cusp tip, canal length, the degree of calcification, size and shape of the canals and the position of the tooth in the jaw are the parameters that determine the specific design of an access cavity.\(^{(18)}\)

Radiographic techniques to aid in locating the canals include \[a\] Conventional radiography: at least two periapical radiographies should be taken using the parallel technique with either a mesial or distal horizontal tube shift, for careful evaluation of the root canal morphology. Martinez-Lozano et al\(^{(20)}\) in their study revealed that by varying the horizontal angle, the number of root canals observed in maxillary premolars was similar with the actual number of canals present. Regarding the fact that the three-dimensional anatomy of the area being radiographed is compressed into a two-dimensional image, the amount of information gained from conventional radiographs and digitally captured periapical radiographs is limited.\(^{(21)}\) Newer diagnostic aids such as computerized axial tomography (CT) scanning greatly help access to the internal root canal morphology. CT images identified a greater number of morphologic variations than panoramic radiographs\(^{(21)}\).  [b] Cone-beam computed tomography: CBCT images always aided in the identification of a more number of root canals than digital radiographic images\(^{(22)}\). A dental operating microscope and CBCT scanning is of very important for locating and identifying root canals, and also CBCT scanning helps in initial identification of the internal morphology of maxillary first molars\(^{(15)}\). [c] Ultrasonic devices: Ultrasonic devices are particularly advantageous when attempting to locate the mesio-palatal canal in maxillary molars due to the cavitation effect of the same. The combined use of an operating microscope and ultrasonic devices help in the detection of mesio-palatal canals in maxillary first permanent molars\(^{(23)}\). [d] Microscopes: One of the major benefits of using a microscope is to increase the possibility of locating and accessing calcified and additional canals\(^{(24)}\).  [e] Transillumination: Transillumination can also aid in detecting calcified canals\(^{(25)}\). [f] Other methods: It is suggested that staining the Pulpal floor chamber with 1% methylene blue dye. It is a water-soluble dye that can be irrigated into a dry pulp chamber. The dye is absorbed into canal orifices and serves to visually map the hard-to-find canals. The sodium hypochlorite champagne bubble test is another aid to locate orifice. To identify the presence of two buccal roots if present, probing the buccal sulcus to feel the root eminences and furcation anatomy may also help. To identify the presence of two palatal roots in maxillary molars, Probing the palatal sulcus to feel the root eminences and furcation anatomy may also help. 17% EDTA and 95% ethanol to clean and dry the pulp chamber floor prior to visually inspecting the root canal system can be done\(^{(12)}\). The commonest variation is the presence of a second mesiobuccal canal in maxillary first molar. Here in this case the palatal root has Vertucci type II canal configuration and the mesiobuccal root presents a type II canal configuration as suggested by Gulabivala et al.\(^{(1)}\) The incidence of second mesiobuccal canal has been reported to be between 18% and 96.1%\(^{(16)}\). Other variations include One,\(^{(26)}\) Four,\(^{(9)}\) Five roots\(^{(27)}\). Case reports with six root canals\(^{(28)}\) or with a C-shaped canal configuration\(^{(29)}\) have also been reported earlier. Maxillary first molar of 3 root configuration with 6 canal has been reported by many others\(^{(30,31,32)}\).
Conclusion

Importance of root canal variations should not be underestimated, although their incidence is rare. Careful examination of preoperative and mid treatment radiographs and the internal anatomy of teeth are essential for the success of endodontic treatment. These discussions confirm the necessity for meticulous examination of the tooth pulpal floor at high magnification under proper illumination of the dental operating microscope and emphasize the importance of newer imaging techniques like CBCT in preoperative assessment. Knowledge of root canal configuration and its variations, the use of magnification (operating microscope) and the combined use with ultrasonics increased the detection of additional canals are all important aids that are needed for successful treatment. Endodontic science and technology are continually evolving to enable clinicians to identify, disinfect and seal root canal system predictably and efficiently.

Re-attachment of Tooth Fragment—A Case Report

Parthasarathy Rajasekar1, Suresh Mitthra2, Venkatachalam Prakash3, Arunajetasan Subbiya4
1Final Year PG Student, 2Reader, 3Professor, 4Professor and Head, Department of Conservative Dentistry and Endodontics, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research, Narayananpuram, Pallikaranai, Chennai, Tamilnadu, India

ABSTRACT

This case report describes and analyses a tooth fragment reattachment technique used to resolve crown fractures of the anterior teeth. This treatment allows a conservative approach to traumatic coronal lesions offering a better possibility of maintaining aesthetics and function. The adhesive reattachment is a simple system to achieve good aesthetic and functional results. When tooth and fragment margins are intact, the reattachment technique without any tooth preparation is a simple and predictable procedure.

Keywords: Tooth fragment, re-attachment, trauma.

Introduction

Dental trauma often has a severe impact on social and psychological well being of a patient. The majority of dental injuries involve anterior teeth, especially the maxillary incisors, whereas the mandibular central incisors and maxillary lateral incisors are less frequently involved. Crown root fracture (CRF) is a type of dental trauma, usually resulting from a horizontal impact, which involves enamel, dentin and cementum, often occurring below the gingival margin and depending on whether pulp involvement is present or absent, which may be classified as complicated or uncomplicated. A fractured anterior tooth requires immediate clinical attention and if untreated, can cause damage to dentition and even have a psychological impact on the patient (1).

Factors influencing the management of coronal tooth fractures are:

- Extent of fracture (biological width violation, endodontic involvement, alveolar bone fracture),
- Pattern of fracture
- Restorability of fractured tooth
- Secondary trauma injuries
- Presence/absence of fractured tooth fragment and its condition-
- Occlusion
- Esthetics
- Cost and prognosis (2).

The choice of the esthetic restorative treatment of fractured anterior teeth include composite resin restoration, fragment re-attachment and ceramic restorations (full crowns, laminate veneers or ceramic fragments). When the tooth fragment is present and in good working condition, the best option for the treatment of a coronal fracture fragment is reattachment (3).

Case Report: A 35 year-old male patient presented to the Department of Conservative Dentistry and Endodontics, Sree Balaji Dental College and Hospital, Chennai, after sustaining a complicated crown root fracture to his maxillary left lateral incisor due to fall on the ground. The patient’s medical history was unremarkable. No mobility of the injured tooth was recorded and there was no apparent trauma to the soft tissues in the extraoral and intraoral examination. On hard tissue examination,
Ellis Class III fracture was seen in the coronal portion of tooth No. 22, which extended from cervical 3rd of crown on labial aspect to 2 mm sub-gingivally on the lingual aspect. The fractured fragment was loosely attached to the tooth [Figure 1 A].

Periapical radiograph showed that the root formation was complete with no extrusion [Figure 2A]. The patient expressed the desire to maintain the tooth and restore it due to the lower cost compared to an indirect restoration. A detailed explanation about the treatment plan was given to the patient, which included root canal treatment and reattachment with fiber post. The treatment plan was accepted by the patient and written statement of informed consent was obtained.

Local anesthetic was administered and the segment was removed with minimal force and recovered and stored in normal saline to prevent discoloration and dehydration [Figure 1B]. Following a detailed examination, the adaptation of the fragment was checked. The working length was determined with an electronic apex locator (Root ZX, J. Morita Corp., Japan) and confirmed with radiograph. Then the orifice was sealed with temporary restoration. Gingivectomy was done in 22 for making the palatal margin supra-gingivally [Figure 1C]. The patient was recalled the next day and the root canal was enlarged to size F5 with Protaper Gold rotary files till the working length. About 3% sodium hypochlorite was used as irrigant during the preparation. The root canal was dried with paper points (Spident, Hand Rolled, Korea) and obturated only at the apical third.

The root canal was prepared for the post placement from the coronal two third of the canal with peso reamers. The fiber post (FIBRAPOST PD, Switzerland) was tried in the canal and adjusted to the desired length. Space was also prepared in the pulp chamber of the fractured crown fragment for receiving the coronal portion of the post and the core. The alignment of the coronal fragment was verified with the post in place [Figure 1D]. The root canal was etched with 37% orthophosphoric acid, rinsed, blot dried with paper points and bonding agent (PRIME and BOND NT, DENTSPLY) was applied. The post was then luted in the canal using dual-cured resin luting cement (Rely X, 3M, USA). The inner portion of the coronal fragment was similarly etched and bonded to the tooth using flowable composite resin after proper shade matching [Figure 1E]. Finally, occlusion was checked and postoperative instructions were given to the patient. Clinical and radiographic examinations were carried out after 1 month and the tooth responded favorably [Figure 2B].

Discussion

Fractured anterior teeth can cause pain, fear and emotional concern to the patient about his or her appearance (4). An immediate restoration of esthetic appearance by preserving the natural tooth is usually the best option to offer these patients. The tooth fragment reattachment offers the following advantages like better esthetics i.e. shade matching and translucency, minimal invasive technique, incisal edge wear similar to adjacent teeth, functional rehabilitation, less time consuming than provisional restoration, positive, emotional and social response from the patient and it is used as a transitional restoration for a young patient (5,6).

Reattachment of the fractured fragment is indicated when fracture site has an easy access and the size of the fracture is significant. The remnant fragment has to be intact, kept hydrated and it has to fit accurately onto the tooth without compromising the occlusion. The use of a post depends on the size of the fracture and the pulpal involvement.

Important factors for tooth reattachment are degree of the fragment’s adaptation to the remaining structure, fragment retention, fracture location and pattern. The quality of fit between the segments is clinically important factor for the longevity of the reattached crown. According to the amount of the restoration, posts are used to support the fragment, which increases retention and distributes stress along the root (7). In addition, using fiber post along with self/light cured resin cement, as in the present case, gives a monobloc effect, protecting the bond from rotational and twisting forces (2,5).

Resin based restorative materials with tooth-colored fiber post are considered the best option because of several advantages such as a suitable elastic modulus, esthetics, good bonding between post and cement, lower chair time and minimal tissue removal. It is also reported that the use of a fiber post with fractured teeth, as it interlocks the two fragments, minimizes the stress on the reattached tooth fragment (8).

Early retrospective studies indicate that clinical performance of fiber posts is promising and the failure rate recorded is 2% over a period of 4 years (9). Cavalleri et al. reported a better long-term prognosis for the reattachment of crown fracture comparing to composite resin restorations (10).

The study conducted by Yucel et al. in 2008 evaluating the restored teeth using reattachment technique of fractured fragment to the remaining tooth, showed a successful result after a 24 months follow up. Additional preparation of the tooth is one of the most widely studied technical variations (11).

Some authors have found that tooth preparation (dentin grooves, over-contouring technique, chamfering, beveling, etc.), prior to reattachment, can provide higher fracture resistance compared with simple bonding (12,13,14).

However, in order to reduce the technical sensitivity of the procedure and the length of the clinical phase, several studies and case reports have attempted to simplify the procedure by eliminating any additional preparation in the traumatized tooth (15,16).

In addition to the preparation of post space, a vent was created in the coronal separated segment as a leeway for the excess cement to flow out without buildup of any hydrostatic pressure. A similar technique has been recommended by Tosun et al. reattachment using Ribbond material (17).

Conclusion

Reattachment of fractured fragment is an option that provides immediate esthetic, functional and biologic restoration. It could be the first choice for crown fractures of anterior teeth as it is conservative and less time consuming treatment. The presence of intact edges of the fractured fragment, easy access to the fracture line and adequate isolation during the procedure play an important role in successful re-attachment.

Vertical Root Fracture—Diagnosis, Surgical Perspectives and Management—A Review

Joseph Changankary Pia1, Suresh Mitthra2, Venkatachalam Prakash3, Arunajetasan Subbiya4
1Third Year PG Student, 2Reader, 3Professor, 4Professor and Head, Department of Conservative Dentistry and Endodontics, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research, Narayanaapuram, Pallikaranai, Chennai, Tamilnadu, India

ABSTRACT
Endodontically treated teeth are often associated with vertical root fracture (VRF) and it becomes difficult to differentiate a tooth with this condition from an endodontically failed one or one with concomitant periodontal involvement. The cause of VRF is mainly trauma and iatrogenic reasons. Both complete and incomplete VRF constitute an ongoing problem in dentistry because they are difficult to be diagnosed in the early stages. In majority of the cases, tooth extraction is the only reasonable treatment when the VRF is finally diagnosed. Treatment options included extraction of single rooted teeth, but with the advent of adhesive dentistry. There is a paradigm shift towards preservation of these teeth.

Keywords: Vertical Root Fracture, Multiple sinus, Pain

Introduction
Vertical root fracture (VRF) is defined as tooth fracture that run along the long axis of the tooth or deviate in a mesial or distal direction. They commonly occur in older patients in posterior teeth due to iatrogenic causes. (1) According to the American Association of Endodontists, “A vertical root fracture is a longitudinally oriented fracture of the root which originates from the apex and propagates to the coronal part.” (2) According to the literature, vertical root fracture is the third most common reason for extraction of an endodontically treated tooth. (3) VRF represents 2-5% of the crown/root fractures, with the greatest incidence occurring in endodontically treated teeth and in patients older than 40 years of age. (4) VRF is an important threat to the tooth’s prognosis during and after endodontic treatment. Teeth with VRF poses difficulties in diagnosis, treatment and usually associated with a poor prognosis.

Classification of VRF:
A. Based of separation of the fragments:
   i. Complete fracture
   ii. Incomplete fracture
B. Based of relative position of fracture
   i. Supraosseous fracture
   ii. Intraosseous fracture

Aetiology
I. Restorative treatment
   i. Excessive removal of tooth structure during cavity preparation, causing weakening of cusps.
   ii. Delayed expansion of amalgam
   iii. Excessive polymerization shrinkage of composite resins
   iv. Improper reproduction of occlusal anatomy causing deflection occlusal contacts.
   v. Extensively restored,
vi. forceful seating of crowns,
vii. intracoronal restorations (inlays),

II. Endodontic treatment
i. Access cavity preparation- mechanical weakening of tooth structure
ii. Cleaning and Shaping of root canals - increases tooth fracture. (6)
iii. Placement of a crown considerably increases the mechanical forces. (7)
iv. Narrow mesio-distal root like maxillary second premolar, mesio-buccal roots of maxillary molars and mesial roots of mandibular molars- root fracture increases (8)
v. Root canal obturation causes wedging effects (7)
vi. Stress from cementation of post, due to hydrostatic pressure - cause relative deformation of roots. (9)
vii. Repeated dislodgement of a post or a post crown (10)

III. Parafunctional habits: Non-endodontically treated and unrestored posterior teeth with no caries may occasionally fracture due to repetitive excessive occlusal forces, leading to ‘fatigue root fracture’. (11) This may be observed in individuals with heavy masticatory musculature, habits such as
i. Chewing ice
ii. Abrasive foodstuffs consumption
iii. Parafunctional habits. (5)

The compounding effects of all these increases the possibility and risk for vertical root fractures.

Clinical evidence

Pain and Swelling: In majority of cases of VRF mild pain is the only symptom. (12) Spontaneous dull pain on mastication or slight tooth mobility may be present in some cases. Local chronic inflammation due to infection leads to discomfort and soreness, mild to moderate pain, pain on biting, bad taste and swelling of soft tissues. Some swelling of soft tissues is usually present. The swelling is usually broadbased, and midroot in position compared to apical location in periapical abscess. Swelling and tenderness over the root is present during palpation.

Sinus tract: A sinus tract is commonly found in (1342%). In VRF, sinus tract is located close to the gingival margin as opposed to nonvital teeth where sinus tracts are located more apically (differential diagnosis from endodontic infections). Although single sinus tract is most frequently seen in many cases, intraoral swelling with multiple sinus tracts is not uncommon.

Pockets: Isolated pockets with probing characteristics of sinus tracts are pathognomonic. Probing along one position around the circumference of tooth in presence of otherwise normal attachment usually indicates that the tooth is fractured (as opposed with periodontal disease, where the pocketing is generalized around a large part of the tooth). Deep probing in two positions on opposite sides of the infection is almost pathognomonic for the presence of a fracture. These pockets extend from gingival sulcus part way or all of the way to the apex. Generally pockets are narrower with normal depth of sulcus on either side. Periodontal abscess is one of the clinical findings in cases of vertical root fracture, which result from chronic inflammation at the fracture line.

Fracture lines: A crack or incomplete fracture line in the crown may be the only clue for the detection of vertical root fracture in some cases. Methods to delineate fracture lines include trans-illumination using fibre optic light, staining with dyes and surgical exposure

Others: VRFs also detected during obturation of root canal. Sharp cracking or popping sound during root canal filling, a sharp stab of pain, bleeding in the canal or enlarged canal allowing large number of accessory cones - any one of these signs/symptoms or a combination, during root canal filling, should be suspected for VRF. It is extremely rare for all these findings to be present in a single case of vertical root fracture. All of these clinical findings should be carefully observed and correlated along with the radiographic findings to get conclusive evidence for VRF.

Radiographic features of VRF: Radiographic features of VRF vary widely as:

i. Diffuse widening of periodontal ligament,
ii. Dislodgement of retro-filling material, (14)
iii. Vertical bone loss, (15)
iv. Separation of root fragments (16)
v. Displacement of apical portions of root. (17)
vi. Presence of ‘radiographic halo’ or J shaped radiolucency.
vii. Double images or radioopaque images due to overlapping of fragments.

viii. Periodontal type lesions are also not uncommon.

ix. In an endodontically treated molar, bifurcation radioluency in conjunction with other areas is the first radiographic evidence of VRF.

x. Presence of dehiscence’s and fenestrations (18)

xi. V- shaped diffuse bone loss on roots of posterior teeth.

xii. Radiolucent areas adjacent to obturating material or spreader void type lucent areas.

xiii. In mandibular molars, furcation radioluency is also seen.

xiv. Hair like radiolucency

Histopathogenesis of vertical root fractures: VRF invites various irritating agents like bacteria and their metabolites, necrotic pulpal tissue, sealer components and food debris, which are forced into the fracture site during mastication. The source of bacteria in the fracture site may be due to communication from the gingival sulcus or from the canal itself (which are not removed completely from the root canal). This results in the periodontal breakdown and deep probing defects usually associated with the VRF. Although the “hollow tube theory” is disputed, the fracture represents a considerable area of exposure to the canal space for substances to enter, deteriorate and then exit as irritants. (19)

Diagnosis of vertical root fracture: Diagnosis of VRF poses a diagnostic challenge because fracture line may not be visible as long as it has not extended to the cervical region. Some of the diagnostic aids include:

i. Strong coaxial illumination along with good magnification

ii. Bite test - The clinician use rubber wheels, cottonwood sticks or tooth slooth fracture detector to replicate masticatory motion. This test can be performed tooth-by-tooth or cusp-by-cusp. When the patient responds with pain, the dentist should inquire if the pain is similar to his or her chief complaint.

iii. Transillumination test - a strong fiberoptic light passed through the tooth (provided there is no restoration to block light transmission) in a horizontal direction at the gingival sulcus may help the clinician to visualize a crack. When a crack is detected in the tooth, the light will be deflected, reducing its transmission through the tooth, and the fractured segment on the other side of the crack will appear darker.

iv. Periodontal probing test - Done by probing with a thin periodontal probe which reveals a narrow, isolated, periodontal defect in the gingival attachment. In the absence of any other associated periodontal disease, this narrow defect is consistent with an underlying bony dehiscence that is secondary to a VRF.

v. Visual illustration - Expose a radiograph with a Gutta Percha point placed in the defect helps to track the exit and the entry point of the fracture line into the periodontal ligament space.

vi. Vitality tests - Electrical, Thermal or Laser Doppler flowmetry is helpful in diagnosing a VRF, especially in sound teeth. When the patient complains of a sharp, sudden pain, especially while chewing, pulp testing provides valuable diagnostic information. Often, the fracture is incomplete but extends to the pulp, where it eventually causes necrosis.

vii. Disclosing dyes - Helps the clinician to visualize a suspected crack.

Treatment of Vertical Root Fracture: A variety of approaches have been attempted and used to treat the VRF

i. Cyanoacrylate: It is used to bond the fragments of anterior teeth. (20) While the treated teeth were comfortable at a 16-month follow-up, long-term prognosis was considered poor due to deep pocketing and resorption. An in vitro study (21) assessing the resistance to fracture of root segments bonded with glass ionomer cement, composite resin, and cyanoacrylate concluded that the bond strengths of composite resin and cyanoacrylate were superior to glass ionomer cement.

ii. GIC: It bonds around the fracture line, preventing propagation of the fracture. (22) Glass ionomer and amalgam condensed into the coronal half to two-thirds of the root canal in teeth with incomplete
vertical root fractures is reported to be successful at eight-month follow-ups (23) but long-term follow-ups have not been recorded in literature

iii. Calcium hydroxide: Promotes tissue repair and resolves osseous defects before the roots were restored. Teeth that are treated with calcium hydroxide, then ‘reinforced’ with glass ionomer cement, have shown healing at six-month follow-up appointments. (24) Studies using an expanded poly-tetrafluoroethylene Gore-Tex membrane to establish a new periodontal attachment after the fragments have been bonded with glass ionomer cement have reported differing results; six teeth failed in a twelve-month period. (25)

iv. Repositioning and Fixation with wire: Takatsu et al. (26) used orthodontic elastics to join the buccal and palatal segments of a vertically fractured maxillary second molar which were then sealed with a photoscured resin liner and then it was endodontically treated and restored with a cast crown. However, in most cases of VRF in anterior teeth, extraction is the only available treatment option. For posterior teeth, Luebke(5) has proposed four basic categories of treatment.

1. Treatment Plan 1A: In case of incomplete, supra-osseous fractures with viable pulp and no radiographic changes or periodontal defects restore the tooth with full coverage temporary crown and evaluate after 3 months. If the patient is asymptomatic, a permanent crown is cemented with polycarboxylate or glass ionomer cement. In case of pulp degeneration, additional treatment, as outlined in Plan 1B or Treatment Plan 2 is indicated.

2. Treatment Plan 1B: In case of incomplete supraosseous fractures with non-viable pulp but no radiographic changes or periodontal defects, restore the tooth with a full coverage stainless steel crown and initiate calcium hydroxide therapy. Recall must be done in a 3-month interval. After 9–12 months of calcium hydroxide therapy, if the bone level is unchanged, endodontic therapy is performed and a permanent crown is placed. If a pocket develops along the fracture line, switch to Treatment Plan 2.

3. Treatment Plan 2: In case of incomplete intraosseous fractures with non-viable pulp and a periodontal pocket along the fracture line exploratory surgery is indicated for the visualization of the fracture line and the osseous defect. When the fracture line stops short of the osseous defect, the required periodontal surgical procedure is carried out to restore the defect. Based on the status of the pulp, Treatment Plan 1A or 1B is initiated. If the fracture line extends beyond the osseous defect, Treatment Plan 3 is initiated.

4. Treatment Plan 3: In case of complete intraosseous fractures with non-viable pulp, bone loss and periodontal pocket for single-rooted teeth, extraction is indicated. In case of a multi-rooted tooth where fracture is confined to one root, or if it passes through a furcation, either root amputation, hemisection or extraction is indicated.

Conclusion

The constant ingress of bacteria from the oral cavity into the VRF provides an open pathway to the supporting alveolar tissues. Multiple treatment modalities have been suggested for the treatment of VRF but in vain. Unfortunately, by the time the diagnosis is made, severe bone loss has already occurred making the prognosis of the tooth poor, indicating a need for extraction. It has been reported from the literature that management of cases with VRF involves extensive procedures often with poor outcomes. Where successful outcomes have been claimed, the long-term prognosis is yet to be proven. The practitioner should be vigilant at all times and VRF should be ruled out.

Efficacy and Safety of Oral Premedication on Pain after Nonsurgical Root Canal Treatment—A Review

Wesly Sophrenia1, Arumugam Karthick2, Nagarajan Geethapriya3, Arunajatesan Subbiya4
1Final Year PG Student, 2Professor, 3Reader, 4Professor & Head, Department of Conservative Dentistry and Endodontics, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research, Narayananapuram, Pallikaranai, Chennai, Tamilnadu, India

ABSTRACT

Postoperative pain is more likely to arise within a few hours following root canal treatment. Patients who have postoperative pain need analgesics that have fewer side effects for relieving the pain. Postoperative discomfort reduction by various preoperative means is a tried and tested method. Here, we predict symptoms that arise after treatment and try to deal with them before they begin. For those patients presenting with preoperative pain, it has been reported that up to 80% of this population will continue to report pain of different degrees even after endodontic treatment. A number of factors concerning the etiology of postoperative pain have been evaluated. The main contributing factors of pain during root canal treatment comprises of mechanical, chemical, and microbial injuries to the pulp or periradicular tissues which are induced or exacerbated during treatment. Pretreatment analgesia is providing analgesia to patients before initiation of endodontic treatment, which can decrease the establishment of central and peripheral sensitization and has the potential to reduce postoperative pain and postoperative analgesic intake. Administration of a nonsteroidal anti-inflammatory drug before root canal therapy will interfere with the inflammatory process before it begins; therefore, presumably decreasing postoperative pain.

Keywords: Post operative pain, premedication, analgesics, NSAIDS

Introduction

Postoperative pain after root canal therapy is a major concern for dentists and their patients, with pain having been reported to occur in 3%–58% of patients treated (1–4). Nagendrababu and Gutmann (5) identified various preoperative and procedural factors that were related to postendodontic pain and were associated with periradicular tissue injury as a result of mechanical instrumentation, chemical irrigants, intracanal medicaments, and microbial effects. To address these concerns, various procedures, such as occlusal reduction (4,6), the placement of intracanal medicaments (7), and the provision of postoperative medications (8) are used routinely to reduce postoperative pain after nonsurgical root canal procedures. Oral medications are preferred by patients over other parenteral routes because of ease and convenience of use, resulting in better compliance.

Many randomized controlled trials (RCTs) (9–12) support the use of oral premedication in reducing or eliminating postoperative pain after nonsurgical root canal treatment. Premedication can decrease central and peripheral sensitization, which has the potential to reduce postoperative pain (10). The effectiveness of various oral premedications, including ketorolac (10), prednisolone (10,11), indomethacin (9), ibuprofen (9,13–15), piroxicam (16), gabapentin (17), lornoxicam (17), tapentadol (18), etodolac (18), zintoma (Goldarou Pharmaceutical Co, DOI Number: 10.37506/v10/i12/2019/ijphrd/192322
Postoperative pain- Incidence and etiology:

Postoperative pain is more likely to arise within a few hours following root canal treatment. Patients who have postoperative pain need analgesics that have fewer side effects for relieving the pain. Postoperative discomfort reduction by various preoperative means is a tried and tested method. Here, we predict symptoms that arise after treatment and try to deal with them before they begin. For those patients presenting with preoperative pain, it has been reported that up to 80% of this population will continue to report pain of different degrees even after endodontic treatment (20,21). A number of factors concerning the etiology of postoperative pain have been evaluated. The main contributing factors of pain during root canal treatment comprise of mechanical, chemical, and microbial injuries to the pulp or periradicular tissues which are induced or exacerbated during treatment (22). For example, a clear indication of the relationship between microbial interactions and periapical tissues is that flare-ups are more likely to occur in necrotic cases (infected) than in vital cases (non-infected) (23,24). Mechanical irritation to the periradicular tissues include over-instrumentation and over-extension of filling materials, chemical irritation include apical extrusion of irrigants, intra-canal medicaments and filling materials (25,28). Many endogenous chemical mediators, particularly prostaglandins, have been associated with inflammation and its related pain.

Treatment of post-operative pain: For endodontic pain, nonsteroidal anti-inflammatory drugs (NSAIDs) are one of the most frequently taken analgesic medications (27,28). Administration of NSAIDs before root canal treatment can block the COX pathway, and thus the pain sensation can be blocked even before it begins. In contrary with these findings, Attar et al. declared that preoperative administration of NSAID treatment did not significantly reduce postoperative pain (24). NSAIDs inhibit inflammation and induce analgesia by inhibiting the activity of cyclooxygenase enzyme COX. Two forms of COX enzymes have been identified, COX-1 and COX-2. COX-1 enzymes are present in tissue at all times and responsible for synthesizing prostanoids that have a cytoprotective function. COX-1 enzymes regulate normal cell activities in the stomach, kidneys, and platelets. COX-2 enzymes normally are not present in tissue (other than in kidneys) and come into play when tissue injury and inflammation occur. Thus, NSAIDs exert their analgesic, antipyretic and anti-inflammatory action by central as well as peripheral mechanism. The main disadvantage of long-term therapy with NSAIDs is the risk of gastrointestinal disturbances which have often limited their clinical utilization. Pretreatment analgesia is providing analgesia to patients before initiation of endodontic treatment, which can decrease the establishment of central and peripheral sensitization and has the potential to reduce postoperative pain and postoperative analgesic intake (10,29). Administration of a nonsteroidal anti-inflammatory drug before root canal therapy will interfere with the inflammatory process before it begins; therefore, presumably decreasing postoperative pain.

Aceclofenac is a predominantly potent inhibitor of COX-2 which is used for pain management. It shares structural similarities with another NSAID, diclofenac. The therapeutic index of aceclofenac is reported to be four times more potent than diclofenac, a well-established NSAID in clinical use. It has also shown better gastric tolerance when compared to other NSAIDs. Its plasma half-life of approximately 4-6 hours is more than 99% bound to plasma proteins (20). Paracetamol has lower adverse drug effects like gastrointestinal disturbances and worldwide used analgesic and antipyretic. However, there is still debate about its exact mechanism of action. It primarily inhibits COX-2 and then COX-1. It may also affect additional inflammatory pathways by inhibiting other peroxidase enzymes such as myeloperoxidase. It has a comparatively weaker analgesic and anti-inflammatory activity. This explains its inability to significantly reduce postoperative pain at 6 hours and 12 hours due to the inflammatory response of the body due to extrusion of debris following cleaning and shaping (30).

In a study by Konagala et al. (31), the administration of piroxicam or dexamethasone or deflazacort reduced postoperative pain after 6, 12, and 24 h effectively compared to the placebo group. In addition, all the drugs
including placebo showed similar pain ratings at other time intervals (48 and 72 h). Mokhtari et al. stated that indomethacin and ibuprofen significantly reduced the postoperative pain 8 h after treatment with no significant difference at 12 and 24 h after treatment.\(^9\)

Glucocorticoids are believed to excite the production of anti-inflammatory cytokine tumor growth factor-β in target cells through pre- and post-transcriptional mechanisms. The bioequivalence of deflazacort and prednisolone has been investigated in various situations. In normal controls, 15-mg deflazacort inhibits T-cell reactivity to the same extent as 12.5 mg prednisolone, but for a longer period of time. Patients treated with long-term corticosteroids might be expected to have some complications during the endodontic treatment such as a rapid periapical bone destruction caused by the combined effect of a subclinical infection, suppressed immune response, reduced bone mineral content, and negative balance of the bone remodeling process in the jaws. However, single oral doses are safe over short-term usage, without side effects or contraindications.\(^{32–34}\)

Piroxicam is a long-acting NSAID with a potent anti-inflammatory activity similar to indomethacin and has good analgesic activity. They lower prostaglandin release at inflammatory site and decrease the production of IgM rheumatoid factor. Chemotaxis of leukocytes and ratio of T-helper to T-suppressor lymphocytes are also reduced. Thus, it can inhibit inflammation in diverse ways \(^{31,32,10}\). Piroxicam’s half-life of 50 h could favorably overcome the intense pain up to 48 h following the endodontic treatment and is suitable for short-term analgesic and long-term anti-inflammatory actions.

Smith et al. also reported that the combination of ibuprofen 600 mg and acetaminophen 1000 mg is more effective than placebo.\(^{29}\) Due to its diverse activity in the control of inflammatory process, dexamethasone group resulted in greater reduction of postoperative pain, similar to published literature \(^{32,33,36}\). Among two corticosteroid drugs, dexamethasone and deflazacort, deflazacort resulted in less pain reduction than dexamethasone during test periods \(^{35}\).

The adverse effects reported for tapentadol and etodolac were nausea, vomiting, headache, dizziness, and heartburn, whereas ketorolac studies reported headache and dizziness \(^{18}\). One study \(^{17}\) on lornoxicam reported gastrointestinal pain, whereas zintoma \(^{15}\), indomethacin \(^{9}\), prednisolone \(^{11}\) and ibuprofen \(^{9,15}\) had no reports of any side effect.

**Conclusion**

The oral route does bestows a convenient, economic and non-invasive route of administration to most patients and is preferred because of the clinically effective and convenient technique as compared to the use of intramuscular or intravenous injection which may lead to discomfort and fear and is not well accepted by some patients \(^{36,37}\).

ABSTRACT

Many associated risk factors are shared by systemic diseases and oral infections that could confound a relationship between them. Periodontal disease has received considerable interest when these interrelationships were studied. Endodontic infections have received much less attention, despite the fact that many of microbial pathogens are common in those 2 diseases. Many of the systemic diseases were found to affect the outcome of endodontic treatment. A number of observational studies and a longitudinal cohort study have described, at least in part, a possible association between systemic involvement and endodontic periapical infection. To date, the role of systemic medical conditions as a modulating factor in the development of endodontic periapical infection has been a subject of controversy with authors who found a strong association and those who found weak to no association. Therefore, the purpose of this review was to discuss the pathogenesis and scientific evidence reporting any relationships between lesion of endodontic origin and risk of systemic diseases.

Keywords: Systemic disease, apical periodontitis, periapical infection, diabetes mellitus, CVD, Liver disease

Introduction

Many associated risk factors are shared by systemic diseases and oral infections that could confound a relationship between them (¹⁻³). Periodontal disease has received considerable interest when these interrelationships were studied. Endodontic infections have received much less attention, despite the fact that many of microbial pathogens are common in those two diseases. Many of the systemic diseases were found to affect the outcome of endodontic treatment. Diabetes mellitus was found to be associated with significantly reduced endodontic treatment outcome of teeth with preoperative infections, suggesting that diabetes may serve as a disease modifier (⁴⁻⁵). Also, both diabetes and hypertension were found to be associated with reduced survival of endodontically treated teeth (⁶). Therefore, at this time, systemic conditions and disorders can be considered modulating factors affecting oral infection progression rather than acting as the causative etiologic factor (¹⁻³,⁷⁻⁸). A number of observational studies (⁷⁻⁹⁻¹¹) and a longitudinal cohort study (¹²) have described, at least in part, a possible association between systemic involvement and endodontic periapical infection. To date, the role of systemic medical conditions as a modulating factor in the development of endodontic periapical infection has been a subject of controversy with authors who found a strong association (¹³⁻¹⁵) and those who found weak to no association (⁷,¹⁶,¹⁷). Therefore, the purpose of this review was to discuss the pathogenesis and scientific evidence reporting any relationships between lesion of endodontic origin and risk of systemic diseases.
Cardiovascular Disease (CVD): Many studies confirmed an association between endodontic pathosis and CVD. In a recent pair-matched, cross-sectional study An et al (18) reported a significant association between apical periodontitis and CVD. Gomes et al (12) explored the association between CVD and endodontic pathosis in a retrospective cohort study and reported that endodontic pathosis can act as an independent predictor of an incident of CVD. In a case-control study, Costa et al (19) explored the prevalence of endodontic pathosis in patients who were diagnosed with CVD. They reported that the prevalence of endodontic pathosis in a group of patients with CVD is twice that observed in the group without CVD. In a low-biased study by Caplan et al (10), they reported that there is an association between endodontic pathosis and CVD among those 40 years old. Also Pasqualini et al (20) reported that endodontic pathosis may be a risk factor for CVD. Also it should be mentioned that none of these studies can elucidate a cause-and-effect relationship between these two conditions. To date, Gomes et al (12) and Caplan et al (10) are the only well-designed longitudinal studies to report on the association of endodontic pathosis and CVD. The role of inflammatory mediators in the initiation and progression of CVD has been suggested that elevated levels of different inflammatory mediators were found to be possibly associated with risk of future CVD (21–23).

Diabetic Mellitus (DM): Elevated levels of circulating interleukin 6 and tumor necrosis factor-a after inflammatory reactions can increase insulin resistance by impairing glycemic control (24). Regarding the association of endodontic pathosis in patients with DM, the current evidence is inconclusive and insufficient to suggest an association. Britto et al (25) reported “no main effects of sex, diabetes diagnosis, or age (the covariate) on the 3 outcomes of interest—nonsurgical endodontic treatment with lesions, nonsurgical endodontic treatment without lesions, and no nonsurgical endodontic treatment with lesions.” However, all men with type 2 diabetes who had endodontic treatments were more likely to have residual lesions after treatment. Sanchez-Dominguez et al (26) reported the prevalence of endodontic pathosis was not significantly higher in poor or good control groups, although endodontic pathosis was reported to be highly correlated with hemoglobin A1c levels. These findings are in agreement with a recent review that reported inconclusive evidence about the association of diabetes with a higher prevalence of root canal treatment (27), Marotta et al (14) explored the association between endodontic pathosis and DM. They reported that teeth from individuals with DM were significantly more associated with endodontic pathosis. Lopez-Lopez et al (28) and Segura-Egea et al (29) also examined an endodontic pathosis–DM association. On the basis of these 2 case-control studies, patients with DM were more likely to be diagnosed with endodontic infection compared with healthy individuals. In a retrospective cohort study by Britto et al (25), association between endodontic pathosis and DM was denied. Well-designed longitudinal studies with accurate diagnostic methodology and matching criteria are needed to support any premise that endodontic treatment could improve serum hemoglobin A1c levels in patients with DM.

Chronic Liver Disease (CLD): Castellanos-Cosano et al (30) reported that teeth in patients with liver transplants were more associated with endodontic pathosis compared with the control group. Arvaniti et al (31) reported that CLD patients have 4 times increase of mortality after infection because their immunologic system has become compromised. These authors speculated that the reason could be due to increased levels of endotoxins, bile acids, nitric oxide, carbon monoxide, and cytokines such as tumor necrosis factor-a and interleukin 6.

Blood Disorders: Castellanos-Cosano et al (30) explored this association and reported that subjects with hemophilia had a higher likelihood of endodontic pathosis than the control group. However, these findings should be evaluated cautiously because of high chance of bias after lack of appropriate diagnostic tools and matching between study groups. Because the inflammatory process and healing outcome both involve the activation of vascular response, these mechanisms are physiologically closely involved (32). In hemophilic patients it has been hypothesized that angiogenesis during the healing phase is impaired (33).

Bone Mineral Density: The authors reported an association between the presence of endodontic pathosis and low bone mineral density (27). In patients with periodontitis, osteoporosis has been reported as a risk indicator to progression of periodontal disease (34).

The review addressed pathogenesis, but there is also a need to address endodontic outcomes as they relate to systemic diseases. One of the current clinical healthcare challenges is to lower costs by controlling factors that
may lead to systemic disease. If a definite cause-effect relation is confirmed between endodontic pathosis and systemic diseases such as CVD, DM, and CLD, oral healthcare providers might be able to contribute to lowering the cost of treating such disease by prevention of chronic oral infections.

In the CVD group, there were few studies with low level of bias\(^{19,18,20}\) and in the DM, CLD, blood disorders, and bone mineral density groups, there was no well-designed study with a low level of bias, which necessitates the need for longitudinal cohort studies to assess the association between endodontic pathosis and systemic diseases. Another limitation is that most of the included studies used panoramic radiography for detecting apical periodontitis, which can affect the accuracy of the results. Also none of the studies had confirmed the presence of apical periodontitis by using pulp vitality tests, which can increase the chance of detection bias. If a periapical radiographic lesion is not associated with a tooth with a necrotic pulp, that periapical radiographic lesion may be non-odontogenic. Another potential risk of bias that might lower the quality of available evidence is the lack of appropriate matching between study and control groups. Therefore, well-designed longitudinal studies with appropriate diagnostic tools such as cone-beam computed tomography are required to confirm the potential association between systemic disease and endodontic pathosis.

**Conclusion**

The present review assessed the association between endodontic pathosis and different systemic conditions including CVD, DM, CLD, blood disorders, and bone mineral density. On the basis of the available evidence, there might be an association between some systemic diseases and endodontic pathosis.

Ultrasonic Tips in Surgical and Non Surgical Root Canal Therapy: A Review of Literature

Sahithi Reddy1, Alagarsamy Venkatesh2, Nagarajan Geethapriya3, Arunajatesan Subbiya4

1Second Year PG Student, 2Professor, 3Reader, 4Professor and Head, Department of Conservative Dentistry and Endodontics, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research, Narayananapuram, Pallikaranai, Chennai, Tamilnadu, India

ABSTRACT

Dentistry has been revolutionized by the development of ultrasonic tips. It gives a minimally invasive approach, and with optimum magnification it can favor a successful conservative treatment. Ultrasonics are ideal for endodontic use and offers many applications and advantages like improved techniques and use of materials, and helps enrich the way endodontics is being practiced beginning from access preparation to re-treatment and also surgical treatment. They offer numerous advantages over conventional methods and a viable option employed by the dentists. Most frequent applications of ultrasonics in endodontics are access refinement, finding calcified canals, and removal of attached pulp stones and intracanal obstructions, increased action of irrigating solutions, condensation of gutta-percha, placement of mineral trioxide aggregate, in surgical endodontics and root canal preparation. Due to its efficiency there is an increased focus on the use and possible consequences of ultrasonics. This review article describes the various uses of ultrasonics in surgical and non surgical root canal treatment in a clinical perspective.

Keywords: ultrasonics, retro-tips, RCT, root-end cavity, post

Introduction

The sound energy with a frequency above the range of human hearing, which is 20 kHz is known as ultrasound. The frequencies employed range between 25 and 40 kHz1. There are two basic methods of producing ultrasound namely Magnetostriction and Piezoelectric principle. Piezoelectric units are preferred over magnetostrictive units as they have higher frequency (40kHz vs 24 kHz) and work in a linear, back-and-forth, “piston-like” motion2. It is ideal for endodontics and offers many applications and advantages like improved visualization and a more conservative approach to selectively remove tooth structure. It offers opportunities that are not possible with conventional treatment, leading to improved techniques and use of materials, and helps enrich the way endodontics is being practiced.

The concept of using ultrasound in endodontics was first introduced by Richman in 19573. Martin and Cunningham in 1985 coined term endosonics and defined it as the ultrasonic and synergistic system of root canal instrumentation and disinfection4,5. After Gary Carr introduced first ultrasonic tips, there was increased focus on the use and possible consequences of ultrasonic root-end preparations during apicoectomy. Most frequent applications of Ultrasonics in endodontics are access refinement, finding calcified canals, and removal of attached pulp stones and intracanal obstructions, increased action of irrigating solutions, condensation of gutta-percha, placement of mineral trioxide aggregate, in surgical endodontics and root canal preparation6,7. The ultrasonic tips are classified based on use as surgical tips.
and non-surgical tips which further include vibratory tip, access refinement tip, bulk removal tip, troughing tips. Based on design they are classified as active and non-active tip, smooth or milled, diamond coated and non-diamond coated tips. Based on metallurgy they are either stainless steel and nickel titanium and based on the attachment type they are S-threaded and e-threaded6.

**Use in Surgical Endodontics:** The root-end therapy has been revolutionized by the development of ultrasonic and sonic retrotips. It provides increased access to root ends with smaller osteotomy because of the various angulations of the retrotips and their small size7. These conservative cavities follow the original path of the root canal leading to a centered root-end preparation reducing the risk of perforation8. The retrotip design does not require a beveled root-end resection access thus exposure of dentinal tubules is reduced and apical leakage is minimized3. It is a timesaving technique that has a lower failure rate and produces less smear layer in a retro-end cavity compared to a slow-speed handpiece9. A medium power setting is recommended for use. The cavity walls should be parallel and follow the anatomic outline of the root canal. Root-end cavities should be initiated with a diamond-coated retrotip, using its better cutting ability to prepare the main cavity. This aids in the removal of root canal obturation materials and should be followed by a smooth retrotip to smooth and clean cavity walls5. A better quality surface is produced by the prototype diamond-coated retrotips, in less time than the SS retrotips, which in turn caused fewer cracks. DC retrotips removed more dentine than SS retrotips and should therefore be used with care to avoid over-preparation or perforation10.

An ultrasonically activated condenser tip can be used for retrograde filling. The ultrasonic vibration is said to improve the flow, setting and condensation of the materials to dentinal walls increasing the seal11. It was demonstrated that, with the adjunct of US, a significantly better seal with MTA was achieved. It was observed that ultrasonically condensed MTA is radiographically denser and lesser voids were seen. But excessive ultrasonication adversely affected MTA properties. It was recommended to use 2 seconds of ultrasonication per increment12. On a contrary, Aminoshariae et al., observed that Hand condensation resulted in better adaptation to the walls and less voids than the ultrasonic method and hand condensation should be considered the preferred method for placement of MTA13. Polishing root end material and apical surfaces can be done using ultrasonics. It may be beneficial in the elimination of extra-radicular bacteria14.

**Use in pulp chamber:** The advantage of ultrasonic tips is that they do not rotate, thus enhancing safety and control, while maintaining a high cutting efficiency. This can be applied when the risk of perforation is high. Ultrasonics works well when breaking through the calcification that covers the canal orifice. E.g: CPR 2D, BUC 2. A troughing tip is a good choice for this task E.g: BUC1, Bigger tips with a limited diamond coated extension should be used during the initial phase of removing interferences, as they offer maximum cutting efficiency and enhance control while working in the pulp chamber. The diamond-coated pear tip, creates a smooth, clean flat troughing groove that facilitates canal location. The diamond-coated, ball tip provides fine cutting control when preparing a troughing groove and is less aggressive than the pear tip, yet it has the same clinical indications2. For locating orifices thinner and longer tips facilitate working in deeper areas, while maintaining clear vision16. Ultrasonic cutting seems to be significantly influenced by the power setting as larger fragments of dentin are removed at higher power, and by the ultrasonic unit type used. Therefore, care should be taken while searching for canal orifices, as aggressive cutting may cause an undesired modification of the anatomy of the pulp chamber2.

**Use in Root Canal:** Ultrasonics failed to demonstrate superiority as a primary instrumentation technique, as no improved debridement was accomplished compared with hand instrumentation7. The relative inefficiency of ultrasonic debridement has been attributed to file constraint within the unflared root canal space. A modification of the technique in which ultrasound is activated for a few minutes after hand preparation has instead resulted in greater canal and isthmus cleanliness compared with hand preparation alone15. Despite the multitude of studies conducted on ultrasonic root canal preparation with ultrasonically activated files, the current consensus is that this is not a viable clinical technique.

**Use in disinfection of root canal:** Cleaning webs and fins is only possible through movement of the irrigation solution by ultrasonics, as they cannot be mechanically cleaned16. Ultrasonics creates Cavitation which is minimal and is restricted to the tip and Acoustic streaming effect which is significant and has been shown
to produce sufficient shear forces to dislodge debris in instrumented canals\textsuperscript{20}. A higher velocity and volume of irrigant flow is created in the canal during ultrasonic irrigation. It can also improve disinfection of root canals, probably because organic tissues enters the streaming field that is generated are disrupted\textsuperscript{2}. When sonic or ultrasonic files are used in small, curved canals, they may bind, thus restricting their vibratory motion and cleaning efficiency. To prevent a dampening effect, sonic or ultrasonic files should not contact the canal walls; therefore, the use of smooth files is recommended\textsuperscript{21}.

**Use in obturation:** Ultrasonically activated spreaders have been used to thermo plasticized gutta-percha in a warm lateral condensation technique. Ultrasonic spreaders vibrate and produce heat, thermoplasticizing the gutta-percha. It achieved fewer voids, homogeneous three-dimensional obturation. Of the various methods of ultrasonic softening, the more accepted way is ultrasonic activation after placing accessory cone\textsuperscript{22}. The activation times of 10 and 15 s and power setting 5 produced root canal fillings with fewer voids than cold lateral condensation without sealer\textsuperscript{23}. It has been demonstrated that placement of sealers with an ultrasonically energized file promoted a better covering of canal walls with better filled accessory canals than placement of sealers with hand instruments\textsuperscript{2}.

**Use in re-treatment:** Ultrasonics can be used for removal of silver points, fractured instruments, and cemented posts and the use is not restricted by the position of the fragment in the root canal or the tooth involved. It facilitates post removal with minimal loss of tooth structure and root damage. For silver post removal, Ultrasonic tip (Eg: VT, CPR 1, Osada Enac ST9) is placed for few seconds followed by air drying to loosen the silver point\textsuperscript{24}. A fiber-reinforced composite post with a significantly lower modulus of elasticity than stainless steel or titanium, conducts vibration less efficiently. To increase the action, ultrasonics without water spray is applied to posts cemented with resin cements, because of the increase in heat it dislodges early. Different bur kits have been proposed to remove fiber posts\textsuperscript{25}. An improved performance might be obtained if fiber posts are removed with kits followed by subsequent ultrasonic instrumentation\textsuperscript{26}.

**Conclusion**

The concept of minimally invasive dentistry and the desire for preparations with small dimensions has stimulated new approaches in cavity design and tooth-cutting concepts. And ultrasonics are playing an important role in achieving this in endodontics beginning from access preparation to re-treatment and surgical treatment. They offer numerous advantages over conventional methods and a viable option be employed by dentists.

Occupational Hazards in Dentistry—A Review

Alagarsamy Venkatesh¹, Balasubramanian Anuradha², Suresh Mitthra², Sanjana T³

¹Professor, ²Reader, ³Undergraduate Student, Department of Conservative Dentistry and Endodontics, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research, Narayananpuram, Pallikaranai, Chennai, Tamilnadu, India

ABSTRACT

Occupational health hazards are not uncommon. Continuous education on potential risk, precautions and protocols should be rapidly instituted to greatly reduce or even eliminate the occupational hazard. This review article is regarding the occupational hazards in the field of Dentistry, various classification and its management has been discussed

Keywords: biohazard, radiation, aerosols, dental materials

Introduction

Occupational health hazards are present in every profession, which is an unavoidable circumstance for the dentist and his team. Precaution has to be taken while practicing to prevent these hazards. A study by Brooks SL et al [1] reported that dentists, more frequently have worse health problems than other high risk medical professionals.

Definition:

- Occupational hazard is the risk to a person usually arising out of employment.
- It can also refer to a work, material, substance, process, or situation that predisposes, or itself causes accidents or disease, at work place. [1,2,3]

Classification:

These hazards are grouped into:

1. Physical
2. Chemical
3. Biological
4. Mechanical
5. Social aspects

Handbook of Occupational Hazards and Controls for Dental Workers by government of Alberta in year 2011 classified as follows:

- Biological
- Chemical
- Physical
- Psychological

Babaji P et al stated that dentists during clinical practice are exposed to variety of work related hazards which are classified into five types: [4,5,6]

1. Physical
2. Chemical
3. Biological
4. Psychological
5. Musculoskeletal disorders

Physical Hazard: The dentists are at risk of physical injuries during dental procedures that includes:
Poor illumination: Causes- eye pain, eye strain, headache and eye fatigue

Excessive brightness:

Causes- discomfort and visual fatigue: The study done in Norway reported that public health dentists complained 13% of eye problems. An investigation done on Flemish dentists in Belgium revealed that 52% had vision problems and eye injuries. [4,6,7]

Prevention

- Sufficient and suitable lighting
- Natural or artificial is advised

Radiation [8-11]: Dental radiology gives rise to a significant dose of radiation to the bone marrow in the skull and cervical spine, the oral mucosa, the thyroid and the eye. Dental personnel are exposed to both ionizing and non-ionizing type of radiations

Non- ionising radiation injury - Exposure to Dental Curing Light and Lasers

Causes- conjunctivitis and keratitis: Non-ionising radiation has become an important concern with the use of blue light and to cure various dental materials (for example composites and other resins) (Gambhir, 2011).

Lasers: The main occupational hazards associated with them are:

- Eye damage
- Skin damage
- Fire
- Smoke inhalation (cellular and viral debris)

Prevention

- Good workplace design

Ionising radiation injury-Exposure to radiation: Causes- acute erythema, dermatitis, chronic skin cancer, bone marrow suppression, damaged to eye including cornea. Radiation effects are cumulative and this damage is totally painless yet life threatening. Ionising radiation is a well established risk factor for cancer. The study conducted among Canadian dentists reported that occupational doses of ionizing radiation among dentists and dental workers have decreased markedly since 1950s. [5]

Prevention

Following are the recommendations for safety of the practitioner [5, 11-5]

- Buying standard radiographic equipment, which rigidly follows the National Council on Radiation Protection and Measurements (NCRP) and ISI recommendations.

Curing Lights: Curing lights have become an integral part of daily practice in restorative dentistry. In this regard, visible light-cured resin-based composites are the predominant restorative materials for both anterior and posterior restorations (Singh, 2011). Halogen and LED units are by far the most frequently used in daily practice. From an occupational safety perspective, the blue light used to cure composite is not well tolerated by the human eye (i.e. solar retinitis).
● Well-collimated and filtered beam of at least 1.5 mm of aluminium filtration, should be available.

● Special conch shell designs are recommended for the X-ray departments. During construction use special barium plaster, which absorbs the scattered radiation.

● Dental surgeons must use a film badge provided by the Baba Atomic Research Centre (BARC), Mumbai for personnel monitoring.

● Operator should leave the room or take a position behind a suitable barrier or wall during exposure of the film.

● Walls must be of sufficient density or thickness.

● The operator should stand at least 6 feet from patient, at an angle of 90° to 135° to the central ray of X-ray beam.

● Lead aprons routinely used for all patients and children special thyroid shield should be used.

● Use of fast films

● Films should never be held in place by the operator (use film holding instruments).

● The radiographic tube should never be stabilized by the operator or patient during the exposure.

● To ensure the above, advice to use film badges. These badges contain a piece of sensitive film or radiosensitive crystal by which the quantity of radiation exposure or dose can be determined. The instrument used to measure radiation dose is known as dosimeter.

Pressure System [16-18]: Typical pressure equipment used in dentistry includes:

● Autoclaves

● Compressed air systems (fixed and portable).

The failure of pressure equipment can result in serious injuries to staff/patients and cause major damage to structure/property. The control measures to prevent such failures relate to the mechanical integrity of the equipment involved.

Autoclaves: The most serious risks associated with autoclaves are the uncontrolled release of stored energy include:

● Scalding

● Explosion of sealed glass containers containing liquids.

Control measures to mitigate such risks include:

● Determine the type of equipment and control system (manual or automated)

● Assess the risk of door opening violently, underpressure;

● Verifying “nil” pressure before opening door;

● Operator training and instruction;

● Thorough examination of pressure equipment as per schedule 12 part b of the safety, health and welfare at work (general application) regulations 2007 to 2016,

Compressed air systems: The most serious risks associated with air receivers come from the uncontrolled release of stored energy. i.e., catastrophic failure of vessel whilst under pressure.

Control measures:

● Thorough examination of air receivers (every 26months as per Schedule 12 Part B of the Safety, Health and Welfare at Work (General Application) Regulations 2007 to 2016

● Maintenance and inspection (as per manufacturer’s recommendations and undertaken by competent person).

Injury due to sharps [7,8]: Exposure-prone procedures (EPPs) include situations where the worker’s hands (whether gloved or not) may be in contact with sharp instruments, needle tips or sharp tissues (spicules of bone or teeth) inside a patient’s wound or confined anatomical space where the hands or finger tips may not be completely visible at all times. There is an increased risk of transmitting blood-borne viruses between Dental health professionals and patients during these procedures.

Prevention

● The use of personal protective equipment (disposable gloves)

● Vaccination of employees

● Prevention of re-capping needles

● Reporting of incidents, response and follow up.
**Aerosol:** It is defined as particles less than 50 µm in diameter. These are produced from operating site and suspended in the air and are airborne infection in dentistry. Therefore, are contaminated with bacteria and blood. [14-20]

Procedures Shown To Produce Airborne Bacterial Contamination:
- Ultrasonic and sonic scalers - Shown to be the greatest source of airborne contamination.
- Air polishing - Bacterial counts show that airborne contamination is nearly equal to ultrasonic scalers.
- Air-water syringe - Bacterial counts indicate that airborne contamination is slightly less than ultrasonic scalers.
- Tooth preparation with an air turbine hand piece - Minimal airborne contamination if a rubber dam is used.

**Prevention:** High volume evacuator will reduce airborne bacteria by nearly 99%.

**Chemical Hazards** [21-25]: Dentists are exposed to many various types of chemicals that are hazardous while providing care. These include beryllium, silica, powdered natural rubber latex (NRL), formaldehyde and mercury.

- **Silica:** Inhalation of dust containing free silica or silicon dioxide in ceramic laboratories leads to silicosis.
- **Beryllium:** Some of the dental alloys contain beryllium and if it inhaled while working on items such as dental crowns, bridges, and partial denture framework, they can cause chronic beryllium disease (CBD). As per Occupational Safety and Health Administration (OSHA) specification, employees cannot be exposed to more than two microparticles of beryllium per cubic meter of air for an 8 hour time weighted average.
- **Formaldehyde:** is one of the chemical agents routinely used in the clinical set up mainly for disinfection of operatory area. Liquid and vapour forms of formaldehyde causes severe abdominal pain, nausea, vomiting and eye irritation.
- **Natural Rubber Latex (NRL):** Latex gloves (dusted with cornstarch powder) form an efficient barrier against most pathogens. Unfortunately most of the professionals are allergic to latex content of gloves. The powder in latex gloves itself is not the allergen. It only provides binding sites for latex protein and aids in carrying the protein into the skin. It has also been reported that airborne powder particles causes asthmatic allergic reactions or even anaphylaxis. Dental personnel should note that latex is present in other personnel protective equipments like masks, eyewear, rubber dam and clinical gowns.

**Clinical symptoms of latex allergies include:** urticaria, conjunctivitis accompanied by lacrimation and swelling of eyelids, mucous rhinitis, bronchial asthma and anaphylactic reaction.

**Dental Materials:** Many products used in dentistry may act as allergen to a part of population. The free monomers may cause a wide range of adverse health effects such as irritation to skin, eyes or mucous membranes, allergic dermatitis, asthma and parasthesia in the fingers.

**Nitrous oxide** [21-24]: The National Institute for Occupational Safety and Health (NIOSH) in 1994 issued a warning to hundreds of thousands of medical, dental professionals who work with nitrous oxide (N₂O). If used in high concentrations during anesthetic administration, it causes increased absorption and thereby liver and kidney damage with neuralgic disease and congenital abnormalities.

**Mercury:** Waste dental amalgam is considered to be hazardous waste. Mercury causes the formation of „neurofibrillar tangles,“ which are one of the two diagnostic markers for Alzheimer’s disease. In February, 1998, it was announced that mercury from amalgam fillings can permanently damage the brain, kidneys, and immune system of children.

**Prevention:** Amalgam capsules, waste amalgam, amalgam sludge and used amalgam filters on suction units as well as extracted teeth with amalgam fillings must be segregated from other waste, stored in special UN-approved, labelled containers with vapour suppressant.

**Biological Hazard** are constituted by infectious agents of human origin and include viruses, bacteria and fungi. Therefore it is greatest concern to the dental professional. They are HIV, HBV, HCV and Mycobacterium tuberculosis. A dentist can become infected either directly or indirectly.

Possible sources of exposure to biological agents for dental healthcare professionals include:
Contact with contaminated sharps
- Respiratory infectious disease through splatters from bodily fluids and/or projectiles while using high-speed rotary handpieces.
- Environmental biological contaminants from water/ventilation systems (for example, legionella).

Musculoskeletal disorder \(23,28\): It has been reported that young and less experienced dentists experience more musculoskeletal disorders compared to older and experienced one. Common problems are, low back pain, shoulder pain, headache, hand and wrist pain. Low back pain is more prevalent than other types. The cause of musculoskeletal problem is due to, repeated unidirectional twisting of the trunks, working in one position, prolonged static periods and operators flexibility.

Prevention of Neck, Shoulder and Back Disorders
- Change Posture
- Use Support
- Safe reaching [within a distance of about 20 inches (50 cm)]
- Normal arm posture
- Use Comfortable Equipment
- Manage Time

Legal Hazards: To help assure a safe work environment in dental treatment, the hazard awareness and prevention of legal risks should be made known to all clinical workers of the dental hospital.

Psychological Hazards: Dentists encounter numerous sources of professional stress, anxiety, and depression, beginning in dental clinic.

Some of the main types of mental health promotion interventions are:
- At organisational level – ensuring adequate staffing levels and skill mix, organising shift patterns.
- At organisation/individual interface level – improving relationships, establishing support groups, improving person-environment fit.
- At individual level- stress management, counselling

Dental Unit Water Lines (DUWLs): Dental Unit Water Lines (DUWLs) are prone to microbial contamination, build-up of biofilm and are a potential source of legionellosis. The manufacturer’s instructions should be followed for the periodic disinfection of water lines. Regular disinfecting with a chemical agent is the most effective approach.

Summary

Dentist has to upgrade their existing knowledge by participating in continuing dental education, regular workshops and seminars on occupational hazards. Dental clinic design has to be made with, sufficient lighting, ventilation, engineering control measure and equipped with appropriate personal protective. More effort should be made by management officials to educate the staff about the importance of vaccination.

Conclusion

Occupational hazard is an unavoidable circumstance for the dentist and his team. The aim of infection control is to control iatrogenic, nosocomial infections among patients, and potential occupational exposure of care providers to disease causing microbes during provision of care. Disease transfer to the dentist and dental staff during dental care is considered an “occupational exposure” to a given pathogen while disease transfer from one patient to another in the dental clinics is considered “cross-infection”. Therefore, the dental health care provider must be knowledgeable about the diseases commonly encountered in the dental operatory and must follow high standards of infection control for the safety of the patients and the dental health care workers.

Role of Photodynamic Therapy in Endodontics—A Review

Jagadeesh Shuruthi1, Dhakshinamoorthy Malarvizhi2, Suresh Mitthra3, Arunajetasan Subbiya4

1Second Year PG Student, 2Professor, 3Reader, 4Professor and Head, Department of Conservative Dentistry and Endodontics, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research, Narayanaapuram, Pallikaranai, Chennai, Tamilnadu, India

ABSTRACT

The irrigants used commonly do not always eradicate the entire microbial flora in infected root canals. Thus in quest other strategies, such as photodynamic therapy (PDT) have been developed. The word photodynamic means the applications of the dynamics of photons of light on the biological molecules. German physician Friedreich Mayer performed the first study, which was first called as photo-radiation therapy with porphyrins (1913) in humans. Photoactivated disinfection is based primarily on the interaction of a photosensitive antibacterial agent and a light source which uses a nontoxic dye named photosensitizer (PS) and lowintensity visible light. In the presence of oxygen, these combine to produce some cytotoxic species. The PS molecules attach to the bacteria membrane. Irradiation with a specific wavelength of the light may result in the production of singlet oxygen, resulting in rupture of the microbial cell wall. There are several applications for PDT in dentistry.. Photodynamic therapy has also been used to disinfect caries dentin before the restoration, disinfecting oral tissues before or during surgical procedures, treating denture stomatitis, and treating oral candidiasis in immunocompromised patients. Photodynamic therapy can also be used in combination with mechanical instrumentation and chemical antimicrobial agents, such as sodium hypochlorite.

Keywords: photodynamic, biofilm, endotoxin, irrigants.

Introduction

The effect of microorganisms on the evolution of pulpoperiapical lesions has been demonstrated in numerous studies. Due to the complex anatomy of the root canal system, eradication of microorganisms from infected root canal systems is a complicated task.(1-3) Chemical irrigation in endodontic treatment conceives a suitable bactericidal effect; however, commonly used irrigation solutions, such as chlorhexidine and sodium hypochlorite (NaOCl) and intracanal medicaments, such as calcium hydroxide cannot completely eradicate the entire microorganisms in infected root canals.(6) To increase the disinfection level of the root canal system, several other strategies, such as photodynamic therapy (PDT) have been developed.

Principle: It is based on the principle that if the photosensitiser is excited by light source of suitable wavelength, it will be activated from the ground level to the triplet state and produce free radicals, which have a site-specific toxic effect to the cells. Longer the life time of the triplet state, cell constituents enables the excited PS to interact more with the surrounding molecules which leads to the formation cytotoxic products. The resultant products usually cannot migrate more than > 0.02 mm after its formation and thus it is ideal for local application, since and hence it avoids damage to the distant molecules, cells and organelles. (7) Several studies
have shown that PDT is lethal to most of the bacteria except for some gram-negative bacteria because they have a special cell wall due to which PDT is effective. [8]

**Photosensitizer:** The various photosensitizing agents available and which are commonly used are

1. Tolonium chloride - peak absorption, 633nm
2. Methylene blue - peak absorption, 670 nm
3. Rose Bengal - peak absorption, 550 nm
4. Aluminium disulphonated pthalocyanine - peak absorption, 675 nm
5. Porphyrin conjugates, polysine conjugates and chlorine conjugates with different peak absorption

**Light Source:** PDT require light source for activation of the PS agent at a specific wavelength and the light source available for PDT belongs to three major groups

1. Broad spectrum lamps
2. Light emitting diode lamps
3. Lasers

**Effect on Bond Strength:** An in vitro study evaluated the effect of the PAD system on the bond strength of AH Plus, Sealapex, and MTA Fillapex root canal sealers using the push-out test design. Findings concluded that AH Plus and MTA Fillapex sealers had greater bond strength when compared with Sealapex root canal sealers. It was also revealed that the PAD system adversely affected the bond strength of the MTA Fillapex root canal sealer to dentin[9].

**Biological Response to Photodynamic Therapy:** The biological response to PDT is influenced by the dye concentration, preirradiation period, environmental pH, light source, presence of exudates, and the energy dose. One minute is considered to be effective to achieve cellular uptake of toluidine blue O, and 5 minutes to achieve that of methylene blue[10,11]. Bhatti et al[12] demonstrated a dose-dependent relationship between concentration of toluidine blue O and its associated lethal effect. Some other studies also found that increase in concentration of methylene blue may cause a decrease in number of colonies recovered after the irradiation[13,14].

**Effect on Endotoxin:** Endotoxin is a part of the cell wall of the Gram-negative bacteria, which is composed of lipids, polysaccharides, and proteins and referred to as Lipo polysaccharides(LPS) [15]. When free to act, endotoxins cause no cell pathosis, but they can however stimulate competent cells to release some chemical mediators[16]. Macrophages have been regarded as the main target [16,17]. Endotoxins can act on neutrophils, macrophages, and fibroblasts, thus leading to release of a large number of inflammatory mediators, such as tumor necrosis factor, alpha-interferon, interleukin (IL)-1, IL-5, IL-8, and prostaglandins[16]. Shrestha et al [18] showed that the antibacterial PDT with chitosan-conjugated rose Bengal nanoparticles can result in inactivation of LPS and consequent reduction of all inflammatory marker.

**Effect on Endodontic Microbiota:** Photodynamic therapy can be used in combination with mechanical instrumentation and chemical agents, such as NaOCl and hydrogen peroxide. Garcez et al[19] showed that endodontic treatment alone reduced 90% of bacteria, whereas PDT alone reduced it by 95%. However, the combination of these two treatment methods, reduced bacteria significantly by 98%. In another study, Garcez et al showed that the endodontic treatment alone may produce a significant decrease in microbial count, whereas using the combination of endodontic treatment with PDT all teeth were bacteria-free [20]. Garcez et al have also demonstrated that usage of PDT added to endodontic treatment of infected canals with the optical fibre may be better than when the laser is used directed at the cavity [21]. Meire et al[22] compared the antimicrobial efficacy of neodymium-doped yttrium aluminium garnet (YAG), erbium-doped YAG (Er:YAG), two commercial antimicrobial PDT (aPDT) systems, and revealed that NaOCl is the most effective, while Er:YAG laser also resulted in high reductions of bacteria. Both aPDT systems resulted in a weak reduction of bacteria. George and Kishen[23,24] showed that the PDT destroyed the integrity of cell wall, deoxyribonucleic acid (DNA), and membrane proteins of bacteria. Damage degree was influenced by PS solvent employed during PDT. Soukos et al[25] used methylene blue as PS and concluded that there was complete elimination of all bacteria except Enterococcus faecalis. Pourhajibagher et al[26] investigated the effect of PAD on reduction of microbial diversity and count, related with primary endodontic infections and concluded that TBO (toludine blue O)-mediated PAD is an effective method in exhibiting efficient antimicrobial activity due to the substantial reduction of the microbial diversity and count in the primary endodontic infections.
Conclusion

Several strategies, such as usage of intracanal medicaments, e.g., calcium hydroxide, irrigating solutions, e.g., NaOCl and chlorhexidine, and PDT have been advocated to increase the disinfection level of the root canal system. It is used effectively to kill gram negative or gram positive bacteria, fungi, viruses and various bacteria that are present in complex biofilm.

ABSTRACT

Objective: To evaluate the effect of modifying the liquid component of conventional GIC with 10 v/v % and 50 v/v % Chitosan on fluoride release and flexural strength in comparison to conventional GIC.

Method: The liquid component Conventional GIC was modified by adding 10 v/v % and 50 v/v % Chitosan. To evaluate fluoride release, 90 discs of 10*2mm were prepared, stored in 50ml distilled water for 1hr, 24hrs and 1 week and measured in DR-2000 spectrophotometer. To measure flexural strength, 30 samples of 10*2.5*2.5mm were prepared, loaded until fracture in Universal testing machine.

Statistical Analysis: One-way analysis of variance and student Newman Keul test were used to analyze the data.

Results: The accumulated fluoride release at various time intervals were greater for 50 v/v% Chitosan modified GIC than the other groups. Mean Flexural strength of 10 v/v% Chitosan modified GIC was found to be statistically significant than the other groups.

Conclusion: Chitosan enhances the Fluoride release and flexural strength properties of conventional GIC.

Keywords: Chitosan, flexural strength, fluoride release, glass ionomer cement, spectrophotometer.

Introduction

Glass ionomer cement [GIC] has been used as a dental restorative material for more than four decades and its unique properties include direct adhesion to tooth and base metals [¹], anticariogenic properties [²], thermal compatibility with tooth, minimized microleakage at the tooth–enamel interface and biocompatibility. Its disadvantages such as brittleness, low tensile and flexural strengths has limited its use to low stress-bearing sites such as Class III and Class V cavities [³]. To overcome these disadvantages, incorporation of materials were tried out including bioglass, CPP-ACP, nanoclay, Chitosan and so on.

Chitosan is a hydrolyzed (deacetylated) derivative of chitin and found to be the principal component of the protective cuticles of crustaceans [⁴]. The medical properties of Chitosan include antifungal and antibacterial activity [⁵], non-toxicity, biocompatibility, biodegradability and muco-adhesion [⁶]. Chitosan has been widely use in dentistry including augmentation of edentulous ridge [⁷], for osteogenesis [⁸], for increasing salivary secretion [⁹], as a guided bone regeneration tool [¹⁰] and to improve wound healing [¹¹].

Fluoride release is one of the major advantages of GIC and this advantage should not be compromised by adding additives. There are only few studies in literature that evaluates the fluoride release and flexural strength...
properties of Chitosan modified GIC. So the aim of this study is to evaluate fluoride release and flexural strength of Chitosan-modified GIC (10 v/v % and 50 v/v %) in comparison to conventional GIC. The null hypothesis is that the addition of chitosan does not influence the properties of conventional glass ionomer cement.

Materials and Method

Preparation of Chitosan modified GIC: In a 100 ml standard flask, 20 mg and 100 mg of Chitosan powder (Sigma Alrich, Manopolise, USA) was dissolved in 0.3 N acetic acid and made up to 100 ml by adding acetic acid in order to get 0.2mg/ml and 1mg/ml Chitosan Solution respectively. [21] 10 v/v% and 50 v/v% Chitosan modified glass ionomer solution was prepared by adding 0.1ml of 0.2mg/ml of Chitosan solution to 0.9ml of GIC liquid and 0.5 ml of 1mg/ml Chitosan solution to 0.5ml of GIC liquid respectively.[12,21] Fuji II GIC (GC dental Industrial Corporation, Tokyo, Japan) was used in this study.

Group I: Conventional GIC
Group II: 10 v/v % Chitosan modified GIC
Group III: 50 v/v % Chitosan modified GIC

Fluoride Release: Powder liquid ratio (2.7g/1g) as recommended by manufacturer of Conventional type II GIC was used to prepare the samples of groups I, II, III (n=90) by packing the material into a circular PTFE mould of 10mm internal diameter and 2mm height and pressed between glass microscopic slides. The cement was allowed to set and incubated at 37 ºC and 100% humidity for 24 hours. They were then transferred into individual glass flasks containing 50ml of distilled water. 30 samples of each group was sub grouped into subgroup a (1 hour), b (24hours) and c (1 week). Fluoride release from the samples were determined by SPADNS’ spectrophotometric method of fluoride determination, which is based on the principle that the presence of fluoride affects the rate of absorption of light leading to change in optical density and from the optical density the fluoride content (mg/L) is measured with HACH DR-2000 spectrophotometer at 580nm.

Flexural Strength: Ten samples of each group was prepared by placing the material into a PTFE mould of 25*2.5*2.5 mm and pressed between glass microscopic slides. After one hour, specimens were removed and ground to 25*2*2mm cross sectional dimension (600 grit silicon carbide paper), rinsed with tap water, cleaned and stored in distilled water at 37º C for 24hours. The specimens were then transferred to universal testing machine and loaded at a cross head speed of 1mm/min until the specimen fractures. The flexural strength was calculated based on the formula

$$FS = \frac{3Fl}{2bh^2},$$

where F is the maximum load at fracture in MPa, l is the distance between the supports (20 mm), b is the width of the specimen (in mm) and h is the height of the specimen (in mm).

Statistical Analysis: Results of fluoride release and flexural strength test were statistically analyzed using statistical package of social sciences (SPSS) version 10.0 and the data were analysed using one way analysis of variance (ANOVA) and the multiple comparisons between the experimental groups were done with post hoc- STUDENT NEUMAN KEUL test. Statistical significance was taken as p < 0.001.

Results

The mean value of fluoride release and flexural strengths of all the three groups [I, II, III] were tabulated [Table I].

The mean flexural strength of group II was highest when compared to the groups I and III and it was found to be 50.3% more than Group I. Although Group III had the highest mean fluoride release, its mean flexural values were lower than group II but higher than group I [Table I]. Statistical comparison between the Groups showed they were statistically significant (p < 0.001).

Discussion

Glass ionomer cements are the most preferred restorative material for management of cervical lesion because of its reliable bond to dentin [13]. The main disadvantage of GIC is its lack of wear resistance and fracture toughness [14]. Therefore efforts were taken to reinforce GIC which resulted in different kinds of self cured GIC, water hardening versions, amino-acid residue modified GIC and so on. In accordance with the previous study of Petri DFS et al, in our study the liquid component of conventional GIC was modified by adding different concentration of Chitosan. [15] Chitosan is positively charged because of its free amino group which reacts with surfaces/polymers with negative charge forming covalent and ionic bonds, thereby allowing improvement of properties.

In the present study, fluoride release was measured by spectrophotometry, in which SPADNS’ utilizes the reaction of the zirconium-dye lake with that of the Fluoride. The stronger the concentration of fluoride, the lighter the color of the solution will be, which is measured in HACH DR-2000 spectrophotometer at 580nm [16]. This makes it a simple and accurate method of determining fluoride content in a solution.

In the present study, fluoride release was measured by spectrophotometry, in which SPADNS’ utilizes the reaction of the zirconium-dye lake with that of the Fluoride. The stronger the concentration of fluoride, the lighter the color of the solution will be, which is measured in HACH DR-2000 spectrophotometer at 580nm [16]. This makes it a simple and accurate method of determining fluoride content in a solution.

The result of the present study revealed significantly greater amount of fluoride was released by Group III samples than groups I and II at the end of 1 hour, 24 hours and 1 week.

In the previous study 10 v/v% Chitosan modified GIC released the maximum amount of fluoride when compared to 25 v/v% Chitosan modified GIC [15] but to the contrary, in our study, 50v/v % Chitosan modified GIC had the greatest fluoride release followed by 10v/v% Chitosan modified GIC and conventional GIC.

The fluoride release increases as a function of time. The accumulated fluoride release values of the present study were significantly lower than the other studies [17,18]. This might be due to differences in manipulation and slight variations in setting time. Intra and inter group variability of the GIC specimens were found in the present and other studies [19].

Three point bending test remains the choice for evaluating the glass ionomer’s flexural strength as it has a lower standard deviation, lower co-efficient of variation and the less complex crack distribution produced by it when compared to other test designs[20].
Results of this study showed that group II had the highest flexural strength followed by group III and group I which is in accordance with the previous study [15]. Chitosan increases the flexural strength of the material. The probable reason might be that the hydroxyl and acetamide groups of chitosan bind to hydroxyl group of powder particles and carboxylic groups of polyacrylic acid by hydrogen bonding. During this reaction the interfacial tension among GIC components was reduced which resulted in improved mechanical properties.

Previous study done by the same authors revealed that 10 v/v% Chitosan had greater microshear bond strength than conventional GIC and 50 v/v% Chitosan [21]. Another study revealed 10 v/v% chitosan had no deleterious effect on microleakage of GIC [22].

In one study, it was found that Chitosan modified glass ionomer cement could be used as a root filling material that could allow adhesion and growth of gingival tissues.[23] Another study highlights the improvement of antibacterial property and adhesion of GIC to enamel when 10 v/v% of Chitosan was added to conventional GIC. [24] A study by Senthil Kumar et al concludes that Chitosan modified GIC inhibits the bacteria associated with dental caries along with improved physical properties. [25]

Another study compares chitosan and chlorhexidine-cetrimide-modified glass ionomer cements and found that CH modified GIC had better antibacterial effect along with improved physical properties when compared with chlorhexidine-cetrimide modified GIC and conventional GIC. [26]

Further tests should be done to evaluate other properties like setting and working time, shelf life of Chitosan modified GIC to know more about the material characteristics.

Though there are different classes of fluoride releasing materials, their properties need to be improved significantly before considering them as universal restorative materials. Although a single material would be desirable, compromises may be necessary when selecting materials. The results of our study showed that Chitosan modified GIC might prove to be a promising restorative material but it can be indicated for clinical use only after clinical trials are done, as the clinical performance of a material might not be the same as in invitro conditions.

Conclusion

Within the limitations of the present study, it can be concluded that Chitosan enhances the anticariogenic [fluoride release] and flexural strength of the conventional glass ionomer cement.

Third Molar along the Line of Fracture in Mandible—A Systematic Review

Kirthika R.¹, Visalakshi K.², Balakrishnan R.³
Sree Balaji Dental College and Hospital, Pallikaranai-100

ABSTRACT

The aim of this systematic study is to know whether the third molar is to be removed or not when in line of fracture. The angle fracture of mandible is one of the most common site because of the presence of thin cortical bone and the presence of third molar. The presence of third molar increases the incidence for the angle fracture and decreases the risk for condyle fracture. The search terms were the “third molar AND angle fracture” were used to search in the pubmed. Of the total 128 article, 22 relevant article was reviewed. The search criteria was for the last 5 publication year 2013-2018 the resultant articles were 50. In which the duplicates and irrelevant article were removed (28 articles).

Keywords: angle fracture, treatment, complications, third molar, teeth in line.

Introduction

The aim of this systematic review is to analyze surgical removal of teeth intraoperatively during angle fracture is a better option or not. Treatment of mandibular angle fracture is challenging because it seems to be associated with the highest rate of complications such as infection, malunion, malocclusion, and facial nerve damage recorded to range from 0% to 32%. Presence of third molar always influences the angle fracture depending on its root, angulation and position. The presence of third molar can influence the percentage of angle fracture and decreases the incidence of condyle fracture. The angle region is prone to fracture because of the presence of thin cortical bone and presence of third molar. The removal of teeth remain a controversies during open reduction. Retaining the teeth within the fracture line can result in decreased bone contact and blood supply.

Material and Method

This systematic review was done to evaluate the weather removal of third molar is the better option for the treatment of angle fracture. The search was done in PubMed using keywords “third molar AND angle fracture”.

Discussion

Rafael Ferreira e Costa et al (1), he reviewed the complications of mandibular angle fracture post operatively, in most patients the dental element was removed intraoperatively (52.64%). In 26.31% of the patients, the third molar was present in the fracture line; and in 21.05% of the patients, this dental element was absent. Regarding the patients with complication observed, no complications occurred in patients where the third molar was absent, 3 complications occurred when the third molar was in the fracture line (33.33%), and 6 complications occurred when the third molar was removed intraoperatively. Matteo Brucoli et al (2018), conducted a European based study on 489 patients. Sixty complications were observed with a complication rate of 12.3 %. Complications were associated with the absence of third molars (p < .05).

Sahand Samieirad et al (2018), the study sample consisted of 117 patients (63.2% with condylar fractures,
30.8% with angle fractures and 6% with concomitant fractures of condyle and angle). 88.9% of subjects with angle fracture had impacted M3s; however, the impacted M3 was absent in 59.5% of condylar fracture cases. The presence of impacted M3s increased the risk of angle fractures and simultaneously decreased the risk of condylar fractures. Fractures of the angle region are more commonly seen in individuals with superficially impacted (compared to deeply impacted) third molars. Oikrinen, Malmstrom and Halazonetis et al(13), stated that angle fractures were twice as likely to occur in dentate patients compared with edentulous persons. The difference in survival of third molar was statistically significant between right and left side, the left side had a relatively better chance 92.85%. This was probably due to the fact, that the operating surgeon being right handed, had more comfortable and easier access for the left side rather than the right side. Maaita and Alwrikat(4) showed the relevance of various angulations of mandibular third molar to the risk of an angle fracture. They showed a higher risk of angle fractures in the vertical and distoangular positions of mandibular third molar. However, Maaita and Alwrikat showed a higher fracture risk from deeply impacted mandibular third molar both in the ramus and occlusally. This study coincides with the result to Iida et al he also stated that the root of mandibular third molar in these two groups is directed towards the angle of the mandible, the third molar may act as a wedge splitting the mandibular angle, by which the injury force is redirected toward the mandibular ramus and angle.

Samson et al(2, 5), considered that the tooth in the line of any mandibular fracture can cause complications. Consequent to trauma, pulp necrosis may result that disturbs vascularization and resultantly predisposed to invasion of bacteria from the fracture line in to the tooth pulp. Additionally, marginal bone resorption and the creation of bone pockets may occur post-surgically, when the reduction of fracture fragments is inadequate affecting the relation of the gingiva, teeth and supporting tissues. Presently, several authors favor that tooth in mandibular fracture line can cause complications, but whenever possible, they recommend retaining the tooth in fracture line. This was based on the observation that large number of teeth with a negative response to sensitivity testing, but without clinical and radiological signs of devitalization. They found that the conservative endodontic treatment of teeth in the fracture line does not interfere with healing of the fracture. Macan D et al (10, 13), in 1985 had described the importance of the tooth in the mandibular fracture line, should be retained if its help to stabilize the bone fragments exceeds the ability of such tooth to cause inflammatory complications. In attempting to achieve stability by retaining these teeth. Their retention carried the attendant risks of delayed union and infection of the fracture; it therefore seemed advisable to remove vertically impacted lower third molars. Extraction of a tooth in the line of fracture rendered it less stable and therefore any likelihood of further displacement had to be counteracted. This was achieved by internal fixation usually by means of a single upper border wire.

Malanchuk VO, Kopechak AV (2007)(6, 7) their study reported that when a decision is taken to leave the tooth in the fracture line, it has been suggested to closely check for its vitality after fracture consolidation to perform endodontic treatment whenever loss of vitality is noted. Bobrowski et al (19), in a recent systematic review considered prognosis of 1542 third molars along mandibular angle fractures. In this 1542 cases, in 788 (51.1%) cases the tooth was removed. Of these 788 cases, during the follow-up infection occurred in 84 cases (10.66%). Of the 754 third molar retained 84 (11.14%) cases had infection. This difference had no statistical significance. This study showed that removal of the third molar along the line of fracture did not confer any exemption from infection. Balaji et al., in their study, during fracture reduction, of the 116 cases enrolled for the study, 61 cases had their third molar extracted and another 8 extractions in the 3 months followed. Further 21 molars were needed to be extracted in the 3–6th month follow-up. The cause for removal included development of severe periodontal problem including mobility and periapical lesions. As these could impede the healing, the teeth were extracted. In total, at the end of the study, only 22.4% of the teeth remained. During the healing period, of the 55 teeth that were left behind with the strong notion that they would not impede healing, three cases of infection that required surgical intervention were observed. Additionally of the 55 cases, only 26 (47.27%) cases survived at the end of 6 months.

Ellis E., in 2002 explained that in the pre-antibiotic(12, 14) times, it had been a norm to remove the entire tooth in lines of fracture. This was carried under the school of thought that such tooth would be an area of weakness through which microbes would trespass to cause infections. Extractions were performed prophylactically to avoid infections. With the introduction of antibiotics and antimicrobials, the efforts were directed to save the tooth while the drugs took care of the microbes. However,
the inherent defects of a tooth in the line of fractures could not be underestimated. As per reviews in the subject, Muller as early as in 1964, had recommended that multi-rooted tooth in the line of fracture be always removed. Later, James et al., proposed that tooth with extreme mobility, those with the fracture of root, apical pathology and those not necessary for stability of fracture be removed. In their sample, they removed only 39% of the teeth. Kahnberg and Ridell\(^{(14)}\) found that 59% of teeth left along the line of fracture obtained satisfactory healing. Meechan advocated that the mandibular angle may fracture under the influence of both direct and indirect trauma. He stated that if third molar is present and impacted, after direct trauma, it could affect the occurrence of angle fracture. In such a situation, prophylactic removal may prove beneficial.

Lee et al\(^{(17)}\), in 2003 explained that in partial displacement of the tooth axially from the socket; partial avulsion where the periodontal ligament usually is torn, treatment is to reposition and stabilize the tooth in its anatomically correct position to optimize healing of the periodontal ligament and neuro-vascular supply while maintaining esthetic and functional integrity. Gassner et al\(^{(16)}\), in 1999 in his study of 6000 patients with dental trauma concludes that tooth with crown/root fracture with a mobile coronal fragment attached to the gingiva with or without a pulp exposure, can maintain pulp vitality and restore normal vitality.

Olsburg et al\(^{(18, 19)}\) in 2002 showed successive restoration by definitive treatment alternatives: removal of the coronal fragment followed by a supragingival restoration. He also concludes that most fractured permanent teeth can be saved but fractures extending significantly below the gingival margin may not be restorable. Andreasen and Andreasen\(^{(20)}\), in their works showed that Root fracture i.e., dentin and cementum fracture involving the pulp with a mobile coronal fragment are treated by repositioning and stabilizing the coronal fragment.

**Conclusions**

The removal of teeth in line of fracture has been a controversy to many author. The Champy technique with semi rigid fixation always seems to prove the best fixation method so far. This systematic review concludes by stating that on removal of third molar when the teeth is in line of fracture with the presence of apical infection, dental caries, tooth mobility, root fracture. While on removal at the same time can result in osseous defect which can latter on result in infection on latter part, presence of bone defect and delay in reduction of fracture site.

**Result**
In the 22 article, the controversies on removal or to retain the teeth was discussed and the maximum number of authors concluded that the teeth is to be retained when in line of fracture carried less complication than removing.

Management of Dry Socket—A Review

Saravanakumar¹, Prakash¹, Balakrishnan¹

¹Professor, Dept of Oral and Maxillofacial Surgery, Sree Balaji Dental College and Hospital, BIHER, Chennai, Tamil nadu, India

ABSTRACT

Dry socket is one of the common complications which may befall following the extraction. It is characterized by intense painful episodes, loss of taste sensation and halitosis. However, the pathogenesis is unbeknown but occurs more likely due to blood clot disintegration which has multiplex etiological factors. There are many methods emphasized for the prevention and management of this condition that is empirical and not the standard one. This review article aims to lists possible methods for management of dry socket

Keywords: Osteitis, Alveolitis, Lymphadenopathy

Introduction

Dry socket is also termed alveolar osteitis, which occurs two to three days after the extraction. The first clinical appearance of dry socket was observed in 1896 and was described by Crawford [1]. Birn named this complication as “fibrinolytic alveolitis” [2-4]. Also been denoted by other terms like Alveolar osteitis, Localized osteitis, Post-operative alveolitis, Alveolalgia, Alveolitis Sicca Dolorosa, Septic socket, Necrotic socket, Localized osteomyelitis, Fibrinolytic alveolitis[5,6]. It is characterized by fever, pain with varying intensity and halitosis, with an empty socket, consist of a disintegrated blood clot. On Clinical examination, the gingiva is inflamed with ipsilateral regional lymphadenopathy. The empty socket consists of a denuded bone surface with greyish-yellow slough and necrotic tissue [7]. The pain may be localized, but most often radiates to temporal regions, for the mandible. In the maxilla, pain can radiate to the ocular or frontal region [4]. Dry socket is more common in mandibular third molars has an incidence of 38%; 0.5%-5% for other routine extraction; 1%-45% for mandibular molar extraction [8, 9]. Thus the incidence of dry socket is elated in mandibular molars than maxillary molars.

Etiopathogenesis: Many etiological factors have been proposed, but the exact specific cause for the occurrence of dry socket is unknown. The etiological factors include traumatic extraction causing injury to bone[10]; oral flora which includes bacteria like Treponema denticola, a gram-negative, obligate anaerobic produces plasmin like substance begins the fibrinolytic activity[11]; circulatory factor; poor post-operative care, saliva production; stress; enzyme factors[12]; post-operative irrigation of socket; usage of mouth rinses[13]; clotting factor disorder; nutritional factors mainly vitamins[14]. The pathogenesis is characterized by fibrinolysis by conversion of plasminogen to plasmin that is achieved directly or indirectly. Direct activators are released from bone cells following the trauma. Indirect activators include bacteria and other predisposing factors.

Predisposing Factors: Some Predisposing factors which can provoke the occurrence of dry socket are:

a. Age of the patient – commonly occurs between 20-50 years old people due to an eruption of third molars and are uncommon in younger age due to increased bone elasticity and increased blood circulation with better healing capacity[9,15];

b. Sex of the patient- women is more affected than a male with a ratio of 5:1. Due to alterations in the level of hormones mainly the estrogen during
menstruation, there is an increased chance of occurrence of dry socket in the female. Estrogen can induce fibrinolytic activity indirectly, thus resulting in dissolved blood clot. Estrogen can induce fibrinolytic activity indirectly, thus resulting in dissolved blood clot. 

Oral contraceptive- increased incidence of dry socket is seen in the patient under medication of oral contraceptives. It indirectly activates plasminogen, induces lysis of blood clot.

Smoking- Smoking has shown to have an increased occurrence of dry socket. It is characterized by the inhibition of neutrophil chemotaxis and production of immunoglobulin. Also, nicotine in the cigarette causes vasoconstriction.

Area of extraction and no. of teeth

Insufficient blood supply to the alveolus

Systemic diseases like diabetes

Clinical Management: The royal college of surgeons in England laid National clinical guideline in 1977 for management of dry socket which was further reviewed in 2004. They suggest when a patient approaches a clinic with characteristics of dry socket,

- He/she should be examined and radiograph should be taken to rule out the presence of any retained root or bone fragment to rule out the cause of pain
- The necrotic tissue or food debris present in the socket must be removed by irrigating with 0.12% chlorhexidine digluconate
- Then the socket has to be packed with Obtundent dressing to prevent food debris accumulation and local irritation from the bone. Obtundent should have antibacterial and antifungal property

Commonly used obtundents are zinc oxide eugenol, Alvogyl

The patient can be prescribed with NSAIDS/steroids for reducing the pain sensation if there is no medical complication

The patient should be reviewed every two days to change the dressing and it should be done until the pain gets reduced. They will be instructed to rinse the socket with 0.2% chlorhexidine digluconate with a syringe at home.

The treatments for a dry socket include placement of a self-eliminating dressing such as Alvogyl; placement of an obtundent dressing such as zinc oxide, eugenol, and lidocaine gel; a combination of these therapies and, where appropriate, the prescription of systemic antibiotics.

Various Methods of Management:

- **Zinc oxide eugenol**: Applied in the Gauze or as an ointment. Eugenol contains antiseptic and anesthetic properties thus depress sensory receptors involved in pain perception. But causes local irritation and delayed wound healing.

- **Alvogyl**: Most commonly used and commercially available, consists of eugenol acts as an analgesic, iodoform which acts as antimicrobial agent and butamen which acts as an anesthetic agent, which has to be replaced after every 2 days.

- **Steroids**: Though the topical application of corticosteroids has been reported to prevent the occurrence of dry socket, it only decreased the post-operative pain and not its occurrence. However, the topical application of hydrocortisone and oxytetracycline mixture reduced the incidence of dry socket in impacted third molars.

- **Topical anesthetic gel Oraqix**: Contains 2.5% prilocaine, 2.5% lidocaine, thermosetting agents, hydrochloric acid and purified water. It has antiseptic and anesthetic properties.

- **G.E.C.B Pastilles**: Contains 3% eugenol, 3% guaiacol and 1.6% chlorobutanol as effective ingredients, and Balsam Peru as a base. Haghighat et al 2012, studied the efficacy of GECB pastilles and ZOE, reported that GECB shows more result in reducing the post-extraction complications.

- **SaliCept Patch**: Contains Acemannan hydrogel, the clear inner gel of Aloe Vera, promotes wound healing, augments reticuloendothelial function, regulates the immune response and acts as an anti-inflammatory and antibacterial agent.

- **Vitamin C**: Available as tablet form. It helps in wound healing and promotes antioxidant action thus reduces the infection and inflammatory action. Maria et al concluded that 4000 mg vitamin C dose along with curettage and irrigation shows 100% pain remission in 4 days.

- **Plasma Rich in Growth Factors (PRGF)**: Consist of platelets and fibrinogen which are
obtained from blood that helps in wound healing and osteogenesis[30]. Platelet-derived growth factor (PDGF) and Tissue Growth Factor (TFG) are some of the Growth Factors in this plasma. PRGF, when used along with gelatin sponge, promotes earlier healing of wound when compared to zinc oxide eugenol [31,32]

i. Low-level laser therapy (LLLT): Uses continuous mode gallium aluminium diode laser of 808 nm, 100-mW for 60sec - 7.64J/cm2. Showed improved healing of the wound and enhanced antimicrobial action[24,33]

Of all these methods given that promotes healing of alveolar bone, it has been concluded that early and effective healing of the socket is seen in LLLT therapy and PRGH[23, 24, 34]

Conclusion

Dry socket is the most common condition encountered after the extraction of the impacted third molar. The management of the dry socket is done until the patient relieves from pain and the healing of the socket occurs. Healing of the exposed socket also depends on patient cooperativeness by following post-operative instructions and maintaining proper oral hygiene. The treatment method includes the use of PRGH, LLLT Therapy, Alogyl along with the irrigation of the socket. However, the exact etiology and pathogenesis for the occurrence of dry socket are unknown. In the future, further investigation is required to conclude about exact cause and mechanism so that the proper method of management can be performed.

ABSTRACT

Diabetes Nephropathy is a major microvascular complication of Diabetes Mellitus and the most common cause of End Stage Renal Disease (ESRD) worldwide. Hyperglycemia, a well recognized pathogenic factor of long term complications of Diabetes Mellitus, generates ROS. This attenuates antioxidative mechanisms through glycation of the scavenging enzymes. Excess amount of ROS modulate activation of protein kinaseC, mitogen activated protein kinases and various cytokines and transcription factors which eventually cause increased expression of extracellular matrix (ECM) genes with progression of fibrosis and end stage renal disease. Therefore, this study was carried out to investigate oxidant and antioxidant status in Diabetic patients for manifesting the progression to diabetic nephropathy.

Keywords: Diabetic Nephropathy, Hyperglycemia, Reactive Oxygen Species, Extracellular Matrix, Oxidative Stress.

Introduction

Diabetes is a metabolic disorder characterized by hyperglycemia and often leads to numerous microvascular complications, including nephropathy. The increased oxidative stress was noted in the poor glycemic control patients with chronic diabetes mellitus. High intracellular glucose concentration in chronic diabetes mellitus causes activation of polyol pathway, hexosamine biosynthetic pathway and PKC are major sources of reactive oxygen species (ROS) (Forbes et al 2008), which are collectively involved in the pathogenesis of diabetic nephropathy(Agarwal R et al, 2005). ROS are believed to play a key role in the pathogenesis of diabetic complications because of their reactive chemical property to directly oxidize and damage DNA, protein, lipid, and carbohydrate. ROS activates signal transduction cascades and transcription factors leading to transcriptional activation of profibrotic genes(Julius et al). Further, PKC, transforming growth factor-α1 (TGF-α1) and angiotensin II (Ang II) stimulated by hyperglycemia-induced ROS, in turn, generate and signal through ROS and thus involve in glomerular mesangial expansion and tubulointerstitial fibrosis. It is now clear that the overproduction of ROS plays an important pathogenic role in the development of diabetic nephropathy (Kashiharan et al 2010) explore major therapeutic interventions.¹,²,³

Reactive oxygen species (ROS): ROS are continuously generated in physiological condition and are effectively eliminated by several antioxidative systems. ROS includes mainly superoxide or hydroxyl radicals and other are alkoxyl, peroxy, plus non-radical derivatives of oxygen, specifically hydrogen peroxyde and ozone, which plays a major part in cell signaling, ageing and degenerative disease The amount of ROS produced is finely balanced with the antioxidant activity and when it exceeds cellular defence power or diminishes the production of antioxidants can lead to increased oxidant-derived tissue injury or oxidative stress(Julius et al)⁴,⁵
Sources of ROS in diabetes mellitus: The high glucose concentration in chronic diabetes mellitus induces oxidative stress by generating ROS through an activation of number of enzymatic and nonenzymatic sources in the body. The major sources of ROS in diabetes include polyol pathway, advanced glycation and uncoupling of NADPH oxidases (Kiteda et al 2011).6

Oxidative stress and kidney damage: “SIES” introduced the term oxidative stress, which occurs as a consequence of imbalance between the formation of oxygen free radicals and inactivation of these species by antioxidant defense system. Oxidative stress is recognized as one of the major components in the pathogenesis of diabetic microvascular complication (Kelly D.J et al). Sustained hyperglycemia increases oxidative stress which in turn affects kidney by following mechanisms.

a. Increased advanced glycation end products (AGEs) are produced by the prolonged exposure of amino acids to increased glucose levels. The AGEs cause cellular damage by altering cell protein actions and cell membrane functions;

b. Hypertension and hyperfiltration in the glomerulus (which is the filtering unit of the kidney—there are about one million in each kidney) increases pressure in the glomerulus is decreased by blocking the actions of angiotensin II

c. Increased transforming growth factor (TGF) leads to activation of a number of inflammatory compounds leading to fibrosis in the kidney8,9

Materials and Method

The people were grouped into 2 categories:

Group 1: Controls includes both male and female. Age criteria were not taken into the consideration because they were not showing any symptoms of Diabetes Mellitus.

Group 2: Diabetic patients which includes both male and female. 5ml of blood was collected by vein puncture from the antecubital vein in both Group 1 and Group 2 (N =20) Heparinized sample for estimation of Hydrogen peroxide radical, Superoxide radical, Citrated sample for estimation of plasma Malondialdehyde(MDA), Catalase, Vitamin E Glutathione peroxidase(GP) serum for estimation of Superoxide Dismutase(SOD) Lipid profiles, EDTA sample for stimation of Glycosylated hemoglobin.

Estimation of Glycosylated Haemoglobin: Venous blood mixed with lysing reagent for the preparation of hemolysate. Elimination of the labile Schiff's base is achieved during hemolysis. The hemolysate is then mixed with a weakly binding cation exchange resin. The non – glycosylated hemoglobin binds with resin leaving glycosylated hemoglobin free in the supernatant. The percentage is determined by measuring the absorbance of the glycosylated hemoglobin fraction and the total hemoglobin at 415 nm.

Oxidants and Antioxidants Systems

Estimation of Oxidant Systems

Estimation of Superoxide Radical: Superoxides were estimated by the method of Nishikimi et al., (1972) in erythrocytes using Nitroblue tetrazolium (NBT). Superoxide levels in erythrocyte are expressed in terms of mmoles of NBT reduced/ml/10 min

Estimation of Hydroxyl Radicals: Hydroxyl radicals were estimated by the method of Gutteridge(1987) by their reaction (Hydrogen abstraction) from deoxyribose, resulting in the formation of thiobarbituric acid reactive species. Amount of hydroxyl radicals present in the erythrocyte are expressed in terms of MDA/ml/hr.

Estimation of Hydrogen Peroxide Radical: Estimation of Hydrogen peroxide by the method of Wolff(1994), using FOX reagent containing 2mM xelenol orange, 5mM ammonium ferrous sulphate, 200mM sorbital and 500mM Sulphuric acid. The erythrocyte hydrogen peroxide levels are expressed as µmoles/ml

Assay of Enzymatic and Non-Enzymatic Systems

Enzymatic Systems

Assay of Superoxide Dismutase [SOD]: The Superoxide dismutase activity was determined by the method of Marklund and Marklund [1974] and is based on the inhibition of pyrogallol autoxidation by the enzyme. The values are expressed as the amount of protein required to give 50% inhibition of pyrogallol autoxidation.

Assay of Catalase: The activity of Catalase was assayed by the method of sinha [1972]. The activity of the catalase was arrived at from the amount of hydrogen peroxide consumed and was expressed as µmoles of hydrogen peroxide consumed per minute per mg protein.
**Assay of Glutathione Peroxide:** Glutathione peroxidase was assayed according to the method of Rotruck et al. [1973] with some modification using DTNB. The activity was expressed in terms of µg of glutathione utilized/min/mg protein.

**Estimation of Non-Enzymatic Antioxidants**

**Estimation of Plasma Vitamin E [Vit E]:** Estimation of Vitamin E was done by the method of Barker and Frank [1968] using Dipyridyl reagent. Values are expressed as mg/dl.

**Estimation of GSH:** Estimation of GSH was done by the method of Moron et al. [1979]. Disodium hydrogen phosphate [DSHP] 0.3M. The amount of GSH was expressed as mg of GSH utilized/min/mg protein.

**Oxidative Markers of Biological Macromolecules:** LPO was estimated by the method of Devasagayam and Tarachand [1987]. The malondialdehyde content of the samples were expressed as nmoles of MDA formed/mg protein.

Comparisons made between control and diabetic patients.

Values are statistically significant when *p<0.05, **p<0.01, ***p<0.001 Values mean ± SD for 10 experiments.

**Discussion**

The results on various parameters are useful to diagnose oxidative stress and to assess the relation with diabetes patients which progress to nephropathy.

Table 1 shows the levels of, HbA1c, Oxidance, and anti-oxidance of control on diabetic patients. There was significant difference (p<0.001) in HbA1c between control and diabetic patients.

HbA1c levels are higher in diabetic patients who develop micro and macroalbumin evidence both in type 1 and type 2 diabetes, that poor blood glucose control contributes to the development of albuminuria. Some of the mechanisms that link hyperglycemia to the functional/structural abnormalities of diabetic kidney disease have been elucidated. Extracellularly glucose reacts non-enzymatically with primary amines of proteins, forming glycated compounds. Glucose transported into cells by glucose transporters, is partly metabolized to sorbitol via the polyol pathway and to hexosamines. All these biochemical pathways have been implicated in hyperglycemia induced kidney damage. Furthermore, excess glucose can directly exert toxic effects by activating intracellular signaling pathway and inducing a number of cytokines injurious to the kidney (Gareth et al).

Table 1 also shows the level of oxidants and anti-oxidants level in the control and diabetic patients. It shows that the level of oxidants such as erythrocyte superoxide radical, hydrogen peroxide and lipid peroxide were significantly (p<0.001) increased in diabetic patients when compare to control.

Similar results were seen in the level of anti-oxidants like SOD, Catalase, GPₓ, VIT E which shows...
a decrease in diabetic patients than control group. Insulin deficiency promotes beta-oxidation of fatty acids with resulting increase in Hydrogen peroxide formation.

Studies have shown that glucose catalyzes LPO reactions Elevated glucose has also been shown to increase the activity and expression of the Lipid peroxide enzymes. Also there is an association between free radicals and advanced glycation end products. The Schiff base and amadori products are sources of superoxide radical (Pitt et al 1999). Carboxy methyllysine and pentosidine, which are sugar-derived auto oxidation products known as glycozidation products may initiate and propagate free radical reactions.

Another means by which AGE formation plays a role in Diabetes Mellitus related oxidative stress is through glycation and resultant inactivation of antioxidant enzymes, such as (CU-2N) SOD.

Thus the combined effect of increased free radical production and decreased antioxidant status leads to oxidative stress in the diabetic patients conforms the susceptibility of kidney in development of nephropathy.11-16

Conclusion

Diabetic nephropathy is the most common cause of progressive renal damage and end stage renal failure in patients with diabetes mellitus. Oxidative stress coupled with chronic hyperglycemia has an important role in the pathogenesis of glomerular and tubular functional and structural abnormalities. There has been an increase in the knowledge of the role of oxidative stress in diabetic nephropathy which has directed to the investigation of a number of therapeutic strategies, the success of which has been so far limited. However, timely and judicious use of recent therapies to maintain good glycemic control, lipid levels adequate and blood pressure, along with life style measures such as regular exercise, optimization of diet and smoking cessation, may help to reduce oxidative stress and endothelial cell dysfunction and slow the progression of diabetic nephropathy until more effective therapies become available.

ABSTRACT

Tamm Horsfall Protein or Uromodulin is the most abundant urinary glycoprotein that has a protective function in the bladder mucosal layer. THP is also the primary constituent of renal tubular casts and THP aggregation has been implicated as a factor in the pathogenesis of acute renal failure by causing tubular obstruction. Using ELISA, the autoantibody level of Tamm Horsfall Protein in serum was determined in Hypertensive Patients and control subjects. A significant percentage of hypertensive subjects have a greater risk of renal stone formation, with high autoantibodies level to Tamm Horsfall Protein in serum when compared to control subjects. Hence THP acts as a potential biomarker for nephrolithiasis in Hypertensive patients.

Keywords: Tamm Horsfall Protein Hypertension ELISA Autoantibody Nephrolithiasis.

Introduction

Essential Hypertension: Essential, primary, or idiopathic hypertension is defined as high BP in which secondary causes such as renovascular disease, renal failure, pheochromocytoma, aldosteronism, or other causes of secondary hypertension or mendelian forms (monogenic) are not present. Essential hypertension accounts for 95% of all cases of hypertension (WHO1996). Essential hypertension is a heterogeneous disorder, with different patients having different causal factors that lead to high BP. It has been called “silent killer” because patients with hypertension generally have symptoms whatsoever, often 15-20 years. Hypertension is a major contributor to the development of renal failure, cardiovascular disease, and stroke. These pathologies are associated with vascular functional and structural changes including endothelial dysfunction, altered contractility, and vascular remodeling (A Julius et al, 2014).

Association between Hypertension and Kidney Stone Disease: The prevalence of nephrolithiasis has been reported to be 30% to 79% (Cappuccio et al., 1990) in hypertensive than normotensive subjects. Alterations in calcium metabolism may play an important role in the pathogenesis of both hypertension and nephrolithiasis and have been suggested as plausible mechanism linking this to disorder (Strazullo and Macini 1994). A higher prevalence of hypercalciuria has been reported in patients with essential hypertension (Strazullo, 1991) and alterations of calcium metabolism such as primary hyperparathyroidism that lead to hypercalciuria have been associated with a increased prevalence of hypertension. Several other mechanisms that may link hypertension and nephrolithiasis have been suggested, which include high dietary intake of sodium, low intake of potassium and renal damage.

Tamm Horsfall Glycoprotein: Tamm and Horsfall discovered a glycoprotein in urine that was named the Tamm Horsfall Glycoprotein (THP). THP is the most abundant protein present in the urine of healthy subjects. It is secreted by the thick ascending limb of the loop of Henle (Pennica D. et al1987.)
luminal cell surface by a glycosyl-phosphatidylinositol (GPI)-anchor and then excreted in urine at a rate of 50 - 100 mg/day. It is a monomeric glycoprotein of ~ 85 kDa with ~30% carbohydrate moiety that is heavily glycosylated by polyantennarysialated N-linked glycans. Sialic acid plays an important role in maintaining THP function during kidney stone formation. THP has a strong tendency to forming macroaggregates of several million Daltons.

**Structure of THP**

THP excretion decreases in stone formers and therefore it was proposed as a potential biomarker for kidney stone disease(Glauser A et al, 2000) described THP as the major inhibitor to calcium oxalate crystal aggregation in the urine of healthy individuals(Knörle R et al, 1994). However, other reports showed that stone formers excreted defective urinary THP that devoid of sialic acid with a diminished effect on inhibiting stone formation.THP has been considered as a hidden antigen that is exposed to the immune system only after pathophysiological alteration (Hoyer JR et al, 1990) which then results in formation of antibodies to THP. Anti-THP antibodies have been determined in various kidney diseases.6,7,8

The scope of this study is to investigate the autoantibody levels of Tamm Horsfall protein among the control and hypertensive subjects for early diagnosis of nephrolithiasis.

Hypertensive patients were those from the OPD of hypertensive clinic, department of general medicine, Royapetah Medical College, Chennai.

Patients who exhibited a systolic pressure of >=160mmHg and/or a diastolic pressure of >=95mmHg were included in the present study and the hypertensive patients selected for the study were receiving regular drug treatment for high blood pressure. These patients were established to be essential hypertensives.9,10

5ml of blood samples were collected by vein puncture from the antecubital vein from normal and hypertensive person and immediately transferred to stoppered tube containing 0.1 ml heparin as anticoagulant and transported to lab using a cool container.

**Isolation and Purification of Human Urinary Tamm Horsfall Glycoprotein:** Isolation of Huma Urinary Tamm Horsfall Glycoprotein was carried out by the methods of Gokhale et al. [1997].

**Procedure:** To total volume of 24hrs urine collected with toluene as preservative from normal subjects 0.58 M NaCl was added and left for overnight precipitation the following day the sample was subjected to centrifugation at 20,000xg for 20 mins the pellet was collected and suspended in 50ml of pH 9.0 water and left overnight [THP tends to form a gel into the pH9.0 water]. The following day the sample was centrifuged and the supernatant was saved for further isolation and the pellet [containing the cell debris] was discarded. THP was then precipitated from the water soluble phase by bringing the solutions concentration of NaCl to 0.58M and left overnight at 4oC and on the following day the centrifugation process was repeated and the final pellet was dissolved in 1ml distilled water containing 0.1mM Phenylmethlysulfonylfluoride[PMSF].

**Determination of Autoantibody by Elisa:** Auto Antibody level of the sera was checked using ELISA by the method of Gokhale et al.[1997].

1. Capture material used for coating was WGA, a type of lectin from *Triticum vulgaris* (Sigma) and was purified by affinity chromatography
2. Carbonate buffer [50mM], pH 9.6
3. 15mM phosphate buffered saline pH 7.4[PBS] [15mM NaH$_2$PO$_4$, 15mM Na$_2$HPO$_4$,138mM NaCl, 2.7mM KCl]
4. PBS – 2% BSA 2% BSA to the required amount of PBS buffer.
5. PBS-Tween 20[0.05%]0.05% Tween to the above buffer [PBS-T]
6. Anti-rabbit IgG-HRP diluation[1:10000]
7. Substrate: TMB/H$_2$O$_2$ 20x concentrate ready use to kit from GeneiPvt Ltd which was diluted 1 to 20 just before use
8. 2N Sulfuric Acid
Procedure

Each well on the 96-wells microtiter plate (Maxisorp™, Nunc) was coated with 100 μL of 10 μg/mL lectin WGA in coating buffer [5.0 mM Na2CO3, 34.9 mM NaHCO3, 0.02% (v/v) NaN3, pH 9.6]. Then plates were coated with purified THP [10 microlitre] in carbonate buffer. The plates were washed five times with freshly prepared washing buffer (0.1% Tween 20 in 10 mM phosphate buffer saline (PBS) pH 7.2 for 5 min each. The unoccupied sites on the microtiter plates were blocked with 200 μL blocking buffer (3% BSA in 10 mM PBS, pH 7.2) and incubated at room temperature for 2 hours with a slow rotation (50 rpm) on the orbital shaker. The plate was washed five times with washing buffer for 5 min each wash and dried in an oven at 37°C for 3 hours or until thoroughly dried. Finally, the plates were cooled to room temperature and sealed with an adhesive plate seal, wrapped in aluminum foil and stored at 4°C. TEA buffer was used as blank. After 1 hour incubation at 37°C, the plates were washed five times (rotation, 50 rpm) with 300 μL freshly prepared wash buffer (0.1% Tween 20 in 10 mM PBS, pH 7.2). The plates were placed top down on absorbent paper to remove residual buffer. Hundred microliter of the serum from the control and hypertensive subjects was dispensed in each well and the plates were incubated at 37°C for 1 hour. The plates were washed five times (rotation, 50 rpm) with 300 μL of freshly prepared wash buffer and the residual buffer was removed on absorbent paper. The plates were incubated at 37°C for 1 hour after adding the same volume of anti-rabbit IgG (HRP) horseradish peroxidase conjugate diluted 1:1000 in antibody diluent. The plates were washed five times (rotation, 50 rpm) with 300 μL of freshly prepared wash buffer and residual buffer was removed on absorbent paper.

Colour was developed by adding 100 μL of TMB substrate solution to each well. The plates were incubated on orbital shaker (100 rpm) for 15 min at room temperature in the dark. The reaction was stopped by adding 100 μL of 4 M H₂SO₄ to each well. OD₄₅₀ and OD₆₂₀ (Thermo LabsystemsMultikan Ascent, Finland) were read immediately.

Results and Discussion

Hypertensive patients excrete increased quantities of abnormal THP, with a change in the chemical composition in urine and the extravasations of THP into the renal interstitium may lead to immunization of the host with this antigen and produces high circulating autoantibodies to THP in blood stream. Hence evaluation of increased levels of autoantibodies to THP in hypertensive patients acts as a prognosing tool for nephrolithiasis.12,13,14,15

Conclusion

Uromodulin is considered as a hidden antigen that is exposed to the immune system only after pathophysiological alterations that results in the formation of autoantibodies circulating in the blood stream. Increased circulating autoantibodies and altered Uromodulin excretion in urine acts as a marker for nephrolithiasis in hypertensive patients. Finally, the association of uromodulin with nephrolithiasis and hypertension will need further investigation to clarify the biological effect of the identified risk variants and to assess for the presence of additional linked variants that may have a causal role.

Validity and Reliability of Assessment of Cervical Vertebrae on Lateral Cephalograms—A Review

A. Arif Yezdani1, S. Kishore Kumar2, Kesavaram Padmavathy3

1Professor and Director; 2Professor; 3Associate Professor; Department of Orthodontics and Dentofacial Orthopedics, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research, Chennai, Tamil Nadu, India

ABSTRACT

Knowledge of timing and duration of the adolescent growth spurt is essential to treat skeletal jaw discrepancies in the growing child. The purpose of this review of literature was to evaluate the validity and reliability of the maturational stages of the cervical vertebrae C2, C3 & C4 as seen on lateral cephalograms in the prediction of peak pubertal growth spurt. Literature review purported that cervical vertebral maturity indicators were effective in assessing the circumpubertal growth spurt. The drawbacks of this method of assessment was that it evaluated the skeletal maturity at one point of time and that it failed to pinpoint the peak in mandibular growth. It also did not specify the intensity and amount of residual growth left, factors deemed important for implementing orthopedic therapy.

Keywords: lateral cephalograms; cervical vertebrae; adolescent growth spurt; mandibular growth; dentofacial orthopedics

Introduction

A sound knowledge of the optimal timing of pubertal growth spurt in the growth period is vital for treatment with orthopedic therapy. Information gleaned from chronologic age, statural height from growth charts, dental age, menarche and observation of secondary sexual characteristics too could help in predicting the pubertal growth spurt which occurs one to two years earlier in girls than in boys. However, they lack precise predictive assessment due to various reasons attributed to socioeconomic conditions, environmental influences, climate and nutrition. Many radiologic markers like hand-wrist radiographs and assessment of Middle Phalanx of the third finger (MP3) have been used to predict the onset of pubertal growth spurt in both the genders. However, the lateral cephalogram is currently and widely preferred now in preference to the other radiographic methods as it is routinely taken for orthodontic diagnosis and treatment planning negating the need for the patient to be subjected to an additional radiograph and attendant radiation exposure. The objective of this review of literature was to evaluate the validity and reliability of assessment of cervical vertebrae on lateral cephalograms and its ability to predict the circumpubertal period of growth to help facilitate correction of skeletal jaw discrepancies.

Method

Internationally peer reviewed and valid indexed reference articles pertaining to cervical vertebral maturational indicators as assessed on lateral cephalograms was segregated and perused with the views of the different authors succinctly highlighted.

Discussion

Assessment of the maturational stages of the cervical vertebrae from C2 to C4 to predict the skeletal age of an individual has been in orthodontic practice for over 5 decades. This narration of the literature helps glean valid
information pertaining to its use as an indispensable radiologic biomarker.

Lamparski DG (1975) conducted a study to determine whether maturational changes of the cervical vertebrae as recorded on routine lateral cephalometric radiographs could be used to assess the skeletal age of an individual. He concluded that there was no significant statistical differences between cervical vertebral and handwrist assessments and that the use of cervical vertebrae as a skeletal maturity indicator was valid.

Tanner JM (1981) stated that though adolescent growth spurt varies in intensity and duration from one child to another it is a constant phenomenon and occurs in all children. The peak velocity of growth in height averages about 10cm a year in boys and slightly less in girls. In boys the spurt takes place on average between 12.6 and 15.6 years of age and in girls some two years earlier.

O’Reilly MT et al (1988) investigated the relationship of the cervical vertebral maturation and mandibular growth changes in annual lateral cephalograms of thirteen Caucasian females aged 9 to 15 years of age. The results showed that significant increase in mandibular length occurred in cervical stages 1&2, 2 &3, and 3& 4. Ramal height increased between stages 1 and 2 & Corpus length increased between stages 1-2 and 2 – 3.Stages 1 through 3 occurred prior to peak velocity with 2 and 3 in the year immediately preceding peak growth velocity.

Hassel B & Farman AG (1995) investigated a sample of 11 groups of 10 males and 10 females (220 subjects) aged 8-18 years, from Bolton-Brush Growth Center at Case Western Reserve University. Lateral cephalograms and left hand wrist radiographs were evaluated. The hand wrist radiographs were reviewed using Fishman’s method. It was concluded that by using the lateral profiles of 2nd, 3rd and 4th cervical vertebrae, the orthodontist could evaluate the skeletal maturity of the patient at that one point in time to assess how much growth could be factored into anticipated treatment.

Fernandez GP et al (1998) conducted a study on 113 patients (50 males & 63 females) aged 9-18 years taken from patient files of Orthodontic Graduate Program, Universidad Autonoma de Nuevo Len Mexico. Hand wrist radiograph was evaluated by Fishman method and cervical vertebrae evaluation with Hassel and Farman modification of Lamparski’s method. They concluded that skeletal maturity could be accurately appraised using the cervical vertebrae evaluation from the cephalograms without the need of an additional radiograph.

Franchi L et al (2000) analyzed the validity of 6 stages of cervical vertebral maturation as a biological indicator for skeletal maturity in 24 subjects (15 females, 9 males) and concluded that cervical vertebral maturation appeared to be an appropriate method for the appraisal of mandibular skeletal maturity in individual patients.

Baccetti T et al (2000) evaluated skeletal and dentoalveolar changes induced by the Twin-block appliance in 2 groups of subjects, early treated group of 21 subjects (11 females & 10 males) & late treated group of 15 subjects (6 females & 9 males) with Class II malocclusion treated at different skeletal maturation stages in order to define the optimal timing for this type of therapy. Skeletal maturity in individual patients was assessed on the basis of the stages of cervical vertebrae maturation.

Baccetti T et al (2002) conducted another study on 706 subjects whose lateral cephalogram files from the University of Michigan Elementary and Secondary School Growth Study was used to detect the peak in mandibular growth as measured from Gonion to Gnathion, based on the analysis of cervical vertebrae 2, 3 & 4 with the Cervical Vertebral Maturation (CVM) method of the 5 maturational stages. The peak in mandibular growth was seen to occur between CVMS II and CVMS III.

Mito T et al (2002) conducted a study to establish cervical vertebral bone age as a new index for objectively evaluating skeletal maturation on 176 lateral cephalograms of girls aged 7.0-14.9 years. They measured the cervical vertebral bodies and determined a regression formula to determine cervical vertebral bone age. They also used lateral cephalometric & handwrist radiographs of another 66 girls aged 8-13.9 years. The correlation between cervical vertebral bone age & bone age using Tanner-White (TW) method was determined. The results suggested that cervical vertebral bone age on lateral cephalograms was as reliable at estimating bone age as was the TW method on hand-wrist radiograph.
Roman SP et al\textsuperscript{10} (2002) conducted a study to determine the validity of cervical vertebrae radiographic assessment to predict skeletal maturation. Left hand wrist and lateral cephalometric radiographs of 958 Spanish children from 5-18 years of age were measured. The hand wrist radiographs were assessed according to Grave and Brown method. Cervical vertebrae were evaluated using stages developed by Lamparski & Hassel and Farman. The results suggested that this new method to determine the skeletal maturation was reliable.

Baccetti T et al\textsuperscript{11} (2005) introduced a further modified version of the Cervical Vertebral Maturation (CVM) method for the detection of the peak in mandibular growth based on the analysis of the second through fourth cervical vertebrae in a single lateral cephalogram. The morphology of the bodies of the second (C2), third (C3), and fourth (C4) cervical vertebrae were analyzed in 6 consecutive cephalometric observations (T1 through T6) of 30 orthodontically untreated subjects. The current clinically improved CVM method comprised of six maturational stages (CS1 through CS6). CS1 and CS2 were pre-peak stages & the peak in mandibular growth occurred between CS3 and CS4. CS6 was recorded at least 2 years after the peak pubertal growth.

Damian MF et al\textsuperscript{12} (2007) evaluated 45 patients of both genders, aged 9-15 years, with two lateral cephalograms each taken at a 12-month interval. Establishment of the maturation stages of cervical vertebrae was performed by the method proposed by Hassel and Farman. Based on this evaluation, the patients were assigned to 3 groups. Patients in the initiation (1) or acceleration (2) stages comprised Group I; patients changing from the initiation (1) or acceleration (2) stages to the transition (3) stage comprised Group II; and patients in the transition (3) stage on both radiographs, namely during the growth peak, constituted Group III. For each individual in Groups I, II and III, S-N and Co-Gn cephalometric measurements were assessed on both radiographs and the growth increment in this period was evaluated. The results showed larger growth for Group III, followed by Group I and smaller for Group II. The authors concluded that the CVMI stages were valid for the analysis of cranial growth and especially of mandibular growth at the initial stages of pubertal growth spurt.

Gu Y & McNamara Jr JA\textsuperscript{13} (2007) evaluated the mandibular growth changes of 20 subjects from cephalometric superimpositions on tantalum implants placed into the craniofacial complex during childhood. Lateral cephalograms were available at each of the 6 consecutive stages of CVM. Interval increases in posterior facial height was greater than simultaneous increases in lower facial height. The authors concluded that the peak increase in mandibular length was observed during the interval CS3–CS4.

Gabriel DB et al\textsuperscript{14} (2009) evaluated the reproducibility of CVM stage determination by using a stringent methodology. Ten practicing orthodontists, trained in the CVM method, evaluated the morphology of cervical vertebrae C2 through C4 from 30 cephalometric radiographs using question based CVM method. Intra-observer agreement was only slightly better and clinicians agreed with their own staging only 62% of the time. The authors concluded that CVM method could not be recommended as a strict clinical guideline for the timing of orthodontic treatment.

Wong RW et al\textsuperscript{15} (2009) evaluated the validity of the cervical vertebral maturation (CVM) method as an indicator of skeletal age in the circumpubertal period by correlating it to the hand-wrist method (HWM) in 400 Chinese subjects aged 10-15 years for girls and 12-17 years for boys. The CVM was evaluated by using the method developed by Baccetti et al. The hand-wrist assessment was evaluated according to the method of Hagg and Taranger. The authors concluded that CVS3 in CVM was around the peak of the growth spurt when growth modification treatment by dentofacial orthopedic appliances could be commenced.

Gerenoso R et al\textsuperscript{16} (2010) compared mandibular size in subjects of both genders with Class I and Class II skeletal patterns as defined by the cervical vertebrae maturation. The results indicated that boys with Class I pattern had greater mandibular lengths than girls at cervical stages CS2, CS4 and CS5, whereas in the Class II pattern, the boys had greater mandibular lengths than girls at stages CS2, CS3 and CS4.

Nestman TS et al\textsuperscript{17} (2011) did a study to determine which of the individual CVM vertebral patterns could be classified reliably and which could not. Ten practicing orthodontists trained in the CVM method evaluated the morphology of cervical vertebrae C2 through C4 from 30 cephalometric radiographs using questions based on the
CVM method. The Kendall coefficient of concordance was used to assess the level of inter-observer agreement when determining a “derived CVM stage” for each subject. The authors concluded that weakness of the CVM method results in part from difficulty in classifying the vertebral bodies of C3 and C4 as trapezoidal, rectangular horizontal, square or rectangular vertical.

Ball G et al 18 (2011) tried to establish a pattern of mandibular growth and related this pattern to the stages of cervical vertebral maturation. Lateral cephalograms taken annually from ages 9 to 18 years were evaluated for 90 boys from the Burlington Growth Center, Toronto, Ontario, Canada. Mandibular lengths were measured from articulare to gnathion and incremental growth was determined. CVM stages was assessed by using a 6-stage method. Advanced, average and delayed maturation groups were established. The authors concluded that progression from cervical stages 1 through 6 does not occur annually; time spent in each stage varies depending on the stage and the maturation group.

Mellion ZJ et al 19(2013) did a study to assess the maturation and prediction of the timing of the adolescent growth spurt using the sequential stages in the development of the hand wrist and cervical vertebrae. They concluded that the common assumption that onset and peak occur at ages 12 and 14 years in boys and 10 and 12 years in girls seemed correct for boys but was 6 months to 1 year late for girls.

Vijayashree et al20 (2014) did a study to investigate the relationship between mandibular second molar calcification stages and cervical vertebrae maturity indicators and concluded that. Stage F of Demirjian index, with the root length equal to or greater than the crown height corresponding to stage 3 of CVMI indicated the start of peak in mandibular growth, an appropriate time to plan for functional appliances.

Mc Namara Jr JA, Franchi L21(2018) devised a user’s guide for the cervical vertebral maturation method. They suggested that CVM staging should be used in concert with a thorough evaluation of the hard and soft tissue during the treatment planning process. They also opined that as with any subjective clinical evaluation the reliability of the CVM method improves with experience.

**Conclusion**

- Cervical vertebral maturity (CVM) staging is liable for subjective errors with intra and inter-observer disagreements.
- Onset of the peak mandibular growth cannot be accurately defined by the CVM staging.
- Lack ability to determine intensity and end of growth spurt and that the final stage of development does not necessarily determine growth completion.
- Incorrect positioning of the neck during taking of radiograph could inadvertently change the shape of the cervical vertebra and thus lead to erroneous assessment of its shape.
- A reliable alternative to handwrist radiograph.
- Accurate assessment and reliability of cervical vertebral maturation stages improves with experience of the observer.

Position of Hyoid Bone Between Snorers with Obstructive Sleep Apnea and Snorers without Obstructive Sleep Apnea—A Cephalometric Study

R. Mohan Pradeep¹, S. Kishore Kumar²
¹Department of Orthodontics, Post Graduate, ²Professor and Vice Principal, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research

ABSTRACT

Obstructive sleep apnea is brought about by intermittent upper aviation route deterrent during sleep and it presents as loud snoring, blood vessel oxygen desaturation, sleep fragmentation, and over the top daytime sleepiness. The lateral cephalogram is a routine diagnostic aid in orthodontics. It has been used extensively in the fields of orthodontics and anthropology to record craniofacial form. Recently, it has also suggested that cephalometry could be an adjunctive procedure for assessing craniofacial patterns associated with obstructive sleep apnea. This study was attempted to look at the craniofacial structures of Obstructive sleep apnea patients with those of basic snorers utilizing parallel cephalometric radiographs and to decide the hazard factors for Obstructive sleep apnea in a Dravidian population.

Keywords: Obstructive sleep apnea, hyoid bone, lateral cephalogram

Introduction

Obstructive sleep apnea is brought about by intermittent upper aviation route deterrent during sleep and it presents as loud snoring, blood vessel oxygen desaturation, sleep fragmentation, and over the top daytime sleepiness. OSAS affects 2% to 4% of the general adult population and might be considerably increasingly present in explicit subgroups, for example, hypertensive or cardiovascular breakdown patients.

A few reasons for OSAS have been recommended. It may be a result from a variable mix of anatomical and pathophysiological factors, some of which might be under hereditary control. Relaxation of the upper airway route musculature has been considered in connection to OSAS. Anatomic narrowing of the upper airway route because of modifications in the craniofacial morphology or delicate tissue broadening, the Bernoulli impact, rest act, age, male sexual orientation, nasal check, and fat tissue in the pharynx have been proposed as aetiologies of OSAS.

There are a few hazard factors for OSAS, with the most basic being weight and age. The commonness of OSAS increments with age, with a twofold to triple higher pervasiveness in people greater than 65 years contrasted and those in middle age. There is a connection between a Body massIndex (BMI) of >26 kg/m² and OSAS. Previous research proposed that there might be contrasts in how much stoutness and craniofacial life structures fill in as hazard factors among Asians and Caucasians and that the etiology of OSAS in obese patients may contrast from those in nonobese patients. It is as yet indistinct whether there are anatomical contrasts in cephalometric estimations between extreme OSAS patients and patients experiencing wheezing among nonobese young Asians.

This study was attempted to look at the craniofacial structures of Obstructive sleep apnea patients with those of basic snorers utilizing parallel cephalometric radiographs and to decide the hazard factors for Obstructive sleep apnea in a Dravidian population.
Materials and Method

Sample Size: 25 subjects.

13 subjects were snorers with obstructive sleep apnea

12 subjects were snorers without obstructive sleep apnea

Subject Selection Criteria: This study was conducted in the patients who visited the Outpatient department, Department of Orthodontics, SreeBalaji Dental College and Hospital, Chennai, India. Subjects of both the sexes between 12 to 35 years of age were included in this study. 416 patients were clinically examined and Epworth sleepiness scale questionnaire was given. Out of which 54 patients with the history of snoring were revealed by the patients based on questionnaire (Epworth sleepiness scale) that were included in the study. Of which 11 Individuals could not give a written consent, 2 patients found risky to radiation exposure, 3 patients undergoing orthodontic treatment, 1 patient had undergone orthodontic treatment, 6 patients had gross facial asymmetry, 6 patients had undergone removal of nasal polyp. On exclusion, only 25 snoring subjects were taken for the study.

These 25 snoring subjects were monitored by overnight sleep study using Alice PDx portable monitoring device. Apnea was defined as cessation of breathing for at least 10 seconds. Hypopnea is a decreased effort to breathe of at least 50% less than the baseline and with at least a 4% decrease in oxygen saturation. The respiratory disturbance index (RDI) was calculated as the sum of the total events (apnea and hypopnea) per hour (apnea + hypopnea/sleep time). A diagnosis of obstructive sleep apnea was based on the respiratory disturbance index (RDI). Patients who snored but had an RDI of < 5 were grouped into the simple snoring group, while patients whose RDI > 5 were grouped in moderate obstructive sleep apnea group.

Inclusion Criteria:
- Age: 12-35
- Both males and females
- Patients who were identified as snorers

Exclusion Criteria:
- Patients without the history of snoring.
- Patients who had undergone removal of nasal polyp.
- Patients who had undergone Nasal septal deviation correction.
- Patients who had undergone uvulopalatopharyngoplasty.
- Patients who had undergone somnoplasty.
- Patients who had undergone orthodontic treatment
- Patients currently under orthodontic treatment
- Patients found risky to radiation exposure
- Patients with gross facial asymmetry

Result

Observed frequency statistics are mentioned in Table 1. Expected frequency statistics are mentioned in Table 2. The acquired data were assessed for normality using Chi square test. The statistics results suggest that it accept the Null hypothesis i.e., there is no association or dependency between these two variables.

No statistically significant difference was observed in hyoid bone position between snorers with obstructive sleep apnea group and snorers without obstructive sleep apnea group.

**Discussion**

The lateral cephalogram is a routine diagnostic aid in orthodontics. It is a two-dimensional representation of sagittal aspect of head and neck region. It has been used extensively in the fields of orthodontics and anthropology to record craniofacial form. Recently, it has also suggested that cephalometry could be an adjunctive procedure for assessing craniofacial patterns associated with obstructive sleep apnea17.

Maltaiset al18 have opined that use of cephalometric radiographs to assess the upper airway anatomy is helpful because it is simpler than other methods for measuring airway patency. Parkinenet al19 further confirm in their study that the lateral cephalogram is a valid method for measuring dimensions of the nasopharyngeal and retropalatal region. Tsai et al16 also confirmed in their study that soft tissue variables have much greater influence in obstructive sleep apnea patients.

Tsai et al16 found that the position of hyoid bone in simple snorers was below but near the straight line from C3 TO Me, whereas that position of hyoid bone in severe obstructive sleep apnea patients was far below this line, but in contrary our study shows no significant difference in the position of hyoid bone in both the groups.

**Conclusion**

The position of hyoid bone relative to a line from third vertebra to menton remains at same position in both simple snorers and obstructive sleep apnoea patients.

ABSTRACT

The lingual orthodontic furnishings are in a manifest pretence the only invisible machinery rules available. This appliance system consists of arrangement tariff planned lingual brackets onto the palatal/lingual surface of the teeth. The biggest issue is that lingual braces can be difficult to get used to and wear. The common problems encountered are Difficulties with speech, Tongue soreness Eating, Cleaning your teeth. This review comprises of history, different mechanics that are incorporated in lingual orthodontics and various systems that is used in lingual orthodontics etc.

Keywords: Lingual orthodontics, Esthetic, Adult orthodontics

Introduction

Long durations of unaesthetic appearance due to malocclusion treatment led to the exploration of accordingly self-styled invisible orthodontics which comprises of underling coloured brackets and archwires, ostensible aligner therapy and lingual orthodontics. In any way, these brackets and archwires are obscure from a certain distance unexcelled. Apart from, the clear aligners are quite a distance scarcely vague as it is an authoritative integument closely adapted to the teeth. The lingual orthodontic furnishings are in a manifest pretence the only invisible machinery rules available. This appliance system consists of arrangement tariff planned lingual brackets onto the palatal/lingual surface of the teeth.

History

In 1889, John Farrar printed a “Lingual removable Arch.” The dental literature extolled the benefits of moving teeth with lingual appliances. These early lingual appliances were removable and designed to expand the dental arches.

In 1918, Dr John Mershon published a paper entitled “The removable lingual arch as an appliance for the treatment of malocclusion of the teeth.” In 1922, Mershon’s presentation onlabial and lingual arches with finger springs was reported as being a highlight of the meeting. The idea of development of Current lingual treatment began at identical time (the middle 1970’s) in 2 completely different countries, when it became apparent that bonding of bracket was a viable procedure, and that esthetic plastic brackets were a compromise.

Dr. Craven Kurz began experimenting with lingually bonded brackets in 1973, achieving reasonably good results in simple cases. He became convinced that a lingual warranted edgewise system was possible and would create a major contribution to adult dentistry. His main motivation was to find a way to provide treatment for patients in a less noticeable way. He created his own lingual appliances by modifying labial appliances, using hand modified labial brackets. He restricted his treatment to the jaw teeth for concern that the forces of occlusion would dislodge the brackets placed on the lingual surfaces of the jaw in anterior teeth. At identical time in Japan, Professor Kinya Fujita conducted a research for the purpose of developing an orthodontic technique which would be both hygienic and aesthetically pleasing. A primary motivation for his efforts was to be able to give

care in an exceedingly approach that helped to shield the lips and cheeks of patients taking part in martial arts.

**Advantages**

- The chief advantage of getting lingual treatment lies within the undeniable fact that your braces are non-visible.
- If you are feeling that carrying typical braces would merely be too embarrassing, this is one of the “invisible” orthodontic methods that you might consider.

**Disadvantages**

- The biggest issue is that lingual braces can be difficult to get used to and wear.
- And, in general, every periodic workplace appointment you have got throughout your treatment method takes longer than it might with typical braces.

**The Incognito Lingual Appliance**: Lingual orthodontics has advanced to a highly sophisticated level where CAD/CAM (computer-aided design/computer-aided manufacture) technology is employed to manufacture both the brackets and arch wires for each patient individually in the incognito appliance system. It was launched in 2004 as the first fully customized lingual bracket system in the world. The Incognito appliance is manufactured using state-of-the-art CAD/CAM technology. The first step in the fabrication process is taking accurate polyvinyl siloxane impressions and bite registration using polyvinyl siloxane, and then creating a model in plaster and a diagnostic waxup thereafter (according to my direct instructions). The final model is then sent to dentist, digitally for feedback. The final model is then scanned with a 3-D scanner and the brackets are designed on the computer. This appliance has an advantage over other “invisible” orthodontic appliances for several reasons. Due to its core brackets and wires, all movements can be accomplished. It is a lingual appliance; thus, it does not suffer from any visible issues that are imposed by conventional ceramic brackets, coated or even translucent wires, and aligner attachments.

**Digitally Customized Self-ligating Lingual System**:

Harmony is the lingual system that combines

- Interactive Self Ligating Brackets
- Customized Bonding Pads
- Anterior Positioning Jigs
- Robotically Formed Arch Wires
- Digitally-Assisted Treatment

Using proprietary digital scanning and CAD/CAM technologies, a highly accurate bonding pad is created for the lingual surface of each tooth. The custom-made pad integrates seamlessly with its corresponding interactive self-ligating bracket. The slot of every bracket is positioned ideally on each tooth employing a digitally custom-made adapter that works in conjunction with robotically shaped arch wires to deliver doctor-driven, patient-specific treatment goals. Kafle D et al. reported five cases of midline diastema which was successfully treated with lingual orthodontic appliances. Chaudhari PK et al. reported a case of 19-year-old female patient with Class I malocclusion associated with 80% overbite (closed bite) treated by lingual appliance. As the patient was adult and faculty going, and more aesthetic aware, she chooses lingual orthodontic appliance for the treatment of her malocclusion. Another reason for selecting lingual appliance was the bite plane impact of the lingual appliance which might be useful in bite gap. The patient was highly satisfied aesthetically as well as functionally after the treatment was completed. Khaled M. Abouseada also reported a case of non-extraction treatment of a Class II case with a missing mandibular central incisor treated successfully using a CAD/CAM lingual orthodontic system and concluded that the key to success in lingual orthodontics in terms of both professional and patient satisfaction is practice and training. The Incognito system can be used for all types of malocclusions with the same precision as labial braces.

**Problems or Difficulties Faced with the Appliance**: As a general rule, it’s more difficult to get used to wearing lingual braces than with the conventional ones and time duration is too long. The common problems encountered are:

- Difficulties with speech
- Tongue soreness
- Eating
- Cleaning your teeth
Comparative Biomechanics between Lingual and Labial Techniques

i. Force actions: As the force of application is on the lingual side, the mechanics of tooth movement for lingual orthodontics has different characteristics from the labial one\textsuperscript{13}. Scuzzo and Takemoto\textsuperscript{14} summarized the effects of different forces imposed on teeth by the lingual and labial techniques in the three planes of spaces.

Sagittal plane: From a mesial read, when the same amount of force is applied to anterior teeth in both systems so that the intrusion force equals the retraction force, the net force vector points directly towards the middle of resistance with the labial system and lingual to the center of resistance with the lingual system, producing a lingual tipping force and vertical bowing effect. Therefore, during en-masse retraction in lingual orthodontics, the retraction force should be minimized and more intrusion and palatal root torque is needed.

Vertical plane: The result of intrusive forces on the lingual and labial sides of the higher incisors differs between cases of traditional, labial or lingual inclination. In unremarkably inclined incisors, vertical force applied on both the labial and lingual side lies mesial to the center of resistance (CR) in the horizontal plane, thereby producing a counterclockwise moment. The moment force is applied on the labial facet thanks to greater distance from the chromium as compared thereto once the force is applied on the lingual side. In proclined incisors, both the labial and lingual intrusive forces turn out counterclockwise moments however the magnitudes area unit bigger than that of traditional tooth inclination thanks to increased distances of the points of application of the forces from the CR. In upright incisors (as in a very category II division a pair of malocclusions), labial intrusive force will produce a counterclockwise moment but the same amount of vertical force on the lingual side can turn out a dextrorotary moment and this will increase the lingual inclination of the crowns. This is due to the point of application of the force lies distal to the axis passing through the chromium of incisors. In such cases, it is advised to advance the crowns first and then to perform the intrusion\textsuperscript{15,16}. As way because the higher molars area unit involved, the axis passing to through the CR is closer to the lingual surface. This implies that whenever associate degree intrusive force is applied to the lingual brackets, the crowns of the teeth will rotate in a lingual direction; the opposite will occur whenever intrusive force is applied to the labial brackets: crown rotation can manifest itself in adorning an associate degree exceedingly in a very labial direction. Within the lower arch with traditional tooth inclination, the lingual bracket slot is nearer to the axis passing through the chromium when put next therewith on the labial facet. For this reason, lingual application of force allows easier intrusion coupled with less proclination of the crown, as compared with labial force application. This will additionally generate a lot of distal inclination of the lower molar crowns and a lot of lingual tipping of the lower incisors throughout levelling.

Horizontal plane: In the horizontal plane, the interbracket distance in lingual orthodontics is shorter than that in the labial one. Also, the purpose of application of force is nearer to the tooth axis in lingual orthodontia. Therefore, the rotation moment is a smaller amount than on the labial aspect and it’s more difficult to possess an economical coupling of forces throughout move movement. The short interbracket distance means that the arch wire stiffness is also increased\textsuperscript{17}. A more flexible arch wire is needed, especially in crowded cases. All these factors build correction of rotations tougher with the lingual appliance.

ii. Choice of extractions: With its unique biomechanics, extraction choices in lingual orthodontics often differ from those in labial orthodontics\textsuperscript{18,19,20}. In lingual orthodontia the robust molar anchorage, especially in the lower arch, makes mesial movement of the lower molars difficult.

Also, the lower molars tip distally because the arch is levelled in lingual orthodontia and this change the molar relationship from category I to category II. Therefore, in school I cases, the extraction of the upper first premolars and lower second premolars may be necessary rather than the extraction of the four first premolars. In Class II cases, it’s fascinating to avoid extraction within
the lower arch the maximum amount as attainable and rather to advance and/or slice anterior teeth if the quantity of state of affairs is least. If crowding in the lower arch is severe, extraction of one or more lower incisors may be considered. In Class III cases, bicuspid extraction facilitates the lingual tipping of lower anterior teeth. The distal tipping of lower molars throughout leveling additionally improves the category III molar relationship. All these facilitate the correction of a Class III malocclusion.

iii. Anchorage considerations: It is generally said that a lingual approach gives a greater amount of anchorage than a labial approach. In lingual orthodontia, distally tipping forces square measure perpetually applied to posterior teeth through the archwire, that makes posterior teeth additional immune to anchorage loss than in labial orthodontia. As brackets square measure placed on the lingual surfaces, it is easier to control the vertical height of the lingual cusps through the constant application of buccal root torque, which tips molars lingually. This is particularly helpful in controlling the lingual cusps of the higher second molars, that square measure presumably to be extruded and cause interference. The management of molar extrusion additionally prevents the rotation of the jawbone and also the resultant adverse effects like anterior open bite and deterioration of a Class II relationship. Removal of tongue pressure with a lingual appliance further reinforces molar anchorage, especially in a lower dental arch with narrow bone.

Segmented Mechanics in Lingual orthodontics: Fontenelles pointed out that only segmentation could solve the contradiction of conflicting requirement in lingual orthodontics: low load-deflection rate, constant moment-to-force ratios, and keeping strict control. The appliance was divided into 3 parts, namely, the passive appliance, the active appliance and the guiding component. The passive appliance provided a high load-deflection rate, ensuring maximum stiffness to control the relationships between the teeth included. Because passive systems were meant to supply enough stiffness to tie the teeth into a unit, any sufficiently stiff device could be used, for example, 018.025-inch SS archwire, bonded cast chrome-cobalt splint and bridgework. The active appliance ought to have a coffee load-deflection rate giving a high degree of force constancy, and will turn out the moment-to-force quantitative relation necessary for the tooth movement meant and maintain it as constant as possible. The guiding component was to guide the tooth in its progress along the dental arch, form its initial position to its final location. Anchorage could be provided by varying the line of action of the force. Case reports of different segmental techniques have been published.

Lingual Straight-Wire Technique: With conventional lingual brackets, mushroom-shaped archwires are required with insets between the canine and the premolar and between the premolar and the molar. Vertical steps between the canine and the premolar are often needed. In a study within which the crowns on a plaster model were cut to the animal tissue margins, parallel to the occlusal plane, a few in-out differences on the lingual side were revealed. This study has led to the development of a lingual straight–wire (LSW) technique based on the cervical lingual arch form. The LSW-brackets are given varied degrees of torsion, angulation and bracket thickness for individual tooth. The bracket slots are positioned in order that the direction of archwire insertion is opposite to the Kurz 7th generation appliance. The bracket stem of the LSW-appliance is positioned more gingivally relative to the bonding base and is longer labio-lingually and the bracket is shorter vertically. With the employment of straight wires, wire-bending is minimized and chair-time is reduced. With no inset between the canine and the premolar, there is no variation in the amount of inset associated with archwire changes and also the lateral occlusion remains stable once established. Preformed archwires may be used and slippery mechanics may be simplified. Vertical control of the teeth is possible from an early stage of treatment because vertical steps are not needed.}

Lingual Light-Wire Techniques: In 1982, Paige described a lingual light-wire technique using Unipoint combination brackets with slots oriented in the occlusal-incisal direction and with vertical slots for use of auxiliaries and horizontal slots in unravelling of crowding incisors. There is an animal tissue ‘wing’ to position elastic modules on continuous elastic chains. The problem of short interbracket distance was partially overcome. Using this technique, the lingual tooth contours are much less a variable factor because torque control can be achieved by properly shaped torqueing
auxiliaries and placement of brackets is sensitive only to the incisal-gingival placement. Therefore, indirect bonding is not required. Jenner and McLean also showed that the Begg Appliance, based on the use of ribbon arch brackets and round archwires, provides a relatively simple conversion from labial to lingual mechanics. During bracket placement, the bracket is turned upside down for lingual mechanics. Unlike the edgewise techniques, bracket placement is simplified because torque is not built into the bracket. This removes the necessity to involve the services of business laboratories to position pre-angled bracketson the model prior to indirect bonding. There was conjointly less issue with sequent rebonding of individual brackets if they were dislodged. It is possible to use standard labial bracket bases on the lingual. Archwires for lingually placed brackets required modifications to accommodate the lingual anatomy of the incisors, canines, bicuspids and molars. However, the original three stages of Begg treatment sequences were retained.

Retention in Lingual Orthodontics: Patients who have chosen to have lingual braces are often esthetically demanding and do not like visible retainers. Due to social restrictions, they have limited time to wear retainers. Clear retainers made from 0.4-0.5mm thick thermoplastic material are easy to fabricate and can be delivered on the same day of appliance removal. They are conjointly comfy to wear and cause very little speech interference. However, they break and deform simply in order that they don’t seem to be appropriate for future use. A modified Begg retainer with the anterior part made of transparent retainer wire is esthetically pleasing but the baseplate may cause some discomfort and speech difficulty. The retainer also has to be fabricated in the laboratory. It has been suggested that clear retainers ought to be used throughout the day and a Begg or Hawley retainer for future night wear. For lower incisors with reduced periodontal support, a fixed lingual retainer is used to stabilize the teeth. Scuzzo and Takemoto prefer the .012-inch Australian wire because the finer wire causes little discomfort and the resilience of the wire allows individual movement of the incisors and encourages periodontal fibre rearrangement. This passive retainer may be reworked into associate degree ‘active’ retainer to correct minor tooth malalignment or for finishing a case.

Conclusion

Lingual Orthodontics is the nicest highbrow medicament modality, and is the bludgeon cure alternative for full-grown patients, as the lingual brackets gain the demand of socially active adult patients. Directly the orthodontist considers the counterirritant aspects of the outfit, fashionable alley lingual fitments donate the capacity to delicacy cases close by a resolution and do about to and even beyond that which is achievable with labial appliances. Lingual orthodontics encourages those patients for orthodontic dose who prevail upon aesthetics but hesitant to wear the labial braces.

Comparison of Microleakage among High Strength Flowable Composites Using Total Etch and Self-Etch Adhesives

Aysha M1, Ponnudurai arangannal2, Jeevarathan J3, Amudha. S.4, Aarthi.J.4, Vijayakumar M.4
1Private Practitioner, 2Professor and Head of the Department, 3Professor, 4Senior Lecturer, Sree Balaji Dental College, Pallikarani, Chennai

ABSTRACT

Background: The recent flow-able composites available in the market claim high strength by increased filler content but their performance in micro leakage prevention in still not comparatively reported.

Aim: The aim of the study was to evaluate and compare the microleakage of five commercially available high strength flowable composite as preventive resin restoration using total etch and self-etch adhesives.

Methodology: 100 first maxillary premolars with prominent fissures were selected for the study and sealed with Filtek-Z350 XT Flow, Gaenial Universal Flow, Beautifil Flow Plus, Arabesk Flow and Grandio SO Heavy Flow. Subsequent to sealant application and embedding, the micro leakage was tested by immersing in methylene blue and subsequent stereomicroscopy.

Results: Filtek Z-350 XT was better in self-etch technique over total etch technique. Arabesk Flow and Grandio SO Heavy Flow were better in total etch technique over self-etch technique.

Conclusion: With considerations for pediatric dentistry, self-etch materials are recommended. Further clinical studies have to be carried out to draw relevant conclusions on the clinical perspectives.

Keywords: High strength sealant, flowable, microleakage

Introduction

The occlusal surface consists of deep, narrow pits and fissures, which make mechanical cleaning difficult and favor plaque accumulation. Consequently, it leads to initiation of dental caries, as 85% of dental caries occurs on them.1,2 Another factor responsible for high incidence of occlusal caries is the lack of salivary access such deep fissures, as it prevents effective remineralization3. Better understanding of the caries process and remineralization has catalyzed the evolution in caries management from GV Black’s “Extension for Prevention” to “Minimally Invasive Techniques”.4

The use of diluted composite resin in preventive resin restoration has provided comparable retention rates with unfilled sealants.5,6 The early clinical success of these restorations and development of improved composite resin system have encouraged recent investigators to use new materials and techniques for preventive resin restoration.

Qin M et al (2005) in his study evaluated the retention and caries protection of a conventional preventive resin restoration with flowable resin composite and a flowable compomer. The retention rate and caries prevention of flowable composite group, used as preventive resin restoration was 84.5% when compared to conventional PRR group which was 80.8% by end of 2 years. They also stated that the drawback of conventional PRR technique (filled resin + unfilled resin) could be due to the use of two different materials within the same preparation.7

The recent flowable composite available in the market are high in strength by increased filler content
which are easier to place, more self-adaptable with good viscosity that allows them to be used for minimally invasive preparations and also as a sealant for the unprepared part of the occlusal surfaces.7

Hence this study aims to evaluate and compare the microleakage of five commercially available high strength flowable composite as preventive resin restoration using total etch and self-etch techniques.

**Materials and Method**

This in-vitro study was planned in the Department of Pedodontics and Preventive Dentistry, Sree Balaji Dental College and Hospital, Chennai, Tamilnadu, following the approval of institutional ethical committee (No. ECR/761/Inst/TN/2015)

One hundred extracted human maxillary first premolar which were caries free, devoid of cracks and not restored, were selected for the present study. All root surfaces of the selected samples were cleaned with ultrasonic scaler to remove periodontal tissue remnants and other organic debris. The coronal and the root surfaces were cleaned with aqueous slurry of pumice with the help of a rubber cup in a slow speed contra-angled hand piece (NAC-EC, NSK). The teeth were then rinsed with water jet, and dried. The samples were then stored in normal saline with 1% thymol crystals at room temperature until subjected to experimental procedure.

The samples were dried with absorbent paper and then divided into 2 groups of 50 each, as shown in table 1. The root surfaces of samples in each subgroup were painted with different colors of nail polish leaving the occlusal surface exposed, to differentiate between the subgroups. Pits and Fissures of all the samples belonging to both Group A and Group B were prepared with fissurotomy bur (SS white, micro STF) to a depth of 0.6mm width and 1.5mm height (which co-related with the dimension of the bur as provided by the manufactures). After preparation, samples were stored in distilled water. The occlusal surfaces of all samples were etched for 30 seconds with 35% phosphoric acid (Scotchbond, 3M ESPE). They were then rinsed with water from three-way syringe and dried with a chip blower until chalky white appearance was visible, followed by application of respective bonding agent to the prepared surface with applicator tip and then thinned out using chip blower and cured as per the manufactures instruction with the help of Woodpecker light cure unit (850mW/cm²-1000mW/cm²). Respective sealant was applied and cured according to manufacturer’s instructions.

All the samples were then thermo-cycled in water bath for 500 cycles between 5 ± 2°C, 37 ± 2°C, 55 ± 2°C, with a dwell time of 30 sec. After thermo-cycling the samples were subjected to pH cycling. Artificial saliva and demineralizing solution were prepared according to Chaudhary et al., 2012.8 Each pH cycle consisted of immersing the samples in artificial saliva for 11.5 hours and then in demineralizing solution for 0.5 hours at 37ºC. This pH cycling was done two times in 24hrs for a period of two weeks.

After pH cycling the samples were washed in distilled water and dried with the absorbent paper. The apices of all the samples were sealed with epoxy resin and coated with a double layer nail polish leaving the occlusal surface. They were then immersed in a 1% methylene blue dye solution for 48 hours at room temperature. After which the samples were rinsed in distilled water for 5 seconds to remove the superficial dye and then dried with an absorbent paper.

Each tooth sample were embedded in an auto polymerizing clear acrylic resin block and sectioned bucco-lingually at the mesial, center (middle) and distal surfaces of the restored tooth using hard tissue microtome (Leica SP 1600, Germany). The degree of dye penetration in the occlusal surface of mesial, center (middle), distal was examined under stereomicroscope (MZS0745T+SDI,
Microleakage was assessed by a single observer using criteria described by Zervou et al. The depth of dye penetration on both buccal and lingual side of each slice was assessed and the deepest depth of dye penetration was recorded, tabulated and subjected to statistical analysis.

Statistical analysis was carried out by using Statistical Packages for Social Sciences (SPSS) 20.0 for Windows. One-way analysis of variance was used to compare the microleakage measures of different groups. Multiple comparisons between groups were analyzed using the Mann-Whitney test. Statistical analysis was conducted at a significance level of p<0.05.

SD - Standard Deviation; NS - Non-significant; HS - Highly-significant

1. **Intragroup comparison of total etch technique**
   - Arabesk Flow (Group A4) and the Grandio SO Heavy Flow (Group B5) are found to be highly better, compared with Filtek Z-350 XT Flow (Group A1) and G-aenial Universal Flow (Group A2).

2. **Intragroup comparison of self-etch technique**
   - Filtek Z-350 XT Flow (Group B1) was better compared with other groups.
   - G-aenial Universal Flow (Group B2) was better compared with Grandio SO Heavy Flow (Group B5).
   - Beautifil Flow (Group B3) and Arabesk flow (Group B4) were better over Grandio SO Heavy Flow (Group B5).

3. **Intergroup comparison of both total etch and self-etch technique**
   - Filtek Z-350 XT (Group B1) was better in self-etch technique over total etch technique (Group A1).
   - Arabesk Flow (Group A4) and Grandio SO Heavy Flow (Group A5) was better in total etch technique over self-etch technique (Group B4 and Group B5).

**Discussion**

Traditionally, the tooth surface with questionable active caries has been contraindicated for sealant treatment. In these situations preventive resin restoration, which is a conservative approach to treat pit and fissure caries, has been shown to be very successful in studies over a period of 15 years. 11, 12

Nevertheless, temperature fluctuation in the oral environment can result in microleakage allowing bacterial
penetration at sealant enamel interface. The techniques of thermo-cycling and pH cycling are frequently used to determine the extent of microleakage of any restorative material. Microleakage strictly refers to ingress of oral bacteria, after breakdown of the resin tooth interface which has approximate diameter of 0.5 µm. Methylene blue was used in our study as the size of the molecules was 1.2 nm and moreover it is readily detectable under visible light, soluble in water and diffuses freely. Table 2 shows the mean microleakage scores of various subgroups of Group A samples. The lowest mean value was observed in Group A4 (0.30) whereas the highest mean value was observed in A2 (1.47). The lowest score of Group A2 could be attributed to the lower filler content (64%) and hence better flow and adhesion when compared to Group A2 which had a filler content of 69%. Table 3 shows the mean microleakage scores of various subgroups of Group B samples. The lowest mean value was observed in Group B1 (0.43) whereas the highest mean value was observed in Group B5. The lowest mean value of Group B1 could be due to the smaller particle size (20 nm) enabling better adhesion in comparison to Group B5 which had a particle size of 1000 nm. Table 2 shows comparison of mean microleakage scores within Groups A (total etch) samples using Mann-Whitney test. A4 and A5 were highly significant over A1 and A2.

Table 3 shows comparison of mean microleakage scores within Groups B (self-etch) samples using Mann-Whitney test. B1 was highly significant over the other groups. Table 8 shows intergroup comparison of different high strength flowable composite material. B1 was significant over A1 with p value of 0.02. This could be attributed to the formation of a better hybrid layer with good adhesion and less microleakage in self-etch technique, whereas the rinsing could have affected the hybrid layer in the total etch technique even though the particle size was smaller (20 nm). A4 and A5 was highly significant over B4 and B5 with p value of 0.00, which could be attributed to the lesser penetration of the material to the hybrid layer due to the larger particle size (700nm and 1,000nm respectively) resulting in less adhesion and more microleakage in the self-etch technique.

Conclusion

Within the limitations of the study, Arabesk flow and Grandio SO were highly useful in pediatric dentistry (Total etch technique). 3M (Filtekz350) was good in self-etch technique. As behaviour management and time consumption are very important factors in pediatric dentistry, self-etch materials are seen as a significant improvement over other etching techniques. Further clinical studies have to be carried out to draw relevant conclusions on the clinical perspectives.

Cognitive Linguistic Profile Post Road Traffic Accident

Vasanthi M.1, Nithya B.1, Krishna Prasanth1, Bhuminathan S.2

1Post Graduate Student, MERF Institute of Speech and Hearing, Chennai; 2Assistant Professor, Department of Epidemiology & Research Faculty, COCPAR, Sree Balaji Dental College & Hospital, Bharath Institute of Higher Education & Research

ABSTRACT

In India the incidence of Road Traffic accidents is reported to be 4,64,910 in 2017 among which 1,47,913 lives were dead and 4,70,975 persons were injured. Road traffic accidents result in various complications which will affect the person’s quality of life. One such complication is cognitive linguistic deficit. This case study is about a young man who has cognitive linguistic deficit which is a result of road traffic accident. The patient exhibited several complex cognitive-linguistic issues during the assessment. This includes reduced semantic memory, spared generative memory, reduced speech intelligibility, extensive surgical management and other behavioural problems. And he has speech and language difficulties such as reduced speech intelligibility, paraphasia, circumlocutions were present.

Keywords: Traumatic brain injury, cognitive-linguistic, paraphasia, circumlocution.

Introduction

More than 100,000 lives are lost in India every year and more than 1 million suffer from serious head injuries. The secondary brain injury can result in increased mortality and disability. Traumatic brain injury (TBI) is a sudden damage to the brain due to any blow or external force which is applied to the head. Causes may include car or motor cycle crashes, falls, sports injuries etc., TBI can result in cognitive linguistic impairment and it can often result from right hemisphere brain damage. But this does not have direct effect on language abilities. After TBI people can have problems with attention, problem solving, memory and interpretive language, in which it affects the communication abilities[1]. A person with a cognitive-linguistic disorder may have difficulty paying attention to a conversation, difficulty in topic maintenance, comprehending jokes and metaphors. And mostly cognitive linguistic impairment vary in severity, if a person is having mild deficit may simply have difficulty concentrating in a noisy environment[2]. In contrast if a person with a severe impairment may unable to communicate at all. Generally cognitive domains include memory, executive function, processing and problem solving skills. These domains are controlled by many cortical and sub cortical structures within the brain. If the frontal lobe of the brain becomes damaged due to any trauma, or a stroke happens in the right hemisphere, these cognitive processes can stop working properly. Cognitive deficits also affects the processing skills such as the ability to comprehend what others are communicating[3,4].

Case Presentation: The patient, aged 27, came to the department of speech and language pathology with the complaint of slurred speech. The patient is a case of road traffic accident polytrauma with left frontal depressed fracture and left fronto-parietal subdural haematoma with brain swelling, he underwent left fronto-temporo-parietal decompressive craniotomy and evacuation of subdural haematoma before one year at tertiary care hospital. Cranioplasty was done. The patient was alert, oriented and conscious during the assessment. Following speech, language and cognitive profile was assessed through formal and informal assessment. Speech profile includes since respiration is one of the pre-requisite
factor for speech production, the pattern of breathing was observed during non-speech and speech activity and the client has thoracic breathing pattern, breath support for speech was observed to be inadequate. Patient’s articulation was assessed and he is able to produce consonants and vowels in isolation, CV combinations, word, and sentence level but his speech intelligibility was observed to be poor hence speech intelligibility rating score is 4 (Can understand with difficulty and concentration by family members, but not by others). Articulatory errors were also observed to be present. Language profile reveals that the patient was able to comprehend simple sentences. He was observed to have paraphasia (paraphasia are unintended utterances) and circumlocution(Mostly observed in patients with aphasia when they have difficulty in retrieving any words)in his spontaneous speech. The patient was able to repeat the words and phrases presented by the clinician but was unable to repeat the sentences without missing out words. Confrontation naming, Lexical generative and responsive naming was spared. Word finding difficulties were observed to be present. Cognitive-linguistic profile includes : auditory subtests such as sound count, letter and word discrimination and month backward counting, he was unable to perform all the above mentioned task ; The patient’s episodic memory, working memory, semantic memory, reasoning and problem solving are assessed informally and it reveals impaired cognitive-linguistic skills. The following test tools are administered such as Frenchay’s Dysarthria Assessment (FDA is a test tool which is used to assess severity of Dysarthria) impairment were found in aspects with respect to respiration, function of tongue(protrusion) was observed to be inadequate, he also exhibits difficulty in alternate movements of lips during speech. Overall range and speed of articulators was observed to be reduced. He was unable to perform other task of laryngeal section(pitch variation and loudness variation and has reduced maximum phonation duration.). Speech intelligibility was observed to be reduced in sentence level and conversation. The patient’s speech intelligibility was assessed by using Aliyavar Jung National Institute of Hearing Handicap speech intelligibility rating scale (It is a rating which is assess the individual’s speech intelligibility) and he was given a score 4 (can understand with difficulty and concentration with family members, but not by others).Evaluation of speech subsystems revealed that the patient’s prosodic aspects were inadequate. No concerns regarding swallowing were raised. Through informal cognitive – linguistic assessment, the client had remarkable cognitive – linguistic deficits.

**Discussion**

Road traffic accidents are one of the major cause (60%) for traumatic brain injury followed by falls (20 to 25%)\(^5\). Almost 96 million people are estimated to suffer from traumatic brain injury caused by road traffic accident. Brain injury because of road traffic accident is more common among southeast Asia and Europe \(^6\). The higher order language, general language abilities and cognitive functions are more likely to be affected due to the traumatic brain injury and it was well supported by the study done by Caroline H.S Barwood et al., in which they had included 16 patients with mild traumatic brain injury and they examined the high -level language and cognition based test tools, it revealed the reduced cognitive-linguistic ability compared to age-matched group\(^7\).

**Conclusion**

Traumatic brain injury caused by road traffic accident can result in cognitive-linguistic deficits. Even though there are more studies which talks about cognitive-linguistic deficits due to traumatic brain injury there is a need for more studies across different regions and population. And detailed speech and language evaluation needed to be carried out and in order to assess higher-level language and cognitive-linguistic abilities formal test tools to be used by the speech-language pathologist.

“Eagle’s Syndrome Causing Dysphagia and Throat Pain”—A Case Report

Pavan Kumar Namdar¹, Krishna Prasanth B.², Aravindha Babu N.³, Prabakaran M.⁴

¹Post Graduate, Department of Radiodiagnosis, Sree Balaji Medical College & Hospital, ²Assistant Professor, Department of Epidemiology & Research Faculty, COCPAR, ³Professor, Department of Oral Pathology, Sree Balaji Dental College & Hospital, ⁴Professor & Head, Department of Radiodiagnosis, Sree Balaji Medical College & Hospital, Bharath Institute of Higher Education & Research

ABSTRACT

Eagle syndrome is a condition caused by an elongated ossified styloid process, the cause of which remains unclear. This is a rare finding that often goes undetected in the absence of radiographic studies. Eagle syndrome can occur unilaterally or bilaterally and most frequently results in symptoms of dysphagia, headache, pain on rotation of the neck, pain on extension of the tongue, change in voice, and a sensation of hypersalivation. In this case, we present the diagnostic CT and lateral view plain film radiography findings of a 42-year-old woman with clinical evidence of Eagle syndrome.

Keywords: Eagle’s syndrome; Styloid process elongation; Stylohyoid ligament Ossification

Introduction

Eagle syndrome is a condition caused by an elongated styloid process. Unilateral face, neck and ear pain, stinging pain, foreign body sensation and dysphagia can be observed with this syndrome. Rarely, the elongated styloid process may cause pain by compressing the cervical segment of the internal carotid and the surrounding sympathetic plexus, and that pain spreading along the artery can cause neurological symptoms such as vertigo and syncope.

Case Report: A 42-year-old woman presented at the Otolaryngology Clinic complaining of dysphagia and vague throat discomfort that she had experienced continuously for slightly more than a year. She also complained of occasional radiating pain to her left ear. She had no history of any neck trauma or any surgery done in the neck region.

During the physical examination, a solid mass was felt on palpation of the left tonsillar fossa, and radiographic studies were ordered. Lateral view plain film radiographs showed an elongated ossified styloid process, with the left larger than the right (Fig 1). CT provides complimentary information to that of plain radiography, including definition of the relationship of calcifications to surrounding neck soft tissue structures in the axial plane (Fig 2). On the left, the thick calcified process extended from the stylomastoid foramen to the hyoid bone. So she was diagnosed to have Eagle’s syndrome and was advised for surgical excision of elongated styloid process.

Figure 1: Orthopantomogram showing elongated left styloid process
Figure 2: CT Neck sagittal reconstruction showing elongated left styloid process

Discussion

Eagle syndrome is a group of symptoms that includes recurrent throat pain, foreign body sensation, dysphagia, and/or facial pain as a direct result of an elongated styloid process or calcified stylohyoid ligament. Although approximately 4% of the population is thought to have an elongated styloid process, only a small percentage (between 4% and 10.3%) of this group is thought to actually be symptomatic. No data could be found to correlate degree of elongation of the styloid to severity of symptoms.

Diagnosis is made both radiographically and by physical examination. Palpation of the styloid process in the tonsillar fossa is indicative of elongated styloid, as the normal styloid process is not palpable. Palpation of the tip of the styloid should may exacerbate existing symptoms. Confirmation of Eagle’s syndrome can be made by radiographic studies. Most frequently, a panoramic radiograph is used to determine whether the styloid process is elongated. In reviewing these radiographs, it should be noted that the normal length of the styloid in an adult is approximately 2.5 cm whereas an elongated styloid is generally >3 cm in length. Although Eagle syndrome is thought to be caused by an elongated styloid process or calcified stylohyoid ligament, the presence of an elongated styloid process is not pathognomonic for Eagle syndrome because many patients with incidental findings of an elongated styloid process are asymptomatic. Lateral view radiographs of the skull can be substituted for panoramic radiographs (as in this case), and an anteroposterior view radiograph should be obtained to determine whether there is any lateral deviation of the styloid. As stated earlier, CT is useful in that it provides complementary information to that provided by plain radiographic studies.

The actual cause of the elongation is a poorly understood process. Several theories have been proposed: 1) congenital elongation of the styloid process due to persistence of a cartilaginous analog of the stylohyal (one of the embryologic precursors of the styloid), 2) calcification of the stylohyoid ligament by an unknown process, and 3) growth of osseous tissue at the insertion of the stylohyoid ligament.

The pathophysiological mechanism of symptoms is debated as well. Theories include the following: 1) traumatic fracture of the styloid process causing proliferation of granulation tissue, which places pressure on the surrounding structures; 2) compression of adjacent nerves, the glossopharyngeal, lower branch of the trigeminal, or chorda tympani; 3) degenerative and inflammatory changes in the tendinous portion of the stylohyoid insertion, called insertion tendonitis; 4) irritation of the pharyngeal mucosa by direct compression or post-tonsillectomy scarring (involves cranial nerves V, VII, IX, and X); and 5) impingement of the carotid vessels, producing irritation of the sympathetic nerves in the arterial sheath.

Treatment of Eagle syndrome is both surgical and nonsurgical. Nonsurgical treatments include reassurance, nonsteroidal anti-inflammatory medications, and steroid injections. Surgical treatment is by one of two methods. Otolaryngologist W. Eagle preferentially used a transpharyngeal approach through which the elongated portion of the styloid process was removed. Although this technique does avoid external scarring, it has been heavily criticized because of the increased risk of deep space neck infection and poor visualization of the surgical field (must be performed through the mouth). Alternatively, the elongated portion can be removed by an extraoral approach. Although both procedures are effective in removing an elongated styloid process, the extraoral approach is thought to be superior because of the decreased risk of deep space neck infection and better visualization of the surgical field.

Management of Oropharyngeal Dysphagia Post Hemi-Mandibuloglossectomy

Sri Janani Y.1, Ishwarya R.1, Srilatha1, Krishna Prasanth B.2, Aravindha babu N.3
1Post Graduate Student, MERF Institute of Speech and Hearing, Chennai; 2Assistant Professor, Department of Epidemiology & Research Faculty, COCPAR, 3Professor, Department of Oral Pathology, Sree Balaji Dental College & Hospital, Bharath Institute of Higher Education & Research

ABSTRACT

Dysphagia is a growing concern in patients with tongue cancer that leads to malnutrition, dehydration, weight loss, reduced functional abilities, and fear of eating and drinking which can also lead to depression and reduced quality of life. Glossectomy is removal of the entire or parts of the tongue which may lead to difficulty in swallowing, speech, breathing activities etc. Rehabilitating patients with glossectomy pose a great challenge for the clinicians and hence a careful observation and evaluation of residual oral function should be always carried out in such patients. This article throws light on management of swallowing difficulty secondary to hemi-mandibuloglossectomy in a 79 year old male patient with tracheostomy and Ryle’s Naso-Gastric tube with the attempt of restoring the speech and function of the patient through speech and swallowing therapy.

Keywords: Dysphagia, mandibulo glossectomy, Aspiration.

Introduction

Dysphagia is present in almost 50% of head and neck cancer survivors. Often tongue cancer patients present with oro pharyngeal dysphagia and other co-morbidities like malnutrition, dehydration, weight loss, reduced functional abilities, and fear of eating and drinking which further deteriorates their inability to function and hamper their quality of life (QOL). Dysphagia is present in almost 50% of head and neck cancer survivors. Often tongue cancer patients present with oro pharyngeal dysphagia and other co-morbidities like malnutrition, dehydration, weight loss, reduced functional abilities, and fear of eating and drinking which further deteriorates their inability to function and hamper their quality of life (QOL)1.

Glossectomy is performed mainly for patients who have primary lesion in the tongue and other regions such as floor of mouth. Glossectomy results in severe oral dysfunction with swallowing and resultant aspiration. This procedure can be done via different approaches depending on the size and extent of the lesion. Other associated procedures that are done to glossectomy patients includes tracheotomy, feeding tube placement, neck dissection, floor of mouth resection or mandibulectomy. This case report describes the management of the oro pharyngeal dysphagia in patient with tongue cancer who underwent hemi mandibulo glossectomy and tracheostomy2,3.

Case History/Examination:

A 79 years old male patient reported with the chief complaint of difficulty in swallowing and impaired speech due to partial resection of tongue and the patient had a history of squamous cell carcinoma of the tongue and underwent tracheostomy and mandibuloglossectomy for the same. The patient was also assisted with nasogastrostomy tube for feeding (Ryle’s tube). The patient underwent videolaryngofluoroscope which revealed normal vocal fold movement, with mild aspiration on the left side. Both formal and informal assessments were carried out which includes functional intake oral scale, dry swallow, 4 finger test, Cranial nerve examination, modified water swallow test, Dysphagia severity scale, eating status scale. Vegetative skills such as biting, chewing, blowing, swallowing and sucking were observed to be inadequate. Speech intelligibility was assessed using

DOI Number: 10.37506/v10/i12/2019/ijphrd/192338
AYJNHH revealed a score of 4 (i.e., can understand with difficulty and concentration by family members but not by others). Voicing was observed to be present (Stoma occluded). The patient also had normal pitch and quality with inadequate loudness and endurance. Drooling and pooling of food was observed to be present. The patient was unable to form and control bolus. The patient was unaware of residue present in his mouth, and hard palate. Reduced anterior and posterior tongue movement were observed. The patient also had slow oral transit time, reduced velar elevation/nasal regurgitation. Repeated swallow per bolus and reduced pressure on bolus was observed to be present.

Cranial nerve examination was done using MMSA. Functions of V cranial nerve was affected such as mouth opening, closing, moving the jaw left or right, open jaw while pushed up, clenching of teeth or biting together. Functions of IX cranial nerve such as pharyngeal movement, posterior one third of the tongue were affected. Sensory Functions of VII cranial nerve such as taste (Sweet, salt, sour and bitter) was observed to be affected which was assessed using solution of sugar, salt, vinegar and onion juice and motor functions of XII cranial nerve such as protrusion, and lateralisation were also observed to be affected.

Swallowing assessment done using dysphagia severity scale reveals Food aspiration with no effect of compensatory techniques or food consistency changes is seen, Saliva Aspiration and Oral problems with significant symptoms of preparatory or oral stage without aspiration were observed to be present.

Swallowing Therapy: Management involves hemimandibuloglossectomy surgery and speech and swallowing therapy was provided for 2 weeks, 40 minutes per day. Swallowing therapy techniques includes breathing techniques were provided in order to regulate the normal breathing for swallowing – occlusion of the stoma, supraglotticswallowing maneuver provided in order to protect the airway from aspiration of food and liquid by closing the airway before swallowing, Oro motor exercises for increasing oromotor control, to increase the swallowing pressure and for increasing the adductions of tissues top of the airway. Sensory stimulation (thermal-tactile stimulation), head tilt towards the stronger side and multiple swallowing techniques were used in order to improve the swallowing efficiently.

Discussion

Oropharyngeal dysphagia was present in 50.6% of patients, mostly to solid foods (72.4%)(4). The complete rehabilitation of glossectomy patient, aims at improving the resonance, developing altered articulating surface as well as the pattern which would diminish the deficiencies related to speech and deglutition(1).

This article presents a case report on the management of swallowing consequent to hemimandibuloglossectomy with the attempt of restoring
the comfort, speech and function of the patient through speech and swallowing therapy. Glossectomy patients experience difficulties in the pharyngeal phase of swallowing as well as in the oral phase.4,5,6

Post-swallow residue is considered to be a sign of swallowing impairment and on subsequent swallows it is assumed to pose a risk on aspiration. Post-swallow residue in one or both pharyngeal spaces was significantly associated with impaired swallowing safety on the subsequent clearing swallow for the same bolus (2). Swallowing therapy techniques includes breathing techniques were provided in order to regulate the normal breathing for swallowing – occlusion of the stoma, supraglottic swallowing maneuver provided in order to protect the airway from aspiration of food and liquid by closing the airway before swallowing, Oro motor exercises for increasing oromotor control, to increase the swallowing pressure and for increasing the adductions of tissues top of the airway.8,9,10

**Conclusion**

Evaluation of the patient with Hemi mandibuloglossectomy along with the tracheostomy due to tongue cancer has its impact on swallowing which results in the oropharyngeal dysphagia and reduced clarity in speech. All these difficulties can be restored with the appropriate swallowing and speech therapy options. Well planned efforts could provide efficient and successful rehabilitation, by restoring the comfort and functions of the patient in swallowing, speaking and also enhances the quality of life that are best accomplished in an interdisciplinary team environments.

“Osteopoikilosis–Benign Osteosclerotic Dysplasia”—A Case Report

Pavan Kumar N.1, Krishna Prasanth B.2, Prabakaran M.3, Aravindha Babu4

1Resident, Department of Radiology, Sree Balaji Medical College & Hospital, 2Assistant Professor, Department of Epidemiology, Sree Balaji Dental College & Hospital, 3Professor & Head, Department of Radiology, Sree Balaji Medical College & Hospital, 4Professor, Department of Oral Pathology, Sree Balaji Dental College & Hospital, Bharath Institute of Higher Education & Research

ABSTRACT

Osteopoikilosis is a rare autosomal dominant or sporadic osteosclerotic dysplasias characterised by homogenous, small, multiple, discrete, symmetric round or ovoid radio densities in cancellous bones. Recognition of this asymptoamatic condition by plain radiograph makes other expensive investigations unnecessary. Here we present a case report of 28 yrs-old male incidentally found to have osteopoikilosis.

Keywords: Osteopoikilosis, Benign bone lesions, Asymptomatic

Introduction

Osteopoikilosis is an asymptomatic, autosomal dominant or sporadic, sclerosing dysplasia characterized by multiple, discrete round or ovoid radio densities in cancellous bones.

Case report: A 28 yrs-old male with history of trauma 2 months ago and complains of right upper limb weakness since then came for MRI brain study as suggested by neurologist. MRI revealed a subacute intraparenchymal hemorrhage in left parietal lobe with peri-lesional edema. Radiograph of right shoulder joint was done which revealed multiple, discrete round/ovoid radio densities juxta-articularly involving head of humerus and scapula. Radiograph findings were consistent with Osteopoikilosis. Radiographs of left shoulder joint and pelvis were done to look for involvement of other bones. Consent was taken from the patient.

Discussion

Osteopoikilosis (Osteopathia condensans disseminata; Spotted bone disease) is an asymptomatic sclerotic dysplasia initially described by Albers-Schonberg and Ledoux-Lebard and associates in the early twentieth century. This disorder is seen in both men and women and may become evident at any age. Both inherited and sporadic forms have been reported. An autosomal dominant pattern that becomes more and more prominent in each succeeding generation has also been described.1,2

Osteopoikilosis is an asymptomatic, clinical manifestations, if present are usually mild. Radiologically the abnormality appears as small, well defined, ovoid or lanceolate sclerotic lesions arranged symmetrically around the joints, more commonly the epiphysis and metaphysis of long tubular bones.1–4 Histopathologically these lesions correspond to lamellar osseous tissue containing Haversian systems.3,4

Dermatological abnormalities in form of closely situated, elevated, whitish fibrocollagenous infiltrations (dermatofibrosis lenticularis disseminia or the Buschke–Ollendorff syndrome), a predisposition to keloid formation and scleroderma like lesion are seen in approximately twenty five percent of the cases. Associations with dwarfism, dystostias, premyelopathic

Corresponding Author:
Dr. B. Krishna Prasanth
Assistant Professor,
Department of Epidemiology,
Sree Balaji Dental College & Hospital,
Bharath Institute of Higher Education & Research
Email: mail2kristine@gmail.com
syndrome due to spinal stenosis, organ anomalies (coarctation of aorta, double ureter) and in 15–20% of patients mild articular pain with or without joint effusion have also been reported.2,3

In an epidemiological study of familial Osteopoikilosis by Benli et al a predominance of these lesions was found in the phalanges of hand (100%) followed by carpal bones (97.4%), metacarpals (92.3%), foot phalanges (87.2%), metatarsals (84.4%), tarsal bones (84.6%), pelvis (74.4%), radius (66.7%), ulna (66.7%), sacrum (58.9%), humerus (28.2%), tibia (20.5%) and fibula (12.8%).5

On serial radiographs these sclerotic lesions may show an increase or decrease in size or number with occasional disappearance in children, in sharp contrast with adults in whom these lesions remain more or less static.1

Differential considerations for this abnormality include osteoblastic metastases, tuberous sclerosis and mastocytosis. The blastic metastases primarily involve the axial skeleton, demonstrate osseous destruction and show uptake on bone scintigraphy. The sclerotic lesions in mastocytosis and tuberous sclerosis on the other hand are less well defined, asymmetric and show lesser periarticular preference.6 These findings along with exclusion of the primary malignancy by imaging of the prostate, serum PSA levels, endoscopy, colonoscopy, breast imaging and other ancillary tests may help to arrive at the diagnosis of Osteopoikilosis.

However, Mungovan et al suggested that in a setting of characteristic radiological findings of Osteopoikilosis an abnormal bone scan does not exclude its diagnosis.7

Conclusion
Diagnosis of this asymptomatic condition by plain radiograph makes other expensive investigations unnecessary. Review of other sclerosing bone dysplasias is made to guide easy assessment of such lesions and differentiating the pathologies.

**ABSTRACT**

Xylene is a colorless liquid with the molecular formula C₈H₁₀. A flammable, non-explosive aromatic hydrocarbon, xylene consists of a benzene ring with two attached methyl groups. Xylene occurs naturally in petroleum and small amounts occur in gasoline and jet fuel. It is used in paints, inks, glues and other products. The population at large is expected to be exposed primarily to mixed xylenes, rather than to any of the xylene isomers individually. The general population can be exposed to xylene via inhalation of indoor and workplace air, automobile exhaust, tobacco smoke, xylene-containing solvents, ingestion of contaminated drinking water, and dermal absorption of xylene containing products. Xylene is released primarily from industrial sources. The existence of hazards in the workplace has raised concerns about the potential of these substances for adverse effects.

**Keywords:** Xylene, Dyspnoea, Occupational

**Introduction**

Xylene (Greek word xylo, -wood), xylol or dimethyl benzene is any one of three isomers of dimethyl benzene, or a combination thereof. With the formula (CH₃)₂C₆H₄, each of the three compounds has a central benzene ring with two methyl groups attached at substituents. They are all colorless, flammable liquids, some of which are of great industrial value. The mixture is referred to as both xylene and, more precisely, xylenes. Xylene is released primarily from industrial sources. Studies have shown that xylene is well-absorbed by the inhalational, oral and to some extent by the dermal route. Following prolonged exposure especially by occupational means it is likely to get accumulated chiefly in the muscle and adipose tissues. The health effects of xylene depend on the route of its exposure (1). Inhalational exposure is the most common route of exposure (2, 3). Most of the xylene that enters the body leaves within 18 h following the end of the exposure. Significant amounts of xylene can get accumulated in the body on prolonged exposure as seen in occupationally exposed personnel. Several health hazards have been identified with acute and chronic xylene exposure. These can range from milder symptoms such as dizziness to severe lung congestion with focal areas of interalveolar hemorrhage followed by death. Chronic exposure often results in dizziness, eyes, nose and throat irritation.

**Routes of Exposure:** Exposure to xylene can occur via inhalation, ingestion, eye or skin contact. It is primarily metabolized in the liver by oxidation of a methyl group and conjugation with glycine to yield methyl hippuric acid, which is excreted in the urine. Smaller amounts are eliminated unchanged in the exhaled air. Xylene causes health effects from both acute (<14 days) and also chronic (>365 days) exposure. The type and severity of health effects depends on several factors, including the amount of chemical you are exposed to and the length of time you are exposed for. Individuals also react differently to different levels of exposure. (4)
Inhalational exposure: Acute inhalational exposure to mixed xylene at 200 ppm for 3-5 minutes resulted in irritation of the nose and throat (5). An autopsy of a worker who died owing to several hours of exposure to xylene fumes while painting and reported focal areas of intra-alveolar haemorrhage and pulmonary oedema with severe lung congestion were seen at the acute exposure of 100 ppm (6). An extensive study has reported the signs and symptoms of workers who have been chronically exposed to mixed xylene. A significant increase in throat and nasal irritation has been found in study. Decreased pulmonary function and dyspnoea was reported among histology technicians chronically exposed to xylene in the laboratory. In the same study cardiovascular effects such as flushing, palpitations and chest pains were seen among the histology technicians (7). The author also reviewed 175 workers who are chronically exposed to mixed xylene at 14 ppm has observed a reduction in the grasping power in the extremities. No adverse hepatic and renal effects were observed in the same palpitations and chest pains (8). Several authors have reported various gastrointestinal symptoms such as gastric discomfort, nausea and vomiting in workers chronically exposed to xylene vapours. A number of subjective neurological symptoms such as anxiety, dizziness, inability to concentrate and forgetfulness have been observed among subjects chronically exposed to xylene vapours. A number of subjective neurological symptoms such as anxiety, dizziness, inability to concentrate and forgetfulness have been observed among subjects chronically exposed to xylene vapours (7, 8). Spontaneous abortions were observed in females as pathology technicians who are exposed to formalin and xylene. Although the study could not conclusively conclude that xylene was the direct cause of this effect (9).

Oral exposure: In a post-mortem examination of a person who had committed suicide by the consumption of xylene, occurrence of pulmonary congestion and oedema were noted. No adverse effects were noted in the cardiovascular or gastrointestinal systems. The report was concluded that the death of the person was due to a centrally mediated depression of the respiratory system (10). In the report of an accidental ingestion of xylene in a person, it was found that it resulted in a persistent coma for more than 26 hours (11).

Dermal exposure: In acute dermal exposure of xylene by hand immersion technique in humans by Engstrom et al., and Riihimaki and Pfaffli, it was reported that it was associated with vasodilatation of the skin of the hand, dryness and scaling of the area and skin erythema of the hand. It was also found that in patients with a history of atopic dermatitis who were symptom-free, it resulted in the development of toxic eczema of the hands of such subjects on exposure to xylene. It was also found that in such patients a three time greater absorption rate of xylene was observed compared to the other subjects in the study (12, 13).

Palmer and Rycroft in 1993 also reported the occurrence of urticaria in a female technician of cytology laboratory who was predominantly exposed to vapours of xylene in the occupational environment. It was effectively proved that it was as a result of direct exposure to xylene by the performance of a closed patch test which elicited severe erythema and whealing of the skin (14).

Ocular exposure: Industrial exposure often means simultaneous exposure to a mixture of chemical agents. Many aliphatic and aromatic industrial solvents cause neurotoxic symptoms. Short-term exposure to xylene concentrations below the Finnish threshold limit value (4.1 µmol/l, 435 mg/m3) probably does not cause significant disturbances in the vestibular or central visual system. Higher peak exposure to xylene, particularly combined with the influence of alcohol, might increase accident hazards during or after work (24). Several studies have been observed irritation of the eye on exposure to xylene vapours (5, 6, 15).

Nervous System: The main effect of inhaling xylene vapor is depression of the central nervous system, with symptoms such as headache, dizziness, nausea and vomiting. The effects listed below can begin to occur with exposure to air levels of about 100 ppm. They are reversible and become more noticeable and serious as the length of time of exposure increases (16). Effect of xylene on the central nervous system is attributed to the liposolubility of xylene in the neuronal membrane. It has been suggested that xylene disturbs the action of proteins essential to normal neuronal function either by disruption of the lipid environment in which the membrane proteins function or by direct interaction with the proteins in the membranes (17). It has been suggested that a metabolic intermediate like methyl benzaldehyde could be responsible for the toxicity of xylene. Oxidation of xylene to these intermediates by microsomal enzyme systems may occur in the brain (17). Changes in the levels of various neurotransmitters and lipid composition have been observed in several brain areas following acute- and intermediate-duration exposure to xylene. It is
unclear whether these represent direct effects of xylene or are secondary changes resulting from nonspecific central nervous system depression. Long-term exposure may lead to headaches, irritability, depression, insomnia, agitation, extreme tiredness, tremors, impaired concentration and short-term memory. This condition is sometimes generally referred to as “organic solvent syndrome.” Unfortunately, there is very little information available that isolates xylene from other solvent exposures in the examination of these effects.

**Eyes, Nose and Throat:** Xylene is a strong compound that is used in many household and industrial products. Xylene poisoning can occur when someone swallows these substance by accident and breathes in their fumes. Exposure to approximately 200 ppm can cause Irritation of the nose and throat. Unintentional splash in the eye may damage the surface of the eye, which will heal within a few days.

**Lungs:** Irritation to lungs causes chest pain and shortness of breath when exposed to xylene at a levels of 200 ppm or greater. Extreme overexposure (e.g., in a restricted space) can result in pulmonary edema, a potentially life-threatening condition in which the lungs fill with fluid. However, there is no evidence that repeated, low-level exposure has any long-term effects on the lung.

**Liver and Kidney:** At very high levels of exposure of xylene can injure the liver and kidneys, but this is extremely unlikely to happen without noticeable effects on the nervous system. Generally, such damage is reversible. Low-level occupational exposure does not affect the liver and the kidneys.

**Blood:** There is no evidence that exposure to xylene affects the blood cells in humans. Earlier reports of low red blood cell counts (anemia) may have been due to contamination of xylene with benzene.

**Gastrointestinal Tract:** Symptoms of nausea, vomiting and gastric discomfort were observed in workers exposed to xylene vapors which were reversible.

**Musculoskeletal System:** Workers exposed to xylenes (TWA 14 ppm) reported reduced grasping power and reduced muscle power in the extremities more frequently than the unexposed controls. This is due to the neurological effect rather than a direct effect on the muscles.

**Skin:** Xylene, like other organic solvents, can dissolve the skin’s natural protective oils. Frequent or prolonged skin contact can cause irritation and dermatitis, dryness, flaking and cracking of the skin. Damaged skin may allow greater absorption of chemicals. Xylene easily penetrates most ordinary clothing and can become trapped in ordinary gloves and boots. Xylene trapped in the clothing can cause burns and blistering.

**Cancer:** There is inadequate evidence for the carcinogenicity of Xylene in humans.

**Reproductive System:** The available animal information is insufficient to connect xylene with any reproductive effects. Xylene has produced fetotoxic effects like delayed ossification and behavioral effects in animals, in the absence of maternal toxicity. Xylene inhaled by a woman can reach a developing fetus and can contaminate her breast milk. It is recommended that pregnant and nursing women minimize their exposure to xylene, just as they should minimize their exposure to alcohol, tobacco and other drugs.

**Conclusion**

This study suggests implementing environmental monitoring systems and giving special attention in order to reduce the hazards of xylene. It is carcinogenic for blood components with other aromatic hydrocarbons, so single xylene should be evaluated both in occupational and experimental studies. Xylene emission is high in developed, developing as well as in underdeveloped countries due to extensive usage of petroleum refineries, vehicles, industries and chemical plants. So toxicologists give attention to its noxious effects with its long term use on public health and high exposure of xylene. Efforts to diminish the health hazards in the environment should be made to generate a safer living atmosphere by making the environmental health departments familiar with the health hazards of xylene, safety measures and emergency procedures. Usage of proper personal protective equipment is essential such as decent fume hood, proper white coat, and eye protector, mask to cover nose and mouth, while dealing with health hazardous chemicals like xylene.

Phytochemical analysis of the Ethanolic Extract of the Leaves of Gymnema Sylvestre

Arumugam Rajalakshmi1, Govindarajan Sumathy2

1Research Scholar, Department of Anatomy, Sree Balaji Dental College & Hospital, Bharath Institute of Higher Education and Research, Chennai, Tamil Nadu, India, 2Assistant Professor, Department of Anatomy, Melmaruvathur Adhiparasakthi Institute of Medical Sciences, Melmaruvathur, Tamil Nadu, India; 3Professor & Head, Department of Anatomy, Sree Balaji Dental College & Hospital, Bharath Institute of Higher Education and Research, Chennai, Tamil Nadu, India

ABSTRACT

Gymnema sylvestre is a medicinal plant for the potential management of diabetes mellitus. The leaves are used in herbal medicinal preparation. The present study deals with the antidiabetic and hypolipidemic properties with ethanolic extract of Gymnema sylvestre leaves. The result of the phytochemical study shows its therapeutic value and for treating the patient with type 2 diabetes mellitus.

Keywords: Gymnema sylvestre, Glycosides, Hypoglycemic, Diabetes mellitus.

Introduction

During the last decades, the medicinal plants are used for long term therapy for human diseases. However, now a day, there is an increased demand for using herbs in therapy instead of using synthetic drugs which may have adverse effects on human.

Prevalence of diabetes is increasing with increased changes in the lifestyle at alarming rate. Gymnema sylvestre (Fig-1) is a valuable belonging to the family Asclepiadaceae commonly known as ‘Gurmar’, is one of the most important indigenous medicinal plants of India. The use of this plant is to cure diabetes mellitus in India. The plant is documented to have a beneficiary effect in diabetes due to presence of gymnemic acid.

The gymnemic acid (Fig-2) in leaves suppresses the transport of glucose from the intestine into the blood stream resulting lowering of blood sugar level, cholesterol level, balancing insulin level and also promotes weight loss. Traditionally Gymnema or gurmar is a large woody climbing plant. Both the dried leaf and root powder are used for diabetic medicine. The leaves of Gymnema are reported to be bitter flavor, they temporarily paralyze the sensory perception of sweet and it is also known as sugar destroyer for this amazing property. Gymnema leaves

have the mixture of bioactive constituents tri-terpenes, glycosides and saponin property viz, gymnemic acid, gymnemagenin and gurmarin which represents the antidiabetic property. The leaves of the plant are also used as a digestive, hypoglycemic, antiviral, antiallergic and antiobesity (2) agent for the treatment of diabetes, obesity and dental caries. The main constituent of Gymnema is believed to be gymnemic acid, a mixture of 17 different saponins. This plant consists of gymnamine and the dammarene-type saponins gymnemasides1-5 is responsible for hypoglycemic and antisaccharin effect of the plant. The purpose of this work is concern with screening the plant for antidiabetic and hypoglycemic properties of leaves of Gymnema sylvestre. Gymnema sylvestre has anti diabetic properties and the plant is used as an herbal medicine through the world. Plant triterpenoid Saponin in the cells of plant parts called gymnemic acid and its component gymnemagenin which is the principle control of diabetic (1).

The plant has been used in traditional medicine, most notably to control blood sugar. The Gymnema is used as a lipid-lowering agent and for weight loss has also been examined, primarily in animal studies. However, less or no information is available to support the use of Gymnema for any indication.

Morphology of Gymnema sylvestre:
Gymnemasylvestre (3) is a large, stout, much-branched woody climber. Leaves are opposite, more or less pubescent, usually elliptic or ovate. The flowers are small and yellow in colour, up to 3 inches in length. The taste of leaf is slightly bitter. Chewing the leaves destroys the ability to discriminate the sweet taste, giving it its common name, gurmar or sugar destroyer (4). Gymnema sylvestre is one of the plants with antidiabetic property. The Gymnema leaf powder has a faint pleasant aromatic odour which is tasteless.

Uses of Gymnema:

The following are the wide range of uses of the Gymnema sylvestre

- Reduction in the blood sugar
- Weight loss
- Metabolic syndrome
- Root juice for snake bite
- Root bark is useful as an emetic and expectorant
- Analgesic for body ache
- Also used for malaria and, digestive stimulant, laxative, appetite suppressant and diuretic.
- Moreover it is used as Anti-inflammatory, anodyne (painkiller), liver tonic, emetic, thermogenic, stomachic, anthelmintics, cardiotonic, expectorant, antiptyretic, and uterine tonic.
- Significance place in the treatment of jaundice, constipation, cardiopathy, asthma, bronchitis, amenorrhoa, conjunctivitis, renal and vesical calculi, dyspepsia, leucoderma, and Parkinsonism.
- Conditions like piles, colic pain, dyspsy, phlegm, eye troubles, cardiac, and respiratory diseases are treated with the extract of this plant.

Side Effects of Gymnema: Chronic usage of the drug leads in lowering the blood pressure. It is a hepatotoxic substance which causes damage to the liver. The Gymnemic acid and Gurmarin suppresses the ability to detect the sweet taste (4). Gymnema has been reported to possess a sweet-taste suppressing effect, attributed to the peptide gurmarin (5-9)

Phytochemical Screening: Chemical test were carried out using standard procedures to identify the constituents as described.

Freshly prepared extracts were subjected to preliminary phytochemical analysis to find the presence of the following phytoconstituents, Cardiac glycosides, Anthraquinones, Tannins, Saponins and alkaloids have hypoglycemic (11) activities. These analyses will determine the biologically active compounds that contribute to the flavour, colour and other characteristics of leaves and show their medicinal activity and the hypoglycemic activity of the plant extract.

Sample Extraction were carried out with ethanol and the resulting extract was utilized for the phytochemical analysis

Chromatography: Identification of Gymnemagenin By Thin Layer Chromatography:

After hydrolysis: 100 mg of Gymnema sylvestre extract was dissolved in 10ml of 50% ethanol, and then add 2ml of KOH and heat on a boiling water under refluxed for an hour and then cooled. In this 1.8ml of 1N HCL was added and heated on water bath after cooling the solution. The pH was adjusted to 7.5 to 8.5 with 11%KOH. This solution was dissolved with 50% ethanol and filtered, then 10 microlitre was applied on thin layer chromatography. Gymnemagenin is identified after hydrolysis, and the plate is kept in the solvent system for absorption. The solvent system proportion should be isopropyl alcohol:methanol:chloroform:acetic acid (5:1:3:0.5). Finally, the plate were dried to enable the full colour spot which shows the presence of Rf value 0.34. The (Fig-3) shows the presence of gymnemagenin is given below

![Fig. 3: Thin layer Chromatography](image)

Standard Quantity:

Adult Oral administration (age ≥18):

Hyperlipidemia: patients with type 2 diabetes mellitus, 400mg of Gymnema extract for 18–20 months or 2ml of an aqueous decoction (10 g shade-dried powdered leaves per 100ml), three times daily.

Conclusion

Herbal compounds have received much attention for management of various diseases. When compared it is also safer than synthetic drugs. Anatomical characterization provides further support towards authentication and elimination of adulteration of market sample of potent medicative plants as Gymnema sylvestre. The Gymnema leaf main part is gymnemic acid contains gymnemagenin, which plays a role by treating the diabetic. Presence of different types of phytochemical constituents such as alkaloids, tannins, saponins, anthraquinone and glycosides give an idea that the ethanolic leaf extract of Gymnema Sylvestre can be used as an accessible source for type 2 diabetes mellitus. Further research is necessary to find the active compounds within these plants with their full spectrum of efficacy.

ABSTRACT

Xylene is an aromatic hydrocarbon known for its wide usage in tissue processing, staining and cover slipping in the histology laboratory. The hazards of xylene are well documented, making it a potential occupational hazard for the histopathological technicians. As every other profession became cautious of the occupational hazards, the very speciality that identifies the illnesses became one of the last to become aware and remedy its own hazards. This article aims to discuss the toxicity of xylene and safety measures to counteract the hazards of xylene.

Keywords: Toxicity of xylene, xylene substitutes, xylene

Introduction

The primary purpose of this study is to provide public health officials, physicians, toxicologists, and other interested individuals and groups with an overall perspective of the toxicology of xylene. Xylene or xylol or dimethyl benzene is an aromatic hydrocarbon liquid which is widely used in industry and medical laboratories as a solvent. Xylene is primarily a synthetic chemical. It is a colorless, flammable liquid or gas occurring naturally in petroleum, coal and wood tar, with sweet smell and is so named because it is found in crude wood spirit (Gr. xy‘lon-wood). [1] Xylene was first isolated and named in 1850 by the French chemist Auguste Cahours (1813–1891), having been discovered as a constituent of wood tar. [2]

C₆ H₄ (CH₃)₂ is the chemical formula. It is referred to as “dimethyl benzene” because it consists of a six-carbon ring to which two methyl groups are bound. The three forms of xylene in which the methyl groups differ on the benzene ring: metaxylene, ortho-xylene, and para-xylene (m-, o-, and p-xylene). These different forms are referred to as isomers.

The current Occupational Safety and Health Administration permissible exposure limit for xylene is 100 ppm as an 8-h time-weighted average (TWA) concentration. [2] The National Institute for Occupational Safety and Health recommended exposure limits for Xylene at 100 ppm as a TWA for up to a 10-h work shift and a 40-h work week and 200 ppm for 10 min as a short-term limit. [3]

Studies have shown that xylene is well-absorbed by the inhalational, oral and to some extent by the dermal route. The amount of biomarker of xylene exposure in urine can be analyzed using techniques such as High Performance Liquid Chromatography (HPLC) and Gas Chromatography (GC) [1]. Inhalational exposure is the most common route of exposure [1, 4].

Uses of Xylene: There are many uses of xylene, both in its pure state and in compounds. It is widely used in several industries as well as in dental and medical arenas.
In histology, xylene is used to process and stain tissues. These tissues can then be used in microscopy. This aids histopathology technicians who look at tissues to determine the presence of disease. In tissue processing, tissue has to be embedded in a medium (such as paraffin) to support it and allow it to be cut without damaging the tissue. Fixed tissue is then dehydrated, removing water from the tissue by escalating grades of alcohol. Alcohol, however, is not miscible with paraffin (something that is miscible can mix well with another substance).

Exposure Risks of Xylene: Xylene also poses risks to skin and eyes and is considered a skin irritant. The skin quickly absorbs it. Because xylene is so efficient at removing fats, any contact with the skin will have the same effect. This can lead to drying and cracking of the skin and dermatitis.

Relevance to Public Health: People may be exposed to xylene at hazardous waste sites by inhalation of contaminated air, drinking contaminated water, or dermal contact with contaminated water or subsurface soils and sediments. Both human and animal data suggest that mixed xylene, m-xylene, o-xylene, and p-xylene all produce similar effects, although the individual isomers are not necessarily equal in potency with regard to a given effect. Available case reports, occupational studies, and studies on human volunteers suggest that both short- and long-term xylene exposures result in a variety of adverse nervous system effects that include headache, mental confusion, narcosis, alterations in body balance, impaired short-term memory, dizziness, and tremors.

Preventive Measures

Substitution: After the hazardous effects of xylene became unquestionable, many potential substitutes became available. The Substitutes should perform the same function and also should lessen the hazard. The following chemical components like Limonene reagents, Aliphatic hydrocarbon mixtures, Aromatic hydrocarbon mixtures and Mineral oil mixtures are the substitutes marketed with various trade names. These components have their own advantages and disadvantages.

Local exhaust ventilation: The workplace can be modified to reduce the inhalational hazards by installing local exhaust ventilation with a proper hood. This is very effective in controlling the hazards because it removes the contaminant rather than diluting it. It should be in a fixed position, located close to the source of the hazard. A well-designed hood takes advantage of the natural movement of the contaminant. As the air moves through the duct, it creates friction against the duct walls. Friction is greater at the corners, bends and obstructions of the duct. The overall duct length should be kept as short as possible with as few bends as possible. Various types of air-cleaning devices can be used, like fabric filters, charcoal filters, cyclones, electrostatic precipitators and scrubbers.

Proper protective equipment: Personal hygiene practices and protective equipment reduce the amount of a substance that is absorbed by the worker’s body after he or she has been exposed to it and also prevent hazardous toxic chemicals from being carried home. They include

- Thoroughly washing hands and removing outer protective clothing before entering clean areas
- Usage of impervious clothing such as Buna-N-rubber or Viton gloves and impervious aprons
- A face mask or full-face organic respirator to reduce the inhalational hazards
- Safety goggles/face shields for eye protection
- Periodic medical examinations and biological monitoring of the worker’s body fluids to detect if the exposure to xylene is within limits.

Routine Observation: Xylene can be detected in the end-exhaled air, venous blood and the urine of exposed individuals. However, urinary levels of methylhippuric acid, a metabolite of xylene, appear to correlate better with airborne xylene concentrations than blood or breath concentrations of xylene. Determination of a worker’s exposure to airborne xylene is made using a charcoal tube (100/50 mg sections, 20/40 mesh). Samples are collected at a maximum flow rate of 0.2 L/min until a maximum air volume of 12 L is collected. The sample is then treated with carbon disulfide to extract the xylene. Analysis is conducted by gas chromatography using a flame ionization detector. This method has a sampling and analytical error of 0.10.

Emergency Procedures: In the event of an emergency, remove the victim from further exposure, send for medical assistance and initiate the following emergency procedures.
1. **Eye exposure:** If xylene or a solution containing xylene gets into the eyes, immediately flush the eyes with large amounts of water for a minimum of 15 min, lifting the lower and upper lids occasionally. Get medical attention as soon as possible.

2. **Skin exposure:** The contaminated skin should be washed with soap and water for at least 15 min. If irritation persists, get medical attention.

3. **Inhalation:** If xylene vapors are inhaled, move the victim at once to fresh air and get medical care as soon as possible. If the victim is not breathing, perform cardiopulmonary resuscitation; if breathing is difficult, give oxygen. Keep the victim warm and quiet until medical help arrives.

4. **Ingestion:** If xylene or a solution containing xylene is ingested, give the victim several glasses of water to drink. Get medical help immediately. Do not induce vomiting if the person is unconscious as it is associated with the danger of pulmonary aspiration.

**Discussion**

Xylene, a synthetic hydrocarbon produced from coal tar, is a widely used as a universal solvent. Various health effects due to xylene exposure have been documented in the literature. A number of theories exist for the mechanisms by which xylene exerts its toxic effects on the various systems of the body. The pulmonary, gastric, and ocular effects of xylene are attributed to the irritant nature of the chemical [1]. Some authors have suggested that certain metabolic intermediates such as methylbenzaldehyde may be responsible for the toxic effects of xylene. Inhibition of pulmonary microsomal enzymes by the binding of such toxic metabolites thereby inactivating the enzymes also might contribute to the toxic nature of xylene [10].

The mechanism of nephrotoxicity of xylene may be related to the reactive metabolite formation which subsequently causes irritation of the renal tissues or direct membrane fluidization [1, 10,11,12]. Padilla and Lyerly in their study have demonstrated a decrease in the axonal transport of stimuli following xylene exposure [13]. A decreased hypothalamic catecholamine levels following exposure to xylene has been observed by Andersson et al., [14,15].

Dermal absorption is also a major route of xylene exposure especially among the laboratory workers. Hino et al., has stated that workers with eczema of the hands had higher urinary methyl hippuric acids (xylene metabolite). He has attributed the removal of ceramide of the corneal layer of the skin epithelium thereby leading to the disruption of epithelial barrier to this exaggerated percutaneous absorption of xylene in such atopic individuals [16,17].

In case of oral exposure emesis with ipecac syrup could be done only when one is certain that there is no likelihood of aspiration thereby leading to aspiration pneumonitis [1, 18]. Ellenhorn and Barceloux have suggested the usage of activated charcoal in order to limit the absorption of the chemical in the intestines [1,19]. Sevcik et al., has performed haemodialysis and haemperfusion in order to hasten the removal of xylene from the body [1,20,21].

The biological exposure index of xylene according to ACGIH is 1.5 grams of methyl hippuric acid per gram creatinine in the urine of the exposed workers [22]. As the level of urinary methyl hippuric acid correlates to that of xylene exposure, steps should be taken to detect their levels in the urine of workers periodically. Increase in the levels of the urinary metabolite warrants the necessary steps to reduce their exposure [1,23].

In the field of medical technology histopathology technicians are occupationally exposed to xylene as it forms an integral part of pathological laboratory as a clearing agent of tissue samples. In recent years many researchers have identified xylene substitutes [22].

Ankle and Joshi have suggested the usage of diluted dish washing solution (DWS) to deparaffinise histopathological tissue sections [24]. Metgud et al., have done a study to compare the advantages of xylene free methods over conventional xylene during routine tissue processing. They concluded that such alternatives produced equally good histopathological results [25].

Kunhua et al., have suggested the usage of White oil No. 2 and 14% N-Heptane (SBO) as a novel non-toxic xylene substitute [26]. Premalatha et al., have reported that Mineral oil is a bio friendly substitute of xylene for deparaffinisation of histological sections [27]. Buesa and Peshkov have also highlighted the usage of vegetable oils and limonene based substitutes as clearing agents in the place of xylene [28, 29]. The introduction of such substitutes can help in circumventing the toxic effects of xylene [28-30].
Conclusion

Efforts to reduce the health hazards in the histology laboratories should be made to create a safer working atmosphere by making the histopathology technicians more familiar with the health hazards of xylene, safety measures and emergency procedures. The hazards of xylene are well documented, but the substitutes are not so thoroughly evaluated. Most of the less-expensive alternatives to xylene do not have the same miscibility with alcohol, wax and resinous mountants, and nearly all are sold under trade names without any obvious disclosure of the chemicals of which they are composed. The assumption that they are safe just because the manufacturer says so is ill advised. It may not be comforting to get exposed on a daily basis to large volumes of a product of unknown chemical composition and largely untested health effects. Usage of proper personal protective equipment and a decent fume hood prevents the hazardous effects of xylene. In view of the established adverse effects of xylene, the Indian Association of Occupational Hygiene should make a law to safeguard the histopathology technicians against occupational hazards.

ABSTRACT

With the emergence of multidrug resistance among clinical bacterial pathogens there is a growing need for the development of herbal alternatives for the effective therapeutic management of bacterial infections. Plants and plants products have long been used in traditional folk medicine worldwide. Hence this study was designed to test the antimicrobial efficacy of *Withania somnifera* L. Dunal. (root) against drug resistant bacterial pathogens. Extracts of *W. somnifera* (L.) Dunal (root) was prepared by cold percolation method. Antimicrobial activity of different solvent extracts of *W. somnifera* (L.) Dunal. (root) was studied against drug-resistant clinical isolates of Gram-positive cocci (vancomycin resistant *Enterococcus faecalis* and Methicillin resistant *Staphylococcus aureus*), and Gram-negative bacilli (ESBL *Escherichia coli* and *Pseudomonas aeruginosa*). The standard strains of ATCC 25922 *E. coli*, ATCC 25923 *S. aureus*, ATCC 27853 *P. aeruginosa*, and ATCC 29212 *E. faecalis* were used as controls. Antibacterial activities of extracts were evaluated using agar well diffusion method. Minimum inhibitory concentration was determined by microbroth dilution method. All the extracts (methanol, ethanol, acetone and chloroform) were inhibitory to gram positive bacteria tested. Nevertheless, inhibitory effect was pronounced in the methanol and ethanol extract, against Gram negative bacteria (Both ATCC and clinical strains). Further based on the phytochemical and GC-MS analysis, it could be speculated that the antibacterial activity exhibited by the methanol extract of *W. somnifera* root could be attributed to the presence of phenolic compounds, flavonoids, steroids and terpenes.

Keywords: Antibacterial efficacy, ESBL, *E. coli*, *Withania somnifera*, MRSA, VRE, *Pseudomonas aeruginosa*.

Introduction

Antimicrobial resistance is one of the greatest threats currently faced by the global community. With the emergence of multidrug resistance among clinical bacterial pathogens the therapeutic management of such infections are limited leading to increased morbidity and mortality1,2. Nevertheless, there is a substantial drop in
the discovery of newer antibiotics\(^3\). Plants and plants products have long been used in traditional folk medicine worldwide. As per the WHO report, nearly 70-95% of the people in the developing countries currently rely on traditional medicines for primary care\(^4\). A traditional system of medicine practiced in India, Ayurveda (a component of AYUSH) is primarily based on the plant extracts and other plant derivatives for the treatment of various ailments\(^5\). Hence, the exploration and evaluation of plant based potential antimicrobial compounds against drug resistant pathogens gains significance. The traditional way of testing the efficacy of herbal extracts on susceptible bacterial strains and standard strains becomes inappropriate. Hence, this study was designed to test the antimicrobial efficacy of plant extracts on drug resistant bacterial pathogens.

*Withania somnifera* (L.) Dunal. (commonly known as Ashwagandha, Indian Ginseng) belongs to the family Solanaceae. *W. somnifera* is widely cultivated in India and has long been used in traditional systems of medicine. Aswagandha is rich in alkaloids, (isopelletierine), steroidal lactones (withanolides, withaferins), saponins containing an additional acyl group (sitosterolides VII and VIII), and withanolides with a glucose at carbon 27 (sitosterolides IX and X)\(^6\)\(^8\). Withanolides are the main constituents of this plant, which is similar to the ginsenosides of Panax ginseng and hence called as Indian Ginseng. Among the Withanolides, withaferin A and withanolide D are known to possess the most biological activity. Various studies have proved the antioxidant, anxiolytic, memory enhancing, antiparkinsonian, antivenom, anti-inflammatory, hypolipidemic and antitumor properties of *W. somnifera*. Of note, *W. somnifera* extracts were reported to induce catecholamines and antioxidants, glutathione, glutathione peroxidase and hence is used in the treatment of various ailments including stress, anxiety, insomnia arthritis and neurodegeneration\(^7\)\(^8\). The antibacterial potential of *W. somnifera* root extract against bacterial pathogens has been reported by previous studies\(^9\)-\(^12\). Nevertheless, antibacterial potential of *W. somnifera*on drug resistant bacterial pathogens is yet to be explored. Hence, this study was designed to assess the antibacterial efficacy and the phytochemical constituents present in the root extracts of *W. somnifera*.

**Materials and Method**

The root of *W. somnifera* was shade dried and powdered; the active principles were extracted with different solvents with increasing polarity such as Acetone, chloroform, methanol and ethanol by cold percolation method. These solvents were evaporated to dryness using vacuum evaporator. The dry powder of the different extracts were dissolved in 10% DMSO\(^13\).

The extracts were screened for antibacterial activity against clinical isolates of ESBL-producing *Escherichia coli, Pseudomonas aeruginosa*, methicillin-resistant *Staphylococcus aureus* (MRSA), and vancomycin-resistant *Enterococcus faecalis* (VRE).

The resistant phenotype exhibited by the study isolates was confirmed by standard microbiological methods. According to the CLSI guidelines, ESBL production was confirmed by combined disc method using ceftazidime (CAZ): 30 μg; ceftazidime -clavulanic acid (CAC: 30 μg/10 μg) and cefotaxime (CTX: 30 μg); cefotaxime-clavulanic acid (CEC: 30 μg/10 μg) against clinical isolates of ESBL-producing *Escherichia coli, Pseudomonas aeruginosa*, methicillin-resistant *Staphylococcus aureus* (MRSA), and vancomycin-resistant *Enterococcus faecalis* (VRE).

The resistant phenotype exhibited by the study isolates was confirmed by standard microbiological methods. According to the CLSI guidelines, ESBL production was confirmed by combined disc method using ceftazidime (CAZ): 30 μg; ceftazidime -clavulanic acid (CAC: 30 μg/10 μg) and cefotaxime (CTX: 30 μg); cefotaxime-clavulanic acid (CEC: 30 μg/10 μg) against clinical isolates of ESBL-producing *Escherichia coli, Pseudomonas aeruginosa*, methicillin-resistant *Staphylococcus aureus* (MRSA), and vancomycin-resistant *Enterococcus faecalis* (VRE).

**Statistical Analysis**

Mean and standard deviation of the zones of inhibition were measured from the three sets of experiments in each case. One-way ANOVA was used to assess the statistical significance of the same.
Results

The results of antibacterial activity exhibited by various extracts of *Withania somnifera* (roots) against clinical isolates and control strains of Gram-positive and Gram-negative bacteria are depicted in Table 1. The MIC of the various solvent extracts is indicated in Table 2. GC–MS assay was also performed to find out and segregate potential compounds for the antibacterial activity [Figure 1]. GC-MS analysis revealed the presence of 66 phytochemical constituents (Table 3).

**Discussion**

The results of the agar well diffusion assay revealed that, the methanol and ethanol extracts of *W. somnifera* exhibited better antibacterial activity against MRSA compared to ATCC *S. aureus* (p=0.0048, p=0.0022). However, no statistical significance was found with regard to the antimicrobial activity of acetone and chloroform extracts against the standard and clinical strains of *S. aureus*. Also, methanol extract of *W. somnifera* was found to be exhibit pronounced antibacterial activity against MRSA compared to the ethanol, acetone and chloroform extracts (p=0.0031, 0.0011, 0.0053).

Ethanol extract of *W. somnifera* was found be effective against ATCC *E. faecalis* but not VRE (p = 0.0031). However, no statistical significance was found with regard to the antimicrobial activity of methanol, acetone and chloroform extracts against the standard and clinical strains of *E. faecalis* (p = 0.7677, 0.5185, 0.6434).

Methanol and ethanol extracts of *W. somnifera* was found be effective against ATCC *E. coli* and ESBL producing *E. coli* (clinical strain). Both the acetone and chloroform extracts did not possess antibacterial activity against both the standard and clinical strains of *E. coli* and *P. aeruginosa*. Interestingly, ethanol extract of *W. somnifera* was found be effective against drug resistant clinical isolate of *P. aeruginosa* compared to all the other extracts (methanol, acetone and chloroform, p=0). Our findings are in contrast with Alam et al., (2012) who had reported WSroot ethanol to exhibit pronounced antibacterial activity against *E. coli*, but not against *P. aeruginosa*.

Phytochemical analysis and GC-MS analysis of the methanol extract of *W. somnifera* (root) revealed the presence of steroids, triterpenes, phenolic compounds, saponins, tannins. Previous reports had documented the inhibitory potential of flavonoids against pathogenic bacterial species. The active constituents of root extract of *W. somnifera* is reported to be similar.
to that of the Asian ginseng (Panax ginseng) viz., steroidal lactones with ergostane, including withanone, withaferin, withanolides, withasomidieneone and withanolide C7. Mishra et al., 2007 has also documented the presence of withanolides, a steroidal lactone to be abundant in in the methanol extracts of W. somnifera roots. Terpenoids have been reported to possess a broad spectrum antibacterial activity. In line with these reports it could be speculated that the antibacterial activity exhibited by the methanol and ethanol extracts of W. somnifera root could be attributed to the presence of phenolic compounds, flavonoids, steroids, terpenes and withanolides.

Antioxidant compounds such as ascorbic acid, anthocyanin and polyphenols have been reported to exhibit antibacterial activities. These compounds are reported to cause hyper-acidification at the plasma membrane interface of the pathogen, which ideally alters ATP synthesis by the disruption of the H+ -ATPase. These antioxidants are also documented to initiate iron deprivation or hydrogen bonding with vital proteins such as microbial enzymes thereby inhibit microorganisms. Ascorbic acid, anthocyanin and polyphenols with antioxidant potential are reported to be vulnerable to polymerization in air through oxidation reactions and the polymerization size is known to govern their toxicity. Consequently, oxidized condensation of antioxidant compounds may result in the toxification of microorganisms. Jaleel, 2009 has reported the root of W. somnifera is a good source of both enzymatic and non-enzymatic antioxidants. Previous studies have confirmed the presence of ascorbic acid in the in the root extract of W. somnifera. In line with various studies, it could be speculated that the antioxidants ascorbic acid, anthocyanin and polyphenols in the root extract of W. somnifera might contribute to its antimicrobial activity against the drug resistant gram positive and gram negative pathogens tested in this study.

ABSTRACT

Diabetic Foot ulceration is one of the major devastating complication of diabetes. Diabetic foot ulcers (DFUs) infected with multidrug resistant bacterial strains is often associated with prolonged hospital stay, increased treatment cost, significant morbidity and mortality. DFU infected with Methicillin Resistant *Staphylococcus aureus* (MRSA) if untreated may lead to amputation.

Materials & Method: Type 2 diabetic Subjects (Mean age 56 years)(n=27) with infected foot ulcers were included in his study. After wound debridement, samples were taken from the base of the ulcer using sterile cotton swabs and nasal swabs were also collected from the study subjects and were processed as per standard Microbiological methods.

Results: The overall isolation rate of *S. aureus* in DFU was 18.5%. Among the *S. aureus* isolates screened for MRSA, all the isolates from the DFU ulcers (n=4) and those isolated from the nares (n=3) of the diabetic subjects were found to be MRSA. Of note, 3 of the study subjects in whom MRSA was isolated from the DFU samples were found to harbour MRSA in their nares. Nevertheless, all the isolates were susceptible to linezolid, netilillin, gentamicin and amikacin. No significant statistical difference was observed in the antimicrobial resistance percentage among the DFU and nasal isolates.

Conclusion: Our study results imply that, screening for MRSA colonisation would better predict a patient’s probability of MRSA infection and guide the clinicians in antimicrobial treatment decision making.

Keywords: Diabetic foot, MRSA, Methicillin

Introduction

Foot ulceration in diabetes is one of the most significant and devastating complication of diabetes and is a major medical, social and economic problem. Diabetic foot ulcers (DFU) especially those infected with multidrug resistant bacterial strains is often associated with prolonged hospital stay, increased treatment cost, significant morbidity and mortality¹. If not treated promptly, DFU can lead to amputation of the infected foot. *Staphylococcus spp* especially, *S. aureus* is the most common pathogen isolated from DFU, of which 15-30%
are reported to be Methicillin Resistant *Staphylococcus aureus* (MRSA)\(^2,3\).

Previous studies document that, patients with asymptomatic nasal colonization of MRSA may serve as potential reservoir for transmission of MRSA and are at higher risk of acquiring subsequent MRSA-associated infections\(^4,5\). Also, mean nasal carriage rate of MRSA in patients with insulin dependent diabetic is reported to be 56.4\(^\%\)\(^6\), thereby are at potential risk of acquiring MRSA-associated infections, especially DFU. Hence, this study was aimed to determine the prevalence of MRSA and antimicrobial susceptibility profile of MRSA isolated from diabetic patients with foot ulcers and to assess the risk of MRSA associated diabetic foot infection (DFI) among the MRSA nasal carriers.

**Materials & Method**

Type 2 diabetic Subjects (n=27, male (n=14): female (n=13) in the age range of 40-72 years (Mean 56 years) with infected foot ulcers were included in his study. Infection of DFU was diagnosed according to the criteria proposed by the International Consensus on the Diabetic Foot\(^7\). Wagner classification was used to grade the ulcers\(^8\). Wound swabs and nasal swabs were collected from the study participants who were admitted for management of DFU in a tertiary care centre in Chennai, South India. Demographic details were collected.

After wound debridement, samples were taken from the base of the ulcer using sterile cotton swabs and nasal swabs were also collected from the study subjects. Samples were transported to the Microbiology laboratory in ice. The samples were processed as per standard Microbiological methods\(^9\).

Gram positive cocci in clusters that were catalase positive were provisionally designated as *Staphylococcus* spp. Discrimination of *S. aureus* from Coagulase Negative *Staphylococci* (CoNS) was performed based on the results of the slide and tube coagulase test followed by selective isolation of *S. aureus* on Mannitol Salt agar. Antibiotic resistance profile of the staphylococcal isolates was determined by Kirby-Bauer method. Susceptibility to amikacin, gentamicin, cephalexin, co-amoxiclav, co-trimoxazole, tetracycline, erythromycin, ciprofloxacin, ofloxacin, norfloxacin, netillin, teicoplanin, linezolid as per CLSI guidelines\(^10\).

Screening for methicillin resistance was done using disc diffusion method, cefoxitin discs (30 µg) and oxacillin (5 µg) diffusion method and oxacillin agar (6 µg/mL) screening method (CLSI, 2018). Detection of vancomycin intermediate resistance *S. aureus* (VISA) was determined using vancomycin discs (30 µg). The minimum inhibitory concentration of oxacillin and vancomycin was determined by microbroth dilution method as per CLSI guidelines\(^10\).

**Results**

The isolation rate of *Staphylococcus* spp from DFU was 18.5\%, of which 80\% were *S. aureus*, while 20\% was found to be CoNS. Of the 27 diabetic subjects included in the study, nasal swabs were collected from 24 subjects. A total of 20 *Staphylococci* were isolated from the external nares, of which 17 (85\%) were found to be CoNS and only 3 (15\%) were confirmed as *S. aureus*.

Among the *S. aureus* isolates screened for MRSA, all the isolates from the DFU ulcers (n=4) and those isolated from the nares (n=3) were found to be MRSA. There was 100\% concordance in the results of cefoxitin disc diffusion method and oxacillin salt agar (6 µg/mL) screening method. All the MRSA isolates ((DFU (n=4), nasal (n=3)) exhibited resistance by both the methods. In our study, the MIC\(_{50}\) and MIC\(_{90}\) of oxacillin against MRSA isolated from DFU samples (n=4) and those from the nares (n=3) was found to be >128 µg/mL. None of the *S. aureus* isolates exhibited resistance to vancomycin. The MIC\(_{50}\) and MIC\(_{90}\) of vancomycin against *S. aureus* isolated from DFU samples (n=4) was found to be 0.5 µg/mL and 1 µg/mL respectively and those from the nares (n=3) was found to have MIC\(_{50}\) and MIC\(_{90}\) of 0.25 µg/mL.

Antibiotic resistance profile of the staphylococcal isolates is depicted in table 1. None of the *Staphylococcus* isolates were resistant to linezolid, netilin, gentamicin and amikacin. No significant statistical difference was observed in the antimicrobial resistance percentage among the DFU and nasal isolates.

### Discussion

In our study, *Staphylococcus* was the most frequent bacteria (18.5%), isolated from the DFU specimens of which a high proportion (80%) were *S. aureus*. Our results were in line with findings of previous studies that have reported *S. aureus* as the predominant pathogen isolated from DFU infections (63% (China\(^3\)), 41% (Salem, Tamil Nadu, India\(^11\)), 43% (in Karnataka, India\(^12\), 26% (Assam, India\(^13\)), 43.8% (in Taiwan\(^14\)), 16.47% and 11.8% (in Kenya\(^15, 16\)). Also, a single centre retrospective cohort study of DFU patients from 2010-2016 has reported *S. aureus* as the predominant pathogen associated with recurrent episodes (1-13 episodes) of DFU\(^17\).

The overall incidence of MRSA in our study was 18.5%. This is in line with previous studies that showed by a similar prevalence range of MRSA in DFU is 4-36%, (7% (Murali et al., 2014)\(^8, 7.7% (Benwan et al., 2012)\(^16, 17.9% (Sotto et al., 2012)\(^19, 19% (Sugandhik&Prasandh, 2014)\(^11, 24.1% (Lin et al., 2018)\(^14, 36% (Vu et al., 2014)\(^20, 43.2% (Zubair et al., 2011)\(^11). Also, previous reports have documented that a higher percentage of the *S. aureus* in DFU were MRSA, 63.4% (Tentolouris et al., 2006)\(^22, 60.5% (Shettigar et al., 2016)\(^12, 41% (Jain & Barman, 2017)\(^13. Herein, we report a still higher occurrence of MRSA among *S. aureus*(100%).

In our study, most of the *Staphylococcus* isolates were sensitive to linezolid (100%), netillin (100%), gentamicin (100%), amikacin (100%), teicoplanin (80%) which is in agreement with a recent Indian study\(^13. Of note, 3 of the study subjects in whom MRSA was isolated from the DFU samples were found to harbour MRSA in their nares. This is of clinical relevance as previous reports suggest increased probability of nasal colonisation of diabetic patients with MRSA increases the risk of MRSA in DFU. A recent Taiwanese study reported an overall nasal *S. aureus* carriage rate was 16.4% and nasal MRSA carriage rate was 2.8%\(^14.

MRSA nasal-swab screening is generally used for determining isolation precautions\(^23. In concurrence with the previous reports, our study results imply that, screening for MRSA colonisation at the time of admission (in case of hospital stay)/first visit (in case of outpatients) would better predict a patient’s probability of MRSA infection and guide the clinicians in antimicrobial treatment decision making and would eventually shorten hospital stay and medical costs\(^23, 33.

Eagle Syndrome: A Case Report

Melody Khwairakpam¹, Charumathi², A. Amudhan²

ABSTRACT

Eagle’s syndrome (ES) arises when an elongated styloid process or calcified stylohyoid ligament causes recurring throat pain or foreign body sensation, dysphagia, or facial pain. The additional signs may involve neck or throat pain with radiation to the ipsilateral ear. These symptoms and sign could be confused with those attributed to a wide variety of facial neuralgias. ES is diagnosed radiologically and by physical examination. The primary treatment of ES is surgical. Here we report a case in which the patient presented pain and difficulty during swallowing.

Keywords: Eagle syndrome, 3D imaging, tonsillectomy, neck pain.

Introduction

Eagle Syndrome (ES) or Stylohyoid syndrome is an uncommon pathology of the head and neck that creates orofacial pain. The pain is caused by the elongation of the styloid process and by the incomplete or total calcification of the stylohyoid ligament.¹,²

Eagle syndrome is an infrequent, clinical state caused by elongation of the styloid process or mineralization (ossification/calcification) of the stylohyoid ligament. The length of the styloid process is usually 2 to 2.5 cm and elongation beyond 2.5 cm causes Eagle syndrome that was first described in 1937.³ The diagnosis of ES is done by clinical and radiographic methods. Nevertheless, ES is commonly underdiagnosed due to its low prevalence and insufficient knowledge of craniofacial and cervico-pharyngeal syndromes. Furthermore, as its symptoms are miscellaneous, health professionals and patients tend to confuse this disease with other disorders.

Case report: A 38-year-old male patient named Mr. Subhramani M came to the outpatient department of Oral Medicine and Dental Radiology at Sree Balaji Dental College and Hospital, with a chief complaint of pain and difficulty while swallowing food. History revealed pain was insidious in origin, dull to moderate in intensity and intermittent in nature. The intensity of pain was exacerbated by movements such as looking up and turning face to the left side. In addition, the patient also had a sensation of a foreign body in the throat on swallowing. On correlating the chief complaint, history of presenting illness a provisional diagnosis of “Cervicofacial Lymphadenitis” was given. On radiographic examination, Orthopantomogram demonstrated excessively ossified styloid processes bilaterally (Fig 1). The patient also underwent a CT 3D reconstruction imaging which showed a heavily ossified styloid process extending from the base of the skull antero laterally and caudally to the level of hyoid bone on both sides, which measured 6.7 cm on the left side and 6.1 cm on the right side, suggestive of Eagle’s syndrome. (Fig 2)

Figure: OPG shows an increased length of the styloid process in both right and left side.
Discussion

The prevalence of abnormal styloid process length in the general population is around 4% and it is even higher if calcification of the stylohyoid complex is also considered. Normally, it is an asymptomatic condition. Just 4% of all patients with an abnormal styloid process’ length are symptomatic, meaning the incidence of Eagle syndrome is around 0.16% among global population. Most studies report a length of 25–30 mm as normal for a styloid process. Depending on the clinical features, the Eagle syndrome can be illustrous into two types i.e. the classical and the stylocarotid type. The first type involves history of pharyngeal trauma or tonsillectomy. This type has been related to fibrous or scar connective tissue enmeshed of 5th, 7th, 9th & 10th cranial nerves. In contrast, the stylocarotid forms associate to condensation of the internal and external carotid arteries as well as a stimulation of the perivascular sympathetic fibers. The pain manifests a similar distribution to the course of the carotid vessels, aggravate during different head movements, correspond with a syncopic event, aphasia, irradiates into the infraorbital and parietal area, while both tonsillectomy and neck trauma are typically absent from the patient’s history. ES can be managed by both surgical and nonsurgical means. Nonsurgical treatments require supportive counseling to the patient, analgesics, and steroid injections. Surgical management can be done using transpharyngeal or extraoral method. The latter is thought to be superior because it is less likely to cause deep space infection of the neck.

Conclusion

Eagle syndrome is a complex disorder requiring detailed knowledge of its signs and symptoms to make the right diagnosis and give a suitable succeeding treatment. It can be erroneous for many alternative conditions that must be excluded. Knowledge regarding pain syndromes associated to styloid process is essential for all health professionals involved in the diagnosis and management of neck and head pain to rationalize the line of management.

ABSTRACT

Keratocystic odontogenic tumors (KCOTs) are called for their disputed peculiar characteristics, varied origin, unique propensity to recur, disputed treatment methods and can occur anywhere in the jaw, but mainly seen in the posterior part of the mandible. On radiographically, it present, as well-defined radiolucent lesions with smooth and generally corticated margins. They are benign intraosseous tumors of odontogenic origin that occur most mainly in the jaw. The average reported recurrence rate ranges from 30 to 62 present.

Keywords: Keratocyst, Odontogenic, Molar, Ramus

Introduction

An odontogenic keratocyst, which was one, considered as a third most common odontogenic cyst and is replaced by a new term, i.e., “Keratocystic odontogenic tumor”. In 2005 WHO the term as a KCOT due to its tumor nature. and defined as “a benign unicystic or multicystic intraosseous tumor of odontogenic origin, with a characteristic lining of parakeratinized stratified squamous epithelium and potentially aggressive, infiltrative behavior."¹² It is considered as tumor because of following three reasons, i.e. behavior as report before, the KCOT is locally destructive and mostly recurrent, histopathology studies showed the basal layer of the KCOT budding into connective tissue along with mitotic figures in the suprabasal layers and the presence of a tumor suppressor gene- PTCH (patched)³ and multiple KCOTs may present as one of the stigmata of the inherited NBCCS. It is also known as Gorlin syndrome.⁴

Case report: A 27-year-old female had come to the hospital, with a chief complaint of an abnormal finding during the Orthodontic examination of OPG. History revealed that the patient consulted an orthodontist for treatment of malocclusion. The OPG radiograph revealed an abnormal finding for which she was referred to an oral physician. On extraoral inspection, revealed that there was no facial asymmetry or evidence of swelling, ulceration, and sinus tract and fistula formation over the cheek and on palpation, it was non-tender. On intraoral examination, there was no evidence of swelling in alveolar mucosa in relation to 38, 37. On palpation, it was non-tender, obliteration and expansion of the buccal cortical plate were noticed. Based on the OPG radiograph features a provisional diagnosis of Benign Odontogenic cyst/tumor of the left mandible.

Investigation: Routine blood investigations revealed normal values. An intraoral periapical radiograph (IOPA) revealed a radiolucency in relation to 37, 38 extending to the anterior border of ramus posteriorly. Superiorly extending from the alveolar ridge corresponding to 37, 38 teeth region. (Fig: 1) The mandibular occlusal radiograph revealed normal anatomic landmarks in relation to 34, 35, 36, 37, and 38 with the mild expansion of the cortical bone. (Fig: 2) The site of the lesion was present in relation to the left side of ramus and posterior body of the mandible which was approximately 4 x 2cm in size and oval in shape, extended from the mesial, root of 37 in the periapical region to the posterior of the ramus of mandibular, periphery was well defined corticated border, smooth in margin, internal structure was completely
radiolucent and the effect on surrounding structure was destruction pattern of bone and the mandibular canal was pushed downward. No evidence of root resorption. (Fig: 3) **CT facial bones,** Coronal view reveals an expansile osteolytic lesion measuring approximately ~4.5 x 1.7 cm involving the angle and the body of the left mandible (HU-26) and mild cortical thinning seen at the region of the angle of the mandible. (Fig: 4) Incisional biopsy and aspiration were done under local anesthesia on the left retromolar area a bony window was created of cystic lining were taken. The microscopic examination revealed cystic lining epithelium with underlying connective tissue stroma, the lining epithelium is 4-6cell layer thick(Fig: 5) and of the parakeratinized stratified squamous type with palisading basal cells and numerous keratin fleck seen within the lumen. (Fig:6)The connective tissue is densely collagenized with diffuse mild chronic inflammatory cell infiltrate and mild vascularity is noticed. Based on clinical, radiographic and histopathologic features a final diagnosis of Keratocystic Odontogenic tumor on the left side of the mandible in relation to the 38, 37 teeth region was given.

Discussion

OKC is one of the common aggressive odontogenic cysts owing to its comparatively high recurrence rate, frequently seen in the second and third decades. The typical clinical features involve a likely for local destruction and a propensity for multiplicity, mainly when the lesion is related with nevoid basal cell carcinoma syndrome or Gorlin-Goltz syndrome. In inclusion to multiple KCOTs, nevoid basal cell carcinomas, multiple epidermoid cysts, bifid ribs, calcification of the falx cerebri, frontal bossing, also identify NBCCS and medulloblastoma. It may be found in the population, which ranges in age from infancy to old age. There is a slight male predilection. Literature review suggests, mandible is involved in 60%–80% of cases, with a noticeable tendency to involve the posterior body and ascending ramus of mandible. Toller (1967) recommended that epithelial linings of OKCs had inherent growth possible and was the first to propose that there was at least support for concerning them as benign neoplasms. Later, Ahlfors et al. (1984) also proposed that OKC should be considered as a benign cystic neoplasm because of its distinctive features like local destruction and high recurrence, the basal layer of the OKC (KCOT) showed budding into connective tissue and inactivation of PTCH (“patched”), a tumour suppressor gene, which is also seen in NBCC. The patients with OKCs may also complain of pain, swelling or discharge and rarely involve with paraesthesia of the lower lip. Some are unaware of the lesions until they reach a large size or formed pathological fractures. In cases, some OKCs may be determined unexpectedly during the radiographic inspection. In many cases, patients are astonishingly free of manifestation as far as the extent of the cyst to a large size. Nonetheless; at least half of all lesions are come to know as incidental radiographic findings. Due to the tendency of OKCs to grow inside the medullary bone, they can become very large without causing, any clinical signs or symptoms. In the present case there was no pain and discharge was present. In the present case there was no pain and discharge was present. OKCs appear as small, round or ovoid, radiolucent areas with clear sclerotic margins and many are unilocular radioluencies with a smooth periphery. Some of the unilocular lesions have scalloped margins and are misinterpreted as multilocular lesions. The curved internal septa may be present in some cases giving the lesion a multilocular characteristic and may be misdiagnosed as ameloblastoma but the later has a soap bubble or honeycomb pattern. When in a pericoronal position a KCOT may be identical from a dentigerous cyst. The lesion is likely to be a KCOT if the cyst outline is related to the tooth at a point apical to the cementoenamel junction. On histopathology, the epithelium appears 6 to 8 cell layers with wavy parakeratotic epithelial cells; report as corrugated parakeratinized epithelium. The basal layer appear palisade hyperchromatic columnar to cuboidal cells frequently report as “picket fence” or “tomb-stone” characterize with keratinaceous substance in the cystic cavity. Morgan and colleagues classify the surgical treatment technique for KCOT as conservative which involve enucleation, with or without curettage, or marsupialization which maintain the anatomical structures, but have a chance of higher recurrence rate and aggressive treatment which involve peripheral ostectomy, chemical curettage with Carnoy’s solution or en-bloc resection. Some current studies have shown a feasible treatment method for KCOT, such as cyclopamine, a plant-based steroidal alkaloid, which prevents the cellular response to the sonic hedgehog (SHH) signal activity. Zhang et al. suggested that antagonists of SHH signaling factors could successfully treat KCOTs. They recommend that the intracystic injection of a smoothened (SMO) protein antagonist have the greatest potential as a future treatment option. The average reported recurrence rate ranges from 30% to 62%. The presence of residual epithelium after the treatment is one of the contributing parts of the high recurrence rate. KCOT linings are very thin and brittle and so more hard to enucleate than cysts with thick walls. A long-term follow up of 5-10 years is suggested. In some KCOT, linings may have the features of epithelial dysplasia or show characteristics of ameloblastoma. Tumors with such characteristics infrequently develop into squamous cell carcinoma or ameloblastoma.
Conclusion

KCOT is a main odontogenic tumor with neoplastic nature. The complete clinical and radiographic examination together with histopathological investigations should be done. However, with suitable and advanced imaging modalities, we can strongly suspect this entity, and they help us in selecting the necessary treatment protocol, as it is an aggressive tumor.

ABSTRACT

Vascular anomaly is the term used to implicate various vascular pathology, including proliferating vascular tumors and vascular malformations.

Vascular malformation of the parotid gland is a rare condition where very few cases have been reported in the literature. The clinical and radiological features of vascular malformations often mimic those of other pathologic entities, causing diagnostic confusion. Furthermore, the imaging appearance of low flow and high flow vascular malformations can vary, making the diagnosis challenging. Here we report a case of a 40 years old, female who presented with the complaint of swelling in the left parotid region for one year. Imaging revealed a vascular malformation involving the left parotid gland. Superficial Parotidectomy was planned

Keywords: Vascular Malformation (VMs), Hemangioma, Parotid gland.

Introduction

The benign salivary gland tumor most commonly pleomorphic adenoma involving the parotid gland is usually reported in clinical practise and to find a case of vascular malformation involving parotid gland is rare. The common term used for both tumors and vascular malformations is Angioma¹. In 1996 the International Society for the Study of Vascular Anomalies (ISSVA) classified vascular anomalies into two main groups: proliferating vascular tumours (haemangiomas) and vascular malformations. Vascular malformations are further classified into low and high blood flow groups and complex combined groups. These classification had improved the management and treatment options for various vascular anomalies which are distinct from each other². Vascular tumors are either benign or malignant and Vascular malformations may be lymphatic, capillary, venous, arteriovenous malformations or arteriovenous fistula. Venous malformations (VMs) are the low-flow vascular malformation composed of vascular channels with estimated incidence rate of 1 in 10000³,4.

Capillary and lymphatic malformation are also part of low flow vascular malformation⁵. Here we report a case of low flow vascular malformation involving left parotid parenchyma. It is important to make a radiological diagnosis before performing FNAC, surgical resection in these cases to avoid complications⁶. Interventional radiology plays an important role in diagnosing low flow vascular anomalies over conventional USG.

Case Report: A 40 year old female patient reported to the out patient department with painless swelling in the left side below the ear for 1 year which occurred spontaneously and gradually increased to attain the present size (fig 1). The swelling was increased on tilting the face towards the left side (Turkey Wattle Sign). On physical examination the swelling was soft, non tender, afebrile, compressible, fluctuant and the margins were ill defined. Surface was smooth and the skin over the swelling was pinchable with no visible pulsations. No other secondary changes were present. There was no associated lymph adenopathy. Ultrasonography (USG)
revealed large cystic lesion containing few specks of ring calcification. The cystic spaces show particulate matter with Brownian movement suggesting fluid/abscess (fig2). But the Doppler ultrasound failed to demonstrate high-flow vessels in and adjacent to the mass and did not show any positive Doppler shift. Following this Computed Tomography (CT) was done which showed a moderately defined 5.8*3.8cm sized heterogenous soft tissue density lesion with multiple nodular calcifications, few showing central lucencies suggestive of phleboliths is seen replacing most of the left parotid gland (fig3). Following this contrast was injected in to a vein in the arm and post contrast CT images revealed progressive enhancement of lesion with pooling of contrast in delayed images and no significant washout(fig4 b)

The radiological diagnosis was given as low flow vascular malformation involving left parotid parenchyma. Patient was planned for Superficial Parotidectomy.

Discussion

Vascular lesions has been in discussion for many years and understanding these anomalies is still a challenge to the clinicians. Vascular tumors (hemangioma) refers to cell proliferation are distinguishable from vascular malformation which occurs due to altered vascular morphogenesis. Vascular malformation of parotid gland is a rare condition and the frequency has been 0.5% for Bears et al, out of 760 parotid tumors and at 0.6% for Byars et al, who had reported 460 cases of parotid tumors. There was a marked female predilection in most of the studies by Achache M et al.

Vascular malformation are painless, with no associated symptoms and patients usually complaints of facial asymmetry due to swelling. A typical characteristic feature noted is ‘Turkey wattle sign’ which demonstrates enlargement of facial mass on dependency of the head.

Although clinical diagnosis can be made, surgical intervention demands accurate radiological diagnosis. As a part of radiological investigation USG, plain and contrast enhanced CT was done. Although USG showed cystic lesion with ring calcification, that demonstrates particulate matter with Brownian movement suggesting fluids/abscess but it did not show positive Doppler shift failing to indicate a vascular lesion. Sixteen percent of VMs have minimal or no flow, that might reflect very low flow below detectable limits and a possible cause of diagnostic confusion.

USG is less sensitive in diagnosing vascular anomalies and is useful during the proliferative phase and Doppler ultrasound typically demonstrates high flow vessels surrounding the mass.
Plain CT images showed heterogeneous soft tissue density lesion with nodular calcification suggestive of phleboliths and progressive enhancement of lesion with pooling of contrast was seen in delayed contrast image than immediate contrast image indicating a low flow vascular malformation of left parotid parenchyma. CT is the choice for identifying phleboliths and when the concern involves bony invasion. Though Doppler ultrasound can provide adjuncts for the evaluation of VMs it cannot be used as an effective diagnostic tool in diagnosing low flow vascular malformation. The primary imaging modality of vascular malformation is contrast CT and MRI.

Conclusion

The aim of the treatment is to prevent bleeding, preserve and restore functions and to improve cosmesis. Treatment options are laser, cryotherapy, embolization. Despite improved imaging modalities cure rate continues to be suboptimal for vascular malformations. This probes for further research for improving management of VMs.

Implant Dislodgement into the Maxillary Sinus: A Review Literature

Vijay Ebenezer¹, Balakrishnan Ramalingam²

¹Professor and Head of the Department, ²Professor, Department of Oral and Maxillofacial Surgery, Sree Balaji Dental College and Hospital, Bharath University, Chennai, Tamilnadu, India

ABSTRACT

Background: Displacement of dental implants into the maxillary sinus is rare, but it primarily occurs in patients with severe pneumatization of the maxillary sinus and/or deficiency of the alveolar process. Some complications such as the infection of the paranasal sinuses and formation of the oroantral fistula can be followed by the displacement of a dental implant. Therefore, the displaced implant has to be removed immediately with surgical intervention show and another plan for rehabilitation should be considered.

Main body: The conventional procedure for the removal of a displaced implant from the maxillary sinus involves sinus bone grafting and new implant placement performed in two or more steps with a significant time gap in between. Simplification of these surgical procedures can decrease the treatment duration and patient discomfort.

Conclusions: In this review, we discuss the anatomical characteristics of the maxillary sinus and the complications associated with implant displacement into the sinus.

Keywords: Dental implant displacement, Maxillary sinus, Simultaneous treatment

Introduction

Severe maxillary sinus pneumatization and thin residual alveolar bone can lead to the displacement of dental implants into the maxillary sinus during placement or after prosthetic restoration. Biting forces on the implant prosthesis and surrounding structures can also result in displacement of the implant. Displacement can occur more often in patients who undergo simultaneous implant placement and bone grafting after sinus elevation [¹]. Another factor is the decreased height of the residual alveolar bone, in particular implant placement in bone with a minimal height of less than 4 mm with simultaneous bone grafting through sinus elevation [²]. Galindo et al. stated that differences in the air pressure between the maxillary sinus and nasal cavity and an autoimmune reaction to dental implants, which causes bone resorption due to peri-implantitis, can also result in implant displacement [³]. Other influencing factors include the lack of the primary stability, the surgeon’s lack of experience, temporary denture usage without relieffordrilling, and the inappropriate application of force during the removal of nonintegrated implants [⁴]. Immediate removal of displaced implants is usually recommended. However, when the removal is delayed, the sinus infection needs to be controlled by antibiotics and nasal decongestants before removal of the implant using Caldwell-Luc approach or an endoscopic technique [⁵]. After removal of the displaced implant, implant placement with bone grafting can be performed stage by stage. However, this conventional approach is extremely long and delays appropriate rehabilitation of the edentulous area. In this review, we discuss the anatomical characteristics of the maxillary sinus, conventional approach for the removal of displaced...
implants from the maxillary sinus, and complications associated with implant displacement and describe a simplified treatment process for the removal of displaced implants with simultaneous sinus bone grafting and new implant placement.

Discussion

The maxillary sinus is a pyramid-shaped cavity lined with mucoperiosteum-containing cilia. The base is at the lateral nasal wall and the apex is toward the zygomatic bone and zygomatic arch. The maxillary sinus is connected to the nasal cavity through the maxillary ostium, which is an opening into the nasal cavity. This opening is relatively far from the floor of the maxillary sinus. The mucoperiosteal lining of the maxillary sinus is known as the Schneiderian membrane, which is approximately 1.0-2.0 mm thick. The posterior superior alveolar nerve and vessels usually pass through the maxillary sinus, and the average distance from the nerve to the crestal ridge of the alveolar bone is 16.9 mm [6–8]. The maxillary sinus in adults measures 25–35 mm in width, 36–45 mm in height, and 38–45 mm in length [8]. As time passes after the loss of maxillary teeth, the maxillary sinus generally expands to fill in the space through resorption of the alveolar bone. This so-called pneumatization caused by basal bone loss due to reinforced osteoclastic activity in the maxillary sinus membrane [9, 10] can lead to perforation of the maxillary sinus membrane. The other most common factor that contributes to perforation of the sinus membrane is the presence of septa, which exhibits an incidence rate of 31.7% for the premolar region. Complications associated with dental implant displacement into the maxillary sinus may be an intraoperative or postoperative complication. The displaced implant can disturb the anatomy around the maxillary sinus and inhibit mucociliary clearance by the cilia in the sinus membrane. Furthermore, mucosal thickening may occur, and scattered bone graft material may obstruct maxillary ostium to result in maxillary sinusitis and congestion. In the event of maxillary sinusitis and blockage of the ostium, an oroantral fistula can develop. Alberto et al. described that accidentally displaced implants can also migrate from the maxillary sinus to the upper structures such as the paranasal sinuses, orbital floor, or cranial fossa through mucociliary clearance against the force of gravity, changes in the air pressure of the nasal cavity, a foreign body reaction, and local tissue necrosis. Some studies have described that implants displaced into the maxillary sinus may not result in maxillary sinusitis. [11, 12] Galindo-Moreno et al. reported two cases of antral implant migration. The migrated implant that had been left behind on request of the patient showed no signs of clinical complications at 4-year follow-up visit. On the other hand, [13] Regev et al. and Raghoebar et al. suggested that the displaced dental implants in the maxillary sinus result in chronic maxillary sinusitis because of a foreign body reaction and need to be eliminated through surgical intervention, even if the patient is asymptomatic. Treatment modalities for a compromised maxillary sinus containing displaced dental implants as aforementioned, the basic principle is immediate removal of the displaced implant. However, when removal is delayed, the sinus infection should be controlled at the patient’s first visit. To prevent mucosal thickening and maxillary sinusitis, amoxicillin with clavulanate and nonsteroidal anti-inflammatory drugs need to be prescribed with pseudoephedrine hydrochloride for 1 week before surgery. Initially, management strategies for displaced dental implants in the maxillary sinus included the Caldwell-Luc procedure and conservative observation in the absence of signs or symptoms. Lately, minimally invasive maxillofacial surgery is preferred, with functional endoscopic sinus surgery (FESS) and conservative intraoral surgery with the formation of a bony window in the lateral wall of the maxillary sinus being representative procedures. Tsiodoulos et al. reported a case involving a patient who was operated under general anesthesia using a minimally invasive approach. A small rectangular bony window in the lateral wall of the maxillary sinus was created under direct vision. After the removal of the displaced implant from the maxillary sinus, the removed bony window was repositioned at the end of the surgery as it was guided by holes and stabilized by absorbable sutures. Nogami et al. reported a case involving a patient who was operated under local anesthesia. Four holes were created and osteotomy was performed using piezoelectric instruments. Following removal of the bony fragment, the displaced implant was identified with rigid endoscope and removed by dental suction. The bony fragment was repositioned and fixed with absorbable sutures. Subsequently, shorter and wider implants (by 1–2 mm) can be placed with or without sinus bone grafting after confirmation of the residual alveolar bone height and width on cone beam computed tomography images obtained 4–6 months later. In the most of the reported
studies mentioned above, removal of the displaced implant, sinus bone grafting, and new implant placement were divided into two or three individual procedures. Delayed implant placement is usually indicated when primary stability cannot be obtained or when extensive perforation of the sinus membrane or severe sinus infection is present. However, these divided procedures delay rehabilitation of the edentulous area.

**Conclusions**

Dental implants displaced into the maxillary sinus should be removed immediately. However, immediate removal is occasionally not possible because of the patient's condition or the dentist's lack of technical experience. In such cases, maxillary sinusitis should be controlled with proper measures, including antibiotics and nasal decongestants, before surgical intervention. Subsequently, implant removal and simultaneous new implant placement with sinus bone grafting can be performed through an extended bony window. This new approach decreases effort, time, and patient discomfort and accelerates the rehabilitation process.

The Correlation between Corrosion and Dental Implant Failure—A Review

Vijay Ebenezer

Professor and Head of the Department, Oral and Maxillofacial Surgery Department, Sree Balaji Dental College and Hospital, Pallikaranai, Chennai

ABSTRACT

The commonly used replacement for natural teeth are the titanium dental implants. In spite of many advancement in composition, methods, and structural design, implant failure is a also significant concern for the operating personnel and patient. The lack of Osseo integration is considered to be the major factors leading to the failure of implant. The Occlusal overload, compromised systemic status of the patient, smoking, and implant characteristics are among the other major causes for implant failure. The purpose of this condensed review is to discuss whether corrosion has to play a role in the failure of a dental implant.

Keywords: corrosion, occlusal load, surface roughness.

Introduction

The history of the dental implant goes back to 3000 B.C., to the period when the ancient Egyptian civilization prospered. In this book, we will cover the history of dental implants from the time of Allen’s report, which in 1687 was the first to mention dental replantation and transplantation, and from the 1800s, the period where the practice of modern surgery started, along with the concepts of sterilization and disinfection[10,11]Dental implants in modern odontology, which has become an important option for the replacement of missing single teeth in partially or totally edentulous patients, with very good success rates. Despite complications associated with treatment with implants may occur, and failure can be divided into mainly two categories: early failure, which occurs before the prosthetic phase of treatment takes place and is mainly related to surgical problems that occur during implant placement; and late failure, which can arise from pathologic events involving an implant that has already Osseo integrated[7,8].

Review of Literature

To study the various causes of implant failure by focusing on whether corrosion occurs and if that plays a role in the failure of dental implants thereby giving a foresight on how to handle implant failures (6, 9). Implant failure is caused by many such factors which include perimplantitis, absence of Osseo integration, and implant fracture. It may also be invoked due to operative trauma, micro motion, and overloading. Over the years, many classifications of Implant failures have been proposed by various authors. Till date, no study has suggested the presence of corrosion in any implanted patient and no case of implant failure has been mentioned because of the same (4, 5).

Case Selection and Failure Prevention: The primary regulation is to be filter in selection of cases. Analyze the case completely in a specific manner in accord to the patient’s medical history, and do not involve a very obvious method of treatment as different individuals may need altered treatment criteria as to their separate medical wants (4, 5).

The Working Classification: Working classification classifies implant failures mainly into early and late failures. They are further classified based on etiology, personnel responsible, failure mode, and biological causes (9,8).
Early Failure of Implant: Early failures may occur very soon following placement of implants in the alveolar bone which is between a few weeks to months. They interfere with the healing process or cause altered Healing(6,7).

Etiology of Early Implant Failure:

Implant selection: improper Implant type or bone type, length and diameter of implant, surface impurity, and surface roughness. Surgical placement: off axis placement, lack of initial stabilization, overheating of bone, minimal space between implants, and contamination of implants during placement. Restorative problems: Improper design, occlusal scheme, improper fit, excessive loading, implant fractures. Improper design of prosthesis, Lack of Osseo integration(11,12).

Etiology of Late Implant Failure: Systemic factors diabetes, arthritis, obesity, and osteoporosis. Tissue abuse: smoking, para functional habits, alcoholism, Radiotherapy. Also functional and psychological problems and infections like retrograde perimplantitis(10,11).

Biological Causes of Early Implant Failure: Infections: retrograde perimplantitis, due to traumatic, occlusion, overloading.

Post Operative Care And failures: After successfully placing the implant, it is the patient’s duty to take care of its maintenance in the oral cavity. Inadequate postoperative care, carelessness in maintaining oral hygiene leads to infection in the implant site causing perimplantitis. More bone resorption was noted around fixtures in edentulous patients with poor oral hygiene than in participants with good hygiene (Lindquist et al. 1988).[28] This proves that in addition to surgical precision, personnel involved in its procedure and maintenance are responsible for the fate of implant(3,4).

Conclusion

An implant failure can be of more than one reason. More than a single cause may lead to failure of implant finally. As the dental implants placed are made of titanium, no amount of corrosion has been reported and it has been found that titanium implants are biologically safe. All operating surgeons need to find the necessity to correct the ongoing condition. Accurate data segregation, patient opinion and narrative, and accurate diagnostic instruments will assist in pointing out the reason for the failure of the implant(9,10). An early diagnosis and intervention is always possible if regular patient reviews are undertaken. The treatment option for complications and failing implants is decided by the routing of the actual etiologic causative factor, thus a diagnosis is established and possible etiologic factors identified, the causative agent should be determined and treatment attempted as soon as possible(1,2).

Thus it can be concluded that corrosion does not play any relevance in the failure of dental implants.

Osseointegration of Dental Implants Placed in Free Fibula Graft

Vijay Ebenezer¹, Balakrishnan Ramalingam²

¹Professor and Head of the Department, ²Professor, Department of Oral and Maxillofacial Surgery, Sree Balaji Dental College and Hospital, Bharath University, Chennai, Tamilnadu, India

ABSTRACT

Objective: The aim of this article is to review survival/success rate of dental implants inserted in vascularized free fibula grafts.

Background: Placement of dental implants following mandibular reconstruction during ablative surgery using vascularized free fibula grafts has proved to be a successful technique to achieve good mastication and complete dental rehabilitation. Insertion of implants into the new mandible provides a better access to the bone, interdental relationships are easier to assess, and oral rehabilitation can be acquired in a short span of time.

Result: Study design, treatment methods, follow-ups, defect location, and morphology varied among studies. A definite conclusion could not be reached. Future studies with long-term follow-ups are required.

Conclusion: Osseointegration of dental implants is a relatively safe technique with minimal complications. Patient selection plays a vital role, dental implants may be placed primarily, thus reducing the time to oral rehabilitation. Vascularized fibula grafts are a suitable method of mandibular reconstruction and are amenable to be successful in both primary and secondary endosseous implantation.

Keywords: Free fibula; dental implantation; osseointegration

Introduction

The free fibula osteoseptocutaneous flap is the most preferred for reconstruction of composite mandibular defects. Osseointegration in these has proven to be advantageous. Primary osseointegration of dental implant in these has yielded a better results when compared with the placement of implants in the native mandible. Further more elaborate studies are required to find out the specific indications for osseointegration in patients with malignant oral tumors and in those patients who have undergone radiation therapy.

Segmental mandibulectomy is most often preferred in disease or trauma of the mandible and requires vascularized bone grafts such as fibula free flaps to restore the natural arch of the mandible.¹ ² ³ The fibula has become an important donor site to reconstruct larger mandibular defects as well as to provide enough bone bulk for dental implantation.

Dental implantation used for oral rehabilitation results in improved function by allowing the patient to masticate using an implant-supported fixed prosthesis. Improved lip support and oral competence could be achieved thereby overall patient aesthetics was enhanced.

Materials and Method

A PubMed search was performed from 1990 to 2016 limited to English language and human studies. Studies that reported treatment outcome of implants inserted in vascularized free fibula grafts were included. Primary search identified 220 studies. Variables based on which selection of patients was made are, the pathological nature of the mandible and perioperative radiotherapy,
preoperative determination of soft-tissue and bone requirements, number of osteotomies, rigid fixation method, must be considered for adequate surgical planning and to achieve good outcome.

Discussion

Significant functional and cosmetic deformity are observed in patients undergoing segmental mandibulectomy. Reconstruction with free fibula restores the natural contour of the mandibular arch and recreates the aesthetic mandibular border. The fibula free flap has sufficient bone width and height for large segmental mandibulectomy defects and support osseointegrated implants.

Granulation tissue and soft-tissue overgrowth near dental implants was the most common untoward event. This has also been described in prior reports. The survival outcomes and rates of implant-supported prosthesis use were similar in those implanted primarily and secondarily.

The effects of irradiation on the outcomes of dental implants remain controversial.

Sclaroff et al evaluated the effects of radiation on 22 patients undergoing primary dental implantation of fibula and iliac crest grafts and found no significant differences between those who received radiation therapy and those who did not.

On the other hand, when comparing 22 irradiated and 22 nonirradiated patients, Salinas et al did not find that irradiation exposure affected implantation success rates that were receiving radiation treatment after the fibula free flap. Therefore, a minimum wait period of 6 months after irradiation to place dental implants.

The timing of implantation remains controversial. In properly selected patients, primary implantation allows for better access to the grafted bone to be implanted, eliminates a second operation to place the implants, and allows for oral rehabilitation in a shorter time.

Urken et al first reported primary dental implantation in 9 patients. They concluded that dental restoration provides an additional step in the rehabilitation of patients undergoing oromandibular reconstruction.

Wei et al described their experience with patients undergoing primary dental implantation but cautioned that patient selection is important when considering a primary implantation approach. The timing of implantation becomes clinically important when considering the potential decreased life expectancy of those undergoing such procedures for oncologic reasons. The overall time from segmental mandibulectomy to complete dental rehabilitation with an implant-fixed prosthesis was decreased by nearly half in those implanted simultaneously compared with those implanted in a delayed fashion.

Chiapas et al raised the concern of fibula graft position as it relates to the native mandible. Since the fibula has a shorter vertical height than the native mandible, it has to be placed either at the lower border of the mandible, which improves cosmesis, or at the upper border of the mandible, which decreases implant height. Placing the graft at the lower border of the mandible offers good aesthetic results for facial contour.

Some authors have performed “double barrel” reconstruction, while others placed the fibula graft in between and filled the lower mandibular border with soft tissue to accomplish both goals.

Conclusions

Vascularized free fibula bone grafts provides a firm basis for the placement of dental implants in jaw reconstruction. Implants placed in fibula bone grafts were shown to integrate normally. The double-barrel technique, or increasing the height of the fibula flap by vertical distraction osteogenesis before implant placement in the mandible, is desirable from a functional and esthetic point of view.

Osseous Coagulum in the Placement of Immediate Implant

Vijay Ebenezer

Professor and Head of the Department, Oral and Maxillofacial Surgery Department, Sree Balaji Dental College and Hospital, Pallikaranai, Chennai

ABSTRACT

Loss of tooth causes more of a psychological trauma to the patient than functional loss, particularly if the tooth loss is in the aesthetic segment. Traditional protocols suggested a consolidation period of 3-4 months before placing dental implants. Immediate implant placement, defined as the placement of dental implant immediately into fresh extraction socket site after tooth extraction, has been considered a predictable and acceptable procedure.

Keywords: Dental Implants, Functional loss, Immediate implant, osseoprogenitor, cortico-cancellous, coagulum.

Introduction

Tooth loss causes more psychological trauma to the patient particularly in the aesthetic segment. Immediate implant placement, defined as the placement of dental implant immediately into fresh extraction socket site after tooth extraction, has been considered a predictable and acceptable procedure.

Some of the benefits are like the post extraction periods are eliminated, significant reduction in number of surgical visits, alveolar height and width are preserved. The angulation of the implants are better leading to improved aesthetics and axial occlusal loading. But there are some of the limiting factors in placement of immediate implants, and one of the factor is the void around the implant. Osseous coagulum being a autogenous grafting material is an ideal grafting material.

Block and Kent, 1991 described indications and contraindications for immediate dental implants placement into the extraction sites.

Indication for Immediate Implants:

1. Traumatic loss of teeth with a small amount of bone loss;
2. Tooth lost because of gross decay without purulent exudates or cellulites;
3. Inability to complete endodontic therapy;
4. Presence of severe periodontal bone loss without purulent exudates;
5. Adequate soft tissue health to obtain primary wound closure.

Contradiction for Immediate Implants:

1. Presence of purulent exudates at the time of extraction;
2. Adjacent soft tissue cellullites and granulation tissue;
3. Lack of an adequate bone apical to the socket;
4. Adverse location of the mandibular neurovascular bundle, maxillary sinus and nasal cavity;
5. Poor anatomical configuration of remaining bone.

Rationale Behind Usage of Osseous Coagulum as a Grafting Material: Autogenous bone grafts have been adopted as gold standard from the beginning. The advantages are as follows:
1. There is possibility to retain cell viability.

2. Graft revascularization and no possibility of disease transmission and contain live osteoblasts osteoprogenitor cells and heal by osteogenesis.

Autogenous bone grafts can be harvested either from intraoral or extra oral donor sites. Multiple intraoral locations have been used including the maxillary tuberosity, exostoses, extraction sites and edentulous ridges. The use of osseous coagulum in implant dentistry was first described by E.Carl. Robinson. It uses the mixture of cortico-cancellous autogenous bone particles mixed with blood.

Case Report: A 28 year male patient reported to the outdoor department of oral and maxillofacial surgery at SreeBalaji Dental College and hospital, Chennai with a chief complaint of trauma to anterior tooth and subsequent loosening of the tooth. Clinical examination revealed a fractured tooth and grade 2 mobility suggesting poor prognosis. Radiological evaluation revealed vertical fracture in the root, so it was decided to extract the tooth. The patient was given detailed explanation the procedure, course and cost of the procedure.

Pre-surgical radiographic evaluation was carried out with IOPA radiograph, OPG for appropriate treatment planning. The diameter of the socket at the crestal level was 5mm and the length of the socket was 12mm.

Surgical Placement of Implant: After proper treatment planning, endo-osseous implant measuring 5x13mm in dimension was selected following an injection of lignocaine with 1:100,000 adrenaline, atraumatic extraction of fractured tooth. The extracted socket was evaluated for osseous defects. All the walls were found to be intact. The extraction socket was debrided and after sequential drilling, implant was placed in the socket with an insertion torque of 45NCM. The remaining void was filled up with osseous coagulum. Adequate primary stability of the implant was achieved. Post-op radiograph was taken (IOPA radiograph). Impression was taken with silicon impression materials and healing screw was secured to the implant. Primary closure was done with 2 interrupted sutures.

The patient was put on antibiotic coverage and analgesics for 5 days. The impression was poured with type 4 stone. The abutment was fabricated outside the patient’s mouth on a working cast. The working cast was sent to laboratory for preparation of metal-ceramic crown.

After 2 weeks of healing period the implant was loaded with cement retained crown. The patient was followed up at 3 months, 6 months, 12 months, 18 months.

Discussion

The biologic advantage of immediate implant is the contention that the implant will prevent postsurgical bone resorption seen following tooth extraction as a normal part of the socket healing, it reduces the treatment cost duration, consolidation period. The vitality and osteogenic potential of the osseous coagulum makes it the choice of grafting material. Bacterial contamination is one of the most important factor in the outcome of grafting and prognosis of the implant. Rinsing the collected bone with chlorhexidine can reduce the amount of bacterial contamination.

Psychotropic Drugs Induced Parafunctional Habits and its Influence on Dental Implants: A Review

Vijay Ebenezer

Professor and Head of the Department, Oral and Maxillofacial Surgery Department, Sree Balaji Dental College and Hospital, BIHER, Pallikaranai, Chennai

ABSTRACT

Success of dental implants is multifactorial, it needs efforts from clinician as well as the patients, this article deals with one of the significant factor that causes failure of dental implants which is the parafunctional habits ie the parafunctional habits associated with patient who receives implants which in turn causing implant failure. Antipsychotic drugs also plays a crucial role in developing the parafunctional habits. It is very much acceptable that the parafunctional habits knowingly or unknowingly causing implant failure to that particular patient who has those habits, habits counselling plays a vital role in minimizing its detrimental effects on implants.

Keywords: Parafunctional habits, Implants.

Introduction

Parafunctional habits most commonly refers to the abnormal oral habits like bruxism, tongue thrusting, nail biting or pencil chewing. Patients come to oral and maxillofacial surgeons in need to replace their missing teeth with the best option and choice of treatment, most of the patients doesn’t have the realization of their abnormal oral habits and it becomes straightaway the duty of oral and maxillofacial surgeons to educate the patients about the parafunctional oral habits and its ill effects on receiving dental implants.

Dental implantation is itself technique sensitive and the patient’s part also plays a vital role in the success of the implants. patient’s concern must be fulfilled at the end of the day in a best possible way by the clinician. Thus this article speaks about the education of parafunctional habits to patients and their avoidance to receive the best possible replacement to their natural teeth.

Discussion

Thorough history taking before explaining the procedural aspects of the replacements plays a crucial role. By doing this we can easily find out the parafunctional habit associated with particular patient who comes for the treatment. Pre operative evaluation like bone mapping, radiographs, and the cast models will be the useful tools in planning the surgical procedures. If the patient is suspected to have bruxism, the particular tooth that is in premature contact must be trimmed down slightly and the precise occlusion is achieved and during the final capping procedures the intentional 2mm gap must be given so that the premature occlusal contact of the implant to the normal tooth is avoided of the already known bruxism patient1,2.
If the patient comes for the replacement of the lost tooth with the tongue thrusting habits, patients must be advised to undergo orthodontic treatment for achieving proper occlusion and if there is any skeletal abnormalities then orthognathic surgical procedures must be advised and explained to patient to achieve normal orthognathic profile and hence the tongue thrusting is minimized\(^{4,5,6}\).

**Fig. 2: orthodontic therapy to prevent tongue thrusting**

If the patient comes with intentional nail biting or pencil chewing habits for the replacement of missing tooth, then the patient must be psychologically counselled about their abnormal habits and if needed habit breaking therapy should be performed and then the implantation is carried on.

**Fig. 3: Dental implantation**

**Conclusion**

This discussion about the parafunctional habits and its interferences with the success of the implants is eye opener for the budding oral and maxillofacial surgeons to narrow down to maintain dentulism. All the external aspects must be well known before going into the implantation procedures.

Warfarin Induced Peri Implantitis—A Review

Vijay Ebenezer

Professor and Head of the Department, Oral and Maxillofacial Surgery Department, Sree Balaji Dental College and Hospital, Pallikaranai, Chennai

ABSTRACT

Peri implant infection is a very commonly seen complication following the placement of dental implants. It usually affects both the soft tissue and hard tissue surrounding the dental implants. Studies have shown the prevalence rates of dental implants to be around 56% (1,2). There are several risk factors predisposing a patient with a dental implant to periimplantitis. Some of these include systemic diseases such as diabetes mellitus, immunosuppressive disorders etc., habits such as smoking and alcoholism, poor oral hygiene and improper maintenance of the dental implant. Although a proper protocol has not been found to treat periimplantitis, several conservative and surgical approaches are used to treat periimplantitis. The baseline of treatment is improving the oral hygiene by means of mechanical cleaning and the usage anti-infective oral rinses (2,3). Laser and photodynamic therapy have been found to yield excellent results in the treatment of periimplantitis and have come into light in the recent years. Surgical therapy includes resective therapy and regeneration using bone replacement grafts. The following is a brief review of the various studies done, to understand the etiology, risk factors and treatment modalities of periimplantitis (4).

Keywords: Periimplantitis, peri implant infections, review, periimplantitis treatment

Introduction

In the current scenario, dental implants have become an indispensable means of therapy in dentistry. According to reports, the success rate of implants have been estimated to be around 82.9% (1). The success of a dental implant demands a holistic approach. Post surgical hygiene and soft tissue management are integral components of every dental implant which has been placed. Periimplantitis is bone loss around an implant that is caused by bacteria. The pathogens causing periodontitis and periimplantitis are the same, such as A. actinomycetemcomitans, P. gingivalis, T. forsythia. Bone loss around a dental implant, or gingival inflammation, provides a nidus for anaerobic bacteria, which eventually leads to continued bone loss. According to several studies, the prevalence of periimplantitis is as high as 56%. The most common sign of infection is the presence of exudate. The initial management of periimplantitis includes debridement, short term systemic and local antibiotics, topical chlorhexidine. When there is continued bone loss and recurrence of exudates, surgical intervention will be require for correction.

Discussion

The purpose of this paper is to assess and study the clinical characteristics, the risk factors and the treatment modalities of periimplantitis. To begin with, there have been several definitions that have been reported for periimplantitis. At the consensus for periimplantitis, it has been defined as an infection with suppurative associated with clinically significant progressing marginal bone loss, after the adaptive phase, usually restricted to the first year of function. The American Academy of periodontology, periimplantitis is an inflammatory process around an implant that includes both soft tissue inflammation and loss of supporting bone.
Prevalence: Several studies have been done to analyse the prevalence of periimplantitis.

According to Zitzmann et al., the incidence of periimplantitis is higher in those who have a history of periodontal inflammation. Lindhe and Meyle reported that the incidence of periimplantitis is between 28 and 56%. Mombelli et al. reported periimplantitis in 20% of all implanted patients and in 10% of all inserted implants.

Pathogens: According to a study conducted by Ralf Smeets et al., periimplantitis has been described as a polymicrobial anaerobic infection. A number of pathogens have been detected such as Prevotella intermedia, Porphyromonas gingivalis, Treponema denticola, and Tannerella forsythia. According to Salvi et al., Staphylococcus aureus plays a predominant role in periimplantitis as it has a high affinity towards titanium.

Risk Factors: There are several factors that can predispose a patient with a dental implant to periimplantitis. Although the severity of every factor varies, smoking has been found to be the greatest risk factor. Those with a compromised oral hygiene are also at a high risk of developing periimplantitis. A lack of keratinized gingiva or other soft tissue defects at the site of implantation, systemic diseases such as diabetes mellitus, immunosuppression etc., A history of periodontitis, history of previous failure of one or more implants are some of the other factors predisposing patients to periimplantitis. Wilson et al. in 2009 described iatrogenic causes such as cementisint to also be a cause for periimplantitis to occur. A lack of proper occlusion and parafunctional habits are some of the other reasons for periimplantitis.

Clinical Characteristics: A release of exudate around the site of the dental implant is a common indicator of peri implant pathology. An increased probing depth of the periodontal pocket, sometimes accompanied with bleeding is another characteristic feature, due to the bone loss around the implant. Radiographically, a radiolucency surrounding the dental implant in the shape of a saucer or rounded beaker is observed.

Treatment: The most important step in the treatment of peri-implantitis is improved oral hygiene. The patient should be informed and properly instructed to maintain good oral hygiene.

Treatment Using Drugs: Javed et al. concluded that the usage of systemic and local antibiotics helped in the reduction of pocket depth within a span of one to six years. The commonly used antibiotics are doxycycline, minocycline, amoxicillin and metronidazole. Apart from antibiotic application, antiseptic rinses can also be used as a treatment modality.

Periodontal Treatment: Curettage with Teflon, carbon, plastic and titanium coated curettes has been found to be effective. A reduction in the bleeding has been found after cleaning with the help of piezoelectric scalers as well as hand instruments. Air polishing therapy has been reported to yield.

Laser Therapy: Er : YAG, Er, Cr:YSGG lasers with increased frequency have been used to treat periimplantitis. The results of such treatment yielded better results than that with curettage.

Photodynamic Therapy: It is a relatively new treatment modality, that has come to light in the recent years. It is an alternative approach to decontaminate dental implants. Injecting photosensitive dyes into periodontal pockets, followed by its activation with light helps in killing of periodontal pathogens. According to a study conducted, this therapy helped in significantly reducing the number of prevotella intermedia/nigrescens, Fusobacterium species and beta hemolytic Streptococcus. With the limited number of studies performed on photodynamic therapy, it has been found to be a good treatment modality. But it cannot be used as a primary therapy, as a lot more studies have to be performed and more data has to be collected for better evaluation.

Discussion

Surgical therapy is usually the last treatment modality opted. It usually is a combination of resective and regenerative procedures. Lang et al in the year 2004, introduced the AKUT concept which comprised of a basic regular recall of the implanted patient with repeat assessment of plaque, bleeding, suppuration, pockets and radiological evidence of bone loss. Zitzmann et al introduced a concept of systemic periodontal therapy which is a more widely accepted concept. According to this concept, oral hygiene of the patient has to be constantly checked and improved when necessary through mechanical cleaning and local anti-infective treatments. Only if the above mentioned treatment modalities fails, should resection or regeneration be opted for as the line of therapy.
The principle behind resective therapy is elimination of the peri implant osseous defect through ostectomy and decontamination of bacteria. Serino et al proved through studies that surgical pocket elimination along with bone contouring had tremendous effect on patients with active peri implant disease⁴. Studies show that after and open reduction of the inflamed peri implant soft tissue, followed by osseous surgery, 48% patients showed no signs of periimplantitis and 77% showed peri implant pocket depths of less than 6mm only⁹. Romeo et al showed that marginal bone loss after resective surgery with implantoplasty than that after resective therapy alone. Although resective surgery yields good results, in terms of good aesthetics and long time survival points, regeneration is preferable. Guided bone regeneration has been proven to yield excellent results as per several studies conducted. Singh et al in 1993 showed that there was greater bone regeneration and re-osseointegration during the submerged healing. Grunder et al found that there was no difference between either ways of healing. Lagervall et al conducted a retrospective study with 150 patients, by raising the periodontal flap followed by osteoplasty, followed by the use of bone replacement. A total of 69% was determined to be the success rate for both the procedures. Although several studies have been performed, the results are not sufficient enough to prove the efficacy of bone defect fillings and hence more studies have to be performed to bring more light to this form of treatment.

Conclusion

As stated above, although quite a few several studies have been performed, a proper treatment protocol for periimplantitis has not been implemented. Studies have been conducted using various materials and over various populations. In most of the studies, the follow ups are very short or the sample size used is less.

Paying proper attention to the risk factors that the patient is prone to, followed by maintenance of good oral hygiene can bring about a huge reduction in the number of patients with periimplantitis. Like the famous quote goes – ‘prevention is better than cure’. Steps should be taken by both the implantologist as well as the patient to prevent such peri implant infections which thereby lead to a complete failure of the paced implant.

Non Self Tapping and Self Tapping Implants of the Dental Practice: A Technique Based Compasion

Vijay Ebenezer
Professor and Head of the Department, Oral and Maxillofacial surgerydepartment, Sree Balaji Dental College and Hospital, Pallikaranai, Chennai

Abstract
The Working of self-tapping and nonself-tapping implant design in terms of implant stability, durability and ease in bone present in the maxilla and mandible It involved a total of 150 implants: 75 self-tapping and 75 nonself-tapping. The implants were placed in the various segments of the maxilla and mandible in sites prepared with either lateral bone-condensing or with bone-drilling techniques. Implant stability measurements were performed immediately after implant placement and weekly during a 12-week follow-up period.

Both types of implants placed after bone techniques results in agreeably good stability immediately after placement, as well as during the complete 12-week observation time. After bone condensation, there were no much variation in initial stability or in complete implant stability.

Keywords: tapping, stability, bone preparation.

Introduction
A dental implant is a titanium screw which is placed into bone to replace missing teeth. The implant mimics the root of a tooth in function. It is not only biocompatible, but actually fuses to bone by osseointegration. The growth of osseointegrated implants symbolizes one of the most significant breakthroughs in current dental practice in the oral rehabilitation of partially or fully edentulous patients. The subject of osseointegration or functional ankylosis was first given to us by Branemark and Schroeder through their extraordinary research work. Osseointegration is a direct structural and materialistic union between living bone and surface of the dental implant. A leap towards improved aesthetics and simplified use has blossomed in the application of dental implants in the replacement of teeth.

Self Tapping and Non Self Tapping Dental Implants:
Self tapping dental implants: The design and quality of the apical section of the implant is in such a manner that it is achievable to place it into alveolar bone ridges as it expands the bone by itself. The shape is also self-cutting and self-tapping so the dental implant acts as its own drill (a further time saving design feature) thus only minimal bony preparation is required. This means that once the dental implant site has been prepared using either drilling or, in many cases, site forming, the dental implant can be placed easily.

The self-tapping implants produced exceedingly greater stability than nonself-tapping implants during the entire follow-up period. Thus concluding that the bone drilling is not an effective technique for improving implant stability and, following this technique, the use of self-tapping implants is highly recommended. Implant stability optimization in the soft bone can be achieved by lateral bone-condensing technique, regardless of implant macro design.
Pre tapping: The majority of implants these days are screw in type implants and they come with various aesthetics and highly customized abutments. The “tap in” is an older type of implant.

The poring and rough texture of the implant surface helps it in osseointegration and requires levels of bone preparation before the placement. It is also called non screwing type or non threaded implants\(^{7,9}\).

Study Design: The consisted of two groups group A with “single” tapping implants and 75 samples. Thus 75 implants in total. Out of a vast category only single implant cases of that term were taken into consideration. the second group – b consisted of 75 members with single implants of the self tapping or screw implant category\(^{10}\).

Study: The study involved not only the stability and success of placement but also esthetical and maintenance phase analysis. The materials collected were the pre operative and post operative photographs of the implant site, implant details, review photographs and patient opinion on esthetics and maintenance of the implant. Technique sensitivity was kept in mind of the placement of the implant for each and every case. The data segregation was done and inferred subjectively\(^{3,4}\).

Results

Taking into account both the groups of implants placed significantly higher stability without haste after surgery, also during the complete 12-week observation period compared with those placed following bone drilling. After bone condensation, there were no gross variation in initial stability or in long term implant stability after the first week between both implant types\(^{9}\). From 2 to 12 postoperative weeks, significantly higher stability was shown by self-tapping implants. After bone drilling, self-tapping implants achieved significantly higher stability than non-self-tapping implants during the entire follow-up period. Also measures are made to follow up the cases for stating the longevity of the complete set of samples\(^{8,9}\).

Conclusion

The aftermath of the respective study suggests that bone preparation is not an effective technique for improving implant stability of pre tapping implants and, following the study, the use of self-tapping implants is highly recommended. Implant stability optimization in the soft bone can be achieved by lateral bone-condensing technique, regardless of implant macro-design.

Fluoride Release and Recharge of Glass Ionomer Cements

J Aarthi¹, Amudha S.¹, Vijayakumar M.¹, Asweni M.²

¹Senior Lecturer, ²Tutor, Department of Pedodontics and Preventive Dentistry, Sree Balaji Dental College and Hospital, Bharath University, Chennai, Tamilnadu, India

ABSTRACT
Dentistry has grown a long way from treating conditions to preventing them. Dental caries is one such condition where preventive measures have been adopted to a greater extent. The fluoride anticariogenic action is greatly related to inhibition of demineralization and remineralization of incipient carious lesions. Reports have shown that fluoride released from fluoride-containing restorative materials effectively protected the enamel from demineralization in the region near to the restorative materials.

Keywords: Dental Caries, Fluoride, GIC

Introduction
Dentistry has through years grown a long way to change its perception from treating conditions to preventing them. Dental caries is one such condition, where in its prevention greatly relies on the magical word, “Fluoride”. Its anticariogenic action is greatly related to inhibition of demineralization and remineralization of incipient carious lesions. Reports have shown that fluoride released from fluoride-containing restorative materials effectively protected the enamel from demineralization in the region near to the restorative materials. Amongst the various fluoride-releasing restorative materials, glass ionomer cements (GICs) are novel. This is due to their efficacy in resisting secondary caries formation around restorations.

Glass ionomer cements are made up of a powder and a liquid component. The powder is a calcium fluoroaluminosilicate glass and liquid is composed of polyacrylic acid. These components, when mixed together, undergo a setting reaction involving neutralization of the acid groups by the powdered solid glass base. Significant amounts of fluoride ions are released during this reaction. Modifications of GICs include silver alloy admix, cermet, resin modified glass ionomer cements (RMGIC), compomers and giomers. Comparison of fluoride release between glass ionomer cement, compomers and giomers showed that conventional GICs released higher amounts of fluoride than the latter two.

This review aimed to summarize the various factors related to fluoride release and recharge of glass ionomer cements.

Pattern of fluoride in GIC: There is an initial burst effect of fluoride, which then decreases gradually to reach a sustained release pattern. The initial burst effect can be attributed to 2 reasons: 1) glass particles dissolve in polyalkenoate acid during the setting reaction and 2) initial superficial rinsing effect. The sustained fluoride release during the following days occurs due to the ability of fluoride to diffuse through cement pores and fractures. This initial burst effect is desirable as it reduces the viability of bacteria that may have been left out in the inner carious dentin. Fluoride release is said to be highest during first 10 hours and gradually it decreased to low levels in 3 days. Based on one study, a monthly fluoride release consisting of 200-300 µg/cm² is reported to be sufficient to completely inhibit enamel demineralization.

Factors controlling fluoride release from GIC

Method of mixing: Comparison of short term fluoride release of a hand-mixed and capsulated system of a
restorative glass ionomer cement showed that the fluoride release at a given time was considerably greater for the capsulated system than for the hand-mixed system.\(^9\)

**Effect of pH:** More fluoride is released from GIC when the environment is at a lower pH. Thus, greatest amount of fluoride is released when it is needed the most to prevent secondary caries.\(^7\)

**Nature of fluoride incorporated:** Conventional GIC was compared to glass ionomer activated with fluoride solutions with regard to fluoride release. Apparently, former released significantly higher amounts of fluoride. This could possibly be due to the fact that fluoride liberated by degradation of glass in conventional GICs are probably higher than those introduced in the cements by mixing solution.\(^10\)

**Recharge of GIC**

**Methods of fluoride recharge of GIC:** Use of fluoride mouthwash, fluoridated toothpaste, professional application of fluoride and fluoride in public water supplies are methods of recharge of GIC.\(^5\)

**Factors controlling fluoride release in GIC**

**Glass filler content – With regard to type IX GIC:** Glass filler content with fewer monovalent ions cross linking the polymer chains holding them close together could possibly be the reason for low fluoride release from type IX GIC. This leads to less water transport and, consequently less fluoride release.\(^11\)

**With regard to Compomers:** In compomers, after curing and before contact with water, the fluoride is not free, but bound in the filler particles. These are are enclosed in the polymerized matrix and in the first phase of setting, thus accounting for the low fluoride release.\(^12\)

**With regard to Giomers:** Giomer contains surface prereacted glass ionomer as a fluoride component and thus the fluoride glass within giomer has little or no glass ionomer matrix phase. There is lack of any significant acid base reaction and hence giomer showed little amount of controlled fluoride release after recharge.\(^13,14\)

**Sodium Fluoride:** Disintegration of the matrix regions around glass fillers caused by spodium fluoride solution may result in enhancement of the fluoride recharge ability of the material.\(^15\)

**Toothpaste:** Due to the high viscosity and sticky nature of toothpastes, they are difficult to wash off and are thus trapped in pores and release more fluoride. With the use of scrubbing effect, higher amount of fluoride is possibly incorporated.\(^16\)

**Porosity of materials:** Higher porosity allows deeper diffusion of the recharging agent into the restoration, leading to a higher amount of fluoride storage and release.\(^17\)

**Effect of temperature:** High temperature during topical fluoride application may increase the fluoride recharging and re-release ability of glass ionomer cements.\(^18\)

**Age of the specimen:** Amount of fluoride re-release following recharge is said to increase with the age of the specimen. Fluoride taken up after recharging is likely to occupy the sites which have been previously occupied by fluoride before its release. Thus the amount of fluoride recharger may be limited to the inherent fluoride releasing ability of each material. This is due to the fact that the sites occupied by intrinsic fluoride are fixed and limitative within the materials.\(^19\)

It is reported that the material with higher fluoride release has a higher fluoride recharging ability. Among various restorative materials, type VII GIC is said to have the highest fluoride release and recharging ability. A material’s fluoride releasing property is inversely proportional to its mechanical properties. Thus, restorative materials with high fluoride release have lower mechanical properties.\(^20\)

**Conclusion**

AAPD guidelines for restorative materials states that GIC s have chemical bonding to both enamel and dentin; thermal expansion similar to that of tooth structure; biocompatibility; decreased moisture sensitivity when compared to resins and finally uptake and release of fluoride which has made them universally acceptable and reliable as a restorative material.\(^21\)

Facio Genito Popliteal Syndrome—A Review

S. Amudha¹, J. Aarthi¹, Vijayakumar M.¹, Asweni M.²
¹Senior Lecturer; ²Tutor, Department Pedodontics and Preventive Dentistry, Sree Balaji Dental College and Hospital, Bharath University, Chennai, Tamil Nadu, India

ABSTRACT

The finding of cleft lip and/or palate, congenital sinuses of the lower lip, popliteal pterygium, and genital anomalies in any combination was first termed Popliteal Pterygium Syndrome (PPS) by Gorlin and Pindborg in 1964. Rintala and Lahti (1970), on the basis of the term not being fully descriptive, suggested the eponym facio-genito-popliteal syndrome. Nevertheless, it is the original term which is commonly used. The pathogenesis of the syndrome is obscure, though it has been suggested that the hereditary factor involved predisposes to developmental arrest. In some publications the names of Fevre and Languepin are used as an eponym. A more descriptive term suggested for the condition, on the basis of incomplete expression of the features of the syndrome, is ‘facio-genito-popliteal syndrome’. However, the most widely used term for this disorder is ‘popliteal pterygium syndrome’. Autosomal dominant inheritance with highly variable expressivity and incomplete penetrance is widely accepted.

Keywords: Facio-genito-popliteal Syndrome, Popliteal Pterygium Syndrome.

Introduction

The finding of cleft lip and/or palate, congenital sinuses of the lower lip, popliteal pterygium, and genital anomalies in any combination was first termed Popliteal Pterygium Syndrome (PPS) by Gorlin and Pindborg in 1964. Rintala and Lahti (1970), on the basis of the term not being fully descriptive, suggested the eponym facio-genito-popliteal syndrome. Nevertheless, it is the original term which is commonly used. The pathogenesis of the syndrome is obscure, though it has been suggested (Rintala and Lahti, 1970) that the hereditary factor involved predisposes to developmental arrest (Pashayan et al., 1974).¹²

In some publications the names of Fevre and Languepin are used as an eponym. A more descriptive term suggested for the condition, on the basis of incomplete expression of the features of the syndrome, is ‘facio-genito-popliteal syndrome’. However, the most widely used term for this disorder is ‘popliteal pterygium syndrome’. Autosomal dominant inheritance with highly variable expressivity and incomplete penetrance is widely accepted.³

Interferon regulatory factor 6 (IRF6): IRF6 is the principal gene involved in this disorder. The location of mutations identified in families with PPS is non-random. In 34 of 36 families with PPS, the mutation is located in exons 3, 4 or 9.⁴

Cleft lip and cleft palate (CLP) are common disorders that occur either as part of a syndrome, where structures other than the lip and palate are affected, or in the absence of other anomalies. Van der Woude syndrome (VWS) and popliteal pterygium syndrome (PPS) are autosomal dominant disorders characterized by combinations of cleft lip, CLP, lip pits, skin-folds, syndactyly and oral adhesions which arise as the result of mutations in interferon regulatory factor 6 (IRF6). IRF6 belongs to a family of transcription factors that share a highly conserved N-terminal, DNA-binding domain and a less well-conserved protein binding domain. To date, mutation analyses have suggested a broad genotype–
phenotype correlation in which missense and nonsense mutations occurring throughout IRF6 may cause VWS; in contrast, PPS-causing mutations are highly associated with the DNA-binding domain, and appear to preferentially affect residues that are predicted to interact directly with the DNA.5

IRF6 plays a key role in the formation and maintenance of the oral periderm, spatio-temporal regulation of which is essential for ensuring appropriate palatal adhesion. In mammals, adhesion and fusion of the palatal shelves are essential mechanisms during the development of the secondary palate; failure of these processes leads to the congenital anomaly, cleft palate. The mechanisms that prevent pathological adhesion between the oral and palatal epithelia while permitting adhesion and subsequent fusion of the palatal shelves via their medial edge epithelia remain obscure. In humans, mutations in the transcription factor interferon regulatory factor 6 (IRF6) underlie Van der Woude syndrome and popliteal pterygium syndrome.6

Clinical Features: The features of the syndrome are highly variable and show a wide range of expressivity even within families. Orofacial, cutaneous, musculoskeletal, and genital anomalies occur.

Orofacial Anomalies: Characterised by cleft lip with or without cleft palate, paramedian lower lip sinuses, eyelid webbing, syngnathia. Orofacial anomalies also include micrognathia, ankyloblepharon, and choanal atresia. Intraoral tissue bands (syngnathia) were found in 42-6% of cases. They can seriously affect mouth opening and need to be removed surgically within the first year of life, or directly after birth if limitation of opening the mouth is so severe that feeding problems occur. Ankyloblepharon filiforme adnatum is found in approximately 20% of cases.3, 7

Theogaraj et al reports in their paper three prevailing theories to explain the aetiology of choanal atresia as follows:
1. Persistence of the bucconasal membrane.
2. Persistence of the buccopharyngeal membrane.
3. Overgrowth of the horizontal and vertical processes of the palatine bone.

Cutaneous and Musculoskeletal Anomalies: The popliteal web contains a palpable cord of connective tissue, and may contain the popliteal artery and the peroneal nerve. The cord usually extends from the heel to the ischial tuberosity. It may seriously limit extension, abduction, and rotation of the leg. In some subjects it was reported to be so tight that the heel almost touched the buttocks, while in other cases it could just be felt as a tight string without any severe limitation of the range of movements. Absence of muscles or abnormal muscle and tendon insertion may occur. On surgical intervention, care must be taken not to cut the vessels or nerves which supply the lower leg. The popliteal webs make this syndrome particularly important to the orthopaedic surgeon. The resultant fixed flexion deformity can be severe, at times approximating the ischium to the calcaneus. The neurovascular bundle is contained in the web’s posterior subcutaneous (S.C.) margin, which makes surgery precarious and difficult.8 Anomalies of nail and digits, talipes equinovarus, spina bifida occulta, bifid ribs, and short sternum are also described.3, 7

Genitourinary Anomalies: Genital anomalies include hypoplastic labia majora, vagina and uterus, clitoral hypertrophy, cryptorchidism, bifid or absent scrotum and ambiguous genitalia.3, 7

Growth and Mental Development: There is no growth disturbance and intelligence is usually normal.3, 7

Prenatal Diagnosis: Prenatal diagnosis is possible by means of sequence analysis of the IRF6 gene in DNA extracted from the chorionic villus or amniotic fluid, or by means of intrauterine ultrasound.9

Prenatal sonography may detect an associated cleft lip/palate along with inability of the fetus to stretch the knee. Magnetic resonance imaging is the test of choice before resection of fibrous bands and Z-plasty of the web.10,11

Molecular genetic testing. If the disease-causing mutation has been identified in the family, prenatal diagnosis for pregnancies at increased risk is possible by analysis of DNA extracted from fetal cells obtained by amniocentesis (usually performed at ~15-18 weeks’ gestation) or chorionic villus sampling (usually performed at ~10-12 weeks’ gestation).

Note: Gestational age is expressed as menstrual weeks calculated either from the first day of the last normal menstrual period or by ultrasound measurements.
Ultrasound examination. Prenatal ultrasound examination may detect a cleft lip later in pregnancy, but it is less likely to detect a cleft palate or lip pits. A level 2 targeted ultrasound examination at a center that routinely performs such procedures is most accurate.

Requests for prenatal testing for conditions such as IRF6-related disorders are not common. Differences in perspective may exist among medical professionals and within families regarding the use of prenatal testing, particularly if the testing is being considered for the purpose of pregnancy termination rather than early diagnosis. Although most centers would consider decisions about prenatal testing to be the choice of the parents, discussion of these issues is appropriate. Prenatal testing may provide the benefit of preparing the parents and family for a child with a facial difference or disability. However, the clinical manifestations of IRF6-related disorders are variable and cannot be predicted in the offspring.

Preimplantation genetic diagnosis (PGD) may be an option for some families in which the disease-causing mutation has been identified.

**Diagnosis:**

**Clinical Diagnosis:** IRF6-related disorders span a spectrum from isolated cleft lip and palate and Van der Woude syndrome (VWS) at the mild end to popliteal pterygium syndrome (PPS) at the more severe end.

To make the diagnosis of popliteal pterygium syndrome, an individual must have one or more of the following in addition to features of Van der Woude syndrome listed above:

- Popliteal pterygia
- Syndactyly
- Abnormal external genitalia
- Ankyloblepharon
- Pyramidal skin on the hallux
- Intraoral adhesions

**Molecular Genetic Testing:** Gene. Mutations in IRF6 are known to be associated with Van der Woude syndrome and popliteal pterygium syndrome. Genetic variants in IRF6 contribute risk for isolated cleft lip and palate.

**Clinical testing**

- **Sequence analysis**
  - Popliteal pterygium syndrome. Sequence analysis of exon 4 of the IRF6 coding region detects mutations in approximately 72% of individuals with PPS [de Lima et al 2009]. Additional sequencing of the entire coding region of IRF6 detects mutations in approximately 97% of individuals with PPS (N=37) [de Lima et al 2009].
  - Deletion/duplication analysis
    - Popliteal pterygium syndrome. A study of seven individuals with PPS did not identify any deletions in IRF6 [Schutte et al 1999], nor were any reported in the larger study of de Lima et al [2009]. Since almost all individuals with PPS have had a mutation identified by sequence analysis, the contribution of deletions to this phenotype is likely very small. 12

**Treatment:** The overall prognosis of the popliteal pterygium syndrome is good. Patients often undergo a series of plastic surgery operations, usually starting in the newborn period and extending into puberty.

In the newborn period the ankyloblepharon and oral synechia are excised to enable eye opening and proper feeding.

Cleft lip and palate repair are done in consecutive sessions starting in the first year of life. An artificial palate can be placed temporarily if feeding is difficult. The cleft palate will usually be closed within the first year of life. Speech and hearing problems may develop secondary to the clefting abnormality. If salivation from the lower lip pits is severe, these need to be surgically removed. 3

The bilateral choanal atresia required urgent surgery to establish an airway. Immediately after birth, the baby was intubated because of respiratory distress. 13

Surgical treatment is preferred because the results of conservative treatment, including serial casting or traction, have been unsatisfactory. Among these surgical treatments, lengthening of the soft tissues such as the skin, muscles and ligaments using resection of fibrous bands and Z-plasty was the most preferred technique. 14
An Ilizarov external fixator is commonly used for correction of shortening or deformity, and it is also employed for the treatment of joint contractures. According to Gillen et al. the device allowed all 4 of their patients with PPS to obtain 0° of knee extension, but 15-30° of contracture recurred postoperatively. This is rebound phenomenon is a major obstacle in the treatment of PPS.15

Gradual soft tissue lengthening with an Ilizarov external fixator can be one of the optimal procedures when excision of fibrous band and Z-plasty are not possible due to adhesion to the nerves or blood vessels in the popliteal pterygium. 15

During the operation special attention needs to be given to the vessels and nerves within the pterygium. Postoperatively, plaster casts and physiotherapy are used to maximise long term results. Cryptorchidism may require surgical intervention within the first three years of life.

Genetic counselling: IRF6-related disorders are inherited in an autosomal dominant manner. Most individuals diagnosed with an IRF6-related disorder have an affected parent; however, penetrance is incomplete and de novomutations have been reported. The risk to the sibs of the proband depends on the genetic status of the proband’s parents. If a parent of the proband is affected or has an IRF6 mutation, the risk to the sibs of inheriting the mutation is 50%. Prenatal diagnosis for pregnancies at increased risk is possible if the disease-causing allele in the family member is known. Prenatal ultrasound examination may detect a cleft lip in some fetuses later in pregnancy, but it is less likely to detect a cleft palate or lip pits. 12

Intranasal Local Anaesthesia: A Recent Advancement in Pediatric Dentistry

Jeevarathan J1, Ponudurai Arangannal2, Vijayakumar M3, S. Amudha3, V. Anupama4

1Professor, 2Professor and Head, 3Senior Lecturer, 4PG Student, Department of Pedodontics and Preventive Dentistry, Sree Balaji Dental College and Hospital, Bharath University, Chennai, Tamilnadu, India

ABSTRACT

Intranasal local anaesthesia is a recent advancement in pediatric dentistry. Here we try to give a better and comfortable mode of administration of local anaesthesia for kids for their better cooperation. Intranasal anaesthesia in other words needle free anaesthesia has rapid onset, ease of delivery, painless administration, high medication bio availability as its advantages. Kovacaine mist is a spray type of intranasal local anaesthesia that is effective only on permanent and primary anteriors, primary molars, permanent premolars.

Keywords: Anaesthesia, Intranasal, Kovacaine.

Introduction

Kovacaine mist a needle free local anaesthesia, effective on maxillary anteriors and premolars was introduced by Mark kollar and st. Renatus into the dental world. The most common means of anesthetizing a maxillary tooth is intraoral supra-periosteal injection of local anesthetic, commonly referred to as a maxillary infiltration. Local anesthesia is achieved by penetration of a needle through the buccal mucosa and submucosal deposition of a local anesthetic solution proximal to the root apex of the tooth.

Fear of a painful dental injection and subsequent avoidance behavior are significant barriers to regular visits to the dentist.1 In a study by Eliezer Kaufman, et al. that asked patients to grade pain, discomfort, and pressure on a visual analog scale as associated with needle insertion, operator finger position in the mouth, and pressure at injection, local infiltration in the anterior maxillary region yielded the highest needle insertion and finger position discomfort scores.2 Importantly, patients’ fear of injections can delay needed dental care. Surveys indicate that 30-40 million people in the US avoid going to the dentist because of fear of pain and anesthetic injections.3-5 Therefore an anesthetic procedure that would avoid the discomfort of a local anesthetic injection thus obviating fear and anxiety about receiving a “shot,” would greatly benefit dental patients. Further, for procedures involving more than one maxillary tooth on the same side, a trans-nasally applied anesthetic agent that could anesthetize multiple maxillary teeth at once instead of use of repeated infiltration injections would be a major convenience for patients and dentists.

In addition, avoidance of injection in dental anesthesia eliminates the risk of exposure to blood borne pathogens via needle sticks, a recognized occupational hazard in dentistry. In an ongoing attempt to reduce the risk of exposure to blood borne pathogens, Congress passed the Needlestick Safety and Prevention Act (effective in 2001) that requires the use of needle-free technology whenever possible to eliminate employee exposure to blood and other potentially infectious materials. This law provided further incentive to develop anesthetics that can be delivered in a “needle-free” manner. Infiltration injection may fail because of individual differences in response to the drug administered, cortical plate bone density, tissue vascularity, and variations of neuroanatomy.

Nasally applied tetracaine hydrochloride has been used successfully and safely for many years for anesthetizing tissues before diagnostic and surgical procedures. Addition of a nasal decongestant to a tetracaine formulation has been used when anesthetizing the nasal cavity. A common nasal decongestant for this purpose is 0.05% oxymetazoline hydrochloride.

### Parts of BD Accuspray:

**Dental work without needles**

Delivered as a nasal spray instead of a needle, the nasal spray anesthetizes the upper teeth for dental procedures.

**The ‘Old’ Way**

Anesthetic injection
A needle is inserted into the appropriate location and anesthetic is injected directly towards the nerve pathways. This method can have complications ranging from mild to severe, including:
- Injection into a blood vessel delivering too much anesthetic too fast.
- Injection of air bubble through poor technique.
- Shock from psychogenic trauma.
- Bacterial infection of the needle tract.

**The ‘New’ Way**

Nasal Spray
Anesthetic is sprayed into the nose, where it affects the nerves that travel through the nasal cavity to the upper teeth. This blocks pain signals from traveling back to the brain.

**Applications**

The nasal spray can be used for procedures on all teeth of the upper arch except for the back molars.

**Procedures that can be performed include:**
- Fillings
- Root canals
- Crowns
- Gum procedures

**Parts of BD Accuspray:**

- **Soft conical plug**
  The plug forms a seal with the nostril preventing expulsion of fluid.

- **Malleable stylet**
  The malleable stylet allows 180° positioning of the nasal plug.

- **Accurate dosing**
  The syringe enables the accurate measurement of drugs to be delivered.

- **Pressure**
  High applied pressure ensures that drugs are atomized into a fine mist of particles through the tip of the plug.

- **Atomization spray**
  The spray atomizes drugs into a fine mist of particles: 90-100 microns in size.
Soft conical plug forms a seal with nostril preventing expulsion of the fluid. Through the automisation spray it automises drug into a fine mist of particles 30 – 100 microns. The malleable stylet allows 180 degree positioning of the plug.

**Technique:**

It’s a two way technique. One it s 0 – 15 degree angulation from the middle nasal septum of nose and the other the syringe inserted into the nose is in 45 degree angulation from the imaginary line from the canthus of the eye.

**Mechanism:** Kovacaine mist works on a two way mechanism. one when it is sprayed into the nasal cavity it anaesthetizes the nasal branch of anterior superior alveolar nerve and there by anaesthetizing the maxillary anteriors.on the other hand it anaestetises the infra orbital nerve and the main trunk, whenever middle superior alveolar nerve is connected with anterior superior alveolar nerve it is also anaesthetized.

**Advantages:**
- Rapid onset
- Ease of delivery
- Painless administration
- Bio availability

**Disadvantages:**
- Short active period.
- Works only on maxillary anteriors and primary molars.
- Causes mild irritations like stuffy or running nose, eye tearing, sore throat.

**Kovacaine Mist–Uses in Dental Procedures:**
- Restorative procedures
- Polpotomy
- Pulpectomy
- Extractions
- Majorly helpful in patients with ECC.

**Conclusion**

Kovacaine mist, could potentially be used as a safe and effective alternative to maxillary infiltration for anesthetizing maxillary premolars and anteriors to achieve pulpal anesthesia. Kovacaine mist was well-tolerated by the subjects who received the drug in this clinical trial and had a low rate of adverse events all of which were mild and of short duration, mainly including headache and runny/stuffy nose.

Supernumerary Teeth—Mesiodens—A Case Report

Ponnudurai Arangannal1, Jeevarathan J2, Amudha S3, J Aarthi3, Aysha Banu M4

1Professor and Head, 2Professor, 3Senior Lecturer, 4PG Student, Department of Pedodontics and Preventive Dentistry, Sree Balaji Dental College and Hospital, Bharath University, Chennai, Tamilnadu, India

ABSTRACT

Supernumerary teeth may be encountered by the general dental practitioner as a chance finding on a radiograph or as the cause of an impacted central incisor. They may also be found intraorally following spontaneous eruption. The most common supernumerary tooth which appears in the maxillary midline is called a mesiodens. Treatment depends on the type and position of the supernumerary tooth and on its effect on adjacent teeth.

Keywords: Hyperdontia, Mesiodens, Phylogenetic Theory

Introduction

Hyperdontia is a developmental anomaly in which an extra tooth/teeth are formed and these were referred as supernumerary teeth.1-2 According to Garvey et al3a supernumerary tooth is one that is additional to the normal series and can be found in almost any region of the dental arch. According to Schulze4 it is defined as any teeth or tooth substance in excess of the usual configuration of twenty deciduous and thirty-two permanent teeth.

Numerous theories have been proposed to explain the development of the supernumerary teeth but they remain controversial. The first is the phylogenetic theory (atavism) which suggest that the ancestors had three central incisor but now largely been discarded by the embryologist. Next is dichotomy theory which suggests that the tooth bud is split to develop two separate teeth of which one is supernumerary. The third is the hyperactivity of the dental lamina which is the most widely accepted. According to this the remnants of the dental lamina or palatal offshoots develop in to supernumerary teeth. The last is the combination of genetic and environmental factors referred as unified etiologic explanation. Autosomal dominant and a sex linked pattern have also been proposed to be the cause.5

Supernumerary teeth are classified based on number as single or multiple. They are also classified based on morphology as accessory and supplemental. Accessory teeth are again classified based on shape as conical (peg-shaped), tuberculate (barrel shaped) and odontome which can again be either complex or compound. Based on the location in the dental arch they are again classified as Mesiodens (between incisors), paramolars (beside a molar), distomolars (distal to molar) and parapremolars (beside a premolar). Multiple supernumerary teeth can be associated with syndrome or also without it. The various syndromes which are associated with supernumerary teeth are Cleidocranial dysostosis, Gardners syndrome, Cleft lip and palate, Fabry-Anderson’s syndrome, Chondroectodermal dysplasia, Down syndrome, Orofacial dystosis, Crouzon disease, Hallermann Sheriff syndrome and Nance Horan syndrome.6

The prevalence of supernumerary teeth ranges from 0.15% to 3.9%in the permanent teeth in normal population and this increases to 28% in cleft lip and palate patients. It is five times more common in maxilla than mandible. Sexual dimorphism was reported by many authors with

Bharath University, Chennai, Tamilnadu, India
male to female ration of 2:1. It is less common in deciduous teeth with an incidence of 0.3% to 1.7%. Majority of the supernumerary teeth remain impacted and only 25% of the anterior supernumerary teeth erupt spontaneously. The frequency of erupted primary supernumerary teeth is greater than the permanent supernumerary teeth (75 Vs 25%). Mesiodens is the most frequent supernumerary teeth encountered with an overall prevalence of 0.15 to 1.9%. It may occur individually or as multiples were it is referred as mesiodentes. Mesiodentes in the permanent dentition is called rudimentary mesiodentes and those seen in primary dentition as supplemental mesiodentes. Based on morphology they can be conical, tuberculate and molariform. Mesiodens may erupt normally, stay impacted, appear inverted, take an ectopic position and follow an abnormal path. Palatally placed mesiodens is the most common type and is usually unerupted.

The various problems associated with supernumerary teeth are failure of eruption, displacement of permanent tooth, crowding, delayed eruption, diastema, rotations, development of cystic lesions and resorptions of adjacent teeth. Management is mainly extraction but the time depends on the developmental stage of dentition i.e. primary, mixed and permanent.

**Case Report:*** An 5 year old male patient reported to the department of pedodontics and preventive dentistry with a complaint of presence of conical shaped tooth in the anterior region(Fig 1). His medical was unremarkable. His family history revealed that his father had a erupted mesiodens on the palatal aspect which was later extracted. No significant abnormality was noted in the extra-oral examination. Intra-oral examination revealed a normal soft tissues and a primary dentition stage. Mesioocclusal caries was noted in the lower right and left second primary molar and upper right and left first primary molar.

Distoocclusal caries was noted in the upper right and left upper second primary molar. Root stumps were also seen in the lower right and left first primary molar region. Caries was also found on the mesial surface of right and left upper lateral incisor and in both the proximal surface of left upper central incisor He was on his first dental visit. A conical shaped supernumerary tooth was found in the place of right upper central incisor. History revealed that primary incisor exfoliated uneventfully and replaced by this supernumerary tooth.

Radiographic examination included intra-oral periapical radiographs for the entire molar segment and for the upper anterior region. Treatment plan was explained to the parent and an informed consent was obtained.

A proper size celluloid crown (Company) was selected, trimmed and using light cured composite (company) the erupted supernumerary teeth was reshaped as primary central incisor(fig 2). Pulpal therapies were done for all the primary molars and stainless steel crowns (Company) were placed. Crown and loop space maintainar was given in the lower second primary molar area after the extraction of the lower first primary molars. The carious upper anterior teeth were restored with composite (Company).
Discussion

Any extra tooth in the dental arch is referred as supernumerary teeth. Supernumerary teeth in the midline between the central incisors are referred as mesiodens. These teeth are most commonly associated with many syndromes but no such syndromes were seen for the patient.

The development of supernumerary teeth remains controversial and unknown, but it considered as a multifactorial inheritance disorder. Of the several theories proposed the hyperactivity of the dental lamina is most commonly accepted. According to this theory the remnants of dental lamina or the palatal extension of the active dental lamina could develop into an additional tooth. But genetics factors are also strongly suggested for its development. As it is reported in familial generations, siblings and also in twins it is thought to be of autosomal dominant condition. Since it is more common in males some proposed it could be of a sex linked pattern. Thus the cause could be due to genetic predisposition and as the child is a male it can also be of sex linked pattern but both are not confirmatory.

The various complication that could arise as a result of supernumerary teeth are failure of eruption, displacement of permanent tooth, crowding, delayed eruption, diastema, rotations, development of cystic lesions and resorptions of adjacent teeth. Apart from this a new complication encountered was the early exfoliation of the right primary central incisor due to eruption of normally placed mesiodens. This exfoliation was considered early as there were no permanent tooth was erupted until now and the root of the contralateral primary central incisor shows only mild root resorption.

Since the erupted mesiodens was not esthetically pleasing both to the child and the parent it was reshaped as primary right central incisor as it was in a favorable position in the dental arch. Similar case was also reported by Tatel who reshaped the mesiodens as a left primary central incisor for a 3 year 9 month old child. Crown and loop space maintainer was given to the lower second primary molars as the permanent first molar were erupting to prevent any space loss. The parents were also informed about the rotated permanent central incisor and they may need any interceptive procedures later when it erupts spontaneously or even when it failed to erupt.

Conclusion

Esthetics is of great concern even to the child. Restoring it will increase the self esteem of the child. In the modern preventive dentistry treatment approach early detection and management of all supernumerary teeth is a necessary part of it. Timely intervention will eliminate the occurrence of various complications and hence radiographic evaluation on suspected patients is of much importance. But in this case only time should reveal whether surgical removal at a very early stage has any positive outcome.

ABSTRACT

Context: Dentists should detect the patient’s level of anxiety and eliminate the anxiety prior to the treatment to provide a successful treatment and to establish a positive attitude towards dentistry.

Aim: To evaluate the effect of exposure to positive dental experience video on dental anxiety among 6 to 11 years old children using Venhams picture test and Chota Bheem-Chutki scale.

Method and Material: Hundred children between 6 to 11 years were selected randomly for the study. Pre-intervention anxiety level was recorded using Chota Bheem Chutki scale (CBCS) and Venham picture test (VPT) while the children were sitting in the waiting area. After that the positive dental experience video was shown to the children for 2 minutes. Later, the anxiety level of children was again measured using both the scales. That was taken as the post intervention scores.

Statistical analysis used: All the scores were statistically analyzed by SPSS version 22. Paired t test was used to compare the scores obtained from both the scales and Pearson correlation test was performed to obtain correlation among the scales used in the study.

Results: The mean anxiety score of children before intervention and after intervention using VPT was 3.25 ± 1.67 and 0.43 ± 1.32; for CBCS was 1.84 ± 0.71 and 1.05 ± 0.21. The difference between intervention and after intervention value was highly statistically significant p-value <0.001.

Conclusions: This study showed that exposure to positive dental video can significantly reduce anticipatory dental anxiety in children.

Keywords: Dental anxiety, Venham picture test, Chota Bheem Chutki scale,

Introduction

Dental anxiety is a major barrier for dental care utilization. It is confirmed that anxious patients have more decayed and missing teeth which impacts seriously on the quality of their lives. Anxiety is defined as a non specific feeling of apprehension, worry, uneasiness/dread, the source of which may be vague or unknown. Dental anxiety refers to patient’s specification toward dental situation-associated stress. Despite the technical advantages dental anxiety remains to be a major problem. It is present worldwide and not limited to a population or country. Child’s dental anxiety has
always been a matter of concern for the dentists due to its various complications like prolonged chairside time, behavioural management problems, avoidance of dental care and the strong influence it has on the child’s future attitude towards the dental treatments. Assessment of dental anxiety in children and addressing the individual’s needs is a crucial factor in patient management. Dental anxiety in patients is also a recognized problem for the dental health care providers. Anxious patients were considered the most stressful situations a dentist might face. Increased levels of dental anxiety obscure the proper diagnosis of the actual dental problem. It also affects the quality of the treatment performed. Anxiety yields a negative attitude towards dentistry thus reflecting in the relationship between the patient and the dentist. Hence, it is of paramount importance that dentists should be able to accurately detect the patient’s level of anxiety and eliminate the anxiety prior to the treatment to provide a successful treatment and to establish a positive attitude towards dentistry. One approach known as modeling given by Kuhn and Allen may be used to develop positive associations with dentistry through the promotion of positive images of children experiencing dental treatment. Several scales have been developed to measure the anxiety level of the patient. One such scale is the Venham picture test (VPT) which uses eight pairs of images that expresses various anxiety levels. VPT have been used in numerous studies to assess dental anxiety before dental treatment; however, these scales present with certain drawbacks such as figures on the VPT scale are all male which might pose difficulties when a young patient is a girl. In addition, the ambiguous nature of some figures on the scale are confusing for the child to choose, thus making it a time consuming procedure. Moreover, the figures used in these scales are not familiar for the children. The newly devised Chota Bheem Chutki scale (CBCS) developed by Sadana G et al using the popular cartoon characters Chota Bheem and Chutki expressing six different expressions overcomes the disadvantages of VPT scale.

**Aim**

1. To evaluate the effect of exposure to positive dental experience video on dental anxiety among 6 to 11 years old children using Chota Bheem-Chutki scale

**Objective**

1. To find out anticipatory anxiety level in children before intervention and determine the impact of positive dental experience video on dental anxiety of children.

2. To compare anticipatory anxiety level in children before intervention and after intervention.

3. To find out the reliability of the CBCS in comparison to VPT scale

**Subjects and Method**

The sample size for the present study was calculated using the formula:

\[ n = \frac{4PQ}{L^2} \]

\[ P = 6.3\% \text{ (as per previous studies); } Q = 100 - P, L = 5\% \]

The present study was conducted to evaluate the effect of exposure to positive dental video on dental anxiety among 6 to 11 years old children visiting the outpatient department (OPD) of paedodontics and preventive dentistry using Chota Bheem-Chutki scale. The children were selected randomly based on the inclusion and exclusion criteria.

**Inclusion Criteria:**

- Children with no history of major illness
- First dental visit
- Accompanied by the parent or guardian.

**Exclusion Criteria:**

- Physically and mentally challenged children
- Children with history of previous dental visit
- Children that became upset at viewing the video

Parents/guardians were informed regarding the study and consents were obtained from them. The study was started after taking ethical clearance by the ethical committee of the institute.

The parents and the children were made to sit in the waiting area and the anxiety level of the children was recorded using CBCS and VPT. The children were asked to point out the image which they felt that best related their emotional state at that moment. This was taken as the pre intervention score. After that the positive
A dental experience video was shown to the children for 2 minutes. Later, the anxiety level of children was again measured using both the scales. That was taken as the post intervention scores. All the scores were statistically analyzed by Statistical Package for the Social Sciences (SPSS) version 22. Paired t test was used to compare the scores obtained from both the scales and Pearson correlation test was performed to obtain correlation among the scales used in the study.

**Results**

A total of 100 children reporting to the department of paedodontics and preventive dentistry during their first dental visit were selected for the study.

Table I illustrates the mean anxiety score of children before intervention and after intervention using VPT which was $3.25 \pm 1.67$ and $0.43 \pm 1.32$ the difference between these value was highly statistically significant $p$-value $<0.001$

Table II illustrates the mean anxiety score of children before intervention and after intervention using CBCS which was $1.84 \pm 0.71$ and $1.05 \pm 0.21$ the difference between these value was highly statistically significant $p$-value $<0.001$

Table III shows the correlation between CBCS and VPT before intervention and after intervention which was $r = 0.560; p<0.001$ and $r = 0.848; p<0.001$ a strong correlation was found between VPT and CBCS

**Discussion**

Dental anxiety is a common condition in children and adolescents. Various studies have shown a prevalence of around 6–20% independently of culture and country.$^{8,14}$ There are number of instruments are available to measure dental anxiety in children.$^{15}$ The Venham picture scale is widely used and easily administered.$^{16}$

In the present study relatively new Chota Bheem-Chutki scale was used since it is simple, easy to understand and children are familiar with the cartoon characters used in the scale, therefore they can easily relate them to it. 6 to 11 years old children were selected for the study as they were likely to have the cognitive ability to self-report their anxiety.$^{17}$

In the present study the anxiety level of children in waiting area was found to be high similar to the study done by Gangwal RR et al (2014), $^{18}$ this could be due to a close connection between the development of dental anxiety in children and family dental fear.$^{19}$ Bergius M et al (1997) identified that high dental anxiety level in children was associated with vicarious learning in the family.$^{8}$

In the present study it was found that the anxiety level of children following exposure to two minute positive dental video reduced significantly compared to the initial anxiety level in waiting area similar to the studies done by Fox and Newton (2006)\(^6\) and Gangwal RR et al (2014)\(^8\) who showed that viewing positive images of dentistry and dentists resulted in short-term reduction in anticipatory anxiety in children.

In the present study, there was a strong correlation between VPT and CBCS similar to the findings of Sadana G et al (2016).\(^7\) Furthermore, when child patients were asked which scale was the simplest and easiest to understand, majority of them chose the CBCS.

**Limitation:**

- Positive dental video used in the study were not validated
- Cartoon characters used are not universally acceptable

**Conclusion**

This study showed that exposure to positive dental video can significantly reduce anticipatory dental anxiety in children. Chota Bheem Chutki scale yielded comparable results to the Venham picture test, it can be used as a new alternative tool for dental anxiety assessment in young children.

Formocresol—Myths and Facts

Vijayakumar M¹, Amudha S¹, J. Aarthi¹, Asweni M²

¹Senior Lecturer, ²Tutor, Department Pedodontics and Preventive Dentistry, Sree Balaji Dental College and Hospital, Bharath University, Chennai, Tamilnadu, India

ABSTRACT

Formocresol is used in endodontic therapy for pulp canal sterilization. Formocresol contains 10% formaldehyde, 35% cresol, and 15% glycerol. Various researchers have said that formocresol is effective in fixing the pulpal tissue, and it also has an impact on the enzymes and connective tissue surrounding the apices of the treated teeth. Hence, this paper reviews the history, sources, pharmacokinetics of formaldehyde and cresol, carcinogenicity, mutagenicity, clinical success and controversies regarding the safety of formocresol as medicament.

Keywords: Formocresol, controversies, endodontic therapy

Introduction

Formocresol has been utilized by dentists for over 100 years as a medicament in the treatment of primary teeth requiring therapeutic pulpotomies. Even today most dentists use formocresol manufactured at the same composition recommended in 1904 (Buckley type formula, 19% formaldehyde, and 35% cresol in a vehicle of 15% glycerine and water).

Formocresol is regarded as the gold standard and remains the most commonly used material for pulpotomies. Probably the first report of formaldehyde containing pulp medicament being used was in 1874 when Nitzel applied a Tricresol-formalin tanning agent.

Some concern has been expressed by Lewis BB et al in 1981; Ranly DM in 1984; Ketley CE et al in 1991; Waterhouse PJ in 1995 in the last 25 years regarding the use of formocresol for vital pulpotomy treatment of primary molars due primarily to its mutagenic, carcinogenic, and toxic potential when used in high concentrations and under specific conditions.

Ubiquity of Formaldehyde: Daily formaldehyde exposure is a fact of life. Formaldehyde is found in the air we breathe, the water we drink, and the food we eat. The World Health Organization (WHO) has estimated that daily consumption of formaldehyde approximates 1.5–14 mg/day (mean, 7.8 mg/day), although daily intake from food is difficult to evaluate. Owen et al in 1990 estimated that North Americans eating a typical North American diet ingest 11 mg/day. In unpopulated areas, outdoor air contains approximately 0.2 parts per billion (ppb) of formaldehyde. In populated areas with truck and automobile traffic, however, air concentrations range between 10 and 20 ppb. There have also been instances of high concentrations of formaldehyde in the air inside homes. In 2002–2003, Health Canada found formaldehyde levels of 2–81 ppb in homes in Prince Edward Island and Ottawa, Canada. Second-hand cigarette smoke might contain up to 0.4 ppm of formaldehyde. The National Institute for Occupational Safety and Health in the United States has stated that formaldehyde is immediately dangerous to health and life at concentrations of 20 parts per million (ppm) and higher.

The estimated formaldehyde dose associated with 1 pulpotomy procedure, assuming a 1:5 dilution of formocresol placed on a no. 4 cotton pellet that has been squeezed dry, is approximately 0.02–0.10 mg.

Sources of Human Formaldehyde Exposures

- Atmospheric formation: Photochemical oxidation of organic compounds
- Internal combustion engine exhaust
- Fertilizer production
- **Hydrogen sulfide scavenger:**
  - oil operations
- Household products:
  - Dishwashing liquid
  - Antiseptics and disinfectants
  - Carpet cleaners
  - Carpets
- Preservatives and embalming solutions
- **Cosmetics (maximum concentration, 0.3% v/v):**
  - Fingernail hardeners (maximum concentration, 5% v/v)
- Tire and rubber manufacturing
- Paper products
- Adhesives
- Latex paints
- **Resin production:**
  - Phenolic-formaldehyde resin
  - Urea-formaldehyde resin
  - Pentaerythritol resin
- Permanent press fabrics
- Manufactured wood products
- Forest and brush fires
- Tobacco products

**Pharmacokinetics and Metabolism of Formaldehyde:**
As a normal cellular constituent, it is mostly present in a nonreactive, reversibly bound form. Formaldehyde is produced endogenously from certain amino acids and choline, as well as by oxidative demethylation of steroids and xenobiotic. According to Casanava M *et al* in 1988 the concentration of endogenous formaldehyde in the blood of rats, monkeys, and humans is approximately 0.1 mm, and this concentration is not measurably altered by exposure to airborne formaldehyde.

Exposure of humans, monkeys or rats to formaldehyde by inhalation does not alter the concentration of endogenous formaldehyde in the blood because of its rapid metabolism. Following intravenous infusion, the biological half-life of formaldehyde in monkey blood is approximately 1.5 minutes, with a concurrent rise in formic acid levels indicating metabolism of the formaldehyde. *Bhat HS et al in 1988* expected exogenous formaldehyde has with a biological half-life of 1.0 to 1.5 minutes in human plasma.

Formaldehyde, and the oxidation product formate, is key intermediates compounds in the “one-carbon pool”, which in turn is utilized for the biosynthesis of purines, thymidine, and certain amino acids, which are incorporated into DNA, RNA, and proteins during macromolecular synthesis. Formaldehyde also reacts covalently with amino and sulphydryl groups in target tissues and with DNA, forming unstable hydroxymethyl protein adducts, known as DNA-protein cross-links (DPX). It has been shown that DPX may act as a replication block, which could lead to a variety of deleterious effects including chromosomal aberrations, deletions, or even cell death.

**Pharmacokinetics of Cresol:** The second active ingredient in formocresol, cresol, has received little attention in the debate about formocresol safety or in investigations of formocresol efficacy. According to Ranly D in 1984, Cresol has poor solubility, and because of this, it has been assumed that it does not enter systemic circulation. Cresol is highly lipophilic, however, and has been shown to completely destroy cellular integrity, which presumably would allow for deeper tissue fixation by the formaldehyde component of formocresol. No data exist regarding cresol metabolism or elimination in humans or other mammals, and there is virtually no information about environmental sources of cresol to which humans might be exposed. Last, no human studies have been published that have examined plasma concentration after exposure to cresol.

Benzyl alcohol is present as a bacteriostatic preservative in many multidose intravenous drugs and solutions. It also occurs naturally in many plants, including raspberries and tea, and is an essential ingredient in many essential oils. Benzyl alcohol is oxidized rapidly to benzoic acid, conjugated with glycine in the liver, and excreted as hippuric acid. It has no carcinogenic or mutagenic potential, and the allowable daily intake, as established by WHO is 5 mg/kg.
Mutagenicity, Genotoxicity, and Cytotoxicity: Exposure of cells to formaldehyde leads to the formation of DPX. The most common types of DNA damage induced by formaldehyde are clastogenic lesions; including sister chromatid exchanges (SCEs), micronuclei and chromosomal aberrations, and deletions. Levels of formaldehyde-induced DPX are considered to represent a good molecular dosimeter of formaldehyde exposure at sites of contact and are frequently used for risk modeling and prediction of formaldehyde carcinogenicity for different species. DPX have been shown to occur only at the site of initial contact in the nasal mucosa of rats and in the upper respiratory tract of monkeys exposed to formaldehyde4.

Dental studies have not supported the contention that formaldehyde, as used in dentistry, is mutagenic. Zarzar et al in 2003 performed formocresol pulpotomy on 20 children by using Buckley's original formula. Peripheral venous samples were collected from each child immediately before and 24 hours after the pulpotomy, and lymphocytes were collected from each blood sample for cell culture and cytogenetic analysis. No statistically significant differences were found between the 2 groups in terms of chromosomal aberrations, chromatid breaks, or chromatid gaps. Also, Zarzar et al concluded that formocresol is not mutagenic and he observed chromosomal aberrations in 1 (5%) of the 20 patients but were unable to determine whether formocresol or other variables accounted for this finding.

Ribeiro et al in 2004 and 2005 reported 2 studies respectively that assessed the mutagenic potential of formocresol as well as several other chemicals commonly used in dentistry. With a mouse lymphoma cell line, cultured human fibroblasts, and a series of formocresol dilutions similar to clinical doses, these authors found that formocresol did not produce detectable DNA damage and should not be considered genotoxic.

Laboratory investigations of root canal sealers containing formaldehyde, which are used in endodontic procedures, have demonstrated cytotoxicity by Huang Th et al in 2004. For several reasons, however, these investigations are not comparable to formocresol pulp studies. A larger quantity of formaldehyde is released from root canal sealers than during Pediatric formocresol pulpotomy because of the large quantity of sealer used. Moreover, contact of formocresol with vital pulp tissue during pulpotomy is restricted to only a few minutes, whereas root canal sealer remains in the root canal and forms part of the final restoration, with the potential for further release of formaldehyde3,4,5.

Carcinogenicity: There is considerable evidence that prolonged inhalation of formaldehyde induces highly nonlinear dose-related increases in the incidence of tumours of the anterior and posterior lateral meatus of rats. There is marked increase in tumour incidence at concentrations greater than 6ppm (7.2mg/m3) formaldehyde while concentrations of 2ppm (2.4mg/m3) and lower do not induce malignant nasal tumours.

The most recent evaluation by IARC in 2004 reclassified formaldehyde as being “carcinogenic to humans”. This conclusion is largely based on the statistics from reports of increased mortality from nasopharyngeal cancer which have emerged from studies of US industry workers published by NCI. However, only a small number of peoples all of whom worked at a single industrial plant were found to have cancer. Nevertheless, the Chemical Industry Institute for Toxicology Centres for Health Research (CIIT) in 1991 considers that the risk of developing cancer is negligible until formaldehyde exposure reaches levels associated with cytotoxicity, which is in the range 600 to 1,000ppb.

The possibility that inhaled or ingested formaldehyde might induce cancers at sites distant from the respiratory or gastrointestinal tracts has been investigated in numerous long-term toxicity studies performed in rodents. Leukaemia was not observed in any of 7 long-term inhalation bioassays in rodents, and it was not observed in 3 drinking water studies in which rodents were exposed to doses as high as 1.9 – 5 g/L. Leukaemia was observed in a single drinking water study, in which Wistar rats were exposed to doses as high as 1.5 g/L. That study, however, is regarded by the Cancer Assessment Committee of the U.S. Food and Drug Administration as questionable, and the data are unreliable because of a lack of critical detail and questionable histopathologic conclusions.

Immune Sensitization: According to Block RM et al in 1976, despite evidence from dogs that formocresol can produce antigenic activity in dental pulp tissue but Rolling and Thulin in 1976 found no increase in either immune response or allergic reactions in 128 children who had undergone formocresol pulpotomy.
More evidence supports the work of Rolling and Thulin. A Canadian study done by Pross HF et al in 1987, urea formaldehyde foam insulation (UFFI) off products in the homes of subjects with asthma found that long-term exposure had no effect on immunologic parameters. Doi et al in 2003, found that the prevalence of IgE sensitization to formaldehyde was very low among Japanese children, regardless of whether they had asthma; furthermore, they found no clinical relevance of formaldehyde-specific IgE. Hence, the suggestion that formocresol “sensitizes” children has not been supported.

**Buckley’s Formocresol:** The use of formaldehyde for the disinfection of inflamed pulps first was reported by Lepkowski in 1897. This technique caused intolerable pain, but it was not until 1904 that a modified formula was introduced by Buckley. This latter material contained Tricresol and glycerine on an empiric basis (rather than on a chemical or biological basis) and was clinically more acceptable.

Garcia-Godoy et al in 1982 used a 1 min application of full strength formocresol, and found that it produced less inflammatory response and tissue reaction when compared with 3 min and 5 min applications.

The cytotoxic effects of formocresol, although known to earlier workers, were not fully understood and were based upon subjective criteria. Buckley in 1904 stated that there was no necessity to use formaldehyde in the same strength in non-vital teeth containing nonsupputative material as in teeth which contained putrescent material. Straffon and Han in 1968 concluded that a lesser concentration of 1/50 formocresol solution did not interfere with the prolonged recovery of connective tissue and that it might have suppressed the initial inflammatory response. Loos and Han in 1971 concluded that a 1/5 concentration of Buckley’s formocresol was as effective as the full strength formula, and allowed for a faster recovery of the affected cells and therefore represented a safer medicament. Gazi et al in 1981 found that a 50% dilution of formocresol in propylene glycol was significantly less irritating than a full-strength formula.

**Quantitation and Timing of Formocresol:** Intracanal medications (of nonspecific disinfecting agents) are applied in various ways and quantities. Their use is controversial. Some authorities recommend large quantities, while others favor smaller amounts. Some confine the medication to the coronal portion of the canal, whereas others rely on a vehicle, such as a paper point, to carry the liquid drug apically.

_Sommer et al in 1962 suggest_ applying medications to a blunted paper point that has been placed into a dried canal. No mention is made of drug quantity.

_Nichols in 1967 recommends_ the use of a paper point saturated with medicamerit. “The point should fit the canal fairly closely, so as to allow the maximum volume of drug to be applied and to provide close contact between it and the root dentin.”

_Grossman in 1965 advocates_ “pumping” the medicament into the root canal to allow it to come into contact with the tissue to be sterilized.

_Schilder in 1965_ on the other hand, recommends the use of smaller amounts of drugs and also suggests that medication is secondary to a thorough debridement of the canal. He recommends that the medication be placed only on a small pledge of cotton confined to the pulp chamber. Because of the volatile nature of these drugs, no attempt need be made to introduce them into the root canal. The empty canal may act as a reservoir for any exudate that may develop following instrumentation.

_Stewart et al 1969_ also stress the need for complete debridement, since it serves the same purpose as wound debridement in surgery. The more complete the removal of irritants, the more completes the repair. However, they seem to advocate the use of larger amounts of medication when they state that “by increasing the volume of the root canal, greater quantities of medication can be sealed in to destroy the remaining microorganisms.”

_Leavitt et al in 1967_ reported that formocresol applied to a pledget of cotton taped to the inside top cover of a blood agar Petri dish seeded with specific bacteria produced a zone of inhibition on the seeded media.

_Marshall et al in 1967_ developed a technique, utilizing extracted teeth, for in vitro culturing studies which effectively simulated the in vivo conditions of root canal infection.

By using a minimal effective dose of a nonspecific drug, it would seem possible to lessen the undesirable inflammatory reactions, the accompanying pain, and probable tissue damage.
Although much has been studied about the irritating and harmful effects of certain drugs applied topically or locally, to our knowledge no data have been published on attempts to quantitate an effective minimal dose for root canal drugs.

The effectiveness of formocresol as an antimicrobial agent was studied by combining the Petri dish method of Leavitt et al and the culturing method of Marshall and Savoie in 1967. Formocresol in small concentrations was found to be very effective, under the conditions described, in eliminating microorganisms.

Formocresol in Blood: The foundation of the argument against the use of formocresol in dentistry is the belief that, upon placement in the pulp chamber, unmetabolized formocresol (primarily formaldehyde) becomes systemically distributed. Free formaldehyde present in the circulation could react with macromolecules, thereby potentially causing mutagenic and/or cytotoxic changes in muscle, liver, kidney, heart, spleen, and lung tissue.

Conclusion

It is highly unlikely that formocresol, when judiciously used, is genotoxic or immunotoxic or poses a cancer risk to children who undergo one or more formocresol pulpotomy procedures. Definitive data to support this hypothesis are lacking, however, such evidence is needed before definitive conclusions can be reached.

Abscess on Periodontium—A Review

Preethe Paddmanabhan¹, Bhuvaneswarri¹, Ramya V¹, Vidhya¹, Sajid T. Hussain¹

¹Reader, Department of Periodontitis, Department of Periodontitis, Sree Balaji Dental College and Hospital, Bharath University, Chennai, Tamilnadu, India

ABSTRACT

Periodontal symptom is that the third most frequent dental emergencies, representing 7-14% of all dental emergencies. There square measure numerous aetiology tributary factors post medical aid symptom, impaction of foreign objects, the factor that altering tooth morphology etc. The diagnosis is done by analysis of signs and symptoms. The Treatment of periodontal abscess has been a challenging for many years. The main aim of this article is to review and evaluate the articles of Periodontal abscess.

Keywords: Periodontal abscess, Incision and drainage and antibiotics, gingival pain, forigen objects, Periodontal Abscess, Gingival abscess

Introduction

Abscess is localised collection of pus purulent material collected in cavity caused by destruction of tissues. There are three type of abscess:

1. Gingival abscess
2. Periodontal abscess
3. Pericoronal abscess

Odontogenic abscesses include a broad group of acute infection that originate from tooth or periodontium. Abscess are associated an array of symptoms, including purulent inflammation, in periodontal tissues which causes pain and swelling. An acute, destructive process of periodontium resulting in localised collection of pus communicating with the oral cavity through the gingival sulcus or periodontal sites & not arising from tooth pulp.

Gingival abscess: Acute inflammatory condition of the gingiva characterised by purulent exudates without attachment loss. Following traumatic insult: e.g., injury by a fish bone, tooth brush bristle, etc., implantation of virulent bacteria into the gingival connective tissue leads to excessive gingival inflammatory reaction.

A gingival abscess was also defined as a localized purulent infection that involves the marginal gingiva or interdental papilla.

Abscesses of the periodontium is defined as localized acute bacterial infections which are confined to the tissues of the periodontium. They are classified as abscess associated with periodontal tissues.

1. a gingival abscess is a localized purulent infection that involves marginal gingiva and interdental papilla
2. pericoronal abscesses surrounding the crown of a partially erupted tooth;
3. combined periodontal and endodontic abscess are the localized, circumscribed abscesses originating from either the dental pulp or the periodontal tissues surrounding the involved tooth root apex and/or the apical periodontium
4. periodontal abscesses which are localized purulent infections within the tissue which involves periodontal tissues leads to destruction tissue and bone loss. These are known as lateral periodontal abscess or Parietal abscess.

The, accurate diagnosis and the immediate treatment of the abscesses are the important steps in the management of patients presenting with such abscesses.

Classification

Periodontal relation abscess: When there is acute inflammation from the biofilm periodontal abscess occur. classification based on aetiological criteria
Non-Periodontitis connected abscess: once the acute infections originate from another native supply. eg. Foreign body impaction, alteration in root integrity

Classification based on the course of the disease

Acute periodontitis symptom: The abscess develops during a short amount of your time and lasts for a couple of days or every week.

An acute symptom typically presents as an abrupt onset of pain on biting and a deep throbbing pain during a tooth within which the patient has been tending to clench.

The gingiva becomes red, swollen and tender.

Acute periodontal abscess: This abscess develops in a short period of time and last for few days or a week. An acute abscess develops with a sudden onset of pain on throbbing pain in tooth in which the patient has been tending to clench The gingiva becomes red swollen and tender chronic Periodontal abscess. This condition that last for long time and often develops slowly In chronic stages, a nasty taste and spontaneous bleeding may occur.

The adjacent tooth is tender to bite on and is sometimes mobile. Pus may be present as also may be discharges from the gingival crevice or from a sinus in the mucosa overlying the affected root. Pain is usually of low intensity.

1. Classification based on number
2. Single abscess: Abscess confined to a single tooth.
3. Multiple abscesses: Abscess confined to more than one tooth.

Histopathology: It has been reported that the microorganism colonize the periodontal

Abscesses are primarily Gram negative anaerobic rods. Although they are not found in all cases of periodontal abscesses, high frequencies of Porphyromonas gingivalis, Prevotellaintermedia, Fusobacteriumnucleatum, Campylobacter rectus, and Capnocytophagasp spp have been reported. Periodontal bacteria found in culture studies are

1. Porphyromonas gingivalis-55-100% (Lewis et al 9)
2. Prevotellaintermedia- 25-100% (Newman and Sims 7)
3. Fusobacterium nucleatum -44-65% (Hafstrom et al 8)
4. Actinobacillus actinomycetemcomitans-25% (Hafstrom et al 8)
5. Camphylobacter rectus- 80% (Hafstrom et al 8)
6. Prevotella melaninogenica-22% (Newman and Sims 7)

Etiology

1. Changes in composition of microflora, bacterial virulence, or in host defence could also make pocket lumen insufficient to drain increased suppuration 9
2. Closure of margins of periodontal pocket may lead to extension of infection on the surrounding tissue due to pressure on suppuration inside the closed pocket. Fibrin secretion may lead to localised accumulation of pus may lead to closure of gingival margin to the tooth surface10.
3. The development of periodontal abscess in periodontitis may occur at different stages during the course of the infection as an exacerbation of an untreated periodontitis during periodontal therapy in refractory periodontitis or during periodontal maintenance. Also fibrin secretions leading to the local accumulation of pus, may favour the closure of gingival margin to the tooth surface.
4. Changes in compositions of the microflora, bacterial virulence or in host defences could also make the pocket lumen inefficient to drain the increased suppuration.
5. Treatment with systemic antibiotics without subgingival debridement in patients with advanced periodontitis may also cause abscess formation.
6. Abscess can formed due to inadequate scaling, which will allow calculus to remain in deepest pocket area while resolution of inflammation in coronal pocket area will occlude the normal drainage and entrapment of the sub gingival flora in deepest part of the pocket. Also calculus might get dislodged and pushed into the soft tissue after procedures like scaling

Non-periodontitis Related Abscess:

1. Impacted of foreign bodies such as tooth brush bristles, a piece of dental floss, orthodontic elastics
a dislodged cemental tear, food (such as fishbone) into the gingival tissues and so on can result in abscess formation. Periodontal abscess caused by foreign bodies related with oral hygiene aids, have been named “oral hygiene aids have been named “oral hygiene abscess”

2. Lateral perforation of root during endodontic therapy and trauma to the tooth

3. Local factors affecting morphology of roots such as cemental tear, external root resorption, invaginated tooth and cracked tooth may predispose to periodontal abscess formation

**Diagnosis**

The diagnosis of periodontal abscess usually based on the chief compliant and history of presenting illness. The relevant medical and dental history is mandatory for proper diagnosis of the case. Usually the severity of pain and distress will differentiate an acute from a chronic abscess. The dental history can provide information about periodontal treatments, endodontic therapy and previous abscess. The suspected area should be carefully probed for continuity of the lesion with the gingival margin serve as a clinical evidence that the abscess is periodontal. Other findings are ovoid swelling of gingiva, pain tooth mobility, tooth elevation, suppuration either spontaneous or on digital pressure and the presence of deep periodontal pockets. Radiographically, it appears as discrete area of radiolucency along the lateral aspect of root. However, lesion in the soft tissue wall of periodontal pocket are less likely to produce radiographic changes than those deep in the supporting tissues.

**Differential diagnosis:** The differential diagnosis of Periodontal abscess is clinically important to allow the dentist to more clearly understand the condition or circumstances to arrive to a conclusion from following diseases like (Ludwigs angina, space infections of orofacial regions) and plan the treatment.

**Treatment:** The principles of management of periodontal abscess are as

1. Local measures –
   a. Drainage
   b. Elimination of the cause

2. Systemic measures- Antibiotics in combinations with local measures

   1. Drainage through periodontal pocket: There are 8 steps in the drainage through periodontal pocket.
      a. Topical anaesthesia is prepared.
      b. The pocket wall is gently retracted with a probe/curette in an attempt to create an initial drainage through a pocket entrance.
      c. Gentle digital pressure is applied
      d. irrigation is done to clear the exudate of the pocket wall
      e. If the lesion is small and has good access, scaling and Root planning is done
      f. If the lesion is large, drainage cannot be established through scaling and root planning major clinical signs are established through antibiotic therapy
      g. In such patients systemic antibiotic with short and high dose regimens is recommended.

   b. Drainage through external incision

   If the lesion is large, pin –pointed, fluctuating, an external incision can be made to drain the abscess. The steps are as follows:

   A. Abscess is drained and isolated with guaze and sponge.
   B. Local anaesthesia and nerve block is prepared.
   C. Vertical incision is given through a more fluctuating area of abscess on No 11 or 15 Blade
   D. Tissue which is lateral to incision is separated using periosteal elevator/curette
   E. Light digital pressure is given with moist guaze pad
   F. In patients with marked swelling and redness, it is recommended to have systemic antibiotics as an intial treatment to avoid damage to healthy periodontium.
   G. Periodontal surgery.
      a. Surgical therapy of gingivectomy or flap procedures has been advocated mainly in abscess
      b. Surgical flaps have been proposed in cases in which calculus left subgingivally after treatment.
      c. The main objective of this therapy is to eliminate calculus and to obtain drainage at the same time.
d. A therapy with combination of flap with deep scaling and irrigation with chlorhexidine have also been proposed

D. Systemic antibiotic with or without local drainage

Antibiotics are preferred mode of treatment. However local drainage of abscess is mandatory to eliminate the etiological factors. The recommended antibiotic usually follows the culture and sensitivity test. The antibiotic usually given

1. Phenoxymethylpencillin 250-500 mg qid 7-10 days
2. Amoxycillin/Augmentin 250-500 tds 7-10 days
3. Metrodinazole 250 mg tds 7-10 days can be combined with amoxicillin. The use of metrodinazole is contraindicated in pregnant patients in children below 10 years.

E. Extraction of teeth

1. Extraction of teeth is a last resort to treat periodontal abscess. Certain guidelines should be followed before extraction of teeth.
   a. Horizontal mobility more than 1 mm
   b. Class II- III furcation involvement of a molar
   c. Probing depth >8mm
   d. Poor response to therapy
   e. More than 40% alveolar bone loss.

Conclusion

The Periodontal abscess typical clinical and histopathology feature. The most prevalent organism p gingivalis P. intermedia and fusobacterium. Different therapeutic alternatives have been proposed for the treatment of the periodontal abscess. Among these incision and drainage scaling and root planning are the sole therapy for the treatment of the periodontal abscess.

Periodontal Maintenance: A Necessity for Treatment Success

Bhuvaneswarri¹, Sneha V.², Bagavad Gita³
¹Professor, ²Post Graduate, ³Professor & Head of the Department, Department of Periodontology, Sree Balaji Dental College and Hospital

ABSTRACT

The main aim regarding periodontal therapy, is to ensure an healthy oral environment, devoid of plaque, biofilm, by physical disruption and by adjunctive chemical means. This review examines the therapeutic goals necessary for periodontal maintenance, the protocol necessary for adequate maintenance, supportive periodontal therapy (by the clinician, by the patient), evidence based approach of maintenance care and also about the new approaches. This review concludes that even after proper treatment, long term stability is ensured only with good maintenance of oral hygiene, by avoiding risks i.e. smoking and with regular maintenance care programme.

Keywords: supportive periodontal care, maintenance care, maintenance protocol, periodontal maintenance.

Introduction

The main aim in regard to prophylaxis would be prevention of disease. Measures are usually taken for disease prevention(¹) either after completing periodontal therapy or dental implant therapy(²). Maintenance care is essential for the long-term success rate of periodontal treatment. Due to this a concept involving very specific requirements for ongoing periodontal care was designed and it was decided that professional maintenance was mandatory for long term stability post periodontal therapy(³)

Therapeutic Goals of Periodontal Maintenance:

i. The main and foremost goal is to minimise (or) prevent the recurrence of disease progression (³) in patients, who were previously treated for periodontitis, for peri-implantitis(²). "Compendium of Continuing Education in Dentistry (Jamesburg, N.J.: 1995 or any types of gingivitis.

ii. For either the prevention, or to reduce the incidence of tooth or implant loss, by monitoring the dentition & the prosthetic replacements of the natural teeth.

iii. For increasing the probability of locating & treating any other conditions in the oral cavity.

There are three components in the maintenance of periodontal tissue(⁴), after completion of periodontal therapy they are,

° Maintenance Care by the Patient: Maintenance of proper oral hygiene

Avoidance of tobacco smoke(⁵)

Management of systemic illness, such as diabetes, etc.,

° Maintenance Care by Dental Professional:

1. Prophylactic removal of supragingival deposits.

2. Elimination of factors which can lead to plaque-retention, such as any ill-fitting restorations, prosthesis etc.

3. In Supportive Periodontal Therapy, there are interventions which address the cause, the pathophysiologic mechanism (or) the sequelae of the recurring disease like presence of subgingival biofilm, inflammation, tooth mobility etc.
Follow up-care post treatment\(^{(4)}\), is usually planned after completion of initial periodontal therapy.

The destructiveness associated with periodontal diseases is highly preventable, but it is difficult to manage, and it requires regular and proper intervention by the dental professional. Follow-up care is especially difficult, if the patients are diagnosed with any underlying disease.

Supportive periodontal therapy (or) periodic recall for periodontal maintenance and recall for the maintenance of dental implants are all compressively known as procedures which are called as periodontal maintenance.

**The Maintenance Protocol:**

- Focus during assessment should be on any recent change (or) any new pathology.
- The patient should be given a brief re-assessment based on general health, medication, or other therapy and the dental history.
- With regard to the measures taken by the patient, the clinician should discuss his findings with the patient and this opportunity must be used to motivate the patient towards better oral hygiene practices. Behaviour change counselling should be done for smoking cessation\(^{(5)}\). At the end of the maintenance visit\(^{(6)}\), decision with regard to the interval of the recall visit is decide, if it should be altered or kept as before.
- Post completion of periodontal (or) implant therapy, maintenance should start at an interval of 3 months.
- The stability should be evaluated continuously and the frequency of the recall visit should be decided based on the individual. If the patient has established adequate level of plaque control in regard to the past measurements the interval can be prolonged.

**Supportive Periodontal Therapy:** It is suggested that patients with prior history of periodontal issues should have a periodontal maintenance at least 4 times/year, this is so that the progression of the disease is decreased. The maintenance schedule is usually individualised to the needs of each patient.

Pocket debridement procedure suppresses the subgingival microflora present, but the baseline levels returns within days (or) months. The reversal to the, pre-treatment levels generally occurs from 9 to 11 weeks, depending on the patient.

The factors which determine the time required for periodontal maintenance are:

- Number of teeth (or) Implant present
- Patient co-operation
- Oral hygiene efficacy & compliance
- Systemic health
- Instrumentation access
- History of disease (or) complication
- The distribution & depth of the sulci

The innermost time period, traditionally used for periodontal maintenance is about 45-60mins.

Plaque control is considered as an important factor, for the maintenance of dental implants and natural teeth

Effective method for maintenance of implant oral hygiene includes

- Interdental brushes
- Dental floss
- Dental tape
- Floss ribbons and
- Topical chemotherapeutic agents

**Treatment Sites for Periodontal Maintenance:** The effectiveness of periodontal management majorly depends on the understanding & co-operation that exists between the dentist, the patient and the periodontist.

If the patient, is a case of recurrent gingivitis (or) a case of slight chronic periodontitis they can be maintained by a general dentist.

If the patient gives a history of chronic periodontitis, with moderate attachment loss, maintenance of the periodontium is done alternated between the general dentist and the periodontics.

If the patient gives a history of severe periodontal attachment loss (or) an aggressive form of periodontitis, maintenance of the periodontium\(^{(6)}\) is done by the periodontist and the general dentist maintains other general aspects for the patient.

Supportive periodontal therapy is classified into two types,
Evidence Based Appraoch of Maintenance Care: There are 5 lines of evidence, they are:

- Accumulation of large amounts of bacteria, on teeth and implants should be avoided.
- The local etiological factors should be eliminated or controlled.
- An important step, is to remove any bacteria deposits on teeth and on implants.
- Stability for long-term after periodontal therapy, is possible only if the patient maintains good oral hygiene and is included in regular maintenance care program\(^{(6)}\).
- The factors that influence the severity and incidence for the recurrent periodontitis is the type & frequency of maintenance care. Good maintenance of oral hygiene\(^{(4)}\) is more important than proper and regular professional intervention.

Maintenance & Residual Pocket:

- Prophylactic measures\(^{(7)}\) should be done regularly in order to maintain the microbiological state achieved by the periodontal therapy.
- The recontamination of the already traded sites can be prevented.
- If the bacteria have regained access to the subgingival area (or) if they were never entirely removed from there, the procedure don’t have that much of effect on them.
- So in order to prevent the disease recurrence in residual pockets periodic interventions is done.
- Local application of an antibiotic, cannot be considered as an appropriate prophylactic procedure\(^{(8,9,10)}\), but it is considered as a good option for treating a contained infection.

New Approaches: New approaches are required to help the efficiency of maintenance care, it is less likely to cause damage, and it can be implemented easily and should be cost-effective. Also when viewed from a public health point, there is a notion that periodontal disease is a perceptible risk factor for CVS, stroke & premature birth. Due to which it becomes increasingly important to control and prevent the disease in a cost-effective manner.

Conclusion

Long term stability after periodontal therapy is possible with good maintenance of oral hygiene by the patient, avoid risks (such as smoking) and with regular maintenance care programme. There is conclusive evidence from clinical studies that systemic and regular monitoring of periodontal parameters is necessary to detect and intercept any new or recurrent disease. Individual variations to disease susceptibility will determine the frequency and level of professional input required

Rank/Rankl Factor in Periodontitis—A Review

J. Bhuvaneswarri1, V. Ramya2, Preethe Padmanabhan2, Sajid T. Hussain2, Vidhya Rekha U.3

1Professor, 2Reader, 3Sr. Lecturer, Department of Periodontics, Sree Balaji Dental College & Hospital, Velachery Main Road, Pallikaranai, Chennai, Tamilnadu, India

ABSTRACT

Periodontitis is a multifactorial disease which is defined as inflammation of the supporting tissues of the teeth. It causes progressively destructive changes leading to loss of alveolar bone and periodontal ligament. An extension of inflammation from gingiva into the alveolar bone and periodontal ligament. Periodontal disease is bacterial host interface disease. One such factor which is thought to be of host modulating is RANK/RANKL system. This review is about the periodontal panorama about the system which might be therapeutic modulation of periodontal disease.

Keywords: rankl, rank, Bone Resorption, Bone Remodelling, Osteoprotegrin.

Introduction

Periodontal disease is associated with various disease like chronic inflammatory disease cardiovascular disease, rheumatid arthritis etc. The host which modulates this disease is RANK/RANKL it is a protein, which belongs to the cytokine family. It mediated the immune system in the body. It belongs to the TNF family.[1]

RANKL/OPG balance is an important factor in regulating bone resorption in periodontal and periapical diseases.

Receptor activator of nuclear factor kappa-B ligand (RANKL), belongs to the tumor necrosis factor ligand superfamily member 11 (TNFSF11), the activation of TNF induces cytokine (TRANCE), osteoprotegerin ligand (OPGL), and osteoclast differentiation factor (ODF).

RANKL is a type II membrane glycoprotein and belongs to the tumor necrosis factor (TNF) superfamily.

Functions of Rank/Rankl:

Regulates osteoclast formation.

Involved in normal bone modelling and bone remodelling.

Involved in various pathological conditions with increased bone turn over.

Critical signalling pathway for cellular differentiation and development of epithelial tissues in various organs.

Mechanism of Action: Osteoclast and osteoblast and their precursors were thought to control bone metabolism. Recent discovery of RANK and its ligand are thought to be the factor control. RANKL and osteoprotegrin are the key protein which involved in activation, differentiation of osteoclast and osteoclast precursors.

RANKL is expressed in osteoblast, stromal cells, chondrocytes, and mesenchymal cells and also activated T & B cells express RANKL.
**RANK** is expressed in osteoblast, stromal cells, chondrocytes, monocytes, dendritic cells.

The decoy receptor **Osteoprotegrin** is expressed in fibroblast, periodontal ligament cells.

RANK expression is increased due to activity of RANKL, IL-1, oncostatinM, vitamin D3.

Decreased in the number of RANK molecules on the surface of osteoclast is induced by IL-4.

Osteoclast differentiation and activation are driven by the interaction of RANK with its ligand, RANKL. Osteoprotegrin (OPG) is a decoy receptor of RANKL that inhibits RANK-RANKL engagement in osteoclastogenesis and bone resorption with an inflammatory stimulus, the RANKL/OPG ratio increases in periodontal and periapical tissues and leads to stimulation of osteoclast activity and pathologic bone resorption.[4,5,11,12]

**Discussion**

The initial stages of infection activate the immune defences, including mechanical barrier and inflammatory response, bacterial invade the tissue macrophages and other cells present the antigen. T cells are regulators of bone turnover. The T cells activates the macrophages can activate indirectly osteoclasts and their precursors and expressing rankl. Lymphocytes present in periodontal diseases express RANKL and it activates osteoclast. The intracellular cascade that produces cytokine involved directly or indirectly in osteoclasts activation. When cytokines activated it act with the network of cells. These suggest that immune system plays a major role in bone resorption in periodontal disease.[6,7,8]

The current concept is that rank/rankl/opg pathway is one of the important pathogenesis of inflammation and to activate in bone resorption in periodontal disease; rankl activates bone resorption and opg has inhibited bone resorption. Studies done in rankl/opg, ratio augmented in serum/plasma of patients affected by periodontitis with decreasing opg. Many studies has found that rankl/opg level is in saliva and gingival crevicular fluids of patients affected by periodontitis compared with healthy controls. In another review done by bostanci reported an increased rankl/opg ratio and in that study rankl is increased, whereas opg is decreased in periodontitis compared to healthy control, that the ratio is increased in smokers and diabetics. There are no due studies that correlate rankl/opg oral fluids. Thus it cannot be used as biomarker.[9,10,13]
Conclusion

RANKL expression in periodontal tissues is a very complicated process that involves many factors. RANKL is identified in lymphocytes, stromal cells, and many other cell types in periodontal tissues which play an important role in direct or indirect regulatory roles. Cytokines such as IL-1β and TNF-α can upregulate RANKL expression in periodontal cells and increase osteoclast formation. Figure 1 summarizes the major cells and cytokines related to RANKL expression.

Stress and Periodontium—A Review

Preethe Padmanabhan¹, J. Bhuvaneswarri², V. Ramya³
¹Reader, ²Professor, ³Reader, Department of Periodontics, Sree Balaji Dental College & Hospital, Velachery Main Road, Pallikaranai, Chennai, Tamilnadu, India

ABSTRACT

Stress is an association of physiological and psychological reactions of a person confronted to a change of situation he cannot face. The relationship between stress and any disease is explained by hormonal modifications and behavioural changes induced by the stress. Research has suggested that stress and depression are two factors that play a role in the development and progression of periodontal disease. It is not clear, however, whether these factors lead to periodontal disease through physiological or behavioural changes, or by some combination of the two. The purpose of the present review article is to explore the associations between psychological factors, psycho immunologic variables, behaviour, and clinical measures of periodontal disease.

Keywords: Psychosocial factors, Depression, Life events, Glucocorticoids

Introduction

There is a strong relationship between periodontal disease and psychosomatic illness and they are well established in specific conditions like acute necrotising ulcerative gingivitis.[1,2] Studies well establish that there is a strong association between depression and periodontal disease. There are also fewer studies demonstrate the importance of oral infection and stress.[3-5] Evidence support the importance of stress on progression of periodontal disease and response to its treatment.[6] Studies also explain there is an interaction between immune system that alter the oral health behaviour.[7] Stress is said to influence the host defenses, exerting an immunosuppressive effect, increasing one’s vulnerability to disease.[8-10] Cytokines and other humoral mediators of inflammation are potent activators of the central stress response, and the glucocorticoids released via this mechanism might regulate the recruitment of immune cells into inflamed tissues, in order to cope with the psychological stress and depression. Few studies have demonstrated the importance of subjective factors in oral infections and stress.[11-13] There are numerous studies have impact on stress and periodontal disease however further studies are needed to establish the true phenomena.

Effect of stress on cortisol and salivary levels on chronic periodontitis: A Cross sectional study done in of sample size 111 patients to evaluate the physiological stress and salivary cortisol levels and its effect on chronic periodontitis.

One hundred and eleven dentate individuals, of age 40 years and above, were selected. The clinical examination included, the number of teeth present, plaque index, Probing Pocket Depth, and Clinical Attachment Level. Assessment of Psychological stress levels were done by a questionnaire and were correlated with salivary cortisol levels, which were estimated biochemically by using the Enzyme-Linked Immunosorbent Assay (ELISA) method. Statistical analysis was done by using the student ‘t’ test and Mann Whitney test. According to observation, chronic periodontitis showed a significant correlation with hypercortisolemia (P<0.0001), work tension (P<0.04), economic problems (P<0.0001), clinical stress syndrome (P<0.0001), plaque index (P<0.0001), and unsecured job (P=0.003). Stress may
be considered as an important risk factor for periodontal disease. Routine salivary cortisol assessment may be an economical and useful diagnostic marker to rule out stress in periodontitis patients[14].

**Molecular and endocrine mechanism of stress response:** Stress can result in the degeneration of the immune system, mediated primarily through the hypothalamic – pituitary – adrenal and sympathetic adrenal medullary axis. The stress-induced responses are transmitted to the hypothalamic/pituitary/adrenal (HPA) axis to promote the release of corticotropic-releasing hormone (CRH) from the hypothalamus and glucocorticoids from the adrenal cortex.

Stress perceived by the brain stimulates the hypothalamus to produce CRH, which is released into the hypophyseal portal system, activating the pituitary gland to release adrenocorticotropic hormone (ACTH), which in turn induces release of corticosteroids from the adrenal cortex.

Glucocorticoids also inhibit the cascade of the immune response by inhibiting macrophage-antigen presentation, lymphocyte proliferation, and lymphocyte differentiation to effector cell types such as helper lymphocytes, cytotoxic lymphocytes, natural killer cells, and antibody-forming B cells. Corticosteroids also inhibit production of cytokines including IL-1, IL-2, IL-3, and IL-6, tumor necrosis factor, interferon gamma, and granulocyte and monocyte colony stimulating factors. Glucocorticoids inhibit arachidonic acid-derived proinflammatory mediators such as prostaglandins and leukotrienes.

Glucocorticoids also induce endogenous anti-inflammatory proteins and lipocortins, which have the capability of inhibiting phospholipase A2, thereby inhibiting generation of eicosanoids. Hence, the stress-related stimulation of the HPA axis with the production of glucocorticoids such as cortisol has major suppressive actions on immune and inflammatory responses. This represents the major effector arm of the CNS-hormonal axis. There is also an afferent or feedback arm consisting of stimulation of the HPA axis by cytokines. Glucocorticosteroids, including cortisol, then depresses immunity including secretory IgA, IgG, and neutrophil functions, all of which may be important in protection against infection by periodontal organisms. Secretory IgA antibodies may protect by reducing initial colonization of periodontal pathogens. IgG antibodies may exert protection by opsonizing periodontal organisms for phagocytosis and killing by neutrophils. This then gives rise to increased susceptibility, which leads to the establishment of periodontal infection which, in turn, results in destructive periodontitis.

Periodontitis is brought about by tissue-destroying factors such as IL-1 and matrix metalloproteinases activated by the periodontal pathogens, as well as by the direct effects of pathogenic bacteria. The second major pathway to be activated is the sympathetic nervous system. Stress induced activation of the hypothalamic nervous system results in the release of highly active hormone such as catecholamines. These catecholamines released during stress, contributes to the development of hyperglycemia by directly stimulating glucose production and interfering with the tissue disposal of glucose.

Catecholamines are known to alter the blood flow. Peripheral vasoconstriction may affect important oxygen – dependent healing mechanisms, such as angiogenesis, collagen synthesis and epitheliazation. The release of Catecholamines results in hormonal secretion of norepinephrine from the adrenal medulla, which results in a range of effects that may act to modulate immune responses. Increased sympathetic stimulation can also act to decrease salivary secretions typically experienced as anxiety induced dry mouth. Stress that is associated with immune challenge has been called immune stress or inflammatory stress[15].

**Behaviour changes due to mental stress response:** It is hypothesized that the main effects of stress occur through behavioural changes which affect atisk health behaviours such as smoking, poor oral hygiene, and poor compliance with dental care. There is also a possibility that stress leads to other behavioural changes such as overeating, especially a high-fat diet, which then can lead to immunosuppression through increased cortisol production[16,17].

**Social psychology and stress response:** Clinical observations and epidemiological studies indicate that there is a relationship between experiences of negative life events and the development and progression of periodontal disease (Monteiro da Silva et al 1996, Moss et al. 1996, Genco et al 1998)[18].
The effect of adverse life circumstances is supported by a large body of research. Stressful lifecircumstances and life change events, such as bereavement or divorce, academic stress or change in employment status, affect levels and activity of killer cells and suppressor-cytotoxic T cells.

The impact of psychosociological factors will lead to chronic stress. This chronic stress will also have an great impact on systemic diseases in our body eg. Cardiovascular system and immune system. Smoking due to stress will lead to periodontal disease by altering the immune mechanism. Smokers are likely to develop periodontal disease 10 times more than the non smokers. Low parental social factor have been related to teen smoking.

Systemic inflammatory disease and its impact on stress: Rheumatic arthritis have a strong relation with stress. Risk factors include smoking poor oral hygiene stress and immunosuppressive disorder. Stress has been a major factor for necrotizing ulcerative gingivitis. Corticosteroid level are found high in urine in patients with acute necrotising ulcerative gingivitis. In one study by Moss et al found psychologically depressed human individuals who smoked has a high titre of Tannerella Forsythia were to found to have more severe and chronic periodontitis. The author explain that depression will reduce patient willingness to perform physical activities leading them to give less attention to their mouth which inturn leads to calculus formation. Holmes (1967) developed a scale to measure stress in terms of life changes. In this scale, the life events are ranked in order, from the most stressful (death of a spouse) to the least stressful (minor violations of the law).

Conclusion

Studies have shown that there is a strong relation between stress and periodontium. Further more systemic disease associated with periodontal disease such as diabetes, cardiovascular disease, preterm low birth weight. Further more studies need to come to prove the strong association between stress and periodontal disease.

Lipoxins—Resolution of Inflammation—A Review

Preethe Paddmanabhan¹, Ramya V.¹, Bhuvaneswarri J.¹
¹Reader, Department of Periodontitis, Sree Balaji Dental College and Hospital, Bharath University, Chennai, Tamilnadu, India

ABSTRACT

The lipoxins include lipoxin A and lipoxin B. The appearance of these molecules signals the resolution of inflammation. Lipoxins are lipoxygenase derived eicosanoids and are generated from arachidonic acid. They are highly potent, possessing biologic activity at very low concentration, and inhibit neutrophil recruitment, chemotaxis, and adhesion.

Keywords: lipoxin, anti-inflammatory, resolution of inflammation, anti-fibrotic, leukocytes, mesangial cells

Introduction

Inflammation: Inflammation is a pathophysiological response to infection or tissue damage. The agents causing inflammation may be Infective agents- like bacteria, viruses. Immunological agents- like cell mediated and antigen antibody reactions. Physical agents- like heat, cold, radiation, mechanical trauma. Chemical agents- like organic and inorganic poisons. Inert materials- such as foreign bodies.

Types of inflammation: Acute inflammation is of short duration and represents the early body reaction, resolves quickly and is usually followed by healing. Chronic inflammation is of longer duration and occurs either after the causative agent of acute inflammation persists for a long time or the stimulus is such that it induces chronic inflammation from beginning.

Mechanisms of neutrophil and macrophage driven resolution

Chemokine depletion mechanism

Neutrophil apoptosis

Lipoxins: The term lipoxins LXs is an acronym for lipoxygenase (LO) interaction products. These lipid mediators were first recognized to have dual anti-inflammatory and pro-resolution activities. 5S, 6R, 15S-trihydroxy-7,9,13-trans-11 cis-eicosatetraenoic acid and its positional isomer 5S,14R,15S-trihydroxy-6,10,12-trans-8-cis-eicosatetraenoic acid (LXB4) are the principal species formed in mammals. (Serhan et al., 1986a,b).

Pathways: There are two main lipoxygenase pathways. Lipoxygenation of arachidonic acid by 15-LO in epithelial cells and monocytes, 5-LO in neutrophils. The second major route of LX formation involves platelet/leukocyte or platelet/leukocyte microaggregate interactions that promote LX formation by transcellular conversion of the 5-LO epoxide product, LTA4 to LXA4 and LXB4 by the LX-synthetase activity of the 12-LO in platelets. In addition to the transcellular routes, another recognized source of LX biosynthesis involves a form of cellular ‘priming’ with the esterification of 15-HETE in inositol-containing phospholipids within the membranes of human neutrophils (Brezinski and Serhan, 1990). Discovery of this pathway suggests that during disease or host defence, precursors of LX biosynthesis might be stored within the membranes of the inflammatory cells and released after stimulation. Specific cytokines – Interleukin 4 (IL-4) and IL-13, putative negative regulators of inflammatory and immune responses,
promote transcellular LX generation through enhanced expression of 15-LO in monocytes and epithelial cells (Nassaret al., 1994; Munger et al., 1999).

**Metabolic Inactivation of LXs:** LXs are rapidly generated in response to stimuli, act locally and undergo rapid metabolic inactivation. Using monocytes or isolated enzymes, it has been possible to demonstrate that the major route of LXs degradation is via dehydrogenation at C-15 and possibly by w-oxidation at C-20 (Serhan et al., 1995; Clish et al., 2000). ATLs are converted in vitro to their 15-oxo-metabolite with a slower rate compared to native LXs, indicating that the hydrogenation step is highly specific (Serhan et al., 1995). ATLs, when generated in vivo, display longer biological half-life than native compounds and enhanced ability to evoke bioactions (Serhan et al., 1995; Maddox et al., 1997; Clish et al., 1999). Synthetic LX Analogues The rapid inactivation and short half-life of LXs in vivo have prompted the development of novel analogues designed to resist metabolism, maintain their structural integrity and bioavailability and their potential beneficial bioactions.

The discovery that 15-epi-LXA4 was equipotent in in vitro assays to LXA4, but was a poorer substrate for PGDH.

15-epi-LXA4 has enhanced metabolic stability over LXA4 in vivo, its pharmacokinetics remain poor, which, in addition to low chemical stability, creates challenges for development of analogues with better therapeutic potential.

A series of LX and ATL analogues were designed with specific modifications of the native structures of LXA4 and LXB4, such as the addition of methyl groups on C-15 and C-5 of LXA4 and LXB4, respectively (Serhan et al., 1995), and phenoxy or parafluorophenoxy groups at C-16 of both LXA4 and 15-epi ATL, protecting the molecules from the w-oxidation and dehydrogenation in vivo (Serhan et al., 1995; Maddox et al., 1997; Clish et al., 1999).

**Conclusion**

Resolution is now looked upon as a complex process where apoptosis of neutrophils and their subsequent clearance herald potent anti-inflammatory, tissue-restoring mechanisms. To fully appreciate the complexity of such processes and to design resolution-based therapeutic strategies, future work is needed to discern differences in the mechanisms of resolution in acute and chronic inflammatory disorders as well as decipher the tissue-specific resolution networks.

Role of Complement System in Dysbiosis and Periodontal Inflammation—An Overview

Ramya V.1, J. Bhuvaneswarri2, Preethe Padmanabhan1

1Reader; 2Professor, Department of Periodontics, Sree Balaji Dental College & Hospital, Velachery Main Road, Pallikaranai, Chennai, Tamilnadu, India

ABSTRACT

Compliment system is tradionally known as a cascade of anti microbial proteins in the blood. It is recognised as a key system for immune surveillance and homeostasis. It has a major link between the innate and the adaptative arms of the host immune response. They exist as pro enzymes and circulate as inactive forms. On activation, they become active, acquire enzymatic or esterase activity, react in particular sequence and cause damage to the neighbouring cells. This review discusses about the dysbiotic transformation of the periodontal pathogens that lead to destructive mechanism and loss of periodontal bone support.

Keywords: complement cascade, haemostasis, immunological surveillance toll like receptors, gingipains.

Introduction

Complement System a Key System of Immune Surveillance: Innate immune system is the resistance to infections that an individual possesses by virtue of his or her genetic and constitutional make up. It may be nonspecific, when it indicates a degree of resistance to infections in general, or specific where resistance to a particular pathogen is concerned1.

Complement Functions

- lysis of bacteria and infected cells
- opsonization to enhance phagocytosis
- phagocyte attraction and activation
- regulation of antibody responses
- clearance of immune complexes

Fig. 1: Stages of Complement System

Complement Components: In this, the complement proteins that exist as proenzymes undergo a chain reaction on activation. The nomenclature of complement components can broadly be described in three main headings

- Complement proteins
- Regulatory proteins
- Associated proteins

The Classical Pathway5: The complement cascade can be triggered by distinct mechanism.
A. Classical

B. Lectin or Alternative: All will converge with the third complement component (C3). The following mechanism takes place.

1. Recruitment and activation of inflammatory cells (via C3Ar and C5Ar)

2. Anaphylotoxins that activate specific G PROTEIN coupled receptors [CD88]

3. Microbial opsonisation and phagocytosis (opsonins)

4. Lysis of susceptible microbes.

These complement interactions can amplify innate immune and inflammatory responses through synergy with toll like receptors. And thereby they provide barriers against the spread of invading bacteria. The complement system and TLR sense pathogens through pattern recognition and trigger the activation of anti microbial and inflammatory responses, thereby initiating adaptive immune response. Therefore the pathogens by targeting complement/TLRs could impair innate immune response, dysregulate host defense. Thus complement system is a network of interacting fluid phase regulatory mechanisms and cell surface associated molecules that trigger, amplify, and regulate immune and inflammatory signalling pathways.

Fig. II: Pathways of Complement System in Pathogenesis

Role of Tolllike Receptors in Innate and Adaptive Immunity: Toll like receptors (TLRs) are germ-line encoded pattern recognition receptors expressed on cells of the innate immune system. They recognise structural components of various microorganisms called as pathogen –associated molecular patterns. Recognition of PAMPs by toll –like receptors will initiate signal transduction pathways, will lead tp generation of inflammatory cytokines and development of a major histocompatibility complex which instruct the development of antigen –specific acquired immunity. Engagement of TLRs on dendritic cells by pathogens play a major role in skewing responses toward Th1 or Th2 cells.
**Regulatory Proteins:** Regulatory proteins are mainly inhibitors or inactivators of the individual steps of complement activation. Since spontaneous activation of complement may occur and lead to auto cytolysis, the main aim of these proteins is to keep the process into control. 10-15 proteins chemically and functionally characterized, some are free in fluid phase to inactivate and some are bound to the cell membrane. Associated proteins Conglutinin – Conglutinin K is a non antibody naturally occurring β2 bovine serum protein. Immuno conglutinin – immuno conglutinin is an auto-antibody to fixed C3 and C4, found in sera of subjects frequently after microbial infections or following immunization with infecting agents. Cobra venum factor – cobra venum factor is a snake C3b in mammalian serum. It can act as C3 convertase. C splitting enzyme – these enzymes can activate C3 and split into fragments in a manner similar to C3 convertase of classical and alternate pathway.

**Complement System and its Role in Periodontal Pathogenesis:** In addition to constituting a “first line of defense", complement is today acknowledged as a factor promoting an adaptive immune response and a key to maintaining host–microbial homeostasis. By virtue of regulator proteins and different propensities to attach to host cells and microorganisms, complement proteins discriminate between healthy host tissue, cellular debris, apoptotic cells and foreign intruders, and tune its response accordingly (7–9). On one hand, complement eradicates invasive pathogens. On the other hand, continuous complement activation and modulation by, e.g. the subgingival biofilm, may enhance local tissue destruction and chronic inflammation, providing the biofilm with essential nutrients, ensuring biofilm persistence. Periodontitis is characterized by the presence of a hyper-activated phenotype of neutrophils with enhanced proinflammatory activity. As complement is a potent activator of neutrophils via complement receptor 3 (CR3) and the C5a receptor (C5aR), it is likely involved in the hyper activation of neutrophils.

Although bacteria populating the tooth associated biofilm essential for the initiation of periodontitis, it is actually the host inflammatory response causing Periodontitis, rather than direct bacterial action. So, it seems reasonable that periodontal disease could be prevented by interventions aiming to control inflammation and counteract microbial subversion of the host response. Activated complement fragments are abundantly found in the gingival crevicular fluid (GCF) of periodontal patients. Complement can be found in GCF at upto 70-80% of its concentration in serum. GCF from periodontitis patients displays complement-depended hemolytic activity, suggesting the presence of a functional complement system in gingival inflammatory exudates. Periodontitis requires a susceptible host. Susceptibility to periodontitis is determined by genetic factors that may predispose to hyper inflammatory responses or by environmental factors (diet and stress) and risk related behaviour (smoking) can modify the host immune response in a destructive response. 11, 12 Regardless of periodontal disease susceptibility, the control of host inflammatory response is considered central to treatment of periodontal disease. Therefore identifying key inflammatory pathways that mediate periodontal tissue destruction has vital implications.

The Periodontitis is induced by polymicrobial bacterial community, where in distinct roles that synergies to cause destructive inflammation. The colonization of associated pathogens trigger the host response leading to symbiotic to a dysbiotic microbiota. The pathogens over activate the host inflammatory response and cause resorption of supporting bone and thereby a positive feedback loop is enabled where the inflammatory tissue breakdown products are used as nutrients by dysbiotic microbiota, which further exacerbates inflammation. The key pathogen P. gingivalis especially induces the conversion from a symbiotic community structure to a dysbiotic, one capable of causing destructive inflammation and periodontal bone loss. Colonization of the periodontium by P.gingivalis impairs innate host defense by instigating a subversive C5Ar-TLR2 cross talk that lead to dysbiotic transformation of the periodontal microbiota. The dysbiotic community in turn causes C3 –dependent inflammatory bone loss, the hallmark of periodontitis resulting in inflammatory environment selects for inflammophilic bacteria that feed on inflammatory breakdown products, thereby promoting further bacterial growth and dysbiosis. 13,16

Complement split products are, in general, either absent or present at low concentrations in the gingival crevicular fluid of healthy individuals, but abundantly present in both the gingival crevicular fluid and serum of patients with periodontitis (82–90). Thus, C1q, factor B, factor Bb, C3, C3a, C3b, C3c, C3d, C4, C5, C5a, C5b and C9 have all been detected in diseased periodontal
tissue, on the surface of subgingival bacteria and in the gingival crevicular fluid from patients with established periodontitis14

**Evasion of Complement by Pathogenic Oral Bacteria:**
In general, bacteria can evade complement through three strategies: (i) proteolytic inactivation of complement components; (ii) recruitment of inhibitory regulators of complement; and (iii) hijacking of inhibitory regulators of complement. P. gingivalis inhibits the complement cascade by enzymatic breakdown of C3, mediated by a group of cysteine proteases called gingipains. Moreover, C5b is proteolytically degraded by P. gingivalis, which inhibits MAC formation. Prevotella intermedia possesses the ability to break down C3 via extracellular cystein proteases interpain A (InpA). Binding of P. gingivalis’ fimbriae to CR3 inhibits IL-12 production in macrophages and seems to reduce: (i) differentiation of naïve T cells into type 1 T-helper cells; (ii) production of interferon-c and tumor necrosis factor-a (TNF-a); and (iii) activation of natural killer cells. In periodontal pockets, TLR2, TLR4, TLR5 and TLR6 expression is increased enabling epithelial cell recognition of extracellular microbial structures, which induces production of IL-8 and matrix metalloproteinases by the epithelial cells.17

**Conclusion**

On the basis of evidence, locally applied complement inhibitors can potentially block periodontal inflammation and thereby provide protection as an adjunctive therapy to standard periodontal treatment. Being host modulation approach, complement inhibition is advantageous to antimicrobial approaches since it is host response that primarily inflicts damage upon periodontal tissues.

Ectodermal Dysplasia—a 10-Year Prospective Study of Implant and Tooth Retained Full Mouth Fixed Restoration

D. Narayana Reddy¹, T. Lalitha²

¹Professor, Dept of Prosthodontics & Implantology, ²Professor, Dept of Oral Medicine & Radiology, Sri Balaji Dental College & Hospital, Chennai

ABSTRACT

Ectodermal dysplasias are congenital disorders which presents with the complete anodontia, oligodontia, hypodontia with poorly developed alveolar ridges. The case reports the replacement of the missing teeth by fixed metal-ceramic bridge after the growth completion with the help of the endosseous implants and the remaining natural teeth with the implant – natural teeth rigid connection. The ridge expansion in the anterior maxilla and the sinus lift in posterior maxilla was done for the implant placement in the compromised alveolar bone. The prosthesis functioned successfully after the 10 year period. The radiographs after the 10 year period showed some marginal bone loss around the implants and the occlusal wear of the ceramic prosthesis.

Keywords: hypohidrotic ectodermal dysplasia, anodontia, oligodontia, hypodontia

Introduction

Ectodermal dysplasia (ED) is the congenital deficiency of the formation of the two or more ectodermally derived structures of the teeth, hair, nails and the sweat glands. The ectodermal dysplasia syndromes are associated with the disorders of the other mesenchymal structures along with the associated ectodermal structures. The ectodermal dysplasias are broadly classified into hidrotic and hypohidrotic or enhidrotic types depending on the presence or absence of the sweat glands.

The hypohidrotic ectodermal dysplasias are more common than the hidrotic ones. The hypohidrotic ED is commonly transmitted by X-linked transmission. The males with the transmitted X chromosome are affected by the severe form of the disorder. The females with single affected X chromosome are usually carriers of the disorder with the milder clinical features. The female carriers of the hypohidrotic ectodermal dysplasia have higher incidence of hypodontia of upper and lower incisor associated with the peg shaped teeth form, and the incidence of microdontia of the 2nd molars than the general population.¹

The hypohidrotic ectodermal dysplasia presents with the lack of the sweat glands leading to the hyperthermia of the body with deranged temperature control. The people affected by the disorder have the typical facial features of the frontal bossing of the forehead, saddle nose and the deficient formation of the maxilla. The lack of the supraorbital hair and eye lashes is seen along with deficient formation of the scalp hair. The facial hair in the male is deficient. Discoloration of the skin around the eyes is present. The deficiency of the maxilla causes the concave profile to the face.

Intraorally congenital missing of the primary and permanent teeth are seen. Hypodontia with the missing of 1 to 5 teeth and oligodontia with the missing of more than 5 teeth are the typical features of the ectodermal dysplasia. Hypodontia and oligodontia is seen in the form of the congenital missing of the primary and the permanent teeth associated with the deformed peg shaped teeth present. The alveolar bone is thin with the deficient formation due to the lack of the teeth. The deficient formation of the salivary glands leads to dry mouth. Commonly the permanent central incisors, 1st molars and the canines are present with the other teeth missing in maxilla whereas in the mandible canines, 1st premolar and 1st molar are present in order with other teeth missing. More commonly maxilla contains more number of teeth than mandible.²

The hidrotic ectodermal dysplasias are associated with presence of the sweat glands, The disorder is transmitted by the autosomal transmission with the equal
incidence in male and females. The disorder is associated with the abnormalities of the nails (hypertrophy, dystrophy) which is not seen in the hypohidrotic type.

The diagnosis of the ectodermal dysplasia is done by the clinical features. Biopsy of the skin is useful in diagnosis of hidrotic and hypohidrotic types. The mode of inheritance is diagnosed by the family history.

The dental management of the anodontia is by the replacement of the missing teeth in the earliest age of 2 years. The early replacement of the missing teeth will improve the esthetics, speech and masticatory function development. The removable dentures allow the growth of the jaws till the adolescence and then endosseous implant treatment with the teeth fixation is possible after the growth of the jaws is completed. However the use of one or two implants for the retention of the overdenture at the age of 6 years serves the function till the completion of growth. The endosseous implants can be successfully placed and provide support for prosthetic restoration in patients with ectodermal dysplasia. The ectodermal dysplasia does not interfere with the osseo integration of the endosseous implants.

The poorly developed alveolar bone provide the insufficient bone for the osseointegration of the end osseous implants. The vertical alveolar growth results in the submergence of the implants relative to the adjacent natural dentition when implants are placed adjacent to the erupting permanent natural dentition.

Case Report: A 18 year old girl from a village at Nellore district of Andhra Pradesh attended the department with the complaint of multiple missing teeth in year 2007. The patient had sparse hair which was unusually light brown colored. The patient had missing eye brows and eye lashes. The frontal bossing of the forehead with the deficient formation of the maxilla was present. The concave facial profile was present due to maxillary hypoplasia. Periorbital darkening of the skin was present. The patient complained of reduced sweating and the dry skin.

Intraorally oligodontia of the permanent teeth was present with the loss of more than 6 teeth. The upper and lower canines were present apart from upper left 2nd premolar and lower right 2nd molar. All the teeth present were deformed with the conical shape. All of the teeth were single rooted including the molar of the mandible and the roots were of normal length. The patient’s alveolar bone is thin due to the lack of the teeth.

The patient was diagnosed of hypohidrotic ectodermal dysplasia based on the clinical features of reduced sweating, absence of hair, and oligodontia of maxilla and mandible. The mode of transmission can be explained by X chromosomal transmission with the missing and hypoplasia of the teeth, deficient hair and the dry skin. The patient gave the history of consanguineous marriage of their parents. Both of the parents had hypodontia or oligodontia of the teeth but they did not show the other features of ectodermal dysplasia.

The patient was treated with the endosseous implants of the maxilla and mandible. In the maxilla two machined endosseous implants (ADIN, ISRAEL) were placed in the region of 16 and 22. The implant in the region of the 1st molar was placed after the indirect sinus lift using osteotomes as the height of the bone was 6mm in the region. The 10mm length and 4.2 mm diameter implant was placed after the sinus lift. The 3.8mm diameter and 10mm length implant was placed in the left lateral incisor region after osteotomy.

The implants were uncovered after waiting for 3-6 months in the year 2008 with delayed loading protocol and gingival formers were placed for soft tissue healing for 2 weeks. The implant and the natural teeth supported rigid metal- ceramic fixed bridge was planned for the patient till the 1st molar teeth with the shortend dental arch of the upper and lower jaws. The short arch reduced the length of the distal cantilever and unfavourable torque on the of the implants and natural teeth.

The remaining natural teeth were prepared for full veneer ceramic crowns to support the fixed teeth. Impressions were taken at abutment level with polyether impression material. The casts were mounted in semi adjustable articulators after the face bow transfer. The patient’s condylar guidance was transferred to the articulator. The abutments were machined in the laboratory to be parallel to the natural teeth preparations. Acrylic crowns and pontics were fixed at the proper vertical height. The Full ceramic fixed teeth were fabricated with the group function occlusion scheme in eccentric movements and
fixed in the patient’s mouth with zinc phosphate cement. The pontics 16, 26 and 36 were of cantilever type with implants in the anterior region.

The patient was recalled at regular intervals for the examination of the implants and the ceramic teeth. After 10 years in 2018 the patient was recalled and occlusal surfaces of the ceramic crowns and pontics were found with attrition and the metal was exposed in the posterior region of the jaw mostly on the left side of the jaw. Radiographic examination was done in the year 2018 after the satisfactory function of the prosthesis for 10 years. The marginal bone loss of 1-2mm was seen in the implants at 16 and 42 region of the right side and 32 region of lower jaw. The marginal bone loss of 2-3mm was observed at the 22 region of the upper jaw. The patient was satisfied with the prosthesis and the retention of the prosthesis in the mouth was not disturbed. The patient did not complain of the pain. The patient’s occlusion is undisturbed with the maintenance of the original group function eccentric occlusion.

**Discussion**

Diagnosis of the hypohidrotic ectodermal dysplasia is done by the presence of the classic clinical features of absence of sweat glands, oligodontia (6 or more missing teeth), the hypoplasia of the teeth that are present with the peg shape absence of the hair on the scalp. Since both of the parents had the dental features of the ED and they being close relatives the X chromosomal transmission can be explained for the transmission in the patient.

The replacement of the teeth at the early age can be done by removable dentures with or without implant support. The early replacement of the teeth leads to better speech and social development of the child. Albert D Guckes et al reported by clinical studies that permanent replacement of the teeth by the implant treatment is deferred till the completion of the growth as the implants are submerged or drifted with the growth of the jaws. However the mandibular implants are not submerged or drifted as the mandible grows at the ramus region and can successfully be used as overdenture abutments of mandible with the periodic relining.

The ectodermal dysplasias are associated intraorally with the deficient formation of bone, narrow ridge along with the anodontia or oligodontia. The absence of the teeth with the lack of the occlusal stimulation leads to reduced bone density. The teeth which are present are usually of hypoplastic with the irregular shape. Gerald keams et al and Y Wangs et al reported by their clinical studies that the ectodermal dysplasia does not interfere with the osseointegration of dental implants and their function under masticatory loads. The female patient of 18 years of age completed the growth of the jaws. The poorly developed alveolar bone created problems in the implant placement. The maxillary anterior implant was placed after the ridge expansion by osteotomes as the alveolar ridge was not fully developed, The maxillary molar implant was placed with the indirect sinus lift with the help of the osteotomes.

Summers R B reported the osteotome technique for implant placement in narrow and shallow ridges with additional advantage of condensation of the bone around the implants with more density of the bone. He reported the maxillary sinus lift with osteotomes and immediate implant placement in patients with the moderately deficient alveolar bone as successful method of implant similar to the regular treatment. Successful clinical results with the sinus lift procedure of maxilla with the immediate implant placement were reported by Giovanni B Bruschi et al. And Scipioni at al. The successful functioning of the prosthesis after 10 years intraorally in the present case is in conformity with the earlier clinical reports.

Osseo densification as the newer method of increasing the primary stability, bone density and implant surface to bone contact was proposed by Huwais.S in 2013 and 2014. The osseo densification improved the primary stability and bone expansion in narrow ridges by the elastic nature of the bone. With the newer densau burs the alveolar bone was autografted around the implant in dense layer improving the primary and secondary stability instead of substraction of the bone during osteotomy with the regular burs.

Patients natural teeth of the normal length of roots with hypoplastic crowns were splinted with the implants with the ceramic fixed teeth by implant-tooth connection with the rigid connection between the tooth and implant. Lang NP et al reported the better prognosis of teeth-teeth connection and implant-implant connection than the tooth – implant connection. This is explained by the differential movement of the tooth and the implant.
The movement of the periodontal ligament of the natural teeth is about 10 to 100 times more than the bone-implant junction under horizontal forces. The Osseo integrated implants with the direct attachment to the bone without the periodontal ligament moves only due to the elasticity of the alveolar bone compared to the periodontal ligament.

The tooth-implant retained denture of the patient functioned for the past 10 years with the marginal bone loss of the upper implants bilaterally. Similar results were reported by Naeetie at al with the tooth-implant rigid connection of favorable long term stability with the minimal complications of tooth intrusion but more marginal bone loss compared to the non-rigid tooth-implant connection. The lesser marginal bone loss and increased intrusion of the natural teeth were reported with non-rigid tooth-implant connection.

The teeth 16, 26 and 36 were cantilevered pontics with abutment situated anteriorly. The length of the cantilever with the single molar pontic is less than half of the antero posterior length of the implant and teeth connected resistance arm length. The length of the pontic in relation to the resistance arm is within acceptable limits of torque. The pontics and retainers presented with the attrition of occlusal surfaces by the exposure of the metal coping done by ceramic nickel chromium. The wear of the occlusal surface is controlled by the duration of the prosthesis usage, hardness, opposing tooth surface and masticatory habits of the individual.

Conclusions

1. Osteointegrated implants are successful treatment option in ectodermal dysplasia patients as the normal patients.
2. The ridge expansion and the sinus lift procedures can be utilized successfully in the ectodermal dysplasia affected children for placing implants in the jaws with deficient alveolar bone formation.

3. Implant – Tooth rigid connection can utilized successfully in ectodermal dysplasia affected individuals for rehabilitation by the fixed restoration of the missing teeth.

Cast Partial Denture—A Case Report

S. Chandrakala¹, Ganesh Ramesh², Sanjna Nayar³

¹Final Year Post Graduate, ²Professor, ³Professor and Head, Department of Prosthodontics, Sree Balaji Dental College and Hospital, BIHER

ABSTRACT

Multiple missing teeth situation always claim careful attention and meticulous treatment planning. It becomes more challenging when unilateral or bilateral distal extension situation exists. Successful treatment can be done with some contemporary and conventional treatment planning. This clinical report describes about the treatment planned for a 35 years old patient with a partially edentulous upper and lower jaw. The prime consideration was given to aesthetics and masticatory function.

Keywords: Cast Partial, Masticatory function, Removable Partial Denture, surveying, retainers

Introduction

Restoration of partially edentulous arches is challenging for a clinician where the clinician has to give due consideration in satisfying patient requirement. Removable partial denture is considered to improve both aesthetic and masticatory function. Masticatory performance and bite force are the objective measurement in evaluating masticatory function while designing a removable cast partial denture¹. Situations, when financial, systemic or local conditions preclude the use of fixed Prosthodontics conventional treatment planning can be done. In such cases a well - designed cast partial denture (CPD) can be an excellent treatment alternative².

Prosthodontic rehabilitation of distal extension partially edentulous situations remains challenging. The support of is derived from edentulous ridge and terminal abutment teeth. The terminal abutments act as fulcrum while functional movements of CPD as well as retentive clasps exert force on abutment teeth which may jeopardize the periodontium of these teeth³.

Case Report: A 35-year-old female reported to the Department of Prosthodontics, Sree Balaji dental college and hospital with the chief complaint of multiple missing teeth in maxillary arch and inability to chew food properly. Medical history was not significant. On oral examination, teeth missing in maxillary arch were 13,15,16,17 and 22,23,26 and 37 and 46,47 in mandibular arch.

After radiographic examination and diagnostic model study, interocclusal distance was found to be adequate. Treatment was carefully planned by taking into consideration patient’s aesthetic need and economical condition. Treatment plan included cast partial denture in the maxillary arch and mandibular arch.

Procedure

A detailed examination revealed oral hygiene was satisfactory. The diagnostic casts were made and mounted in the semi adjustable articulator. Diagnostic models were analyzed and surveyed. Mock up mouth preparations were done on the diagnostic models and the desired preparations were executed on the teeth intraorally in the patient’s mouth.

After evaluating, framework design was RPI system on 15, cingulum rest on 13 embrasure clasps on 24,25 and simple circle on 27,36,38,44,47 and closed horse shoe as maxillary major connector and lingual bar as mandibular major connector. Mouth preparations was done in the patient’s mouth and final impressions was
made with monophase polyvinyl siloxane impression material (Aquasil Lv Ultra, Smart Wetting Impression Material, Dentsply, Detrey Gmbh, Konstanz, Germany) using a light cure special tray. The casts were poured in die stone (Ultrarock, Kalabhai Karson Pvt Ltd, Mumbai, India). Master cast surveying procedure was carried out to block the undercuts and refractory casts were made using phosphate bonded investment material\(^1\). Wax pattern for maxilla and mandible were contoured using preformed wax patterns. The refractory model with the wax pattern was invested and casting procedure was carried out. The casted cast partial denture was finished and polished in the conventional manner. The metal framework was tried in the patients’ mouth for proper seating. The occlusal rim was made and bite registration was done. Teeth setting was done and wax trial was carried out in patient’s mouth. After satisfactory consent from the patient, processing was done and the cast partial dentures were delivered to the patient.

**Discussion**

There are several treatment options for the rehabilitation of partial edentulism. Depending on the given diagnostic factors and patient’s perspective, best treatment plan should be selected for the patient. The procedure explained in the rehabilitation of this patient is a way of restoration of partially edentulous arches with increased masticatory efficiency and appearance. The decision to use cast partial denture design should be carefully considered. Clasp-type removable partial dentures should be used whenever practical because of their lower cost, ease of fabrication and maintenance, and the predictability of results. The impact strength, compressive strength of the alloys with acrylic resins is better than the non-metallic acrylic denture\(^1\).

Areas of concern in a Kennedy partial denture designing that need to be self-cleansing are surfaces of framework near the proximal surfaces of abutment, area under the major connector and interproximal areas. During the course of follow up, the cast partial denture was evaluated at these three places to check the efficiency of both self-cleansing ability and patient care\(^2\). Cast partial denture is less subjected to breakage and has effective transmission of thermal changes\(^6,7\).

Krall and others investigated to state that the presence of removable partial denture is an important fact for nutritional intake and the replacement of missing teeth could help people maintain a healthy diet\(^6\). Other investigators have reported that partial tooth loss results in altered food acceptability, just as edentulism is associated with poor diet and compromised nutrition and tooth loss may cause dietary change.
Success of the prosthodontic treatment relies on the proper selection of denture type to provide adequate retention, stability, and aesthetics. Challenging situations like unilateral or bilateral distal extension can be dealt successfully with conventional treatment planning (cast partial denture). Technique followed in the treatment of this patient is a simple but yet effective treatment plan for providing an optimum satisfactory treatment for an individual.

Clinical Remount in Complete Denture

Sanjna Nayar¹, Sanket Rajendra Jadhav²

¹Professor & Head of the Department, ²Postgraduate Student, Department of Prosthodontics, Sree Balaji Dental College & Hospital, Bharath Institute of Higher Education & Research, Narayanapuram, Pallikaranai, Chennai

ABSTRACT

Proper occlusal relationships are a part of successful prosthetic treatment for edentulous patients. Fabrication of complete dentures involves clinical and laboratory procedures that should be performed precisely for achieving success with fabricated dentures. These occlusal errors can be corrected, (1) in a patient’s mouth or (2) by recording new centric relation and remounting dentures on an articulator. The second method is more viable because the denture base moves over the oral mucosa which is unable to identify premature contacts in centric occlusion and tooth guided eccentric excursions. This article depicts the modest and effective clinical chairside remounting procedure.

Keywords: Occlusal errors, Occlusal adjustments, Interocclusal record, Patient remount, Clinical remount, Customized Mounting Platforms

Introduction

During the try-in stage, the established occlusion is subject to change because of inaccuracies in mounting procedures, distortion of the record bases, unfastened mounting rings, or processing errors. Minor faults can be corrected by selective grinding with dentures in the patient’s mouth if a split cast remounting procedure is immediately used after the dentures are processed.¹⁻⁷ However, a general survey on dental practitioners revealed that less than 5% of dentists use the split cast procedure to repair the errors of processing.⁸ Besides, the displaceable oral soft tissues and saliva also interferes with the selective adjustive procedure. For these reasons, clinical remount is preferred by a few practitioners.⁹ The clinical remount is an essential step in the fabrication of complete dentures and it is used to ascertain favourable occlusion.⁹⁻¹⁸

Clinical Remount Procedures: As described by Charles M. Heartwell and Arthur O. Rahn², a clinical remount is carried out by orienting the mandibular denture to the maxillary denture using an interocclusal record with the jaws in centric relation.

Place two thicknesses (approximately 1 1/2 mm) of passive-type wax on the occlusal surfaces of the mandibular teeth. Soften with a flame from an alcohol torch or immerse in the water at 130°F.
Carry to the mouth and have the patient close into the wax when the jaws are in centric relation. The closure must be short of tooth-to-tooth contact. The wax record is not acceptable if the teeth penetrate to make contact. Chill with cold air and remove it.

Do not return the wax record to the mouth, as it may be distorted by the patient. Trim the wax so that only mild indentations remain, and expose the facial side so that the seating of the maxillary denture can be visually checked.

After properly orienting the mandibular denture to the maxillary denture using the interocclusal record, secure it with sticky wax. Seat the mandibular cast in the denture and attach it to the mandibular member of the articulator with plaster.

To check what has been recorded to the patient’s centric occlusion, make another wax interocclusal record. Replace the dentures on the articulator. With the condylar elements freed, place the teeth in the indentations in the wax record. The condylar elements should rest against the stops.

Repeat the procedure until two consecutive records are accepted. When the accuracy of the articulator mountings is verified, occlusal disharmony when the jaws are in centric relation or eccentric relation can be corrected by selective grinding procedures.

According to George A. Zarb and Charles L. Bolender, a clinical remount involves remounting of dentures on the articulator using accurate interocclusal records made in the patient’s mouth which is important in correcting the occlusion.

On a maxillary denture, the posterior teeth are slightly lubricated with petroleum jelly and the denture is firmly seated in the mouth. Two pieces of wax wafer (e.g. Aluwax) is immersed in a water bath of 130°F (54°C) for 30 seconds. Both the temperature and the time are critical in achieving a uniformly softened wax.

The mandibular denture is then seated with the index figures bilaterally positioned on the buccal flanges. The mandible is guided into centric relation by placing the thumbs on the anteroinferior portion of the chin in such a way that some guidance is directed towards the condyles. The patient is guided in a hinge movement, closing lightly into the wax.

The mandibular denture is carefully removed from the mouth and placed in ice water to chill the wax. The dentures are removed from the ice water and dried. The imprint of the opposing teeth should be crisp and about 1mm deep, with no penetration of the interocclusal wax record by opposing teeth. The Aluwax is thoroughly chilled before the dentures are returned to the patient’s mouth and the patient is guided into centric relation, as previously described.

The record is acceptable if there is no tilting or torquing of the dentures from initial contact to complete closure. If the record does not satisfy these criteria, the procedure must be repeated.

After the dentures and wax are chilled and dried, the mandibular denture is positioned on the remount cast. The maxillary denture teeth are carefully positioned in the wax index and secured with a drop of sticky wax in the canine and second molar regions bilaterally. The condylar controls must be locked into centric position. Plaster is used to secure the mandibular denture to the lower member of the articulator.

The Centric Relation Record should be verified for accuracy before any tooth adjustments. Aluwax is used and the centric recording is repeated. After chilling and drying of the wax record, the dentures are returned to the articulator. With the articulator locked in centric relation, the maxillary teeth should fit properly into the new wax record. If all the teeth drop simultaneously into the wax record, the mounting is correct. If the opposing teeth do not fit exactly into the indentations in the new record, either the original mounting was incorrect, or the patient gave an incorrect relation when making the second record. To evaluate this, return the dentures with the chilled wax record to the mouth and check the accuracy, as previously described.

The procedure as mentioned above can also be performed by using Impression Plaster or Bite Registration Paste, instead of Aluwax, as given by Carl O. Boucher.

In 2012, Chauhan MD et al published an article regarding a simplified chair-side remount technique using customized mounting platforms (CMP). In this article, the following advantages of a simplified remounting procedure using the customized mounting platforms were mentioned: 1) remount casts are not fabricated
separately for remounting complete dentures; 2) the mandibular denture can be remounted quickly with a new centric relation record, in case of incorrect centric relation record; 3) blocking out undercuts from the tissue surface of denture is not necessary; 4) mounting can be performed at chair-side with minimal mess; 5) the putty impression material can be conserved as a record to be used in successive appointments if needed.

This clinical remount technique utilizes maxillary and mandibular CMPs that are fabricated over mounting plates of the articulator.1

**Fabrication of CMPs:** Boxing wax is applied around the outer edge of the maxillary and mandibular mounting plates to form diverging housing for holding the dental plaster. Reduce the boxing wax to a diameter of 6.5cm at the opening. Trim the height of maxillary boxing wax to 2.5cm and mandibular boxing wax to 2cm.

Pour dental plaster to fill both the divergent cylinders, allow the dental plaster to set and remove the boxing wax. Carve a horse-shoe shaped groove on the flat surfaces of both the divergent cylinders thus formed.

Mix self-cure acrylic resin into two spools and place over the grooves of both maxillary and mandibular divergent cylinders to form U-shaped positive replica of edentulous ridges. Make sure the vertical ridge height is 5 to 6 mm.

Make buccal and lingual undercuts over these acrylic edentulous ridges with fissure bur that will provide a port for the putty impression material during mounting of the dentures. The finishing and polishing of both the CMPs are done.

**Clinical remount of the dentures:** Warm Aluwax is used to make a centric relation inter-occlusal record to confirm the closure without contact of the denture teeth or bases.

Attach the maxillary and mandibular CMPs in the articulator. Place the putty impression material in the form of a U-shaped roll over the mandibular acrylic resin edentulous ridge on the CMP and position mandibular denture on it.

Secure the maxillary denture over mandibular denture with the help of the centric interocclusal record in aluwax and place the putty material in the region of the alveolar ridge and close the upper member of the articulator into the putty material.

After the putty impression material has set, open the articulator and remove the interocclusal record. The putty material serves as remount casts.

Place the articulating paper over the dentures and close it. Adjust the occlusion.

**Discussion**

The remount procedure of the finished dentures is a constituent part of prosthetic patient treatment in the practice of complete dentures. Correct occlusal relationships are a part of the success in prosthetic treatment for edentulous patients with complete dentures.

The errors in occlusion should be corrected on the articulator rather than in the patient’s mouth. It is not good to correct occlusal errors in the patient’s mouth due to the movability of dentures on the denture foundation and often inadequate willingness of patients to cooperate, result in incorrect representation of occlusal relationships in maximum intercuspation and excursive mandibular tooth guided movements.20

As per a review made by Babu RR, Nayar SV21, the T-Scan occlusal analysis system (Tekscan), a Microsoft compliant system, records occlusal contact sequence in 0.01s increments. A piezoelectric foil sensor is placed inside patients mouth and the recorded data is viewed and analysed on the software. The T-Scan identifies the time magnitude and the distribution of the occlusal contacts. Lyons MF et al22 evaluated that patient can feel more widespread contact sensation at the end, the reason being that the establishment of true and measurable bilateral simultaneous occlusal contact is achievable using the T-Scan.

As described by Rudd M Morrow, Kenneth D Rudd, John E Rhoads23, tooth occlusion in the clinical remounting procedure is reconstructed in the articulator and an attempt is made to correct both the clinical and laboratory inaccuracies in the centric relation and establishes the occlusion that ensures even pressure in all areas of the arch.

According to the Clinical Evaluation made by Al Quran F24 in 2005, out of one hundred complete denture
patients, the first group (50 patients) received complete denture with a clinical remount procedure performed and the second group (50 patients) received complete denture without a clinical remount. A four-point, nine scale Patient Denture Satisfaction questionnaire was used to evaluate the patient’s satisfaction with their dentures. The author found that the total patient satisfaction score, with a maximum of 36 points, was higher in the clinical remount group (P=.007). Differences were statistically significant in favour of the clinical remount group for general satisfaction, fit of the mandibular denture, mastication ability, and maxillary and mandibular denture comfort. When a clinical remount procedure was used, results showed a remarkable improvement in the comfort of upper dentures and the fit and comfort of the lower dentures.

**Conclusion**

Within the limitations of this review article, following conclusions were drawn:

1. The clinical remount for complete dentures is recommended on denture insertion to reduce clinically observed areas of discomfort and reduce the number of recall appointments.25

2. Therefore, it is highly recommended that clinicians incorporate this procedure into their routine for fabricating complete dentures as it minimizes patient dissatisfaction.24

3. The T-Scan system identifies the time and force characteristics of occlusal contacts, and hence, establishing true and measurable bilateral simultaneous occlusal contacts is a clinically attainable reality by using this system.21

Psychological Benefits with Denture Characterisation in Edentulous Patients—A Review

Sanjna Nayar¹, Kalyani Ramkumar Sadhana²

¹Professor & Head of the Department, ²Postgraduate Student, Department of Prosthodontics, Sree Balaji Dental College & Hospital, Bharath Institute of Higher Education & Research, Narayanapuram, Pallikaranai, Chennai, India

ABSTRACT

With the increase in active and healthy elderly individuals, the demand for highly aesthetic prosthetic treatment is also increasing. Achieving a healthy-looking smile for a patient, through the reconstruction of missing teeth and surrounding soft tissue using aesthetic prosthetic material, is one of the most important duties of dentists. Denture characterisation is very effective for enhancing removable denture with more natural and pleasing appearance. This review article describes various efforts that were made for characterisation of denture base and teeth in a removable prosthesis.

Keywords: Complete denture, Characterisation, Aesthetics

Introduction

For the aesthetic appearance of an artificial denture, characterisation of the denture plays a significant role which is achieved by modification of the form and colour of the denture base and teeth to produce a more lifelike appearance.¹

The denture base (denture base modification) and the denture teeth (denture teeth characterisation) are the two components involved in characterisation of the complete denture.²

Denture base characterisation: Creating accurate denture base contours and matching the denture base colours to the patient’s oral tissues are the factors involved in denture base characterisation.

Wax characterisation of the denture base: The even, pink, gleaming surface of an average acrylic denture quickly reveals its false. Therefore, the surface of the denture base can be modified by replicating gingival recession, frenalum, gingival stippling and rugae pattern, to give an appearance similar to that of the natural tissues, in the trial denture base.

Gingival stippling: In 1974, Rosenthal RL, Kemper JT described blow wax technique for stippling dentures. The use of non-concentric burs for stippling dentures was given by Gonzalez-Casefont Am et al. in 2002. Stippling is also introduced in the wax using synthetic sponge made from low density polyurethane foam, as described by Nayar and Craik in 2007.³⁻⁵

Palatal rugae: A simple method of adding palatal rugae to a complete denture was given by Gitto et al. in 1999, which involves the use of tin foils to reproduce the pattern from the cast to the wax up or using it over the processed complete denture as a template to add autopolymerising resin on existing denture. Fernandez et al. in 2015 gave a technique that involve addition of rugae pattern by impressing the cut putty impression over softened wax.⁶⁻⁷ Patterns of rugae, incisive papilla and mid palatine raphae can be added using softened wax on a wax dropper. Alternatively, pre-formed wax pattern can be used which are available in different thickness.⁸

Colour characterisation of denture base: When the acrylic resins were first used in 1940s, there was no background of experience or adequate research information on oral pigmentation available to the manufacturers of acrylic resins for dentistry. They were content with a light pink, the characteristic colour of the normal gingiva. Any deviation from this light pink was considered pathologic.

In 1944, Dummett began a study of pigment variations in the healthy oral tissues of the Native Americans. This clinical study and others followed in 1960, helped to establish and publicize the fact that physiologic pigmentation of the gingiva is a normal finding in many people of all races and nationalities. Gerhard and Sawyer in 1966 noted the critical comments of a large percentage of Native and Latin American patients at the dental clinic of Loyola University of Chicago regarding pink denture base resins. They found that a conventional denture base resin produced a special shade for Loyola University and modified with the pure chalk in a burnt umber colour was more acceptable to patients with heavily pigmented oral tissues.

Any prosthesis constructed for oral cavity must simulate the colour of the surrounding natural tissue for an acceptable aesthetic result. The colour effect of any denture base must be evaluated in its ultimate environment, the mouth of the wearer.

In 1995 Joseph J Berte and Carl A Hansen came up with custom tinted denture base characterisation by visible light cure lamination, in which urethane di methacrylate and tinting powder lamination, chemically bonded to a methyl methacrylate denture base, produces a natural distribution of the tints. The characterisation is protected by a hard, clear layer of urethane, this lamination is achieved either in the laboratory, bore processing the denture or after the denture have been fabricated.

Pattanaik et al., in 2011, described the method of internal characterisation of the denture base by using tissue paper to carry and retain acrylic stains which are incorporated in the denture base at the time of packing stage. Also they described the method of characterisation of a denture base in 2013 using auto-polymerized pour type denture base resin and acrylic stain using a modified laboratory procedure for the augmentation of lip support which was given by Shimizu et al.

Denture teeth characterisation: Selection of anterior teeth with respect to the size, form and colour and arrangement of anterior teeth to suit the patient’s need and characterising the denture teeth are the factors involved in denture teeth characterisation.

Selection of teeth: Williams in 1914 laid down the first simple rules of dental aesthetics. He introduced the square, ovoid and tapering concept in choosing the form of teeth, an ovoid face required ovoid teeth, and a tapered face required tapered teeth.

Sears in 1952 summed up nearly total concept of aesthetic dental prosthesis, that when the laterals are nearly as broad as the other front teeth, it is said to have a strong or masculine appearance. When the laterals are narrower than average, it is feminine or delicate.

The dentinogenic concept as described by Fisher and Frush, using sex, personality and patient age applied to anterior tooth size. They have related sex to size differential between central and lateral incisors with less differential in men than in women. They described how dentogenic interprets the personality factor. The attention towards the personality factor allows a realistic approach to the problem posed by the undeniable of using artificial substances to create an illusion of reality in the smile. Also it paves the path for the further sex and age refinements which are necessary for dentogenic restoration. The personality factor has been shown to be one that can be employed specifically for the predetermination of aesthetic results and can help to eliminate the unsatisfactory trial and error procedure for obtaining acceptable aesthetic results. Advanced age also causes the teeth to appear small due to narrowing mesiodistal width resulting from interproximal wear.

A great deal of attention has been placed on the theory of matching teeth to face form. Frush and Fisher stated that rugged aggressive men tend to have squared
teeth with broader central incisors. Younger more delicate women are more likely to have tapering or ovoid teeth with rounded incisal edges. Hardy, 1960, preferred teeth with labial convexity, both gingivo-incisally and mesio-distally. He felt that they reflect light differently than a flat tooth.

Krajicek in 1956 and Payne in 1975 suggested that, the use of custom molded teeth enables the dentist to use replacements made from natural teeth. These teeth give a more natural appearance than the teeth obtained from the commercial manufacturers.

Arrangement of teeth: Hardy discussed the factor of family resemblances and aid in working out the aesthetic problems. More specifically, the profile of the face, arch form and the smile line of the patient are guides to initial placement of anterior teeth. The inclination of the maxillary and mandibular anterior teeth are generally parallel to the profile of the patient’s face due to the pressure of the lips on these teeth during development. The arrangement and arch form of the anterior teeth have a definite relationship to the arch form of the residual ridge. Martone in 1967, stated that the key to aesthetics lies in asymmetry. Asymmetry in tooth arrangement should have slight modification in the position of incisors such as overlapping, rotation, small diastemas, and incisal variations. They may change the light reflection just enough to produce the artistic dental composition desirable for the patient.

The concept of separateness as described by Sharry is most important, it helps in achieving the realism we are striving for. At the wax up stage, the interproximal surfaces of the anterior teeth are routinely cleaned with dental floss, so that each tooth is seen as a separate and distinct entity in the complete denture. The concept of divine or golden proportion have also been described and provide useful guidelines for the selection and positioning of anterior teeth.

Staining of the denture teeth: Tooth shades and stains can be used to replicate textures and features like attrition facets, cervical stains, crack lines and mamelons. The method for staining teeth can be done before teeth arrangement or after processing of the dentures. Composite resin stain kits are available to add stains to the teeth to individualise the denture. Thomas J Donohue in 1983 described the facial characterisation of anterior artificial teeth by creating striations, grooves and fracture lines using various abrasive stone wheel of various diameter and inches.

Conclusion

In a questionnaire survey on denture aesthetics and denture base characterisation done by Matsuda k-I, et al. in 2016, of all participants, 65% were concerned about their denture appearance and over 50% were concerned about their denture gum appearance and 70% of participants were interested in denture base characterisation.

The treatment with characterised complete denture prosthesis can produce a more lifelike appearance compared with conventional denture that produces artificial look in edentulous patients, also aids the patients in developing proper speech, enhanced aesthetics and dramatic social and psychological benefits.

ABSTRACT

Pain control is an important part of dentistry. Although most of them can cope with local anesthetic injections, a few are needle-phobic, and giving them an injection presents a challenge to the dentist. For other, the paresthesia which may linger for hours after the completion of the dental procedure is more objectionable than the injection. In the past decade, there has been renewed interest in the applications of electronic pain control in dentistry and several electronic dental anesthesia machines are currently being advertised and used. This communication is to bring certain developments regarding the electronic dental anesthesia.

Keywords: Electronic dental anesthesia, Needle free anesthesia, Pain free anesthesia, Funny stickers.

Introduction

Pain is an unpleasant sensory and emotional experience associated with actual or potential tissue damage, or described in terms of such damage. Providing anesthetic injections is always associated to the pain of the needed prick. The privilege of inventing general anesthesia goes to Dr. William T G Morton, a dentist from Boston in 1864. But this technique has been cumbersome, time consuming & carries a risk of morbidity and even mortality. Hence, was considered unsuitable for minor dental procedures. This then lead to the development of local anesthesia, which was first demonstrated by Karl Collar of Vienna in the year 1884. Today, Local Anesthesia (LA) is one of the most commonly employed drugs in dentistry, and probably the most important ones too [1,2].

In dentistry, local pain management is a critical component of patient care. When efforts to achieve proper anesthesia becomes unsuccessful, the resulting stress in both patients and the clinician grows to significant levels. Traditional local anesthesia obtained by dental injections has several drawbacks such as anxiety, psychological factors, local and systemic toxic reactions, paresthesia caused by laceration of regional nerve fibers and acidic pH of LA causing local irritation. The application and induction of LA has always been a difficult task and this demands an alternate method that is more convenient and effective. An alternative was found to LA by the application of TENS in dentistry. In 1967, use of transcutaneous electrical nerve stimulation (TENS) was introduced in dentistry. This became an alternative to overcome the drawbacks of LA, during pain management, by a non-invasive and safe manner [1,2,3].

In recent years, modifications have been made to make TENS useful in the dental setting.

Malamed et al. use the term electronic dental anesthesia or EDA when referring to the applications of
TENS to dentistry [4]. The explanation of the mechanism by which TENS produces anesthesia is based on several theories describing mechanism of pain transmission. \[1,5\]

**Development of EDA**\[1,2,5\]

**Electric Fish:*** The use of electricity for anesthesia dates back to 100 years as seen in the drawings in Egyptian temples which suggest use of the Electric fish/Nile Catfish (termed Malopterus electricus) for medical purposes. Another fish referred to as Torpedo marmorata (torpedo ray or electric ray) has also been used for similar applications; it emits 40 to 50 V with a frequency of 200 to 1000 Hz and an impulse train of 100 to several thousand. In 46 AD, piscine electrotherapy was developed by Scribonius Largus specifically for the relief of pain. In the middle Ages, Redi, Perault, Richer, Borrelli, and Lorenzini also noted numbness with the use of torpedo fish.

**Electric Device:*** As the electricity was associated with anesthesia, other attempts were made to apply it to use. In 17th century Von Guerich constructed an electrostatic generator. Kleist and Musschen brook of Leyden developed a method of storing a charge in a vessel – The Leyden Jar. In 1744, Kratzenstein used electricity in medicine. In 1759, electricity was used to relieve pain for sciatica, hysteria, headache, kidney stone, gout, cold feet, pleuritic pain, and angina pectoris. An important contribution of Benjamin Franklin was development of theory and terminology of positive and negative charge and idea of balance charge. These devices which stored electricity were bulky and impractical for use.

**Battery Powered Machines:** Later electric batteries replaced the electrostatic generators and Leyden jar. They helped in creating smaller devices for the above purpose. In 1800s, acupuncture the Chinese method of therapy was used by Jean Baptiste Sarlandiere and Fabre-Palaprat along with the application of current to the body. And this became accepted as “electropuncture”.

**Gate-Control Theory:** With the proposal of the Gate Control Theory by Melzack and Wall in 1965, a rational basis for electroanalgesia was elucidated. The large fibers were more sensitive towards the electric current and were the ones responsible to present pain. In 1967, Wall and Sweet further stated that electrical stimulation could block pain. The chronic pain was managed by partial cordotomy, but this was major surgery and had high risk of failure. This had the advantage of pain relief without side effects of chordotomy and also had control over the amount of current needed. TENS was born when Shealy attempted to demonstrate the feel of stimulations to the candidates and now is being regularly used for trigeminal neuralgias \[1,7,5\].

**How Does it Work??**

It is a therapy that uses low voltage electrical current for dental pain relief. The exact mechanism has not fully been discovered. But studies reveal that it does reduce pain. It may be because the electrical impulses scramble all the pain signals that are sent to the brain by the nerves. Or yet another theory states that, the way these electric signals interact with the nerves will help the body to produce endorphins- body’s natural pain killer. That is either it blocks pain impulses peripherally or excites the pathway to brain for activity of endogenous analgesic system like opiate like peptides (enkephalin and endorphins). The two important leaps were, the patients were relieved off their pain without the side effects of chordotomy. The amount of current required control pain could be kept under control. This entire process works on the basis of the widely known Ohm’s law \[1,2\].

TENS delivers a low-frequency electrical stimulus (via electrodes) to an area of the body in which swelling (edema) has occurred (e.g., the knee). The electrical stimulation produces skeletal muscle contraction, causing a pumping of the fluid out of the area. This helps to speed recovery from injury. With electrodes applied intraorally and the current delivered at a higher frequency, pain control was achieved \[4\].

**The Components:** When a conducting path is provided between two points of different electrical potential, a current passes from one point to the other. This flow will depend on Ohm's law \(A = V/f\) which states that the current intensity in a circuit \(A\) is directly proportional to the force across the circuit \(V\) and inversely proportional to the resistance of the circuit \(f\). The components include the **Body Circuitry** where in the body poses a combination of series and parallel circuits. With a TENS unit, the electrode delivers the current to the skin or mucosa. While using dental electro analgesia, it is very important to realize that each tissue has a different resistance to electric stimulation. The **Wave forms** used are...
1. A balanced, symmetrical, biphasic, exponentially decaying wave form

2. A balanced asymmetric square wave form

3. A 16,000 Hz semi-square wave form.

The range of Frequency can be used to demonstrate the signals. Depending on the frequency, the stimulation provides distraction from the dental procedure and stimulates the placebo response as well as the release of various endogenous opioids and autacoids.

Equipment

Controls: The machine comes with a variety of controls. Most machines come with 2 complete circuits or channels, each with amplitude and frequency controls.

Electrodes: The ease of placement of electrodes and the ease of working around them is an important factor in determining whether a practitioner will stay with this technique long enough to produce a clinical success. Intra oral electrodes come in 3 forms

- Sponges
- A conductive fabric
- Adhesive material.

Probes for LA: Some machines have a hand held probe that can be used in place of LA. All types of injections can be done pain free, if a careful slow injection technique is used and electrodes are placed within a few millimeters of where the needle will be inserted.

Technique: The process involves placement of 2 small sponges inside the patient’s mouth or on the face. These are attached to a control box that the patient uses to select the depth of the anesthesia. The whole unit is powered by battery. After turning the machine on, the sensation felt would be a pulsating itch, also described as a mild tingle or twitch. It takes about 2 minutes once the machine is turned on.

The advantages of TENS include a needle free approach without shot, no injection and a quick, numb-free recovery period, without any slurry speech associated. There can be control over the amount of anesthesia administered and also lesser risk of allergies. Being non-invasive it can be used to achieve anaesthesia in needle-phobic patients. Patients may also be able to self-administer TENS treatment and learn to titrate dosages accordingly to manage their painful condition. This results in positive acceptance by the patients.

It is to be avoided in patients with Cardiac pace makers as the Pace makers get triggered by a 2Hz TENS signal and give heart rate of 130 beats per min stimulating cardiac plexus and carotid body can cause severe hypotension that can lead to cardiac arrest. It is contraindicated in pregnant women. It can cause possible damage to eyes. Transthoracic and transabdominal electrodes (seldom used in dentistry, but when used), can cause dysrhythmias. TENS devices have shown to increase the blood flow in the extremities. Therefore, can lead to aneurysm, stroke and transient ischemic patients should not receive TENS. Pulsing of TENS could also trigger an epileptic event. It is contraindicated in any pain of unknown etiology, as it can mask the warning signs of a serious underlying disorder. [7]

Application of TENS

Analgesic effects of TENS: Relief of acute pain like Postoperative pain, Labour pain, Dysmenorrheal pain, Musculoskeletal pain, Bone fractures, Dental procedures.

Relief of chronic pain like Low back, Arthritis, Stump and phantom, Postherpetic neuralgia, Trigeminal neuralgia, Causalgia, Peripheral nerve injuries, Angina pectoris, Facial pain, Metastatic bone pain.

Non-analgesic effects of TENS like Antiemetic effects and healing aid: Postoperative nausea associated with opioid medication

Nausea associated with chemotherapy or Morning sickness or Motion/travel sickness

Improving blood flow; Reduction in ischaemia due to reconstructive surgery

Reduction of symptoms associated with Raynaud’s disease and diabetic neuropathy

Improved healing of wounds and ulcers

Indications in Dentistry [1,2,3,8,9,10,11,12]: The application of TENS in dentistry is wide. Starting from extractions, endodontics, acute pulpitis in which LA and nitrous oxygen sedation have not given adequate pain control, they have had some success using TENS.

In Pedodontics TENS has shown satisfactory success rate on patients as young as 3 years old. In
Myofunctional pain dysfunction, if pain is muscular in origin or is inflammation of the joint, there is a good success rate, as high as, 80% in some cases. In Periodontal treatment routine procedures like scaling, root planning, curettage, pocket probing can be done with a minimum of discomfort using TENS. In Operative dentistry TENS works best with teeth anterior to molars. It enables multiple quadrants to be worked on at a time. Electric stimulation hastens the regeneration of damaged tissues as in case of Trigeminal neuralgia. It has been found to be an effective, easy to use therapy with minimal side effects in patients suffering from trigeminal neuralgia not responding to conventional treatment. Low frequency TENS used in treating TMJ pain by contracting and relaxing muscles in a precise sequence and at a scientifically determined rate so they are able to eliminate toxins and muscle tension— as an electric-stimulated self-massage. In addition to relaxing the muscles TENS stimulates the release of endorphins, hormones that can block pain and improve mood. Application of TENS increases the salivary flow rate in healthy individuals as well as in xerostomic patients. Hargitai et al in 2005 found increased salivary flow in two-thirds of healthy adult subjects after application of TENS on the skin overlying the parotid glands. Their results also suggested that for TENS to be effective, baseline saliva flow should be present.

Certain other useful applications of TENS have been: an excellent analgesia during various procedures like rubber dam placement, cavity preparation, pulp capping and other endodontic procedures, prosthetic tooth preparations, oral prophylaxis as well as extractions. It is also used to reduce the discomfort from injection of local anaesthesia and to alleviate periodontal pain associated with orthodontic separation.

**Discussion**

TENS or the EDA has found multiple applications in dentistry. It may not be better than the local anaesthesia but has been found comparable [8]. Various studies have suggested its use for anaesthesia been preferred more by the patients who would prefer to prevent needles and also the benefits of immediate recovery. A pilot study using Ultracalm Electronic dental anesthetic unit was conducted on a small group and suggested 14 out of 20 subjects preferred EDA and found it to be a more comfortable approach for dental procedures. [8] The studies on pediatric patients suggest the same [8,9,13,14].

**Vibrajet**: It is a small battery operated attachment that snaps onto the standard dental syringe. It delivers a high frequency vibration to the needle that is strong enough for patient to feel.

**Dental Vibe**: Another system that uses vibration diversion based on the pain gate theory. It is a cordless, rechargeable, hand held device that delivers soothing, pulsed, percussive micro oscillations to the site where an injection is being administered.

**Accupal**: It is a cordless device that uses both vibration and pressure to pre-condition the oral mucosa. It provides pressure and vibrates the injection site, at 360 degrees proximal to the needle penetration, which shuts the “pain gate” according to the manufacturer. Another anesthesia delivery system which is a must to mention is CCLAD- i.e. computer-controlled local anesthetic delivery vehicles to regulate the delivery and rate of flow of local anesthetics at the injection site, lessening potential discomfort associated with injections. Here the undesired extraoral soft tissue anesthesia can also be prevented.

It incorporates the composites of the computer technology to control the rate of flow of the anesthetic solution through the needle. It has techniques like A-MSA, P-ASA, STA. These are two types.

I. Wand/compudent system - This system enables the operator to accurately manipulate the needle placement with fingertip accuracy and deliver the LA with a foot activated control

II. Comfort control syringe -It differs from compudent system in that there is no foot pedal

**Conclusion**

TENS is considered any time better in eliminating the fear of pain due to dental injection and has the advantage of being non-invasive and safe to handle. The equipment that exists is a viable, preferred alternative to local anesthesia in many operative and periodontal procedures.

It can’t altogether replace but is a good alternative to LA in some situations. It provides with multiple benefits if patient selection is well done and safely handled.

Laboratory Remounting of Complete Denture: A Systematic Review

Sanjna Nayar¹, Preeti Patel²
¹Professor & Head of Department, ²First Year, Post-Graduate, Department of Prosthodontics, Sree Balaji Dental College & Hospital, BIHER, Chennai

ABSTRACT

Statement of Problem: Simpler methods have been tried to correct processing errors in the fabrication of complete denture but the importance of inclusion of laboratory remounting procedure is uncertain.

Purpose: The purpose of the systematic review was to assess the relevance of laboratory remounting procedure on the complete denture.

Materials and Method: One electronic database (PubMed) was searched through in July 2019. The terms “laboratory remounting” AND “occlusion” were chosen. The titles and abstracts were screened and the studies which performed laboratory remount were selected.

Results: After duplicate removal, the database search showed 10 studies. Out of which 5 were retrieved for full-text assessment. 5 randomized control clinical studies were included and 1 review study.

Conclusion: A laboratory procedure is advised to reduce occlusal disharmony and provide comfort to patients and reducing recall appointments.

Keywords: Remounting, Occlusion, Selective grinding, Dentures

Introduction

Complete dentures are prosthetic replacements for missing teeth and surrounding structures which are made to restore the missing functions and aesthetics. Properly constructed dentures offer tissue comfort, good function, and aesthetics, harmoniously to the patient. Correct occlusion provides comfort, functional movements of the mandible while maintaining the muscular tonicity. Errors in any one procedure of denture processing disrupt the entire occlusion in the denture.

The failure to achieve proper occlusion of teeth in complete denture happens due to many reasons including improper jaw relation, improper posterior teeth placement, incorrect curing method and changes due to polymerization shrinkage and water sorption. When the occlusal adjustments are not corrected, it causes discomfort, unfavorable jaw movements and ultimately loss of alveolar bone. The bone undergoes often remodeling to relieve the soft tissues from the pressure of occlusal disharmony and ultimately resorption. These errors occurring in the processing of the denture can be timely corrected by laboratory remounting.

Laboratory remounting is the repositioning of the polymerized denture on the articulator and correcting the occlusion through the process of selective grinding (reducing the high contacts while maintaining the proper form of the tooth) in the centric and eccentric occlusion to assist any changes occurred after the processing of denture and deflasking using split cast mounting technique¹.

Often, both the laboratory and clinical remounting procedures have been taught to the students in dental
schools but these procedures are not followed in the daily clinical situation. Reasons for lack of remounting procedure implementation could be either due to the investment of extra time and manwork or ill-belief that denture will “settle in” within some time or dentists being unaware of the errors encountered while implementing remount procedure.

Our aim is to inculcate laboratory remount procedure into the routine fabrication procedures of complete denture which is often skipped during the fabrication process.

Method

The Preferred Reporting Items for Systemic Review (PRISMA) protocol was followed as much as possible. Numerous online databases were searched systematically to find trials of laboratory remounting of complete denture prosthesis. The search method included the use of keywords and Medical Subject Headings (MeSH) using the terms “laboratory remounting” AND “occlusion” in PubMed during 1st-2nd July of 2019. An evaluation of the search results was done in the first selection process. The abstracts of potentially relevant studies were checked and finally, some articles which included authors, objectives, treatment groups, follow-up, outcomes, and significant results were selected.

Results

The online databases search resulted in a total of 10 studies. After the titles were reviewed in the first selection criteria, 5 potentially relevant articles studies remained. Out of which, 4 studies were included for which the titles appeared relevant and 6 were excluded and the reasons were the inclusion of clinical remounting procedure, remount procedure being used in removable partial denture and survey studies. The online database search was followed by a manual search through the references of the included studies, one review articles were selected through the process. The 4 studies were a randomized controlled trial.

Discussion

Qualitative lab procedures were found to show minimal occlusal changes but could not completely remove the occlusal disharmony. In 1972, a survey of British practitioners and dental students rarely used the remounting procedure in their clinical practice, only 6.5% of them used the remounting procedures to correct the occlusal discrepancy. On the contrary, Levin conducted a survey within US and Canadian dental school, where they taught the students the use of laboratory remounting procedure, clinical remounting and the use of disclosing paste to check the pressure development in the underlying soft tissues.

In 2008, Shigli did a study to find whether the correction in occlusion was in co-relation with patient comfort and the number of visits after insertion. He found laboratory remounting with clinical remounting and selective grinding improved patient comfort level compared with the patient who didn’t receive either or both of the remounting procedure. The control group, received both laboratory and clinical remount procedures along with occlusal corrections; Group LRO subjects received only laboratory remount with occlusal corrections; and Group OOC subjects underwent routine procedures in complete denture construction without remount corrections and only occlusal corrections where required, intraorally. A pilot study was conducted to identify the feasibility of a close-ended questionnaire designed by the investigator and containing 5 questions regarding the comfort, pain, masticatory ability, swallowing, and occlusal contacts of maxillary and mandibular complete dentures. The evaluation was performed following the subject’s use of the dentures for 7 days. All 30 subjects were examined for tissue irritation at this time. The evaluation was conducted by a single examiner who was unaware of the groups to which the subjects belonged. An analysis of statistical difference between the treatment groups for the number.
of postinsertion visits, comfort, pain during mastication, swallowing, and areas of tissue irritation during use of complete dentures was assessed using the chi-square test and Kruskal-Wallis test (alpha = .05).

It is seen that denture base changes in contour when kept stored in water due to water sorption phenomenon. Campbell summarized that denture retention increases due to water sorption property. Skinner and Cooper expressed water sorption compensate the shrinkage occurring the acrylic resin base. On the contrary, Woelfel and Paffenbarger said that linear changes which show up after processing are greater than its rehabilitation. McCartney demonstrated that there is 25% of the average midpalatal base distortion is seen when the resin is boiled in the curing cycle. Also, 50% of the occlusion disharmony is seen dentures with short-cure processing. Complete definitive polishing of the occlusal surfaces is avoided at this step because the dentist usually remounts the denture at the time of insertion.

If in case, the laboratory remount procedure is skipped or missed, it can be corrected through clinical remount and selective grinding. But laboratory remount always remains the foremost option. The occlusion disharmony created by processing is usually corrected by remounting the master cast with the denture base in place, without removing it and equalize the occlusion on the articulator.

Conclusion

The choice is not whether to remount but when to remount the denture.

Any complex procedure requires patience and practice to get the desired results. Remounting of dentures is one of such similar case, where the inclusion of this step saves up a lot of chairside time and provides comfort to the patient by providing short time period appointment and denture with occlusal harmony.

Management of Flabby and Compressible Ridge in Maxilla Using Double Tray Impression Technique—A Case Report

Monika D.¹, U. Aruna², Sanjna Nayar³

¹Post Graduate Student, ²Professor; ³Professor and Head, Department of Prosthodontics, Sree Balaji Dental College and Hospital, Chennai

ABSTRACT

Construction of complete dentures and its performance in function depend on accurate impression of the denture bearing and limiting areas. Complete denture fabrication in clinically compromised situations such as flabby ridges is a challenging task for the clinician. In this case report, a newer technique was proposed of impression making of the flabby ridge using a double tray to ensure an accurate and easy impression of these tissues.

Keywords: Flabby Ridges, Double Impression Technique, SpecialImpression, Compressible Tissue

Introduction

Flabby ridge is predominantly seen in the upper anterior region and is commonly associated with features of combination syndrome, as mentioned by Kelly¹. However in this case in addition to anterior flabbyridge, posterior compressible tissues are seen in slopes of hard palate. Flabby ridge can be defined as a mobile soft tissue which is located on the superficial aspect of the alveolar ridge². In the presence of displaceable ridge, fabrication of a stable denture becomes an arduous challenge. Flabby ridges get easily displaced under occlusal forces owing to poor support, resulting in compromised denture retention as a consequence of loss of peripheral seal². According to MacEntee, support for the complete dentures is significantly compromised if the flabby ridge has more than 2 mm displacement under pressure³,⁴. Retention, support and stability of complete dentures is compromised by flabby ridges unless the tissue is appropriately managed and manipulated by special impression techniques. Multiple techniques for the management of flabby ridges have been proposed ⁵.

In another study by Osborne, two different impression materials using two separate custom trays were utilized⁶ typically these “flabby ridges” are composed of mucosal hyperplasia and loosely arranged fibrous connective as well as more dense collagenised connective tissues. In the soft tissue, varying amounts of metaplastic cartilage and/or bone have been reported.

Management of a flabby ridge is mainly by three approaches:

1. surgical removal of fibrous tissue prior to conventional prosthodontics,
2. implant retained prosthesis
   i. fixed,
   ii. removable,
3. conventional prosthodontics without surgical intervention ⁸,⁹

A poor ridge is better than no ridge, which could be a sequel to surgical excision of the flabby tissues. The objective of complete denture prosthodontics is restoring aesthetics, comfort and function by replacement of missing dental and alveolar structures using a stable prosthesis. Preferably, the residual ridge is overlaid with 1.5–2 mm thickness of the masticatory mucosa for adequate soft tissue support for the denture ¹⁰. This case report presents a modified double tray impression technique for flabby ridges.

**Case Report:** A 67 year old female patient reported to the department of prosthodontics and crown and bridge, sree balaji dental college and hospital, with a chief complain of ill-fitting maxillary complete denture for the past 7 months. The patient reported that she had recently been provided with a maxillary complete denture, which she described as ‘loose’. On intra-oral examination, an edentulous maxillary arch with displaceable anterior flabby ridge and highly compressible tissue in the posterior region was observed. (Fig.1) Following discussion with the patient regarding the available treatment options, it was planned to provide the patient with a new conventional complete denture by special impression using a dual tray technique.

1. A primary impression was made of both the maxillary and the mandible edentulous arches using irreversible hydrocolloid impression material Alginate (Zelgan, DENTSPLY) using edentulous stock trays. so that the tissues can be recorded with minimum distortion.

2. A maxillary cast was poured and the flabby ridge area was marked, (Dental plaster, Type II) followed by fabrication of custom tray spaced (3 mm), first tray using auto polymerizing resin with (DPI RR cold cure resin) A special try is fabricated over the wax spacer and locating resin lock is located in the centre of palate during fabrication (Fig. 2). This helped to accurately locate the second part of special tray using a stop, thereby allowing for a pre-planned even thickness of impression material.

3. The tray was tried in the patient mouth and the flanges were adjusted to be 2 mm shorter than the depth of sulcus using a slow-speed motor and carbide acrylic-trimming bur. (Fig.3)

4. Special tray along with double spacer wax over flabby area. (Fig.4) A pick up tray is fabricated after applying petroleum jelly to all the surfaces, covering the first part of the special tray fabricated out using light cure polymerizing resin (Delta Poly Tray). (Fig.5)

5. Multiple holes are made in the pickup tray in the flabby area. Light body elastomeric impression materials [PVS (Aquasil, DENTSPLY)] is placed on the area covering flabby ridges and medium body/mono phase elastomeric impression material medium body [PVS(Aquasil DENTSPLY)] is placed in rest of the hard palate and master impression are made. (Fig.6)

6. The impression was evaluated carefully for defects and any excess material on the periphery was removed. (Fig.6)

![Fig. 1: Intra Oral View](image1)

![Fig. 2: Primary Cast](image2)

![Fig. 3: Fabrication of special tray using auto polymerizing resin Special tray with the locating lock region](image3)

![Fig. 4: Fabrication of special tray using light cure resin 3 mm wax spacer over the flabby with spacer](image4)
Flabby ridges provide poor support for the denture, and it could be argued that the tissue should be removed surgically to improve the stability of the denture and to minimize alveolar ridge resorption. However, in a situation with extreme atrophy of the maxillary alveolar ridge, flabby ridges should not be totally removed because the vestibular area would be eliminated. Indeed the resilient ridge may provide some retention for the denture. To overcome this a prosthetic approach of modification in recording such extremely resilient alveolar ridge is a conservative approach.

A particular problem is encountered if a flabby ridges are present within an otherwise ‘normal denture’ bearing area in denture, if the flabby tissue is compressed during impression making. Clearly, an impression technique required which will compress non flabby tissue to obtain support and at the same time, will not displace the flabby tissue.

Various techniques have been recommended and there is controversy as to whether a mucocompressive technique which compresses the mobile tissue aiming to achieve maximum support from it or whether a mucostatic technique with the aim of achieving maximum retention should be employed. Flabby ridges when recorded using a conventional method are compressed during impression. The elastic recoil of flabby fibrous soft tissue during function results in instability and loss of denture retention and dislodgement.

Several impression techniques and methods have been described in the literature for recording flabby tissue during impression making. However, there is no evidence to support that one particular impression technique will provide a stable and retentive denture on flabby ridges as compared to others. Managing a patient with flabby maxillary ridge can be a challenging problem. Standard mucocompressive impression techniques are likely to result in an unretentive and unstable denture as the denture will be constructed on a model of the flabby tissue in a distorted state.

In the conventional prosthodontics approaches, managing a patient having a flabby maxillary ridge with standard mucocompressive impression techniques is likely to be terminated in an unretentive and unstable complete denture. The use of selective pressure or minimally displacing impression technique should facilitate overcoming some of these limitations. An abused oral tissue due to ill-fitting dentures is another clinical condition commonly encountered by the prosthodontist. This case report details with modified double tray impression technique by fabricating a special tray in order to control the pressure during impression making thereby providing better retention and stability to the denture.

**Conclusion**

Fibrous or flabby ridges in complete denture fabrication are a challenge to deal with. But with modified impression making techniques one can overcome this problem and prevent it from hindering in the success of denture fabrication, thereby providing adequate retention, stability, support and patient satisfaction with the functioning of the denture.

Tooth Supported Over Denture—A Case Report

Lakshmi S1, Sanjna Nayar2
1Postgraduate, 2Head of the Department, Department of Prosthodontics, Sree Balaji Dental College & Hospital, BIHER

ABSTRACT
Prosthodontic rehabilitation of a patient with few teeth remaining is always challenging for a dentist. Overdenture is a complete or partial denture prosthesis supported partly by soft tissues and partly retained by natural teeth and is a viable option when compared with conventional complete denture. The concept of conventional tooth-retained overdentures is a simple and cost effective treatment than the implant overdentures. When few firm teeth are present in compromised dentition, they can be retained and used as abutments for overdenture fabrication. This helps to improve the retention and stability of the final prosthesis significantly. The following case report discusses the use of resilient stud attachments to retain maxillary and mandibular overdentures.

Keywords: Hybrid dentures, overdentures, precision attachment, Tooth supported overdenture

Introduction
Complete dentures using one or more modified natural teeth for stability, support and retention. The diagnosis, treatment plan and clinical procedures for this type of denture involve knowledge and skill in several areas in dentistry. A tooth supported complete denture/overdenture is a dental prosthesis that replaces the lost or missing natural dentition and associated structures of the maxilla and mandible and receives partial support and stability from one or more modified natural teeth. The overdenture accomplishes three tremendously important goals, first is it maintains teeth as part of the residual ridge, second is decrease in rate of resorption, third is increase in the patient’s manipulative skills in handling the denture. A study by Crum and Rooney compares bone loss between patients with conventional dentures and patients with overlay dentures. By retaining the mandibular canines in the use of overdenture, the resorption of the alveolar bone surrounding these teeth was reduced by eight times. Retention and stability of overdentures can be improved by attachments or magnets. Attachments for overdentures are classified as studs, bars, magnets, telescopic which can be rigid or resilient. Stud attachments (Rhein 83 srl, Bologna, Italy) consist of matrix (a sphere with a flat head) available in preformed plastic patterns which cast to copings on abutments and patrix (Elastic rubbers) made of nylon and Teflon available in different colours corresponding to different retention degrees, both in normal and micro sizes.

Case Report: A 69 Year old female patient reported to the department of prosthodontics crown and bridge, with a chief complaint of missing teeth in upper and lower front and back region. Past history revealed extraction of maxillary and mandibular teeth except 13, 23, 33, 43 and 44 due to periodontal disease. Extraoral examination showed no abnormalities, and acceptable esthetic profile. Intraoral examination showed high and well-rounded completely edentulous maxillary and mandibular ridge. After clinical and radiographic examination, the diagnostic casts were studied which showed sufficient interocclusal space to accommodate the stud attachments. Treatment plan included extraction of teeth with poor prognosis, endodontic treatment for the retained teeth followed by fabrication of attachment of retained overdentures. 13, 23, 33, 43, 44 were treated endodontically. After abutment preparation, Abutment...
teeth were prepared for short copings followed by preparation of post space preparation were made with addition silicone (Zhermack, elite HD+). Copings were checked for the fit and pick-up impressions were made with an addition silicone (Zhermack, elite HD+) and light body (Zhermack, elite HD+). Wax patterns were prepared for metal denture bases and casted in cobalt chromium with prefabricated housings for patrix in the region of abutments. Primary impression was made with irreversible hydrocolloid impression material. Impressions were poured and special trays were fabricated with self-cure acrylic resin. Border moulding was done for both the arches with low fusing compound (DPI Pinnacle tracing sticks). Final impression was made with regular body elastomeric impression material (Aquasil Ultra, Dentsply Sirona). Master casts were prepared and occlusal blocks were fabricated. Maxillomandibular relations recorded and transferred to semi-adjustable articulator with the help of face-bow. Teeth settings was done and try in was made in patient’s mouth for phonetics, vertical and centric relation and finally esthetics. Vertical dimension was verified and centric and eccentric contacts were checked. Abutment teeth were cemented with the copings and dentures were delivered. Post insertion instructions were given and patient was recalled after 1 week, 1, 3, 6 and 12 months interval to evaluate the abutments.
When a patient presents with few remaining teeth, not ideally located to support fixed partial denture or removable partial denture, attachment retained overdenture could be a better option. Other options of treatment could be magnetic retained overdentures or Telescopic overdenture or implant supported overdenture. Bar attachments compared to stud attachments require more amount of interocclusal space, unaesthetic due to the bulkier denture base and anterior teeth arrangement will be difficult. Various Stud attachments are available which are selected based on vertical space available, crown/root ratio, type of coping, number of teeth support, amount and quality of bone support, location of abutments, type of opposing dentition, angulation of the root to the occlusal plane. Rheins stud attachments were used in this case due to their simplicity in design, ease in maintenance and minimum leverage. Resilient attachments permit vertical movement during mastication reducing stress transfer to the abutments (stress breaking function) and direct the forces to the residual ridge acting as stress redirectors. Precision attachments provide enhanced retention for the prosthesis. They may be rigid or resilient. Resilient attachments with built-in stress-breaking action compensate for the multidirectional loading forces acting on the overdenture prosthesis. Stud attachments are one of the oldest attachment systems in use.

They can be divided into two groups:

- Extraradicular, in which male component projects from the implant
- Intraradicular, in which the male component is a part of denture base.

Ball attachment, Locaters, O-ring attachments, Extracoronal Resilient Attachment (ERA) attachments are the most commonly used in implant supported overdenture. ERA attachments are rigid attachments and are best suitable for parallel implants. Ball attachments are considered as the simplest type of attachments for clinical application with implant-supported overdentures. But, the main drawback of this system is that the O-rings gradually loose retention, and must be replaced periodically.

Robert J. Krum conducted a study to determine the amount of vertical residual bone loss in the anterior part of the maxillae and mandible in two groups of patients: One with complete maxillary dentures and mandibular overdentures and the other group with complete maxillary and mandibular conventional dentures. It was concluded that patients treated with complete maxillary dentures and mandibular overdentures demonstrated less vertical alveolar bone reduction than patients with complete maxillary and mandibular conventional dentures. The metal denture is less subject to breakage, denture supporting tissues respond more favourably to metal base which may be related to greater ease in maintaining cleanliness of metal base and to effective transmission of thermal changes through the metal base. Patient was satisfied with the dentures at follow-up.

**Conclusion**

A comprehensive evaluation, multi-disciplinary approach and a sequential treatment plan are important for a long-term successful outcome. To provide a successful treatment, the clinician should have a thorough knowledge of various attachments available, their
use in various clinical situations, their advantages and disadvantages. The patient’s physiological dimension is maintained through the preservation of teeth and bone. Tooth supported complete dentures are a valid approach to preventive prosthodontics10.

Correction of Class II Skeletal Malocclusion with an Infra-Zygomatic Crest Bone Screw Approach

A. Arif Yezdani¹, Priya Chatterjee², S. Kishore Kumar³, Kesavaram Padmavathy⁴

¹Professor & Director, Department of Orthodontics and Dentofacial Orthopedics, ²Department of Orthodontics and Dentofacial Orthopedics, ³Vice Principal and Assistant Director (R&D), Department of Orthodontics and Dentofacial Orthopedics, ⁴Associate Professor, Department of Microbiology, Research Laboratory for Oral-Systemic Health, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research, Chennai, Tamil Nadu, India

ABSTRACT

Introduction: This case report describes the treatment of a Class II skeletal malocclusion with a prognathic maxilla and retrognathic mandible with severely proclined maxillary incisors and lingually blocked mandibular right lateral incisor with entire maxillary arch distalization and use of infra-zygomatic crest bone screws devoid of extraction of premolars.

Method: Treatment involved strap-up of a pre-adjusted edgewise appliance, MBT technique (0.022 X 0.028 - inch slot). A non-extraction approach was recommended despite the case warranted premolar extractions. Infra-zygomatic bone screws of length 14mm and diameter 2mm was used for the distalization of the entire maxillary arch. The case was assessed at start of orthodontic treatment (T1) and end of orthodontic treatment (T2).

Results: At T2, the severe pre-maxillary prognathism and mandibular anterior crowding with lingually locked right lateral incisor was corrected with the canines and molars finished in Class I relationship. Normal overbite and overjet with a pleasing soft tissue profile was satisfactorily achieved.

Conclusion: Infra-zygomatic bone screws can be effectively used as absolute skeletal anchorage to correct Class II skeletal discrepancy with maxillary prognathism and severe proclination of maxillary incisors devoid of premolar extractions.

Keywords: infra-zygomatic bone screw, skeletal Class II discrepancy, maxillary arch distalization, skeletal anchorage

Introduction

Treatment of Class II skeletal discrepancy patients pose a challenge to the orthodontists. However, this has become a thing of the past with the advent of Temporary Anchorage Devices (TADs) used as skeletal anchorage.

Mini-implants are placed in many anatomic sites with the popular implant sites being the buccal cortical plate in the maxilla and mandible, palate, retromolar area in the mandible and lingual aspect of the maxillary alveolar process. The advent of orthodontic bone screws has widened the horizon of orthodontic treatment wherein borderline surgical cases and extraction cases can now be treated non-surgically and with a non

extraction approach. Entire maxillary arch retraction is now possible with the use of infra-zygomatic bone screws in contrast to routine inter-radicular TADs which are not very effective as they lie in the path of tooth movement and would have to be repositioned quite often.

The infra-zygomatic crest (IZC), a common site for insertion of Temporary Anchorage Devices (TADs), is a crest of bone originating intraorally from the buccal plate of the alveolar process connecting to the zygoma, lateral to the roots of the first and second maxillary molars. The inferior portion of it is subdivided into the IZC 6 and IZC 7 areas, respectively, whereas superiorly it extends 2cm or more upto the zygomatic-maxillary suture. Uribe6 and Melsen7 preferred the intraoral anatomical ridge of IZC for routine placement of TADs.

Mandibular buccal shelf (MBS) located bilaterally in the posterior part of the mandibular body, anterior to the oblique line of the mandibular ramus and buccal to the roots of the first and second molars has also been proposed as a suitable extra-alveolar mini-screw insertion site to help retract the mandibular dentition distally.8

This case report highlights the treatment of an adolescent male patient with a skeletal Class II discrepancy with severe prognathism of the pre-maxillary segment and severe proclination of maxillary anteriors, treated effectively with the judicious use of infra-zygomatic bone screws.

**Diagnosis and Etiology:** A 13-year-old male presented with severe forward placement of the maxillary incisors and severely crowded mandibular incisors with a lingually locked mandibular right lateral incisor.

**Clinical assessment (Fig. 1)**

**Extraoral assessment:** The patient had a brachycephalic head with an euryprosopic face, convex profile, posterior divergence, incompetent lips, deep mentolabial sulcus, acute nasolabial angle, clinical low mandibular plane angle with no signs of temporomandibular joint dysfunction.

**Intraoral assessment:** Oral hygiene was satisfactory. The maxillary arch was V-shaped with severely proclined maxillary central incisors. The mandibular arch was U-shaped with severe crowding of mandibular incisors with 42 lingually locked. Increased deep bite with
occlusal trauma to the palatal rugae area was another evident finding. The mandibular dental midline was shifted to the right due to the lingually blocked 42. On both sides, the molar relation and canine relation was end-on and in occlusion increased overjet and deep bite was observed.

Radiographic assessment (Fig. 2).

The pre-treatment panoramic radiograph confirmed the presence of all permanent teeth with normal alveolar bone crest levels. Analysis of the pre-treatment lateral cephalometric radiograph revealed a Class II skeletal pattern, with a prognathic maxilla and retrognathic mandible, with a low mandibular plane angle and severely proclined maxillary incisors and moderately proclined mandibular incisors.

Treatment objectives: The main treatment objectives were to improve soft tissue profile, smile aesthetics and the existent lip incompetency. Since the premaxillary prognathism was starkly evident rather than the retrognathism of the mandible, greater emphasis was laid for the correction of the former in conjunction with correction of severe maxillary anterior proclination and lingually locked mandibular right lateral incisor. Despite Careys’ analysis and Upper arch analysis forebode a severe tooth-size archform discrepancy necessitating extractions, a non-extraction decision was taken to treat the case. Infra-zygomatic bone screws were recommended for entire maxillary arch distalization.

Treatment alternatives: Orthopedic treatment with a functional appliance and headgear could have been advocated as a first phase of treatment for the Class II skeletal discrepancy with a prognathic maxilla and retrognathic mandible. However, we chose to correct the severe maxillary and mandibular dento-alveolar problem with a non-extraction approach initially and then subsequent to complete alignment of the maxillary anterior teeth we chose to distalize the entire maxillary segment back. As the patient was still in the circumpubertal growth spurt as evidenced by the assessment of the cervical vertebral maturational stages on the lateral cephalogram, we surmised that normal growth would take care of the retrognathism of the mandible in the remaining years of the patients’ available pubertal growth spurt. To distalize the entire maxillary segment back extra-radicular infra-zygomatic bone screws were advocated.

Treatment progress: Preadjusted edgewise brackets (MBT prescription, 0.022 x 0.028-inch slot) (3M Unitek, Monrovia, CA, USA) were bonded. Aligning and levelling was done with 0.014-inch Nickel Titanium (NiTi) archwires (aw), followed sequentially with 0.016-inch NiTi, 0.016x0.022-inch NiTi, 0.016x0.022 stainless steel (SS), & 0.017x0.025-inch SS aw. Infrazygomatic bone screws (Bioray, Orthosystems,
Mumbai, India) of length 14mm and diameter 2mm were placed in Infra-zygomatic Crest of the maxillary second molar region (IZC 7) bilaterally and the entire maxillary arch was distalized using a power chain from the IZC bone screws to the crimpable hook crimped onto the 0.017x0.025-inch SS aw with a force magnitude of 300-350g. To ensure effective distalization, extraction of the maxillary third molars bilaterally was advised.

An additional MBT bracket was also placed on the lingual aspect of the lingually blocked mandibular right lateral incisor and a 0.014-inchNiTi aw was passed lingually through that bracket to help move the tooth into the mandibular arch after creation of space with an open coil spring on a plain 0.018-inch SS aw, followed sequentially by the same sequence of wires as mentioned above. The case was eventually finished with 0.019 x 0.025-inch SS aw.

Results

The patient showed remarkable improvement in the correction of the prognathism of the premaxillary segment and severe proclination of the maxillary anteriors by the combined use of IZC bone screws and fixed appliance therapy. The lingually locked 42 was aligned and levelled with a non-extraction approach too with the fixed appliance therapy. A Class I canine and molar relation with normal overbite and overjet with a pleasing soft tissue profile was achieved at the end of treatment.

Discussion

The key factor for successful mini-screw placement is primary stability. Many authors have reported the versatility of the buccal cortical plate of maxilla and mandible as effective placement sites. The important factors for placement in the buccal cortex of the maxillary and mandibular cortex are, sinus morphology, nerve location, buccolingual bone depth, inter-radicular distance, and soft tissue anatomy.

Borderline surgical and extraction cases can now be effectively treated non-surgically and with a non-extraction approach thanks to the advent and judicious use of absolute anchorage produced by micro-implants and extra-radicular bone screws. The inter-radicular micro-implants and the extra-radicular infra-zygomatic and mandibular buccal shelf screws are both used for the purpose of skeletal anchorage.

In the case reported the patient showed remarkable improvement in his facial esthetics. Despite the maxillary incisors being severely labially proclined by 12mm, a non-extraction approach was decided to tip them palatally first and then move the entire maxillary dental arch distally thereby avoiding extractions of maxillary first premolars. To facilitate the distalization of the entire maxillary arch, infra-zygomatic bone screws were advocated as they were extra-radicular in nature and would not interfere with the distal movement of the maxillary teeth.

The preferred TAD site of IZC 6 is anterior to the anatomic ridge and buccal to the mesiobuccal root of maxillary first molar, whereas for IZC 7 it is distal to anatomic ridge and buccal to mesiobuccal root of maxillary second molar. The cortical bone thickness is about 1.1-1.3mm and the attached gingiva is 1.0mm in the maxillary first molar region. IZC 7 site is usually the preferred site for TADs as the alveolar bone is thicker on the buccal surface of the second molars. In contenttion with this tenet we preferred to place the IZC screw in the IZC 7 TAD site (Fig.3). The knowledge of the above was also taken into consideration in the selection of the screw length which was 14 mm in length and 2mm in diameter such that the screw threads would engage cortical bone securely and ensure primary stability. The angulation of the screw was kept at 55-70 degrees inferior to the horizontal plane as suggested by Liou to ensure maximal buccal bone engagement. To prevent soft tissue irritation, they were placed in attached gingiva with a clearance of 1.5mm from the base of the TAD platform to the soft tissue as advocated by Shih Yh et al and Chang MJ et al.

Fig. 3: Mid treatment panoramic radiograph with IZC bone screws in situ & MBT prescription 0.022x0.028-inch slot with 0.017x0.025-inch SS aw with IZC bone screws in situ
The entire maxillary arch was observed to have been distalized by 3mm. The increased overjet of about 12mm was corrected to an ideal overjet of about 3mm and the increased maxillary incisor exposure of 7mm was also reduced to 3mm post treatment due to the retrusive and intrusive effect produced by the power chain attached to IZC. The severely crowded mandibular arch with the lingually blocked mandibular right lateral incisor was also effectively aligned and levelled without sacrificing the first premolar on the right lower quadrant. Maxillary and mandibular dental midlines were harmoniously coincident post treatment. Soft tissue harmony and balance was adequately achieved in both the frontal and profile views with a much desired consonant smile arc (Fig.4). Post treatment panoramic radiograph showed normal alveolar bone crest levels and post treatment lateral cephalometric analysis validated the results clinically achieved (Fig.5).

Fig. 4: Post treatment extraoral and intraoral

Fig. 5: Post treatment lateral cephalometric and panoramic radiograph
Fixed lingual retainers were given for both maxillary and mandibular dental arches to prevent relapse.

**Conclusion**

IZC bone screws can be a viable alternative for correction of a Class II skeletal discrepancy with a prognathic maxilla avoiding the need for premolar extractions.

Skeletal Maxillary Bilateral Posterior Crossbite Correction with Decortication and Bone Autograft Augmentation

R. Rajesh Murugan¹, A. Arif Yezdani²
¹Post Graduate Student, ²Professor and Director; Dept. of Orthodontics and Dentofacial Orthopedics, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research, Chennai, Tamil Nadu, India

ABSTRACT

Background: Intentional injury to the periodontium by either corticotomy, piezocision or micro-osteoperforations triggers increased alveolar bone remodelling due to the regional acceleratory phenomena leading to accelerated tooth movement. Periodontal augmentation with bone graft provides structural integrity to the periodontium minimising occurrence of tell-tale relapse. Selective decortication and bone autograft augmentation were the procedures advocated for the accelerated correction of the skeletal maxillary bilateral posterior crossbite and open bite malocclusion in the case reported.

A 18 - year-old female patient presented with a mild skeletal Class III malocclusion with increased bi-maxillary dento-alveolar protrusion, anterior open bite, forward tongue posture and imbricated and rotated mandibular incisors with maxillary bilateral posterior crossbite. A nonextraction treatment plan was recommended.

Method: A week subsequent to strapping of pre-adjusted edgewise appliance, MBT prescription (0.022 x 0.028-inch slot) and Hyrax device, full thickness mucoperiosteal flaps were reflected in the maxillary buccal regions. Decortication was done with surgical perforations and augmented with bone autograft taken from the symphyseal region of the patient. Two weeks later activation of the Hyrax device was done twice daily with the other orthodontic adjustments performed fortnightly untill completion of treatment.

Results: Rapid correction of the skeletal maxillary bilateral posterior crossbite was achieved in 2.5 months and the complete malocclusion was treated in 7 months.

Conclusion: The accelerated correction of the malocclusion could be attributed to the regional acceleratory phenomenon triggered by the intentional surgical insult effected by the decortication procedure and the stable result thus observed was attributed to the periodontal augmentation by the bone autograft.

Keywords: skeletal maxillary bilateral posterior crossbite; anterior open bite; bone autograft

Introduction

Accelerating orthodontic tooth movement with shortened treatment duration has caught the attention of adult and late adolescent patients who now desire accelerated osteogenic orthodontics with its other attendant distinct advantages like improved post treatment stability, differential and enhanced envelope of tooth movement.¹ Since osteotomy was more destructive it has been replaced by corticotomy as the preferred surgical method to accelerate tooth movement.²
Wilcko et al³ attributed the rapid orthodontic tooth movement to the demineralization-remineralization of the alveolar bone subsequent to corticotomy procedure resembling the phenomena of Regional Acceleratory Phenomenon (RAP) which in actuality is a cascade of physiologic healing events following surgical wounding of cortical bone.⁴,⁵

Selective decortication is subsequently augmented with bone graft which could either be an autograft, xenograft or alloplast. This periodontal alveolar augmentation with bone graft corrects the bone dehiscences, root fenestrations and provides volume to the thinned alveolar cortices so that the teeth could be moved into a stable environment to mitigate post treatment relapse.⁶

Hence, selective decortication of the buccal aspect of the maxillary cortical bone in conjunction with bone autograft augmentation was suggested for the correction of the malocclusion in the case reported.

**Case Report**: A female patient aged 18 years presented with anterior open bite with forward placement of maxillary and mandibular anteriors with bilateral maxillary posterior cross bite.

Clinical and radiographic assessment (Fig 1):

**Extra-oral assessment**: The patient had a mesoprosopic face, straight profile, incompetent lips, clinical high mandibular plane angle with no signs of temporomandibular joint dysfunction.

**Intra-oral assessment**: Maxillary arch was U-shaped, asymmetrical with proclined maxillary incisors. Mandibular arch was U-shaped, asymmetrical with proclined, mildly rotated and imbricated mandibular incisors.

In occlusion, increased overjet, anterior open bite and maxillary bilateral posterior cross bite was observed with coincident maxillary and mandibular dental midline with class III molar and canine relation on right and left sides with lowdown forward tongue posture.
The pre-treatment panoramic radiograph confirmed the presence of all permanent teeth with mesio-angular impaction of 48 and normal alveolar bone levels. Analysis of the pre-treatment lateral cephalometric radiograph revealed a skeletal Class III pattern with an orthognathic maxilla and prognathic mandible with a high mandibular plane angle and severely proclined maxillary and mandibular incisors. (Table 1).

Aims and objectives

1. Achieve lip competence.
2. Correction of anterior open bite.
3. Correction of maxillary bilateral posterior crossbite.
4. Correction of protruded maxillary and mandibular teeth.
5. Correction of imbricated and rotated mandibular teeth.
6. Correction of class III canine and molar relation.

Corticotomy procedure with bone augmentation was advised as the anterior open bite and maxillary bilateral posterior crossbite were the pertinent clinical findings to be addressed in a short period of time. Since the patient had a straight profile, a non-extraction approach was advocated. The proclined maxillary and mandibular incisors were of less concern for the patient in comparison to that of anterior open bite. A week prior to the surgical procedure, MBT prescription Pre Adjusted Edgewise Appliance (PEA) Therapy (0.022 x 0.028-inch slot), (3M Unitek, Monrovia, CA, USA) with upper and lower 0.014-inch nickel titanium archwires was strapped up along with Hyrax device (rapid palatal
expansion device) in situ. (Fig.2). The patient underwent decortication of the buccal aspect of the maxillary alveolar bone and subsequent grafting with autograft with bone harvested from the symphyseal region.

Fig. 2: Orthodontic strap up with PEA (MBT 0.022 x0.028-inch slot) and Hyrax device

**Surgical procedure:** Autograft harvested from the symphyseal region was mixed with nova bone putty and platelet rich plasma and kept ready to be augmented subsequent to the decortication procedure. (Fig.3). Buccal sulcular incisions were done and full thickness mucoperiosteal flaps were elevated in the posterior maxillary alveolar regions on the buccal aspect. Perforations were made with surgical bur selectively on the buccal aspect of maxillary cortical bone from the regions 14 to 17 and 24 to 27 with a slight dip into the alveolar spongiosa to create the bleeding points and the freshly decorticated sites were then augmented with the prepared bone autograft and covered with a guided tissue regeneration membrane. (Fig.4). The flaps were then returned to their original position and sutured with interrupted non resorbable sutures. A periodontal dressing was subsequently given.

Amoxycillin 500mg and anti-inflammatory drugs t.i.d/week were prescribed. An antiseptic mouthwash was advised. Two weeks later the sutures were removed and the non-steroidal anti-inflammatory drugs were asked to be discontinued.

Fig. 3: Bone autograft harvested from symphyseal region.
Orthodontic Procedure: Orthodontic treatment was commenced 2 weeks after suture removal as premature suture removal can result in gingival recession, opening of interproximal embrasures and flap displacement. The Hyrax device was activated daily with 2 quarter turns with the other orthodontic adjustments done at 2 weekly intervals until completion of treatment. Initial aligning and levelling was done with upper and lower 0.014-inch nickel titanium archwires, upgraded to 0.016-inch nickel-titanium archwires and subsequently to 0.016 x 0.022-inch and then to 0.017 x 0.025 nickel titanium wires and finally finished with 0.019 x 0.025-inch stainless steel archwires.

Results

The skeletal maxillary bilateral posterior cross bite was corrected within 2.5 months with normal interdigitation of the posterior teeth in occlusion due to RAP. Correction of the anterior open bite was adequately achieved with lip competency and good soft tissue facial esthetics. (Fig.5).
Discussion

Orthodontic tooth movement occurs as a result of remodelling of bone brought about in the presence of inflammatory mediators such as TNF-alpha, IL-1, IL-8 and via induction of osteoclasts via RANK-RANKL pathway.7-10

Bone remodelling can also be speeded up by mechanical stimulation of the periodontal ligament, of which vibration and lasers show most promise effected mainly by osteoclastogenesis brought about by induction of signalling molecules such as c-fos, nitric oxide and Mitogen Activated Protein Kinase and RANK/RANKL pathway. 11

Non-surgical interventions too can accelerate orthodontic tooth movement by stimulating bone remodelling.12-15 However, in the case reported we have used the reliable surgical procedure of corticotomy. The use of alloplast and xenograft in accelerated osteogenic orthodontics has been widely reported in literature with predictable results.16-17 However, as autograft has been regarded as the gold standard in bone grafting procedures we have used the autograft harvested from the patients symphyseal region for the augmentation procedure.

The maxillary bilateral posterior crossbite was satisfactorily corrected with the maxillary posterior teeth being moved into an increased bone volume provided by the bone autograft. The alveolus as such is now considered as an operative orthopedic entity from a “whole bone perspective” irrespective of circum-maxillary sutures or periodontal ligament. Anterior open bite and rotated and imbricated mandibular incisors was also adequately corrected and a Class I canine and molar relation was achieved in about 7 months. Maxillary inter-premolar and inter-molar widths were increased dramatically post expansion with the hyrax device. There was no increase in the mandibular plane angle and anterior facial height post treatment, a finding most desirable because any increase in the same would have been disastrous for the facial esthetics of the patient who already had a mild leptoprosopic face pre-treatment. Lower lip to E-plane approached normal values post treatment. Closure of anterior open bite was also enhanced with retroclination of maxillary and mandibular incisors showing a remarkable improvement in her soft tissue profile and smile esthetics. Parallelism of the roots was well maintained. (Table 1). RAP

triggered by the corticotomy procedure created an osteopenic condition that probably led to the rapid correction of the malocclusion. Bone augmentation with an autograft increased the volume of the buccal bone which facilitated the teeth in palatal crossbite to be moved into an increased volume of bone provided by the bone autograft, a thing deemed impossible without attendant fenestrations and dehiscence of bone sans bone graft. The periodontal alveolar augmentation with the bone autograft undoubtedly increased the bone volume of the thin buccal maxillary cortices which are at increased risk for relapse subsequent to orthodontic tooth movement during the expansion procedure as has been widely reported in literature. 18. This bone augmentation also facilitates arch development and maximizes metabolic response during orthodontic treatment.19

The patient was seen every 2 weeks to take advantage of the RAP phenomenon throughout the phases of aligning, levelling, crossbite and open bite correction.

In the case reported no root resorption was observed as the bone density was reduced due to osteopenia and the bone matrix transportation that occurred facilitated the correction of the maxillary bilateral posterior crossbite. No pain nor loss of tooth vitality was observed in the case treated in concordance with what has been reported in literature. 20-21

Fixed lingual retainers were given for both maxillary and mandibular dental arches. Selective decortication facilitated the correction of the malocclusion in one third the treatment time required for conventional orthodontics and the alveolar augmentation with the bone autograft stabilized the correction achieved with less tendency for relapse and minimal risk of attendant complications.

Conclusion

The selective decortication procedure speeded up the correction of the maxillary bilateral posterior crossbite and open bite malocclusion in one third to one fourth the treatment required for conventional correction of the malocclusion and the augmented bone autograft provided excellent bone volume for the much needed post treatment stability results in such cases.

Class II Skeletal Jaw Discrepancy Correction with Herbst Appliance

A. Arif Yezdani¹, Prashanth Sreenivasan², R. Padmavathi², S. Kishore Kumar³, Kesavaram Padmavathy⁴

¹Professor & Director, Department of Orthodontics and Dentofacial Orthopedics, ²Department of Orthodontics and Dentofacial Orthopedics, ³Vice Principal and Assistant Director (R&D), Department of Orthodontics and Dentofacial Orthopedics, ⁴Associate Professor, Department of Microbiology, Research Laboratory for Oral-Systemic Health, Sree Balaji Dental College and Hospital, BIHER, Chennai

ABSTRACT

Introduction: This case report describes the treatment of a skeletal Class II malocclusion with an orthognathic maxilla and retrognathic mandible with severely proclined maxillary incisors, imbricated mandibular incisors, deep bite, convex profile and horizontal mandibular growth pattern treated with the Herbst appliance.

Method: Visual treatment objective was initially done to confirm the effectiveness of the use of a functional appliance. Treatment involved the use of a fixed functional appliance namely, Herbst appliance to advance the mandible forwards. The case was assessed at T1 and T2 of the initial orthopedic phase of treatment.

Results: At T2, the retrognathism of the mandible was adequately addressed and the facial convexity reduced dramatically. The molars attained a Class I relation and the facial soft tissue profile improved drastically with elimination of lower lip trap.

Conclusion: Functional retrusion of the mandible can be effectively treated in the pubertal period of growth spurt with the judicious use of a fixed functional bite jumping appliance such as the Herbst.

Keywords: pubertal growth spurt; skeletal Class II jaw discrepancy; retrognathic mandible; Herbst appliance

Introduction

Class II skeletal jaw discrepancy since time immemorial has posed an enigma to the practising orthodontists. Removable functional appliances like activator, bionator, Frankel functional regulator, Twin-block, etc., were viewed with skepticism as they did not produce the continuous alteration in the mandibular position in the neuromuscular environment deemed necessary to cause sufficient remodeling of the condyle and increase in mandibular size.

Herbst appliance was first introduced in 1905 but was lost in oblivion until it was resurrected in 1979 by Hans Pancherz. It was indicated in the permanent dentition just or after the peak in pubertal growth spurt but not in mixed dentition as this stage was prone for relapse due to unstable cuspal interdigitation. A stable cuspal interdigitation was deemed necessary for long term stability results. It was also reported that during therapy, sagittal condylar growth occurred along with marked changes in the morphology of the mandible with a high-pull headgear-like effect on the maxillary complex.

Many types of Herbst appliance were introduced to the orthodontic fraternity in the form of banded, bonded,
acrylic splint and cast silver splinted Herbst. 3-6 Herbst with headgear therapy was also used to treat severe Class II malocclusions with prognathic maxilla and retrognathic mandible. 7

The short–and long-term effects of Herbst appliance on the dentofacial complex, masticatory system and occlusion was effectively analysed in a series of articles by Pancherz H. 8-14

This case report highlights the treatment of an adolescent female patient with a skeletal Class II discrepancy with orthognathic maxilla and retrognathic mandible with severe proclination of maxillary anteriors, imbrication of mandibular anteriors and deep bite in the circumpubertal period of growth treated effectively with the Herbst, a fixed functional bite-jumping appliance.

**Diagnosis and Etiology:** A 13-year-old female presented with severe forward placement of the maxillary incisors and crowded mandibular incisors with a lower lip trap.

Clinical assessment (Fig. 1)

---

**Extraoral assessment:** The patient had an euryprosopic face with a brachycephalic head, convex profile, posterior divergence, deep mentolabial sulcus, acute nasolabial angle, incompetent lips, decreased lower anterior facial height and clinical low mandibular plane angle with no signs of temporomandibular joint dysfunction.

**Intraoral assessment:** Oral hygiene was satisfactory. The maxillary arch was average shaped with severely proclined maxillary anteriors. The mandibular arch was average shaped with imbrication of mandibular incisors. The dental midlines were coincident with each other and the facial midline with a Class II molar and canine relation on both sides. In occlusion increased overjet and deep bite was observed.

Radiographic assessment(Fig.2). Analysis of the pre-treatment lateral cephalometric radiograph revealed a Class II skeletal pattern, with an orthognathic maxilla and retrognathic mandible, a low mandibular plane angle and severely proclined maxillary incisors and moderately proclined mandibular incisors.

**Fig. 1: Pre-treatment extraoral and intraoral**

**Fig. 2: Pre-treatment lateral cephalometric radiograph**
**Treatment objectives:** The main treatment objectives were to improve the convex soft tissue profile and jaw base relationship with advancement of the mandible forwards, reduce overbite and overjet, achieve a Class I canine and molar relation, correct the imbrication of mandibular anteriors, eliminate lower lip trap and improve lip competency.

Orthodontic treatment comprised a phase I growth modification therapy using Herbst appliance. Since the skeletal Class II discrepancy was characterized with a retrognathic mandible with the patient in the circumpubertal growth spurt, greater emphasis was laid on the correction of her functional retrusion.

**Treatment alternatives:** An initial orthopedic phase of treatment with a functional appliance was the treatment of choice. Removable functional appliances like activator, bionator, Frankel Functional Regulator and Twin-block appliance could have been used to correct the retrognathism of the mandible, but since these functional appliances are of a removable nature, patient cooperation was questionable. Fixed functional appliance was advocated to ensure good patient cooperation and favourable treatment results. Although various types of fixed functional appliances are available in the market, Herbst appliance was chosen as the treatment of choice for the correction of the class II skeletal discrepancy with retrognathic mandible. Assessment of the cervical vertebral maturational stages of cervical vertebrae C2 through C4 on the lateral cephalogram depicted an ideal circumpubertal growth period to correct the skeletal Class II jaw discrepancy.

**Treatment progress:** A clinical visualized treatment objective was done and was found to be positive. A construction bite was taken in a Class I molar relation. Maxillary and mandibular first molars and first premolars were banded and an upper and lower impression was taken. These bands were then transferred to the impressions and working models were made. The construction bite then facilitated the mounting of the upper and lower casts onto the articulator. Fabrication of the wire framework was done on these models. A 0.9mm stainless steel wire was used to form the wire framework on the maxillary and mandibular casts. The wire was adapted on the palatal gingival aspect of the maxillary first permanent molars and premolars bilaterally with an interconnecting transpalatal arch with a similar fabrication done for the mandibular cast with a lingual sectional extension touching the lingual surfaces of the mandibular anteriors thereby fortifying the desired total anchorage of the appliance. The wire framework was then soldered to the respective molar and premolar bands. The plunger was then screwed tight with hex head screws with a wrench to prevent the telescoping parts from slipping off the pivots. The amount of bite jumping is determined by the length of the tube. In order to prevent the plunger from slipping out of the tube when the mouth is opened wide, the length of it is kept at maximum. Too long a length would injure the buccal mucosa distal to the maxillary permanent first molar. The Herbst is versatile in that it not only permits vertical opening but also lateral movements of the mandible. (Fig.3). Reactivation of mandibular advancement can be achieved with advancers available in five lengths from 1mm to 5mm crimped onto the plunger.

![Fig. 3: Herbst appliance in situ](image-url)
Results

An appreciable amount of sagittal and vertical growth was achieved in the 6 months of treatment period. A combined mandibular skeletal and maxillary and mandibular dental changes was responsible for the improvement in occlusal position. The Wits appraisal improved to normal values. An increase in mandibular length with mesial movement of mandibular molars and posterior movement of the maxillary molars was responsible for the correction of Class II molar relation and the overjet correction was mainly due to a posterior movement of upper incisors with an increase in mandibular length and proclination of lower incisors. A Class I molar and canine relation was achieved with a reduction in overjet and overbite by 5mm and 3mm respectively. Soft tissue profile improved dramatically with elimination of the lip trap. (Fig.4)

Discussion

Worldwide, Class II malocclusion is highly prevalent and in the orthodontic offices its treatment is one of the most frequent. As the patient was in the pubertal growth period and a potential candidate for functional appliance treatment, a fixed functional appliance was advocated. The fixed Herbst appliance in contrast to the other removable functional appliances like activator, bionator or Frankel II was advocated as it had several advantages such as: (1) active treatment is short (6 to 8 months), (2) works 24 hours a day, (3) doesn’t require patient compliance. A phase I growth modulation therapy with the Herbst was advised to reduce the facial convexity and improve the skeletal jaw discrepancy by advancing the mandible forward and correcting the buccal segment and incisor relationships to a Class I. The sagittal changes achieved were a result of a combination of skeletal and dentoalveolar changes. The mandible was advanced by 5mm as was evidenced by the Co-Gn measurement and the increase in SNB angle to 2°, post treatment. The Class II molar relation was corrected as a result of mesial movement of mandibular molars and distal movement of maxillary molars. Lower anterior facial height increased by 2 mm with a slight increase in mandibular plane angle. (Fig. 5), (Table 1).
Superimposition of the pre and post treatment changes were evidence of the treatment changes achieved with the Herbst (Fig.6). The long-term effect of Herbst appliance treatment on the vertical jaw base relationship, expressed by the mandibular plane angle (ML/NSL) was evaluated by Ruf S and Pancherz H and it was found that it was unaffected by Herbst therapy, but post treatment a continuous decrease took place with male subjects showing a larger angular decrease than female subjects with no statistically significant difference among normodivergent, hypodivergent and hyperdivergent subjects. A favourable soft tissue environment was created with elimination of the lip trap. Flores-Mir C et al in a systematic review of treatment of Class II division 1 malocclusion with splint-type Herbst appliances were of the opinion that in the attainment of final occlusal results, dental changes were as important as skeletal changes and to support these conclusions long-term, prospective, double-blinded, randomized clinical trials were suggested as mandatory.

In the case treated bilateral Class II molar relation was corrected to Class I as it was a symmetric Class II Herbst treatment. Bock NC et al. assessed retrospectively the short-term stability and effectiveness of Class II subdivision Herbst nonextraction treatment and concluded that symmetric Class II Herbst treatment was successfully similar to Class II subdivision Herbst treatment with however, a slight Class III molar tendency in the original Class I side in the subdivision patients. Sanders et al. evaluated a group of Class II subdivision malocclusions with cone-beam computed tomography and concluded that along with a skeletal etiology it was due to an asymmetric mandible that was shorter and more posteriorly positioned on the Class II side.

The treatment limitations of Herbst appliance is that in nongrowing patients the skeletal changes are minimal with the treatment effects confined to the dentoalveolar area with an increasing risk for development of a dual bite with TMJ dysfunction symptoms. However, favourable changes in condylar and glenoid fossa remodeling with a double contour of the glenoid fossa has been widely reported.
In Herbst therapy, forward position of the chin is due to summation of 3 factors, namely, condylar remodeling, glenoid fossa remodeling and positional changes of the condyle within the fossa and that the TMJ and chin changes are more sagitally orientated. The Herbst appliance could also be an alternative to orthognathic surgery in borderline skeletal Class II cases as it is has also been reported to be more effective at the end of the growth period in Class II patients.

Conclusion

Herbst appliance, a fixed functional orthopedic appliance used in the pubertal growth spurt period for the female adolescent patient was found effective in the correction of the skeletal Class II jaw discrepancy characterized with a retrognathic mandible.

Effect of Acetaminophen and Ibuprofen in Orthodontic Tooth Movement—A Review

A. Arif Yezdani¹, Mansi Giri²

¹Professor & Director, ²Post Graduate Student, Department of Orthodontics and Dentofacial Orthopedics, Sree Balaji Dental College and Hospital, Bharat Institute of Higher Education and Research, Chennai, Tamilnadu, India

ABSTRACT

Orthodontic force application causes an inflammatory event in the periodontium resulting in bone resorption and subsequent orthodontic tooth movement (OTM). The release of inflammatory mediators like prostaglandins E2 and Interleukin-1β act as potent stimulators of bone resorption. Application of heavy force results in pain and to relieve the same non-steroidal anti-inflammatory drugs (NSAIDs) are prescribed. These NSAIDs negate the inflammatory reactions by interfering with the synthesis of prostaglandins(PG), thus inhibiting orthodontic tooth movement. The purpose of this mini-review of literature was to highlight the effects of the two commonly used drugs, namely acetaminophen and ibuprofen on their pain relieving ability and effect on OTM. It was concluded that acetaminophen was a potent analgesic that could be used to relieve the discomfort associated with orthodontic treatment as its effect was at the central nervous system level and not at the cell membrane level as also since it inhibited the PG synthesis very slightly its inhibitory effect on OTM was not a matter of concern. On the other hand, Ibuprofen served as a mild analgesic as also inhibited OTM with its anti-inflammatory effect.

Keywords: Acetaminophen; ibuprofen; prostaglandins; orthodontic tooth movement

Introduction

The essence of orthodontic therapy is the attainment of a stable functional occlusion and to achieve this goal there is a need to move the teeth though alveolar bone via application of mechanical forces. This applied mechanical force elicits an inflammatory reaction in the periodontal ligament and alveolar bone housing the tooth. The cells of nervous, immune and endocrine systems aid in the activation and response of the periodontal ligament and alveolar bone cells during orthodontic tooth movement.¹ Prostaglandins (PGs) are membrane phospholipids generated in response to physical stimulators or localized irritants.²,³ Grieve et al ⁴ also reported the presence of PGs and Interleukin-1β, the 2 potent mediators of bone resorption in the gingival crevicular fluid as early as seven days after application of an orthodontic force. These inflammatory mediators play an important role in orthodontic tooth movement in response to an applied orthodontic force.⁵

Patients undergoing orthodontic therapy either during placement of separators or initial archwire placements and during periodic orthodontic adjustments often complain of pain and discomfort. This is especially seen in the first 24 hours after the application of orthodontic force but decreases to pre-placement levels in about 7days.⁶ The periodontal pain that ensues was construed to be a combination of pressure, ischemia, inflammation and edema.⁷ BurstoneC ⁸ identified an immediate pain response subsequent to placement of an arch wire related to initial compression of the periodontal ligament and a delayed pain response that occurred a few
hours later attributed to hyperalgesia of the periodontal ligament. Patients are often prescribed analgesics to control pain caused by the orthodontic appliance in the first few days after appliance placement.\textsuperscript{9}

The most commonly prescribed drugs are the non-steroidal anti-inflammatory drugs (NSAIDs), whose anti-inflammatory effects are a direct result of the inhibition of the biosynthesis of prostaglandins when they act over the cyclooxygenase pathway involved in catabolism of arachidonic acid, present in the phospholipidic membrane of the cells.\textsuperscript{10} The drugs used routinely in orthodontic therapy to relieve pain and discomfort are acetaminophen and Ibuprofen. Hence, the purpose of this mini-review of literature was to ascertain the effects of these two drugs on pain relief and orthodontic tooth movement.

\textbf{Para-aminophenol derivatives:} In 1887, Phenacetin was introduced and was used extensively as an analgesic-antipyretic, but was later banned due to analgesic abuse nephropathy. Acetaminophen (Paracetamol, N-acetyl-p-aminophenol, Tylenol, etc.) is the active metabolite of Phenacetin. Paracetamol (acetaminophen), the de-ethylated active metabolite of phenacetin, was introduced in the last century but came into common use only in 1950.

Acetaminophen belongs to the family of para-aminophenols. It exerts an analgesic effect by raising the pain threshold in response to stimuli. It is available as an over the counter drug as also in numerous combinations with narcotic and non-narcotic analgesics (like aspirin and other salicylates), barbiturates, caffeine, antihistamines, etc. It is an effective alternative to aspirin as an analgesic–antipyretic agent. It is weak in its action as an anti-inflammatory drug but is well tolerated with low incidence of gastro-intestinal side effects.

\textbf{Mechanism of action:} The weak anti-inflammatory effects of acetaminophen have been tied to its decreased ability to inhibit COX in the presence of high concentrations of peroxides which are usually found at the sites of inflammation. A dose of 1000 mg results in approximately 50\% inhibition of both COX-1 and COX-2 in whole blood assays ex vivo in healthy volunteers. The central analgesic action of paracetamol is due to its inhibitory effect on COX-3 enzyme in the brain and is known to raise the pain threshold similar to that of aspirin. It however has weak peripheral anti-inflammatory component due to poor inhibition of PG synthesis in peripheral tissues. The analgesic action of aspirin and paracetamol is additive.

Acetaminophen is suitable for analgesic or antipyretic use and is particularly valuable for peptic ulcer patients in whom aspirin is contraindicated, as also in aspirin hypersensitivity or children with a febrile illness. The conventional oral dose of acetaminophen is 325-650 mg every 4-6 hours with the total daily doses to not exceed 4000 mg (2000 mg/day for chronic alcoholics). A dose of 10 mg/kg may also be used. Acetaminophen is usually well tolerated at recommended therapeutic doses. Single or repeated therapeutic doses of acetaminophen have been shown to have no adverse effects on the cardiovascular and respiratory systems, platelets, or coagulation.

Generally, NSAIDs, due to their potential for slowing tooth movement are not recommended for use during orthodontic treatment. Acetaminophen has minimal effects on prostaglandin synthesis. Paracetamol is thought to reduce pain centrally rather than peripherally by inhibition of COX-3 in the brain and the spinal cord. Hypothetically, because acetaminophen is inactive as an anti-inflammatory agent in peripheral tissues, it should have no adverse effect on PG biosynthesis and subsequent bone resorption associated with orthodontic tooth movement, unlike the other NSAIDs. Roche JJ et al.\textsuperscript{11} in their study on New Zealand white rabbits undergoing orthodontic treatment, concluded that acetaminophen had no effect on the rate of tooth movement. Arias OR et al.\textsuperscript{12} conducted a study on Wistar albino rats to study the effects of acetaminophen on orthodontic tooth movement. They concluded that acetaminophen did not significantly reduce the numbers of resorption lacunae and osteoclasts in the pressure area of the incisors moved as a result of orthodontic treatment as also it did not alter osseous regeneration or dental movement as its effect was at the central nervous system level and did not affect the peripheral secretion of PGs and in comparison to ibuprofen and acetylsalicylic acid did not affect OTM and was the analgesic drug of choice for treating pain associated with orthodontic treatment. Kehoe MJ et al.\textsuperscript{13} concluded that acetaminophen was the drug of choice for the relief of minor discomfort associated with OTM after a series of animal experiments was done to study the effect of ibuprofen, acetaminophen and misoprostol on PGE synthesis and OTM. Acetaminophen, a proven analgesic lacks the anti-inflammatory properties of
NSAIDs and does not affect the rate of orthodontic tooth movement making it the drug of choice for the relief of orthodontic pain.

**Propionic acid derivatives (Ibuprofen):** Ibuprofen, an alternative to aspirin, was introduced in 1969. It is the most commonly used NSAIDs and the first member of the propionic acid class of NSAIDs to come into general use and be available as an over the counter drug.

**Mechanism of action:** Propionic acid derivatives are nonselective COX inhibitors which have effects and side effects common to other traditional NSAIDs. Propionic acid derivatives, in particular naproxen, has demonstrated prominent inhibitory effects on leukocyte function. Data suggests that naproxen acts as an efficient analgesic and aids in relieving morning stiffness. Ibuprofen is well absorbed orally and is highly bound to plasma proteins (90-99%), but its displacement interactions are not clinically significant. Use of ibuprofen does not require alteration of dose of oral anticoagulants and oral hypoglycemics.

Ibuprofen has been rated as the safest conventional NSAID by the spontaneous adverse drug reactions reporting system in U.K. Ibuprofen (400mg) has been found to be equally or more efficient than a combination of aspirin (650 mg) + codeine (60mg) in relieving dental surgery pain. Concurrent treatment with ibuprofen and low dose aspirin has been found to prevent irreversible COX inhibition. Thus it may antagonize the anti-platelet and cardioprotective effect of low dose aspirin. Intravenous ibuprofen is administered at a dose of 100-800 mg over 30 minutes every 4-6 hours to relieve pain and fever.

Discomfort and pain after initial separator or arch wire placement during activation visits are commonly experienced among orthodontic patients. Blockage of prostaglandin synthesis in peripheral tissue influences the mechanism for preoperative anti-inflammatory effect. Administration of NSAIDs before the procedure, aids in inhibiting the prostaglandin synthesis and concurrently decreases the inflammatory response.

It has been also reported that the efficacy of preoperative analgesic consumption of ibuprofen taken one hour before archwire or band placement decreased the pain level in patients from two hours after bonding until nighttime and that it significantly decreased pain caused by mastication within two hours compared to when ibuprofen was administered postoperative. Ibuprofen significantly inhibited the production of prostaglandin E (PGE) in the periodontal ligament and subsequently decreased the rate of tooth movement.

JB Walker et al 14 evaluated the impairment of OTM caused by NSAIDs with data sourced from biomedical literature and concluded that NSAIDs can impair OTM and that acetaminophen was an appropriate alternative to NSAIDs for pain associated with orthodontic treatment.

In a study by Ngan P et al 15 it was reported that Ibuprofen was a preferred analgesic in the treatment of discomfort because of post orthodontic adjustments. In comparison to a placebo pre-operative administration of ibuprofen suppressed post-operative pain. 16 It has also been reported that Ibuprofen stimulates the release of beta-endorphin, a natural endogenous analgesic. 17, 18

Shetty et al 19 suggested that NSAIDs like ibuprofen had an inhibitory effect on the release of prostaglandins during initial tooth movement and thereby may cause an impediment in the rate of tooth movement as also was a less potent analgesic than acetaminophen whose effect on PG synthesis was insignificant.

Gonzales et al 20 studied the effect of acetaminophen, aspirin, meloxicam, celecoxib and prednisolone and their effects on tooth movement and root resorption on rats and concluded that depending on dose thresholds celecoxib and prednisolone may interfere with the arachidonic acid cascade thus interfering with tooth movement though with reduced propensity for root resorption. 20

Bartzela et al 21 did a systematic review of literature on the effects of dietary supplements and medications on the rate of experimental tooth movement. They reported that increased tooth movement occurred with therapeutic administration of eicosanoids whereas their blocking led to a decrease. NSAIDs decreased tooth movement, but paracetamol (acetaminophen), a non-NSAID analgesic had no effect. Parathyroid hormone, thyroxin and corticosteroid hormones increased tooth movement whereas estrogens reduced tooth movement. Dietary calcium seemed to reduce tooth movement whereas Vitamin D3 stimulated it and bisphosphonates had a strong inhibitory effect on tooth movement. They concluded that information on the consumption of the above medications was essential in discussing the treatment planning with the patients as these medications might have a profound influence on the rate of OTM.
Conclusions

- The drugs that inhibit the liberation of PGs are a viable option to control pain and inflammation during orthodontic treatment.
- Acetaminophen does not alter osseous regeneration or orthodontic tooth movement because it acts at the central nervous system level and does not affect the peripheral secretion of PGs.
- Ibuprofen inhibits PGs at the peripheral level thus affecting osteoclastic activity and resultant deceleration of orthodontic tooth movement.
- Acetaminophen is the suggested drug of choice rather than ibuprofen to relieve pain and discomfort during the course of orthodontic therapy.

ABSTRACT

In orthodontic treatment planning decisions assessment of growth status plays a vital role and that the adolescent growth spurt is considered an ideal time to mete out growth modification therapy. Various radiologic and non-radiologic skeletal maturity indicators have been in use with its attendant advantages and disadvantages. Insulin like Growth Factor-1 (IGF-1) is one such non-radiologic biomarker that could be used to estimate the amount of available growth present to help treat jaw discrepancies in the circumpubertal period of growth as the mean levels of it has been reported to be high during cicumpubertal growth. Internationally peer reviewed and valid indexed reference articles pertaining to IGF-1 and its predictive usefulness in estimating the peak pubertal growth spurt used alone or in combination with the other radiologic skeletal maturity indicators was segregated and diligently perused. Information gleaned from the literature review revealed that IGF-1 was indeed effective in assessing the circumpubertal growth spurt. It had a high correlation with the cervical stages C3 and C4 as seen on lateral cephalograms as also with the stages pertaining to peak pubertal growth as seen on handwrist radiographs and middle phalanx 3 (MP3) on periapical x-rays. IGF-1 was an effective and alternative biomarker for estimation of peak pubertal growth spurt used alone or in combination with the other radiologic biomarkers.

Keywords: Insulin like growth factor-1; growth hormone; pubertal growth spurt; skeletal maturation

Introduction

Chronologic age, dental age, physical characteristics and peak height velocity, are highly unreliable methods to predict pubertal growth spurt.¹ The other pertinent methods of assessing skeletal maturity and peak mandibular bone growth are hand wrist radiograph, assessment of degree of cervical vertebral maturation on lateral cephalograms and recording of MP3 stages on periapical X-ray films.² These radiographic methods are however highly subjective techniques, involving radiation exposure. A quest for a non-radiologic biomarker was a long felt need. Insulin-like growth factor-1 (IGF-1) is one of the main mediators of growth hormone in promoting skeletal and muscular growth.³ The circulating IGF-1 increases with increase in growth hormone (GH) at puberty. IGF-1, a polypeptide hormone and a mediator of GH is produced both locally and systemically and its increase in level has been correlated with the pubertal growth spurt.⁴ A study on newborn rats has shown that the condyle is more responsive and sensitive to IGF-1 than the femoral head.⁵ Brabant G et al.⁶ had reported explicitly the reference ranges of serum IGF-1 levels in male and female subjects according to chronological age. Hence, this review of literature would throw light on the contention that IGF-1 is a widely used skeletal maturity indicator in the assessment of skeletal maturity.

Assessment of IGF-1 as a biochemical marker has been widely reported in literature right from its discovery by Salmon Daughaday in 1957. Its mean peak levels have been compared with the other radiologic skeletal maturity indicators such as handwrist radiograph, Middle phalanx of the third finger and cervical vertebral maturational stages as seen on lateral cephalograms. This review of literature helps one to understand the importance of the use of IGF-1 as a biologic skeletal maturity indicator.

Masoud M et al 11 (1985) reported in a longitudinal study that the mean Insulin-like Growth Factor-1 (IGF-1) levels in rabbits progressively increased from 2 weeks of age to their peak readings at 12 weeks in males and 14 weeks in females, followed by a progressive decline to pre-pubertal levels and that for each of the growth parameters measured in individual animals between 8 and 16 weeks of age a positive correlation coefficient was found between serum IGF-1 and growth increments.

Juul A et al12 (1994) conducted a cross-sectional study of 1030 healthy Caucasian population with 877 children and adolescents and 153 adults between 0-80 years of age and divided them into three groups. Height, weight, body mass index and pubertal developmental stage was recorded according to Tanner method. Blood samples were drawn from antecubital vein, centrifuged and the serum stored at -20° C for up to 4 months before analysis. The authors related IGF 1 levels to age, sex, sexual development and body mass index (BMI). They reported that the mean serum IGF 1 concentration increased slowly in prepubertal children with a steep increase during puberty followed by a decline post puberty upto 25 years and that in normal prepubertal children serum IGF-1 levels was not influenced with BMI.

Juul A et al13 (1995) reported that IGF-1 is bound to specific Insulin like growth factor binding proteins (IGFBPs) especially IGFBP-3 which is also regulated by GH and whose levels increase with age in children, with maximal levels observed in puberty.

Woods KA et al 14 (1996) described a child with a homozygous defect of the IGF-I gene that was associated with growth failure before and after birth, indicating that IGF-1 is critical for prenatal as well as postnatal growth and that the patient’s neurologic development was also abnormal suggesting the role of IGF-1 in the development of the central nervous system.

Okazaki K et al 15(1999) investigated the involvement of IGF-1 in osteophyte formation and concluded that IGF-1 regulated the initiation and development of osteophyte formation in an autocrine and/or paracrine fashion.

Butler AA et al 16 (2001) in his review of literature stated IGF-1, IGF-2 and IGF-1 receptor were critically important for normal growth and development of an organism. Gene-deletion of these elements has demonstrated that IGF-1 is important for both prenatal and postnatal development, whereas IGF-2 is important during prenatal stages only and that local tissue IGF-1 production was unaffected and may compensate for the lack of the liver IGF-1 suggesting the role of endocrine vs. autocrine/paracrine function of IGF-1.

Visnapuu V et al17 (2001) investigated the distribution of growth hormone (GH) and insulin-like growth factor 1 (IGF-1) receptors in temperomandibular joint (condyle) and compared the findings with that of long bone epiphyseal plates in rats. The localization of the receptors was examined in vivo by immunohistochemical methods in 1 to 21 day old rats. They reported that GH receptors were detected in various components of the TMJ but not in the fibrous articular surface or in the cartilage layers of the condyle whereas IGF-1 receptors were found in the fibrous articular surface of the condyle and in the superior and posteriorsuperior regions of the condylar cartilage. Early post-natal growth and development of mandibular condylar cartilage is IGF-1 dependent but not GH dependent.

Mohan S et al 18 (2003) evaluated the relative contribution of the GH/IGF axis to the development of peak bone mineral density (BMD), and measured the skeletal changes in IGF-I knockout (KO), IGF-II KO, and GH-deficient lit/lit mice and their corresponding control mice at day 23 (prepubertal), 31 (pubertal), and 56 (postpubertal) in the entire femur by dual energy x-ray absorptiometry and in the mid-diaphysis by peripheral quantitative computed tomography. The data demonstrated that: 1) mice deficient in IGF-I exhibited a greater impairment in bone accretion than mice deficient in IGF-II or GH; 2) GH/IGF-I, but not IGF-II, is critical for puberty-induced bone growth; and 3) IGF-1 effects on bone accretion during prepuberty are mediated predominantly via mechanisms independent of GH, whereas during puberty they are mediated via both GH-dependent and GH-independent mechanisms.
from the onset of puberty. The authors measured mean blood spot IGF-I levels in a cross-sectional study of 83 patients (44 females, 39 males) on recall to begin orthodontic treatment, in active treatment, or in post treatment follow-up. The results showed that mean blood spot IGF-I levels were significantly higher in the late pubertal stages than in the prepubertal, early pubertal, and post pubertal stages. Linear correlation showed that IGF-I levels had a significant positive correlation with cervical skeletal maturity from the prepubertal to the late pubertal stages, and a significant negative correlation from the late pubertal to the post pubertal stages. In the post pubertal stage, IGF-I levels had a negative linear correlation with increasing time since the onset of puberty and with chronological age. The authors concluded that blood spot IGF-I could be used as a skeletal maturity indicator and might be useful in detecting residual mandibular growth in young adults.

Masoud M et al 20 (2008) hypothesized that IGF-1 levels would also correlate with cervical skeletal maturity and would be highest at the cervical stages that correspond to the greatest amount of facial growth. The authors measured mean blood spot IGF-I levels in a cross-sectional study of 83 patients (44 females, 39 males) on recall to begin orthodontic treatment, in active treatment, or in post treatment follow-up. The results showed that mean blood spot IGF-I levels were significantly higher in the late pubertal stages than in the prepubertal, early pubertal, and post pubertal stages. Linear correlation showed that IGF-I levels had a significant positive correlation with cervical skeletal maturity from the prepubertal to the late pubertal stages, and a significant negative correlation from the late pubertal to the post pubertal stages. In the post pubertal stage, IGF-I levels had a negative linear correlation with increasing time since the onset of puberty and with chronological age. The authors concluded that blood spot IGF-I could be used as a skeletal maturity indicator and might be useful in detecting residual mandibular growth in young adults.

Masoud MI et al 22 (2012) hypothesized that IGF-I levels could be used as a skeletal maturity indicator. IGF-I levels were estimated from blood samples using chemiluminescence immunoassay (CLIA) method. CVM was evaluated using a six-stage method of evaluating cervical vertebrae. 53.3% of subjects at CS-3, 66.7% subjects at CS-4, and 6.7% subjects at CS-5 showed IGF-I levels in peak range. They concluded that serum IGF-I levels in females correlated well with skeletal maturity determined by CVM and MP3 stages and increased sharply during early pubertal stages followed by a decrease in late puberty. They also hypothesized that serum IGF-I testing can be undertaken as a preliminary screening test in patients in whom the orthodontist predicts the possibility of using myofunctional appliance but in whom the chronologic age is not suggestive for a growth modification therapy.

Masoud MI et al 22 (2012) in his study developed the use of a biologic marker, (IGF-1), as an indicator for the timing and intensity of mandibular growth. This was done by measuring annual changes in mandibular length and studying how they relate to blood spot IGF-1 measurements & cervical stages. They concluded blood spot IGF-1 testing is a promising tool for predicting the timing and intensity of mandibular growth spurt without the restrictions involved in the radiographic techniques for assessing skeletal maturity.

Ishaq RAR et al 23 (2012) conducted a study on 120 Egyptian subjects (60 females and 60 males) in circumpubertal age group and compared the IGF-I levels at different CVM stages. They observed the highest mean IGF-I levels in stage 3 of cervical maturation in females and in stage four in males.

Jain S et al 24 (2013) aimed to associate serum IGF-1 levels with cervical maturation stages (CS) 3, 4, and 5 on lateral cephalograms of 45 male subjects to find out peak serum IGF-1 levels among the three stages. Serum IGF-1 levels were estimated from blood samples using chemiluminescence immunoassay (CLIA) method. CS was evaluated using a six-stage method of evaluating the cervical vertebrae. 53.3% of subjects at CS-3, 66.7% subjects at CS-4, and 6.7% subjects at CS-5 showed IGF-I levels in peak range. They concluded that serum IGF-I levels could be used as an additional tool to optimize orthodontic treatment timing.

Gupta S et al 21 (2012) investigated the validity of Insulin like Growth Factor -1(IGF-1) as a skeletal maturity indicator by comparing serum IGF-1 levels with the stages in cervical vertebral maturation (CVM) and in the middle phalanx of the third finger (MP3). The study population was selected by using simple random sampling technique and consisted of 30 female subjects in the age range of 8—23 years who had blood sample, lateral cephalometric and MP3 radiographs taken on the same day. Serum IGF-1 estimation was carried out on the blood samples using chemiluminescence immunoassay (CLIA) method. CVM was evaluated using method by Baccetti et al and MP3 staging was done using Rajagopal & Kansal method. Their results showed that serum IGF-1 levels in females correlated well with skeletal maturity determined by CVM and MP3 stages and increased sharply during early pubertal stages followed by a decrease in late puberty. They also hypothesized that serum IGF-I testing can be undertaken as a preliminary screening test in patients in whom the orthodontist predicts the possibility of using myofunctional appliance but in whom the chronologic age is not suggestive for a growth modification therapy.

Gupta S et al 25 (2015) did a cross sectional study to assess serum insulin-like growth factor-1 (IGF-1) levels in 60 subjects, 30 males and 30 females in the age range of 8—23 years, at various cervical vertebral maturation (CVM) stages and concluded that IGF-1 values in CS5 in males had higher mean values than females, whereas in CS3 in females had higher mean values than in males indicating earlier onset of pubertal spurt in females and more delayed and longer pubertal spurt in males.
Jain S et al \textsuperscript{24}(2017) did a study to determine the relationship between IGF-1 levels, IGFBP-3 levels with CVM staging to track the pre pubertal and pubertal growth spurts in female patients in North Indian population and concluded that IGF-1 and IGFBP-3 both could serve as a potential biochemical indicator for assessment of skeletal maturity.

Tripathi et al\textsuperscript{27} (2017) assessed the levels of serum IGF-1 and serum osteocalcin and compared them with cervical vertebral maturation index (CVMI) stages. They concluded that serum IGF-1 showed peak levels at CVMI stage 4 and stage 3 in males and females, respectively, with statistically significant interstage differences except stages 3 and 4 in females and that osteocalcin followed IGF-1 across all CVMI stages but showed insignificant interstage differences.

### Conclusions

- IGF-1 could be used as a potential skeletal maturity indicator without the hazard of additional radiographic exposure.
- In comparison to prepubertal, early pubertal, and postpubertal stages, late pubertal stages exhibit higher mean IGF-1 blood spot levels.
- Mandibular condyle is sensitive and more responsive to IGF-1.

A Comparative Evaluation of Shear Bond Strength of Orthodontic Brackets Bonded to Porcelain Fused Metal Crowns Treated with Different Surface Conditioning Techniques—An Invitro Study

Mazhar Ahmed Mohammed1, S. Bhuminathan2
1Senior Lecture, Department of Orthodontics and Dentofacial Orthopedics, Care Dental college, Guntur, Andhra Pradesh; 2Professor, Sree Balaji Dental College and Hospital, BIHER, Chennai

ABSTRACT

With the increase in adult orthodontic treatment comes the need to find a reliable method for bonding orthodontic brackets onto metal or ceramic crowns and fixed partial dentures. In this study, shear bond strength and surface roughness tests by scanning electron microscope study were used to examine the effect of 5 different surface conditioning methods: 37% phosphoric acid gel, 9% Hydrofluoric acid, sandblasting + 9% Hydrofluoric acid, Sandblasting + Silane, Fine diamond bur roughening + silane for bonding metal brackets to ceramic surfaces of feldspathic porcelain. A total of 60 human maxillary premolar teeth extracted for therapeutic purposes from patients seeking orthodontic treatment were collected, and 50 ceramic crowns were fabricated onto the premolar teeth following crown preparation. 10 natural teeth were used as controls, they were acid etched in conventional manner using 37% phosphoric acid. Metal brackets were bonded using a light-curing composite. The samples were stored in distilled water at physiological temperature (37°C) for 1 day, and thermocycled 500 times between 5°C and 55°C. Shear bond tests were performed with a universal testing device, and the results were statistically analysed. Ceramic surfaces conditioned with sandblasting followed by application of Silane produced maximum bond strength of 12.34 ± 0.95 MPa comparable or even better than the control group 11.03 ± 1.63 MPa followed by 9% Hydrofluoric acid 11.48 ± 0.98 MPa & Fine Diamond Bur roughening + Silane 9.28 ± 1.11 MPa. Ceramic surfaces conditioned with 37% Ortho Phosphoric acid produced least SBS of 5.51 ± 0.88 MPa and hence not suitable for bonding Orthodontic brackets in a clinical scenario. Statistical tests showed significant difference between and within the groups in shear bond strength and P value also was highly significant, i.e. ***p<0.001. The SEM photomicrographs of all the six different surface preparations revealed different surface morphologies & were corroborative of SBS values. Even though 9% Hydrofluoric acid and Fine diamond bur roughening produced clinically acceptable SBS values, because of their technique sensitivity and side effects, they have to be used with great care and caution. sand blasting followed by the application of Silane coupling agent was found to be the best porcelain surface conditioning method.

Keywords: Bond Strength; Metal Brackets; Ceramic Surfaces; PFM's: Surface-Conditioning; Sand Blasting.

Introduction

The introduction of acid etch bonding technique by Buonocore1,2 in 1955, brought the concept of bonding various resins to enamel with applications in all fields of dentistry, including orthodontics. With the development of reliable and reproducible bonding techniques to enamel surfaces, cemented bands were replaced by bonded brackets on incisor, cuspid and bicuspid teeth. Newman3 1965 was the first person who used epoxy resin for bonding stainless steel brackets to enamel.

By the late 1970s bonding of orthodontic brackets had become an accepted clinical technique in routine fixed appliance treatment. Conventional adhesive system uses three different agents- an enamel conditioner, a primer solution and an adhesive resin in the process of bonding orthodontic brackets to the tooth.
With the increased number of adults seeking orthodontic treatment, clinicians often have to bond orthodontic brackets to teeth that have different types of restorations, including amalgam, gold, composite and porcelain. Banding is an alternative but is considered aesthetically unacceptable, particularly with anterior teeth. The application of direct bonds to fixed bridgework is preferable to banding.

Various methods have been tried to improve the bonding of orthodontic brackets to porcelain surfaces by pre-treating porcelain surface by mechanical or chemical means, or by a combination of both. Silane is an agent which chemically adheres with porcelain surface but if used alone doesn’t have enough cohesive force. In micromechanical attachments use of hydrofluoric acid, orthophosphoric acid increase surface area of porcelain and help to retain flowable composite.

Materials and Method

The present study was conducted in the Department of Orthodontics and Dento-facial Orthopedics, Sibar Institute of Dental Sciences, Takkellapdu, Guntur and Department of Organic Coatings & Polymers, Indian Institute of Chemical Technology, Habsiguda, Secunderabad.

Sixty human maxillary premolar teeth extracted for therapeutic purposes from patients seeking orthodontic treatment in the Department of Orthodontics and Dento-facial Orthopedics, Sibar institute of dental sciences were collected & stored in normal saline after treating them with hydrogen peroxide for one week.

Inclusion & Exclusion Criteria for Teeth Selection:

Teeth with no signs of caries
Teeth free of restorations
Teeth with no cracks on the crown as a result of the pressure of the extraction forceps.
Teeth with no cement remnants as a result of previous orthodontic treatment.
Teeth with fluorosis, hypoplasia or abnormalities of crown morphology, which may have affected bracket bonding, were excluded.

Fifty Porcelain Fused Metal Crowns were fabricated over the extracted maxillary premolar teeth after crown preparation for the study purpose, and ten extracted maxillary premolar teeth were acid etched in conventional manner using 37% phosphoric acid for 30 seconds. Composite bonding was done which acted as controls to compare the bond strength with Porcelain Fused Metal crowns.

Method

Bonding procedure: The teeth collected were grouped into six groups of ten each (Group I to Group VI).

And Following six protocols were executed for surface preparation.

Fig. 1: Porcelain Fused Metal Crowns were fabricated over the extracted maxillary premolar teeth & Mounted on Acrylic Blocks

Group 1: Orthodontic brackets were bonded to enamel surfaces on ten teeth in Group I which acted as control group, teeth were acid etched with 37% phosphoric acid gel for 30 seconds, thoroughly washed, and air dried using 3-in-1 syringe, followed by application of primer & bonding agent (Transbond XT 3M, light cured composite resin).
Group II: Porcelain Fused Metal Crowns were etched with 37% phosphoric acid gel for 30 seconds, thoroughly washed, and air dried using 3-in-1 syringe, followed by application of primer & bonding agent.

Group III: Porcelain Fused Metal Crowns were etched with 9% Hydrofluoric acid for 90 seconds.

Group IV: Porcelain Fused Metal Crowns were air abraded using 30 µm aluminum oxide particles from 10 mm distance with 250 Kpa pressure for 2-3 seconds using sandblaster machine, & etched with 9% Hydrofluoric acid for 90 seconds.

Group V: Porcelain Fused Metal Crowns were air abraded using 30 µm aluminum oxide particles from 10 mm distance with 250 Kpa pressure for 2-3 seconds using sandblaster machine, followed by two coats of silane coupling agent application and air dried.

Group VI: Orthodontic brackets were bonded on ten Porcelain Fused Metal crowns belonging to Group VI, which were roughened using Fine diamond bur 30µm.

Subsequent to bonding, the samples were stored in distilled water at physiological temperature (37°C) for 1 day, and thermocycled 500 times between 5°C and 55°C with a dwelling time of 30 seconds using a computerised thermocycling device (Nova Inc., Konya, Turkey) prior to shear bond strength testing.

Shear Bond Strength Testing In order to maintain a consistent debonding force in a controlled direction, teeth were mounted on to an acrylic jig (self cure clear acrylic by DPI). Jig was fabricated using 1.2 cm diameter Low Density Poly Ethylene (LDPE) block.

In this jig facial surface of the porcelain crown was kept exactly parallel to the debonding force or perpendicular to the floor. The force to debond was recorded with a universal testing machine (Autograph Model AGS 10 ANG, Shimadzu, Japan). A crosshead speed of 1mm/min was used. Debonded surfaces were observed under a scanning electron microscope for the types of failures after the debonding procedure.

Following debonding the surfaces under the debonded brackets were coated with gold and palladium solution to prepare the specimens for viewing under scanning electron microscope model Hitachi- S520, Japan; Oxford Link ISIS-300 UK at 500x and 1500x magnifications.

Fig. 2: Specimen Mounted on Universal Testing Machine

Results

The data was normally distributed and the results were tabulated for Minimum, Maximum, Range, Mean, Standard Deviation and Standard Error for all the groups of the study.

Parametric tests for comparison of six groups with respect to shear bond strength by one way ANOVA test and Pair wise comparison of six groups with respect to shear bond strength by Newman-Keuls multiple comparison post hoc procedure were done.

Both the tests showed significant difference between and within the groups in shear bond strength and P value also was highly significant, i.e. ***p<0.001.

Scanning Electron Microscope Results: The SEM photomicrographs of all the six different surface preparations revealed different surface morphologies.

For the porcelain-fused-metal crowns treated with 30 µm Al2O3 and Fine diamond bur 30 µm, loss of the glazed surface and mild roughening were seen. Uniform peeling or an erosive appearance with shallow penetration and undercuts was observed when compared with chemical etching. Hydrofluoric acid etching demonstrated mild roughening of the surface and orthophosphoric acid etching produced minimal change and did not appear to alter the glazed porcelain surfaces.

*p<0.05, **p<0.01 and ***p<0.001

**Discussion**

**Group I - 37% Phosphoric acid:** Orthodontic brackets bonded to enamel surfaces on ten natural teeth (maxillary 1st premolars) in Group I which acted as control group, were acid etched with 37% phosphoric acid gel for 30 seconds gave clinically acceptable and significant bond strength of 11.03 ± 1.63 MPa.

**Group II - 37% Phosphoric acid:** Porcelain surface preparation using 37 % Phosphoric acid gave significantly low SBS of 5.51 ± 0.88 MPa. These results were not in acceptable range for the orthodontic bonding.

**Group III - 37% Hydrofluoric acid:** Preparation with Hydrofluoric acid (HFA) produced significantly high bond strength of 11.48 ± 0.98 MPa, which was similar to the reports of previous studies. Surface conditioning with HFA successfully increased the adhesion of the composite resin to the porcelain surfaces by producing physical or topographical changes in the porcelain surface.

This was an expected result as HFA facilitates micromechanical retention between porcelain and composite resin. When the two acids, HFA and Phosphoric acid were compared, higher bond values were obtained in the HF acid treated group. However, HFA should be used with great care as it is capable of causing severe trauma to soft tissues and tooth substance (Hayakawa et al., 1992).

**Group IV – Sand blasting + Hydrofluoric acid:** In the mechanical preparation we used sandblasting in combination with 9% hydrofluoric acid etching and bracket bonding with composite material.
Surface preparation with 30 µm Al₂O₃ particles produced a uniform peeling appearance of the porcelain with deeper penetration and more undercuts compared to roughening; which increased potential mechanical retention. Hydrofluoric acid further acted by dissolving the crystalline and glassy phase of the ceramic (But this combination also seemed to cause irreversible alteration to the porcelain surface)

**Group V – Sand blasting + Silane:** Gave the maximum SBS value in this study, which is 12.34 ± 0.95 MPa.

These results were comparable to the previous studies done by Kocadereli *et al.* and Schmage *et al.* In contrast, Zachrisson reported earlier to these studies that silane application to sandblasted porcelain did not provide clinically acceptable bond strengths and suggested abandoning this technique.

In a study carried out by Tamer Türk *et al.* stated that samples coated with silane, but not exposed to chemical or mechanical roughening, were considered as the control group but demonstrated bond failures during thermocycling.

Barbosa *et al.* (1995) reported the premature loss of brackets bonded to glazed ceramic surfaces coated with silane after 7 days of water immersion. They explained that this premature loss was due to the high solubility of silane in water.

**Group VI – Fine Diamond Bur roughening + Silane**

Gave an SBS of 9.28 ± 1.11 MPa.

- These results were comparable to the previous studies done by Kocadereli *et al.* and Schmage *et al.* In contrast, Zachrisson reported earlier to these studies that silane application to sandblasted porcelain did not provide clinically acceptable bond strengths and suggested abandoning this technique.
- In a study carried out by Tamer Türk *et al.* stated that samples coated with silane, but not exposed to chemical or mechanical roughening, were considered as the control group but demonstrated bond failures during thermocycling.
- Barbosa *et al.* (1995) reported the premature loss of brackets bonded to glazed ceramic surfaces coated with silane after 7 days of water immersion.
- They explained that this premature loss was due to the high solubility of silane in water.

Barbosa *et al.* (1995)In their study stated that roughening with coarse diamond burs resulted in higher SBS when compared with other groups, i.e. glazed and deglazed surfaces with sandpaper disks. Silane presents a chemical link between the dental ceramic and the composite resin, and the organic portion of the molecule enhances the wettability of the ceramic surface, thereby displaying a closer micromechanical bond (Lu *et al.*, 1992).

However, in order to obtain a viable bond between the orthodontic bracket and the ceramic surface, mechanical or chemical roughening is inevitable (Wood *et al.*, 1986; Kao *et al.*, 1988; Barbosa *et al.*, 1995; Gillis and Redlich, 1998; Huang and Kao, 2001.

**Conclusion**

On comparing the effect of different surface conditioning methods on bond strength of brackets bonded to porcelain fused metal (PFM) crowns the following conclusions were drawn:

PFM surface conditioned with sand blasting followed by application of Silane (group V) produced maximum bond strength comparable or even better than the control group followed by groups III and VI. PFM surface conditioned with 37% Ortho Phosphoric acid (group II) produced least SBS and hence not suitable for bonding Orthodontic brackets in a clinical scenario.

Even though groups III and VI produced clinically acceptable SBS values, because of their technique sensitivity and side effects, they have to be used with great care and caution.

The best porcelain surface conditioning method recommended clinically for bonding Orthodontic brackets to porcelain fused metal crowns was sand blasting followed by the application of Silane coupling agent.

Soft Tissue Predictions in Orthodontics—A Review

E Thulasiram1, B Ragavendra2, R. Harini2
1Senior Lecturer, 2Post Graduate Student, Department of Orthodontics, Sree Balaji Dental College and Hospital, BIHER Chennai

ABSTRACT

The soft tissue covering the teeth and bone is highly variable in its thickness, and this variation may be greater than the variation found in the position and size of the teeth and bone. An esthetically pleasing face is regarded as one in which various facial features are well proportioned and balanced and relate well to other facial features.

Keywords: Soft tissue, Anthropologists, Puberty

Introduction

Face is beautiful & shows harmonious features if the proportions of its individual components are right”. That means “no individual structure is over emphasized in relation to others”. This is what he refers to as balance.

Soft tissue profiles for what constitute an excellent face have been repeated many times by representation of several disciplines including artists, anthropologists, reconstructive surgeons and orthodontists. St. Thomas expressed a direct relationship between beauty and mathematical numbers, the “FABONCCI SERIES”. According to him symmetry results from dynamic symmetry. In 16th century Leonardo da Vinci’s panting of the face contained in a large square and further divided in to small rectangles was interpreted as geometric recreation, Edward angle, believed that ideal occlusion is necessary for esthetics. He favored Greek profile to be ideal.1

Orthodontists base their treatment planning primarily on cephalometric evaluation. Recognizing that the orthodontic specialty has gone too far with its obsession with the placement of teeth at certain angulation on the basal bone and its effect on facial esthetics. It is common to hear that the treatment goals should be geared to the achievement of an overall facial balance. The true objective from the point of view of esthetics is to treat dentition to the face; however, an average face is considered more esthetic than one that is atypical. By knowing the soft tissue traits and their normal range, treatment plan can be designed to normalize the facial traits for a given individual.2

For a long time, orthodontists have focused on the horizontal lip position as the most important feature in determining beauty. Several lines have been introduced to assess the anteroposterior position of the upper and lower lips and the esthetic quality of the profile. The crux of the need for measuring was stated by Moroney as “It is always useful when we can measure things on a ruler instead of simply calling them big or small. Better treatment goals can be set if we quantitate the soft-tissue features which contribute to or detract from that “physical attractiveness stereotype”

With the advent of cephalometric various hard tissue analysis were used with no attention to soft tissues based on the assumption that soft tissue will anatomically adapt to the corrected dento-skeletal relation. In an article on soft tissue profile fallacies of hard tissue standards by Park and Burstone, showed that though dento-skeletal parameters were corrected to the ideal cephalometric norms soft tissue facial esthetics were not adequate. This land mark article marks the shift of the paradigm.3

One of the commonly used methods to visualize the probable soft tissue outcomes of orthodontic treatment is the cephalometric prediction tracings. However, prediction tracings have their drawbacks like variability in lip thickness, the degree of lip eversion and lip tonicity. Also the final artistic rendition of a predicted tracing may differ from one clinician to another. Therefore, these traditional tracings are often helpful only to the clinician and not the patient, since the
resulting soft tissue changes do not truly represent the patient’s final facial esthetic outcome.

The use of computers has greatly simplified the prediction process. Software systems can be programmed using mathematical algorithms to generate digital cephalometric tracings, capture pre-treatment profile photographs, and blend the tracings and photographs to produce a simulated post treatment appearance.

Konstiantos et al in 1994 did a study to examine the validity of the prediction of soft tissue changes after orthognathic surgery using computer software. The results indicated that for some of these landmarks the amount and direction of soft tissue changes differed from the actual4,5,6.

Konstiantos et al in 1994 did a study to examine the validity of the prediction of soft tissue changes after orthognathic surgery using computer software. The results indicated that for some of these landmarks the amount and direction of soft tissue changes differed from the actual.

Oft Tissue Changes with Growth Changes in Lip Length & Thickness Associated with Growth:
Subtelny measured longitudinal soft-tissue growth of upper & lower lip, the nose, & the soft tissue chin. Upper lip rapidly increases from 1-3 yrs, and then reduced between ages 3-6 yrs and again rapidly increases from 6-15 yrs.3,6,7,8,9,10

Thicknes: Greater thickness in vermilion region than region overlying point A, In both male & female Upper lip increased in thickness from 1 to 14 yrs.

Vig and Cohen documented both upper & lower lip grew more than skeletal lower face. The lip incompetency at age of 6 yrs. corrected by age 16 yrs. The vertical growth of the lips is definitely related to age and gender.

Length rapid increased in 1yr.-3yr. Markedly decreased 3yr,progressive increase in length of the Upper lip until the age of 15 yrs. Thereafter, growth in length slows down appreciably.

Mamandras found that most of the maxillary lip length in female was achieved by age 14. In male upper lip grows by age 18 but not complete. Lower lip length in female was achieved at the age of 16yrs & in males achieved at the age of 18 yrs.

Genecov found that males between age 7- 17, has greater increase in upper lip length than females.

Male -> 2mm vertical height of upper lip.

Females- < 1mm vertical height of upper lip.

Vertical relationship of the incisal edge of the Upper central incisor to the tip of the upper lip was relatively stable after complete eruption of the Upper central incisor.

Relationship of the Lower lip to the incisal edge of the Lower central incisor also established when the Lower incisors finished erupting at the age of about 9 years.

Maxillary lip length:
- Rapid increase lip length was 10 -16yrs in Male, 10 – 14yrs for Female.
- Overall increase of maxillary lip length 21.43% and 12.11% for Male and Female respectively.
- Significantly different between male and female subjects at 0.1, 0.05, and 0.005 levels for the ages of 14, 16 and 18 years respectively.

Maxillary lip thickness:
- Percentage of the overall increase from 46.33% for the Male & 14.68% for the female subjects
Most of the change in lip thickness were seen in Female between 10 and 14 years and in Male between 8 to 16 years of age. After which thinning of lip is seen

**Mandibular lip length:** In male age between 12-16yrs with small increase, half the size, between ages 8 and 12.

In female mandibular lip length increases between the age of 10-16yrs and almost no changes are seen between 8-10yrs & 16-18yrs.

**Mandibular lip thickness**

- Increased steadily for both male and female subjects from 8 - 16 years of age, and reached a plateau between the ages 16 and 18
- Rapid increase lip thickness is seen in Male between 14-16 yrs of age, In Female between 10 - 12yrs & 14 - 16yrs.

**Nasal Growth & its Contribution to the Profile:**

Subtelny documented the downward & forward growth of the nose that occurs during maturity. In male & female vertical dimension of nose showed more growth than A-P projection. In male nasal growth spurt occurred at 10 -16 yrs. & in female nasal growth seen around age 12 years and girls have slightly more nasal growth than boys during the early period of adolescence. Nasal bone growth completed before age 10, but soft tissue grew downward & forward with the maxillary complex. Class II malocclusion subject had more elevation of bridge of nose than did class I malocclusion subject. Class I subjects tended to have straight noses.

Genecov pointed out that nasal projection in females remained virtually constant from age 12 to 17. In males it grew from age 12-17. Nasal tip projection shows an early peak for girls between ages 9 -10 & for boys 13 -15 yr.

**The Chin:** Chin is the third most important soft tissue mass of the face.

Genecov studied soft tissue chin thickness from age 7 -9 measured from pg to pg’, in female it was 11.7 mm & in male it was 10.8 mm, after that 1.6 mm increased to age 17 in female & 2.4 mm increased to age 17 in male. As a result both had similar soft tissue chin thickness at age 17.
**Soft Tissue Changes between Ages 18 and 42**: Class I subjects between ages 18 & 42.

**Changes in males**
- Profile straightened & lips became more retrusive.
- Nose increased in size in all dimensions.
- Increased soft tissue thickness at pg.
- Decreased upper lip thickness with slightly increased lower lip thickness.

**Changes in females**
- Profile did not become straighter, & lips did not become more retrusive.
- Nose increased in size in all dimension.
- Decreased soft tissue thickness occurred at pg.
- Decreased upper lip thickness with slightly increased lower lip thickness.

**Nasal Changes**: Nasal projection increased & nasal tip moved more inferiorly.

**Lip Thickness**: Lips become less prominent & also located more inferiorly.

**Nasolabial Changes**: With the decrease in the lip prominence & lowering of the nasal tip, the nasolabial angle becomes more acute.

**Dental Changes**
- Upper incisor becomes more upright & lower incisor become more protrusive.
- The lower part of face appears to lengthen.
- The interlabial line descends down.

**Discussion**

**Soft tissue prediction is by 3 methods**
1. Cephalometric prediction
2. Tracing overlay method
3. Template method
4. Computer prediction
5. Cast prediction

**Changes with Normal Growth**
- Nasal growth
- Lip growth
- Chin growth

**Lip growth**[^1][^2][^3][^4][^5]: Vertical lip growth goes beyond the skeletal growth
- For males: 18 years
- For females: 14 years
- Mandibular lip growth is greater than maxillary lip growth
- For females: 16 years
- For males: 18 years

Lip thickness increases up to
- Males: 16 years
- Females: 14 years

The differential lip thickness between the two genders is consistently noted in these studies may mean the effect of extraction therapy on facial profile will be more noticeable in females than males because female lips do not thicken much during puberty so any extraction plan for females with straight to convex profile should be considered with caution.

The analysis of lip fullness on 12-13 year old males should include an understanding that although the lip becomes thicker, the rate of nasal growth is proportionally higher therefore lip fullness relative to the nose decreases.

**Nasal growth**
- Downward and forward growth of nose occurs during maturity
- Vertical growth of nose is greater than anterio-posterior growth
- For males growth spurts took place between 10 – 17 years and centered around 13 to 14 years
- Females, have steadier growth curve, till 12 years
- In females at 12 years of age will not have a drastic change in profile after the extraction therapy due to minimal increase in nasal projection in the following 2 years but when considering a boy of same age incisal retraction will produce less optimal result owing to increase in anterio-posterior nasal projection.

Chin growth
- That males and females will attain similar lip thickness of chin by the age of 17 years
- In adolescent patient with marginal lip fullness, orthodontic placement of incisors becomes very important, in these cases incisor retraction to reduce over-jet may result in undesirable effect.\textsuperscript{16}

Changes in Nasolabial Angle with Incisor Retraction:
Nasolabial angle change on incisor retraction is 1.6 °: 1mm, Nasolabial angle: LAFH = 2.2 °: 1mm, Nasolabial angle: mandibular plane angle is 3:1.\textsuperscript{17,18,19}

Changes in Upper Lip with Incisor Retraction: Upper lip thickened 1 mm with 3 mm of retraction of the upper incisors.

Upper incisor retraction to upper lip and lower lip retraction

Was 2.9:1 and 1:1, respectively.

Soft Tissue Prediction Based on
Tooth movement
Skeletal change

Tooth Movement: Not all parts of the soft tissue profile directly follow the underlying skeletal profile because of variation of thickness of soft tissue covering the face.

With incisor retraction, the upper lip rotates backwards around the subnasalae with reduction in prominence of lip relative to their sulcus.

Correlation analysis discloses that upper lip response is related not only to upper incisor retraction but also to lower incisor movement, mandibular rotation and lower lip position.

Lower lip moves less predictably with retraction of incisors than dose the upper lip.

The lower lip is much more self-supporting and not as dependent on the lower incisors.\textsuperscript{20,21,22}

Summary and Conclusion

“\textit{Beauty is in the eyes of the beholder}”

The facial proportions or measurements represent attempts to define preferred norms that are regarded as attractive. Attractiveness or facial beauty is subjective and culturally biased. So we can say that “beauty is in the eyes of the beholder”. Although recognizable, it can neither be defined nor amendable to measurement.

There is no universal ideal face. The facial measurements & proportions outlined are static frontal & Profile measurements. So, in addition to esthetic facial balance, there are other factors that contribute to overall perception of beauty. Among these are skin & hair correlation and style, facial expression and animation.

Careful examination and documentation of soft-tissue features will permit the reversal of negative traits and the maintenance of positive features in individuals, thereby enhancing clinical treatment. If the primary objective is facial improvement, soft tissue analysis becomes paramount in treatment plan.

The controversy still exists as to the ability of an orthodontist to predict soft-tissue changes at the time treatment is planned for a patient. Different study showed that with maxillary incisor retraction there is increase in nasolabial angle, increase in lip thickness of strained lips, retrusion of upper and lower lip, and increase in lip length. The nasolabial angle also increases with increase in LAFH with treatment mechanics as well as increase in mandibular plane angle.

So, during treatment planning one should know the soft tissue changes with maxillary incisor retraction & put them in a harmonious relationship.

Vertical Discrepancies in Orthodontics—A Review

S. Kishore Kumar¹, R. Padmavati², T. Shoba³
¹Professor, ²Post Graduate, Department of Orthodontics, ³Assistant Professor, Department of Pathology, Sree Balaji Dental College and Hospital, BIHER

ABSTRACT

A malocclusion created due to a vertical discrepancy is of great interest in the field of orthodontics, because of its etiology, treatment planning and tendency to relapse in the post treatment period. It is important for an orthodontist to recognize its numerous components and understand their interrelationships. This article reviews some of the relevant literature and also some diagnostic and treatment planning suggestions to the orthodontist

Keywords: vertical discrepancies, open bite, deepbite

Introduction

The two kinds of malocclusions present in a case of vertical discrepancy are- Open bite and Deep Bite. The vertical dimension is unique in that the growth rate is highest and lasts the longest in this direction. Since growth tends to increase the vertical distance between the maxillary and mandibular jaw bases, performing treatment during this period is most advantageous, as stated by Rakosi (¹). He also states that vertical dimension is not stable. Late growth of the mandible may increase an already existing increase in vertical dimension, accentuating the malocclusion thus occurring due to the discrepancy. This work will reveal the review of literature the classification, diagnosis and management of the vertical discrepancies in Orthodontics.

According to Profit (²), Overbite is defined as the vertical overlap of the incisors. Overbite is explained as the percentage of the mandibular incisor crown, that is overlapped vertically by the maxillary incisors, when the teeth are in centric occlusion (²).

Overbite values range from zero to more than 100%. Deep bite is usually more prevalent than open bite (²). Anterior open bites occur more often than posterior open bites (²).

Etiology of Vertical Discrepancies: Vertical malocclusions develop due to interaction of many different etiological factors; most importantly mandibular growth. Habits such as thumb sucking and abnormal tongue resting position (³) abnormal facial height (excessive vertical growth) may cause an open bite malocclusion. Growth processes associated with vertical malocclusions must be understood along with normal and abnormal functioning of the soft tissues, i.e., the lips and the tongue, in order to successfully diagnose and plan treatment for such cases. Growth prediction of the mandible will therefore be of great importance to the treatment plan. The direction of growth of the condyle, direction of the mandibular growth characterize the development of a deep bite or an open bite. Björk and Skieller (⁴) demonstrated that the direction of the growth of the lower jaw varies greatly.

Patients with upward and forward growth of the mandibular condyle often have reduced anterior facial height and deep bite. The direction of the mandibular growth expressed at the chin, is vertical (⁵). Patients with a downward and backward growth of the mandible, with the so-called ‘long-face syndrome’. The associated dental eruption pattern of the posterior teeth is generally vertical.
Classification of Vertical Discrepancies in Orthodontics

I. Classification of Incisor Relationships in the Vertical Dimension: Ballard and Wayman first gave a classification of the incisor occlusion in 1964 (6), which in turn was based on the work of Backlund (7). Brook and Shaw (8) gave the British Standard Institute Classification of Malocclusion, considering incisor occlusion. This classification is considered superior to Angle’s classification because the posterior teeth did not influence the occlusion on the incisors.

The BSI-classification is as follows:

Class I: the lower incisor edge precludes with or lies immediately below the cingulum plateau of the upper central incisors.

Class II: the lower edges lie cervical to the cingulum plateau (middle part of the palatal surface) of the upper incisors.

Div I: there is an increase in overjet and the upper central incisors are usually proclined.

Div 2: the upper central incisors are retroclined. The overjet is usually minimal, but may be increased.

Class III: the lower incisor edges lie coronal to the cingulum plateau of the upper incisors. The overjet is reduced or reversed.

Modified British Standards Institute for Incisor Classification. (9)

Class I: Lower incisor edge occludes with the middle part of the palatal surface.

Class II: Lower incisor edge occludes with the cervical third of the palatal surface.

Class III: Lower incisor edge occludes with the incisal third of the palatal surface.

II. Classification of Deep Overbite: Depending on the etiology, overbite can be differentiated into Developmental deep bite and Acquired deep bite (1)

Developmental deep bite/Genetically determined deep overbites is further classified as:

- Skeletal deep overbite: There is a horizontal growth pattern observed in cases of skeletal deep bite. E.g. Class II Div 1 malocclusion.

- Dentoalveolar deep bite: A dental deep bite is caused by supraocclusion of the incisors. In such cases, the interocclusal clearance is usually small. i.e., the overbite is functionally a pseudo over-bite.

Acquired deepbite maybe caused by the following factors:

- A lateral tongue thrust produces an infraocclusion of the posterior teeth leading to a deep overbite. E.g. Class II div 2 malocclusion.

- Premature loss of deciduous molars

III. Classification of Openbite: Thomas Rakosi (1) states two kinds of factors which are concerned with the etiology of an open bite. They are:

Epigenetic factors: These include posture of the tongue, morphology and size of the tongue, skeletal growth pattern of the maxilla and mandible, particularly the mandible and the vertical relationship of the jawbases.

Environmental factors (10): Andrew Richardson (11), proposed an etiology-related classification:

- Transitional openbite.
- Open bite, due to habits.
- Open bite, due to the presence of:
  - Local pathology.
  - Skeletal pathology.
- Non-pathological or skeletal openbite.
- Skeletal (ab initio) openbite
  - Open bite that is improving.
  - Open bite, which is deteriorating.
  - Improving but later deteriorating type of open bite.
- Skeletal (de novo) openbite
- Open bite, due to the morphology and behavior of the tongue and lips.
Evaluation of Skeletal & Dental Relationships in the Vertical Plane of space

Open Bite

Esthetic Considerations\(^\text{(12)}\): The following relationships may be considered in evaluating esthetics:

- Balance between the nose, lips, and chin profile.
- The nasolabial angle.
- The configuration of the lips.
- A short upper lip
- The length of the lower third of the face and, the relative prominence or retrusion of the chin affects appearance.

Functional Considerations\(^\text{(12)}\): Cayley \(^\text{(13)}\) stated that anterior open bite and tongue thrust swallowing are closely associated. According to Bahr and Holt \(^\text{(12)}\), four types of tongue thrust activity may be differentiated, and subsequently form the basis for differentiating types of openbite:

- Tongue thrust without deformation.
- Tongue thrust causing anterior deformation
- Tongue thrust causing buccal segment deformation with a Posterior open bite
- Combined tongue thrust, causing both an anterior and a posterior open bite is another common dysfunction. This is called a complex open bite by Moyers and is more difficult to treat.

Clinical Considerations\(^\text{(12)}\): Depending on the severity of the malocclusion, various forms of anterior open bite may be observed.

- A simple open bite exists in cases in which more than 1mm of space may be observed between incisors, but the posterior teeth are in occlusion.
- A complex open bite - open bite extends from the premolars or deciduous molars on one side to the corresponding teeth on the other side
- The compound or infantile open bite is completely open, including the molars.
- The iatrogenic open bite is the consequence of orthodontic therapy,

Sassouni\(^\text{(14)}\) constituted facial characteristics of a skeletal open bite clinically as:

- Extruded incisors.
- Lower anterior facial height exceeds the upper anterior facial height.
- Large teeth present in the dentition.
- Crowding and dental protrusion.
- Impaction or ectopic eruption of molars.
- Palatal vault is high and narrow.
- Mouth is wide.
- Broad lips, kept apart at rest.
- Mouth breathing.
- ‘Chinless’ appearance

Cephalometric Criteria \(^\text{(12),(15)}\): Nanda\(^\text{(16)}\) gave the morphological basis of an open bite being associated with:

- Large gonial angle.
- Lack of compensating Curve of Spee.
- Large vertical anterior maxillary dimension(ANS -Mn)
- Anteroposterior rotation of the maxilla and mid -cranial fossa.
- Long mandibular corpus length.

Treatment of Open-Bite in the Deciduous Dentition \(^\text{(12),(17)}\): Treatment with screening appliances or activators is indicated. Extraoral orthopedic appliances such as chin caps can be used effectively to redirect growth. Treatment should begin when patients are 7 to 8 years of age\(^\text{(18)}\).

Treatment of Open Bite in the Mixed Dentition\(^\text{(12)}\): Three types of open -bite malocclusion may be differentiated in the mixed dentition period:

1. Dentoalveolar open bite
   - In the early mixed dentition period, screening therapy is indicated.
   - In the late mixed dentition, with a severe tongue thrust or posture problem, screening
therapy may be unsuccessful\(^{(19)}\). Constricted arches can be expanded during this stage using palatal expanders.

- Swallowing exercises (i.e., swallowing without thrusting, putting the tip of the tongue behind the upper or lower incisors)

2. Skeletal open bite.

- Treatment with activators combined with extraction and extraoral force application is considered.
- In extreme cases, with divergent rotation of the jaw bases, removal of four first premolars and fixed appliance therapy is the best approach to treatment.
- Severe cases might require orthognathic surgery, with impaction of buccal segments and even sagittal split osteotomy in some cases to close the bite and provide stable correction. M. Arat and H. Iseri\(^{(20)}\) evaluated the orthodontic as well as orthopedic approach to the treatment of skeletal open bite

3. Combined openbite: Most skeletal open-bite cases are probably at least partially attributable to abnormal perioral muscle function. Rolf and Christine Frankel \(^{(21,22)}\) supported this.

Elimination of abnormal perioral muscle function resulted in correction of skeletal relationships

**Treatment of Open Bite in the Late Mixed Dentition**

- Functional Appliance Therapy Activator
- Bionator-Open Bite Appliance
- Frankel Function Regulator
- Twin Block Vertical Activation

**Treatment of Open Bite in the Permanent Dentition\(^{(12)}\)**

- **Bite-blocks** intrude the posterior teeth and, thus, make possible autorotation of the mandible
- Transpalatal lingual arch
- Orthognathic surgery

**Recent Advances In Treatment of Open Bite**

**Meaw-Multiloop Edgewise Archwire Therapy**

- It was introduced by Dr. Young. H. Kim \(^{(23)}\).
- Double edgewise brackets with .018 slots with an auxiliary vertical slot are used.
- 16*22 stainless steel wire is used to fabricate the archwire with the vertical and horizontal loops.

**Miniscrews:** Miniscrews are relatively simple and easy to insert, less traumatic, stable for the optimal force, and make it possible to apply a force immediately after insertion\(^{(24)}\). Surgical intervention is the first treatment objective for open bite correction if the periodontal condition is unsuitable for molar intrusion \(^{(25)}\). Since the tendency for relapse is higher in adults, it is important to choose both a stable and predictable treatment method. This can be accomplished using temporary anchorage devices such as osseointegrated implants,\(^{(26)}\) miniplates,\(^{(27)}\) onplants, and miniscrews. Midpalatal miniscrew implants have been recently used for molar intrusion. Intrusion provides a more stable treatment result than extrusion

**Active Vertical Corrector:** The Active Vertical Corrector (AVC) works as an energized bite block. By the use of effective posterior intrusion of teeth, the mandible is allowed to rotate in upward and forward directions. The uniqueness of this appliance is that it allows the clinician to correct anterior open bite problems by actually reducing anterior facial height. The AVC force system generated by repelling magnets is considered superior to a static bite block appliance energized only by the intermittent force from the muscles of mastication

**Deep Overbite**

**The Morphologic Characteristics of the Deep Overbite**

**Dentoalveolar Deep Overbite:** The deep overbite caused by the infraocclusion of molars has the following symptoms:

- The molars are partially erupted.
- The interocclusal space is large.
- A lateral tongue posture and thrust are present.
- The distances between the maxillary and mandibular basal planes and occlusal plane are short.
The deep overbite caused by overeruption of the incisors has the following characteristics:

- The incisal margins of the incisors extend beyond the functional occlusal plane.
- The molars are fully erupted.
- The curve of Spee (compensating curve) is excessive.
- The interocclusal space is small.

**Skeletal Deep Overbite**

**Morphologic Characteristics**

- The posterior border of the ramus is nearly vertical.
- At the dentition level, the upper and lower incisors have their long axes nearly parallel and are vertically extruded, while the molars are intruded.
- The dentition exhibits a tendency towards small teeth.
- At the soft tissue level, the lips are thin with an excess of lip height relative to face height. This gives a curled appearance to the lips. There is a deep furrow or sulcus between the prominent chin and the lower lip.

**Cephalometric Criteria**

- The anterior facial height is short, particularly the lower facial third, whereas the posterior facial height is long.
- Fred F. Schudy, states that the relative anterior dental height (ANS to MN) determines in large measure the character of the act of swallowing.
- The horizontal cephalometric planes are approximately parallel to each other.
- The interocclusal clearance is usually small.

Sassouni enumerated the factors in the development of a deep bite:

- Lack of vertical growth between the cranial base and the maxillary posterior teeth.
- Excess of growth of the ramus and posterior cranial base.
- Mandible rotates in a closing direction.
- Pharyngeal space is large.
- Tongue is set posteriorly.

**Treatment Planning**

**Treatment of Deep Overbite During Growth**

- functional appliance therapy activator
- bionator
- twin block-vertical activation

**Treatment of the Dentoalveolar Deep Overbite:**

During eruption of the posterior teeth, the therapy can be performed with an activator to guide the eruption. In cases of extreme lateral tongue thrust, a palatal plate with a lateral tongue crib can be used to discourage the habit. If an additional cheek-sucking habit is evident, it can be eliminated with a modified labial bow.

**Treatment of Skeletal Deep Overbite:**

The treatment of a skeletal deep overbite requires consideration of the sagittal dimension.

Most skeletal deep overbites are combined with Class II sagittal intercuspation. The treatment of it can be handled with several therapeutic approaches.

- Growth inhibition of the upper jaw and growth promotion in the lower jaw combined with dentoalveolar changes
- headgear in combination with an activator.

**Treatment of Deep Overbite in Permanent Dentition**

**Intrusion Arches**

- K-SIR (Kalra-Simultaneous intrusion and retraction)
- Connecticut intrusion arch
- 3-piece intrusion arch for simultaneous intrusion and retraction
- Intrusion retraction mechanics
- Burstone’s segmented arch.
- Mushroom Loop Archwire.

**Conclusion**

The problem of a vertical discrepancy is multifactorial. Diagnosis is the key to the correct management of the dental and skeletal structures. Pattern, variability and timing of growth is an important concept. In diagnosing a malocclusion in the vertical dimension,
it is important not to concentrate on one aspect of the patient’s overall condition to an extent that other significant features may be overlooked. Orthodontic malocclusions are almost always the culmination of a developmental process and not of a pathologic process. Classification has traditionally been an important tool in the diagnosis-treatment planning procedure. Early orthodontic treatment remains the ‘gold standard’ for contemporary care.

Magnets and Orthodontics—A Review

Jeenu Raj¹, Kishore Kumar S²

¹Post Graduate Student, ²Professor, Sree Balaji Dental College and Hospital, Chennai

ABSTRACT

The last few decades visualized magnets being used in orthodontics and dentofacial orthopaedics and attempts have been made to evaluate the biological implications of magnets and magnetic fields during clinical application. This article gives an overview about magnets in general and its possible applications in orthodontics.

Keywords: Applications, magnets

Introduction

A new treatment modality is trying to emerge proving to overcome the reservation and criticism. The practical difficulties associated with the old technique paves way to promulgate a new technique. Before practicing any new technique, a thorough knowledge about it is mandatory.

History

In ancient time, a particular kind of iron called as magnetite was discovered to have the property of attracting unmagnetized iron. It got named after the town of Magnesia from where it was discovered.

The magnets proved to show no adverse bio-effects on human environment. These reports gave entry to magnets in the field of medicine and dentistry and now in orthodontics also. In dentistry, magnets were used first in 1953 as implants for denture retention by Behrman and Egan.¹

In orthodontics, elastics, springs, and screws have been the conventional source of force, with drawbacks like lack of patient’s co-operation, force degradation and irregular activation intervals. Blechman and Smiley used magnets first in orthodontics ² proving magnets to have sufficient duration and intensity. They are operator controlled and controls all three planes with no patient discomfort. Rare earth magnets like samarium cobalt, introduced by Becker in 1970 eventually replaced previously used magnetic alloys like Al–Ni–Co, ferrite and platinum–cobalt magnets which were bigger in size, expensive with risk of demagnetization.

Types of Magnetic Material

Ferrite Magnet Ferrite of barium and strontium are highly resistant to demagnetization and available in both isotropic and anisotropic form. They are not used in orthodontics.

Aluminum–Nickel–Cobalt Magnets They have high field strength at a reasonable cost and are physically strong with density of 7.3 g/cm³. They are available in both isotropic and anisotropic forms. But the risks were demagnetization and large size.

Rare Earth Magnets

More recently Samarium–Cobalt (SmCo) and Neodymium–Iron–Boron (NdFeB) magnets are available. These rare earth magnets are 20-times stronger and smaller than the previous magnets.

Rare earth metals when incorporated, increases their ability to be magnetized, to get coercivity property and increases Curie temperature. The rare earth magnets produce high force relative to their size due to the

DOI Number: 10.37506/v10/i12/2019/ijphrd/192382
property of magnatocrystalline anisotropy. They also give maximal force at short distance when compared to elastics.

**Samarium–Cobalt Magnet:** It is a powdered, metallurgically processed, inter-metallic alloy of Cobalt and rare earth metals. It is available in two forms, SmCo₅ and Sm₂Co.

1. Superior magnetic properties when compared to other rare earth magnets except Nd–Fe–B magnets.
2. Low demagnetization making it ideal and small for orthodontic use.
3. High resistance to demagnetization with time.
4. High Curie point of 680°C allowing heat sterilization and manipulation with heat up to 200°C without demagnetization.
5. High corrosion resistance since they are parylene coated
6. They are brittle but stronger than NdFeB magnets.

**Neodymium–Iron–Boron Magnet:** The most recently developed alloy with highest magnetic energy per unit volume. It has both isotropic and anisotropic form. When compared to SmCo magnets, they are less brittle and are 240-times more susceptible to corrosion. They are of three types.

1. Neo 1i
2. Neo 3i
3. Neo 5i

**Magnetic Properties**

**Magnetic Field:** The space around a magnet where its influence is felt is known as magnetic field. The poles of a bar magnet experience forces of attraction or repulsion in any magnetic field. Like poles repel and unlike poles attract.

**Hard Magnet:** Magnet that is resistant to demagnetization in the presence of higher magnetic field at higher temperatures and lesser size of 1 mm or less.

**Soft Magnet:** Magnets that become demagnetized in the presence of higher magnetic field at higher temperature and lesser size of 1 mm or less.

**Flux Density (B):** It is the magnetic field strength on the pole face of a magnet which depends on the material and shape. It is measured by Hall Probe. The units of flux density are Gauss (G), Tesla (T) and Millitesla (mT).

**Coercive Force:** It is also known as field intensity and denoted as Hc. It is the strength of the demagnetizing field where flux density is zero. The unit is Oersted.

**Coercivity:** It is the strength of the external field to demagnetize the material. A high coercivity is needed to prevent the magnetization of permanent magnets when they encounter fields produced by other sources.

**Coulomb’s Law:** This law states that the force between two magnetic poles is proportional to their magnitudes and inversely proportional to the square of the distance between them.

**Curie Point:** Rare earth magnets tend to lose their magnetism at room temperature. Pierre Curie (1859–1906) observed that magnets tend to lose their properties if subjected to a specific temperature that causes their domain to return to random distribution. This point of temperature is called Curie point. In orthodontics, this has been overcome by combining magnets with other elements making it effective appliances that can be heat sterilized.

**Three Dimensional Centripetal Orientation of Attractive Magnetic Force:** When two magnets are displaced in all three planes, they attract to a complete overlap. Centripetal attraction in all three spatial dimensions gives the operator complete tooth control on precise engagement.

**No Interruption of Magnetic Force Lines by Intermediate Media:** Any media interposed between two magnets cannot stop the passage of magnetic force lines. Intra-oral magnets remain attracted to each other even if soft or hard tissues get in between them.

**No Friction in Attractive Force Configuration:** Attracting magnets are useful in controlling the three spatial dimension. This feature is called centripetal orientation. When an attractive force configuration is used, frictional forces are excluded. But repulsive forces may induce friction in the appliance and demands an increase in force threshold.
Biologic Concept of Magnetic Force and Histological Changes

- Magnetic forces inflict a minimal stress to a point
- No subcutaneous changes as inflammation occurs under magnets.
- Obvious inhibitory effect on the bone lining osteoblasts which by feed back mechanism promotes osteoclasts differentiation.
- Magnets by making the erythrocytes thinner and longer, enables them to pass through the compressed capillaries in the PDL during orthodontic loading. Thus the chances of necrosis is reduced.
- The dental pulp or gingival tissue remains unaffected on exposure to magnetic field.
- Increased proliferation and systemic activity in fibroblasts in the presence of static magnetic field have been reported by McDonald in 1993 and also a doubling of alkaline phosphatase in osteoblast like cells were noted.

Magnetic Force in Orthodontics: Magnetic force is applied in orthodontics for

1. Relocating impacted teeth.
2. Arch expansion.
3. Distalization/mesialization of teeth.
4. Intrusion of posterior teeth in open bite cases.
5. Class II correction with functional appliance.
7. Closure of midline diastema.
8. Uprighting and derotation of teeth.
9. Retainers.
10. Magnetic brackets.
11. PUMA—hemi facial microsomia.
12. Class II correction with magnetic twin block (Clark). Non-extraction and extraction cases.
13. Non-extraction and extraction cases.
15. Extrusion of fractured teeth.
16. Fixed magnetic appliance.

Magnetic Activator Device (MAD): Used for the correction of

1. Mandibular deviations (MAD I).
2. Class II malocclusion (MAD II).
3. Class III malocclusion (MAD III).
4. Skeletal open bite (MAD IV).

The SmCo magnets when used in attractive or repelling mode achieves orthodontic and orthopedic correction. In MAD, attracting magnets are used on a two piece activator which allows freedom for mandibular movement. In Class II malocclusions with open bite, it is combined with posterior repelling magnets on the maxillary plate for arch expansion which is called magnetic expansion device (MED). MAD IV for skeletal open bite uses a combination of posterior repelling magnets and anterior attracting magnets. (Figure 1)

Figure 1: Magnetic activator device

Active Vertical Corrector: An adaptation of the present day bite block therapy introduced in 1986 by Dr. Eugene L. Dellinger. It is a simple removable appliance with posterior occlusal bite blocks containing repelling magnets for posterior teeth intrusion, rotating the mandible upward and forward thereby treating skeletal open bite.

Growing subjects show more skeletal changes whereas adults show more dental changes. (Figure 2)
**Fixed Magnetic Appliance:** This appliance consists of upper and lower acrylic splints with SmCo magnets placed in repelling mode. The acrylic blocks are bonded and extended along the posterior segment, with a wire continuing from these splints to the incisors, thus transmitting the repelling force to the entire arch (Figure 3).

![Figure 3: Fixed Magnetic Appliance](image)

**Magnetic Twin Block:** Dr. William J. Clark has modified twin block by using SmCo and neodymium-boron as attracting magnets to occlusal inclined planes to maximize the orthopedic response to treatment.

**Attracting Magnets:** built into the initial construction bite pulls the appliances together and encourages the patient to occlude actively and consistently in a forward position.

**Repelling Magnets:** built into the occlusal inclined planes apply additional stimulus to forward posture as the patient closes into occlusion. But the amount of activation is not clear and reactivation of the inclined planes would deactivate the magnets.

**Indications:**

1. Patients with weak musculature who fail to respond to functional therapy.
2. Where speed of treatment is an important consideration.
3. To correct unilateral mandibular displacement in growth.

But if the attractive force is too strong, the appliance may get displaced or acts as a monoblock, loosing the advantage of twin block flexibility (Figure 4).

![Figure 4 (A, B) Magnetic Twin Block](image)

**Repelling Magnets:** Gianelly et al and TakamiItoh et al used repelling magnets for distalizing molars.

A modified Nance appliance, fixed to the maxillary first premolars with a wire extending from the first premolars to the palatogingival surfaces of the incisors is soldered to the framework of the appliance. An acrylic button contacts the incisors. An auxiliary wire, with a loop at its end, is soldered to the labial surfaces of the first premolar bands so that both approximate the mesial surfaces of the first molar bands. Now the magnets could only be separated if the molars moved distally or the incisors moved mesially.

The magnets exert a force of 200–225 g, but drops substantially as space opens. When 1 mm of space opens, the force reduces to 75 g. So retying the ligature once a week is mandatory to ensure at least 75 g of force against the molars. The molars distalize about 3 mm in 7 weeks for patients without second molars and 0.75–1 mm per month for patients with second molars.

Blechman and Alexander introduced miniaturized magnets for distalizing molars. They found that the light force generated by these magnets, is adequate for a rapid and translatory molar distalization (Figure 5).
Magnetic Brackets: It consists of a SmCo magnet with an edgewise bracket on one surface to receive arch wires and a mesh on the other surface that facilitates direct bonding to teeth. They deliver 250 g of force.

Though shorter treatment time and good biocompatibility, it involves complex of laboratory preparations. Kawata developed a modified version with a slot in the magnets, allowing simultaneous edgewise arch wire mechanics with an attractive magnetic force system.

Propellant Unilateral Magnetic Appliance (PUMA): This was introduced for stimulating an autogenous costochondral graft in hemifacial microsomia consisting of SmCo magnets embedded in lower acrylic bite blocks in the repelling mode.

Magnetic Appliance for Treating Snoring Patients with and without Obstructive Sleep Apnea Syndrome: Mats Bernhold and Bondemark designed this appliance in 1998. During sleep, when the masticatory muscles are relaxed, the mandible moves backward and closes the upper airway space. So two intra-oral occlusal splints, maxillary and mandibular, each with four parylene coated NdFeB magnets are used. This appliance demands full tooth coverage of splints to prevent undesired tooth movement.

Rare Earth Magnets and Impaction: Rare earth magnets are used for erupting impacted teeth. A magnetic bracket is bonded to an impacted tooth and intraoral magnet linked to a Hawley type retainer is used to guide the erupting tooth

Functional Orthopedic Magnetic Appliances (FOMA): It is used to correct to Class II (FOMA II) and Class III malocclusion (FOMA III). FOMA II consists of an upper magnet placed anterior to a lower magnet in a non-displayed jaw relationship. Both magnets are incorporated in the upper and lower plates. The FOMA III consists of an upper and lower plates with magnets incorporated in each plate and upper magnet is retracted periodically.

Magnets for Midline Diastema: Rectangular attractive magnets (SmCo) of 5 mm × 3 mm × 1 mm delivers 117.5 g of force on each maxillary central incisor to close midline diastema.

Extrusion of Fractured Teeth: The magnetic system with one or two cylindrical parylene or SS coated NdFeB magnets is placed in the coronal part of the tooth remnant with a thin layer of composite. Axially over the root, another larger parylene coated magnet of 5 mm × 5 mm × 2 mm is embedded in acrylic with a maximum gap of 2 mm. After adequate extrusion, the tooth can be restored.

Magnets in Extraction Cases: The magnetic assembly attached to the upper sectional arch wire is free for sliding through the occlusal upper molar tube and is ligated to the mesial aspect of the upper canine bracket. The lower magnet is attached to a similar sectional arch passing through the occlusal tube of the lower molar band. The upper and lower magnetic pole in attraction must face each other and generates force necessary to move the upper canine distally along the base arch wire. The upper canine retraction can be enhanced if needed by adding a third magnet to the lower sectional arch and positioned mesially to repel the upper magnet. The lower arch anchorage can be protected by a heavy arch wire.

Non-extraction Case: For this, the upper magnet is attached mesial to the upper molar tube and the lower magnet mesial to the upper magnet with 0 mm gap, if maximum force is required. When both magnets are positioned the line of their pole faces is approximately 70° from the horizontal plane to reduce interference from mandibular movement.

Magnetic Retainer: The same magnets used for closing the midline diastema can be refixed on the palatal aspect of maxillary incisors after recycling.

Magnets in Posterior Single Tooth Molar Cross Bite: It is essentially a single tooth intrusion or extrusion system which consists of:
1. **An adjustable magnetic module** attached on the upper molar.

2. **Magnetic module** attached on the lower molar.

3. **A bond on segmental arch wire**

4. **A set-screw wrench.** For adjusting the locking system in the adjustable magnetic module in a repulsion mode (intrusion) onto the tooth, with a buccal offset in the arch wire, allowing cross bite correction to occur simultaneously with intrusion.

**Functional Magnetic Appliances:** Rare earth magnets are buried in acrylic at the midline lingually. A maxillary guiding prong that slides on the lingual acrylic of the lower appliance during closure pushes the mandible forward into the desired protrusive relationships as the attractive magnets contact. This unloads the condyle like other functional appliances except that the functional stimulus is more.

**Recycling:** Recycling does not affect the biocompatibility and force stability of the magnets even though the process involves autoclaving. It is proven that cytotoxicity is high for uncoated SmCo5 magnets and low for NdFeB magnets. But magnets should not be recycled for ethical reasons and they also demagnetize during the process.

**Conclusion**

Though magnets have the potential to pave its way into orthodontics entitled “magnetic orthodontics”, further long term studies are required to probe into the biological effects of magnets.

Mandibular Symphyseal Distraction Osteogenesis—A Review

R. Padmavati¹, S. Kishore Kumar²

¹Professor, ²Post Graduate, Department of Orthodontics, Sree Balaji Dental College and Hospital, BIHER

ABSTRACT

Mandibular symphyseal distraction osteogenesis (MSDO) is nothing but regular distraction osteogenesis (DO) performed at the symphysis wherein, the new bone formation occurs between bone segments that are gradually separated by incremental traction. Treatment planning decisions in the transverse dimension are based on the mandibular arch width and form. Mandibular symphyseal distraction osteogenesis supplements orthodontic treatment to resolve mandibular anterior width deficiencies or dental crowding. This article focuses on indications, orthodontic preparation, surgical procedures, complications, long term effects and stability of mandibular symphyseal distraction osteogenesis.

Keywords: Mandible, Osteogenesis, Osteotomy.

Introduction

Transverse mandibular symphyseal deficiency is an important cause of mandibular incisor crowding. Transverse mandibular deficiencies in growing patients are commonly corrected with orthodontic expansion, using lip bumpers¹⁻³, Schwarz devices⁴, or functional devices⁵,⁶. These appliances show stable results for younger patients, particularly patients who presented with lingually tipped teeth. Whereas anterior expansion in adult patients is unstable and tends to relapse toward the original dimension. In such cases, mid symphyseal distraction has been suggested for correction of transverse mandibular deficiencies. However there is risk of relapse in MSDO when the osteotomised bone segments are improperly fixed. Greater stability could be expected if the expansion is performed at prescribed rate and rhythm, allowing better adaptation of the soft tissues, and allowing bone to grow in the between osteotomised segments⁷

Distraction osteogenesis (DO) originated as a method to repair skeletal deformities and large, non-healing, segmental bone defects resulting from injuries suffered by Russian soldiers during World War II. The method, which increases the length of bones by causing new bone to form between two surgically separated segments of bone was discovered inadvertently by a nonsurgically trained general practitioner, Gavril Ilizarov, in a small town in Siberia. Subsequently, Professor Ilizarov became a renowned orthopaedic leader due to the revolutionary advancements in bone management arising from DO⁸,⁹.

Symphyseal distraction osteogenesis was pioneered by Guerrero (1990). Tab 1 shows the evolution of distraction osteogenesis

**Rationale for Mandibular Symphyseal Distraction**

**Osteogenesis:** With the advent of symphyseal distraction to increase the transverse width to correct imbrigation of lower anteriors, the other methods of increasing transverse width with lip bumpers, myofunctional appliances, midline osteotomy and bone grafting have become obsolete in clinical practice, so much so that symphyseal distraction has become gold standard for transverse width correction in cases of “v” shaped skeletal arch.

While planning for symphyseal distraction, the antero-posterior position must be considered using model analysis by placing them in the anticipated final occlusion to prevent either over- or under-performing the expansion. Such analysis helps in obtaining a appropriate skeletal change as planned, thereby reducing the need for dental compensations.

In patients with a complete buccal crossbite where the maxillary dentition telescopes over the mandibular dentition, the possible etiologies could be related to a habit, an excessively large maxilla, or a skeletal mandibular transverse deficiency associated with hypoglossiahypodactyilia syndrome. Previously, the only method of correction was a vertical symphyseal osteotomy, rotating the two hemi-mandibles laterally, placing a bone graft, and fixating. In MSDO, bone grafts are not needed and the regenerated bone, once ossified, has the same properties as the innate mandibular bone.

Before planning mandibular symphyseal distraction, it is essential to predict the requirement of maxillary transverse expansion. Such maxillary transverse deficiencies can be corrected with rapid maxillary expansion (in adolescents), SARPE (surgically assisted rapid palatal expansion), MARPE (miniscrew anchored rapid palatal expansion) or a segmental LeFort I osteotomy followed by mandibular symphyseal distraction osteogenesis.

In the maxillary arch, it has been suggested that for every 1.0 mm of rapid maxillary expansion, approximately 0.7 mm of arch length gain can be realized. Ricketts et al. (1982) stated that 1 mm of intermolar expansion increased the perimeter by 0.25 mm, although the method for obtaining this guideline was not revealed. According to 3D simulation (Motoyoshi et al., 2002), a 1 mm increase in arch width results in a 0.37 mm increase in the arch perimeter. When these rules are applied, a 1–1.5 mm increase in the arch perimeter is expected permissible limit. To adequately use the arch length in posterior alignment, the teeth adjacent to the osteotomy must first be moved into the regenerate bone.

An occlusogram analysis is an accurate method for planning symphyseal distraction. Conventionally the mandibular arch has been considered as the template for determining arch width and arch form, whereas in cases where MSDO has been planned the maxillary arch is used as the reference arch to determine the appropriate amount of mandibular expansion. The current maxillary width is drawn on a 1:1 copy of the models. Then, the appropriate amount of buccal overjet is transferred to the mandibular acetatesheet. The amount of symphyseal distraction required is the distance between planned transverse dimension and the current mandibular transverse dimension represents.

The occlusogram analysis allows planning of all tooth movements to be performed on an acetate tracing prior surgical procedure, thereby helping the clinicians to determine whether the movements are too large or impractical beyond biological limits before performing any orthodontic or surgical procedures. Such intricate planning reduces unnecessary and inappropriate treatment.

**Pre Distraction Orthodontic Preparation:** Once a heavy rectangular wire is fixed on the maxillary arch, separators are placed on the mandibular molars and premolars.

3-5 days after the separators placement, the bands are fitted and impressions are taken for band transfer. The Hyrax screw is adapted to the bands, and is soldered as anteriorly and vertical (Fig 2A) as feasible to allow near-normal tongue movement and speech. One or two days before surgery, the appliance is placed on the lower arch.

Obtaining the necessary lower incisor root divergence for safe placement of osteotomy cut is one important factor to be considered to avoid root damage.
Proclination of the mandibular incisors during distraction is a clinical concern. Significant proclination was observed in patients who did not have orthodontic wires placed before the distraction procedure. Proclination was probably due to the distraction pattern of the tooth-borne device, which disproportionately rotated the segments laterally and anteriorly. Del Santo et al 2000 in his study observed that patients who had orthodontic wires in place at the time the postdistraction radiographs were taken showed no changes in incisor inclination, suggesting that orthodontic treatment compensated for the proclination produced by distraction. Therefore it is important to bond all the brackets before surgery.

**Types of the Distractor:** MSDO distracters are classified into three types:

- Bone borne variety (Fig 1)  
- Tooth borne variety (Fig 2)  
- Hybrid variety (Fig 3)  

The interdental osteotomy is done generally between the central incisor roots. Osteotomy cuts given for MSDO varies from that of orthognathic surgery by the fact that excessive care must be taken to preserve as much periosteum, endosteum, periodontium, and bone as possible in the distraction site. If too much tissue is traumatized or removed, a greater void is created and callus formation is slower and less organized.

The location and vector of the distraction force are of great importance because they might influence the shape of the distraction gap, if the force is applied near the center of resistance of the mandible, the distraction will produce pure translation of the segments and the distraction gap will have parallel margins. However, if the force is applied above the center of resistance, rotation of the two segments might be expected, resulting in a disproportionally larger gap in the dentoalveolar area than in the basal area.

Bell et al., 15 however, performed mandibular symphyseal DO in monkeys and showed disproportional movement between the bone segments and dental tipping when using tooth-borne DO devices. Hollis et al16 confirmed adverse dental effects with tooth-bone devices in 4 dogs; the teeth moved approximately twice as much as the bone segments. Del Santo et al17 confirmed that symphyseal distraction, using a tooth-borne device, was disproportional because width increases between the second molars were greater than biantegonion width increase. Bone-borne expansion devices have a greater potential for proportional movement than do tooth-borne appliances. Furthermore, the procedure does not involve tooth movement, and more stable results can be expected. Whereas on the other hand the risk of tissue inflammation or irritation 19 is lower when using toothborne distractors, they are much less expensive than the bone-borne titanium appliances, also the need for second surgery to remove the distractor and bone screw is avoided.

Success of DO lies in the formation of a high quality, highly organized callus. Therefore latency period plays a very critical role. Without allowing time for a callus to form, callus manipulation cannot occur. Without a good callus, the quality of the regenerate bone can be adversely affected, resulting in poor quality bone, fibrous union, nonunion, tooth loss, periodontal defects, and other complications. The latency period is five - seven days. young children require a shorter latency period as healing is accelerated and older patients may require a slightly increased latency period because of a slower rate of healing.

Proper rate, rhythm and distraction vector contributes to the success of MSDO.
The tooth-borne expansion appliance - activated 8 turns at the time of surgery (2 mm) or until there is blanching of the gingival tissue.

- The bone-borne appliance - activated 4 turns at the time of surgery (2 mm).

Distracting too fastly can lead to poor bone quality, poor union, fibrous union, or partial union. Distracting too slowly can lead to premature consolidation and an inability to obtain the planned amount of expansion. Prescribed rate of distraction is 1 mm a day. The rhythm of distraction refers to the number of increments required per day to reach the preplanned distraction. Most of the tooth-born appliances are designed for approximately 0.20–0.25 mm per activation, whereas most bone-borne appliances are set at approximately 0.50 mm per activation. After distraction is completed, the expansion screw must be sealed with flowable composite for the stabilization.

**Postdistraction Orthodontic Movement:** CBCT or Intra oral periapical radiographs to be taken every two weeks after distraction is completed to assess the radiodensity of the distraction cite. Tooth movement should be initiated only after radiographic evidence of consolidation is observed. Occlusal X-rays allow accurate visualization of the teeth, distraction site, and evidence of calcification. Stabilization period of three months is sufficient to observe calcification of the site. The distractor should never be removed until this evidence is observed because the rigidity it provides increases the quality of the callus. To prevent premature mesial migration, arch wire stops, an open coil spring, or an acrylic tooth can be placed in the distraction space. Allowing the teeth to move into the gap too early could lead to periodontal defects, bony defects, and potential loss of one or more teeth. Brackets placed presurgically to diverge roots should be repositioned into ideal positions. Application of light continuous force to the teeth adjacent to the distracted bone segments simultaneously when the acrylic tooth is reduced mesially will aid in space closure. The distractor is usually maintained in position for 45-60 days after surgery. The results of a study done by H. İşeri and S. Malko 2005 suggest that a consolidation period of approximately 3 months seems to be sufficient to prevent post-distraction relapse following mandibular widening. If the bone regeneration is slow in the distracted region, the distraction appliance may be maintained in place for as long as three months. To maintain the expansion obtained from distraction, a passive 0.036-inch stainless steel lingual arch should be placed after removal of distractor.

**Retention and Stability:** Essix type retainers may not be rigid enough to maintain the increased transverse dimension. If patient is more concerned about esthetics, it should only be used during the day and a Hawley retainer used for evening wear. A fixed canine-to-canine wire will adequately maintain the canine width and anterior alignment, but it does not aid in maintaining any posterior expansion. Hawleys retainer with integral lingual support wire is a good form of mandibular retention.

Symphyseal distraction significantly increased intercanine and intermolar arch widths, which led to incisal proclination if presurgical orthodontic manipulation was not performed. This dental tipping often results in long-term incisal instability. Long-term follow-up study 17 of PA radiographs did not show any significant transverse change, neither skeletally (bicondylar, bigonion, and biantegonion widths) nor dentally (intermolar and intercanine).

**TMJ Considerations:** Effect of MSDO on the temporomandibular joint and supporting structures is of great importance for a successful treatment. For every 10 mm of expansion approximately 3 degree of rotation occurs at the condyle.20

Study by Braun et al 21 revealed that the condyles are laterally displaced in a linear fashion in proportion to the amount of targeted symphyseal distraction. It is fortunate that the TMJ appears to accommodate these displacements22 because symptoms were not introduced, or, if present before treatment, symphyseal distraction did not exacerbate them.

**Complications**

Complications after mandibular midline distraction surgery are mostly mild or transient. Following is the list of complications that may occur during or immediately post surgery 23, 24:

- Injury to lower incisor root during surgery
- The risk of tissue inflammation or irritation
- Post surgical swelling
- Loosening of screws
Recession development after mandibular midline distraction
- development of scar strictures
- reossification incase of longer latency period

**Conclusion**

Individualized diagnosis and treatment planning are essential to appropriately address each patient’s needs and goals. Symphyseal distraction osteogenesis offers an alternative treatment method to resolve crowding and transverse mandibular deficiencies with more stable results.

A Review on Soft Tissue Prediction Techniques in Orthodontics and Orthognathic Surgery—Evolution of Three Dimensional Techniques

Kalaiselvi A.1, Kishore Kumar S.2

1Post Graduate Student, 2Vice principal and Professor, Department of Orthodontics and Dentofacial Orthopaedics, Sree Balaji Dental College and Hospital, BIHER, Chennai

ABSTRACT

The criteria for a successful treatment outcome is not only the correction of skeletal and dental abnormalities but also an aesthetic improvement as judged by both patients and practitioners. The objective of treatment simulation is to allow the clinician to visualize and manipulate the soft tissue structures, so to compare different treatment alternatives. The purpose of this study is to provide a overview on how various three dimensional soft tissue prediction techniques evolved and improved through years.

Keywords: Three dimensional techniques, soft tissue, surgical- orthodontic treatment outcome

Introduction

Facial soft tissue (skin, connective tissues, fat and muscles), facial skeleton (bone and cartilage) and dentition square measure the 3 vital tissue teams in odontology and orthognathic surgery, which can be referred to as a triad. This triad plays a decisive role in planning orthodontic therapy and orthognathic surgery. There are five general methods of visualising, planning and predicting surgical-orthodontic treatment outcomes- starting from acetate tracing to 3-D planning.

Treatment planning and the prediction of treatment outcomes in orthognathic surgery have conventionally relied on tracing of cephalometric radiographs manually and the use of hard-to-soft tissue ratios. However, in recent years, three dimensional (3D) computer planning and CAD/CAM has attained popularity as an accurate surgical simulation that is valuable for clinician to patient communication, surgical planning, and the assessment of treatment outcomes. Various commercial programs are available for 3D soft tissue prediction, which varies by the physical model they utilize. Some are based on models that require landmarking and depends on interpolation between points, whereas others use dense volumetric models, including finite element models (FEM), mass tensor models (MTM), or mass spring models (MSM). Technological developments have led to the development of different three-dimensional (3D) technologies such as multi planar CT and tomography scanning, 3D photography modalities and surface scanning. Moss et al (1988) added emphasis to the previous methods of 3D-planning by including laser scanning to model the soft tissue response to hard tissue movements.

Discussion

Uses of Soft tissue prediction: (Taylor 1998)

1. Plan mechanics.
2. Plan type of surgery and nature of osteotomies.
3. A basis for communication
4. A basis for informed consenting.
5. A basis for splint construction.
7. Assess need for extractions.
8. Provides a reasonable prediction of soft tissue changes, that can provide a basis for computer imaging.

Evolution of various soft issue prediction techniques:

1. The first method has been in use for the past 20 years. “Acetate tracings” (Figure 1 & 2) of skeletal structures are manually repositioned over the original cephalometric tracing to simulate the proposed surgical movements.
2. Manipulation of patient photographs called a "photometric plan".

3. Computerised diagnostic and bobbing up with package that created a soft tissue profile ‘line drawing’ as a result of manipulation of digitised structures of lateral cephalometric radiographs.

4. Computerised diagnostic and coming up with software package that “integrates video images” with the patient’s lateral cephalograph to aid in planning and predicting. Video imaging is advantageous over other prediction techniques in 2 ways: 1. The image facilitates communication between clinician and patient. 2. Valuable aid in treatment planning decisions by providing a manipulatable image for the orthodontist and surgeons to decide on the best soft tissue outcome. (Harradine 1985, Sarver 1988, Sinclair 1995).

5. "Three-dimensional" engineering Figure 1(B) for planning and predicting orthodontic and orthognathic surgery outcome. (Moss et al 1988)

---

**Figure 1: Acetate Tracings**

**Figure 2: Three Dimensional Engineering**

2-Dimensional Radiographic Analysis: In order to use a computer programme to plan orthognathic treatment, the radiograph needs to be digitised prior to analysis.

Two methods are described (Travess and Juggins, 2007):

1. **Direct computer digitisation** of the radiograph:
   - The radiograph is placed onto a digitising light box. Anatomical points are entered into computer using a cursor or electronic pen.

2. **Indirect computer digitisation** of the radiograph:
   - Image is captured (scanned image or true digital image) and stored on the computer.
   - Image displayed in orthognathic programme and digitised using a cursor.

Studies have shown that the direct and indirect methods of cephalometric analysis are comparable (Richardson, 1981; Oliver, 1991; Sarver, 1998). There are advantages of using the indirect method:

- Digital storage of radiographs allows easy access when required. Use of magnification, alteration of brightness and contrast allow more detailed visualisation of the image.

**Orthognathic Prediction Software** are programmes available for the analysis and prediction of orthognathic treatment. Few softwares are listed below:

- OPAL image version 2.2
- Dolphin imaging 10
- Dentofacial Planner 8.05
- Quick Ceph Image
- Computer assisted simulation system for Orthognathic surgery (CASSOS)

**Three-dimensional computer technology:** Using 2-D it is not possible to achieve a realistic and acceptable result. From the 1980s, the shortcomings of these techniques induced an increase in the use of three-dimensional(3D) imaging techniques, such as facial surface laser scanning, 3D stereophotogrammetry (3D photography) and (3D) video-imaging to render the facial soft tissue surface. Reconstructions of digital imaging and communications in medicine (DICOM) files from multislice CT (MSCT), cone-beam CT (CBCT) imaging or MRI slices to display the skeletal structures and digital dental models to display the dentition were also investigated.

**3D surface imaging:** Facial scanners provide a complete 3-D topography of the facial structures and surface, analysis of the symmetry and facial proportions. Thus it provides an qualitative and quantitative assessment of the treatment outcome of various esthetic and reconstructive procedures.
Stereophotogrammetry: The various 3-D prediction methods which are mentioned above can analyze facial characteristics in three dimensions whereas stereophotogrammetry is the method of choice in anthropometric research.

Bruke and heard in 1967 introduced the concept of stereophotogrammetry. It is a prediction method that uses means of triangulation and camera pairs in stereo configuration to recover the 3-D distance to features on facial surface. It provides high-resolution representation of the face without direct exposure.

Digitized facial landmarks used in direct and indirect anthropometric measurements: Tr- trichion; G- glabella; N- nasion; Prn- pronasale; C’- columella; Sn- subnasale; Ls- labiale superius; Sl- sublabiale; Pg- pogonion; Me- menton; Ex- exocanthion; En- endocanthion; Os- orbitale superius; Or- orbitale; Ft- fronto temporale; Zy- zygion; Chk- cheek; T- tragion; Pra- preaurale; Sa- superaurale; Pa- postural; Sba- subaurale; Al- alare; Ac- nasal alar crest; Itn- inferior point of the nostril axis; Stn- superior point of the nostril axis; Cph- crista philtri; Ch- cheilion; Go- gionion (Figure 2)

Figure 3: Digitized Facial Landmarks Used in Anthropometric Measurements

Donatsky et al (1997) applied a computerised cephalometric, orthognathic surgical programme (in simulation, treatment planning and postsurgical records, to assess precision and stability of bimaxillary surgery. They concluded that the this programme is useful in orthognathic surgical simulation, planning and prediction, and also in evaluation of surgical precision and stability. The simulated treatment plan can be transferred to model surgery and then on to surgical procedures. The results suggest that this technique yields acceptable postoperative precision and stability.

The limitations of plain film radiographs are well documented and the recent introduction of cone beam computed tomography (CBCT) imaging came into existence enabling three-dimensional (3D) visualization of the bony skeleton and dentition. There are many reported applications for CBCT in the field of orthodontics and maxillofacial surgery, which can allow planning of orthognathic surgery entirely in 3D. A commercially available software package for 3D orthognathic planning (MaxilimH, Medicim NV, Belgium) is independently reviewed by Hashmat Popat and Stephen Richmond in Cardiff University, UK familiarizing the reader with the technique for creating a virtual 3D patient.

Digital three-dimensional image fusion processes for planning and evaluating orthodontics and orthognathic surgery.

This is a new 3-D prediction technique which can capture the complete triad with optimal quality. This technique involves ‘image fusion’ of different imaging techniques to create a 3D virtual head that can display all triad elements. These methods are accurate and reliable tools for documentation, analysis, treatment planning and long term follow up.

Image fusion models. An image fusion model is defined as a composition of at least two different imaging techniques. The principle of image fusion is based on the creation of a single data set that contains all three structures that is the facial soft tissue, the skeleton and the dentition using segmentation by thresholding.

3D data can be fused using three different methods:

1. Point based matching without the use of a reference frame.
2. Point based matching with the use of a reference frame.
3. Surface based matching

Advantages:

1. Multiple simulations of different osteotomies and skeletal movements can be made within the virtual operating room, aiding decision making regarding aesthetic and functional predictions.
2. This fusion model replaces the need for model surgery, since the virtual head can also be used to design a surgical wafer.

3. Post operative evaluation will give feedback on the performed procedure and can be used for teaching purposes.

4. Long term follow up of various orthognathic deformities and procedures

5. Ideally, the data is acquired with an ‘all in one’ imaging technique, which would reduce the differences in facial expression at the moment of acquisition.

Disadvantage:

All currently available fusion models are expensive and need improvements before they meet the demands of improved prediction and simulation.

Knoops et al\textsuperscript{14} compared the prediction accuracy of Dolphin, ProPlan CMF, and a probabilistic finite element method (PFEM). He concluded that Dolphin uses a landmark-based algorithm allowing for patient-specific bone-to-soft tissue ratios, which works well for cephalometric radiographs but has limited three-dimensional accuracy, whilst ProPlan and PFEM provide better three-dimensional predictions with continuous displacements.

Geert Van Hemelen a, Maarten Van Genechten a, Lieven Renier a, Maria Desmedt b, Elric Verbruggen c, Nasser Nadjmi a,\textsuperscript{15} Compared the accuracy of 2-D traditional techniques with 3-D prediction techniques and concluded that the 3D planning approach provides more accurate soft tissue planning. However, the 2D orthognathic planning can be comparable with 3D planning when it comes to hard tissue planning. Possible disadvantages of 3D are the cost of the CBCT scans and software packages, the learning curve, and the greater amount of time required. So 3D planning can only fully replace conventional 2D planning when these issues are dealt with. The accuracy can offer clear guidance to a surgeon during the planning and the interpretation of a 3D surgical procedure

Conclusion

From the literature it can be concluded that the new three dimensional soft tissue prediction techniques are accurate and reliable in predicting the treatment outcome when compared with other conventional techniques, though certain limitations are reported in different studies assessing the validity of different prediction methods. With continued technological advancements we can look forward to more accurate prediction methods that facilitate greater success in orthodontic and orthognathic surgery and greater patient satisfaction.

ABSTRACT

Measuring the three-dimensional force–moment (F/M) systems applied for correcting tooth malposition is highly desirable for accurate spatial control of tooth movement and for reducing traumatic sideeffects such as irreversible root resorption. In this article, we have reviewed the application of smart brackets with CMOS micro-censors on the base of the brackets to quantify these force moment system.

Keywords: Smart bracket · Force · Moment · Measurement · Microsensor · Fixed appliance

Introduction

It is imperative to determine the amplitude of three dimensional force-moment system applied for orthodontic correction to understand the manner of tooth movement and to largely reduce secondary responses¹. When this force-moment system is not taken into consideration, it might lead to many undesirable effects affecting the periodontal structures²³. In contempt of these risks, determining these force moment systems is continuing to pose a practical difficulty.

The three-dimensional force- moment system on individual teeth with an orthodontic multibracket appliance is a complex, statically indeterminate system⁴⁵ (Fig 1)(Proffit, 2000a; Burstone, 2005)

![Fig. 1: Force and moment components in 3 dimensions](image)

**Historical Perspective:** Many apparatus having detachable brackets and extra oral force moment transducer were developed for the measurement of these force moment systems in situ, but they had many constraints like increased chair side time, limited measurement accuracy, increased measurement bias
and the amount of friction between the bracket and the wire was not taken into account.6,7,8

With the development in the field of micromechanical systems, micro electronic chip incorporated with stress sensors encapsulated with the brackets helped in quantifying the external loads.9

In the earlier attempts, the sensors only measured single force systems, later attempts were made to determine all the three dimensional force moment system, i.e, the 6 external forces (force and moment in the x,y,z plane).

The Smart Bracket:

A smart bracket is basically an integration of CMOS (complementary metal oxide semiconductors) and base of the bracket base. A microelectromechanical system with stress sensors spread out over the chip area was structured. The sensors were placed at the base of the brackets (Fig 2) to accurately determine the amount of force acting. They had an epoxy resin coating both above and below the sensor to protect it from external elements.10 The earlier developed smart bracket model had a base of 8 x 8 mm², and was about 2.5 times greater than that of a standard bracket. But then, the recent smart bracket designs have the same size as that of an conventional bracket.

![Fig. 2: smart bracket with CMOS sensor at the base of the bracket](image)

CMOS Sensors: They are second generation image sensors that convert light to electrons.11,12,13 This sensor comprises of diffused silicon resistors capable of measuring stress in the surface of the sensor exploiting the piezo-resistive effect of silicon.14,15

When tooth movement begins and when force levels are exerted on the tooth, the CMOS sensors detect these force and saves it as an energized data. This can be accessed by inserting the sensor into a computer and interpreting the values.18,19

Mechanical Characterization: For calibration, the smart bracket was exposed to different combinations of force-moment that are similar to therapeutically exerted loads on the teeth.20,21 By this, the interrelations between the stress signals in the sensor chip and the force-moment systems externally applied to the bracket were evaluated.

Limitations:

- The sensor in the bracket that is bonded to the tooth structure can be contaminated due to various factors by saliva, temperature changes in the oral cavity etc.
- Undesirable application of force on the dentition can result in dislodgement of the sensor.

Conclusion

The future application of smart brackets in orthodontic therapy may contribute to minimizing the negative side-effects of tooth movement, in particular root resorption, and to increasing therapeutic efficiency.

A Review on Rapid Maxillary Expansion

S. Vaibava Keerthana¹, Kishore Kumar², V. Thailavathy³

¹Post Graduate, ²Professor, ³Reader, Department of Orthodontics, Sree Balaji Dental College and Hospital, Chennai

ABSTRACT

Rapid maxillary expansion (RME) is an orthopedic procedure that utilizes optimum forces to correct transverse maxillary arch discrepancies. There has been various designs of Rapid Maxillary Expanders that has evolved over time and their usage in various clinical conditions. It has been used not only to correct maxillary constriction but also to create additional space in the dental arches to relieve crowding. The review on the RME renders various evidence-based facts about types, designs and uses of RME appliances and promotes the better understanding of their biomechanical effects and their clinical implications among the orthodontic fraternity.

Keywords: rapid maxillary expansion, mid palatine suture, circummaxillary suture.

Introduction

The type of skeletal expansion where the midpalatine suture is split and the palatal shelves are moved away from each other is referred as the rapid maxillary skeletal expansion. The expansion is caused at the maxillary complex, the palatal vaults, the maxillary teeth and the adjacent periodontal structures. This paper mainly aims at reviewing the various conditions where RME is indicated and about the various designs of RME, the long term stability of the expansion and the recent evolution and paradigm shift in the field of maxillary expansion.

Anatomy: The mean transverse growth of maxilla ranges approximately about 6.5mm between the age 6-17years.

Maxillary bone fuses with the palatine bone and the vomer bone to form complete hard palate and greater part of lateral wall of nasal cavity. The interpalatine suture forms the junction of the premaxillae, maxilla, and the palatine bone. The mid palatine suture is described as an end to end type of suture with its characteristic change in morphology during growth.

Initially, the suture remains as a straight high density suture line that does not have interdigitations, followed by scalloped appearance of high density suture line that are separated only by small low density spaces. Interdigitation increases and fusion occurs in the posterior area first and the ossification progresses from posterior to anterior where resorption of cortical bone occurs with the formation of cancellous bone. This anatomical reason causes the expansion to occur more anteriorly than posteriorly. A significantly greater degree of obliteration was found orally than nasally.

The amount of rapid maxillary expansion depends on the patency of the midpalatine suture. 5% of suture closes by the age of approximately 25 years. Ossification comes very late anterior to incisive foramen – this is important when planning surgical freeing in late instances of RME. The ideal time for proceeding for RME would be CVM category 1 or MP3 F stage. RME is best to carry before CVM 4 or MP3 H stage.

Factors influencing the rapid maxillary expansion: Severe nasal obstruction/stenosis, metabolic and genetic disorders causing premature synostosis and also any systemic disease affecting the suture patency and the flexibility of the craniofacial complex should be treated.
prior to expansion. Intraorally, forces delivered by RME may cause deleterious effects on the periodontium and might lead to traumatic injuries. Choosing the form, rigidity and flexibility of the appliance decides if the expansion occurs only at the inferior free borders of the maxilla or if it reaches to the basal portions. The rate of expansion is maintained around 0.3-0.5mm per day. With increasing age greater rigidity of the bones are seen and the bony movements are restrained. When the maxillary molars are buccally inclined, conventional expansion will tip them further into the buccal musculature and if the mandibular molars are lingually inclined, the buccal movement to upright them will increase the need to widen the upper arch.

**History of Rapid Maxillary Expansion:** In 1860, E.C. Angell successfully split maxilla using a jack screw appliance. He is considered the father of rapid maxillary expansion

FARRAR (1888) and CLARK C. GODARD (1893) discussed the feasibility of lateral expansion with mid palatal suture opening

WRIGHT in 1912 reported a 6.5mm widening of nasal cavity with rapid maxillary expansion.

In late 1940s GRABER advocated RME for the treatment of cleft lip and palate patients. In 1970’s Hass started using RME and he evaluated stability in 1980.

LATHAM (1971) believed that growth at the midpalatine suture ceases at the age of three years

BJORK AND SKIELLER (1974) found that growth at the suture might be occurring as late as 13yrs of age.

PERSSON AND THILANDER (1977) in a study on cadavers found that 5% of the suture was obliterated by age 25years.

EPKER AND WOLFORD (1980) stated that in patients above 16years of age attempts in achieving expansion failed due to fusion of various craniofacial structures.

**Comparison between Slow and Rapid Palatal Expansion**

RME showed significant buccal tipping than SME with increase in the intermolar angle.

Maxilla moved forward, mandible showed backward rotation and, at transversal level both skeletal and dentoalveolar showed significant changes due to Rapid Maxillary Expansion.

SME showed significant dentoalveolar changes. Light forces are applied per activation (2-3 lbs in SME) around 10-20 lbs amount of force is applied in RME. In SME rate of midpalatal suture separation allows a more physiologically tolerable and adaptive response and long term stability is proven to be more in SME

**Contraindications of RME:** Patients with anterior open bites, high mandibular plane, poor periodontal health, patients where suture ossification is complete, Single tooth crossbites, Bone loss on buccal aspect of the teeth, convex profiles, adults with severe skeletal discrepancies.

**Clinical Effects and Indications of RME:** Patients with unilateral or bilateral posterior crossbites involving several teeth, patients with class II division 1 malocclusion or patients with class III malocclusion are indicated for RME therapy. Reichenbach and Taatz stated the foot (mandible) is unable to be moved forward in the shoe (maxilla) due to transverse constriction. The wider shoe (maxilla) will allow the foot to assume its normal relationship.

RME helps in interceptive treatment of palatally impacted canines and provides adequate space for canines to erupt by relieving crowding. In class III growing patients, RME with maxillary protraction appliances, Circummaxillary sutures disarticulates with an element of anterior displacement of the maxilla as a result of the pivoting effect of the pterygoid plates during palatal separation, as well as correcting the associated crossbite. Improvement of hearing in patients who suffer from conductive hearing loss as a result of Eustachian tube stenosis or middle ear problems. The recovery in hearing occurs due to functional normalization of the pharyngeal ostia of the Eustachian tube, secondary to the orthopaedic effects of the RME but long term improvement in hearing remains questionable.

Nocturnal Enuresis can also be controlled by relieving mouth breathing issues. Primary headache symptoms disappeared in 32 patients and reduced in rate and intensity in 9 patients after RME therapy.

**Effects of RME on the Maxillary Complex:** Separation of midpalatal suture, requires 900-4500 grams of force which disarticulates the circummaxillary sutures leading to orthopedic expansion.
The force given by RME appliance compresses the periodontal ligament, bends the alveolar processes and causes dentoalveolar tipping of the molars, and opens the mid-palatal suture.

Bonded hyrax is more preferable in vertical growers. Maxilla gets rotated in both sagittal and frontal planes. Maximum anchorage of the expansion device, using the tissue-borne acrylic appliance, seems preferable in order to minimize the incidence of buccal surface root resorption.15

RME caused increase in nasal cavity width by laterally displacing the wall of the nasal cavity

The maximum von Mises stresses were found along the frontomaxillary, nasomaxillary, and frontonasal sutures, followed by the zygomaticotemporal and sphenozygomatic sutures.16

The transient polymorph response was noted in the first 12 hours followed by an influx of macrophages and fibroblasts into the defect occurred by 24 hours. The margins of the suture underwent bone formation in the following 3-4 days. With the cessation of the expansion force (2 to 3 weeks), remodeling of both the bone and the suture occurred by the osteocytic and fibrocytic cell series until normal sutural dimensions were achieved. The mineral content within the suture rose rapidly during the first month after the completion of suture opening but returned to its initial level within three months. RME is clinically indicated by opening of a diastema between the maxillary central incisors.18 The gap created between the central incisors was about one and half as great as the distance the screw had been opened. The entire cycle was completed in four to six months time even with incisors spaced as much as 8mm after appliance manipulation.18

A 5.1% percent increase in nasal volume has been reported after RME therapy by Deeb W in Pubmed.18

RME might cause about 4mm of expansion in the intercanine width of the lower anteriors and about 6mm in the molars

Retention and Relapse of RME: Transpalatal arch or an acrylic plate may be used as a retainer to maintain the transverse dimensions and extractions should be planned after expansion. The causes of Relapse: High stress accumulated between the articulations of the craniofacial complex. Tension produced in the palatal mucosa, Imbalance between the buccal and lingual pressures. Fixed retainer placement immediately after expansion, followed by intermittent removable appliance is recommended20

Various Designs of RME7: Almuzian et al., explained the various designs of RME. Haas design allows the appliance to be tooth tissue borne with more parallel expansion forces on the alveolus and has the potential for causing palatal tissue irritation. Isaacson and Ingram, reported that single activations of the jackscrew (0.2mm) produce forces ranging from 3 to 10 pounds and that multiple activations can produce forces up to 20 pounds. The Derichsweiler appliance is similar to the Haas design except for the absence of buccal connectors. The Isaacson design, known as Minne-Expander, is similar to the Hyrax expander with the exception that the expansion screw is replaced with a coil spring. Its main disadvantage is continuous expansion force due to latent kinetic energy accumulated.

Haas regimen: Two turns per day, until desired expansion

Timms regimen Adolescents: Two turns/day until desired expansion

Adults: Four quarter turns/day until desired expansion

Isaacson regimen: Two turns/day for first 4–5 days followed by one turn/day

Hybrid regimen: Combination of two or more of the above

Hybrid appliance is bonded by an occlusal cap to abutment teeth and anchored by palatal temporary anchorage devices (TADs) to reduce anchor teeth tipping while maximizing the orthopaedic outcomes. It acts as both bone-borne and tooth-borne appliance.

Fan shaped expander is used in sectional expansion of maxillary anteriors. As stated by CenkDoruk, the upper incisors were tipped palatally in the RME group, but they were tipped labially in the fan-type RME group. Sadeddin found greater expansion in the intercanine
width than in the intermolar width. The fan-type RME avoided tipping posterior teeth. The ratio between the intercanine and intermolar width expansion was nearly 4:1 in the fan-type RME and 0.75:1 in Hyrax.

Sarpe\textsuperscript{22}: In skeletally matured patients, transverse hypoplasia can be corrected by means of a surgically assisted rapid maxillary expansion.\textsuperscript{22} The procedure causes a substantial enlargement of the maxillary apical base and of the palatal vault, providing space for the tongue for correct swallowing and thus preventing relapse. A significant improvement in nasal breathing is found due to the enlargement of nasal valves and increase in nasal volume.\textsuperscript{22} On following distraction osteogenesis, one has to look for optimal equilibrium between maximal mobility of the maxilla and minimally invasive surgery to avoid complications.\textsuperscript{22}

BERGER et al. reported on two groups of patients using both RME and SARME with a hyrax expander. In the RME group the ages ranged from 6 to 12 years. In the SARME group the ages ranged from 13 to 35 years. They concluded that there is no difference in the stability of SARME and RME. Relapse was mentioned without the amount being quantified.

MARPE\textsuperscript{23,24}: Rapid palatal expansion might be recommended for patients at the final pubertal growth stage, and also adult patients with maxillary constriction. It represents a treatment solution that can potentially avoid surgical intervention. When performed in association with rapid palatal expanders, it might enhance the skeletal effects of the latter. Of the various designs of expansion appliances, MARPE (miniscrew-assisted rapid palatal expander) has been modified for better clinical outcomes. MARPE prevents the rotation of the maxillary complex hence produces favourable results in hyperdivergent patients. It represents a treatment solution that can potentially avoid surgical intervention. Of the various designs of expansion appliances, MARPE (miniscrew-assisted rapid palatal expander) has been modified to allow its operational advantages and outcomes to become familiar in clinical practice.\textsuperscript{24}

Recent Trends–Design of Automated Maxillary Expansion Appliances: Various appliance designs available commercially vary from simple tooth tipping devices to rigid orthopedic expanders. Manual adjustment and activation of the screw is one of the major disadvantage. Automated RME appliances overcome this defect as this device serves as a combination of butterfly expander, microgear, micromotor and microcontroller to produce light and continuous pressure on the Midpalatal suture. Self-activation is possible by micromotor under the control of microcontroller. Patient errors such as missed or reversed screw turns are greatly minimized.\textsuperscript{25}

In First phase, tiny hole section of the expander is replaced with microgear followed by mechanical modification of the butterfly expander in phase II. The purpose of this micro gear is to interface with micro motor, and when the micro motor spins it will turn this micro gear to a desired position. The third phase is microcontroller system design. Fourth phase is system integration. In fifth phase, testing and preliminary clinical trial of the new automated RME appliance will be done. At present the construction of the appliance is in phase 4. From this test, more modification can be made, if needed, to make the appliance perform as required.\textsuperscript{25}

Conclusion

The review enables us to understand on the basic biological and mechanical principles involved in Rapid maxillary expansion. Thorough understanding of the design structure enables us in effective clinical applications. The literature review takes us through the evolution of the appliances and the paradigm shift that has took place in the field of maxillary expansion.

Temporary Anchorage Devices—A Review

Jeenu Raj1, Kishore Kumar S.2
1Post Graduate Student, 2Professor, Department of Orthodontics, Sree Balaji Dental College and Hospital, Chennai

ABSTRACT
In orthodontics, anchorage has been a matter of concern for many years. In addition, the greater number of mutilated cases, uncooperative patients have all added to the growing need for skeletal anchorage. Anchorage Devices brought about a revolutionary change to obtain absolute anchorage without patient compliance. Anchorage promises to serve as controllable and efficient anchors for any type of tooth movements the orthodontist would want to make. The successful use of implants has widened the horizons in orthodontics and has gained much popularity in the recent years.

Keywords: Mini implants, Skeletal anchorage, Osseointegration

Introduction
Anchorage is a matter of great importance in orthodontics. Many techniques to control anchorage like extraoral anchorage, use of opposing anchors, increasing no of anchorage units, relying mainly on patient compliance have been used. Temporary Anchorage Devices (TADs) brought about a revolutionary change to obtain absolute anchorage without patient compliance. Thus, TADs promises to serve as controllable and efficient anchors for any type of tooth movements the orthodontist would want to make.

Evolution of Skeletal Anchorage: It was in AD 600 in the Mayan population that implants were first used. In 1809, Maggiolo inserted gold roots to support teeth. In 1891, Hartman, proposed that dentures be fixed to the jaws using metal screws. In 1945 Gainsforth and Higley published the concept of using implants to enhance orthodontic anchorage by using vitallium screws for canine retraction in dogs.

In the 1960s, P. I. Brånemark, a Swedish physician and orthopedic surgeon, coined the term osseointegration. The first clinically reported use in humans was done by Creekmore and Eklund in 1983. In 1985, Jenner and Fitzpatrick described mini plates. In 1995, Block and Hoffman came up with osplants for orthodontic anchorage. However, mini-implants seldom made its way until in 1997 when Kanomi described mini screws specifically made for orthodontic use.

Classification of TADs
1. According to site
   - Subperiosteal
   - Endosseous
   - Transosseous
2. According to the biological behavior
   - Osseointegrated
   - Non osseointegrated
3. According to insertion technique
   - Self -tapping
   - Self-drilling
4. According to surface characteristics
   (a) Threaded - Non-threaded
   (b) Porous - Non-porous
5. According to implant material
   - Bioactive

DOI Number: 10.37506/v10/i12/2019/ijphrd/192387
6. According to implant degradation
   - Biodegradable (Polylactide, polyglycolide)
   - Non biodegradable (Titanium)

Primary Versus Secondary Stability: Immediately after placing implants, their retention is entirely mechanical, primarily due to the characteristics and amount of the bone contacting the implant especially the cortical bone. This type of mechanical retention is called primary stability. For orthodontists, this is an advantage as it allows the implant to be immediately loaded, which forms the key for any implant procedure.

Following the placement of an endosseous implant, primary mechanical stability is gradually replaced by biologic secondary stability as the osteoclasts remove old, damaged bone and osteoblasts form new bone. This second phase of increased stability is referred to as secondary stability. It happens due to the osseointegration around the implant. The stability observed clinically is composed of both primary and secondary stability.

The factors responsible for achieving the primary stability are - Implant diameter, implant length, number of flutes and design of threads, cortical bone thickness, bone density, placement technique and location.

After placing the implant the bone regeneration and remodeling contributes to increasing the secondary stability.

Biomaterial Used in Implants: The ideal requirements for implant biomaterial are:

**Biological properties**
- Should provide osseointegration.
- Should not be harmful to hard and soft tissue.
- Should not contain the toxic substances.
- Should be free of a potentially sensitizing agent that can cause an allergic reaction.
- Should not be carcinogenic.
- Should be tasteless and odorless.

**Physical properties**
- Should be stable dimensionally.
- Should be of adequate strength and resilience
- Should resist biting or chewing.

The osseointegrated dental implants are composed of 99% titanium. The medical grade titanium used for general body implants can be classified as grade I to IV. Commercially pure titanium (C P Ti) is used widely for implants because of its superior mechanical properties and excellent biocompatibility. The titanium alloy (Ti - 6Al - 4V) (grade V) is the material of choice for orthodontic miniscrews. Its increased modulus of elasticity, six times that of bone enables the use of long and thinner screws without breakage25.

**Mini Implant Screw Design:** Orthodontic mini screw has 4 components Head, Neck, Platform, Body

**Treatment Considerations**

**Age of the patient:** The patient’s age is important as implants are problematic if used in growing children for the following reasons

1. Implants in anterior maxilla is contraindicated due to the possibility of the mid palatal suture being open
2. Resorption in the posterior part of the maxilla due to growth changes could lead to exposure of implant into the sinus
3. With growth, the posterior aspect of mandible continues to undergo growth changes in all the planes of space and definitive implant placement in this area would be difficult to estimate.

**Periodontium**

**Bone support**

Quality – Best is thick, compact, cortical bone with core of dens trabacular cancellous bone

Quantity – 6mm buccolingual width with sufficient tissue volume is the best

**Mucogingival problems:** soft tissue heights of <2mm or > 4mm may present a challenge

**Oral hygiene:** Good oral hygiene before and after implant insertion is needed
Systemic manifestations
1. Diabetics delays healing
2. Habits – smoking is contraindicated due to delayed or inadequate tissue healing and osseointegration

Radiographic analysis: Things to be noted are

Periapical pathology: Radioopaque/radiolucent regions above the inferior alveolar region or below the maxillary sinus

- Adequate space above IAN or below maxillary sinus (2mm from the inferior alveolar canal or below the maxillary sinus)
- Adequate interradicular area
- Bone quality and quantity

Placement of TADs: Implant insertion sites should be based on the amount of attached gingiva and cortical bone, the angulation and size of implant and foremost, the type of tooth movement.

The most often used insertion sites in the maxilla are: Inter radicular alveolar areas: the width of buccal cortical bone on the entire maxillary alveolar process is less (3mm to 4mm), so it requires longer screws.

- Most common sites are – Between second premolar and first permanent molar
- Between the first and second permanent molar
- Between the two central incisors (intrusion)
- Between lateral incisors and canines (intrusion)
- Infrazygomatic region – zygomatic buttress
- Palatal areas: thickness and quality of cortical bone is excellent.
- Maxillary tuberosity region
- Mid palatal area

The CBCT study by Deguchi et al. suggested that the best available site in the posterior maxilla are:

1. mesial or distal to the first molar,
2. angulation of 30° apical to the long axis of the tooth, and
3. length 6 mm of bone contact and diameter 1.3 mm.

Another site is the palate. Benefits include- quality of palatal bone and noninterference with the roots of the teeth.

In Mandible: Inter radicular alveolar area – since the cortical bone on the buccal area in the mandible is very dense, the screws are of smaller size and the possibility of root contact is less.

- Most common sites are – Between second premolar and first permanent molar
- Between first and second permanent molar
- Between two central incisors
- Between mandibular canine and premolar buccally
- Buccal shelf area
- Mandibular symphysis facially
- Extraction spaces.

Sites to be avoided : inferior alveolar nerve, artery, vein, mental foramen, maxillary sinus and nasal cavity

According to Poggio et al., the mesiodistal widths of the interradicular space are more favourable between the mandibular permanent first and second molars at almost every level, starting 2 mm below the alveolar crest. The region in between the mandibular second premolar and first molar is the second best location.

Bittencourt et al. conducted a study to determine the optimal interradicular spaces for miniscrew placement in the mandible and maxilla using CT images at varying heights of 2, 5, 8 and 11 mm from the alveolar crest. According to him the best site in the maxilla, is at a height of 6-9 mm from the crest of second premolar and first molar and in the mandible, at a height of 9-12 mm between the molars.

Ideally, the screws used for orthodontic anchorage must be thin (1.3mm to 1.5mm) and tapered to avoid accidental root contact. Generally, for maxilla, length should be 8mm to 10mm and for mandible 6mm to 8mm.

Screw Angulation: If we see at the area from canine to the second premolar in the maxilla, the cortical bone
buccally is thin. So angulation is required to avoid screw touching the roots. The space between the roots is shaped like an inverted pyramid. The space gradually increases in width to about 5mm as the root tapers apically.

Placing the implant at an angulation of 30 to 40 degree to the long axis of the teeth in the maxilla will keep the screw in the widest space available between the roots apically. In the mandible, the buccal cortex is made of dense bone and curves out more buccally from gingival margins. So a shorter screw than the one used in the maxilla is acceptable. Also the angulation can be reduced to 10 to 20- degree with little risk of touching the roots.

Application of TADs

**Intrusion:** In a study conducted by Mittal et al., the upper incisors were intruded to a mean value of 2.8 mm(mean time period of 3.3 months) without molar extrusion.\(^\text{13}\) According to Yao et al, the mean intrusive movement of the maxillary first molars was 3-4 mm, with a maximum of over 8 mm. \(^\text{14}\)

**Distalization:** A study conducted by Gelgor et al., to investigate the efficiency of intraosseous screws for maxillary molar distalization, the force resulted in 88% molar distalization and 12% reciprocal anchorage loss with no significant vertical changes. The advantages of this treatment approach were elimination of compliance-dependent complex intraoral and extraoral anchorage aids, relatively predictable treatment outcomes and favorable esthetics. \(^\text{15}\)

**Protraction:** Molar protraction is one of the most difficult tooth movements to accomplish, especially in horizontal growth pattern and a deep bite as molar protraction deepens the bite. For protracting molars, microimplants are generally placed between the roots of the mandibular canine and first premolar or first premolar and second premolar. \(^\text{16}\)

**Retraction:** The retractive force will have intrusive, extrusive and intermediate force depending on the vertical position of the implant. \(^\text{18}\) An RCT carried out by Sibaie et al. \(^\text{19}\) concluded that:

1. En-masse retraction with mini-implants eases the biomechanics involved and effectively controls the antero-posterior and vertical movements of anterior and posterior teeth.

2. It avoids the disto-palatal rotations and distal tipping of retracted canines, and eliminates spaces distal to the lateral incisors following canine retraction.

3. Significantly shortens the treatment duration.

**Uprighting:** In moderately tipped second molars, mini screws can be inserted between the second premolar and first molar. An open coil spring can be used initially to unlock the second molar and later the molar uprighting spring is hooked on the mini screw head to deliver a tip back moment. For severely tipped second molars, a button is bonded to the distal surface of second molar and a miniscrew can be placed in the retromolar region. The third molar position should be considered.

**Tranverse correction:** Tausche et al reported an average increase in the transverse dimension at the alveolar bone to be 7.52 mm in the premolar region and 7.17 mm in the molar region, noting a greater skeletal increase with the use of TADs. \(^\text{20}\) However, Lagravere’s study using CBCT found that immediately after completion of appliance activation, the skeletal and dental changes for both treatment groups were similar. \(^\text{21}\)

**Success/Failure of TADs:** Success of TADs is defined as a miniscrew with minimal mobility and inflammation and the ability to obtain full functional correction either through direct or indirect anchorage. \(^\text{22}\)

Failure is defined as severe clinical mobility of the mini implant requiring replacement, spontaneous loss or loss of a mini implant while checking its mobility with the cotton tweezers less than 8 months after placement or before the end of treatment.

**Surgical Procedure**

1. Topical anesthesia

2. Infiltration anesthesia – to determine whether the implant is touching the roots of teeth or not.

3. Aseptic preparation

4. Drilling

5. The final root position of the screw is to be such that the curved funnel at the neck should be cutting against the bone. The head, neck and hox of screw should be away from the soft tissues.
Loading of Implants: There are two types of loading. Delayed loading and immediate loading.

Branemark, believed that all implants should undergo a healing period of 4-6 months before functional loading.

Tarnow et al believed that immediate loading of implants could be carried out if the implants are splinted together which minimizes the micromotion.

Loading also includes the dynamic (variable force levels) and static (constant loads of uniform force) loading. It has been shown that statically loaded and unloaded implants has more cortical lamellar bone at the neck and the apex of implants. The implants which are dynamically loaded displayed bone craters and howships lacunae around the implant neck showed higher levels of bone resorption.

The Timing of Orthodontic Force Application: For orthodontic mini-implants, as primary stability is more important than osseointegration, no significant difference exists between immediate loading and delayed loading within force limits of 200-300 gms if primary stability is achieved. However, it is better to wait for approximately 2-3 weeks to allow soft tissue healing.

Complications of Orthodontic Implants

Complications During Insertion
1. Trauma to the dental root or periodontal ligament
2. Implant slippage
3. Nerve impingement
4. subcutaneous air emphysema
5. Maxillary sinus and nasal perforation
6. Bending, fracture and torsional stress of implants

Complications under Orthodontic Loading
1. Miniscrew migration
2. Soft-Tissue Complications a. Aphthous ulcers b. Soft tissue inflammation, infection, and peri implantitis c. Soft-tissue covering the miniscrew head and auxiliary

Complications During Removal
1. Screw fracture
2. Partial osseointegration

Conclusion

The introduction of mini implants in orthodontics extended the boundaries of an orthodontists limitation, enabling the clinician to offer more predictable results within a short duration, avoiding complex methods and reducing the fear of undesired side effects of conventional techniques. But long-term clinical trials to establish clinical guidelines in using implants for both orthodontic and orthopaedic anchorage is needed in the near future.

Assessment of Facial Asymmetry in Patients Reporting for Orthodontic Treatment

Niha Naveed¹, A. Sumathi Felicita², Kannan Sabapathy³
¹PG Student, Department of Orthodontics and Dentofacial Orthopedics, Sree Balaji Dental College and Hospital, Chennai; ²Associate Professor, Department of Orthodontics and Dentofacial Orthopedics, Saveetha Dental College and Hospital, Chennai; ³Professor and Head, Department of Orthodontics and Dentofacial Orthopedics, Sree Balaji Dental College and Hospital, Chennai

ABSTRACT

Aim and Objective: To evaluate the prevalence of facial symmetry in patients and its correlation with different morphometric and skeletal malocclusions among those reporting for orthodontic treatment.

Background: Facial asymmetries exist in all individuals. It is commonly stated that the right side of the face is not an ideal replica of the left side. Facial asymmetry can be associated with different types of malocclusion and growth patterns. Significant facial asymmetry causes both functional as well as aesthetic problems. Hence this study was undertaken to evaluate the prevalence of asymmetry in patients reporting for orthodontic treatment.

Materials and Method: This study was conducted on 162 patients in the Department of Orthodontics, Saveetha Dental College and Hospitals, Chennai, within the age group of 14 to 26 years. Extra-oral photographs of the frontal view of patients were taken in a standardised manner. The Rule of fifth was modified and a midline was marked through the sagittal section of the face. The parts on the left and right side of the face were measured in pixels and compared. The deviations were noted in each part and statistically analysed to correlate with the type of malocclusion and growth pattern.

Results: All the three parts in the face were not equal on either side. Facial asymmetry was more concentrated on the lateral part when compared to the other two parts. Asymmetry is seen more in patients with class II malocclusion, horizontal and average growth patterns when compared to other malocclusion and growth patterns.

Keywords: Facial asymmetry, malocclusion, growth pattern.

Introduction

Facial asymmetry is defined as the inconsistency in size, shape and arrangement of one side of the face from the opposite side when viewed in relation to the medial sagittal plane. Facial asymmetry is important in aesthetic evaluation of the craniofacial region. Facial asymmetry within limit is recognized as normal, but, severe asymmetry of the facial features is not acceptable.¹

Many human body parts undergo development with bilateral symmetry. This implies that the right and left sides can be divided into identical mirror images. However, due to biological factors inherent to processes of development as well as environmental disturbances, perfect bilateral symmetry is rarely found.²

The face often presents with a mild degree of asymmetry. It derives from the fact that the lower and midface develop from the medial and lateral nasal processes as well as maxillary and mandibular
processes, and despite being intrinsically coordinated, these structures might imply failure of development or maturation of such embryonic processes.3

In the literature, a number of causal factors have been highlighted in the development of facial asymmetries. Asymmetries could have pathological, traumatic, functional or developmental causal factors.4 The etiology of facial asymmetry can be grouped into hereditary factors of prenatal origin and acquired factors of postnatal origin.5 The causes of facial asymmetry can be grouped into three main categories: (I) congenital, of prenatal origin; (II) acquired, resulting from injury or disease; and (III) developmental, arising during development and of unknown etiology.3

As for the classification of craniofacial asymmetries, the structures involved and established that asymmetries could be classified as dental, skeletal, muscular or functional.1

Based on skeletal analysis of deviation of the chin and bilateral difference between mandibular rami length, asymmetry is classified into 4 types. The four types of asymmetry would be as follows: patients with deviation of the chin and bilateral difference between mandibular rami length; patients with bilateral difference between mandibular rami length, only; patients with deviation of the chin, only; and patients with changes in volume on one side of the mandible, only, without deviation of the chin or discrepancy between mandibular rami length.6

Clinical examination allows asymmetry to be assessed in sagittal, coronal and vertical dimensions, and it is the most important diagnostic tool in assessing the condition.3 At smiling, analysis should assess whether dental midlines coincide with facial midline, inclination of the occlusal plane and the amount of bilateral gingival exposure. Intraoral clinical examination should focus on assessing malocclusion, tipping of posterior and anterior teeth, crossbite and the presence of functional deviation of the mandible.3,7

In order to determine patient’s facial midline, specific soft tissues landmarks and structures are used as reference. Thus, sagittal facial midline corresponds to a line perpendicular to the ground, passing through the glabella. Other landmarks of the upper and midface can also be used as reference, since these regions are less likely to present with bilateral asymmetry. Half the interpupillary distance, the subnasal point or the philtrum can also be used as reference to determine the midline in cases with some sort of imbalance near the glabella. Patient’s tip of the nose and chin, however, present with greater variation.6

In order to have asymmetry assessed, patients must be in upright position, looking forward, with teeth in normal occlusion and relaxed lips. Additionally, having patient’s upper and lower views often aids in determining asymmetry. A common procedure is the use of a piece of dental floss stretched from the region of the glabella to the lower chin, passing through the philtrum.9 Another procedure used to assess inclination of the occlusal plane in vertical direction is asking the patient to bite a wooden sheet, so as to determine how the latter relates to the pupillary plane on both sides.

Clinical examination shall be supplemented with other diagnostic tools like casts, photographs, radiographs, tomography and bone scintigraphy. They help to locate and measure precisely the structures involved in asymmetry.9

Different methods of radiographic assessment are available to locate and measure the magnitude of facial asymmetry. Lateral cephalogram provides limited information, as structures on the right and left sides are overlapped.

Thus, at present, the examination most often recommended to overcome the aforementioned disadvantages and allow thorough assessment of craniofacial asymmetries is computed tomography, especially cone-beam computed tomography (CBCT).9

In dentistry, cone beam CT (CBCT) is used widely because of less radiation dose and low cost. Also, because CBCT ensure high-dimensional accuracy in measurement of the facial structures, CBCT is an excellent method for evaluation of facial asymmetry.10 Previous 3D studies in patients with mandibular prognathism paid attention to the morphology of the mandible such as ramal height, body length and ramal inclination, and showed a result that mandible is a dominant factor in facial asymmetry.11

In general, skeletal deviation more than 4 mm is mandatory to make asymmetry visible in an individual’s face.5,12,13,14 Whenever the degree of asymmetry is lower, the condition tends to be considered mild and unperceivable. Nevertheless, asymmetry perception or
blinding will also depend on individual characteristics, such as soft tissue thickness in that region. For this reason, other authors consider an asymmetrical face as having bone deviations equal to or greater than 2 mm\(^{15,16,17}\).

The purpose of the present study was to investigate asymmetry in soft tissue by means of rule of five with a modification in standardised frontal photographs.

**Materials and Method**

**Selection of Subject:** The study was performed on 162 subjects reporting to the Department of Orthodontics, Saveetha Dental College and Hospitals, Chennai. The chosen patients were within the age group of 14 to 26 years. All the selected subjects had a normal appearance with no obvious deformities. Subjects with history of orthodontic treatment, congenital abnormalities, trauma, cyst, tumours or any pathological abnormalities and missing molars were excluded. The subjects’ age, malocclusion type and growth pattern were recorded.

**Photographic Technique:** A small rectangular mirror was attached to the top of the camera such that the lower border of the mirror was horizontal. The camera was placed on a standard adjustable tripod stand. The arms and adjustable plates of the tripod stand were set so that the camera was horizontal. In this study, a Sony Alpha SLT-A58 digital camera was used which stores the photographs digitally that can be later transferred to the computer. The camera has a resolution of 20.1 Mega pixels with APS HD CMOS Sensor. The inbuilt motorized zoom lens with a lock-on autofocus range to infinity and auto object framing ensured that the images were of high quality. Frontal view photographs in natural head position (NHP) were taken using the digital camera under standardised conditions:

- **Shutter speed:** 1/40 sec
- **Exposure program:** Normal program
- **F-stop:** f/5.6
- **Aperture value:** f/5.6
- **Max Aperture value:** f/5.6
- **ISO speed ratings:** 3200
- **Focal length:** 50.0 ± 5.0 mm
- **Lens:** DT 18-55mm f3.5-5.6 SAM II
- **Pixel dimension X:** 2352 ± 230
- **Y:** 2780 ± 195
- **Orientation:** Normal
- **Resolution X:** 775 ± 50
- **Y:** 775 ± 50
- **Resolution unit:** Inch
- **Compressed bits per pixel:** 1
- **Colour space:** sRGB

The Camera was placed at a distance of 90 cms in front of the subject. The height of the camera was so adjusted such that the lower border of the mirror attached to the top of the camera coincided with the subjects’ eye level. This ensured that the level of each subject’s eyes was constant in relation to the lens. Earrings and eye glasses were removed and long hairs were tied back. The photographic method is a quantitative method that is not only valid and reproducible but also non-invasive, convenient to use, less technique sensitive, low cost and takes soft tissue morphology into consideration compared to radiographic method.

**Photographic Analysis:** The digital photographs are transferred from the camera to the computer for analysis of facial asymmetry. The following divisions were made on the photographs:

1. Right postaurale- right exocanthion (pa r-ex r),
2. Right exocanthion- Right endocanthion (ex r-en r),
3. Right endocanthion- midline (en r-m),
4. Midline- left endocanthion (m-en l),
5. Left endocanthion- left exocanthion (en l-ex l),
6. Left exocathion- left postaurale (ex l-pa l)

This is a modification of the Rule of Fifths where the middle fifth of the face is divided into two by a midline passing through the sagittal section of the face. Thus the face is divided into median, middle and lateral parts on the right and left side of the midline. This is to note the deviation in the left and right sides of the midline in the middle portion of the face which cannot be analysed using the original rule of fifths. Vertical lines were drawn...
and the measurements were made using a digital ruler in the MWSNAP 3.0 version software in pixels.

**Statistical Analysis:** Statistical analyses were performed using SPSS version 22.0. If p-value was less than 0.05 then it was statistically significant. One way ANOVA tests were performed to compare the mean differences between parts, to compare the mean differences between growth patterns in each part separately and to compare the mean differences between parts in each growth pattern separately, to compare the mean differences between malocclusion types in each part separately and to compare the mean differences between parts in each malocclusion type separately. Tukey HSD Post Hoc Tests were performed for multiple comparisons.

**Results**

**Comparison of Asymmetry in Three Parts:**
Asymmetry between the mean value measurements of the three parts are given in table1 and 2. Relation of Asymmetry with skeletal malocclusions and growth patterns are given in tables 3,4 and 5,6

Discussion

Facial asymmetry is evaluated by a number of methods such as frontal photographs, radiographs, stereophotogrammetry, 3D photogrammetry etc. (9,14,18–27) Each method has its own advantages and disadvantages. Of these methods, frontal photographs are the most common and easiest methods. This method involves the identification of landmarks and calculated individual linear measurements between them.

The rule of fifth as introduced by Powell and Humphries in 1984, had four lines that divided the face into five segments each with an eye width. However, in such an analysis, the asymmetry cannot be clearly explained in the medial part. Hence a midline was introduced in the rule of fifth, dividing the face into right and left halves and thereby evaluating the asymmetry. This midline divides the medial fifth into right and left parts.

This analysis was performed in random patients reporting for treatment in department of orthodontics in Saveetha Dental College and Hospitals. This analysis would depict the prevalence of asymmetry in this patient population. All measurements were made in standardised photographs and the measurements were done in computer software to prevent method error. These measurements were related to the patients’ skeletal malocclusion and growth patterns.

When the three parts of either side were averaged and compared, there was significant difference between the three parts. There was significant difference when the median part was compared with the middle and lateral parts. There was significant difference when the middle part was compared with the median and lateral parts. Similarly, there was significant difference when the lateral part was compared with the median and middle parts. In the lateral part, there was a much significant difference between their right and left halves.

When the three parts where related with the different skeletal malocclusion, there was no significant difference in the linear measurements. In class 1 and class 2, there was significant difference between the three parts.

When the parts were related to the different growth patterns, there was significant difference in the horizontal growth pattern when compared to the vertical and average growth patterns. In horizontal growth pattern,
there is significant difference between the right and left halves of the lateral part.

**Conclusion**

All the three parts in the face were not equal on either side. Facial asymmetry was more concentrated on the lateral part when compared to the other two parts. Asymmetry is seen more in patients with class 2 malocclusion, horizontal and average growth patterns when compared to other malocclusion and growth patterns. Ironically, there is no significant facial asymmetry in patients with vertical growth pattern or skeletal class 3 malocclusion. This could be due to the less sample size of Class 3 and vertical growing patients.

Pigmented Lesions of Oral Cavity—A Short Review

N. Anitha¹, N. Aravindha Babu², L. Malathi¹, E. Rajesh¹
¹Reader; ²Professor, Oral Pathology and Microbiology, Sree Balaji Dental college and hospital, BIHER

ABSTRACT

Pigmentation of oral mucosa occurs due to accumulation of pigments and thereby leading to colour change. Pigmented lesions of oral cavity can be physiologic or pathologic. The pigments causing discolouration can be either from external sources (exogenous) or internal sources (endogenous). Certain drugs can also cause pigmentation of the oral mucosa. Benign and malignant tumours of melanocytic origin can also be pigmented in nature. Endocrine diseases (adrenal) can also cause pigmentation. Diagnosing pigmented lesions requires thorough knowledge of various causes and proper diagnosis is important for planning the treatment.

Keywords: Pigmentation, Pigments, Melanocytes

Introduction

Pigmentation of oral mucosa could be due to accumulation of pigments and leads to colour change of the tissues.¹ The normal colour of healthy oral mucosa is pale pink and colour variation can be due to number of factors like inflammation, pigments.² Pigmented lesions can be commonly seen in oral mucosa and it could be physiologic or pathologic in origin. Physiologic like racial pigmentation and pathologic like systemic diseases (Addison’s disease) and malignant neoplasms (Melanoma).³

Pigmented may be exogenous or endogenous in origin. Exogenous pigmentation occurs due to foreign body implantation. Endogenous pigmentation could be due to endogenous pigments such as melanin, hemoglobin, hemosiderin and carotene.⁴

Classification

- Pigmented lesions
  - Physiologic pigmentation
  - Exogenous and Endogenous pigmentation
  - Drug induced pigmentation
  - Post inflammatory pigmentation
  - Heavy metal pigmentation—Lead, Bismuth, Mercury, Silver, Arsenic, Gold
  - Neoplastic
  - Endocrinal diseases

Physiologic pigmentation: Physiologic pigmentation or racial pigmentation is commonly seen in African, Asian countries. This pigmentation ranges from light brown to dark brown. Most common intraoral site of such pigmentation is attached gingiva. Pigmentation can also be seen as brown patches in buccal mucosa, hard palate, lips and tongue.³

Exogenous and Endogenous pigmentation

Endogenous pigmentation: Endogenous pigmentation include melanin, hemoglobin and hemosiderin and they are produced by body’s own metabolism. The endogenous pigmentation are caused by these endogenous pigments.⁵ The most important of endogenous pigment is melanin and this is synthesized by melanocytes (in basal epithelial layer) and transferred to keratinocytes. Melanocytes produce melanin in membrane-bound organelles called melanosomes.⁵

Melanin related pigmentation can be lesions such as oral melanotic macule, Nevus, Malignant melanoma and basilar melanosis with incontinence. Melanotic macule is benign pigmented lesion. It occurs as brown or brown black pigmentation and asymptomatic. Nevus is pigmented lesion presenting as a flat, slightly elevated or as a tumour. The colour can be bluish gray, brown or black and sometimes non-pigmented.

Ecchymosis also known as bruises occurs after injury and common site is lips. Trauma causes erythrocytes to come into submucosa and appears as red macules and later degrades to hemosiderin giving brown colour.

Hemochromatosis is chronic, progressive disease with excessive iron deposition in organs and tissues and leads to organ toxicity. Hemochromatosis is a genetic defect which causes excessive iron absorption.

**Exogenous pigmentation:** Exogenous pigmentation can be caused by traumatic deposition into submucosa, ingested, absorbed into blood stream and precipitated into connective tissues particularly in gingiva(areas of chronic inflammation).

Amalgam tattoo(blue black in colour) is a focal pigmentation in oral mucosa(gingiva, alveolar mucosa) caused by large amalgam restoration.

Graphite tattoo(gray or black) as permanent discolouration when pencil points broken off into gingival tissue.

Hairy tongue is caused by defective desquamation of filiform papillae and involves dorsal surface of tongue. Depending on the etiology it can be brown, white or green.

Pigmentation can happen with heavy metal ingestion. An increase in the levels of heavy metals such as lead, bismuth, mercury, silver, arsenic and gold in the blood causes oral mucosal discoloration. Bismuthism caused by medicinal use of bismuth preparation cause metallic taste, burning sensation of oral cavity and blue black bismuth line on gingival papillae. Lead in the paints, glazes, cooking vessels, batteries, ointment and containers cause plumblum. Metallic taste, excessive salivation, dysphagia and a line “ Burtonian line ” seen along gingival margin. Mercurialism also called pink disease or acrodynia is caused due to mercury toxicity. Excess salivation and darker gums than normal are usually noticed. Chronic exposure to silver compound called as argyrosis. The exposed body surface such as nail bed shows deep discoloration. Skin is gray, violet or cyanotic and in oral mucosa the pigmentation is diffuse throughout gingiva and mucosal tissue. Arsenic poisoning from industrial exposure or therapeutic consumption. Oral tissues are painful, deep red in color and often produces ulceration.

Auric stomatitis is caused by used of gold for treatment (Rhesus arthritis, lupus erythematosus and leprosy). It leads to vesicle and ulcerations of oral mucosa and faint blue or purple discoloration.

**Drug Induced Pigmentation:** Oral mucosal pigmentation is caused by certain drugs. The pathogenesis of drug-induced pigmentation depends on the drug used. It may involve accumulation of melanin, deposits of the drug or its metabolites, synthesis of pigments by the drugs or iron deposition after damage to dermal vessels.

Drugs such as phenothiazines and minocycline are deposited in the skin or mucosa and react with melanin and form drug pigment complex. Tetracycline, Cotrimazole are common drugs associated with oral pigmentation. Also colchicines, ketoconazole, pyrimethamine and barbiturates may cause pigmentation.

Chloroquine and other quinine derivatives cause blue-grey or blue-black mucosal discoloration commonly in the hard palate. These drugs are used in treating malaria, cardiac arrhythmia, systemic and discoid lupus erythematosus and rheumatoid arthritis.

Patients infected with Human Immunodeficiency virus are treated with Zidovudine(AZT), Ketoconazole and clofazamine. These patients show oral brownish pigmentation.

**Postinflammatory Pigmentation:** Mucosal pigmentation can be seen in long standing inflammatory disease of mucosa(Lichen mucosa). Mucosa shows brown-black pigmented areas adjacent to erosive or reticular lichen planus.

**Neoplastic pigmented lesions**

Melanocytic nevus: Melanocytic nevus is benign tumour resulting as a consequence of melanocytic growth and proliferation. Oral nevi presents over the age of thirty and clinically appears as brown or blue nodule or macule. Oral nevi may be congenital or genetic disorder. It could be acquired with genetic and environmental factors.
Malignant melanoma: Malignant melanoma is malignancy arising from melanocytes. Oral melanoma as a primary lesion accounts only 1% of all melanomas. Oral melanoma presents as a macule, plaque or a mass. They can be well-circumscribed, irregular and pigmented focally or diffusely and sometimes may lack pigment (amelanotic).

Other diseases causing mucocutaneous pigmentation:
Hypoadrenocorticism (Addison disease) caused by trauma, autoimmunity, infection, neoplasia, genetic disease, medications shows decreased corticosteroid levels. The adrenal gland and pituitary gland are linked through a feedback mechanism. Whenever there is reduced corticosteroid levels the anterior pituitary gland is stimulated to secrete Adrenocorticotropic hormone (ACTH). ACTH acts on adrenal cortex and results secretion of corticosteroids. By this feedback causes pituitary to slow ACTH secretion. When there is low corticosteroid levels ACTH secretion persists. The alpha-melanocyte stimulating hormone gene also originate from same host gene harboring ACTH. As the serum ACTH level rises there is increase in alpha melanocyte stimulating hormone. It stimulates melanocytes directly and increases melanin production. This results in diffuse mucocutaneous pigmentation and in the oral cavity diffuse patchy melanosis in multiple mucosal surfaces can be seen.

Cushing disease: Cushing disease is caused by usually neoplastic activation of pituitary activation leading to continuous secretion of ACTH and alpha melanocyte stimulating hormone into the blood stream. Diffuse mucocutaneous pigmentation may be seen as first sign of the disorder.

Peutz-Jeghers syndrome: Peutz Jeghers syndrome is a genetic disease associated with mutation in tumour suppressor gene (STK11/LKB1). This condition is characterised by intestinal polyposis and increased susceptibility to different types of cancer. In this disease labial, perioral and acral macular pigmentation may represent earliest clinical manifestations. Macules are resembling dark freckling but without increase or diminished color intensity due to sun exposure.

Conclusion
Pigmentation in the oral mucosa when noticed should be diagnosed by which it could treated appropriately. Knowledge about the etiologic factors for occurrence of pigmentation in the mucosa and skin aids in diagnosis. The different clinical presentation of pigmentation should also be known by practioners. Muco-cutaneous pigmentation in certain endocrine diseases may be an additional diagnostic feature.

Common Adverse Effects of Using Mouth Wash in General Population—A Short Review

L. Malathi¹, N. Anitha¹, N. Aravindha Babu², K. M. K. Masthan³

¹Reader, ²Professor, ³Professor & Head, Dept of Oral Pathology Sree Balaji Dental College & Hospital, Bharath Institute of Higher Education and Research.

ABSTRACT

People use mouth rinses as a part of their oral hygiene in their day to day life. Although rinses impart some benefits to users, improper use of mouth rinses may result in various side effects. Usually mouthwashes are antiseptic solutions intended to reduce the microbial load in the oral cavity, although other mouthwashes might be given for other reasons such as for their analgesic, anti-inflammatory or anti-fungal action.

Keywords: mouth wash, oral hygiene, antiseptic, allergic reaction.

Introduction

Many person uses mouth rinses as a part of their oral hygiene in their day to day life. Although rinses impart some benefits to users, improper use of mouth rinses may result in various side effects. Usually mouthwashes are antiseptic solutions intended to reduce the microbial load in the oral cavity, although other mouthwashes might be given for other reasons such as for their analgesic, anti-inflammatory or anti-fungal action. Additionally, some rinses act as saliva substitutes to neutralize acid and keep the mouth moist in xerostomia (dry mouth). Cosmetic mouth rinses temporarily control or reduce bad breath and leave the mouth with a pleasant taste. Health Survey suggests that mouth washes are most commonly used by younger adults, but adults of all ages may benefit from them.

Types of Mouth Washes

- **Fluoride Mouth Wash**: Fluoride in mouth washes contains sodium fluoride which helps protect the teeth from cavities and tooth decay. Since fluoride can be found in tooth paste and tap water, too much fluoride contain mouth wash is not good for the tooth.

- **Antiseptic Mouth Wash**: This type of mouth wash is very common usually contain alcohol mostly used by people with mouth infection to stop bacterial growth. This is also helpful for people who have halitosis or bad breath. This is used together with the proper brushing of teeth and flossing. Over use of antiseptic mouth wash result in discoloration of teeth.

- **Cosmetic Mouth Wash**: Cosmetic mouth wash freshen your breath or to mask bad breath.

- **Natural Mouth Wash**: Natural mouth washes are alcohol-free mouthwash. Their ingredients are safer to use as compared to other type of mouth wash.

Benefits of Mouth Wash

- Freshens the breath – mouth wash temporarily reduces bad breath temporarily. It is an effective tool in the fight against tooth decay, gingivitis and promotes the healthy teeth and gums.

- Prevents plaque buildup – various mouth washes help prevent plaque buildup in your gums and in between the tooth

- Removes particles – mouth wash can be used before brushing to rinse out any loose particles in your mouth

- Prevent from cavity forming – regular use of mouth washes before and after brush and floss, reduce the chances of cavity forming. Mouthwashes that contain fluoride can prevent cavities and strengthen the enamel.

**Fluoride Mouth Washes**: Fluoride containing mouth wash used to prevent cavities, fluoride is mineral that helps the teeth stronger and more resistant to decay caused by acid and bacteria. fluorside containing mouth wash leading to serious allergic reaction including rash,
itching, swelling in the face, tongue, throat, severe dizziness, and trouble in breathing.

Most commonly used over the counter mouth wash have antiseptic properties, mouth wash uses more than twice per day increases pre-diabetes/diabetes risk over 3 years. Most mouth wash contain antibacterial ingredients, which could impact oral microbes critical for nitric oxide formation, and in turn predispose to metabolic disorders including diabetes. Mouthwashes generally contains an antiseptic such as benzakonium chloride, antibiotic agents, essential oils used as flavors, alcohol, sodium perborate, zinc chloride menthol, thymol, eucalyptol, glycerine, and boric acid. These substances can cause allergic reaction. Prolonged use of a mouthwash in which the alcohol concentration is high can induce white lesions in oral mucous membrane.

Anti Septic Mouth Washes: Anti septic mouth rinses on the market today have 3 main ingredients. One is called quaternary ammonium compound cetylpyridinium chloride, or CPC—an antiseptic that has been used since 1939 and is still included in many current mouthrinses at formulations ranging from 0.045-0.075%. It’s important to note that 0.045% is the minimum recognized therapeutic concentration; yet, many mouthrinses contain CPC at concentrations below this and do not provide anti-plaque/anti-gingivitis benefits.

A second common antimicrobial ingredient found in mouthrinses is chlorhexidine, or CHX—a bacterial bisbiguanide antiseptic that is found only in prescription products such as Peridex and PerioGuard. CPC can interact with negatively charged ions in toothpaste, which may lower its biological activity and reduce its clinical efficacy. CPC and CHX also may precipitate negatively charged dietary chromogens in food and beverages, which can lead to tooth staining. Chlorhexidine gluconate is a prescription germicidal mouthwash that decreases bacteria in mouth. It is the most effective antiseptic mouthwash primarily prescribes to treat the inflammation, swelling, and bleeding that comes with gingivitis.

Cosmetic Mouth Wash: Cosmetic mouth rinses may temporarily control or reduce bad breath and leave the mouth with a pleasant taste, but none of the cosmetic mouth rinses help reduce plaque, gingivitis, or cavities.

Natural Mouth Wash: Using a natural mouthwash in conjunction with regular brushing and flossing is a good way to reduce oral bacteria and maintain or achieve optimal oral health and hygiene.

A natural mouth rinse, uses pure essential oils extracted from flowers, root stems, cinnamon, and peppermint. Most commercial mouth wash contain of alcohol to kill bacteria, it is only effective for short duration. An alcohol-free mouth rinse is better because it is equally effective at eradicating germs without the irritation.

Oral health is an excellent indicator of overall health. Infections of the oral mucosa can result in inflammation in other parts of the body because the oral mucosa provides a direct pathway into the bloodstream. Use a natural mouth rinse and toothpaste for highly effective cleansing and to help protect against gum disease.

Adverse Effects of Mouth Wash

Staining: Chlorhexidine might cause staining of tooth surfaces, restorations, and the tongue. If patient have anterior white filling dentist do not recommend chlorhexidine mouth wash.

Alteration in Taste: It alters the permanent taste sensation.

Tarter Formation: Regular use of chlorhexidine mouth wash increases the tartar formation.

Allergic Reaction: There is possibility of allergic reaction.

Pregnancy & Breast Feeding: Chlorhexidine mouth wash is not safe for fetus. In breast feeding mother this mouthwash may pass through breast milk and affects the child. In children it is not recommended under the age of 18.

Color Stability of Dental Resin – Based Composite Materials: The color of dental restorative material should be maintained throughout its functional life time in an oral environment. The frequent use of mouth wash may affect the color stability of these composite restorations.

Conclusion

Better to avoid regular use of alcohol-based mouth wash. Natural mouth wash is good without any side effects.
effects. It maintains good oral health & hygiene. For long term use, natural mouth which is extracted from flower, herbs & essential oils are good.

Dentoalveolar Abscess—A Review

Nishanth G.1, Aravindha Babu N.2, N. Anitha3, L. Malathi4
1Post Graduate Student, 2Professor, 3Reader, Sree Balaji Dental College and Hospital, Bharat Institute of Higher Education (BIHER) Chennai

ABSTRACT

Periodontal abscess is the third most frequent dental emergency, representing 7–14% of all dental emergencies. Numerous aetiologies have been implicated. The diagnosis is done by the analysis of the signs and symptoms and by the usage of supplemental diagnostic aids. The treatment of the periodontal abscess has been a challenge for many decades. In the past, the periodontal abscess in periodontal diseased teeth was the main reason for tooth extraction. Today, three therapeutic approaches are being discussed in dentistry, that include, drainage and debridement, systemic antibiotics and periodontal surgical procedures which are applied in the chronic phase of the disease. The localization of the acute periodontal abscess and the possibility of obtaining drainage are essential considerations for successful treatment. The aim of this review is to give a clear idea about periodontal abscess and its management.

Prevalence:
Prevalence of Periodontal abscess is relatively high constituting about 6-14% of all dental emergencies, and is also the most important reason for people seeking dental care. It is the third most common dental emergency [1st is Pulpal infection (14%-25%),...
followed by pericoronitis (10%-11%). Among all emergency dental conditions, periodontal abscesses represent approximately 8% of all dental emergencies in the world \cite{2}, and up to 14% in the USA \cite{3-5}

**Pathogenesis:** Entry of bacteria into the periodontal wall initiates the process of periodontal abscess. With the infiltration for bacteria into the periodontium, the presence of bacteria and bacterial products initiates inflammatory process with activation of inflammatory response. Inflammatory cells and extracellular enzymes cause tissue destruction followed by inflammatory infiltrate resulting in encapsulation of bacterial mass and pus formation. Quantitative lowering of tissue resistance and virulence of bacteria present determines the course of infection.

**Classification \cite{1, 2}:**

1. **Based on etiological factor**
   
   - **Periodontitis related abscess:** Infection originates from biofilm (deepened periodontal pocket).
   
   - **Non-periodontitis related abscess:** Infection originate from another local source, E.g- foreign body impaction, altered root integrity.

2. **Based on course of the disease**

   - **Acute periodontal abscess:** Has very short period of development with sudden onset and lasts for few days or weeks. Represents as deep and throbbing pain while biting and patient shows tendency towards clenching. Gums appear red, swollen, tender with no evidence of pus discharge initially, as the disease progresses shows pus discharge and fluctuation with enlargement of associated lymph node.

   - **Chronic periodontal abscess:** Has a longer period of development and usually slow onset. Represents itself with fowl breath, low intensity pain, spontaneous bleeding with tenderness on the adjacent tooth often associated with mobility. Pus discharge maybe evident along with discharge from gingival crevice or overlying mucosa.

3. **Based on number**

   - **Single abscess:** associated with single tooth.
   
   - **Multiple abscess:** confined to more than one tooth.

**Microbiology:** The culture of periodontal abscesses have revealed a high prevalence of the following bacteria:

1. Porphyromonas gingivalis-55-100% Lewis et al \cite{6}
2. Prevotella intermedia- 25-100% Newman and Sims \cite{7}
3. Fusobacterium nucleatum -44-65% Hafstrom et al \cite{8}
4. Actinobacillus actinomycetemcomitans-25% Hafstrom et al \cite{8}
5. Campylobacter rectus- 80% Hafstrom et al \cite{8}
6. Prevotella melaninogenica-22% Newman and Sims \cite{7}

**Predisposing Factors:** Numerous predisposing factors have been proposed, to develop an abscess. The factors are as follows:

- Change in the composition of the microflora, virulence of bacteria or in host defences could also make the gingival pocket lumen inefficient to drain the increased suppuration \cite{9}. Closure of periodontal pockets may lead to the spread of the infection into the surrounding tissues, due to the pressure of the suppuration inside the pocket. Local accumulation of pus because of fibrin secretion, may favour the closure of the gingival margin to the tooth surface \cite{10}. Small periodontal pockets are especially associated with furcation defects. These become isolated and can favour the formation of an abscess. After procedures like scaling where the calculus is dislodged and pushed into the soft tissue.

**The Iatrogenic Factors Which are Associated with Periodontal Abscess:** Post scaling periodontal abscess. eg. Due to the presence of fragments of the remaining calculus that may block the pocket entrance or when a fragment of the calculus is forced into non-inflamed portion of the tissue, Post surgical periodontal abscess When the abscess occurs immediately followed by periodontal surgery. It is often due to the incomplete removal of the calculus in subgingival portion. Perforation of the tooth by an endodontic instrument. The presence of a foreign body in the periodontal tissue (e.g. Suture/pack) Post antibiotic periodontal abscess \cite{11}

**Diagnosis:** Diagnosis of periodontal abscess is primarily based on chief complaint, history of presenting illness; medical and dental history are also essential for proper diagnosis. Severity of pain and symptoms differentiates
between chronic and acute abscess. Important points in history taking includes:

If the patient is under the supervision of any physician or dentist, or is under any medication that might affect periodontal diagnosis and treatment, history of dental treatments which might affect the diagnosis. Habit of smoking might affect as it would severe the condition and reduce the response towards the treatment. Proper history taking is followed by examination of patient and the lesion. The steps include:

Systemic condition- Evaluating medical status of the patient and symptoms indicating any systemic condition, immune status, age, distress, fatigue.

Extra oral examination- Tenderness, symmetry, colour change, presence of fluctuance and sinus tract, limitation in mouth opening, enlargement of regional lymph node.

Intra oral examination- Examining any change in dentition or mucosa; colour, contour and consistency of gingiva; suppuration (if any) either spontaneous or on application of pressure, or from sinus; mobility, extrusion from the socket, tenderness on percussion of the associated tooth; evaluating oral hygiene and periodontal status.

Radiograph\(^{[12]}\): Various radiographic techniques such as periapical, bitewing, OPG are used to assess the periodontal status of the patients, revealing either normal architecture of bone or loss of interdental bone, or evident bone loss along with loss or widening of periodontal space. Periapical and bitewing radiographs are used to assess the marginal bone status or periapical condition of the tooth. Also insertion of gutta percha point into the sinus tract while taking a radiograph shows the track of the abscess.

Vitality Test\(^{[12]}\): Assessing the vitality of the tooth using either thermal or electrical means helps in ruling out any pulpal infection associated with the tooth.

Microbial Test\(^{[10],[12]}\): Culturing and sensitivity testing of the samples obtained from the pus discharge from sinus or abscess or gingival sulcus aids in specific antibiotic administration.

Lab Finding\(^{[2]}\): Elevated count of blood neutrophils, monocytes and leukocytes is suggestive of increased immune response to bacterial toxins in periodontium and aids in confirming the diagnosis.

Others: Presence of multiple abscess is often suggestive of increased blood glucose levels, and altered immune status of diabetic patients. Thus, assessment of blood glucose level by fasting and random blood glucose or glycosylated hemoglobin level is essential before treatment planning, to ensure proper prognosis.

Immediate Management: Immediate management is usually advised in life threatening conditions such as space infections from oro-facial regions or diffuse spreading infections E.g., facial cellulitis. Immediate hospitalization and supportive therapy along with intravenous infusion is always recommended. Based on the general/local signs and symptoms, investigation results and severity of the infection, start of the therapy can be either immediate or delayed to some extent. In case of non-life-threatening condition with systemic signs and symptoms, systemic analgesics and antimicrobial administration can be recommended\(^{[8],[11],[12],[13]}\). But empirical antibiotics are recommended before the analysis of culture and sensitivity test is done which depends on severity of the infection. Commonest empirical antibiotics administered include: metronidazole 200-400mg tds for 5-7 days, Phenoxymethylpenicillin 250-500mg qid 5-7 days, amoxicillin 250-500 mg qid 5-7 days. Alternative antibiotics in case of penicillin allergy include: erythromycin 250-3500mg qid 5-7 days, doxycycline 100mg bd 7-14 days, clindamycin 150-300mg qid 5-7days.

Initial Therapy: Initial therapy is recommended when there is no systemic toxicity or for lesions with resolved systemic toxicity and chronic periodontal abscess\(^{[13]}\). Initial therapy constitutes

1. Abscess pocket irrigation with saline and antiseptics,
2. Removal of foreign body (if any),
3. Scaling on the root surface or sulcus draining using probe,
4. Debridement and compression of soft tissue wall,
5. Oral hygiene instructions,
6. Review after 24-48 hrs; followed by definitive treatment after a week.

Treatment options in initial therapy of periodontal abscess include- drainage through pocket by retraction
or incision; scaling and root planning; periodontal surgery; systemic antibiotics; tooth extraction

**Definitive Treatment:** Definitive treatment is done depending on patient needs and prognosis following the reassessment after initial treatment for restoring function, esthetics and maintaining proper periodontal health of the patient

**Conclusion**

Diagnosis of periodontal condition with lowered periodontal health along with periodontal abscess has high and favorable response towards initial and definitive treatment than a single case with either hindered periodontal health or periodontal abscess condition. Also, in case of extraction of tooth various factors such as degree of furcation involvement, degree of clinical attachment loss, degree of mobility, patient’s susceptibility towards periodontitis due to any systemic conditions should be under taken before proceeding with the treatment. Often reoccurrence of periodontal abscess is noted in patient undergoing supportive periodontal treatment. Hence, Early and timely intervention is essential in management of periodontal disease as it has high chance of tooth loss.

Drug Induced Lichenoid Reactions—A Literature Review

Nishanth G.1, Aravindha Babu N.2, E. Rajesh3, K. M. K. Masthan4

1Post Graduate Student, 2Professor, 3Reader, 4Professor and Head, Sree Balaji Dental College and Hospital, Bharat Institute of Higher Education (BIHER) Chennai

ABSTRACT

The terms oral lichenoid reactions or oral lichenoid lesions refer to histologically and clinically similar to oral lichen planus. These lesions are described according to the causative factor involved, including direct contact with dental restoration materials, drug-related lesions, and lesions associated to graft-versus-host disease. Drug-induced oral lichenoid reactions were first cited in 1971 by Almeyda and Levantine. Since then, many drug substances have been associated with such lesions. The most common agents are NSAIDs and ACE inhibitors.

Keywords: Lichen planus, Lichenoid reaction, Dental materials, NSAIDs

Introduction

The terms oral lichenoid reactions or oral lichenoid lesions refer to lesions histologically and clinically similar to oral lichen planus [1]. The literature uses different terms to describe lesions of this kind [2]. The etiological factor involved, including alterations resulting from direct contact with dental restoration materials, drug-related lesions, and lesions associated to graft-versus-host disease [1, 2]. Drug-induced oral lichenoid reactions was first mentioned in 1929, and were later cited in 1971 by Almeyda and Levantine [3]. Many of the cases were documented among United States military personnel during the war in the Pacific, southeastern Europe and Indonesia. They also reported cases with an apparent relationship between the clinical findings in these individuals and the prophylactic use of antimalarial drugs. Since then, many other drug substances have been associated with such lesions [4].

Epidemiology: The accurate epidemiological characteristics of these lesions are difficult to establish, due to the diverse terms used as a final diagnosis of lichen planus where the histopathological and clinical findings are less similar than in classical lichen planus [3]. Second thing, the absence of histological confirmation in most of the published articles on OLP related disorders makes it difficult to establish their actual prevalence or incidence [5]. It is believed that the prevalence of OLRs due drug substances is increasing. According to many authors [6], newly marketed drugs that are generally used among the population, such as antihypertensive agents, can cause such lesions as side effects.

Etiopathogenesis: The etiopathogenic mechanism is not known. The literature has reported a series of triggering factors, such as dental restoration materials, graft-versus-host disease, and a broad range of drugs [6, 7]. Many materials commonly used in restoration treatments in the oral cavity has been identified as triggering elements, including silver amalgam, gold, cobalt, palladium, chromium and even non-metals such as epoxy resins [7,8]. Bäckman and Jontell [9] in turn have pointed to dental material coadjuvants such as dental tartar deposited upon the materials, oral breathing and hyposialia as etiological factors. These authors published the case of a patient with all three factors who developed a lichenoid reaction in the absence of dental restoration. On the other hand, many drug substances are reportedly able to produce such reactions. The most common agents are non-steroidal anti inflammatory drugs and angiotensin converting enzyme inhibitors [10, 11]. These drugs are used

in combination, thus the possible existence of synergic effects between them is there. A few authors think of it as very likely that the alleged “Grinspan disorder”, in which oral lichen planus is identified with diabetes mellitus and blood vessel hypertension, is in reality essentially a case of oral lichenoid response prompted by the medications at the same time used to treat the last two ailments [12].

**Clinical Manifestations:** The clinical manifestations of oral lichenoid lesions are indistinct from those of oral lichen planus [7] with mainly erythematous erosive lesions. Most of these lesions are characterized by the presence of whitish streaks known as Wickham striae, seen in lichen planus [13]. However, a very significant factor of OLP is their location, and the absence of bilaterality of the manifestations [2, 6]. In sedate actuated lichenoid responses, no particular clinical highlights have been depicted prepared to do solidly separating them from lichenoid responses brought about by different variables. The main piece of information in this sense is a precursor of later or ceaseless introduction to some medication substance. Therefore, a differential analysis must be set up, considering cases related to the utilization of dental materials where the sores are found in contact with or near the helpful materials, and affirming that the patient has no forerunners of join versus-have ailment [14].

**Diagnosis:** The analysis of OLRs depends on their clinical attributes and the histological discoveries [9, 15]. In any case, the affectability and particularity of histological finding are low [4]. What’s more, no complete atomic analytic markers have been set up to date [16]. Van der Meij et al. [6] have proposed an alteration of the demonstrative criteria of the World Wellbeing Association for oral lichen planus and lichenoid responses. As these are cause – impact sores, the most exact symptomatic piece of information is assurance of whether the injuries vanish in the wake of wiping out presentation to the speculate etiological factor [8]. Nonetheless, on account of medication actuated injuries, suspension of the medicine may put persistent wellbeing in danger [13]. Moreover, much of the time such measures are not helpful and solid as an analytic technique, since the sores may take a long time in settling in the wake of suspending the presume prescription [3, 17].

**Final diagnosis of oral lichen planus and oral lichenoid lesions:** The clinical and histopathological criteria must be included in order to establish a final diagnosis. Both the clinical and histopathological criteria must be met in order to diagnose oral lichen planus. The term oral lichenoid lesions is to be used under the following conditions:

1. Clinically characteristic of oral lichen planus but histologically only “compatible with” oral lichen planus
2. Histologically characteristic of oral lichen planus but clinically only “compatible with” oral lichen planus
3. Both clinically and histologically “compatible with” oral lichen planus.

Modified World Health Organization criteria for the diagnosis of oral lichenoid reactions (OLRs), oral lichenoid lesions (OLLs) and oral lichen planus (OLP). Van de Meij et al., 2007 [6].

**Treatment:** The management of such lesions first requires identification of the triggering factor, and the elimination of exposure to it. In the case of drug-induced OLRs, due evaluation of the risk/benefit ratio of suspending the medication is required. As has been commented, even if the causal medication can be suspended, the lesions may take several months in improving. In addition, the pharmacological treatment of OLRs is often not feasible, because the long list of agents capable of causing such lesions includes many substances used to inhibit autoimmune T lymphocytes responses. These drugs are commonly used to treat very severe forms of lichen planus in its atrophic – erosive presentation, and in particular include dapsone, levamisole, tetracyclines and interferon [18, 19].

**Conclusion**

Oral lichenoid rections should be perceived as a separate entity happening because of dental restorative materials, medications, and drugs. In spite of the fact that they share clinical and histological likenesses to OLP adequate information has been exhibited in writing for their separation. It is fundamental that oral clinicians and dermatologists perceive this reality, particularly since their treatment is considerably more issue based contrasted with the exact treatment of OLP. In perspective on late investigations featuring their dangerous potential severe rules should be followed in their administration to maintain a strategic distance from or identify early the harmful changes.

Oral Manifestations and Complications of Diabetes Mellitus

R. Hariharan¹, N. Aravindha Babu², R. JayasriKrupaa³, K. M. K. Masthan⁴
¹Post Graduate Student, ²Professor, ³Reader, ⁴Professor and Head of the Department, Department of Oral pathology and Microbiology, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research

ABSTRACT

Diabetes is a clinically and genetically heterogeneous group of metabolic disorders manifested by abnormally high levels of glucose in the blood. Diabetes mellitus is a chronic disease affecting all age groups. There are 2 major types of diabetes mellitus are type I, Insulin dependent type and type II, Non insulin dependent type. Gestational diabetes is a state of abnormal glucose tolerance during pregnancy. It is one of the major disease increasing the mortality and morbidity worldwide. Hyperglycemia in diabetes is caused by insulin deficiency and insulin resistance. The common oral manifestations in diabetics are periodontal diseases, fungal infection, salivary dysfunction, burning mouth syndrome, delayed wound healing etc. This article aims to review and increase the awareness among the dental professionals about oral manifestations and complications of diabetes mellitus.

Keywords: Hyperglycaemia, Xerostomia, Burning Mouth Syndrome, Periodontitis.

Introduction

Diabetes Mellitus (DM) is a metabolic disorder characterized by the presence of chronic hyperglycaemia accompanied to greater or lesser extent by alterations to carbohydrate, protein, and lipid metabolisms¹. The overall prevalence of diabetes among adults over 18 years of age has increased from 4.7% in 1980 to 8.5% in 2014 and the World Health Organization (WHO) predicts this will increase to 439 million, almost 10% of adults in 2030². Therefore, dental professionals can play an important role in diagnosing and managing patients with diabetes.

Oral Manifestations in Diabetes Mellitus: Diabetic patient presents with impaired immune system and decreased bactericidal activity. The severity of symptoms are directly proportional to the degree and duration of the hyperglycemic status. Oral manifestation in diabetes are are Xerostomia, dental caries, periodontal disease and gingivitis, oral candidiasis, burning mouth syndrome (BMS), taste disorders, rhinocerebralzygomycosis (mucormycosis), aspergillosis, oral lichen planus, geographic tongue and fissured tongue, delayed wound healing, salivary dysfunction, altered taste and other neurosensory disorders, impaired tooth eruption, and benign parotid hypertrophy³. Periodontitis is more frequent and severe in patients with diabetes with poor glycaemic control. Dry mouth is the second most common manifestation that occur next to periodontitis. Early identification and/or management of these oral manifestations may help in the early diagnosis of diabetes and in attaining better glycaemic control.

Periodontal Diseases: Periodontal disease is the sixth most common complication of all diabetic complications⁴. Patients on taking food, there is slow release of periodontal pathogens and their metabolic products into oral tissues thereby causes bacteremia and endotoxemia. It results in an increase in serum levels of inflammatory mediators such as Inter-leukin 6 (IL-6), fibrinogen, and C-reactive protein (CRP). Systemic inflammation can also increases insulin resistance level and hence hyperglycemia occurs. The appropriate periodontal treatment by dental professionals can lower the level of proinflammatory mediators, thereby maintaining the blood glucose level⁵.

*AGEs: advanced glycosylation end products.

There are many theories which propose factors such as advanced glycation end products (AGEs), alteration in collagen nature, and altered immune function that causes defects in neutrophils function which sets the favourable environment for accumulation of bacteria in the tissue and also advanced glycation end products, which results from prolonged and chronic hyperglycaemia and increased secretion of pro-inflammatory cytokines such as tumour necrosis factor-α and prostaglandin E-2. The increase in collagenase activity along with the reduction in collagen synthesis will adversely influence collagen metabolism. This altered collagen metabolism would cause delayed wound healing as well as periodontal tissue destruction. Smoking is the primary risk factor for periodontal disease in diabetics.

**Periapical Diseases:** The dental pulp of diabetic patients differ from the normal pulp tissues, and pulpal tissues have dental collateral circulation, impaired immune response, and an increased risk of infection or pulp necrosis. Hyperglycemia is a stimulus for bone resorption by osteoclastic activity, inhibition of osteoblast differentiation, and a reduced capacity for bone recovery. A recent review concluded that current knowledge about the microbiology of endodontic infections and inflammatory reactions is limited, and that such knowledge could help implement new forms of treatment for these patients. Further research is needed to better understand the issue and so increase the success rates of endodontic treatment among these patients.

**Dental Caries:** It is known that diabetic patients are more susceptible to periodontal and salivary (xerostomia) disorders, which can also lead to tooth decay and loss. Salivary secretion dysfunction, periodontal and sensory disorders could increase the incidence of developing new and recurrent dental caries and tooth loss. The cleansing and buffering capacity of the saliva is diminished in patients with diabetes mellitus resulting in increased incidence of dental caries. Decreased salivary secretion, increased of carbohydrate level in parotid gland saliva, growth of oral yeasts, increased count of Mutans streptococci and lactobacilli are other factors responsible for increased incidence of caries.

**Salivary Dysfunction:** Patients with diabetes usually experience polydipsia and polyuria. In most times, constant dryness of the mouth remains and
xerostomia occurs. Xerostomia would cause impact on oral tissues and cause inflammation and pain. It also increases the incidence of periodontal infections and tooth decay. Diabetes mellitus is associated with chronic complications such as neuropathy, microvascular abnormalities and endothelial dysfunction that lead to deterioration of microcirculation and this may play a role in reduction of the salivary flow rate and composition. Sialosis is defined as asymptomatic, non-inflammatory, non-neoplastic, bilateral chronic diffuse swelling mainly affecting the parotid glands. Sialosis has been found to be more prevalent in patients with diabetes mellitus. Xerostomia also increases the level of salivary pathogens.

**Oral Infections:** Fungal infections: Oral candidiasis is an opportunistic infection caused by Candida albicans species. Candidal infection is more prevalent in patients with diabetes. The predisposing factor for candidiasis in diabetics is smoking habit, denture wearing, poor glycaemic control and use of steroids and broad spectrum antibiotics. Xerostomia also increases the risk of occurrence of candidiasis.

Bacterial infections are also common in diabetic patients since they are more prone to it. A prospective study conducted by Rao et al. concluded that submandibular space was more commonly involved in bacterial infection followed by buccal space.

**Taste Dysfunction:** The causative factor for taste dysfunction are metabolic and endocrine diseases. Patients of poor glycaemic control may have this taste dysfunction. Diabetic patients who suffer from neuropathy have a higher taste threshold.

**Neuro Sensory Disorder:** Oral dysesthesia or burning mouth syndrome (BMS) is a burning and painful condition affecting the oral cavity, most commonly palate, tongue, throat and gingivae, usually without any clinical signs. Tingling, numbness, dryness or sore mouth can also occur in combination with BMS. Its etiology includes systemic, local, and psychological factors (stress, anxiety and depression). The common associated conditions for BMS are dry mouth, menopause, candidal infection, diabetes mellitus, cancer therapy, psychological problems and acid reflux. BMS affect the ability to maintain good oral hygiene in patients with diabetes. Diabetic neuropathy could be the underlying cause of BMS in patients with diabetes.

**Delayed Wound Healing:** Delayed wound healing and delayed bone formation are known complications of diabetic patients. Delayed wound healing is due to poor soft tissue regeneration because of altered collagen metabolism such as increased collagenase activity and decreased collagen synthesis. Management of wounds in diabetic patients is more complex than normal individuals. The possible underlying causes for the delayed wound healing are delayed vascularisation, reduced blood flow, a decline in innate immunity, decreased growth factor production, and psychological stress.

**Oral Mucosal Diseases:** Oral Lichen Planus (OLP) and recurrent aphthous stomatitis are most common oral mucosal diseases in patients with diabetes. OLP is common in patients with type 1 diabetes compared to type 2 diabetes. This is because, OLP and type I DM are of autoimmune disease in origin. In type I diabetes mellitus, acute hyperglycaemia causes alteration in the immune responsiveness in diabetes mellitus. Atrophic-erosive oral lesions are more common in patients with diabetes with OLP.

**Conclusion**

There is increasing evidence that chronic oral complications in patients with diabetes adversely affect blood glucose control. Prevention and management of oral complications, especially periodontal disease, in patients with diabetes is important due to their possible adverse effect on glycaemic control. This review implied, an understanding of the way diabetes affects oral health is necessary for both clinicians and patients, therefore research in this field should be encouraged.

Oral Conditions in Renal Disorders

R. Hariharan1, N. Aravindha Babu2, R. Jayasri Krupaa3, K. M. K. Masthan4

1Post Graduate Student, 2Professor, 3Reader, 4Professor and Head of the Department, Department of Oral Pathology and Microbiology, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research

ABSTRACT

Kidney disease is a worldwide disease, with higher rate of increasing incidence and prevalence. Chronic renal failure is a disease in which chronic destruction of nephrons occurs and ends up in irreversible loss of kidney function associated with reduced Glomerular Filtration Rate (GFR). Renal function is measured using GFR by estimating Creatinine Clearance (CC). Patients suffering from End Stage Renal Disease (ESRD) may also encounter with hypertension, anaemia, infection, risk of bleeding, adverse effects of drugs and several other oral manifestation. Chronic renal failure cause various oral manifestations which affect both teeth and their surrounding tissues. The aim of this article is to provide knowledge for dentist regarding the association between renal diseases and their oral manifestation and to provide guidelines for managing these patients by improving the dental protocols for those patients. By improving the treatment protocol and oral hygiene of these patients, dentist can be able to prevent endocarditis and septicaemia.

Keywords: Chronic Renal failure, Creatinine Clearance, Dialysis, Xerostomia.

Introduction

Chronic renal disease (CRD), a chronic, slowly progressive and irreversible destruction of kidney architecture resulting in diminished kidney function. Renal dysfunction show definite implications in oral cavity by causing pathology 1. The functions of kidneys are maintaining electrolyte balance, filtering the metabolic products, maintaining the volume of extracellular fluid, endocrine function by producing hormones such as erythropoietin, prostaglandins etc 2. As the kidney functions for a prolonged period, the functional unit of kidneys such as nephrons gets diminished in some individuals. In untreated cases, destruction of nephrons can lead to renal failure.

The normal renal function is assessed by measuring Glomerular Filtration Rate (GFR), which is measured by estimating Creatinine Clearance (CC). Normal GFR value 120-130ml/minute/1.73m2 and varies according to age and gender 3. In Chronic Renal Failure (CRF) cases, GFR fall leads to increase un serum urea level. Creatinine Clearance (CC) gives an acceptable approximation to the value of GFR and indicates when there is a fall. Dentist commonly use plasmatic creatinine level to assess the kidney function before prescribing the drug. The normal value of serum Cr is 0.5-1.4mg/dl and it will be more than 1.5mg/dl for renal disorders individuals.

The most common etiologic factors for the CRF are Diabetes mellitus, Hypertension and glomerulonephritis. Treatment options for CRF includes dietary changes, management of systemic diseases, dialysis or a renal graft 4. Cardiac arrest is the most common cause of death in these patients, followed by infection and malignancy. The objective of this article is to describe the oral manifestations of renal disorders and to delivering the management protocolfor treating these patients.

Oral Manifestations: It is estimated that more than 85% of chronic renal failure patients present with oral manifestation. The proper intervention with dialysis
at the earliest period reduce the oral manifestation. Systemic health of an individual is usually expressed in the oral cavity. Chronic Renal Failure (CRF) is one among the systemic disorders which show manifestations in oral cavity. Most common oral manifestations are dry mouth, altered taste impairment, gingivitis, parotitis, enamel hypoplasia and delayed eruption. It can also manifest some of the mucosal lesions such as leukoplasia, lichenoid reactions, aphthous ulcers, angular chelitis, candidiasis etc.

Dialysis patients usually exhibits pallor of the mucosa mainly due to anaemia which occurred because of reduced erythropoietin synthesis. They also predisposes to ecchymoses, petechiae and haemorrhage in oral mucosa. Bleeding tendency in these patients is usually due to alterations in platelet aggregation and renal anemia.

**Xerostomia:** Xerostomia or dry mouth is a frequent and major complaint among patients undergoing dialysis. The causes for dry mouth are dehydration, decreased intake of water, mouth breathing, chemical inflammation, direct uremic involvement of salivary glands etc. Some other conditions which cause dry mouth are retrograde parotitis, metabolic abnormalities and use of diuretics.

**Mucosal Lesions:** Patients undergone renal transplant and on dialysis usually manifest with white patches and ulcerations. Use of immunosuppressive drugs by these patients may cause lichenoid reactions and oral hairy leukoplakia. Uremia usually associated with the incidence of Epstein-Barr virus (EBV) infection and infection resolves on treating uremia. White patches in skin of these patients are called “uremic frost”, which are formed due to deposition of urea crystals on the epithelial surfaces. It is rare in oral cavity because of saliva evaporation.

**Uremic Stomatitis:** Uremic stomatitis can be seen in renal failure patients because of increased levels of urea and other nitrogenous wastes in blood which may be acute in onset. Clinically it may represent as white plaques present on buccal mucosa, floor of the mouth and tongue. Lesion usually present with pain, burning sensation and unpleasant taste. Physician usually detect an odor of ammonia or urine in the patient’s breath. Uremic stomatitis can be of four types such as Erythemopultaceous, Ulcerative, Hemorrhagic and Hyperkeratotic.

**Renal Osteodystrophy:** It is a chronic, spectrum of bone metabolism disorder linked with various pathogenic pathways. In renal osteodystrophy, bone demineralization with trabeculation and cortical loss, giant cell radiotransparencies or metastatic calcifications of the soft tissues occurs. As the bones are demineralized at higher rate, patients were highly susceptible to fracture of bones during dental procedure especially extraction and impaction. Maxillary and mandibular jaw enlargement with dental malocclusion are also common in these individuals. Other some conditions common in renal failure patients are enamel hypoplasia, widening of periodontal ligament, delayed eruption, loss of lamina dura, periodontal damage, tooth mobility, drifting, pulp calcifications.

**Taste change:** Metallic taste is the most common manifestation in CRF patients, which is due to urea content in saliva and splitting to ammonia and carbon dioxide by bacterial urease in saliva. Metabolic disturbances, adverse effects of drugs, decreased taste buds, changes in salivary flow and composition can also cause metallic taste. Higher levels of urea, dimethyl and trimethyl amines and low levels of zinc might be associated with decreased taste perception in uremic patients.

**Mucosal Petechiae and Ecchymosis:** This manifests because of abnormal thrombocyte function, decrease in platelet factor III, decrease in platelet aggregation. Anti coagulants used during hemodialysis can also cause bleeding tendencies in some renal failure patients.

**Candidiasis:** Oral candidiasis will affect 20 to 30% of renal transplant patients. Candidiasis may present as angular chelitis, pseudomembranous or erythematous ulceration or chronic atrophic infection. Anti fungal agents can be given in the form of lozenges and topical gels. Lozenges are effective in curing mild candidal infections. In post transplant recipients viral infections such as herpes simplex virus are predominantly common and use of anti viral agents such as acyclovir (5%) has significantly reduced the frequency of viral infections.

**Periodontal Disease:** Chronic Renal Failure patients show periodontal manifestation such as gingival inflammation, increased levels of plaque and calculus, gingival recession, pocket formation, aggressive periodontal damage etc. Patients with renal failure may receive calcium channel blockers which will cause gingival hyperplasia. Gingival hyperplasia can be treated...
by surgical resection. Platelet dysfunction and effects of anticoagulants cause petechiae and ecchymoses in oral mucosa of CRF patients.

Oral Malignancy: An increased susceptibility to oral malignancy of the lip attributable to the treatment following renal treatment has been reported. The increased risk of malignancy in CRF is because of effects of iatrogenic immune suppression, which in turn increases mucosal susceptibility to virus-related tumors, such as Kaposi’s sarcoma or non-Hodgkin lymphoma.

Dental Considerations: Haemostasis should be ensured by the dentist while they doing any surgical procedures. Most preferable day for patient undergoing dialysis is a day after day of dialysis, since the patient feels more comfortable and the effect of heparin has worn off at the maximum on this period. The haematologist opinion may be required in most of the cases. Various haemostatic agents used in these patients are desmopressin which provide haemostasis for up to 4 hours, cryoprecipitate for up to 36 hours etc. Conjugated estrogen also helpful in haemostasis which persists for 30 days.

Renal failure patients are more prone to infections as they are immunosuppressed because of drug intake. They are at higher risk of getting septicaemia usually without any signs of inflammation. Dialysis may also predisposes blood borne viral infections such as hepatitis. Antibiotics such as erythromycin, penicillin, metronidazole, cephalosporin are given in lower doses, since higher dose can cause damage to central nervous system. Renal failure patients should be considered for antimicrobial prophylaxis before undergoing any invasive dental procedures such as extraction, impaction, periodontal surgery etc. Patients with polycystic kidney and patients receiving peritoneal dialysis may develop bacteraemia which result in peritonitis. Nonsteroidal anti-inflammatory drugs and COX-2 inhibitors should be avoided, as they can cause excessive gastrointestinal damage and nephrotoxic in these patients. Anti histamines can cause xerostomia in patients undergoing dialysis. Systemic fluorides are avoided in these patients because of minimal excretion rate of fluoride in urine by these patients, hence fluoride can be given as topical agent for caries prophylaxis. Antacids containing magnesium, calcium and aluminium should be avoided since they have minimal excretory and absorption rate.

Local anaesthesia is safer unless there is a bleeding tendency in patients. Relative analgesia is given for conscious sedation cases. Most commonly used agent is midazolam rather than diazepam, because diazepam may cause thrombophlebitis at higher risk. Renal failure patients with anaemia are contraindicated for general anaesthesia. General anaesthetic agent can cause myocardial depressant effects such as hypotension. Most commonly used agents are isoflurane and sevoflurane. Thiopentone is used as inducing agent for anaesthesia which is maintained by nitrous oxide at constant administration.

In case of dry mouth, alcohol free mouthwashes and salivary substitutes are recommended. Usually before any procedure, chlorhexidine mouthwash for 60 seconds is recommended. Dosage of pharmacologic therapies must be adapted to creatinine clearance.

Conclusion
The number of renal failure patients and patients under dialysis are increasing day by day. These patients also indeed of dental treatment. Hence intervention of dentist and coordination with the nephrologist is mandatory to fulfil the dental needs of these patients. A proper examination of the hard and soft tissues of oral cavity in patients with renal disorder is essential to diagnose pathologies at an early stage of multi-system disease. Therefore, these patients should be routinely evaluated for oral lesions and treated accordingly.

ABSTRACT
It is a well-known fact that many systemic diseases are manifested in the oral cavity. The ideal management for treating such manifestations is treating the primary cause first and then providing local therapy if needed. Systemic disease which a dentist can encounter in his practice is chronic renal failure (CRF) or end stage renal disease (ESRD). Renal failure is an uncommon condition when compared with ischemic heart disease, stroke, diabetes and cancer and, therefore, may appear to be a relatively minor public health problem.

Keywords: renal failure, dialysis, oral health

Introduction
Chronic renal failure is defined as a progressive decline in renal function and irreversible loss of renal function which is associated with a reduced glomerular filtration rate (GFR). It is important to estimate the severity of the CRF to determine time-related consequences for the patient and the responses required. Patients with CRF, undergoing dialysis or renal transplants, are more susceptible to a number of infections. Its because of the depression of the immune functions and masking of the classic signs of inflammation and infection. Lymphocyte number and function are reduced; neutrophil chemotaxis and phagocytosis are impaired.

Hemodialysis: Haemodialysis is the most common therapeutic modality, which is an artificial method of removing nitrogenous and other toxic products of metabolism from the blood by using a haemodialyzing system. An exchange occurs between the patient’s plasma and dialysate across a semipermeable membrane that allows uraemic toxins to diffuse out of plasma, while retaining the formed elements and protein composition of the blood. It is a life saving intervention which has reduced the mortality of this still fatal disease.

Transient bacteraemias occur in a wide variety of dental treatments, particularly those associated with mucous membranes. Dental management of these patients includes prevention and control of bacteraemias which are of dental origin. Thus, an antimicrobial prophylaxis is essential in these patients. The benefit of dialysis outweighs the risk of life-threatening uraemic complications, but this modality can lead to numerous complications which are of importance to the dentist.

An international group defined published the Kidney/Dialysis Outcome Quality Initiative guidelines, which classify the five stages of kidney disease according to the severity of renal failure as follows:

Stage 1: normal or increased GFR but some evidence of kidney damage reflected by microalbuminurea/proteinurea, hematuria or histologic changes;
Stage 2: mild chronic kidney failure (60-89 GFR milliliters per minute per 1.73 square meters);
Stage 3: moderate chronic kidney failure (30-59 GFR mL/minute/1.73 m2);
Stage 4: severe chronic kidney failure (15-29 GFR mL/minute/1.73m2);
Stage 5: ESRD in which renal replacement therapy has to be considered (< 15 GFR mL/minute 1.73 m2 on dialysis).

Oral Manifestations: The specific oral manifestations were classified into subjective and objective findings. Subjective findings that were included were dry mouth, change in taste of tongue and/or burning sensation on the mucosa. Objective includes uraemicodour, tongue coating, mucosal petechiae or ecchymosis and ulceration. Uraemicodour was recorded by smelling the odour when the patient was talking. Tongue coating, mucosal petechiae or ecchymosis and ulceration were recorded under a torch light illumination. Enamel hypoplasia was noted as diffuse opacities seen on the surface of the teeth.9

Dental Management of Renal Patients: Patients with renal failure require special considerations in relation to dental treatment, not only because of the conditions inherent to the disease and its multiple oral manifestations, but also because of the side effects and characteristics of the treatments they receive.

1. Consultation with the nephrologist provides information on the state of the disease, the type of treatment, the best timing of dental management.10 Any modification of the usual medication used by the patients or of other aspects of their treatment must first be consulted with the nephrologist.11

2. Close cooperation between medical and dental professionals is desirable in order to improve the oral and general health of the patient, based on the creation of a dental care program in the context of a multidiscipline approach to the disease.11

3. Prior to any invasive dental treatment, a complete blood count is to be obtained, together with coagulation tests, in view of the possible hematological alterations.12

4. It is essential to eliminate any infection in the oral cavity as soon as possible, with the consideration of antibiotic prophylaxis when bleeding and/or a risk of septicemia is expected (extractions, periodontal treatments, endodontics and periapical surgery, the placement of orthodontic braces, tartrectomy when bleeding is expected, implant surgery, and the reimplantation of avulsioned teeth).

5. Blood pressure is to be monitored before and during treatment, with the administration of sedation to lessen anxiety.

6. The metabolism and elimination of certain drugs are altered in situations of renal failure

Conclusion

More research in this direction is needed in the future, especially those which concern associated systemic illnesses and CKD and its effects on oral manifestations. Also, other correlating factors such as duration of dialysis, duration of CKD, the medications which are being taken by patients and salivary pH and urea levels have to be evaluated, to properly assess the clinical manifestations

Non-Neoplastic Platal Swellings-Differential Diagnosis

Sangeetha Priya P.,1 N. Aravindha Babu2, E. Rajesh3, N. Anitha3

ABSTRACT

Palatal swellings can at times be a challenging task for a clinician to diagnose. A mass or swelling of the palate can result from developmental, inflammatory, reactive or a neoplastic process. In differential diagnosis, swellings of origin must be considered for diagnosis and treatment. This article reviews various non-neoplastic palatal swellings.

Keywords: palatal swelling, palate, begin, non-neoplastic

Introduction

Palatal swellings may result from a variety of etiological factors, and can originate from the structures within the palate or beyond it. They may be painful when infected or painless as in the case of benign swellings. They may be congenital or acquired in origin. Swellings of congenital origin are associated with unerupted teeth and torus palatinus while acquired conditions resulting in palatal swellings include dental abscess, salivary gland neoplasms, fibro-osseous lesions, fibrous lumps, epithelial and connective tissue neoplasms such as papilloma, squamous cell carcinoma of palate or antrum, brown tumor etc. These swellings can be best examined by inspection and palpation similar with most oral lesions. Radiographs can aid in ruling out pathologies such as abscesses and periapical inflammatory conditions. Routine panoramic radiography can help to discover bony masses arising from the maxilla. As with any lesion, the final diagnosis is achieved after the histological examination; a biopsy must be performed which either will be excisional for a small lesion not thought to be malignant or incisional for a possible malignant lesion or a large lesion. We hereby present a review of the various palatal swellings1,2.

Palatal Torus: The torus palatinus is a common exostosis that occurs in the midline of the vault of the hard palate. The pathogenesis of these tori has long been debated with arguments centering on genetic versus environmental factors, such as masticatory stress.

Most palatal tori are small, measuring less than 2 cm in diameter; however, they can slowly increase in size throughout life—sometimes to the extent that they fill the entire palatal vault. Most tori cause no symptoms, but in some cases the thin overlying mucosa may become ulcerated secondary to trauma. The torus palatinus usually does not appear on routine dental radiographs.
RARELY, IT MAY BE SEEN AS A RADIO-opacity ON PERiapical FILMS if THE FILM IS PLACED BEHIND THE TOrUS WHEN THE RADIograph IS TAKEN. ALMOST ALL STUDIES FROM AROUND THE WORLD HAVE SHOWN A PRONOUNCED FEMALE-TO-MALE RATIO OF 2 : 1. THE PREVALENCE PEAKS DURING EARLY ADULT LIFE.

**Histopathologic Features** of the torus shows a mass of dense, lamellar, cortical bone. An inner zone of trabecular bone sometimes is seen.

**Periapical Abscess:** The accumulation of acute inflammatory cells at the apex of a nonvital tooth is termed a periapical abscess. Acute inflammatory lesions with abscess formation may arise as the initial periapical pathosis or from an acute exacerbation of a chronic periapical inflammatory lesion. Maxillary tooth with periapical abscess may involve the buccal or the palatal aspect. On involving the palatal aspect it should be differentiated and diagnosed with other palatal swellings.

The initial stages produce tenderness of the affected tooth that often is relieved by direct application of pressure. With progression, the pain becomes more intense, often with extreme sensitivity to percussion, extrusion of the tooth, and swelling of the tissues. The offending tooth does not respond to cold or electric pulp testing. Radiographically, abscesses may demonstrate a thickening of the apical periodontal ligament, an ill-defined radiolucency, or both; however, often no appreciable alterations can be detected because insufficient time has occurred for significant bone destruction.

**Histopathologic Features** from pure abscesses are uncommon because the material is in liquid form. Abscesses consist of a sea of polymorphonuclear leukocytes often intermixed with inflammatory exudate, cellular debris, necrotic material, bacterial colonies, or histiocytes. Phoenix abscesses can maintain a soft tissue component; they present as subacutely inflamed periapical granulomas or cysts intermixed with areas of significant abscess formation.

**Fibroepithelial Polyp/Fibrous Hyperplasia:** The epulis fissuratum is a tumorlike hyperplasia of fibrous connective tissue that develops in association with the flange of an ill-fitting complete or partial denture. Typically appears as a single or multiple fold or folds of hyperplastic tissue. There is a pronounced female predilection. This characteristic lesion is a flattened pink mass that is attached to the palate by a narrow stalk. Usually, the flattened mass is closely applied to the palate and sits in a slightly cupped-out depression.

**Histopathologic Features** of the epulis fissuratum reveals hyperplasia of the fibrous connective tissue. Often multiple folds and grooves occur where the denture impinges on the tissue. The overlying epithelium is frequently hyperparakeratotic and demonstrates irregular hyperplasia of the rete ridges. In some instances, the epithelium shows inflammatory papillary hyperplasia or pseudoepitheliomatous hyperplasia. Focal areas of ulceration are not unusual, especially at the base of the grooves between the folds. A variable chronic inflammatory infiltrate is present; sometimes, it may include eosinophils or show lymphoid follicles. If minor salivary glands are included in the specimen, then they usually show chronic sialadenitis.

**Pyogenic Granuloma:** It is an inflammatory hyperplasia which is not uncommon in the oral cavity. Although PG may be seen at any age, the peak incidence is seen in 2nd decade with increased predilection towards the female sex. Anterior gingiva is more commonly affected. PG presents as a solitary smooth or lobulated mass, majority being pedunculated and some sessile. The surface of the lesion is usually ulcerated, friable and covered with white necrotic material resembling pus, because of which the clinicians may have called this lesion as PG. The colour vary according to the age of the lesion, the younger lesions usually appear highly vascular when compared to older ones which appear pink. The diameter of pyogenic granulomas varies from few millimetres to few centimetres.

**Histopathological features** These lesions consist of proliferating endothelial tissue, which is canalised into a rich vascular network with minimal collagen support, presence of polymorphs and chronic inflammatory cells can be appreciated in the edematous stroma along with microabscess formation, mixed inflammatory cell infiltrate of neutrophils are seen near the ulcerated surface, whereas deeper areas show chronic inflammatory cells. Even though the diagnosis of pyogenic granuloma can be accurately done clinically, radiographs and histopathology aid in the confirmation and treatment. Radiographs help to know the underlying bone loss which will rule out peripheral giant cell granuloma, malignancies and other similar appearing conditions.

**Adenomatoid Hyperplasia:** Adenomatoid hyperplasia (AH) is a rare disorder of the minor salivary glands. The true nature of AH is still unknown, and undetermined making it a lesion less explored and hence is the least
considered differential diagnosis. Many believe that it’s a hamartomatous proliferation of minor salivary glands while others consider it as a hyperplastic lesion. Common in the 4th through 6th decades of life with a wide age range. Male preponderance has been noted. Clinically, AH appears as sessile, nodular lesion, most commonly occurring on the palate - hard and soft. The lesion is mostly asymptomatic but occasionally may be painful. AH may vary in size from a few millimeters to larger lesions up to or over 3 centimeters. The lesion may be present for a few months or years but most often is routinely discovered by clinicians. The mucosa over it will be intact and has been said to be of normal color whilst some authors have reported the mucosa to be slightly erythematous or bluish. On palpation, AH will be firm and nontender. Radiographic investigations, often done to rule out erosion of underlying bone, have been routinely done but yielded negative results.

**Histopathological Features:** Under the microscope, the H and E sections show normal salivary acinar lobules, with some showing acinar hyperplasia and dilated ducts with mild chronic inflammatory infiltrate. These help differentiate AH from other benign or malignant salivary pathologies.

**Follicular Lymphoid Hyperplasia:** Follicular Lymphoid Hyperplasia (FLH) of the palate is a poorly understood and very rare non-neoplastic lymphoproliferative disease in the oral mucosa, which may be confused clinically and histologically with malignant lymphoma. The condition most commonly affects elderly women. Usually occurs as a painless, slow growing nonulcerated mass in the posterior hard palate. It is often unilateral but occasionally it may be bilateral or involve a large area of the hard palate. Radiographically, there is no osseous abnormalities, and others laboratory investigations are usually normal.

**Histopatological features** shows lymphoid aggregates in the lamina propria of connective tissue, arranged in structures with discrete lobular appearance, showing numerous lymphocytes in the periphery with scanty cytoplasm and homogeneously basophilic nuclei, forming the mantle zone. In central areas of these lymphocytic formations, germinal centers showed up, showing cells with large and dimly stained nuclei, sometimes revealing conspicuous nucleoli and scanty cytoplasm, tingible-body macrophages and occasional mitotic figures.

**Radicular Cyst:** Radicular cyst is the most common odontogenic cyst which arises from the epithelial cell rests of Malassez in response to inflammation. These cysts can occur in the periapical area of any teeth, at any age but are seldom seen in association with primary teeth. They are most commonly found at the apices of the involved teeth, but sometimes may be seen at the lateral aspects of the roots in relation to lateral accessory root canals. Clinically the cyst appears as a well defined swelling with consistency ranging from hard to soft. RC is usually located in the anterior part of the upper jaw where traumatic injuries are common. The cyst is usually painless and may become painful when secondarily infected. Radiographically most of these cysts presents as a pearshaped or round unilocular radiolucent lesions in the periapical region of the involved tooth. Radiographically, it is difficult to distinguish between a granuloma and a cyst. Aspiration of the swelling helps in differentiating between a cystic and solid lesion.

**Histopathologic features:** The cyst is lined by stratified squamous epithelium, which may demonstrate exocytosis, spongiosis, or hyperplasia. As seen in dentigerous cysts, scattered mucous cells or areas of ciliated pseudostratified columnar epithelium may be noted in periapical cysts. Although some maxillary periapical cysts lined by pseudostratified columnar epithelium may have originated from the adjacent sinus lining, the presence of mucous cells or respiratory-like epithelium. The cyst lumen may be filled with fluid and cellular debris. Dystrophic calcification, cholesterol clefts with multinucleated giant cells, red blood cells, and areas of hemosiderin pigmentation may be present in the lumen, wall, or both. Due to the inability of macrophages and giant cells to remove cholesterol, its presence may be partially responsible for failure of healing of cysts in which the original focus of infection was treated appropriately.

**Dentigerous Cyst:** The dentigerous cyst is defined as a cyst that originates by the separation of the follicle from around the crown of an unerupted tooth. This is the most common type of developmental odontogenic cyst, making up about 20% of all epithelium-lined cysts of the jaws. The dentigerous cyst encloses the crown of an unerupted tooth and is attached to the tooth at the cementoenamel junction. Most often they involve
mandibular third molars. Dentigerous cysts may be encountered in patients across a wide age range, they are discovered most frequently in patients between 10 and 30 years of age. There is a slight male predilection. Radiographically, the dentigerous cyst typically shows a unilocular radiolucent area that is associated with the crown of an unerupted tooth. The radiolucency usually has a well-defined and often corticated border, but an infected cyst may show ill-defined borders.

**Histopathologic Features** of dentigerous cysts shows the fibrous connective tissue wall is loosely arranged and contains considerable glycosaminoglycan ground substance. Small islands or cords of inactive-appearing odontogenic epithelial rests may be present in the fibrous wall. Occasionally these rests may be numerous, and at times pathologists who are not familiar with oral lesions have misinterpreted this finding as ameloblastoma. The epithelial lining consists of two to four layers of flattened nonkeratinizing cells, and the epithelium and connective tissue interface is flat. In inflamed dentigerous cyst, the fibrous wall is more collagenized, with a variable infiltration of chronic inflammatory cells. The epithelial lining may show varying amounts of hyperplasia with the development of rete ridges and more definite squamous features. A keratinized surface is sometimes seen, but these changes must be differentiated from those observed in the OKC3,4.

**Nasopalatine Cyst:** Nasopalatine cyst (NPC) or Nasopalatine canal cyst or Median anterior maxillary cyst occurs in 1% of population, usually seen from 4th to 6th decades with 3:1, male to female ratio and shows predilection. The cyst is often asymptomatic unless they are infected. Sometimes minor tolerable symptoms such as swelling, burning sensation, numbness over palatal mucosa and discharge may be present. A combination of swelling, discharge and pain may be seen. Discharge may be mucoid, in which case the patients feel a salty taste. This tumor presents as a slow growing, firm painless mass. Its MRI is an essential tool for the imaging of soft palate tumors as it aids in determining the extent and nature of the lesion, local spread and also the neoplastic status.

**Histopathologically feature,** a mixture of neoplastic glandular epithelium and myoepithelial cells are seen in this tumor. Along with this a variety of patterns may also be seen1.

**Odontogenic Keratocyst:** The OKC arises from cell rests of the dental lamina. This cyst shows a different growth mechanism and biologic behavior from the more common dentigerous cyst and radicular cyst. OKCs may be found in patients who range in age from infancy to old age, but about 60% of all cases are diagnosed in people between 10 and 40 years of age. There is a slight male predilection. Mandible is the most common site of incidence, but can also occur in maxilla which include 13% in the anterior region, 2% in the premolar region and 20% in the posterior region. Small OKCs are usually asymptomatic and discovered only during the course of a radiographic examination.

**Histopathological features** Microscopically, the thin fibrous wall is usually devoid of significant inflammation. The epithelial lining is composed of a uniform layer of stratified squamous epithelium, usually six to eight cells in thickness. The epithelium and connective tissue interface is usually flat, and rete ridge formation is inconspicuous. Detachment of portions of the cyst-lining epithelium from the fibrous wall is commonly observed. The luminal surface shows flattened parakeratotic epithelial cells, which exhibit a wavy or corrugated appearance. The basal epithelial layer is composed of a palisaded layer of cuboidal or columnar epithelial cells, which are often hyperchromatic. Small satellite cysts, cords, or islands of odontogenic epithelium may be seen within the fibrous wall. These structures have been present in 7% to 26% of cases in various reported series3,12.

**Conclusion**

It is well understood that the palatal mass can pose a difficult diagnostic dilemma for the clinician. The swelling may present with the common characteristics and may be indistinguishable clinically. Emphasis is placed on the importance of obtaining a thorough and comprehensive history and collecting relevant laboratory information. Finally, a biopsy of the palatal mass may be necessary to arrive at definitive diagnosis and determine the optimal management of the patient.

Dental Consideration and Diagnosis of TMJ Arthritis—
A Curren Review

Sangeetha Priya P.1, N. Aravindha Babu2, E. Rajesh3, L. Malathy3

1Post Graduate Student, 2Professor, 3Reader, Department of Oral Pathology and Microbiology, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research

ABSTRACT

TMJ is a unique joint in which translatory as well as rotational movements are possible and where both the ends of bone articulate, in the same plane, with that of other bone. It is a hinge that connect the jaw to the temporal bones of the skull, which are in front of each ear. Temperomandibular joint (TMJ) diseases and disorders are refered to a complex and less understood set of conditions, and disorders of TMJ are manifested by pain in the area of the jaw and associated muscles, and limitations in the ability to make the normal movements of speech, facial expression, eating, chewing, and swallowing. Among the various disorders of TMJ this article is focused on a brief review on TMJ Arthritis.

Keywords: TMJ, Arthritis, Disorder, TMJ pain.

Introduction

According to the medical definition arthritis is defined as the inflammation of a joint. When joints are inflamed they develop stiffness, warmth, swelling, redness and pain. There are over 100 types of arthritis. Out of which TMJ arthritis is a common disease that can cause severe pain and dysfunction in temporomandibular joint (TMJ). TMJ arthritis can occur as a separate finding of a patient or can be associated with any other arthritis affecting the body. And according to Weldon Bell classification TMJ arthritis or osteoarthritis of TMJ is been classified under degenerative join disorder with inflammation. It is primarily a disorder of movable joints characterized by deterioration and abrasion of the articular cartilage with formation of new bone at the joint surface. There is destruction of the soft tissue component of the joint and subsequent erosion with hypertrophic changes in bone. There is breakdown of the connective tissue covering the condyle, articular eminence and the disc. Recently, there are some evidences suggesting that there are some inflammatory components present in osteoarthritis1,2,3.

Anatomy: In order to understand the etiopathogenesis of the disease, the anatomy of the tempromandibular joint has to be viewed. The TMJ is located between the mandibular fossa (glenoid fossa), the inferior surface of temporal bone and condylar process of the mandible. It is a synovial type of joint and it is distinguished from most of the joints by following points.

- Fibrocartilage—articulating surface of the bones is covered by avascular, fibrous connective tissue, which may contain variable number of cartilage cells. Thus called as fibrocartilage.
- Point of closure—the two articulating surface complex of bone carry teeth, whose shape and position influence the movement of joint. It is the only joint with rigid end point of closure.
- Articulation—it has bilateral articulation with cranium, so both the joints must function together. TMJ is a complex joint as it has an articular disc interposed between the condyle and the temporal bone.
Articular Disc: It is composed of dense fibrous connective tissue devoid of any blood vessels or nerve fibers. The central area is the thinnest and is called as intermediate zone. Both anterior and posterior to the intermediate zone, the disc becomes considerably thicker. The posterior border is generally slightly thicker than the anterior border. The disc is generally thicker medially than laterally. The precise shape of the disc is determined by the morphology of the condyle and mandibular fossa.

During movement, the disc is somewhat flexible and can adapt to the functional demands of the articular surface. The articular disc is attached posteriorly to an area of loose connective tissue that is highly vascularized and innervated it is called as retrodiscal tissue. Superiorly, it is bordered by the lamina of connective tissue, which contains many elastic fibers, the superior retrodiscal lamina. This gives necessary freedom for anterior movement of the disc. Since this region consists of two areas, it is called as bilaminar zone.

Attachment of the Articular Disc and its Associated Structures: The articular disc is attached to the capsular ligament anteriorly, posteriorly as well as medially and laterally. This divides the joint into two distinct cavities; the upper or superior cavity which is bordered by the mandibular fossa and superior surface of the disc and the lower or inferior cavity, which is bordered by the mandibular condyle and inferior surface of the disc.

Synovial Fluid: The internal surface of the cavity is surrounded by specialized endothelial cells that form the synovial lining. This lining along with a specialized synovial lining located at the anterior border of the retrodiscal tissue produce the synovial fluid, which fills both the joint cavities. The synovial fluid is formed of viscous fluid, (plasma, protein and mucin), containing varying types of cells (monocyte, lymphocytes, sometimes multi-nuclear leukocytes and macrophage). The main function of the synovial fluid is to provide lubrication to joint surface thereby reducing the wear during joint function and to provide nutrition to disc and the articular surfaces. Thus, TMJ is referred to as a synovial joint.

Etiopathogenesis: The etiology to this disorder can be of three major causes:

1. Overload on the joint: The lesion is brought by an increase in the functional demands of the healthy tissue due to repetitive overload on joint. This will result in breakdown of the joint. The articular surface is covered by fibrocartilage and the underlying subchondral bone which is stress sensitive and subject to extensive remodeling.

Excessive mechanical stress is characterized as a key factor inducing cartilage degradation in the TMJ (Tanaka et al. 2008).

Recent studies have focused on the molecular pathway of articular cartilage degradation and mechanical sensing. The effect of mechanical stress on the mandibular condylar chondrocytes has been evaluated in vitro and in vivo. Excessive mechanical stress induces activation of the plasminogen activator (PA) system, which may lead to proteolysis of extracellular matrix components (Chen W et al. 2013). Long-term experimental disordered occlusion also results in subchondral bone loss and increased osteoclast activation, and the new bone subsequently formed exhibits lower bone mineral density and poor mechanical properties (Zhang J et al. 2013). Other research reported that endoplasmic reticulum stress-induced cell death has an important role in the mandibular cartilage thinning induced by mechanical stress and may be a novel mechanism of chondrocyte apoptosis induced by mechanical force (Li et al. 2013). Excessive joint loading and abnormal dental occlusion have been used to establish TMJOA models (Jiao et al. 2011). Considerable evidence exists that aberrant biomechanical stimulation possesses an important function in the initiation and progression of TMJOA.

2. Deterioration of functional capacity of joint: There may be normal load to the joint but functional capacity is reduced as a part of aging. This occurs due to:

- Slower replacement of chondroblasts—as age advances there is slower replacement of chondroblasts and chondrocytes in the joint.
- Susceptible fibers—the cartilage matrix turns over less rapidly resulting in available fibers to work for longer period of time. This will make them susceptible to fatigue.
- Poor nutrition to joint—as matrix contain less water, the marrow blood flow diminished
which results in poor nutrition to the joint. This will make joint desiccated and brittle⁸⁻¹⁰.

3. Abnormal Remodeling of Subchondral Bone:
By another theory, bone growth does not cease completely after puberty and remodeling of the joint progresses under functional demands. Degenerative joint disease may develop when the remodeling rate of bone exceeds that of the cartilaginous repair. The gross evidence of these changes is the formation of marginal osteophytes with development of new bone in the area adjacent to the cartilage. Studies suggest that increased turnover of subchondral bone plays a role in the initiation or progression of TMJ arthritis. In the TMJ arthritis induced by orthodontic disturbed dental occlusion, subchondral bone loss and decreased bone mineral density were observed following degradation of the cartilage. The chondrocytes within the degraded cartilage may regulate osteoclastogenesis by increasing the ratio of the receptor activator of nuclear factor (NF)–κB ligand (RANKL) and osteoprotegerin (OPG) and ultimately result in subchondral bone loss in TMJ arthritis (Jiao et al. 2011)¹¹.

4. Inflammation: TMJ arthritis is classified as a “low-inflammatory arthritic condition,” as opposed to rheumatoid arthritis, which is classified as a high-inflammatory condition (de Souza et al. 2012). However, considerable attention has been on the importance of inflammation in the progression of TMJ arthritis. Interleukin (IL)–12 and several other inflammatory cytokines, including IL-1β, IL-6, and tumor necrosis factor (TNF)–α, are increased in the synovial fluid of patients with TMJOA (Vernal et al. 2008; Cevridanes et al. 2014). Monocyte chemoattractant protein (MCP)–1 is also elevated in the inflamed synovial tissues and fluids of patients with OA and is highly upregulated in IL-1β–stimulated synoviocytes of the TMJ (Ogura et al. 2010). MCP-1 is speculated to play an important role in recruiting mononuclear cells to inflamed synovial tissues. Expression of IL-1β and TNF-α is reported to be increased in the experimental chronic inflammation of rodent TMJs, implying that they can be one of the causes for the degenerative changes of TMJ; moreover, the biomechanical property of the disc is decreased (Wang et al. 2014), implying that chronic inflammation in TMJ deteriorates the adaptive capability of the TMJ.

The other possible etiology of TMJ arthritis could be:
- **Chondrocyte apoptosis:** Chondrocyte death caused either by apoptosis or necrosis is assumed to be a central feature in the degeneration of osteoarthritic cartilage.
- **Catabolic Enzyme:** The upregulation of catabolic enzymes in the cartilage matrix, such as MMP and a disintegrin and metalloproteinase with thrombospondin motifs (ADAMTS), is involved in the pathology of TMJ arthritis.
- **Estrogen:** TMJ arthritis has a female preponderance and occurs mainly after puberty during the reproductive years (Zhao et al. 2011), suggesting a possible function of female hormones in the disease process. Therefore, the effects of estrogen on condylar cartilage and subchondral bone have been evaluated. Conversion of estrone/17β-estradiol to proinflammatory metabolites can be found in Osteoarthrisis synovial cells of the knee joint; this finding implies that proinflammatory metabolites in synoviocytes may be an important mechanism underlying the proinflammatory effects of estradiol in the inflamed TMJ (Schmidt et al. 2009). Estrogen inhibits the mandibular condylar chondrocyte proliferation via an estrogen receptor (ER)-β–dependent mechanism (Chen et al. 2014). By contrast, estrogen possesses a protective effect on the TMJ chondrocyte through inhibiting the expression of nitric oxide (Hu et al. 2013). Therefore, the role of estrogen in TMJ arthritis pathogenesis is still inconclusive. Moreover, the effects of other female hormones, including progestin and relaxin, on the progression of cartilage degradation in the TMJ should be evaluated further¹²⁻¹⁵.

Clinical Features: Age and sex—it occurs in patients older than 40 years of age and 85% of them are older than 70, with a mean age of 53 years. Females are affected 6 times as frequently as males.
- **Symptoms**—there is unilateral pain over the joint, which may be sensitive to palpation. Patient also experience pain on movements or biting, which
may limit mandibular function. Pain usually worse in the evening.

- Signs—there is deviation of the jaw towards the affected side. Affected joint is swollen and warm to touch. Stiffness of the joint.
- Crepitations—there is presence of crepitation of the joint, the sound indicates degeneration within the articulating surfaces of the joint or disc.
- Jaw movement—there is limitation of jaw movements, which becomes increasingly apparent with function. Pain is usually located to the immediate preauricular region.
- Spasm of muscle—early signs may progress to spasm of the masticatory muscles resulting in stiffness and locking of the jaw. If not treated at this stage, it may lead to irreversible changes in the TMJ.
- Course—normal course is between 1 to 3 years. Severe symptoms last for about nine months, but gradually burn out leaving little or no disability.

Radiographic Findings: Degenerative changes located on the lateral and anterolateral wall of the fossa. Erosion of condyle is the first evidence on a radiograph which occurs on an average, 6 months after the onset of TMJ pain. This will result in enlargement and shallowing of mandibular fossa. Fully developed lesions are saucer shaped on PA view. This is also called as the destructive phase. During the later stages articula eminence is flattened or almost removed and anterior half of the superior convex surface of the condyle is converted into a flat plane.

Management: Elimination of the cause—it includes occlusal adjustment or replacement of the missing teeth and ill fitting prosthesis, grinding, treatment of caries and periodontal disease.

- Relieving the pressure on joint—occlusal adjustment and occlusal splints may reduce pressure on joint and relieve the symptoms.
- Analgesic and anti-inflammatory drugs—for the relief of pain, nonsteroidal anti-inflammatory drugs and analgesics should be given.
- Physiotherapy—heat therapy, diathermy and ultrasonic.
- Myotherapy—muscle exercises, injection of local anesthetic in TMJ.
- Arthroscopic lavage—arthroscopic lavage may give relief in some patients.
- Doxycycline—nowadays, low dose doxycycline (collaganease inhibitor, anti matrix metalloproteinase) is giving relief in many patients.
- Other therapy—glucosamine, chondroitin sulfate have also shown some success in osteoarthritis of TMJ.

Conclusion

Most cases can be successfully treated, although initially it may be difficult to diagnose the problem and find an effective solution. Some cases of pain go away on their own, without treatment. The TMJ-related pain tends to be cyclical and may return again in the future. If the cause is night-time clenching, treatment can be particularly tricky because it is a sleeping behavior and that is hard to control. Patients with ear symptomatology tend to have a prolonged course of illness. Known complications of long standing TMJ dysfunction include alterations in dentition, chronic facial pain and malocclusion. The establishment of a multidisciplinary pain team can assist the practitioners in reducing such complications.

Dental Materials and its Allergic Reactions in Dentistry—
A Review

A. M. Sherene Christina Roshini¹, N. Aravindha Babu², R. Jayasri Krupaa³, K. M. K. Masthan⁴

¹Post Graduate Student, ²Professor, ³Reader, ⁴Professor and Head of the Department, Department of Oral pathology and Microbiology, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research

ABSTRACT

Various dental materials used in dentistry has a potentiality to cause allergic reaction of oral cavity in patients. Certain materials can cause allergic reaction to dentists and technicians. The most common allergic reactions seen in dentists and other dental staffs are allergies to latex, acrylates and formaldehyde. While polymethylmethacrylates and latex trigger delayed hypersensitivity reactions, sodium metabisulphite and nickel cause immediate reactions. Dentists should have proper knowledge about the allergic reactions to dental materials in patients because over the last few years there is a rise in number of patients. Dental materials are suspected to have biocompatibility problems. The materials are composites, latex gloves, local anaesthetic agents, endodontic materials, impression materials and metals. In order to manage the allergic condition, clinician should know about the documented allergic reactions so that they can frame the treatment plan accordingly.

Keywords: Allergic reaction, hypersensitivity, lichenoid reaction.

Introduction

General population are more exposed to allergic reactions now a days. and the dental materials used for restoration, orthodontic instruments etc should provide biocompatibility specifications because they are used for a long time in the oral cavity. Dental metal allergy occurred due to amalgam restorations in the oral cavity which results in stomatitis and dermatitis around the anus (Fleischmann 1928). Manifestations of allergic reaction are in the form of urticaria, swelling, rash and rhinorrhea, where it can also cause laryngeal oedema, anaphylaxis and cardiac arrhythmias which is a life threatening condition. Contact allergy of the oral cavity is a T-cell-mediated (delayed) hypersensitivity reaction. The clinical manifestations differs from burning, pain and dryness of mucosa to nonspecific stomatitis and cheilitis. Certain dental materials are suspected with biocompatibility problems. They are composites, latex gloves, local anaesthetic agents, endodontic materials, impression materials and metals. Currently, due to globalization, liberalization and modernization of dentistry various materials are used for treatment. Hence, the aim of this review article is

- To promote a good evaluation and to monitor the spread of allergic reaction to dental materials
- To create awareness about the incidence of allergy among dentist; thereby progression of allergies can be prevented by recognising it earlier.

Allergy to Resin Materials Composites: During restoration, maximum exposure of formethyl methacrylate (MMA), 2-hydroxyethyl methacrylate (HEMA), ethylene glycol dimethacrylate (EGDMA), and triethylene glycol dimethacrylate (TEG-DMA) is
observed 4. Methacrylates commonly causes contact dermatitis and asthma to dental personnel. Occupational contact allergies are caused due to HEMA, EGDMA and TEG-DMA. Most of the patients have lichenoid-like reactions of lips due to composite components. These patients can be treated by providing antifungal treatment and replacing the existing restoration 5. Although resin-based restorative materials are safe to use, their composition can leach out and cause allergic contact stomatitis in the gingiva and buccal mucosa 6,7. Fisher discovered that MMA monomer is the most commonest causative agent for allergic dermatitis in dentists and dental personnel 8. Percentage of contact allergy to methyl methacrylate is 1% 9,10. Leachable substances from acrylic dentures can be reduced by different methods such as immersing in hot water (50°C) for one hour before inserting into the oral cavity 11 or ultraviolet light 12. In order to reduce the exposure of MMA to patient and dentist, optimum room ventilation is provided. Mucosal irritation can be caused due to overnight denture wear. In order to prevent this condition, patient is instructed to avoid usage of denture at night. 13.

Fissure Sealant: Hallstrom U reported an isolated case, where after fissure sealant placement adverse reactions such as asthma and urticaria were observed and the symptoms disappeared after its removal, Hence suggestive of allergy 14.

Allergy to Amalgam Restoration: Amalgam restorations causes delayed hypersensitivity reactions which are seen as erythematous, pruritic lesions on the oral mucosa and skin of the face and neck. Oral lichenoid lesions (OLL) is the commonest manifestation of this reaction. 15 Burning mouth syndrome (BMS) is another manifestation of mercury allergy. Patch test is performed for identifying BMS in patients, remission can be achieved after replacing mercury restoration. 16 Collecting patient’s complete history of complaint and clinical course is the first step in recognizing allergy induced disease. In 1976, the Council on Dental materials and devices advised to use conventional amalgam condensers instead of ultrasonic amalgam condensers. 17 Mercury vapor production can be avoided by using air conditioners, proper ventilation of the operating rooms and proper handling of amalgam scraps under sulphide solution 18.

Allergy to Nickel-Chromium: Among all metals, Nickel is the common sensitizer 19. It was one of the cause of allergic contact dermatitis in women by Fisher 20. In 1889, Goldman reported the first case of Nickel dermatitis which was characterised by sensitivity to nickel compounds 21. The percentage of nickel allergy is 0.1-0.2% 22. Nickel sensitivity is common in women (4-10 times) than men 23 whereas chromium allergy is rare and is common in men than women (10% in males and 3% in females) 24.

Clinical signs and symptoms of nickel allergy:
- Burning sensation,
- Gingival hyperplasia,
- Numbness on sides of tongue and finally it is confirmed with the help of patch test using 5% nickel sulphate in petroleum jelly 25.

Systemic allergic contact dermatitis is observed in sensitized individuals when they are exposed to nickel 26. If nickel hypersensitivity is diagnosed, then the Ni-Ti arch wire must be replaced with stainless steel wire or titanium molybdenum alloy (TMA) 27. Usually orthodontic treatment with stainless steel appliances does not causes hypersensitivity reaction 28. Non-nickel containing orthodontic brackets include ceramic brackets, polycarbonate brackets and gold brackets are used commonly 29. In children who were treated with old generation SSCs (72% nickel), nickel sensitivity was observed. When this condition was treated by replacing old SSCs with new generation SSC (9-12% nickel) no sensitivity was seen. 28 Invitro nickel leaching from orthodontic materials, space maintainers and arch wires is maximum within the first week and then it decreases 29. Nickel allergy is frequently associated with chromium and cobalt reactivity 30.

Allergy to Titanium: Prevalence rate of Titanium allergy is 0.6% and it has symptoms such as urticaria, eczema, redness of the mucosa. 31 In patients with titanium implants, certain titanium allergic symptoms are observed. They are de-keratinized hyperplastic reactions of the peri-implant tissues and drug rash with eosinophilia and systemic symptoms (DRESS) syndrome. 32 Elements in titanium alloys such as beryllium (Be), cobalt (Co), chromium (Cr) can cause allergic reactions in dental implant patients 33. Patch tests have limited use due to poor sensitivity 34 and the test used to detect titanium sensitization is MELISA test 35. Alternate substances s like Polymethaetherketone (PEEK) which gives mechanical properties and bone forming capacity same as that of titanium are also under investigation. 36
Allergy to Latex Gloves: In 1979, Nutter reported first case of latex allergy. Latex allergy includes children with spina bifida (highest risk), patients who underwent surgery before one year of age, latex-fruit syndrome (allergy to various fruits) and healthcare workers (second highest risk) (Kean T) who have greater risk of latex allergy due to sweating and multiple glove changing. In general population, prevalence of latex allergy is less than 1%. Blinkhorn and Leggate reported a case of angioneurotic edema due to dental rubber dam in a boy. Three cases of patients with delayed hypersensitivity to rubber were described by Smart et al.

For diagnosing latex allergy, there is no test which is 100% accurate. Diagnostic methods are:

- Obtaining medical history,
- Skin patch testing for type IV delayed hypersensitivity,
- Measurement of serum IgE for type I immediate hypersensitivity and
- Glove testing when there is no correlation between patient’s history and IgE results.

The American society of Anaesthesiologists Task Force of Latex Sensitivity recommends patients with latex allergy should undergo surgical procedures in the morning. As directed by FDA, protein levels of gloves should be mentioned on package labels by the manufacturers of NRL gloves as directed by FDA.

Allergy to Local Anaesthetics: Even though LA is a well-tolerated drug, they have adverse reactions. Adverse reactions to lignocaine, prilocaine, mepivacaine or to their components like methylparaben or metabisulphite were reported. Allergic reactions can be caused by psychogenic or intravascular injections. Sensitization reactions are attributed to ester anaesthetics which is one of the breakdown products is the antigenic agent p-aminobenzoic acid. Allergic reactions are reported by local anaesthetics including esters and amides. Syncope is the most commonest adverse reaction of LA. Distinguishing true anaphylaxis from other causes of cardiovascular collapse is important. Hence, anaphylactic nature of these reactions can be confirmed by the serum-mast cell tryptase test.

Skin test helps in identifying true allergy to LA but if the skin reaction is not clear, challenge test is carried out where patient is given subcutaneous injection with graded doses of LA till the therapeutic dose. Three cases of death were reported in a literature, where one with prilocaine combined with felypressin; another with lignocaine alone and third with prilocaine combined with adrenaline. LA may be considered as a factor in these cases. Immediate treatment and active prevention are the treatment plan for adverse reactions with LA. By slowly injecting the aspirating syringe, fear and anxiety can be ruled out.

Conclusion

Since oral cavity is frequently exposed to sensitizing substances, allergic reactions are caused which in turn contributes a rise in healthcare expenditures annually. Allergies to latex, acrylates and formaldehyde are common in dental staff. When polymethylmethacrylates and latex trigger delayed hypersensitivity reactions, sodium metabisulphite and nickel leads to immediate reactions. In order to establish a diagnosis, proper allergic history, clinical examination and confirmatory tests like patch tests and MELISA must be obtained from the patient. Hence dentists should be aware about the allergic reactions to prevent the patient from allergic manifestations in dental clinic since more patients have allergies to different dental materials.

Drug Induced Mucosal Disorders—A Review

A. M. Sherene Christina Roshini¹, N. Aravindha Babu², R. JayasriKrupaa³, K. M. K. Masthan⁴

¹Post Graduate Student, ²Professor, ³Reader, ⁴Professor and Head of the Department, Department of Oral Pathology and Microbiology, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research

ABSTRACT

Generally, drug induced reactions are more commonly seen in population. Certain drugs have the capacity to cause pathologic reactions in the oral and perioral region. Drug induced diseases can help the clinician to determine the relationship with a particular group of drugs. The underlying mechanism is unknown but the final outcome of the disease can be predicted by pharmacodynamics and/or pharmacokinetics. Xerostomia, Swelling, Dysguesia, Nonspecific Ulceration, Vesiculobullous or ulcerative mucositis, pigmentation of mucosa, Gingival enlargement, oral malodour, taste alterations, discoloration of teeth are the clinical presentation of drug induced reaction. This review article gives a brief description about the diseases caused by drugs, so that dentists can update their knowledge for a better diagnosis and treatment.

Keywords: Adverse drug reactions, Drug induced xerostomia, Salivary gland diseases.

Introduction

Patients who intake several drugs for systemic factors may have oral diseases. WHO defined an adverse drug reaction as “a response to a drug which is noxious and unintended, and which occurs at doses normally used in man for the prophylaxis, diagnosis, therapy of diseases or for the modification of physiological function”. Recently, different patterns of diseases have been identified and this can help a clinician to determine a possible cause and adverse reactions of a particular or group of medications. Dentists should take a thorough medical history and should be aware of the problems related to medications and its effects in oral cavity since majority of the population are consuming prescribed and non prescribed medications. This should be done because drugs has its own potential effects on diagnosis and treatment plan ²⁻⁴.

Salivary Gland Disorder: Variety of drugs may affect the function of salivary gland, which may lead to xerostomia, ptyalism, Salivary gland pain and discolouration of saliva.

I. Xerostomia: Diminished secretion of saliva and decreased calcium phosphate concentration in saliva leads to dryness of mouth or Xerostomia. It was found that more than 250 medications claim xerostomia as an adverse effect. Xerostomia can occur in patients with an underlying autoimmune etiology (eg. Sjogren Syndrome) especially to those who also present with Xerophthalmia or evidence of parotid gland swelling. Oral manifestations of reduced salivary flow are increased dental caries, fungal infections, bacterial infections, aphthous lesions, and dysphagia. Drug induced Xerostomia can be managed by Pilocarpine and Bethanechol ⁵.

II. Ptyalism: Increased salivary flow leads to Ptyalism or sialorrhoea. Physiological factors such as menstruation or early pregnancy, local factors such as teething, oral inflammatory lesions, food, medication, or by nasogastric intubation causes salivary hypersecretion ¹¹. Ptyalism can also be caused by heavy metal toxins (mercury and thallium), from exposure to irreversible
acetylcholinesterase inhibitors (insecticides and nerve agents) and by a few other drugs such as yohimbine, mucosa irritanting antibiotics.12

III. Salivary Gland Pain: Salivary gland pain can be caused by antihypertensives, anti-thyroid agents, chlorhexidine, cytotoxics, ganglion-blocking agents, iodides, phenothiazines, and sulphonamides13. Salivary gland pain is rarely associated with guanethidine or guanacline. Drugs which causes salivary gland pain and swelling are Bethanidine, Bretylium, Catecholamine inhalation, Cimetidine, Clonidine, Clozapine, Deoxycycline6-10

IV. Discolouration of Saliva: Discoloration of saliva and other body fluids into red or orange colour are noticed in patients who are treated with clofazimine, levodopa, rifampicin, and rifabutin therapy14.

Oral ulceration: Ulceration in the oral epithelium exposes the nerve endings to the underlying lamina propria, which results in pain or soreness specifically while eating spicy foods or citrus fruits. Oral Ulcers are Inflammatory lesions of the oral mucosa that affect approximately 20% of thepopulation.15 Immunological alterations, infections, nutritional deficiencies, repetitive trauma to the mucosa, food and contact allergies, autoimmune diseases and neoplasms, as well as psychosomatic, genetic and environmental factors are the numerous factors that causes ulceration.16

1. Nonspecific Ulceration: As a result of direct application of drugs like aspirin, hydrogen peroxide, potassium tablets, and phenol containing compounds oral ulceration can be caused. The affected mucosa seems to be whitish and corrugated, with erosion and ulceration of the damaged areas.20

2. Aphthous Ulceration: Aphthous ulcers are the ulcers which resemble recurrent aphthous stomatitis. There are certain examples, they are: Behcet’s syndrome, gastrointestinal diseases, such as gluten-sensitive enteropathy or inflammatory bowel disease, immunodeficiency syndromes such as infection with HIV, cyclic neutropenia and adverse reactions to medications.21 A number of drug are implicated in the development of nonspecific ulceration and oral mucositis, and the lesions are often associated with an equally nonspecific histologic appearance at biopsy. These include barbiturates, beta-blockers, dapsone, NSAIDs, phenazone derivatives, thiazide derivatives, phenolphthalein, sulfonamides, tetracyclines, and sirolimus.22

3. Fixed Drug Eruptions: Initially it appear as edematous areas and erythema that promotes localized, nonspecific ulceration. Most frequently it involves labial mucosa and a clinical course of recurrence at the same location after drug use is diagnostically helpful, but this relationship is not always easy to establish. A number of drugs are involved in the development of nonspecific ulceration and oral mucositis, and the lesions are often associated with an equally nonspecific histologic appearance at biopsy. These include barbiturates, beta-blockers, dapsone, NSAIDs, phenazone derivatives, thiazide derivatives, phenolphthalein, sulfonamides, and tetracyclines.23

4. Mucositis: In Oral mucositis and ulceration, chemotherapy regimens plays an important role particularly those involving methotrexate, 5fluorouracil, doxorubicine, melphelan, mercaptopurine, or bleomycin.24 Within days of commencement of therapy, sloughing and ulceration arises with associated pain which often requires opioid therapy & alteration or cessation of chemotherapy.

5. Pemphigoid Like Reactions: Pemphigoid like reactions can be restricted to the oral mucosa, or they can affect other mucosal or cutaneous sites. Lesions appear as relatively sturdy vesicles or bullae, clinically that break down into shallow ulceration. Thiolcontaining drugs and sulfonamide derivatives are among the most commonly involved medications, as are the therapeutic classes of NSAIDs, cardiovascular agents, antimicrobials, and antirheumatics.25 In drug induced pemphigoid particularly penicillamine-induced disease, oral mucosa is commonly affected.

6. Pemphigus: Although pemphigus foliaceous is uncommon in the oral cavity Pemphigus like reactions may have features of neither Pemphigus vulgaris nor Pemphigus foliaceous. Drugs which
are capable of promoting pemphigus are divided into two main groups according to their chemical structure. They are drugs containing a sulphydryl radical (thiol drugs or SH drugs) and non-thiol. Pemphigus vulgaris may occasionally be combined with drugs active thiol groups in the molecule. Drugs implicated are penicillamine, phenol drugs, rifampicin, diclofenac, and other ACEinhibitors.

7. Lupiod Reactions: Wide variety of different drugs induces systemic lupus erythematosus (SLE). Over 70 agents have been involved in causing drug-induced lupus. They are procainamide and hydralazine, although drugs less commonly associated include chlorpromazine, isoniazid, methyl dopa, penicillamine, and quinine, as well as whole groups of drugs such as anticonvulsants, beta-blockers, sulphonamides.

8. Erythema Multiforme: Drug induced Erythema multiforme is commonly associated to agents such as barbiturates, cephalosporins, NSAIDs, estrogens, phenothiazines, progestogens, protease inhibitors, sulphonamides, sulphonylurea derivatives, and tetracyclines—may give rise to erythema multiforme, and it may be a challenge clinically to differentiate drug-induced erythema multiforme from disease due to other causes.

Oral Malodour: Oral Malodour or Halitosis is bad breath resulting from poor oral hygiene, dental or oral infections, ingestion of certain foods, use of tobacco, and some systemic disease and medications. Drugs which induces xerostomia, may indirectly cause or aggravate this problem, but other drugs, such as isosorbide dinitrate, dimethyl sulphoxide, or disulfiram, can directly cause halitosis.

White Lesions

Lichenoid Reactions: Lichen planus is a chronic systemic disease of the established immune mediated pathogenesis. It is usually a persistent disorder and may persist for many years inspite of several treatment strategies. Certain drugs can promote oral disorders resembling lichen planus and hence they are termed as oral lichenoid drug reactions. After drug withdrawal Oral lichenoid reactions which is an uncommon condition disappears. A characteristic white lace pattern is observed. Lichenoid reactions follows the use of HIV protease inhibitors, antihypertensive agents, antimalarials, phenothiazines, sulphonamides, tetracyclines, thiazide diuretics, and many others.

Oral Candidiasis: Oral Candidiasis is the most common opportunistic infection seen in dental practices. Clinically it appears as creamy, white plaques on the tongue and buccal mucosa, when it is scraped it leaves a red, painful ulcerated surface. Pseudomembranous candidiasis occurs secondary to therapy with broad-spectrum antibiotics, corticosteroids - systemic and inhaler preparations, and other immunosuppressive regimens (e.g., ciclosporin) and cytotoxic therapy.

Black Hairy Tongue (Lingua villosanigra): An elongation of filliform papillae of the tongue to form hair like growth which becomes stained brown or black due to the proliferation of chromogenic microorganisms. This condition is known as Black hairy tongue. On administration of oral antibiotics, poor oral hygiene and excessive smoking in adults this condition can be observed.

Taste Alteration: Individual under various medications may present with subjective complaints of taste changes. Many drugs are associated with taste alteration, which manifests as hypoguesia (decreased taste), dysguesia (distortion of the correct taste), aguesia (no taste). ACE inhibitors, anti-thyroids, beta-lactam antibiotics, biguanides, chlorhexidine, opiates, and protease inhibitors are particularly implicated. Certain patients treated with ACE inhibitors may have dysgeusia, although this adverse effect is self-limiting and reversible within a few months, even with continued therapy. There are newer therapies such as the anti-HIV protease inhibitors, therapy with tripotassiumdicitrato bismuthate chelate, clarithromycin, and lansoprazole therapy for H. pylori infection, terbinafine, intravenous pentamidine, and isotretinoin.

Mucosal Pigmentation: Oral discoloration may be superficial or deep. Superficial discolouration can be due to extrinsic causes and deep discolouration can be due to intrinsic causes.

Extrinsic discolouration is usually caused by habits such as:

- Use of tobacco or betel nut
Intake of coloured foods or beverages
Consumption of drugs (such as chlorhexidine, iron salts, cocaine, minocycline, bismuth subsalicylate and lansoprazole)

The primary causes of intrinsic mucosal hyperpigmentation are: 38

- Amalgam or other tattoo
- Nevus - Melanotic macule
- Peutz-jegher’s syndrome
- Racial pigmentation
- Drugs such as antimalarials and oral contraceptives
- Addison’s disease
- Pregnancy Pigmented lesions of the tongue (dark macular patches) are reported to occur in heroin addicts who inhale the smoke.39

Teeth Discolouration: Teeth stain are mainly caused by the antimicrobial agents such as tetracycline and minocycline. Systemic consumption of tetracycline causes irreversible staining in developing teeth and bones. The most affected region is cervical third of the tooth and staining is directly proportional to the age at drug exposure, dosage and duration of therapy.40 In case of Minocycline, staining occurs after the teeth are fully developed and erupted. It penetrates easily into both soft and calcified tissues. Thus pigmentation is produced by incorporation of the drug from the pulp into the dentin and enamel. Bluegray staining in the middle and incisal thirds of the teeth is produced by the salivary oxidation and gingival crevicular fluid. Minocycline produces irreversible staining. Metals, such as lead or mercury, or drugs that contain metals, such as gold salts, promotes changes of pigmentation at the gingival margin. 41 Overdose with barbiturates, dichloralphenazon, and carbon monoxide can produce discolouration similar to POSTMORTEM PINK-RED COLORATION (a condition where the tooth discoloration is due to hemolysis and exudation of hemoglobin to the dental pulp which is enhanced in the presence of moisture and increased venous pressure.).43

Swellings

A. Gingival Hyperplasia: Gingival Hyperplasia is a known adverse effect of anticonvulsant phenytoin, the immunosuppressant cyclosporine, and the calcium channel blockers which is used for hypertension and angina. Drug induced gingival enlargement can be localized or generalized and it is changed based on the degree of severity. Gingival enlargement typically affects the labial tissues and begins in the interdental papillae.

B. Mucosal Swelling: Drugs are the most common cause of urticarial reactions in adults affecting approximately 15-20% of young adults. Urticaria is a vascular reaction in the superficial layers of the skin, characterized by local edema and raised capillary permeability with wheals (hives), often involving severe itching. Drugs like penicillins, local anesthetic agents, cephalosporin derivatives, angiotensin-converting enzyme inhibitors, aspirin, and barbiturates—may promote angioedema.

Conclusion

Many drugs have the capability to cause adverse effects in the oral cavity. Drugs has the capability to cause conditions such as salivary gland disease, oral ulceration, taste alterations, discoloration of teeth, mucosal pigmentation, white lesions, swellings and oral malodour. These side effects interfere with the patient function and increase risk of infection, pain and possible tooth loss. Most common side effects of drugs are xerostomia, Altered taste and stomatitis. It is important for every health professionals to understand the adverse effects of medication on the oral health of their patients. To diagnose and treat the patients, a proper medical history with prescribed medicines, over the counter drugs and diet should be recorded. Thus healthcare professionals can identify the causative agent and treat the patients accordingly.

Cervical Lymphadenopathy in Dentistry—A Review

A. M. Sherene Christina Roshini¹, N. Aravindha Babu², R. JayasriKrupaa³, K. M. K. Masthan⁴
¹Post Graduate Student, ²Professor, ³Reader, ⁴Professor and Head of the Department, Department of Oral pathology and Microbiology, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research

ABSTRACT

On examination, lymph node enlargement may be an incidental finding, or may be associated with a patient complaint. Over half of the patients examined every day may have enlarged lymph nodes in the head and neck region. Oral health care providers must be able to determine when lymphadenopathy should be investigated further since it has a high frequency of occurrence. But it is the duty of the clinician to search for a precipitating cause and examine other nodal locations to exclude generalized lymphadenopathy. Generally, lymph node larger than 1 cm in diameter is considered as an abnormal lymph node. Malignancy should be considered when palpable lymph nodes are identified in the supraclavicular region, or when nodes are rock hard, rubbery, or fixed in consistency. Patients with unexplained localized cervical lymphadenopathy presenting with a benign clinical picture should be observed for a 2- to 4-week period. This article reviews common causes of lymphadenopathy, and clinical approach to a patient with cervical lymphadenopathy.

Keywords: Cervical lymphadenopathy, toxoplasmosis, tuberculosis

Introduction

Lymphadenopathy is one of the common finding in patients where enlarged lymph nodes in the head and neck region are observed. Aetiology and management of cervical lymphadenopathy varies from patient to patient. Benign lymphoid hyperplasia or reactive cervical lymphadenitis are identified in majority of patients with cervical lymphadenopathy. The spectrum of serious illness such as lymphoma, metastasis from oral cancer, distant metastasis from other primary cancers, acquired immunodeficiency syndrome, tuberculosis (TB), amyloidosis, and deep fungal infections are seen in some cases with enlarged cervical lymph nodes.¹,² Hence dental practitioners should be familiar with various diseases of cervical lymph nodes.

Mycobacterium tuberculosis causes Tuberculosis which is a granulomatous inflammatory process. Commonest form of extrapulmonary Tuberculosis is Tubercular lymphadenitis. In recent years, incidence of tuberculosis started to rise worldwide with increased number of HIV-infected population.³ Manifestations of Tuberculous cervical lymphadenitis are chronic, persistent, painless, slowly growing mass in the neck. Diagnostic modalities such as fine needle aspiration cytology, imaging, etc., are helpful for investigation. Treatment of choice is anti-tuberculous chemotherapy, with or without surgical excision of the involved cervical lymph nodes.⁴

Severe hypertriglyceridemia |

Drug Reactions

The disease may be related to a hypersensitivity response since the mechanism is unknown. This hypersensitivity response includes mucocutaneous eruptions, fever, hematologic abnormalities, organ involvement such as hepatitis or interstitial nephritis, and lymphadenopathy. The hypersensitivity reaction resolves after drug withdrawal. The mortality rate is increased upto 10% even after drug withdrawal.4,5

Infections

**Upper respiratory infections:** Acute bilateral cervical lymphadenopathy is due to viruses and bacteria infecting the upper respiratory tract in both adults and children. Certain viruses causing upper respiratory infections such as adenovirus, influenza virus & respiratory syncytial virus. Bacterial pharyngitis, which is a type of upper respiratory infection is most commonly caused by Group A beta hemolytic Streptococcus. Other common bacteria causing infection are groups B, C, and G hemolytic Streptococci, Corynbacteria, and several anaerobes.

**Symptoms:**
- Cough
- Sinus congestion
- Rhinorrhea, and occasionally fever and
Malaise.

Cervical lymph node may be swollen and tender and persists for weeks.

**Diagnostic Tests:**

- Viral cultures of the nasopharyngeal region
- Bacterial throat cultures or serologic antigen detection are useful in persistent infection cases.

**Local Infection:** Cervical lymphadenopathy is a common feature of localized infection. Cervical adenopathy is often caused due to local bacterial infections of head and neck. The symptoms of bacterial infections are warm, erythematous, enlarged and tender lymph nodes. More than 50% of the time submandibular node involvement is noticed. Staphylococcus aureus and Streptococcus pyogenes are common bacterial pathogens. The origin of local infection may be viral, commonly herpes simplex virus or Coxsackie virus. Primary herpetic stomatitis and herpangina are caused by the above viruses respectively. These diseases are most commonly seen in children and adolescents. Clinical findings are acute painful ulcers of the oral cavity or oropharynx, enlarged bilateral tender lymph nodes in the anterior triangle of the neck, impressive submandibular and submental adenopathy, and occasionally fever and malaise. There are other systemic complications including hepatosplenomegaly or generalized lymphadenopathy but it is not present in these viral infections.

Chronic cervical lymphadenopathy is the most common presentation of nontuberculous mycobacteria (NTM) in children. Most common isolates of NTM are Mycobacterium avium and M. scrofulaceum. Atypical tuberculosis (TB), usually present as a nontender mass in the submandibular region and is most commonly seen in children. Weakly tuberculin skin test is done to the patient where the result may be positive or negative and not have pulmonary symptoms. The infection proceeds gradually with nodal enlargement occurring within weeks to months.

**Cat Scratch Disease:** Clinical feature is Subacute adenopathy which involves cervical region. Bartonella species is the causative organism for this disease. A gram-negative bacterium, specially B henselae known to be pathogenic to humans. Cervical lymphadenopathy involving parotid and submandibular glands have symptoms such as fever, headache, and malaise. Symptoms develops in 10 to 30 days after an infected pet inoculates the host, usually through a scratch. Surface around these nodes is warm, tender, erythematous, and may be indurated or suppurative. Infection with Bartonella species may cause conjunctivitis, encephalopathy, bacillary angiomatosis, peliosis hepatitis, and bacteremia. are also observed. Oral manifestation of cat-scratch disease is bacillary angiomatosis.

**Diagnosis**

- Cat-scratch skin test
- Serologic testing for the presence of antibodies to B henselae.
- Lymph node biopsy with special staining demonstrate cat-scratch bacilli well but culturing this organism requires a 6-week incubation period is required.

This disease is self-limiting in immunocompetent hosts and it resolves without treatment within 2 to 3 months. B henselae infection is seen in immunocompromised individuals, where they have greater morbidity and mortality, for which initiation of antibiotics such as trimethoprim-sulfamethoxazole or erythromycin, may be necessary.

**Tuberculosis:** Mycobacterium tuberculosis is an infectious and communicable organism which causes tuberculosis. There is no definitive signs or symptoms for the individuals with TB. If symptoms becomes clearly visible, then the infected individuals will have signs and symptoms such as weight loss, night sweats, fever, malaise, or anorexia. Persistent cough is commonest symptom associated with pulmonary TB. Other symptoms such as hemoptysis and nonpurulent sputum helps in diagnosis. Mycobacteria may cause chronic granulomatous lymphadenitis, typically within the nodes draining salivary glands. One of the most common extrapulmonary manifestations of tuberculosis is Tuberculous cervical lymphadenitis, or scrofula. Peripheral node disease accounts for approximately 20% of extrapulmonary tuberculosis.

**Toxoplasmosis:** 30% of the human population worldwide have toxoplasmosis which is caused by a parasite Toxoplasmosis gondii that infects a wide range of warm-blooded vertebrates. Cause and source of infection is contact with infected uncooked or undercooked meat.
**T. gondii** is excreted in feces

Up to one year, it survives in soil

Infection can occur due to the ingestion of cysts and oocysts directly from the soil or present in infected meat

After initial phase of infection, pseudocysts disperse to other organ tissue and proliferation of the organism ceases with the host response.

The formed cysts lie dormant and intact within the host, unless the patient’s immune system becomes suppressed.

**Mode of transmission:** *T. gondii* can be transmitted to humans through organ transplant procedures, blood transfusions, or transplacental transmission.

**Common Manifestation:** Lymphadenopathy, with firm, tender enlargement of the cervical nodes.

![Fig. 1: A patient with cervical lymphadenopathy](image)

**Sequelae of congenital infection are**

- Mild nonspecific disease,
- Failure to thrive,
- Lymphadenopathy,
- CNS involvement,
- Intracerebral calcification,
- Ocular disease, and
- Myocarditis.

Diagnosis of toxoplasmosis is based on history and exam findings, and confirmation is done by rising antibody titers—*IgG* titers are typically high during acute infection and will remain at low titers for life. *IgM* titers indicates acute infection and are useful markers during pregnancy. Other diagnostic methods are isolation of *T. gondii* from blood or other bodily fluids, or detecting the parasite by polymerase chain reaction in tissue or body fluid.

**Infectious Agents:** There are broad range of infective organisms which has the potentiality to cause cervical lymphadenitis. It is difficult for clinicians to investigate all the possibilities. In many cases of infections, there are typical signs and symptoms of lymphadenopathy.

**Malignancy:** In a malignant conditions, enlarged palpable lymph nodes of the head and neck may be present. Several metastatic tumors may present as cervical lymphadenopathy; these are tumors of the skin and appendages, oropharynx, larynx, thyroid gland, salivary gland, and nasopharynx. Malignancies from cells in the immune system may also results in lymphadenopathy. The initial manifestation of Hodgkin’s disease and non-Hodgkin’s lymphoma is lymphadenopathy at any site; chronic lymphocytic leukemia and myeloid leukemia may also present with initial signs of lymphadenopathy. Supraclavicular lymph nodes seems to be present in metastasis from remote sites than cervical nodes. Primary sites of tumor presenting with supraclavicular lymphadenopathy include ovaries, lungs, and gastrointestinal tract. The chief complaint of patient can be fever, sweats, weight loss, and anorexia, particularly with acute hematologic malignancies. Other signs and symptoms may include hoarseness, paresthesia, hemoptosis, hematuria, occult blood in the stool, or abdominal pain.

Clinical features of malignant lymph nodes in later stages: firm, rock hard, and fixed-to-deeper tissues
nodes. Nodes may present as unilateral and multiple, or bilateral. In lymphoma, there will be larger, symmetric, firm, mobile, and nontender nodes. In cases of rapidly progressive neoplasia, such as acute leukemia, lymph node enlargement may be painful or tender because of rapid expansion of the node which results in pain. Lymph node biopsies and further diagnostic tests helps in diagnosing malignancy and origin of the tumor can be established.

**Clinical Evaluation**

**Medical History**

- Duration of lymphadenopathy is noted
- Presence of constitutional symptoms such as fever, sweats, weight loss, and anorexia should be gathered.
- History of underlying systemic disease must be taken into consideration.
- Concomitant events should also be investigated since they may correlate with the onset of the patient’s lymphadenopathy
- Associated constitutional symptoms, or other nonspecific signs or symptoms including oral lesions, dental problems, recent trauma, breathing difficulty, odynophagia, or dysphagia should be noted.

**Social and Family History:** History such as patient’s age, occupation, travel experiences, exposure to pets, dietary habits should be obtained. If a definitive diagnosis cannot be made based on the patient’s history and physical examination, then clinical examination is done to obtain a cause. When the history is suggestive of a particular etiology, confirmatory testing is mandatory to identify the illness.

**Clinical Features:** Physical examination of the patient helps in clinical assessment. The prior thing required for clinical evaluation is understanding of head and neck surface anatomy. Identification of the major structures, along with knowledge of the distribution of lymph nodes in the head and neck, will help to find out normal versus abnormal and also the physical findings.
Complete physical examination includes evaluation of the skin, neck, ears, eyes, nose, and throat. Intraorally, the patient’s oropharynx should be examined.

Palpable lymphadenopathy is common in young children. They are frequently exposed to new antigens, and enlarged nodes are typical. Larger lymph nodes (1 cm) are not considered normal in either adults or children. Palpable nodes less than 1 cm in the groin is considered normal in adults. Hence, size of the lymph node is an important criteria for lymphadenopathy. The consistency of the node is also an important factor in lymphadenopathy.

**Location:** The extent of lymphadenopathy is important in differentiating between localized and disseminated disease. Location of enlarged lymph nodes may lead to a source of infection, particularly if the node is tender with inflammation of the surrounding structures. Enlarged cervical lymph nodes are found frequently. Suboccipital nodes may be associated with scalp infections. When supraclavicular nodes are enlarged, there is a strong suspicion of malignant disease, particularly lymphoma or metastatic disease. Virchow’s node present in the left supraclavicular region, indicating metastatic infiltration from a primary GI cancer.13

**Hematologic Testing**
- A complete blood count (CBC) with differential will be helpful to detect cases caused by infectious mononucleosis, leukemia, or lymphoma.
- Neutropenia and thrombocytopenia helps in diagnosing systemic illnesses
- Serology tests are performed to detect toxoplasma, EBV, CMV, herpes simplex virus (HSV), or chlamydia

**Other Diagnostic Tools**
- Imaging studies such as chest x rays, CT scans, MRI and FNAB21
- Chest x rays- to rule out mediastinal lymph node.
- CT scans- used to evaluate the location and nature of the lymph nodes
- MRI-used to evaluate the extent of lymphadenopathy
- FNAB (Fine Needle Aspiration Biopsy) is an adjunctive evaluation of lymphadenopathy.

**Conclusion**

Though lymphadenopathy occurs commonly, we should remember some salient points:
- Most patients doesn’t require a biopsy
- Certain patients do not require laboratory evaluation
- Antibiotics should not be prescribed unless there is a serious complication
- On clinical examination, location, symptomatology, and consistency should be addressed
- If the history and physical findings are suggestive of benign lymphadenopathy, follow up is recommended in 2 to 4 weeks
- The patient should be instructed to report soon if the nodes increase in size
- Investigating the etiology should be improved.

Patient’s medical status should be evaluated to determine if a known illness is causing lymphadenopathy. Malignancy must be considered in a differential diagnosis. If these steps provide no clues for diagnosis then CBC with differential should be ordered. If a patient is found to have an enlarged lymph node, follow up is required for 2-4 weeks to rule out the condition.

Biopsy Report: A Guide For Beginners

E. P. Sridevi Anjuga¹, N. Aravindha Babu²

¹Post Graduate Student, ²Professor, Department of Oral Pathology & Microbiology, Sree Balaji Dental College & Hospital, Chennai, BIHER

ABSTRACT

Descriptive pathology is essential for writing histopathological reports. It is often performed under the pressure of time and accuracy. Precision is important because the patient is still alive and the pathologists must act quickly on the diagnosis. Most of the reports are reviewed and produced by a single pathologist. Therefore, it is possible to make errors or mistakes. Therefore, it is usually possible to make mistakes in writing a biopsy report. A clear unambiguous writing style is important to meet the report's requirements. This review article provides a comprehensive review of different parameters to be considered in writing oral lesion histopathology report.

Keywords: Biopsy, reports, pathology, diagnosis.

Introduction

Oral and maxillofacial pathology is one of the specializations in dentistry that engages with diagnosis, study of etiological factors and effects of disease which usually affects oral cavity, jaw and face. Usually, pathologist will diagnose the disease by clinical, radiographic, microscopic, biochemical investigations or other investigations like examination of organs, tissues, molecules and cells¹. An oral pathologist writes all of the findings that he examines macroscopically and microscopically in a biopsy report that works to help the surgeons and doctors plan further treatment¹. Biopsy writing is also known as descriptive pathology. Descriptive pathology is to identify, describe, explain or interpretate pathological lesions or abnormalities and record all findings in biopsy report². And any misdiagnosis can cause serious problem. Quality control in histopathology is extremely important in order to minimize the potential for misdiagnosis¹.

Components of Gross Description: The analysis of gross lesions starts when the unusual findings are identified and characterized². Before coming to the diagnosis, we should observe the abnormal findings carefully, understand about the lesion and the we have to interpretate. Subsequent features must be noted.

Specimen Received: fresh, in formalin or saline, referred by any surgeon etc³.

Sample tissue in formalin

Specimen Identified: labelled (biopsy number, date, name of patient)³

Describe: whether the tissue is attached with any bone³.

Distribution: geographical arrangement of lesion in the organ or tissue².

Lesion or abnormalities may occur with different distribution pattern, that can be the indicators of disease and help to predict the extent or significance of the findings.

Symmetrical – certain degree of organisation is evident or same

Random – not related to specific structure of organ or tissues.
Focal – a single established lesion
Multifocal – more than one discrete lesion
Miliary – numerous small foci
Segmented – well circumscribed segment or portion of tissue is abnormal
Diffuse – full or entire part of organ is affected.

**Demarcation**: boundaries/limits of a lesion defined from neighbouring tissue.

Well demarcated – discrete, well defined boundaries
Poorly demarcated – abnormal, discontinuous, blurred or undefined boundaries.

**Contour**:
- Raised – heightened or increased tissue or organ to cause expansion. Eg: ulcer, fibroma.
- Depressed – lowered or removed. eg: ulcer, necrosis.
- Flat – lesion is neither elevated nor depressed.

**Shape**: geometric figure which represents the lesion beyond the contour.
- Round
- Ovoid
- Irregular

**Color**: one of the most evident attributes the lesion, especially when the lesion varies from normal color.
- Innate color – colourless or white
- Special pigments - eg: bile
- Dark tissues – high proportion of pigment to tissue. Eg: spleen
- Light tissues - Low proportion of pigment to tissue. Eg: brain.
- Red to reddish black – usually represents blood or haemoglobin pigment.
  (shows haemorrhage or congestion)
- White to grey or yellow – lack of blood. Eg: exudate, fibrosis.
- Brown to black – eg: melanoma.

**Size**: measurement of tissue or organ.
- Uniform and non uniform

**Texture**: appearance of tissue
- Smooth, glossy, rough

**Consistency**: thickness or viscosity.
- Soft, firm, hard.

**Location**: Anatomic sites
- Eg : floor of mouth, vestibular region, buccal mucosa.

**Chronicity**:
- Acute – sudden and short
- Chronic – gradual and extends to long period.

**Severity**: Mild, Moderate, Severe.

**Fundamentals of Pathology Report:**
- Date
- Patient’s details
- Biopsy number
- Referred by
- Type of biopsy
- Site of biopsy
- Clinical findings
- Preoperative diagnosis
- Gross specimen:
  - Number
  - Size
  - Shape
  - Consistency
  - Colour
  - External surface
Margins
Microscopic description
Staging and grading
Lymph node status
Special stains
Final diagnosis
Pathologist signature

Description:

Date¹: Date of receiving, date of biopsy date of reporting has to be mentioned in biopsy report.

Patient’s details¹:
- Name, age, sex has to be mentioned in report
- This segment includes the personal details of the patient that sometimes helps with the diagnosis.

Biopsy number¹:
- A specific number is issued to every patient.
- This number enables the specimen to be tracked at any point in the process.
- Medico-legal lesion

Referred by¹: If the biopsy sample is referred by any doctor/surgeon it had to be mentioned in biopsy report.

Type of biopsy¹:
- Incisional/excisional/cytology
- It gives an idea about the size and location of lesion

Site of biopsy¹:
- Anatomical sites or location has to be mentioned
- Schematic description of the oral cavity should be included in the requisition that would allow the surgeon to identify the biopsy site. Site helps to identify features of the tissue when analyzing them.

Clinical findings¹:
- This section gives a detailed overview of patient’s medical, habit history and history relevant to tissue sample.
- Medical history – cardiac problem, diabetes, cancers, diabetes mellitus.
- It allows an individual to take steps to reduce their risk
- Habit history: smoking/alcohol/areca nut chewing along with frequency has to be mentioned.
- It helps the doctors to rule out any habit related lesion is there or not in patient’s oral cavity

Pre-operative diagnosis¹:
- The clinical diagnosis indicates what doctors expect before the descriptive diagnosis.
- This diagnosis were given before the confirmatory diagnosis.

Figure 2: Gross Examination

Number¹
Shape¹:
- Irregular – Squamous cell carcinoma, leukoplakia.
- Spherical – adenomatoid odontogenic tumor
- Round – mucocele

Outer/External Surface¹:
- Verrucous: verrucous carcinoma
- Smooth: benign tumor
- Corrugated: Odontogenic keratocyst

Margins¹:
- Ill defined – myxoma, squamous cell carcinoma
- Well defined – lipoma, pleomorphic adenoma
Consistency:
- Soft: lipoma, papilloma
- Firm: fibroma, pyogenic granuloma, leukoplakia
- Hard: odontoma, amelogenesis imperfecta
- Mucinous: mucocele

Color:
- Yellow – lipoma
- White – odontoma
- Grayish white – mucocele
- Grayish black- carcinoma

Chronicity:
- Acute
- Sub-acute
- Chronic

Histopathologic Features of Chronic Lesion Shows:
- Uncontrolled cell proliferation,
  - OSMF- Excessive Deposition of extra cellular matrix,
  - Pyogenic granuloma - fibro vascular proliferation.

This is the key component of pathology description. First, pathologists should be familiar with the following before starting interpretation:
- Name of the tissue or organ,
- Site of biopsy,
- Method of fixation,
- Provisional diagnosis,
- Stains used.

There are no standard guidelines for describing histological sections of oral lesions, but tissues of biopsy can usually be described as follows in eight steps.

Magnification of 4X: (Scanner View): Before writing the report, some features should be reported below 4x in the tissue segment:
- Identify all biopsy tissue components and their correlation
- with the provisional diagnosis
- Identification of abnormal/diseased tissue and normal/healthy
- tissue within lesion
- Check the relationship between normal tissue and diseased tissue
- Check for other different processes like degeneration, invasion,
- Proliferation, metastasis, mineralization, decay, necrosis, and
- atrophy

Gross description:
- Identify the epithelium, connective tissue stroma and
- deeper connective tissue stroma.
- Check for cellularity (densely cellular or sparsely cellular)
- Check for margins (well defined or ill defined)
- Encapsulated or unencapsulated
- Deep invading structures like blood vessels, glands,
- neurovascular bundle.

Fig. 3: 4X view of Basaloid squamous cell carcinoma

Magnification of 10X View: Hallmark pattern of cell proliferation in lesion: (Figure 4)

Neoplasm:

In epithelium: Tombstone pattern, honeycomb pattern, palisading arrangement (sheets, islands, cords)
**In connective tissue:** Herring bone pattern, bundle stream, storiform appearance, rosette like arrangement, epitheloid arrangement, fascicular arrangement.

**In salivary gland:**
- Cribriform pattern – adenoid cystic carcinoma.
- Tubular pattern – adenoid cystic carcinoma and basal cell adenoma.
- Canalicular pattern – salivary gland adenoma or carcinoma.
- Acinar pattern – acinic cell carcinoma of salivary gland.
- Comedo pattern – salivary duct carcinoma.

**Odontogenic tumors:** Plexiform sheets, kite tail pattern, corrugated pattern
- Follicular pattern – follicular ameloblastoma
- Fibro-osseous lesion:
  - Chinese script pattern, mosaic pattern

**Type of stroma in sarcoma:**
- Type of proliferation
  - Collagenous stroma – OSMF
  - Cellular stroma – cementifying fibroma
- Necrosis – malignancy and inflammation
- Mixed stroma
- Hyalinized
- Myxoid stroma – myxoma
- Supporting structures(inflammatory) – mild, moderate, dense.

**Magnification of 40X: (Figure 5)**

**Cellular Features:**
- Size: large or small
- Shape: cuboidal, columnar, round, oval, polygonal, pleomorphic.
- Cytoplasmic border: distinct or indistinct
- Cytoplasm:
  - Color: eosinophilic or basophilic
- Amount: scanty, moderate, abundant
- Character: homogenous, fibrillar, granular
- Content:
  - Mucous – empty
- Multiple nuclei – giant cells
- Granular – ameloblastoma

**Nuclear Features:**
- Shape: round, oval, elongate, spindle.
- Location: eccentric, central, compressed
- Chromatin: stippled, vesicular, clumped
- Staining: hyperchromatic
- Mitotic figures

**Nucleolar Features:**
- Number & color - increased in malignancy
- Characteristic features: Fibrous dysplasia – Chinese letter pattern,
- Giant cell granuloma – multinucleated
- Mitotic activity
- Features of malignancy:
  - Invasion, necrosis, haemorrhage, dystrophic calcification, depth of invasion

![Fig. 4: 10x view of basaloid squamous cell carcinoma](image)

![Fig. 5: 40x view of basaloid squamous cell carcinoma](image)
**Pathologic Staging System:** TMN (tumor, metastasis, node invasion) is the medical staging method recommended by the American Joint Commission on Cancer (AJCC) used by many pathologists.

**Grading System:***

- **BORDER’s classification:**
  - Well differentiated (GRADE I) – <25% undifferentiated cells
  - Moderately differentiated (GRADE II) – <50% undifferentiated cells
  - Poorly differentiated (GRADE III) - < 75% undifferentiated cells
  - Anaplastic or pleomorphic (GRADE IV) - >75% undifferentiated cells

**Guidelines for Writing Microscopic Description:**
- Concise, complete, well-organised microscopic description is mandatory
- Specify the major event first and minor event at the end briefly.
- Describe each and every component/parts of lesion. Eg: CYST – lumen, epithelial lining and connective tissue capsule
- Explain the features shown by the majority of cells
- It is not necessary to describe normal tissue
- Use the right term given in the literature.
- Don’t write any useless terms in biopsy report
- Correct punctuation, grammar and spelling is important while writing the report
- Always write the report in active voice/present tense
- Male follow-ups if necessary.
- All histopathologic descriptions should match with your final diagnosis.

**Special Markers/Tests:** Use special stains, immunohistochemical markers, electron microscopy and molecular biology technique if needed.

**Final Diagnosis:** Should be based on all findings in the report.

**Pathologist’s Signature:** The pathologist who signs the report will be responsible for its contents.

**Conclusion**

In view of treatment plan and prognosis, a carefully prepared biopsy report with accurate representation of the lesions can be a valuable complement to oral histopathologist. It takes an hour to establish recommendations for the oral biopsy report format for all types of oral lesions that have not been thoroughly investigated and documented in dental literature. So we have to standardize a biopsy report format inorder to avoid misdiagnosis and to help budding pathologist by providing well-standardised format.

Current Trends in Smart Materials—A Review

Ramachandran Tamilsevi¹, Balasubramanian Anuradha¹, Veronica Arunakumari¹, Ilango Porkodi¹,
Bhaskaran Sathyapriya²

¹Reader, Department of Conservative Dentistry & Endodontics, ²Professor, Department of Anatomy, Sree Balaji Dental College & Hospital, Bharath Institute of Higher Education and Research, Chennai, Tamil Nadu, India

ABSTRACT

Various fields of dentistry have been revolutionized by smart materials. The need for an ideal restorative material resulted in invention of newer generation of materials in dentistry called the smart materials. The smart materials possess the properties which may be altered in a controlled fashion by various stimuli like, stress, temperature, moisture, pH and electric or magnetic fields. Some of the smart materials are biomimetic and mimic the natural enamel or dentin. The current dental materials were worked on to improvise their properties in order to make them smarter. The use of smart materials holds a promising future in terms of improved efficiency and reliability in dentistry. There is a strong trend in material science to develop and would potentially allow newer ground breaking dental therapies with drastically enhanced treatment outcomes.

Keywords: Materials, Resin, Implants, Fibers.

Introduction

The terms ‘smart’ and ‘intelligent’, to describe materials and systems started in 1980’s in United States. Traditional dental materials were designed to be passive and inert without interacting with the oral environment. The current trend in dentistry is changed with the introduction of various smart dental materials which are active, functional and undergoes a purposeful change in the oral cavity. The smart materials can undergo alterations in color, refractive index, distribution of stresses and strains or a volume change etc. They are highly responsive and possess the inbuilt ability to sense and react according to changes in the oral environment, hence called as smart materials[1]. Smart behaviour usually exhibits when a material senses the stimuli from the oral environment and responds in a beneficial, reproducible, reliable and reversible fashion. The significant feature of smart behaviour is its property to return to original state even after the retrieval of stimulus [2]. These properties aids in beneficial application of smart materials in various fields of dentistry. This paper focuses to describe the recent trends in development of smart materials and its applications in dentistry.

Characteristic Features: The smart materials can be altered in a controlled fashion by stimuli, such as stress, temperature, moisture, pH, electric or magnetic fields and has an ability to return to the original state after the removal of stimulus. The shape memory alloys or shape memory polymers are the thermo-responsive materials [3,4] which adopts different shapes at different temperatures with controlled changes in structure. The shape of the magnetic shape memory alloys changes their shape in response to a change in magnetic field. The piezoelectric materials when subjected to stress produces a voltage or vice versa [5]. When voltage is applied to these products, they can undergo changes in shape or dimensions. The materials like pH-sensitive polymers are influenced by the pH of the surrounding media and they swell or collapse [4]. Some of the materials can produce change colour in response to changes in pH, light or applied voltage. Polymer gels exhibits smart behaviour [6]. They have cross-linked polymer networks which may be inflated in the presence of solvents like water.
**Classification:** Smart materials are broadly classified into active and passive materials \(^7\). Active materials sense the external environment and respond to changes respectively. Passive materials respond to external change without the influence of the external control. They also possess self repairing characteristics.

</table>

**Smart Impression Material:** The smart impression materials are void free due to hydrophilic nature. The property of shape memory aids in elastic recovery and resists distortion. The enhanced toughness resists tearing and faster setting pattern without distortion results in precise fitting of restorations. The working and setting time is reduced by atleast 33% with increase in flow of the material by lowering the viscosity \(^8\).

**Smart Coatings for Dental Implants:** The smart coating makes the surgical implants bond more closely with bone and ward off infection. The crystalline layer is created surrounding the implant and an amorphous layer formed reaches the bone. The bone growth is favoured by the dissolution of amorphous layer, by the release of calcium and phosphate thereby promoting the osseointegration. The silver nano particle incorporated implants minimizes the chances for infection in site due to their antimicrobial property.

**Smart Composites:** They are light-activated alkaline, nano filled glass restorative material. When the salivary pH values drop below the critical pH of 5.5, the smart composites releases calcium, fluoride and hydroxyl ions to counteract the demineralization of the tooth surface and thus favours remineralization\(^9\). The smart composites are indicated for class 1 and class 2 lesions in both primary and permanent teeth and could be bulk filled to about 4mm thickness.

**Smart Ceramics:** Smart ceramics are metal free, ultra-thin monolithic material, which contributes maximum strength, biocompatible life like restorations. The restorations are milled from a monolithic block of solid yttria-stabilized zirconia. The combination of high flexural strength, high fracture toughness, and partially stabilized zirconia increases the lifespan of restorations and made the process of restoring teeth to natural form easy and predictable \(^10\).

**Nickel-Titanium (Ni-Ti) Rotary Instruments:** Ni-Ti endodontic instruments contain approximately 55% (wt) Ni and 45%(wt) Ti, equivalent to 50%(at) Ni and 50%(at) Ti \(^11\). The smart behavior of Ni-Ti alloys is because of “super elasticity” and “shape memory”. The advantage of using rotary Ni-Ti files are minimal chances of instrument fracture within the canal during instrumentation, less transportation, less fatigue to the operator and minimal post-operative pain.

**Smart Prep Burs:** They are polymer burs used to remove only the infected dentin \(^13\). The affected dentin which has the ability to remineralize is left intact. The chances of removal of affected dentin and over cutting of tooth structure while using conventional burs can be avoided by using smart preparation burs.

**Smartseal Obturation System:** The C Point system (EndoTechnologies, LLC, Shrewsbury, MA, USA), a
Smart seal obturation system is a point-and-paste root canal filling technique that consists of premade, hydrophilic endodontic points and an accompanying sealer. The deformable endodontic point (C Point) is available in different tip sizes and tapers and is designed to expand laterally without expanding axially, by absorbing residual water from the instrumented canal space.

**Smart Fibres for Laser Dentistry:** Hollow core photonic crystal fibers (PCFs) for the delivery of high-fluence laser radiation capable of ablating tooth enamel have been developed. Sequences of picosecond pulses of Nd: YAG laser radiation is transmitted through a hollow-core photonic crystal fiber with a core diameter of approximately 14 micrometers and is focused on a tooth surface to ablate dental tissue [14].

**Smart Glass Ionomer Cement:** Davidson first suggested the smart behavior of GIC [15]. In response to the stimulus like temperature, change in pH, the gel structure of smart GIC absorbs or release solvent rapidly. The smart ionomer mimics the behavior of human dentin. Resin-modified glass ionomer cement, compomer or giomerare also seen to exhibit these smart characteristics.

**Smart Composites:** Smart composites containing ACP (amorphous calcium phosphate) exhibiting the most rapid conversion to crystalline hydroxyapatite (HAP). ACP when integrated into specially designed and formulated resins to make a composite material, will have an extended time release nature to act as a source for calcium and phosphate which will be useful for preventing caries. ACP-filled composite resins have been shown to recover 71% of the lost mineral content of decalcified teeth [16].

**Smart Antimicrobial Peptide:** The specifically Targeted Antimicrobial Peptides (STAMP) have been developed based on the fusion of a species-specific targeting peptide domain with a wide spectrum antimicrobial peptide domain. This pheromone-guided “smart” material peptide is targeted against the killing of Streptococcus mutans, the principal microorganism responsible for dental caries. They have the probiotic property that will selectively eliminate pathogens while preserving the protective benefits of a healthy oral flora [17].

**Smart Sutures:** They are thermoplastic polymers that have both shape memory and biodegradable properties. When the temperature is raised above the thermal transition temperature, the suture shrinks and tightens the knot, applying the optimum force. The thermal transition temperature is close to human body temperature and this is of clinical significance in tying a knot with proper stress in surgery. Smart sutures are made of plastic or silk threads covered with temperature sensors and microheaters, which can detect infections.

Call for Papers / Article Submission

The editor invites scholarly articles that contribute to the development and understanding of all aspects of Public Health and all medical specialities. All manuscripts are double blind peer reviewed. If there is a requirement, medical statistician review statistical content. Invitation to submit paper: A general invitation is extended to authors to submit papers papers for publication in IJPHRD.

The following guidelines should be noted:
- The article must be submitted by e-mail only. Hard copy not needed. Send article as attachment in e-mail.
- The article should be accompanied by a declaration from all authors that it is an original work and has not been sent to any other journal for publication.
- As policy matter, journal encourages articles regarding new concepts and new information.
- Article should have a Title
- Names of authors
- Your Affiliation (designations with college address)
- Abstract
- Key words
- Introduction or background
- Material and Methods
- Findings
- Conclusion
- Acknowledgements
- Interest of conflict
- References in Vancouver style.
- Please quote references in text by superscripting
- Word limit 2500-3000 words, MSWORD Format, single file

All articles should be sent to: editor.ijphrd@gmail.com
CALL FOR SUBSCRIPTIONS

About the Journal
Print-ISSN: 0976-0245  Electronic - ISSN: 0976-5506, Frequency:  Quarterly
Indian Journal of Public Health Research & Development is a double blind peer reviewed international Journal. The frequency is half yearly. It deals with all aspects of Public Health including Community Medicine, Public Health, Epidemiology, Occupational Health, Environmental Hazards, Clinical Research, Public Health Laws and covers all medical specialities concerned with research and development for the masses. The journal strongly encourages reports of research carried out within Indian continent and south east Asia.

The journal has been assigned international standards (ISSN) serial number and is indexed with Index Copernicus (Poland). It is also brought to notice that the journal is being covered by many international databases.
