Urinary incontinence is a highly prevalent and burdensome condition among women. However, fewer than half of women with symptoms talk to a physician about incontinence. The factors, including knowledge, culture, education, and income, the most dominant factor influence and the reason patient of urinary incontinence not to go to the hospital. The method used in this research is mixed methods with cross-sectional research design. The sample amounted to 70 patients suffering from urinary incontinence. The patients interviewed were 10 patients/informants.The quantitative research with the Kolmogorov test is known that on the variable of educational and income factors, with P >0,05. The knowledge and cultural factors result with P <0,05. There is correlation between knowledge and eastern culture with urinary incontinence patient not treatment at polyclinic RS Hasan Sadikin Bandung, the most dominant factor influencing is the culture factor, as well as the reasons patients with urinary incontinence do not go to the hospital, is due to not knowing that urinary incontinence is a disease and a shame.

Keywords: *Urinary Incontinence, Knowledge Factor, Cultural Factor, Educational Factor, Income Factor.*

Introduction

Urinary incontinence (IU) includes pelvic floor dysfunction, namely pelvic nerve denervation due to labor or lower back trauma.[1] According to The International Continence Society (ICS), complaints of inability to hold urine out involuntarily (Complain of involuntary loss of urine).[1,2.3]

The prevalence of IU in Indonesia is known to be 5.8%.[4] For IU patients, the financial burden that must be borne is not cheap and tends to be expensive from year to year.[5] In addition to financial problems, other problems including the patient's opinion about the severity of the disease, shame to consult regarding incontinence, and trust that incontinence is a normal part of the aging process.[6]

The factor that causes an IU sufferer not to seek treatment or medical help is the lack of wrong knowledge and opinions about IU, this is the biggest obstacle to treatment-seeking behavior.[7-12]

The research conducted by Basu et al. Stated that several things that make women in the UK consider the problem of IU to be less important than other health problems, do not want to see a doctor with the same complaints, busy work, and shame to consult with doctor.[8]

According to the United Nations World Population Prospect: The 2010 Revision Population Database, the life expectancy of women in the world and Indonesia continues to increase.[9] The lack of understanding and understanding of IU is assumed because they assume that this condition is normal from increasing age and can heal on its own. This is a false assumption because IU can be prevented or treated. Delaying treatment even with mild symptoms can lead to a decreased quality of life.[10]

Through in-depth questionnaires and interviews, an analysis of the factors that affect an IU sufferer is not done medically.

Method

This study uses mixed methods (mixed methods). The study was observational analytic and unpaired categorical comparative analysis, with cross-sectional research design. The study was conducted in the Gynecology Obstetrics section with a quantitative method (questionnaire) to determine the factors that influence an IU patient not seeking treatment. The study population was adult women (18-49 years) who came to the RSHS polyclinic and suffered from IU since May 2017 as many as 70 people suffering from IU from 109 people who filled out the questionnaire. Data were analyzed by Chi-square test or by alternative Exact Fisher test and Kolmogorov Smirnov test and binary logistic regression p-value <0.05 was considered statistical significance. The data obtained is recorded in the form then processed using SPSS version 24.0 for Window.[11]

Result

The results of the descriptive study on the test showed in table 1

Table 1: Overview of Knowledge Factors, Cultural Factors, Educational Factors, Factors Income and willingness of patients to seek treatment in a group of patients suffering from IU

Variable		N = 70
No.	**Knowledge Factors**	
1.	Very Low	0(0.0%)
2.	Low	49(70.0%)
3.	Medium	7(10.0%)

2.	Do not want to seek treatment	55(78.6%)

Description: For categorical data, it is presented by number or frequency and proportion while numerical data is presented with mean, median, standard deviation and range

Table 1 describes the patient's In the table above shows that the level of knowledge of patients suffering from the largest IU is in the low category of 70%. In the cultural variable namely eastern culture that is still inherent in Indonesian society, it is seen that most patients suffering from IU have a high eastern culture of 40%.

For education variables, respondents obtained by researchers tended to be the same between patients with IU and patients without IU. In the respondent's monthly income variable, the highest income is below the minimum wage of 77.1%. The patients who suffer from the biggest IU are patients who do not want to seek treatment, amounting to 78.6%, while the remaining 21.4% still want to seek treatment.

Description: For categorical data, the value of p is calculated based on the *Chi-Square* test with an alternative *Kolmogorov Smirnov* and *Exact Fisher* test if the terms of *Chi-Square* are not met. Sign * shows statistical significance.

Table 2 explains the comparison between knowledge, culture, education, and income factors in the group of patients who still want treatment and patients who do not want treatment in patients with IU. In the table above shows that the level of knowledge of patients suffering from IU who still want the highest treatment is in the high category that is equal to 73.3% while those who do not want to seek treatment, the highest level of knowledge is in a low category at 83.6%. In the cultural variable namely eastern culture that is still inherent in Indonesian society, it can be seen that most patients suffering from IU who still seek treatment have a low eastern culture of 60%, whereas in patients who do not want treatment most respondents have a high eastern culture of 49, 1%.

For the education variable, for IU patients who still want to have a lot of treatment are 53.3% of secondary education, then 46.7% of higher education, Whereas the majority of patients who do not want to seek treatment also have a secondary education background, which is 56.4%, followed by a higher education background of 43.6%.

In the respondent's monthly income variable, the highest percentage of income is below the minimum wage, which is 73.3% and the remaining only 26.7% earns above the minimum wage while the largest respondents are those who do not seek treatment. earning above the minimum wage which is equal to 78.2% while 21.8% earns below the minimum wage.

There is a statistically significant percentage difference between the variables of knowledge and cultural factors in the group of patients who are still willing to seek treatment and patients who do not want to seek treatment in patients suffering from urinary inconsistencies.

Table 3: Simultaneous Influence of Knowledge and Culture Factors with Patients who still want treatment and patients who do not want to seek treatment in patients who suffer from IU

Variable	No.	Multivariable Analysis			
		B	SE	OR CI (95%)	Value P
Knowledge Culture	1.	0-.868	0.675	0.420	**0.199**
	2.	2.440	0.963	11.469	**0.011****

Description: Multivariate analysis with binary logistic regression. The independent variables included in the logistic regression model are the independent variables which in the bivariate analysis have a p-value of <0.25. The value of significance is based on the value of p <0.05. The * sign indicates a value of p <0.05, meaning significant or statistically significant.

From the multivariable analysis in table 3, It can be concluded that multivariable only cultural factors affect

patients who still want treatment and patients who do not want treatment in patients with IU.

Discusion

Subjects in the study were 109 patients with 70 people with IU. age 41-49 years which is equal to 61.43%. In the aspect of the respondent's marital status, IU patients were married at 65.71%. In the last aspect of the education of respondents, IU sufferers had the most education with senior high school education at 51.43%. In the aspect of the respondent's work, it can be seen that the greatest number of patients suffering from IU is housewife work of 45.71% while in the aspect of family income per month, respondents who suffer from IU are mostly patients with income below the minimum wage of 77.1%.

Therefore, for those with IU, the financial burden that must be borne due to IU is considered not small and tends to increase from year to year. Daily maintenance costs around 0.3% of Indonesia's 2015 APBN due to the large financial burden, this has caused less than 20% of IU sufferers seeking help medical conditions.[10]

Based on the results it is known that there are many different reasons that cause a person to suffer symptoms of complaints. educational factor, and the reason that the husband's income is not enough. In the reason of the informant who said that she did not know that IU was a disease. Based on research by Setiati and Pramantara, it was explained that in Indonesia urinary incontinence is often not reported by patients or their families. Health authorities, both doctors and other medical personnel also sometimes do not understand the management of patients with IU properly. Even though IU is a health problem that can be resolved.[5,18-22]

The reason for the informant who said that he was embarrassed and taboo was because the customs of the Indonesian East were still considered taboo on such matters. So this makes an IU sufferer find it difficult to seek treatment, especially if IU is experienced by young people. Hatchett's study, et al., In 32 African-American and Latin-American women said that they had a wrong understanding of pelvic floor dysfunction, one of which was urinary incontamination and had not previously known the causes, symptoms, and treatment available for IU. The subjects were very enthusiastic to receive information, especially regarding how to prevent it.[13,15,20]

Educational factors, some women feel embarrassed to discuss it, especially those who have a low educational background.

The reasons for not being treated because the husband's income is only enough to meet the daily needs and needs of the child's school. In addition, even though the respondent has a BPJS (Health Insurance), respondents are afraid of additional costs. This means that the respondent does not have enough costs for treatment. However, there were also respondents who felt they needed treatment, only this would be done later on. Subak's study, et al., On the impact of improving cost-per-individual incontinence revealed that the average cost of individuals decreased by 23% per decrease from seven incontinence episodes per week.[24]

Table 4: Descriptions of four factors which are Knowledge, Cultural, Educational, and Income Factors in ten respondents

No.	Initial Name	Knowledge Factors	Cultural Factors	Educational Factors	Income Factors
1.	S	As a result of giving birth, laugh	Shy	Upper secondary education	Less Income
2.	I	Think of not being a dangerous disease, drinking lots of water	Taboo	Upper secondary education	Less Income
3.	M	Due to drinking lots of water	Shy	Junior secondary education	Income is enough
4.	HN	As a result of giving birth	Shy	Upper secondary education	Income is enough
5.	F	Due to aging, lots of activity, sneezing	Shy	Upper secondary education	Less Income
6.	TH	Due to aging, laugh	Shy	Upper secondary education	Income is enough
7.	RN	Not a disease	Shy	Upper secondary education	Less Income
8.	R	Due to cold, due to coughing and sneezing	Shy	Junior secondary education	Less Income
9.	A	Due to a lot of activity, laugh	Taboo	Upper secondary education	Less Income
10.	NS	Due to aging	Shy	Upper secondary education	Less Income

The limitations of this study in the form of an interview schedule for informants were carried out at the same time the informants were treated at RSHS as patients so that there was the limited time when conducting interviews. Besides being limited by time, informants were also considered to be less comprehensive in answering the researchers' questions so that they had an effect on the quality of the research results.

Conclusion

Based on the description that has been stated, the conclusion is that there is a relationship between knowledge, eastern culture with IU patients who do not seek treatment at the Hasan Sadikin Hospital clinic in Bandung. But there was no relationship between education level and income with IU patients who did not seek treatment at the Hasan Sadikin Hospital polyclinic in Bandung. The most dominant factor affecting urinary incontinence patients who do not go to the hospital is a cultural factor. They did not know that IU was a disease and a shame so it was necessary to disseminate information or counseling from the health staff to the community, or mothers in particular, to be able to educate them that if there were symptoms IU symptoms should be able to immediately seek medical treatment or treatment.

Histopathological Changes in the Liver and Kidney of Albino Mice on Exposure to Zinc Toxicity

Ishraq J. Hassan[1], Ihsan S. Sahi[2]

[1]Department of Physiology, [2]Department of Surgery, College of Medicine, Misan University, Iraq

ABSTRACT

Background: Zinc is one of an essential trace element, it has an important role in many enzymes of the body. It is less harmless in comparison with several other metal ions. Acute zinc intoxication occurs only if there is an exposure to high doses of zinc. Zinc poisoning may be mostly from dietary supplements, including multivitamins, or results from an accidental ingestion of zinc-containing household products.

Aim: The present study was designed to evaluate the histopathological changes of zinc toxicity in liver and kidney of albino mice.

Materials and Method: Fourty-eight male Albino mice divided into four similar groups, the first three groups exposed during 15 days to different zinc concentrations in the form $ZnSO_4$ (60 mg/kg, 80 mg/kg and 100 mg/kg) intraperitoneally. Fourth group set as a control group, treated with saline (0.9%) for the same period of intraperitoneal injection. Sections of liver and kidney were stained with hematoxylin-eosin and examined by light microscopy.

Results: Several changes in the liver and kidneys sections like cell necrosis, congestion, swelling, disappearing of cell borders and others was observed during histopatological examination. It appears from the results that the intensity of tissues defects increased with increasing of zinc toxic concentration.

Conclusion: Results of study suggest that zinc may be toxic for use in mice and cause many toxicological changes in the liver and kidney.

Keywords: *zinc sulfate, toxicity, mice, liver, kidney*

Inroduction

Zinc is an essential micronutrient that almost found in all tissues of the body and is important for DNA synthesis, growth and differentiation of cell, in addition, zinc is essential for the immune system[1,2,3], protein metabolism so, it has an indispensable role for human health[4]. Zinc is less harmless in comparison with several other metal ions. Acute zinc intoxication occurs only if there is an exposure to high doses of Zinc[5]. It has recognized zinc deficiency for many years, but currently, there are limited toxicological data available for zinc[5]. In eukaryotic cells, the physiologically Zn^{2+} concentration is about 10 ng/L but if the level of zinc below 0.06 ng/L lead to trigger of apoptosis and when level rises above 60 ng/L toxicity can ensure[6]. Excessive zinc can cause as many problems in the body as the deficiency. The first signs of zinc toxicity include reduced feed intake, reduced weight gain, bone resorption[7], vomiting, nausea, epigastric pain, fatigue and anemia[6] and excessive Zn may reduce the absorption of calcium or phosphorus [8]. Recent studies improved that free ionic zinc (Zn^{2+}) is a powerful killer of neurons, glia and other cell types[6]. In a study to Servet et al.[9] on 119 autopsy cases to determine the levels of toxic metals (cadmium and lead) and trace elements (zinc and copper) in the liver tissues, they found the average liver levels of metals and trace elements were found 29.5 µg/g, 216 µg/g, 0.39 µg/g and 4.38 µg/g dry weight for copper, zinc, lead and cadmium, respectively. In other study about zinc toxicity, Nilukshana et al.[10] improved that when a person attached

Misan University, Iraq
Email: Ishraq.mcm@uomisan.edu.iq

directly for any cause with zinc phosphide which is a rodenticide caused severe acute kidney injury, abnormal liver profile, pancreatitis and possible myocarditis. The renal biopsy revealed.

As the animal receives higher levels of zinc or toxic amount for long periods of time, the animal will suffer from diarrhea, internal hemorrhage and even death[7]. The more remarkable pathological lesions of zinc poisoning in liver and kidney were focal mononuclear degeneration, necrosis and derangement of liver and kidney[6]. Liobet et al.[11] studied the effect of subchronic oral administration of zinc in Sprague-Dawley rats. Forty female rate were exposed to 0, 160, 320, and 640 mg/kg-day zinc acetate hydrate in drinking water for twelve weeks. The described renal lesions included flattened epithelial cells in the Bowmans capsule, desquamation of the proximal convoluted tabulated tubule and pyknotic nuclei in the 640 mg/kg-day. Intraperitoneal administration of zinc may result an increase in liver mass due to hypertrophy of the hepatocytes[12],[13]. In other study of the effect of zinc toxicity on the liver and kidney of rats for Emmanuel et al.[14]the results were hepatic cells degeneration especially at the portal areas of the livers and glomerular degeneration, mononuclear cells infiltration into the interstices of the tubules and tubular necrosis of the rats kidneys[15].

Aims of this study are:

1. To look at the importance of poisoning of the zinc element and its impact on human and animal health.
2. Study of histopathological changes in liver and kidneys because of zinc toxicity.

Materials and Method

All procedures conducted in this experiment were approved by the local authorities (Faculty of Veterinary Medicine, Basrah University, Iraq).

Experimental Animals: Forty-eight adult male albino mice, 12 weeks old and 20-25 g body weight. They were obtained from the animal house of the Animal House of the Veterinary medicine College, Basrah, Iraq. They were housed in the Animal Room of the Veterinary medicine College, Basrah, Iraq, for 2 weeks before the commencement of the experiment which lasted for 2 weeks. The mice fed appropriately using standard mice chow and water provided ad libitum. All procedures conducted in this experiment approved by the local authorities (Faculty of Veterinary Medicine, Basrah University, Iraq).

Design of the study: Forty-eight adult male albino mice used for the study divided into four groups with 12 mice in each. The first three groups were daily dosed via intraperitonial injection with 60, 80 and 100 mg/kg zinc in the form $ZnSO_4$ for 15 days. An equivalent volume of saline (0.9% NS) administered to the fourth group which set as the control group.

Histopathological examination: We took the sections of liver and kidneys for histopathological preparation and examination. The samples collected and fixed in 10% buffered formalin. Each tissue trimmed to the thickness of 5mm in size, fixed and dehydrated in a series of alcohol concentration, and embedded in paraffin by using an automatic tissue processor. Then the tissue sectioned to a thickness of 5mm micrometer on a microtome. After that, the liver and kidney tissues mounted on the glass slide, de waxed and stained with hematoxylin and eosin (EH). Finally, we examined the liver and kidney tissues using 4x, 10x, and 40x objectives for histological changes, depend on Hair-Bejo et al.[13].

Results

Figure (1) presents the liver section of the control group in which the mice exposed to 0.9% NS only. Note no observable microscopic lesions in the hepatic cells and the central vein of the liver. Figures (2-3) shows changes of liver sections against zinc toxicity. The results show that there were different stages of necrosis in the hepatic cell nuclei, swelling of hepatic cells, congestion of the central vein, and there is a disappearance feature of some hepatic cells. So The results explained that the worse histopathological changes were direct proportion with increasing doses of zinc.

Figures (4) is a section of the kidney of mice set as control croup which exposed to 0.9% NS, shows a normal glomerulus in the Bowmamn's capsule with normal tubules. While the Figures (5-6) present the results for changes of kidney sections against zinc toxicity. They show that there were different stages of swelling in tubular cells that lead to narrowing of the tubular lumen, presence of a proteinous material in the lumen of proximal and distal tubules, and also the pictures show unclearance of the cell borders especially in T3 group which treated with (100 mg/kg zinc).

Discussion

The histo-pathological changes of the liver and kidneys showed a vascular congestion. The result showed also a swelling of the cells with cell necrosis represented by condensation, division and analysis of the nucleus. It may result from the effect of zinc toxicity on the thyroid gland causing hypothyroidism[17] that leads to a decrease of the metabolism rate and then appearance of hepatic changes, or due to a decrease of the blood stream because of anemia, secondary to hypocupremia from zinc toxicity, which the commonest symptom of the zinc toxicity[18]. The administration of the gradual concentrations of zinc toxicity lead to the swelling of the tubular cells, appearance of the cells without the nucleus, which may be because of the accumulation of zinc-metallothionein complex[19] after its reabsorption by the tubules in the kidney, and this complex analysis by lysosome enzymes liberating the zinc ion which is related again with the kidney's metallothionein[19].

The intensity of the toxicity increases with increasing of the zinc dosed, and this leads to an increase in the accumulation of the zinc ions in large quantities till they become more than the ability of the kidney to form the metallothionein synthesis in the kidney is less than in the liver[19].

Conclusion

The present study highlights significant of hepatic and kidney injury after acute zinc sulfate toxicity. We can conclude that the zinc toxicity cause histopathological changes in the liver and kidneys, exacerbated by increased zinc concentration within the body.

Conflict of Interest: The researchers declares that there is no conflict of interests with any other party.

Microbial Inhibition to Water Hyacinth (*Eichhornia Crassipes* [Martius] Solms-Laubach) in Abu Zirk Marsh by Using Selected Fungi

Jameelah Wthaij Ogali Al-Yosef[1], Abdul-Rahman Abduljabbar Al-Kubasi[2], Ihsan Flayyih Hasan Al-Jawhari[3]

[1]Ministry of Science and Technology, Iraq; [2]College of Science for women, University of Baghdad, Iraq; [3]College of Education for pure Sciences, University of Thi-qar, Iraq

ABSTRACT

Native fungi associated with water hyacinth have been identified and evaluated the potential of biological control against waterhyacinth in Abu zirk marsh (south of Iraq).Twelve species of fungi associated with different parts of the waterhyacinth (leaf, petiole) were isolated under sterile conditions in the laboratory.These fungi belong to genera Ascomycota (*Alternaria alternate, Stemphyllium* sp**,,***Aspergillus niger,A.flavus,A.ostianus,A.candidus,A.fumigatus,Penicillumfumiculosum.Trichodermharzianum,T. lignorum*,Basidiomycota (*Rhizoctonia solani)* Zygomycota(*Rhizopus stolinifer*) environmental parameters such as temperature, relative humidity, pwere measured in field and in laboratory,the total occurrence of fungi reached to (146 colony *)A. alternata* and *R.solani* was more frequency *R.solani* showed the severity of disease 91.8%,and ability to change in the wet weight, number of leaves and the height of plant.Thus,evaluated *R. solani* more effective and severe plant death. And can be developed as an effective biological control.

Keywords: *Mycoherbicide, water hyacinth, Native bioagent, Abu zirk marsh*

Introduction

Water hyacinth was found originally from the Amazon basin, and its entry into Africa,Asia,Australia,and North America has been facilitated through human activities,is belongs to the family Pontederiaceae, monocotyledon and aquatic macrophyte, free floating with beautiful clusters of violet and yellow flowers. Various methods to control water hyacinth include manual, mechanical,chemical and Biological control [1],which involves the use of natural enemies (insects and fungal pathogens)[2].Fungal pathogens have gained acceptance as a practical, safe environmentally friendly. Various strains in the genera *Acremonium, Alternaria*, *Cercospora,* and *Myrothecium* have been studied intensively as biocontrol agents and shown to be effective under experimental conditions. First appeared of Eichhornia *crassipes* in Iraq was in the mid-1980s, in Baghdad, after then spread to the Diyala river and parts of the Tigris river and attacked marshes, Including Abu Zirk marsh, which exposed to the invasion of water hyacinth in 2016.The amount of area infection with water hyacinth plants was about 2265875 $Km^2$and thus the percentage reached to 18% [3].The rapid and intensive growth of the water hyacinth plant has caused environmental and economic damage in the marsh. The main objective of this study is development of an effective bio-control strategy for water hyacinth by using fungal pathogens as bioagents, in Abu Zirk marsh by isolating and diagnosing the native fungi associated with the water hyacinth and its pathogenic capacity. The article is the first study in the marshes of southern Iraq.

Materials and Method

Area Study: Abu Zirk marsh is located in Al-Islah District (50 km) east of Al-Nasiriya city. They were located between latitude lines (33°00'-31°40') N, and between longitude lines(45°10'-48°14') E. The marshes are located in a natural depression of an estimated size120 million cubic meters, and the marsh is filled with grasses of reed, papyrus and run through by a stream of a head called Shatt Abu Lahya Figur(1)

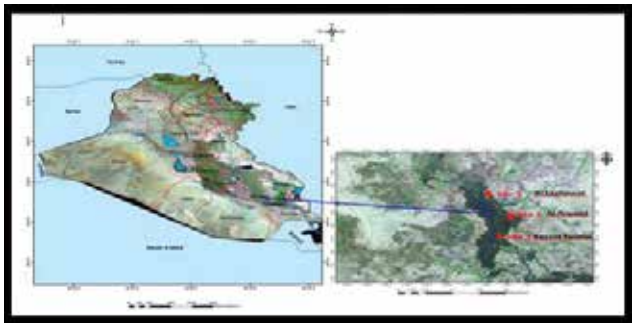

Figure 1: Abu zirk marsh (Google Earth, 2018)

Sampling Collected and Isolation Pathogen: Diseased water hyacinth leaves (showing browning, wilting, yellowing, spots, blights, or combinations thereof) were collected from water bodies in three sites within Abu zirk marsh this site called (1) Al-laghawat, site (2) Al-Rramid, site (3) Sayyid yashua. Infected leaves were collected in sterilized plastic container. Isolation of the pathogen followed the standard procedure on water hyacinth dextrose agar (WHDA) medium. The constituents were as follows (Water hyacinth leaves-200.0 g, Dextrose-15.0 g, Agar-agar- 20.0 g, Distilled water- 1000.0 ml, pH-5.6. Water hyacinth leaves (200 g) were washed in running tap water and then in distilled water. These were boiled for 15-20 min in 500 ml distilled water and filtered through thin gauze cloth for the collection of extract. The rest of the procedure was similar to the PDA pre-paration) [4]. The infected leaves were washed in running tap water to remove soil particles. The infected portions of leaf tissue were from the margins of necrotic or lesions cut into 3-mm pieces by using a sterile scalpel and surface-disinfected for one minute in 10% sodium hypochlorite. The tissue pieces were rinsed three times with sterile water and dried with sterile blotting-pape. Four tissue pieces were done on (WHDA) enriched with chloramphenicol (0.1 mg/l) in order to avoid bacterial growth, pieces were aseptically transferred to the inoculated plates were incubated at 25C° for 3-5 days**.** The fungal colonies were sub cultured individually by using a cork borer (5-mm diameter) and transferred on to freshly prepared PDA media amended with in chloramphenicol (0.1 mg/l) in 80-mm Petri dishes. The plates containing each isolate were arranged in a completely randomized design. The Petri dishes were checked for fungal growth after 4 -7 days and thereafter on a daily basis for 20–30 days. This action was repeated three time until pure cultures were obtained pure colonies of the isolates were grown by single-spore or hyphal-tip techniques. The isolates were stored on agar slants in 6 C° in a refrigerator. Microscopic observation of each isolate was done with an optical microscope at a magnification of40× and fungal isolates were characterized morphologically under a microscope based on their mycelium, fruiting structures and spores and identified according reference to the key of [5], The frequency of occurrence of the isolates were rated as very frequent (>20%), frequent (10%–20%) and infrequent (<10%) according to [6].

Pathogenicity test: Young healthy leaves of water hyacinth were washed under running tap water and then wiped with cotton swab dipped in 70% alcohol. The surface of leaves was injurey by pricking with a sterilized needle. One mycelial disc of 7days old culture was placed on both injured and healthy leaf each, and then covered these leaves with moist sterilized cotton. After these leaves were placed in a sterilized petri dish. At the bottom of the petri dish, sterilized moist filter paper was kept. Plates were incubated at 25 C °. After verifying the disease on the health water hyacinth leaf, the disease was tested on the growing water hyacinth in plastic container measuring (45 cm, 35cm, 20 cm), was kept in Marsh Research Center, Thiqar University. And fill a soil from the same sites was weighed with a kilogram of weight with field water 10 liters, and provided with an oxygen compressors throughout the study period, plants were placed in a plastic container, one plant homogeneous in weight and size as three replicates for each plant. After 7days of acclimate follow the growth Characterizes had taken such as wet weight/gm, total length of plant/cm, total length of root/cm, numbers of leaves/cm) addition to the daily monitoring of air and water temperatures and the relative humidity ratio. Corn oil emulsions were prepared with 35% v:v corn oil amended with 15% lecithin and 5% Tween 20, was diluted in sterile distilled water containing the spores (at a concentration of $1x10^4$ spores/ml in the final oil-water emulsion) [7], 20 ml of the suspension was applied on to water hyacinth leaves by using hand sprayers. The various plant species were also left untreated as controls. Plants were rated for disease symptoms including leaf spots, leaf lesions, and leaf death, and identification of the severity of the pathogenicity of the selected fungus such as *Alternaria alternata* and *Rhizoctonia solani*.

Statistical analysis: $P<0.05$ was chosen as a level of significance for all analyses. SPSS version 17.0 was used for all statistical tests (t- test)

Results and Discussion

Isolation of Fungi: Twelve fungal isolated from different parts in water hyacinth (leaves and petioel). These fungi belong to three genera. The common genera was Ascomycetes (*Alternaria alternata*, *Stemphyllium* sp**,** *Aspergillus niger, A.flavus, A.ostianus, A. candidus, A. fumigatus, Penicillum fumiculosum. Trichoderma harzianum, T. lignorum* the second genera was *Basidiomycota* (*Rhizoctonia solani***),** and third genera was zygomycota (*Rhizopus stolinifer).* The total colony reached to (146 colony).Table (1)showed that *Rhizoctonia solani* was more frequency(61.49%),also *Alternaria alternate* reached to, (60%),but the frequency of *Penicillum fumiculosum* (28.6%), *Trichoderma harzianum* (12.87%), *T. lignorum, Rhizopus stolinifer* reached to (8.58%)*,,Aspergillus niger, A.ostianus*(5.7%), *A. flavus, A. candidus*, *A. fumigatus* and *Stemphyllium* sp reached to (4.2%). For tests and evaluated of severity disease and determined as biocontrol agents waterhyacinth. The statistical methods showed significant differenced were found between the *A. alternata* (leaves), (petiol) and *R.solani* (leaves), (petiol).

Table 1: Isolated fungal species associated with water hyacinth in Abu zirk marsh

Fungal species	S (1) Number		S (2) Number		S (3) Number		Total Colony	Frequency %
	P	L	P	L	P	L		
Alternaria alternate	4	10	2	12	5	9	42	60 %*
Rhizoctonia solani	6	10	4	9	3	11	43	61.49%*

Rhizopus stolinife	1	1	0	1	1	2	6	8.58%
Total	15	36	9	32	15	29	146	
L)leaves,(p), Petoile, (S)site, (0)No recored, (*) significant p <0.05)								

The total occurrence of fungi colony reached to (146 colony).These are widely distributed taxa,. A alternata has been described as a pathogen of water hyacinth in Bangladesh Australia, India and Egypt [8] in the present study have also been reported from El-Morsy screened 22 fungal isolates for their ability to infect waterhyacinth out of which Alternaria alternata, showed 79%, tissue death after four weeks post inoculation[6]. In the present study, Rhizoctonia solani has increased its susceptible of diseases severity to the water hyacinth compared with the rest of the accompanying fungi. [9].

Pathogenecity test: Table (2) showed, the growth development of water hyacinth.The same wet weight was selected in all treatments,with air temperature 40 °C and relative humidity 17%. The other growth parameters were different between the three treatments (1, 2, 3). The total plant height in treatments (1,2,3),were (34 cm,35 cm, 30 cm), root length (23 cm, 20 cm, 16 cm),Numbers of healthy leaves were (60, 57, 40) and the total chlorophyll concentration was(35, 32, 35) respectively in the present study have also been reported from Yirefu [7]. The statistical method showed that significant differences between treatment.

Table 2: Growth characters of water hyacinth as a control

Growth characters	Control		
	Container 1	Container 2	Container 3
Air temperature	40	40	40
Relative humidity	17	17	17
wet weight gm./m^2	105*	105*	105*
Plant height/cm	34	35	30
Root length/cm	23	20	16
Numbers of leaves in plant/cm^2	*60	*57	*40
Total Chlorophyll	35	32	*35
(*) significant *p <0.05*			

Table (3) showed that *R. solani* was more effected with treatment *A.alternata* in plant growth. The wet weight was deceased to 85gm/cm when comparative with control (treatment 3). The statistical method showed that significant difference between these treatment, also plant height was 10 cm,but the numbers of infections leaves were increased to 53/m^2 when compared with control,in the same time the chlorophyll concentration was decreased to 2,but the disease severity was increased to 92.98% also the statistical method showed that significant differences between these treatment.

Table 3: Growth characters of water hyacinth after treatment with *Alternaria alternata* and *Rhizoctonia solani*

Growth characters	Treatment		
	1	2	3
Air temperature ċ	40	40	40
Relative humidity	17	17	17
wet weight gm/cm^2	*94	*85	*120
Plant height/cm	15	10	37
Root length/cm	23	19	17
Numbers of infected leaves/m^2	*52	*53	3
Total Chlorophyll	5	2	*33
disease Severity **DS%**	86	*92.98	*7.5
treatment (1) *A. alternata* suspension, treatment (2*) R. solani* suspension, treatment (3 *)* control (*) significant $p < 0.05$			

We have focused on two fungal pathogens (*Alternaria alternata* and *Rhizoctonia* solani) isolated from diseased hyacinths to develop them as effective agents in biological control. According to [10], the effect of mycoherbicide on water hyacinth can be determined based on its ability to limit host plant development, fewer living, leaves, and more death leaves on individual plants, rather than producing new clones. Analysis of the disease test results indicated that most fungal species effect on water hyacinth. The results showed that there were differences between isolates in the severity of the disease on the water hyacinth were recorded after 6 weeks of treatment in vitro. The severity of the disease for both *Alternaria alternata* and *Rhizoctonia* solani has played an important role in reducing biomass (wet weigh) and plant growth number of leaves, daughters plant. *Alternaria alternata* and *Rhizoctonia* solani as pathogens that will lead to a decrease in plant productivity of biomass. On the other hand, lead to major changes in the physiological characters such as low carbohydrate and chlorophyll and changes in water content [11]. Refer that this fungus caused disintegration of original water hyacinth mats into smaller mats, stunted growth, decline in water hyacinth biomass, reduced flowering potential, reduced daughter plants production and finally rotting of the petioles followed by sinking.

Infected water hyacinth leaves showed necrotic type spots, zonate leaf spots and blight symptoms with varying severities,

Histopathology of plant tissue: Figure (2,3) showed the infection of water hyacienth by treatment with *R.solani* and *A. alternata* and also the penetration of both fungi the epidermis of the upper surface and the lower surface of the leaf through the stomata and penetration of tissue petiole led to damage in the tissues of the palisade layer, and the stability of the fungi in the aerenchyma tissue of the leaf and tissues petiole,these infection with pathogenic fungi causes change in the size spongy layer compared to control,The Transmission Electron Microscopy (TEM) also demonstrates the stability of the fungus hyphae of *Rhizoctonia solani* and spores of *Alternaria alternata*

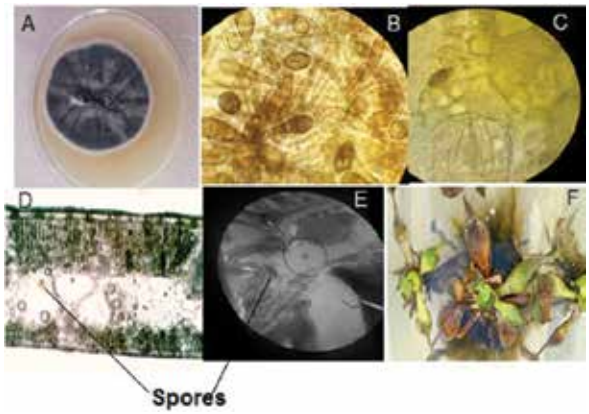

Figure 2: (A) Colony of *Alternaria alternata* on PDA (B) Conidia of *A.alternata* under light microscope (C, D) *Alternaria alternata* spores penetration the epidermis leave of water hyacinth and causing damage in the tissue of leaf (E) TEM micrograph of a spores of *A. alternata* located in the intercellular space of water hyacinth leaf (F) water hyacinth after infection with *A.alternata*.

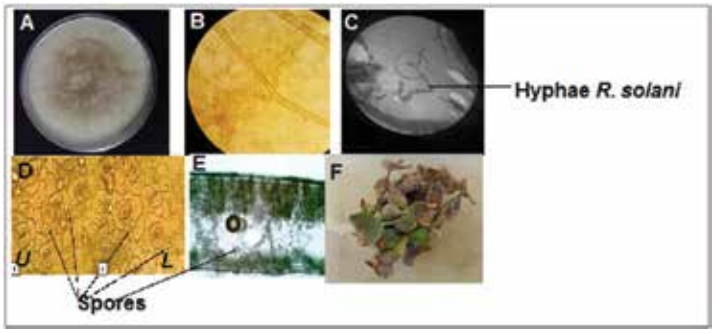

Figure 3: (A) Colony of *Rhizoctonia solani* on pDA (B) hyphae of *R.solani* under light microscope (C) TEM micrograph of a hypha of *R.solani* located in the intercellular space of water hyacinth leaf (D.E) *Rhizoctonia solani* spores penetration epidermis leave of water hyacinth and causing damage in the tissue(F)water hyacinth after infection with *Rhizoctonia solani*

Conclusion

Based on the current findings, we can conclude that, *Alternaria. alternata, Rhizoctonia solani,* could be used as an effective bio control agent against water hyacinth following performance evaluation under natural environmental conditions and their host specificity test.

Conflict of Interest: None of the authors have any conflicts of interest to declare.

Source of Funding: The research was performed independently, there is no funding, influence over study design, analysis, manuscript preparation, or scientific publication.

Ethical Clearance: The project was approved by the local ethical committee in University of Baghdad.

Complications and Lipid Parameters Status among 50 Years and above Age Group Hypertension Population at Primary Health Care Centres of Buraidah City

Asim Fahad AlKhalifah[1], K. Chandra Sekhar[2], Abdulaziz Sulaiman Alsaif[3], Alya fahad Alkhalifah[4]

[1]4th Year (R4) Family Medicine Resident at Saudi Board Family Medicine, Al Qassim Province, KSA.; [2]Professor & Faculty at Hay Al Akhdar Post graduation Training Centre for Saudi Board of Family Medicine, Buraidah, Qassim Province, Saudi Arabia; [3]4th Year (R4) Family Medicine Resident at Saudi Board Family Medicine, Al Qassim province, KSA.; [4]Final Year College of Dentistry, Buraidah private colleges, Buraidah

ABSTRACT

Background: As we all know that Hypertension problem increasing in all over the world. Being Family Medicine specialists, in addition to detection of hypertension problem at early stage and also need to focus more and more on complications identification at the earliest and suggesting proper remedial and life style measures periodically insisting and educating them, minimizing the burden on spending amount by the government and also good quality of life of the individual.

Objectives: To identify the complications of hypertension and lipid profile status among study population.

Materials & Method: A cross sectional institutional based record review study conducted at primary health centers of Buraidah City from January 2018 to June 2018 among 170 persons records 50 years old and above in the concerned primary health care centers. After getting institutional ethical committee clearance, data entered in Statistical package for Social Sciences (SPSS) and necessary statistical tests like simple proportions and chi square tests were applied.

Results: In the study population, about 47.7% were having abnormal triglycerides. among the abnormal triglycerides study group, the prevalence of hypertension with complications was 33.3%. About 20.6% (35/170) individuals were having different complications. Of which, Ischaemic heart disease (IHD) was identified as common complication which accounts 15.3% of all complications noticed in the study population.

Conclusions: Based on the study results, majority of the people were having abnormal lipid parameters and most common complication identified in the study population was ischaemic heart disease. Need strategies to identify the complications at the early stage at primary health care centers for the guidance in the management of the complications.

Introduction

The rampant increase of hypertension in the society is due to undergoing socioeconomic and epidemiological transition, increasing life expectancy is burdened with increasing prevalence of hypertension in urban areas, due to urbanization, less physical activity,unhealthy life style and stress. Hypertension as a significant cause of serious health complications, morbidity and mortality has been recognized in most nations globally particularly in the Western world. It is currently estimated that hypertension affects more than a quarter of the world adult population

Buraidah, Qassim Province, Saudi Arabia
Email: cskalevaru@gmail.com

including the Kingdom of Saudi Arabia. It contributes to the burden of heart disease, stroke, Kidney failure, hypertensive retinopathy, premature mortality and disability. According to the World Health Organization global fact sheet on global burden of diseases, increased blood pressure was one of the leading causes of death and disabilities globally in 2014[1].

The Kingdom of Saudi Arabia government has been increasing funds allocated to the health care sector in the past decade with about $ 61 billion in 2011 which was 12% of the entire national budget and 5 % of the entire gross domestic product in the year 2014with a health per capita of approximately $ 2500 in the same year based on world bank values [2]. The healthcare burden is expected to increase owing to the expanding population, increasing number of elderly persons and the development of related lifestyle diseases such as obesity, hypertension and cardiovascular complications.

Hypertension is one of the leading causes of morbidity, mortality and socioeconomic burdens worldwide particularly among persons above 55 years where its prevalence is between 51-70 % in Saudi Arabia. In terms of associated life complications, hypertension caused about 50% of stroke, heart failure and heart diseases in addition to another 40% deaths among diabetic patients globally in 2013. The highest number of complications arising from hypertension are mainly cardiovascular and include conditions like myocardial infarction, heart failure, cerebrovascular accidents together with visual disturbances, and kidney problems[3].

The complications arising from hypertension in addition to the disease itself creates a huge economic stress on the affected individuals and their families, national health systems, countries and the world at large. It is therefore, an modern epidemic in the public healthcare sector. The global costs for treating hypertension and its complications assessed in various world Bank region was estimated to be about $370 billion which is about 10 % of the overall world budget. The Eastern European regions and Asia spends about 20% of their total budget on high blood pressure and the associated sequelae. Even though the developed nations and high–income countries have the largest share in hypertension spending, there is continuous increase in the expenditure among the developing nations as well.[4]

It is widely accepted that cardiovascular disease is associated with hypertension and increased blood levels of lipids. In relation to the above study results and situations, the following research was carried out to determine the complications of hypertension and together with the associated lipid profile status among individuals records at the primary health care centers of Qassim region. Gravity of complications that cripple the person in physical, mental agonies and leads to drain the family and country resources.

Aims and Objectives

1. To identify the complications of hypertension in the study population.
2. To find the lipid profile parameters association with hypertensive population.
3. To know the annual check up status in hypertensive population.

Materials and Method

Study Design and Setting: This was a institutional based record review cross sectional study carried out in the primary health care centres (PHCC) in Buraidah city. There are 44 primary heath care centres in the city all are functioning and providing the services to the needed people of Buraydah city.

Study Period: This study was conducted from 1st January 2018 to 30th June 2018.

Target Population: All patients above 50 years old visited to the Primary health centre (Based on availability of the records).

Sample Size Calculation: Meta-analysis of prevalence of hypertension in Saudi Arabia among above 50 years age group was reported as 51% per cent. This prevalence is considered to find out the sample size in my study. Finally sample size arrived 170 by using the formulae of $4pq/l^2$ in qualitative studies.

Sampling Method: Simple random sampling method.

Sampling Procedure: Out of 44 primary health care centers in Buraidah City,10 PHCC were selected randomly. As per the requirement, 17 patients records to be collected from each PHC. The selection of the records also used by simple random method. After selection of the record, verified all my study variable and filled in our questionnaire. The pilot study was done on 34 samples. Same process was used to complete the requirement of the sample size of 170.

Exclusion Criteria: Hypertensive patients less than 50 years.

Ethical Clearance: Regional Research Ethics Committee -Qassim Province, issued the ethical clearance certificate to initiate this study.

Method of Data Collection: An questionnaire was prepared based on the availability of information in the records of hypertension files in PHCs and also taken consultation and discussion with the experts in the department and under supervision of the guide. One day before visited to the concerned PHC and met the director of PHC and file room manager and taken appointment and explained in detail about the purpose and methodology of the present study and assured strict confidentiality of information. First 10 PHC selected randomly to initiate the study. From the each PHC, 17 files were selected by simple random method. The pilot study conducted among 34 samples from 2 PHCs.

Data Analysis: Statistical analysis was done by using the statistical software spss -21.0 version. Necessary statistical tests like simple proportions, chi square tests were applied for inferential statistical interpretation.

Results

Table 1: Lipid profile parameters association with Hypertension study population (n = 113)

Triglycerides	Hypertension without complications	Hypertension with complications	Total	P value
Normal	50 (84.7%)	9 (15.3%)	59 (100%)	X^2-5.07, 1df, P-0.02
Abnormal	36 (66.7%)	18 (33.3%)	54 (100%)	
Total	86 (76.1%)	27 (23.9%)	113 (100%)	
Serum cholesterol				**P value**
Normal	74 (74.7%)	25 (15.3%)	99 (100%)	X^2-2.35, 1df, P-0.12.
Abnormal	33 (86.8%)	5 (13.2%)	38 (100%)	
Total	107 (78.1%)	30 (21.9%)	137 (100%)	

Table 1 revealed that in the study population, among the abnormal triglycerides study group the prevalence of hypertension with complications was 33.3% and normal triglycerides study group, the prevalence of hypertension with complications was 15.3%. In the study population, among the abnormal cholesterol study group the prevalence of hypertension with complications was 13.2% and normal cholesterol study group, the prevalence of hypertension with complications was 15.3%. As the sample is small and also having complications sample also very less and hence statistical applications may be inappropriate.

Table 2: Type and duration of complications in study population

Type of complication	Number	Percentage
Retinopathy	7/170	4.1%
Stroke	2	1.1%
IHD	26	15.3%
Total	35	20.6%
Duration of complications		
< 5 yrs	16	45.7%
5-10 yrs	15	42.9%
> 10 yrs	4	11.4%
Total	35	100%

Table 2 highlighted that in the study population about 20.6% (35/170) individuals were having different complication. Of which, ischaemic heart disease (IHD) was identified as common complication which accounts 15.3% of all complications noticed in the study population. In the study population, 42.9% of complications reported between 5-10 years of the duration.

Table 3: Health education versus Hypertension (n = 168)

Health education	Hypertension without complications	Hypertension with complications	Total
Yes	123 (79.3%)	32 (20.7%)	155 (100%)
No	12 (92.3%)	1 (7.7%)	13 (100%)
Total	135 (80.3%)	33 (19.7%)	168 (100%)

Table 3 depicts that in the study population, about 92.2% (155/168) were received health education. Of which about 20.7% were having hypertension with complications.

Table 4: Annual health Check up versus Hypertension (n = 169)

Annual health Check up	Hypertension without complications	Hypertension with complications	Total
Yes	114 (79.7%)	29 (20.3%)	143 (100%)
No	20 (76.9%)	06 (23.1%)	26 (100%)
Total	134 (79.2%)	35 (20.8%)	169 (100%)

Table 4 revealed that in the study population, about 84.6% (143/169) were received annual health check up. Of which about 20.3% were having hypertension with complications.

Discussion

The present cross sectional record review study was conducted at different primary health care centres to study the complications of hypertension and lipid profile status association with hypertension in Buraidah city. In the present study, among the abnormal triglycerides study group the prevalence of hypertension with complications was 33.3%. There was statistically significant association was observed between triglycerides status and hypertension complications (P<0.05). In the study group, among the abnormal cholesterol study group the prevalence of hypertension with complications was 13.2%. As the study record based review study and some records were not having all the parameters. As the sample size is small and due to not available of other lipid parameters not interpreted in the study. In the present study, lipid abnormality individuals itself is less and one of the limitation of the present study findings cannot be generalized into the entire Buraidah population.

But record review studies sometimes will act as eye opener for the better planning strategies for the improvement. Study conducted in Bangladesh by C. M Reza Qureshi Forhad, Asma Kabir et al [5] revealed that it was a cross sectional study in which 159 diagnosed hypertensive patient and 75 with normal blood pressure (normotension) were enrolled for comparison. These patients sought a through health cheek up including blood pressure assessment between May 2012 to April 2013 in Tairunnessa Memorial Medical College and Hospital. Lipid parameters total cholesterol (TC), triglyceride (TG), low density lipoprotein (LDLc) and high density lipoprotein (HDLc) were estimated by enzymatic colorimetric test. Study revealed the results of the mean of Systolic blood pressure and Diastolic blood pressure of hypertensive were higher than normotensive (p<0.001). The serum levels of total cholesterol, triglyceride and LDL-C in hypertensive subject were higher than normotensive persons and statistically significant (p<0.001).

The logistic regression analysis indicates hypertensive were 1.2 times higher total cholesterol, 1.3 times higher triglyceride and 1.2 times higher LDL-C than normotensive persons and was statistically significant (p<0.001). Another study conducted in Riyadh, Saudi Arabia by Abdalla A Saeed et al [6] with background of this study aims to assess the association between lipid profile and obesity among adults in Kingdom of Saudi Arabia

and identify anthropometric predictors of dyslipidemia. overall prevalence of obesity ranged from 33.8 to 44.4 % and the overall dyslipidemia prevalence ranged from about 25 to 44% depending on type of dyslipidemia and anthropometrics used. Prevalence of dyslipidemia and mean concentration of lipids profile were generally significantly higher in obese than non obese. About 45.7% of complications occurred in < 5 years duration of hypertension.

In the present study, about 20.6% (35/170) individuals were having different complications. Of which, ischaemic heart disease (IHD) was identified as common complication which accounts 15.3% of all complications noticed in the study population. Another study on complications and hypertension conducted in Saudi Arabia by M. E. K. Ahmed and I. B. El-Awad [7] carried out a cross-sectional study involving known hypertensive patients so as to find out about its complications. WHO Stage II and Stage III total organ complications were evident in 37.1% of the patients. From the study, mild-retinopathy accounted for 21.6%, followed by albuminuria (15.1%), urea elevation of more than 50mg/dl in 12.9% of the patients and 10.3% had left ventricular hypertrophy and these were the most common stage II complications [7]. Complications record availability at specialist hospitals is different from complication record at primary health centres. As more specialist availability and competency and laboratory facilities availability at primary health centre is different from the specialist hospitals. Family Medicine specialist introduction and periodical trainings and exposure certainly make some difference in complications diagnosis, management and records maintenance in the coming days.

In the study population, about 92.2% (155/168) were receiving health education. Study conducted in Makkah region highlighted about health education versus hypertension by Elzubier, Ahmed G et al [8] revealed that the problem of hypertension in diabetes could be sizeable. Many patients may remain undetected. A diligent search for diabetic subjects with elevated blood pressure should be made through an efficient system of follow up in the PHCC centers through effective health education about the disease and also about possible complications of hypertension [8]. Education also one of the important tool for bringing many changes in the health seeking behaviour of the individuals.

In the present study, about 84.6% were receiving annual health check up. study done in Aseer region by Al-Khaldi, Yahia M et al revealed that the rate of defaulter was high, which indicated an ineffective recall system. A high percentage of patients did not have annual check-ups because of assumption of the lack of laboratory facilities and poor coordination with hospitals. study revealed that the majority of hypertension patients had poorly controlled and reason could be multifactorial [9,10]. In spite of providing all basic health services at the primary health care centres timely improvement, quality annual checkups and timely laboratory facilities, patient and health care team attitude towards regular treatment, identification of the complications, record maintenance and goal towards increase life expectancy to be developed and ultimately minimizing the wasteful resources and cost effectiveness. Need large sample similar studies are required to substantiate the present study findings.

Conclusions

Based on the study results, number of hypertension complications people itself is less. Among them, ischaemic heart disease (IHD) was identified as common complication which accounts 15.3% of all complications noticed in the records. Among the hypertensive individuals, lipid profile abnormality was more. Not only hypertension and even hypertension complications itself exhibits as a “ice berg phenomenon of the disease”.

Cardiac Failure in Misan, Iraq

Khalid Obaid Mohsin

M.B. Ch. B., C.A.B.M, D.M., Head of Internal Medicine Department, College of Medicine, Misan University, Misan, Iraq

ABSTRACT

Background: Categorization of heart failure patients depending on left ventricular ejection fraction (by using echocardiography) is important because there are different causes, comorbid conditions, and response to management. In addition, identifying and treating these comorbidities are the main steps in managing patients with heart failure.

Objectives:

- To determine the types and stages of heart failure in Misan.
- To determine its comorbidities, consequently, reaching better management and prognosis.

Patients and Method: A cross-sectional study was conducted in Al-Sader Teaching Hospital from October 2017 to February 2018. A total number of 60 patients were diagnosed as HF cases according to the full workup (including history, thorough clinical examination, Chest x-ray, electrocardiography, and echocardiography).

Results: A total of 60 patients were diagnosed as heart failure. The distribution of patients was equal in both genders with a predominance of patient aging more than 60 years. Approximately, half of the patients had heart failure with reduced left ventricular ejection fraction and stage D. As comorbidities; about three-quarters of patients had hypertension followed by diabetes mellitus and coronary artery disorders.

Conclusion: The incidence of heart failure and comorbid conditions are increasing with age. The presence of comorbidities is more with the progression of stages in heart failure. Therefore, a frequent medical follow up with 2-Dimensional Echocardiographic evaluations should be encouraged, especially, with older patients.

Keywords: *heart failure, stages, Misan, Iraq*

Introduction

Heart failure (HF) is a clinical syndrome and can be defined as the inability of the heart to pump adequately to maintain a blood flow that can meet the total needs of the body and usually, referred to as a congestive HF [1, 2].

Commonly, patients with HF present with dyspnea, tachypnea, tachycardia, fatigue, excessive tiredness, decreased ability to exercise, and leg edema. The dyspnea is usually getting worse while doing exercise, lying down, and can awake the patient at night [3, 4].

The ejection fraction is usually used to determine the pumping effectiveness of the heart, as well as, to classify the types of HF. Additionally, it can indicate the severity of HF [5]. Therefore, the categorization of HF patients depending on left ventricular ejection fraction (LVEF) is important because there are different causes, comorbid conditions, and response to management [6].

At 2016, European Society of Cardiology classified HF into three types according to LVEF [7]:

- HF with preserved LVEF (≥50%).
- HF with mid-range LVEF (40–49%).
- HF with reduced LVEF (<40%).

Khalid.mcm@uomisan.edu.iq

Moreover, the New York Heart Association classified HF into 4 stages: Stage A, B, C, and D depending on the objective assessment [8].

Furthermore, the comorbid conditions are highly important in patients with HF and may have a role in the treatment decision for HF (some medicines that are used in HF treatment may lead to worsening the symptoms and exacerbating the condition of HF). It is well recognized that HF with preserved LVEF is at more occurrence of comorbidities than HF with reduced LVEF. So, identifying and treating these comorbidities are the main steps in managing patients with HF [9].

For these reasons, this study had arisen to study the HF in Misan province, classifying those patients and to identify their comorbidities, consequently, reaching better management and prognosis.

Patients and Method

A cross-sectional study was conducted in Al-Sader Teaching Hospital in Misan province (South East Iraq) during a period of four months from October 2017 to February 2018.

The patients were selected from the out-patient department, from the echocardiographic unit, and from the in-patient medical department. A total number of 60 patients were diagnosed as HF cases according to the full workup (including history, thorough clinical examination, Chest x-ray, electrocardiography, and echocardiography). The required data was collected through face to face interview with patients.

Finally, an echocardiographic imaging study was done for all patients by a specialist doctor. The first echocardiographic evaluation was done to confirm the diagnosis of HF followed by a second detailed echocardiographic evaluation after the patient was stabilized.

Echocardiographic imaging was performed with GE machine, model vivid, version E9 following the recommendations and the guidelines of American Society of Echocardiography [10]. Categorization and staging of HF were done for every patient following the recommendations and guidelines [7, 8].

Exclusion criteria: any other diagnosis other than HF. In addition, any case rejected to be involved in this study or did not complete the follow-up evaluations was excluded.

The study protocol was reviewed; ethical approval and official permission were obtained from Ministry of Higher Education, College of Medicine in Misan, Misan directorate of health and Al-Sader Teaching Hospital to carry out this study. Informed written consent was obtained from each patient or from their parents. The analysis of data was carried out using Microsoft Excel and was presented in form of tables that interpreted by numbers and percentages.

Results

A total of 60 patients were diagnosed as HF. The distribution of patients was equal in both genders with a predominance of patient aging more than 60 as shown in table 1.

Regarding echocardiographic finding in this study; the patients were classified depending on LVEF. Half of the patients had HF with reduced LVEF and only 10 (16.7%) had HF with preserved LVEF as shown in table 2.

Approximately, half of the patients had stage D followed by C and B stages reaching (35.0%) and (15.0%) respectively as shown in table 3.

Regarding comorbidities associated HF; approximately, three-quarters of patients had hypertension followed by diabetes mellitus and coronary artery disorder reaching (53.3%) and (48.3%) respectively as shown in table 4.

Table 1: General characteristics of patients with HF

Characteristics	Number (%)
Age in years:	
< 60	10 (16.7%)
> 60	50 (83.3%)
Gender:	
Male	30 (50.0%)
Female	30 (50.0%)

Table 2: Classification of HF patients depending on LVEF that determined by echocardiography

Types of HF	Number (%)
HF with preserved LVEF	10 (16.7%)
HF with mid-range LVEF	20 (33.3%)
HF with reduced LVEF	30 (50.0%)
Total	60 (100%)

Table 3: Stages of HF patients depending on the objective assessment

Stages of HF	Number (%)
Stage A	1 (1.7%)
Stage B	9 (15.0%)
Stage C	21 (35.0%)
Stage D	29 (48.3%)
Total	60 (100%)

Table 4: Cardiac and non-cardiac comorbidities in patients with HF

Comorbid condition	Number (%)
Hypertension	42 (70.0%)
Diabetes Mellitus	32 (53.3%)
Coronary artery disorder	29 (48.3%)
Rheumatic fever	13 (21.7%)
Atrial fibrillation	13 (21.7%)
Chronic obstructive pulmonary disease	12 (20.0%)
Chronic renal failure	10 (16.7%)
Cerebrovascular accident	9 (15.0%)
Anemia	7 (11.7%)
Metabolic syndrome	5 (8.3%)
Thyroid disease	1 (1.7%)

Discussion

The current study revealed that there was more risk of developing HF with increasing age of patients in which there were 50 cases (of total 60) older than 60 years and this was in accordance with different studies [11, 12].

Additionally, this study showed that the distribution of patients was equal in both genders whereas Gerber et al study reported a predominance of the male gender in HF cases, especially, in HF with reduced LVEF [12].

Regarding echocardiographic finding in this study; the patients were classified depending on LVEF. The prevalence of HF with preserved LVEF increased significantly in the last decades [13] but the present study revealed that half of the patients had HF with reduced LVEF and only 16.7% had HF with preserved LVEF. These rates were different from other studies which reported about 30–55% of patients had HF with preserved LVEF [14, 15]. Nevertheless, more morbidity and mortality were reported in HF patient with preserved LVEF than those of reduced LVEF [15, 16].

The presence of comorbid conditions was more with the progression of stages in heart failure. Additionally, imaging studies, especially, the 2-Dimensional Echocardiography was essential in categorizing and staging the cases of heart failure.

Approximately, the vast majority (70.0%) had hypertension in this study followed by diabetes mellitus and coronary artery disorder reaching (53.3%) and (48.3%) respectively. The same sequence of commonest comorbid condition was seen with a similar study in Brazil but with fewer rates [17].

Some patient had one or two combined diseases or more together and this would increase the morbidity and make a worse prognosis.

It is of note that such diseases like hypertension, diabetes mellitus, and coronary artery disease are usually increasing with aging and most of the patients in the current study were older than 60 years so more risk to have HF and more risk for comorbidities, subsequently, poor outcome.

In addition, this study revealed the presence of non-cardiac diseases like renal, metabolic, anemia, and thyroid disease associated with HF. It was found that even the non-cardiac comorbidities would increase the risk of death, particularly, in HF patient with preserved LVEF [13, 18].

A further study to follow up those patients to report their outcome is recommended in the future.

Conclusion

The incidence of heart failure and comorbid conditions are increasing with age. The presence of comorbidities is more with the progression of stages in heart failure. Therefore, a frequent medical follow up with 2-Dimensional Echocardiographic evaluations should be encouraged, especially, with older patients.

Dilated Cardiomyopathy in Children

Khalid Obaid Mohsin

M.B. Ch. B., C.A.B.M, D.M., Head of Internal Medicine Department, College of Medicine, Misan University, Misan, Iraq

ABSTRACT

Background: Dilated cardiomyopathy in pediatrics age group is considered as a serious problem with variable prognosis. There are few studies for this issue in Iraq and no previous local study.

Objectives:

- To determine the associated risk factors, clinical presentation in dilated cardiomyopathy.
- To determine its characteristic electrocardiographic and echocardiographic findings.

Patients and Method: A hospital-based cross sectional study conducted during a period of three years from 2009 to 2012 in Misan, Iraq. The diagnosed cases of dilated cardiomyopathy were selected from the referred patients for an echocardiographic evaluation in Al-Sader Teaching Hospital with suspicion of either dilated cardiomyopathy or heart failure. A full history, thorough clinical examination, Chest X-ray, electrocardiography, 2D-Echocardiography were done for all cases.

Results: Children with dilated cardiomyopathy presented with variable symptoms but congestive heart failure was the most common. Male was more predominant than female with median age of 11 ± 2.605 years. Different electrocardiographic findings but tachyarrhythmia was the commonest.

In echocardiography, left atrial size was positively correlated with left ventricular function and the majority had mitral valve regurgitations.

Conclusion: Dyspnea and heart failure were the most common presenting symptoms in children with dilated cardiomyopathy. NYHA class III heart failure was common causing more morbidity and mortality in those patients. Additionally, imaging studies, especially, the 2-Dimensional Echocardiography was essential in confirming the diagnosis.

Keywords: *Dilated cardiomyopathy, children, Misan*

Introduction

Dilated cardiomyopathy (DCM) is the commonest type in pediatrics [(1)]. The incidence in children is reported to be 0.34 to 0.73 per 100.000 per a year [(2)] while in adult; it was found to be 6.95/100.000 per a year as reported by another study in Europe [(3)]. Patients with DCM is usually presented with progressive heart failure with insidious onset but may present as acute onset in about 25% of patients, if associated with lower respiratory infection [(2)]. Cough, shortness of breath, wheezing, irritability, and poor feeding are usually the primary symptoms. Easy fatigability, growth failure, decreased urine output, and pallor may occur [(4)]. Other clinical presentations which occur in about 20% of patients are the following: palpitation, chest pain, orthopnea, hemoptysis, abdominal pain, neurologic deficit, and syncope [(4)]. About half of cases of DCM are preceded by a history of upper respiratory tract infection which is usually of viral origin [(5)]. Coxsackie B (serotypes 1 to 6) is the commonest virus causing DCM in children. Other viruses such as enterovirus, adenovirus, influenza,

Email: mcdmissan@yahoo.com

and rubella are implicated in myocarditis [5]. In addition, familial cardiomyopathy is positive in about 25% of patients [6].

Sometime, DCM is misdiagnosed in pediatrics age group as an upper respiratory tract infection and patient may receive false management for a long time [7]. Moreover, DCM has substantial morbidity, as well as, mortality [8]. Initially, it is well known that one-third of affected DCM cases would die, other third would improve, and the last third would have a chronic disease [7]. So predicting the outcome of DCM is an important in its management as revealed by different studies [9, 10, 11]. For these reasons, this study had arisen to have a baseline data about the natural history of DCM in children in Misan and to determine the characteristic echocardiographic findings.

Patients and Method

A hospital-based cross sectional study conducted during a period of three years from 2009 to 2012 in Misan province (South East Iraq).

The diagnosed cases of DCM were selected from the referred patients (54 cases) for an echocardiographic evaluation in Al-Sader Teaching Hospital with suspicion of either DCM or heart failure. A full history, thorough clinical examination, Chest x-ray, electrocardiography, 2D-Echocardiography were done for all cases. Finally, only 44 cases were diagnosed as DCM and included in the current study.

The first echocardiographic evaluation was done at the referral time to confirm diagnosis of DCM followed by a second detailed echocardiographic evaluation after the patient was stabilized.

Echocardiographic imaging was performed with GE machine, model vivid, version E9 following the recommendations and the guidelines of American Society of Echocardiography [12].

Different electrocardiographic and echocardiographic characteristics of those patients were recorded.

According to the New York Heart Association (NYHA) classification [13], the patients were classified into 4 groups:

NYHA 1: angina, dyspnea, syncope, or palpitation (ADSP) at more than usual physical activity

NYHA 2: ADSP at usual/ordinary physical activity.

NYHA 3: ADSP at less than usual physical activity.

NYHA 4: ADSP at rest or with minimal activity.

Inclusion criteria: age is between 1-12 years, both gender, symptomatic, all patients had left ventricular 2D- ejection fraction (2D-LVEF) < 0.45.

Exclusion criteria: shortness of breath and/or heart failure due to asthma, congenital heart disease, valvular heart lesion, anemia, active pulmonary tuberculosis, and any other diagnosis other than DCM. In addition, any case rejected to be involved in this study or did not complete the follow-up evaluations was excluded.

The study protocol was reviewed; ethical approval and official permission were obtained from Ministry of Higher Education, College of Medicine in Misan, Misan directorate of health and Al-Sader Teaching Hospital to carry out this study. An informed written consent was obtained from each patient or from their parents.

The analysis of data was carried out using Microsoft Excel and was presented in form of tables and figures.

Results

A total of 44 patients with median age of 11 ± 2.605 years were diagnosed as DCM. A predominance of male and negative family history of the same illness was seen as shown in table 1.

All patients were symptomatic and the majority was presented with congestive heart failure at the time of evaluation as shown in figure 1.

According to the NYHA classification**;** the patients were classified into 4 groups: the majority was from NYHA 3 reaching 55% followed by NYHA 2 (32%) as shown in figure 2.

Regarding electrocardiographic finding in this study; tachyarrhythmia was the commonest. Irregular rhythm was recorded in a total of 15(34%) patients while atrial fibrillation only was found in 6(13.6%) patients. On the other hand, all the characteristic findings of echocardiography were shown in table 2.

Valvular regurgitation was a common problem. The majority has mitral and tricuspid valve regurgitations as shown in table 3.

Aortic	1 (2.27%)

Discussion

The current study enrolled a total number of 44 pediatrics age group patients with median age of 11 ± 2.605 years and male predominance. Those cases were presented with dyspnea and during clinical evaluation aided by other imaging studies were diagnosed as DCM.

Different clinical presentations were found but dyspnea and congestive heart failure were the commonest

clinical presentation of DCM. Unfortunately, more than half of congestive heart failure patients were of NYHA class III heart failure (according to NYHA classification) [13] in which more morbidity and mortality were found.

These findings were against Puggia et al study, in which it revealed that pediatrics DCM had less severity in comparison with adult, less LBBB, and short duration of heart failure. This may be explained by the late diagnosis in this study, because most of cases presented initially with NYHA class III heart failure [15].

Regarding electrocardiographic finding in this study; tachyarrhythmia was the commonest. Irregular rhythm was recorded in a total of 15(34%) patients while atrial fibrillation only was found in 6(13.6%) patients. Arrhythmia was a common cause of death in DCM with heart failure functional Class NYHA class III and this was compatible with Dimas et al study [16].

This study revealed that most cases are of idiopathic origin and associated with negative family history of DCM which was in accordance with different studies [15, 17, 18].

According to the World Health Organization, DCM is characterized by dilatation and impaired contraction of the left ventricle or both ventricles [19].

Regarding echocardiography, the present study showed that left atrial size was positively correlated with left ventricular function and the majority had mitral valve regurgitations. Therefore, 2-Dimensional Echocardiography is essential in the diagnosis, as well as, a good predictor in prognosis.

Conclusion

Dyspnea and heart failure were the most common presenting symptoms in children with dilated cardiomyopathy. NYHA class III heart failure was common causing more morbidity and mortality in those patients. Additionally, imaging studies, especially, the 2-Dimensional Echocardiography was helpful in confirming the diagnosis.

Conflict of Interest: No conflict of interest.

Effect of Exercise and Body Mass Index (B.M.I.) on Fitness

Khalidah Nayyef Mustafa

Northern Technical University, Technical Institute, Mosul, Nursing Department

ABSTRACT

Background: Both Body Mass Index (B.M.I.) and fitness level are very important factors affecting risk of many disease or infections such as hypertension especially in obese men(overweight) without any exercise, therefore aim of current study were study the role of both exercise and Body Mass Index (B.M.I.) on the Fitness.

Material and Method: This study has been done upon (180) students in Nursing department (70) males, (110) females, their age ranged between (18-24) years.

Findings: Current study found 55(25 males,30 females) have high level of fitness with B.M.I. ranges between (18 – 30Kg/m^2) and all them always do physical exercise daily. The study showed 80(35 males, 45 females) with less fitness depending on time required to return to rest values of vital signs (25) of them do exercise every day,but (55) don't do any physical activity. Also the study indicates that (45) of sample (10 males, 35 females) have low fitness with B.M.I. ranges between (22-30 Kg/m^2) without any physical activity.

Conclusion: (50%) of the sample of both sex were practise proper sports and average body mass is (19-26 k.g/s.m) is the best concerning physical activity, the level of physical fitness decreases if body mass exceeds (26 k.g/m^2)and proper sports exercises can lessen the negative impact of overweight on physical fitness.

Keyword: *Exercise; Body Mass Index: (B.M.I.) and Fitness*

Introduction

Gymnastic or sports exercises make a series of body self-responses which improve the vascular cardiac system, and play an important role in treating many morbid cases without the use of drugs such as pulse rates, breathing, blood pressure, muscle strength, and sustaining physical fitness.[1] The impact of gymnastic exercises by (10) minutes a day for three successive days is the same as that of the physical fitness when practiced by two minutes a day for (15) days or one minute for (30) days and there was a considerable decrease in weight and increase in vital capacity.[2] Hypertension is of the health challenges all over the world, different epidemic studies indicate that that leads to diseases of blood vessels and kidneys and others. Treating hypertension lessens the risk of the results incurred on being infected with these diseases and the organized gymnastic exercises have played an important role to treat high blood pressure by the use of drugs and clinical results confirm the usefulness of practicing sports on the long run.[3] When comparing physical fitness levels between two groups, the first consists of ordinary people and the second of people suffering from over-weight, when they run for one mile and then taking measure criteria (age, length, weight, and body mass) there was an abstract sharp difference between the two groups as pulse average and blood pressure of each group.[4]

Weak physical fitness among children and adolescents is an important factor that cause health problems in blood vessels later on among middle aged people and develop to other diseases and there is a relation with body mass among normal adolescents and their physical fitness.[5]

Proper sport practice depending on body building and enduring exercises has positive results in that part of the extra energy leaks the thing that improves muscle functions and body systems, practicing bodily exercises for (30) minutes everyday leads to burning sugar molecules as hard labour is sufficient to burn the same amount of sugars.[6]

Sport exercises practicing in fresh air increases the vital capacity which leads to a lot of health benefits, and when using three kinds of labour methods to

distinguish benefits, there was an absolute coincidence with laboratory examinations of blood vessels safety and respiratory system due to the amount of oxygen and comparing it against the standard volume at rest.[7] The impact of these exercises on lessening blood pressure varies in general, when asking normal women and others with high blood pressure to practice trunk, legs, knee and dual muscles exercises during three various periods, the fall in the systolic pressure was obvious in some of these exercises whereas no such thing happened in both groups while practicing other exercises. [8]

The mass of the body has a negative impact when exceeding (30k.g/s.m). When comparing the nutritional state with body mass of a number of university students in Nigeria for a complete year, the laboratory analyses indicate negative effects as to the various body systems.[9] Obesity is one of the increasing health problems in Canada and decreasing it is of the important factors to specify the relation between physical fitness and the working of both the vascular and respiratory systems in the proper manner, and keeping body mass does not lead to obesity in the future. [10] When testing the impact of body weight on the level of physical fitness of many personnel of the marines in Croatia aged (27) with body mass (86.2k.g/m^2), there was an adverse relation between fat rate and three tests connected with physical fitness. In the light of that the weight administration programme was allocated to decrease the appropriate amount on the long run to enable those people to live in the environment and the kind of work they practice.[11] Dancing in fresh air has a positive impact on the blood vessels, when a three-month- dancing programme was conducted on many women ranging from twenty years to twenty-five, there was a positive effect on the systolic and diastolic blood pressure and the average number of inhaling and exhaling per minute which allows entering a larger amount of oxygen. [12]

The aim of study is encouragement people to do continuously exercise to keep normal B.M.I to get highest fitness.

Material and Method

The weight and the length of (180) students were measured, (70) of them are males and (110) females, their age ranged from (18-24) years. Then the body mass was calculated by dividing weight (k.g) by length (cm) then measuring the vital signs for each one of them which are pulse, breathing and blood pressure at complete rest by using (sphygmomanometer and stethoscope).

After that each individual was exposed to physical stress by using the (treadmill) at 7 k.m/h for ten minutes, then directly after the exercise all the vital signs were measured and the time was also measured for the rates to move from a state to state, the criterion used to measure physical fitness was the least time required for the rates to return to their initial state.

Findings

When the experiment was conducted on (180) students at the Nursing Department (70/38%) males whose body masses ranged from (17-30 k.g/m^2), and (110/62%) females whose body masses ranged from (17-33 k.g/m^2).

Table 1: Sample as Gender and Body Mass Index (B.M.I)

Gender	No.	%	B.M.I kg/m^2
Male	70	38%	(17-30)
Female	110	62%	(17-33)
Total	180	100%	

Table (1) showed that people who were in rest their vital signs was within normal range for males (pulse 78/ min, respiration rate 19/min, blood pressure 120/80) and for females (pulse 78/min, respiration rate 16/min, blood pressure120/80) and after exercise there was clear increase in all signs for both sex, for males (pulse 120/ min, respiration rate 40/min, blood pressure 140/80) and for females (pulse 111/min, respiration rate 36/min, blood pressure 130/80)

Table 2: Average of vital signs before and after exercise

Gender	Vital signs during rest			Vital signs after exercise		
	Pulse Beats/ minute	Respiratory rate Once/minute	Blood pressure mm./Hg.	Pulse Beats/ minute	Respiratory rate Once/minute	Blood pressure mm./Hg.
Male	78	16	120/80	120	40	140/80
Female	78	19	120/80	111	36	130/80

In this table (2) illustrate the increased the vital signs (Pulse; Respiratory rate, and Blood pressure) after exercise compared to during rest

Table 3: Sample who having long practise and haven't

Gender	Have practise		Don't have practise		Total
	No.	%	No.	%	
Male	45	50%	25	27.8%	70
Female	45	50%	65	72.2%	110
Total	90	100%	90	100%	180

Results in table -3 showed that both males and females (No.= 45, 50%) were get good practise for suitable period, so females who do not have practise (No.= 65, 72.2%) more than male (No.= 25, 27.8%).

Table 4: Person who have highest physical fitness with good practise

Gender	No.	B.M.I kg/m^2								
		18	19	21	22	24.8	25	26	29.5	30
Male	25	—	6	4	—	7	3	5	—	—
Female	30	8	—	8	5	—	2	—	5	2
Total	55	8	6	12	5	7	5	5	5	2

From the above results, it was seen that the students with the highest physical fitness were those who lasted five minutes to return to the rest rates and their number was (55)-25males and 30females, with body mass (19-26k.g/m^2) for males, and (18-30) for females and all practise proper sports as is illustrated in table (4).

Table 5: Person who have medial physical fitness

Gender	No.	B.M.I kg/m^2										
		17	18	20	22.6	23	24.8	25	25.5	26	27	28
Males have practise	10	—	—	—	6	—	—	—	—	—	—	4
Males haven't practise	25	3	—	7	—	—	4	6	5	—	—	—
Females have practise	15	—	—	3	—	7	—	5	—	—	—	—
Females haven't practise	30	4	6	10	—	—	—	—	—	5	5	—
Total	80	7	6	20	6	7	4	11	5	5	5	4

Table (5) showed that (80) of the sample were have medial physical fitness and they needed (6-7) minutes. Of them (25) practise regular sports and (55) do not and the body mass of this group were (17-28 k.g/m^2).

Table 6: Person who have least physical fitness

Gender	No.	B.M.I kg/m^2					
		22	23	26.9	27	28	30
Males have practise	10	3	—	—	—	—	7
Males haven't practise	—	—	—	—	—	—	—
Females have practise	—	—	—	—	—	—	—
Females haven't practise	35	5	5	3	7	5	10
Total	45	8	5	3	7	5	17

As for the group with the least physical fitness as in table No.(6), of them were (45) as (10 Males and 35 Females) where it took them (8-12) minutes to return to the initial state, most of them were of those who do not practise proper sports and their body mass were (22-30 k.g/m^2).

Discussion

Physical activity is considered one of the important factors that lead to the loss calories that are not needed by the body –the surplus- and preventing fat from concentrating in various body tissues which leads to increase of endurance and physical fitness. The study has revealed that the individuals with the highest fitness are those who practise proper sports exercises everyday, Of the dependable criteria to measure fitness as in our study are pulse rates, breathing, blood pressure, and the time required to return to the rest state and here there is one of the most important indicators to specify the level of the physical fitness besides other criteria as oxygen consumption.[13]

Using up to date devices such as the (treadmill) to gauge the labour has an important effect in getting the results of the students at the preparatory and university stages. It is of benefit in increasing the capacity to endure and strengthening muscles especially legs and trunk muscles and this was emphasised by similar studies in this regard. [14]

Body mass has a noticeable effect on some of the elements of physical fitness. In our research it is noticed that those with a certain body mass can continue doing the exercise using the (treadmill) device longer than the time determined in the research and did not get tired on the contrary to those with larger body mass and this coincides with other studies. [10,15]

The study shows that the individuals with the least fitness do not practise proper sports and their body masses are larger than normal. Those people with medial fitness according to the criteria of the research were practising some physical activities yet improperly. We believe that physical activity lessens the negative impact of body mass which is larger than usual and this is confirmed by other studies. [6]

Conclusions

(50%) of the sample of both sex were practise proper sports and average body mass is (19-26 k.g/m^2) is the best concerning physical activity, the level of physical fitness decreases if body mass exceeds (26 k.g/m^2)and proper sports exercises can lessen the negative impact of overweight on physical fitness.

Analysis of Related Factors with Anxiety Occurrence in Population with the Risk of Coronary Heart Disease in Indonesia

Titin Andri Wihastuti[1], Fajaruddin Fajaruddin[1], Tina Handayani Nasution[1], Kumboyono Kumboyono[1], Yulia Candra Lestari[2]

[1]School of Nursing, Faculty of Medicine, Brawijaya University; [2]School of Nursing, Kendedes Institute of Health Sciences

ABSTRACT

Background: Anxiety is one of the psychological factors as an independent factor of predictors coronary heart disease (CHD) and proven to play a strong role in increasing the risk of CHD doubling.

Aim: Objective of the study is to identify the relationship of socioeconomic status, type of personality and coping mechanism with anxiety occurrence in population with the risk of CHD.

Method: The study used analytical observation with cross sectional approach. The respondents were 111 individuals with the risk of coronary heart disease. The sampling method was purposive sampling. The study was conducted in Malang, Indonesia on April 2018.

Result: Spearman rank correlation test showed a significant relationship between socioeconomic status (p=0.009), type of personality (p=0.038) and coping mechanism (p=0.000) with anxiety occurrence in population with the risk of CHD. Logistic regression test showed that coping mechanism is the most correlation factor with anxiety occurrence in population with CHD risk (OR=5.343) compared with other factor. It is important to provide skills of coping mechanism for population with the risk of coronary heart disease.

Keywords: *socioeconomic status, personality, coping mechanism, anxiety, coronary heart disease, risk*

Introduction

The high prevalence of morbidity and mortality due to coronary heart disease (CHD) became a major health problem in various countries of the world including Indonesia. World Health Organization (WHO) data from 2012 shows that of 56.5 million deaths worldwide, 31% are due to cardiovascular disease where 42.3% is caused by CHD[1]. CHD became the highest cause of death at all ages in Indonesia of 12.9% with a prevalence of 1.5% and the number continues to increase with age (highest group at age 65-74 years). The highest incidence of the majority in women, the population not in school, not working, urban domicile, and low economic status[2].

Epidemiological studies have a clear influence on the risk of CHD, ie irreversible risk factors such as age, sex, ethnicity, genetics, geography and change of life, as well as changeable risk factors such as hypertension, hypercholesterolemia, diabetes, obesity, diet, smoking, exercise, lifestyle, social circumstances and psychological factors[3]. Psychological factors such as stress anxiety and depression are predictor independent factorsand are twice as likely to increase the risk of developing CHD[4]. Acute anxiety leads to hyperventilation resulting in seizures in the heart muscle, increased sympathetic nervous system work and triggering episodes of ventricular arrhythmias that affect cardiovascular health and trigger CHD. Anxiety increased neuroendocrine and platelet activation[5,6].

Factors that affect anxiety consisting of intrinsic factors such as age, experience undergoing treatment and personality type[7]. While extrinsic factors are medical condition or disease diagnosis, and access of information, adaptation process or coping mechanism, socioeconomic status and family disease history. Factors of experience undergoing treatment and diagnosis of disease occur in someone who has suffered from CHD. While the study of this study is a factor that affects the incidence of anxiety in healthy populations that have risk factors for CHD such as age, sex, family heart disease history, knowledge, socioeconomic status, type of personality and coping mechanism.

Methodology

The study used analytical observational design with cross sectional approach. The respondents were 111 individuals with coronary heart disease risk selected using the purposive sampling method. The study was conducted in Kota Lama, a sub-region in Kedungkanandg, Malang City, Indonesia on April 2018. The instrument was questionnaire. Bivariate analysis and spearman rank correlation were used to identify relationship between socioeconomic status, type of personality and coping mechanism with anxiety in population with coronary heart disease risk, while multivariate analysis and logistic regression test were used to identify the most significant factor.

Findings

Table 1: General Characteristics of Respondents by Age

	N	Mean	Minimum	Maximum	Standard Deviation (SD)
Age (year)	111	52.36	27	78	11.722

Source: Primary Data (2018)

Table 1 showed that the average age of respondents is 52.36 years with a standard deviation of 11,722. The youngest age of 27 years and the oldest age of 78 years.

Table 2: Distribution of Respondent Characteristics and Variable

Characteristics	%
Socioeconomic status	
Low	28.8

Source: Primary Data (2018)

Table 2 showed that from 111 respondents, most with moderate socioeconomic status (41.9%), most with type B personality (39.1%), almost half with less coping mechanism (43.7%), and most experienced anxiety is 68 people (61.3%).

Table 3: Spearman Rank Correlation Test Results Between Socioeconomic Status, Type of Personality and Coping Mechanism with Anxiety Occurrence in Population with The Risk of CHD

Variable	Anxiety	
	r	p
Socioeconomic Status	0.247	0.009
Type of Personality	-0.197	0.038
Coping Mechanism	0.367	0.000

Source: Primary Data (2018)

Table 3 shows the p value < α (0.05) meaning that there is a significant relationship between socioeconomic status, type of personality and coping mechanisms with

anxiety occurrence in population with the risk of CHD in Malang.

Table 4: Logistic Regression Test Results Factors Most Associated with Anxiety Occurrences in Populations with The Risk of CHD

Variabel	P Value	Exp (B)	R Square
Type of Personality	0.032	0.560	0.430
Coping Mechanism	0.006	5.343	
Socioeconomic Status	0.966	0.983	

Source: Primary Data (2018)

Based on table 4 it is known that R Square 0.430, meaning 43% of anxiety occurrence in population with high risk of CHD can be explained by factors socioeconomic status, personality type and coping mechanism.

Discussion

1. **Relationship between Socioeconomic Status and Anxiety Occurrence in Population with The Risk of Coronary Heart Disease:** The bivariate analysis showed that socioeconomic status correlated significantly with the occurrence of anxiety in population with risk of CHD, since the *p* value < α (0.05) and the correlation score was positive. This indicates that the lower the socio-economic status of a person, the more likely to experience anxiety. The results of this study are consistent with several research results which show that low socioeconomic status and financial pressures felt to be significantly related to anxiety. Individuals with good socioeconomic status can protect emotional stress and anxiety[8,9,10].Low socio-economic status will cause individuals to experience anxiety more easily, this is evidenced by the results of studies that show the prevalence of anxiety decreases with higher socioeconomic status[7,11]. The prevalence of disease is more prevalent in people with low socioeconomic class.

   In this study also found most respondents who experience anxiety in those who do not work, as housewives, do not have a permanent job and with types of jobs such as car drivers, sellers, factory workers and traders. Anxiety is more common in societies with lower socioeconomic status and then results in acute or chronic physiologic changes in cardiovascular function, increase the risk of CHD. A person with a job status and a fixed income will feel more peaceful life because the problems of daily living and economic needs can be met so as to reduce the burden of thoughts and psychological pressure that can cause anxiety[12,13].

2. **Relationship between Type of personality and Anxiety Occurrence in Population with The Risk of Coronary Heart Disease:** The bivariate analysis showed that there was significant relationship between type of personality and anxiety in population with the risk of coronary heart disease, since the *p* value < α (0.05) and the correlation score was negative. It indicated that type of personality was inversely proportional to anxiety incidents, in which an individual with type A personality was more prone to anxiety compared to individuals who have other types of personality.

   Type A personality is associated with anxiety and increases the risk of CHD[14]. This type of personality feels more anxious and has a negative coping style that increases the risk of CHD[15,16.] This is reinforced by the results of studies that show that the hostile component of Type A personality is the most significant risk factor for stress and anxiety[17].

   The development of the concept of stress, psychodynamics and psychosomatic disorders, personality type is used to be an important idea in which personality type A is associated with stress and anxiety and promotes the development of coronary heart disease[18]. In addition, personality type D is also described as a personality that connects with negative affective and emotional, avoidive coping styles and social inhibitions associated with cardiovascular disease and the development of CHD risk[19].

3. **Relationship between Coping Mechanism and Anxiety Occurrence in Population with The Risk of Coronary Heart Disease:** The bivariate analysis showed that coping mechanism correlated significantly with the occurrence of anxiety in population with risk of CHD, since the *p* value < α (0.05) and the correlation score was positive. This means that the less the ability of coping mechanism, the tendency to experience anxiety is higher. The results of this

study are in line with research that shows that low coping mechanism during adolescence are associated with an increased risk of heart disease during adulthood[20]. Individuals with low coping mechanism ability when faced with difficulties, will be more susceptible to stress that can cause anxiety, depression, anger, impulsiveness and low self esteem.

Coping mechanisms can regulate negative and positive emotions as well as improve self-efficacy in stress relief so that individuals can reduce or eliminate anxiety. Whenever there is a stressor, the individual automatically appears to attempt to cope with various coping mechanisms[21]. The use of coping mechanisms will be effective when supported by individual beliefs against the coping used can reduce or eliminate anxiety. Anxiety should be addressed to reach homeostasis in the individual, both physiologically and psychologically[22].

4. **The Most Significant Factor in Anxiety Occurrence in Population with The Risk of Coronary Heart Disease:** The result of multivariate analysis showed that coping mechanism was the most correlated factor with anxiety occurrence in population with CHD risk since the OR was 5.343. Coping strategies and coping mechanisms are factors that greatly affect the individual's ability to deal with problems, psychological stress and anxiety compared to other factors[23]. Further explained that, the coping mechanism becomes the determinant in problem solving. Coping mechanisms are the most important factor in the individual's ability to control and adapt to psychological problems such as stress, anxiety and depression in addition to biological factors, exercise, and appropriate psychotherapy[24].

   Coping mechanism influenced by motivation, self-efficacy and self-resilience. Identifying coping source and strategy was an effective and efficient method to develop coping mechanism preparing an individual to overcome his or her issues accurately[25]. Coping mechanism is a prominent element in negotiation, management and adaptation towards source of stress and anxiety allowing an individual to adapt and maintain positive, well-balanced life.

Conclusion

There is a significant correlation between asocioeconomic status, personality type and coping mechanism with anxiety occurrence in population with risk of CHD. Coping mechanism is the factor most associated with anxiety events in the population with CHD risk compared with other factors. It is important to provide skills of coping mechanism for population with the risk of coronary heart disease.

What are the Staffing Levels and Maternal Outcomes? A Descriptive Study in Referral Hospitals in Java, Indonesia

Makhfudli Makhfudli[1], Ferry Efendi[1], Anna Kurniati[2], Retnayu Pradanie[1], Susy Katikana Sebayang[3]

[1]Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia; [2]Center for Planning and Management of Human Resources for Health, BPPSDMK, Ministry of Health, Indonesia; [3]Faculty of Public Health, Universitas Airlangga, Banyuwangi Campus, Indonesia

ABSTRACT

Adequate maternity staffs (obstetric/gynecologists, midwives, and nurses) at referral hospitals are crucial to manage obstetric complications and to improve maternal outcomes. This study aims to describe the staffing levels and maternal outcomes in selected referral public hospitals in Java region of Indonesia. The data of 8,396 deliveries with live birth and 522 maternity staffs were collected from six referral hospitals in Java, Indonesia. Descriptive statistics were employed to summarize the study subjects. The maternity staffing levels of the study hospitals were relatively sufficient, however, the maternal mortality ratio and the severe maternal outcome ratio are moderately high. Further studies are recommended to understand the effect of staffing and other possible factors on maternal outcome.

Keywords: *maternal, midwife, nurse, referral hospital*

Introduction

Maternal mortality is the second highest cause of death among women of reproductive age with nearly eight hundreds women died every day from maternal causes.[1] In addition maternal morbidity is experienced by approximately twenty million women around the world that leads to death and disability without prevention or appropriate treatment.[2] Considering the magnitude of this issue, improving maternal health continuously receive a major concern from the global stakeholder. The Sustainable Development Goals set a target to reduce the maternal mortality ratio by 70 deaths per 100,000 live births by 2030.[3]

Despite the declining trend of maternal mortality ratio (MMR), Indonesia is among other developing countries with a high number of maternal deaths. Based on the national population census reports, the MMR has been reduced from 390 per 100,000 live births in 1991 to 305 per 100,000 live births in 2015.[4] This achievement is in line with the increase proportion of skilled birth attendance. By 2015, the percentage of skilled birth attendance has exceeded the national target at 93.1%.[5] However, approximately 20.5% of births are delivered at home.[5]

Skilled birth attendance at health care facilities is a key strategy in Indonesia to prevent delays in managing obstetric emergencies. Based on the 2012 Indonesian Demographic and Health Survey, more than 80% of maternal deaths occur in hospitals.[6] It indicates that women with obstetric complications may not arrive timely at the hospital or may receive inadequate treatment while in the hospitals. The Government of Indonesia stated that delays in making decision to seek care, making referral to health facilities, and managing obstetric emergency care due to constraints in infrastructure and human resources are among contributing factors to maternal mortality.[7]

Health workforce is a central component within the health system. To improve maternal health, appropriate staffing has been strongly recommended by policy makers from international and national institutions. This policy is partly supported by evidence, as various studies have reported the significant relationship between higher staffing

Corresponding Author:

and positive health outcome.[8] A previous review study reported that shortage of health workers and imbalance distribution occur in various public health facilities in Indonesia.[9] This study, therefore, aims to describe the staffing levels and maternal outcomes in several referral public hospitals in Java region of Indonesia.

Method

Study Design, Setting, and Sampling: This study employed an observational study design using the retrospective data from the hospital administrative electronic database. The hospital study location was purposively selected based on the similarity of structural characteristics of the hospitals. Data of obstetric patients and maternity staffs were collected from six referral hospitals with eleven maternity wards within Java region, Indonesia from September to December 2017. The study employed the total sampling technique to capture data of all study subjects. We included all deliveries with live birth (single and multiple births). Stillbirth and incomplete data of deliveries were excluded from the data analysis.

Study Variables: Nursing staffs included registered nurses and diploma nurses, while midwifery staffs consisted of professional midwives and diploma midwives. Variables of staffing levels will be presented as an aggregate at the maternity unit level, including:

1. Nurse to patient: number of nursing staffs per 1000 patient/year.
2. Midwife to patient: number of midwifery staffs per 1000 patient/year.
3. Maternity staffs to patient: number of nursing and midwifery staffs per 1000 patient/year.
4. Proportion of nurses and midwives with bachelor degree.
5. Average years of nursing experience.
6. Average years of midwifery experience.
7. Proportion of permanent staffs.

One variable of the staffing level of obstetrician/ gynecologist (ob/gyn) is presented in ratio per 1000 patient/year at the hospital level.

Variables of maternal outcomes represented the outcome of obstetric patients that are categorized as follows:

1. **Death:** women who died in the hospital from maternal causes
2. **Near-miss:** women who almost died from maternal conditions within 42 days after the pregnancy terminated
3. **Survive:** women who are alive at the time of discharge from hospital.

Other variables represented the characteristics of obstetric patients include:

1. Age
2. Place of residence:
   - Same city : the patients were residents of the city where the hospital located.
   - Other city: the patients were residents of other cities.
3. Admission procedure: referral and non referral.
4. Payment scheme: insurance and out of pocket.
5. Types of delivery: vaginal spontaneous delivery, instrumental delivery, caesarean section, and other assisted delivery.
6. Types of live birth: single and multiple
7. Length of stay: days of hospitalization calculated from the day of admission to the day of discharge.
8. Type of maternal complications underlying causes of morbidity and mortality.

Data Analysis

Descriptive statistics method was employed to analyze the data to generate the study results in forms of frequencies, percentages, mean, ranges, and standard deviation. This method allowed to summarize the characteristics of the study subjects based on the variables selected.

Results

The data of 8,396 patients with live birth deliveries and 522 maternity staffs (medicine, nursing, and midwifery staffs) were obtained from six hospitals. Table 1 displays the statistics summary of variables of staffing levels. The mean nursing staffing level at maternity unit was 26.1 nurses per 1000 patient in a year. The average

midwifery staffing level at maternity unit was 21.8 midwives per 1000 patient per year. The maternity staffs showed an average ratio of 47.9 staffs to 1000 patient per year. The proportion of nurses and midwives holding bachelor degree in maternity units was ranging from 2.0% to 57.4%, with 25.0% at the average. The average years of experience between nursing staffs and midwifery staffs per maternity unit were quite similar at 11.1 years and 11.3 years respectively. The mean of the proportion of permanent staffs at the maternity unit was 74.3%. At the hospital level, the mean of the staffing level of ob/gyn was 13.6 ob/gyn per 1000 patient in a year.

Table 1: Descriptive statistics of staffing levels by maternity unit

n = 11

Staffing levels	Minimum	Maximum	Mean	SD
Nurses to patient	5.0	45.4	26.1	15.09
Midwives to patient	7.1	50.7	21.8	12.24
Maternity staffs to patient	27.8	66.2	47.9	15.32
Proportion of nurses and midwives with bachelor degree	2.0	57.4	25.0	18.74
Average years of nursing experience	2.7	21.6	11.1	5.74
Average years of midwifery experience	6.7	26.0	11.3	5.23
Proportion of permanent staffs	34.9	100.0	74.3	22.42
Ob/gyn to patient*)	6.1	29.9	13.6	8.86

*) calculated at hospital level

Table 2 presents the characteristics of obstetric patients included in this study. The mean age of the study subjects was 29.8 years old. Most of patients (67.1%) were residents of the city where the hospital located. Admission to the hospital were mostly through medical referrals (74.5%). Insurance was the most payment scheme utilized by the patients (84.7%). Surprisingly, although most deliveries were single live birth (98.5%), more than half deliveries were conducted through Caesarean section. Majority of patients (83.9%) were reported to have maternal complications. The mean length of stay in the hospital was 4.2 days. While most maternal outcomes (97.2) were positive, 15 patients died and 221 patients experienced near-miss events.

Table 2: Characteristics of obstetric patients

N = 8,396

Variables	Number (%)	Mean ± SD
Age	-	29.8 ± 6.52
Place of residence		
Same city	5,632 (67.1)	
Other city	2,764 (32.9)	
Admission procedure		
Self-referral	2,138 (25.5)	
Medical referral	6,258 (74.5)	
Payment scheme		
Out of pocket	1,288 (15.3)	
Insurance	7,108 (84.7)	
Types of delivery		
Vaginal spontaneus	3,088 (36.8)	
Instrumental	471 (5.6)	
Caesarean section	4,837 (57.6)	
Type of live birth		
Single	8,266 (98.5)	
Multiple	130 (1.5)	
Complications		
No	1,354 (16.1)	
Yes	7,042 (83.9)	
Length of stay	-	4.2 ± 2.93
Patient outcome		
Death	15 (0.2)	
Near-miss	221 (2.6)	
Survive	8,160 (97.2)	

Table 3 shows the outcome of patients who experienced maternal complications (n=7,051). Most of the underlying causes of maternal mortality and near-misses were complications predominantly related to puerperium and other conditions at 40% and 24.4% respectively. Overall, maternal complications were dominated by conditions specified in the group of other maternal care related to fetus and amniotic cavity and delivery problems (36.4%).

Table 3: Types of maternal complications by patient outcome n = 7,051

Maternal complications	Patient outcome, N (%)			
	Death	Near-misses	live	Total
Oedema, proteinuria, and hypertensive disorder	1 (6.7)	44 (19.9)	1,454 (21.3)	1,499 (21.3)
Placenta praevia, premature separation of placenta and antepartum haemorrhage	1 (6.7)	26 (11.8)	231 (3.4)	258 (3.7)
Other maternal care related to fetus and amniotic cavity and possible delivery problems	2 (13.3)	53 (24.0)	2515 (36.9)	2570 (36.4)
Obstructed Labour	0 (0.0)	4 (1.8)	188 (2.8)	192 (2.7)

Other complications of pregnancy and delivery	5 (33.3)	29 (13.1)	1582 (23.2)	1616 (22.9)
Complication predominantly related to puerperium and other conditions	6 (40.0)	54 (24.4)	666 (9.8)	726 (10.3)
Other not specified complications but may affect the maternal outcome.	0 (0.0)	8 (3.6)	149 (2.2)	157 (2.2)
TOTAL	15	221	6,815	7,051

Discussion

Our study showed that the mean of staffing levels of nurses is slightly higher than the staffing levels of midwives. The minimum ratio and the maximum ratio have a wide range in both nursing and midwifery staffing levels, but narrower range in the maternity staffing level at 47.9 staffs per 1000 patients a year. This finding implies that nursing and midwifery staffs in maternity units may have substitution roles. The availability of ob/gyn in referral hospitals is crucial. In our study, there was a wide range of ob/gyn staffing level among the study hospitals from 6.1 to 29.9 ob/gyn per 1000 patients per year, with an average of 13.6 ob/gyn per 1000 patients a year. A previous study in England, reported that the mean for each maternity staffing levels was 29.6 midwives, 1.4 consultant ob/gyns, and 4.3 junior ob/gyns per 1000 deliveries a year.[10]

In Indonesia, the staffing in the maternity unit is determined based on the hospital classification. Referral hospitals of type A and type B are recommended to have the staffing ratio of one nurse or midwife per patient.[11] This regulation implies that at the secondary or tertiary referral level of care every patient should be attended by either a nurse or a midwife at all shifts. Other countries such as the United Kingdom and Australia also had different recommendation related to the optimum maternity staffing. The UK suggested 36 midwives per 1000 births to manage one to one care throughout the childbirth process and other period of care.[12] In Australia, the suggested staffing levels in maternity inpatient units were one midwife or nurse for every five patients on a day shift and for every eight patients on the evening shift.[13]

In this study, the mean of the proportion of staffs with bachelor degree in maternity units was 25%, while both the mean years of nursing experience and midwifery experience were quite similar at approximately eleven years. Previous studies reported the significant factors of staffs educational background and the duration of staff experience to the improved patient outcome.[14] A previous study reported that the likelihood of patients dying was 30% lower in the hospitals with 60% of staffs with bachelor degree in nursing than in hospitals with only 30% of nursing staffs with bachelor degree.[15]

The average age of obstetric patients in this study was 29.8 years old, insurance users, and mostly admitted through the referral procedure. Most of patients were having maternal complications which may indicate the reason for accessing the referral level of care. This finding is not surprising, considering the data of this study was taken from the 2016 hospital database which was the second year of the implementation of the National Health Insurance system. The system may have contributed to the increasing access of women with maternal complications to referral health facility.

Our study showed that the maternal mortality ratio was 178.8 per 100,000 live births. According the World Health Organization (WHO), the MMR is categorized as moderately high if the range falls between 100 to 299

maternal deaths per 100 000 live births. The MMR in this study is found to be lower than the present MMR at the national level which is probably due to the small sample size and only conducted in one region. The severe maternal outcome (deaths and near-misses) ratio was 28.2 per 1000 live births. This finding is higher than the ratio reported in a previous study in Brazil at 11.08 per 1000 live births.[16]

Most of underlying causes of maternal deaths and near-miss events in this study included puerperal complications, other complications of pregnancy and delivery (including intrapartum haemorrhage and preterm labour), other maternal care related to fetus and amniotic cavity and possible delivery problems, and hypertensive disorder. According to WHO, most of the causes of maternal deaths can be prevented through effective interventions including antenatal care, intranatal care, and postnatal care.[1] These interventions aim to ensure that every pregnant woman is physically and mentally healthy throughout pregnancy and deliver a healthy baby. Effective maternal health care services require adequate and competent health providers.

Conclusion

The staffing level is an essential component to deliver quality of care. The mean of staffing levels of nursing, midwifery and obstetric/gynecology in this study indicated sufficient staffs available at the referral facilities. However, the maternal mortality ratio and the severe maternal outcome ratio are still moderately high indicating that other factors may have influential contribution. Further studies are strongly recommended to explore the relationship between staffing and maternal outcomes by incorporating other possible factors that may affect the association.

Ethical Clearance: The ethical approval for this study was granted by the IRB committee of the Faculty of Nursing at the Airlangga University in 2017.

Source of Funding: This study received funding support from the Ministry of Research, Technology and Higher Education of Indonesia number 004/ADD/SP2H/LT/DRPM/VIII/2017. The funding source was not involved in study design, data collection, analysis or interpretation; in the writing of this report; or in the decision to submit the article for publication.

Estimation of Procollagen Type III Peptide (PIIIP) Level in β Thalassemia Patients

Maryam Kadhim Al-Shemery[1], Arshad Noori Al-Dujaili[2]

[1]Physiology and Hematology, Collage of medical Techniques, The Islamic University, Iraq,
[2]Biology Department, University of Kufa, Iraq

ABSTRACT

Procollagen type III peptide (PIIIP) is established as biochemical markers of liver fibrosis. So that, type III (Pro-C3) can be used as diagnostic tools for liver fibrosis. Collagen type III amino-terminal pro-peptide (PIIINP) is a degradation product of collagen type III, the increase of which may reflect an ongoing fibrotic process. Procollagen type III is found abundantly in skeletal muscle and other soft tissues such as skin, and in negligible amounts in bone. During the late phases of collagen synthesis, the N-terminal end of procollagen type III is cleaved releasing P3NP into the circulation.According to case-control study. This study was conducted with eighty-eight of males that age ranges from 2-29 years, which divided in 60 of males with β-thalassemia whom have visited the Thalassemia Center at Al-Zahraa Teaching Hospital in Al–Najaf province, Iraq, for managed of the disease, and 28 voluntary healthy as a control groups of. The study was carried out from January 2018 to July 2018., Procollagen type III in β-thalassemic patients and healthy groups of males. It also investigates the relationship between these biomarkers levels was measurement by using a solid phase enzyme-linked immunosorbent assay (ELISA) and also, determined Hb, Body Mass Index, splenic status liver function test (ALT, ASTand ALP).

Keywords: *Procollagen type III, ALT, ASTand ALP, β-thalassemia.*

Introduction

Type III collagen contains multiple charged residues in the Xaa and Yaa positions of its chain. Type III collagen is the second most abundant collagen in human tissues after type I and is primarily found in tissues exhibiting elastic properties, such as skin, blood vessels, and internal organs. Type III collagen is common in fast growing tissue, particularly at the early stages of wound repair ([1,2,3,4])

The amino-terminal propeptide of type III procollagen (PIIINP) is an extension peptide of procollagen type III, which is cleaved off during conversion from type III procollagen to type III collagen. PIIINP reflects myocardial fibrosis, which is higher in the tissue of dilated and dysfunctional left ventricles ([6, 7]). Recently, a new ELISA kit was developed by applying monoclonal antibody targeting the N-protease cleavage site of collagen type III pro peptide, which could assess the true synthesis of collagen type III ([8,9,10]).

In the liver type III collagen mainly occurs during the synthesis of type III collagen, the N-terminal pro peptide of procollagen type III (PIIINP) is detached from procollagen type III, so the fibrogenesis results in release of ECM fragments into the blood. Hence the quantity of propeptide of procollagen type III can be a direct indicator of collagen synthesis and its deposition in the extracellular space ([11,12,13]). The increased amount of propeptide of type III procollagen may indicate the transformation of normal liver tissue into connective tissue. N-terminal propeptide of procollagen type III (PIIINP) is generated during the synthesis of type III collagen. PIIINP can be measured in the serum as an indicator of liver fibrosis and cirrhosis ([14,15,16]).

Material and Method

This study was conducted with eighty-eight of males that age ranges from 2-29 years, which divided in 60 of males with β-thalassemia whom have visited the Thalassemia Center at Al-Zahraa Teaching Hospital in Al–Najaf province, Iraq, for managed of the disease, and 28 voluntary healthy as a control groups of. The study was carried out from January 2018 to July 2018.

Collection of Blood Sample: The Blood samples were drawn from vein by sterilized synergies with 5 milliliters. The sample put in the two labeled tubes, first group of tubes contain EDTA as anti-coagulants to prevent clotting of blood to be used for physiological studies. The second group of tubes was without anti-coagulant as gel tubes, for blood to be used for preparing serum for following biochemical and biomarkers.

Hemoglobin Estimation: The hematological parameters were performed on EDTA blood using Mythic 18 (RINGELSAN CO., Turkey) in Hematology Laboratory of Al- Zahraa Teaching Hospital. This device is a completely automated hematology analyzer.

Biochemical Parameters

Measurements of ALP concentration: This was done by a method based on enzymatic colorimetric test, executed with specific kit for test, supplied by BIOLABO**.**

Measurements of AST, ALT, ALP concentration: This was done by a method based on enzymatic colorimetric test, executed with specific kit for test, supplied by BIOLABO.

Biomarker Parameters

Estimation Human Procollagen type III ELSA kit: Specific kit for measuring human IL-1β concentrations in serum was supplied by Elabscience Biotechnology

Statistical Analysis

The data was statistically analyzed through SPSS package (SPSS, Version 23). The descriptive analyses between the patients and control groups of Means and Standard Error. All of these statistically analyzed at significant($P<0.05$).

Results

Procollagen type III level in male β-thalassemia patient and healthy groups are plotted in figure (1)**.** The results are finding a significant ($P<0.05$) increase in Procollagen type III level in β-thalassemia patient group (9.39 ± 0.59) ng/ml than healthy group (4.49 ± 0.22) ng/ml.

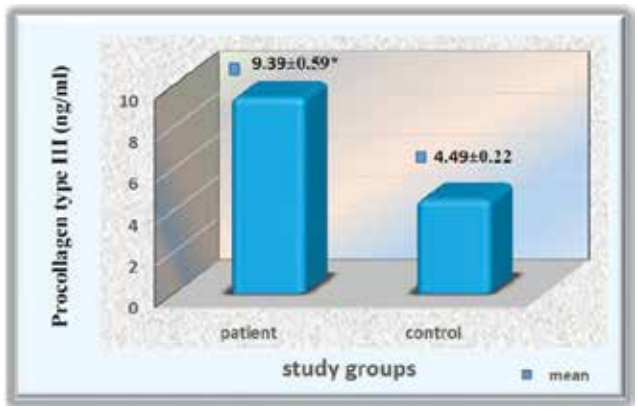

Figure 1: Procollagen type III (ng/ml) level in male patients with β-Thalassemia and control groups

Procollagen type III level in both patient groups as shown in figure (2). The results indicate the presence of a significant ($P<0.05$) increase in mean Procollagen type III level in serum of β-thalassemia intermedia (11.09 ± 0.94) ng/ml, in comparison with that of β-thalassemia major (8.40 ± 0.72) ng/ml.

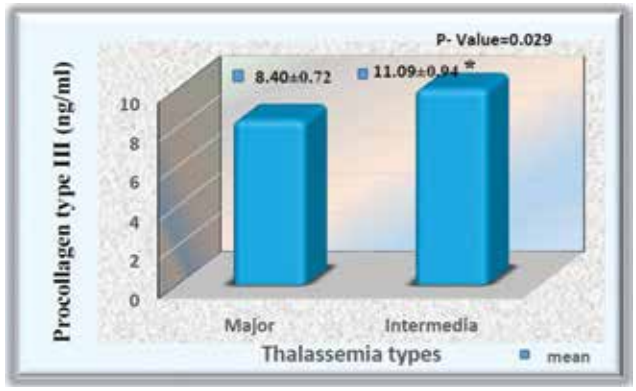

Figure 2: Procollagen type III level (ng/ml) in male patients with major and intermedia β-thalassemia

Mean serum Procollagen type III level values in the studied of the age groups as shown in figure (3). The results demonstrated the presence of a significant ($P<0.05$) increase in serum Procollagen type III level of male patients with β-thalassemia of the age group (2-10) year about (10.40 ± 0.84) ng/ml in comparison with the age group (11-19) about (7.63 ± 1.01) ng/ml.

Moreover, it presented the same significant increase when it was compared of the age group (20-29) about (10.74 ± 1.12) ng/ml, with the (11-19) age group about (7.63 ± 1.01) ng/ml.

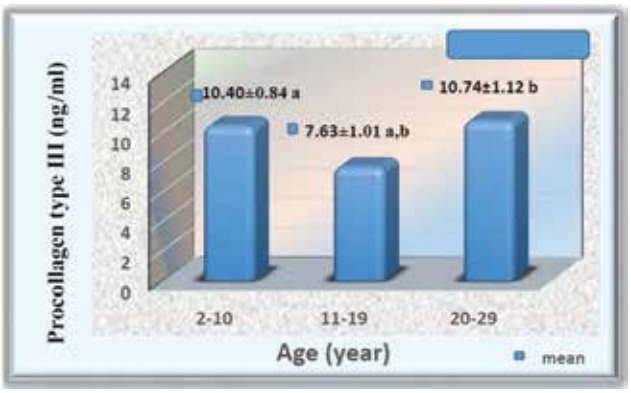

Figure 3: Procollagen type III level (ng/ml) in male patients of β-thalassemia according to age

The statistical analysis showed in figure revealed to no significant differences in serum procollagen type III level between both groups splenectomized (7.86 ± 0.91) ng/ml and unsplenectomized group (10.33 ± 0.75) ng/ml, of male patients with β-thalassemia.

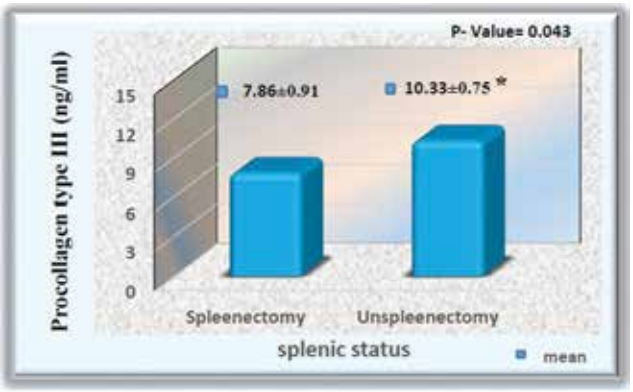

Figure 4: Procollagen type III level (ng/ml) in splenectomized and unsplenectomized of male patients with β-thalassemia

Discussion

In the present study, the liver function test table revealed a significant increase in the levels of ($p<0.05$) in serum levels of ALP, AST and ALT. Current results agree with Zayed, (2018) who suggested that thalassaemia may be causes lesions in liver tissues indicated by elevation of serum liver function criteria levels ([17,18,19]).

ALP value increases in bone turnover and has been reported to be regarded as a marker of bone formation ([20]). Previous study found that serum ALP is a sensitive screening tool for the diagnosis of osteomalacia ([21]).

The same table showed highly significance in AST and ALT levels in male patients with β-thalassemia compared with healthy control group this acceptable with the results of Salama *et al.,* (2015) and Abdulla, (2018). ([22,23])

Many Study of observed that increased levels of AST and ALT in β-thalassemia are due to iron overload, a very low hemoglobin level with very high (AST, ALT) level along with spleenomegaly is suggestive of poor prognosis in these patients. ([24,25,26]).

Data in the present study revealed marked significant elevation in ALT and AST activities as well as total and direct bilirubin levels in thalassemia patients compared to controls. Similar results were obtained by Mansi and Aburjai, (2008) and Attia *et al.,* (2012). ([27,28])

Elevated transaminasaemia in â-thalassemic children is indicative of liver dysfunction and leakage of liver metabolites into the plasma ([29]). Previous study suggested that The iron deposition may cause damage of hepatocyte (ALT & AST elevation) and cholestasis (bilirubin & ALP elevation), liver Injury may be as necrosis of heaptocellular, cholestatic disease or mixed between these two diseases like granulomatous hepatitis ([30,31]).

Rahim, (2017) revealed that the increased serum liver parameters may be caused by iron storage in the liver which is regarded as a notable victim of iron deposition.([32])

The results of this study have revealed a increase in serum PCIII level in male patients with β-thalassemia that compared to the healthy male groups.These results agree with Wang *et al*., (2017), which proved that the elevated of serum PIIINP levels is a potentially sensitive method to predict the risks for iron overload-related liver fibrosis in Chinese thalassemia patients.([32])

Iron overload, that take place in a significant proportion of thalassemia patients because of elevate in gastrointestinal iron absorption ([33]) and/or repeated transfusions, ([34]) reflects iron deposition in the liver, heart and endocrine glands, and cases cardiac failure, endocrine disorder and liver fibrosis ([35]). Transfused iron is accumulated first in the reticuloendothelial cell prior to parenchymal iron loading in the liver and heart ([36]).

Study of Knovich *et al.,* (2009) proposed that liver cirrhosis related to high serum ferritin levels. Although ferritin best reflects bodyiron store, it is an acute phase reactant that readily fluctuates with active infection or inflammation.([37])

Recent study has been showed liver iron deposition can cause lipid peroxidation, that compromises the organelle integrity, thereby partispating to hepatocyte necrosis and apoptosis, and finally causes liver fibrogenesis. Iron can also have assisted the hepatic stellate cells differentiation into collagen producing myofibroblasts([38])

In several studies, it has been shown that PIIINP can be diagnosed in the serum as an indicator of liver cirrhosis and fibrosis ([39]). So that, studies based on PIIINP as a liver damage indicator suggest that tissues with high fibro genic activity or non-mature fibrotic tissue composed communally from type III collagen. These findings raise an intriguing possibility that liver iron overload and liver function are likely correlated with serum markers of liver fibrosis. Eventually, ferritin concentration and liver iron level were significantly correlated with liver dysfunction meatured by AST and ALT ([33]).

Conflict of Interest: There was no any conflict of interest in this study

Source of Funding: There was no fund in this study

Ethical Clearance: Ethical was According to the *Declaration of Helsinki* issued by the World Medical Association, formulated in experimental protocols and independent (ethics committees approval university of kufa/college of Medicine

ABSTRACT

The current study was designed to determine the prevalence of breast cancer compared to other types of cancer patients who are admitted to the cancer tumors Center/Al Sadr Teaching Hospital in Najaf, For the period from February to Jun2017. The rate of breast cancer was 21.2 % (215) of the total number of infected people cancer (1015). this study showed the relation between the type of blood and the prevalence of infection, where the results were (36.3, 32.1, 22.3, 9.3%) by dependent the factions of blood (A, O, B,AB) respectively. The incidence of infection in women who use oral contraceptives was (52.7) compared to those who did not use the pills (5.4). Obesity is also an important factor In the prevalence of infection, where the proportion of women in obese women (64.5) compared to non-obese (16.1). The study also showed that there was a relationship between the level of education and the prevalence of breast cancer, which was the highest rate of infection in uneducated women followed by the holders of primary, preparatory, diploma and the lowest percentage of the bachelor's degree, where the percentages were (36.3,28.8,15.8,11.6,7.4) % respectively.

Keywords: *cancer, contraceptives, blood group, Obesity*

Introduction

The growth of normal cell usually results from a tight balance between growth stop signals and growth stimulation signals. Reproduction happens only when the cells number is increased. The balance is shifted to stimulate growth. This occurs during normal tissue change and during wound healing. Cells differentiate during this process and the reproduction stops. When needed. While in tumor cells there is a defect in this balance, which leads to the continued proliferation of cells and loss of differentiation.

Cancer result from a genetic defect in the body cells that transforms it into cancerous cells that are out of control. They divide and grow at the wrong place and time, leading to the formation of tumors. In initiation phase of cancer occur mutation in DNA copy during the division of the cell. This mutation happens with effect many factors such as viruses infection, radiation, environmental factors, and smoking. when the mutation causes many mutations, the cell becomes more able to life and resistance of immune factors. after that, cancer speared to other tissues.

Type of breast cancer is a solid carcinoma and diagnosed by clinical and postoperative classification It was very important to detect early breast cancer because the patient's survival rate for at least five years from the diagnosis of the disease decreases with the development of the disease

Most disease injured of human-associated with blood group, ABO blood groups are antigenic, polymorphic, found on the erythrocyte surface and some tissue or other cells.ABO discovered by Landsteiner in "1900". In 2015 find the blood types system are important in transfusion medicine. the blood groups are allied with many of diseases including vascular disease, diabetes type 2. so that the study objective to know the relationship between cancer and blood group also study effect some risk factors on the prevalence of disease.

Materials and Procedure

Samples: Blood samples collection from women infected by breast cancer by finger prick method for diagnosis type of blood.

Diagnosis Type of Blood: Diagnosis of blood group directly by used blood group kit.

Result and Discussion

Shows the percentage of breast cancer relative to the total number of the sample studied

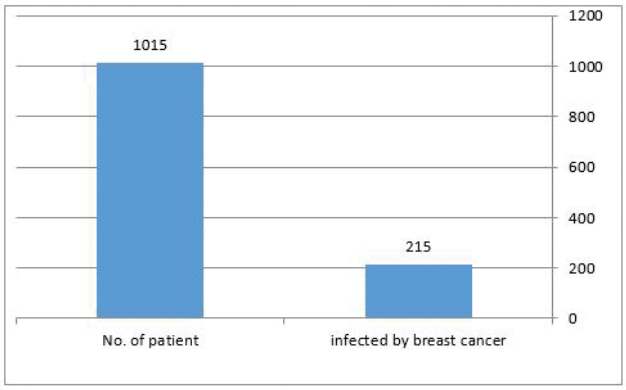

Figure 1: Explain the number patient of infection by breast cancer for a total number of cancer patients

The results showed that the rate of breast cancer reached about 21.2% (215) of the total number of cancer patients(1015) and this indicates the high incidence of breast cancer. A blood sample was drawn for each group of patients with cancer for the purpose of determining the blood type, the result explained the women with blood type (A) have the highest incidence of breast cancer, followed by the type of blood (O, B) and the lowest type of blood (AB) (36.3, 32.1, 22.3, 9.3) % respectively. These results are agree with the results of a number of studies that attempted to prove the relationship of cancer with blood type, although there was a disparity in the outcome, including the study of which found a relationship between blood type and breast cancer. (figure 2)

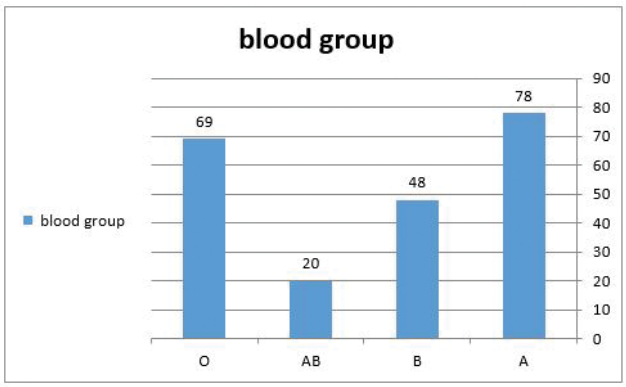

Figure 2: Explain the relation between Blood group and breast cancer

Also the results showed that women taking oral contraceptives are more likely to be infected(figure 3), and this is agree with Nygren et al. This explains that the treatment of (estrogen, progesterone) of the risk of breast cancer by 55-100%, Estrogen plays an important role through its receptors in a process Growth and proliferation of cells in the natural breast tissue, thus increasing the levels of estrogen with a view to pharmacological treatment May lead to the emergence of growth and proliferation of cells from control and the development of cancer

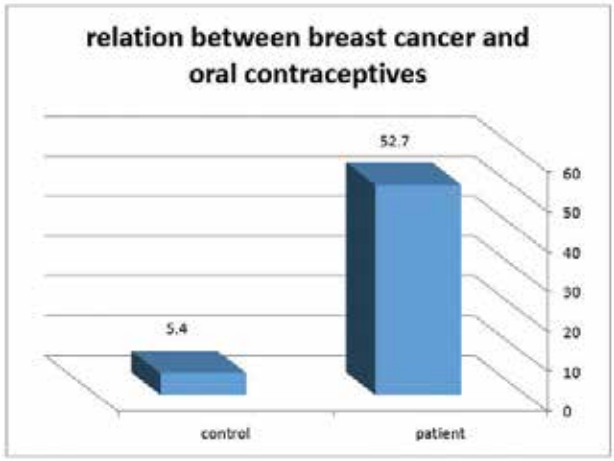

Figure 3: Explain the relation between oral contraceptive and breast cancer

We see a rise in the obesity factor in women with breast cancer compared to healthy women (figure 4) Consequently, obese females are more likely to develop breast cancer, and this is agree with This is because lipid tissue is an important source of estrogen in obese, as fat cells increase the of fat number Sex hormones in the body play a role in the production of estrogens and act to increase the conversion of androgens induced The enzyme aromatase to estrogen, thus increasing levels of estrogen and its effect on the path of growth and proliferation of other cells Thus natural development of estrogen-positive future cancers

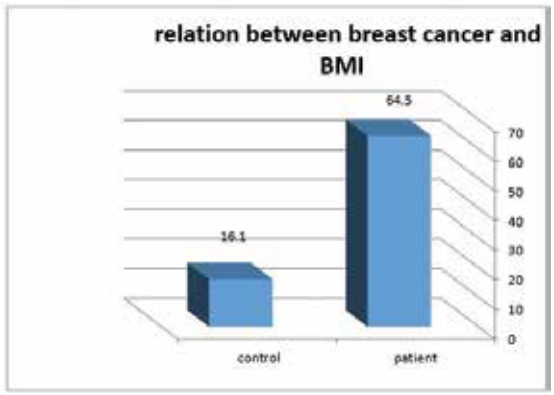

Figure 4: Explain the relation between BMI and breast cancer

The study showed that the level of education for women plays a large role in the prevalence of breast cancer, with 36.3% of the illiterate women, 28.8% of the women with primary education, 15.8% secondary education, 11.6% of the diploma and 7.4% of the Bachelor's degree (figure 5)

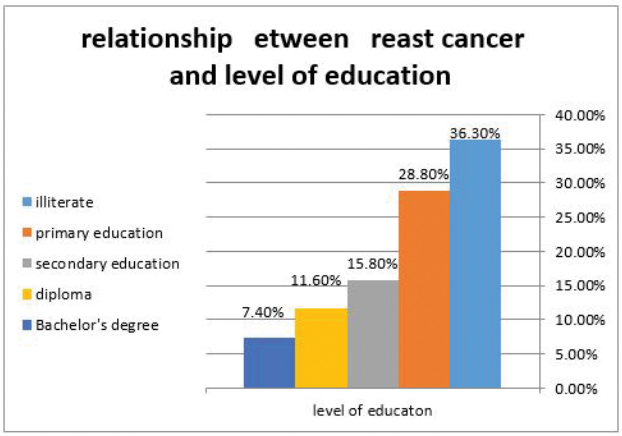

Figure 5: Explain the relationship between level of education and breast cancer

Conclusions and Recommendations

Conclusions

- The rate of breast cancer was higher for other cancers
- The study showed that oral contraceptives were a risk factor for cancer Breast.
- The study showed that obesity is a risk factor for breast cancer.
- The study showed is a relationship between blood groups and breast cancer.

Recommendations

- We recommend that women use oral contraceptives to reduce the risk of breast cancer.
- As obesity is one of the most important factors for breast cancer, women are advised to lose weight and exercise.
- It is necessary to follow a regular breast examination which helps in early detection of the disease.

Strengthen the Spiritual-Based Family Resilience to Overcome the Family Stigma of Leprosy

Nasrudin[1], Ah Yusuf[2], Rachmat Hargono[1], Tjipto Suwandi[1]

[1]School of Public Health, [2]School of Nursing, Airlangga University, Surabaya, Indonesia

ABSTRACT

The high burden of stigma received by the family as a result of leper family members requires resources, support, and resilience so that the family will be able to perform its role in caring for the leper family members and reducing the stigma. The Spiritual based family is an important component of the value system and trust for family life in strengthening family resilience. This spiritual factor will be very influential on coping, support, family acceptance of leprosy patients and the process of treatment and family stigma.

The purpose of this research was to analyze family spiritual factor with family resilience theory approach in overcoming family stigma.

This research used a cross-sectional design. The research population was 174 leprosy families in 21 endemic Leprosy public health centers or *Puskesmas* in Jombang regency of East Java. The samples were 120 families, taken using a Multi-Stage Random Sampling technique. The Hypothesis test used a chi-square test with a p-value <0.05.

The result of the research was that 73 (60.8%) had moderate and high family stigma, 46 (52.5%) moderate spiritual family and 60 (50%) of medium resilience. The family spiritual factor had an effect on family resilience (P = 0.000), and family resilience had an effect on family stigma (P = 0.000).

The conclusion was that family spiritual factors influence family resilience to overcome family stigma. Therefore, it is suggested that the intervention to overcome the family stigma must concern with family resilience and family spiritual factors.

Keywords: *Family, Spirituality, Resilience, Stigma*

Introduction

Based on the conceptual model of stigma, stigma is exists when the elements of labelling, stereotyping, separation, loss of status, and discrimination occur in a power situation that allows stigma components to unfold [(1)]. The cause of stigma in leprosy patients is complex, namely socio-cultural, fear of the causes, manifestations, effects and death from disease, economic, psychological, religious and spiritual [(2,3).] Public stigma effect on the family raises stigma problems for the family and also has an effect on the family's behavior of the leper family members. The results of the previous research conducted in 2017 showed that 39 families of leprosy patients in six endemic leprosy public health centers or *Puskesmas* in Jombang regency of East Java had 29 (74.4%) family stigma, individual factors involved individual stigma, self-concept, and level leprosy defect had an impact toward the family stigma (P = 0.000). Family factors involved family support, family coping mechanisms, knowledge and family perceptions of leprosy had an impact toward the family stigma (P = 0.000) [(4)].

Resilience, support, and strengthening of family resilience are needed by the family in carrying out the family function of caring for the leper family members and overcoming the stigma for the family, family internal stigma and stigma for the lepers. Strengthening of family resilience includes three major components

Corresponding Author:

Jombang regency of East Java Indonesia
Email: nasrudinbinsholeh@gmail.com

are namely: strengthening the family belief systems, strengthening the structure and function of the family as a unit or system (organization patterns), strengthening communication patterns and family strength system in overcoming problems (communication/problem-solving) [4–10]. Family spirituality is the basis of family values and belief systems, the core of all coping and family adaptation, and families seek and rely on the spiritual support of family members as a family way to deal with stigma problems [11–13]. Spiritual is also a family domain, that being a source of family strength and family resilience, hence this research was aimed to analyses family spiritual factor with family resilience theory approach in overcoming family stigma.

Material and Method

This cross-sectional design research was conducted on 2018 – 2019. The study population was a leprosy family in 21 endemic leprosy community health services in Jombang regency of East Java, consisted of 174 families of leprosy patients and they had been diagnosed with leprosy and recorded in a public health center or *puskesmas* data registration. The sample was 120 families taken by using Multi-Stage Random Sampling. The hypothesis test was taken by using the chi - square test with <0.05 significance. Data collected by questionnaires. Respondent from each family was represented by a family member who cares directly for lepers in the family. Assessment topics included 1). The family spiritual factor, 2). The family resilience, and 3). The family stigma. The family spiritual factor data assessed using the family's answer to family religiosity coping, family interdependence in religious and spiritual, family support and togetherness in religious and spiritual, and family spiritual. The family resilience assessed using the family's answer to the family's ability to helping others, growing stronger, acceptance, adjustment, and survival. The questionnaire used to measure the spiritual family was a modified instrument which was created from the religion and problem-solving scale (RPS) instrument based on the concept of religion and the problem-solving process [14], the spiritual response questionnaire from Nursalam [15], and the American Family Strengths Inventory on the component Spiritual Well-Being (SWB) [16,17]. The family resilience measurement questionnaire used the Walsh Family Resilience Questionnaire (WRFQ) (18) and the concept of family resilience processes [19]. Measurements of family stigma were based on the concept of stigma [20], the concept of stigma and social stigma components [21,22], and the concept of family stigma (23) and modified with the Explanatory Model Interview catalog (EMIC) stigma scale for community [24–27]

The univariate analysis used frequency distribution while bivariate analysis applied test chi-square if statistically eligible, if it does not qualify, then it would use the test of Fisher's Exact Test of p value <0.05.

Findings

The Family Spiritual Factors toward the Leprosy Family Resilience Analysis

Table 1: The Influence of family spiritual factor toward the leprosy family resilience in Jombang district East Java Indonesia in 2018

Family spiritual	Lower Resilience		Moderate Resilience		High Resilience		Total		P
	(f)	(%)	(f)	(%)	(f)	(%)	(f)	(%)	
Family Religious Coping									
Low	22	18.3	28	23.3	2	1.7	120	100	0.000
Medium	7	5.8	22	18.3	19	15.8	120	100	
High	1	0.8	10	8.3	9	7.5	120	100	
Family Interdependence in religious and spiritual									
Low	20	16.7	22	18.3	0	0	120	100	0,000
Medium	9	7.5	28	23.3	22	18.3	120	100	
High	1	0.8	10	8.3	8	6.7	120	100	

Conted…

Family support and Togetherness in religious–spiritual									
Low	27	22.5	28	23.3	0	0	120	100	0,000
Medium	2	1.7	23	19.2	21	17.5	120	100	
High	1	0.8	9	7.5	9	7.5	120	100	
Family Spiritual									
Low	19	15.8	20	16.7	0	0	120	100	0,000

Based on table 2, showed that the influence of spiritual family on family resilience after the statistical test, obtained value P = 0.000. It can be deduced that Family Interdependence in religious and spiritual factors. The family support and togetherness in religious and spiritual and the family Spiritual have a significant influence on family resilience.

The percentage of the family spiritual and the family resilience rates were almost half at moderate (> 45%) and only a small (<20%) rate was high. The results indicated that the spiritual family which was the family resources on the family's basic value system was still weak. Thus, these factors lead to family endurance to stress and resilience family.

After the statistical test, it was obtained that the effect of family resilience of family stigma in table 2 was P = 0.000, which means that family resilience has an effect on family stigma. The influence of sub-variable of resilience of the family was only sub-variable of other helping have a p-value = 0.064, while sub-variable Growing stronger (P = 0.000), Acceptance (P = 0.000), Adjustment (P = 0.000) and Survival (P = 0.000) it was concluded that there was influenced by the family stigma.

Discussion

The family spirituality greatly influences the family's ability to deal with their problems, strengthens family relationships and the resilience reflected in family dynamics as a system in carrying out family functions, the parenting styles, the family dynamics, the family development, and the spiritual relationships between generations. The spiritual component of the family includes 1) The Personal faith; 2). The Spiritual and religious praxes (contemplative practices, rituals, and ceremonies); 3). The Faith communities; (4) The Faith communities, connection with nature 5). The Ability to express creative activities (expression through the creative arts); 6). The Community service/ social activism; 7. The intimate relationship with transcendence; 8). The Relationship with God [6,28].

Spiritual strength would strengthen family health, including family commitments, improve emotional health, develop healthy living behaviors, improving healing process (13). The spiritual influence 4 dimensions of family care which were coping, support, acceptance, treatment and treatment process [29]. This condition cause a stressor of the situation for the family, the ability of the family to survive or the ability of family resilience is needed in the overcoming a stressful situation, the ability of the family to adapt, help each other, accept the condition of leprosy patients, change the family structure that support the process of treatment and care as well as the ability to survive together will help families to solve problems and adapt to stressors and will not appear in family stigma [7,28,30].

Family resilience is the ability to bounce back from adversity and then become stronger and able to take lessons from the difficulties encountered. There are three major components of family resilience, namely: family belief systems, family structure and function as an organizational pattern, communication pattern and family strengthening system (communication/problem-solving) [6,9,28,31].

Apparently, the reducing of leprocy occurences still gives bad stigma about the lepers and their family to the people and it is always attached to them. This effect of leprocy in term of physic, psychology and social consequently contribute to the rise of the problem of lepers and their family which represents in the form of stress and its effect on the health of the family. Thus, resources, support and strengthening the resilient of the family is necessary for the family of the lepers to care of their members who suffers of leprocy and also to maintain the health of the family. Furthermore, family should have spiritual control which is a based on value system and family belief. In this case spiritual belief, family and individual religiousity are the core of all copings and family adaptation. Moreover, family try to look for and use family spiritual belief to cope with stigma problem. In general, main concept of family spiritual consists of family religious coping, family interdependence, family togetherness dan personal spiritual (32,33)

Conclusions

The spiritual family includes the family religious coping, the family interdependence in religious and spiritual, the family support and togetherness in religious and spiritual, and the family member spiritual influence on the occurrence of family resilience as well as the stigma to the family with the leper.

Association between Socio-economic Status and Breast Feeding Practices in a Group of Women Delivered During the Previous Year in Kirkuk City

Nazar Ahmed Mahmood[1], Qasim Husein Mohammad[1], Kasim Sakran Abass[2]

[1]Department of Basic Nursing Sciences, College of Nursing, [2]Department of Pharmacology and Toxicology, College of Pharmacy, University of Kirkuk, Kirkuk, Iraq

ABSTRACT

Breastfeeding is considered as an ideal form of feeding in the neonate. It is feeding of babies with breast milk directly from women breasts instead of a baby bottle or other container. The present study aims at investigating the association between breastfeeding practices and socioeconomic status. This cross-sectional study was conducted at Pediatric General Hospital (PGH) in Kirkuk city over a period of seven months starting from January 2016. Consecutive sampling was employed to collect 377 mothers who have children (< 24 months) in PGH. A questionnaire was used to compile the information on the socio-economic factors and practices of breastfeeding. Data was analyzed through descriptive and inferential statistics (Chi-square test). Out of 288 mothers, 377 of them reported being breastfed. A significant difference has been found between breastfeeding practices and some maternal data. These include age ($p < 0.001$), parity ($p = 0.018$), and antenatal session attendance ($p < 0.001$). On the other hand, the regular visit to the PHC during the prenatal period did not affect breastfeeding practices ($p = 0.296$). Moreover, a highly significant association between breastfeeding practices and socioeconomic status of mothers has been shown. These include educational level ($p = 0.002$), occupational status ($p < 0.001$), and family income ($p < 0.001$). Breastfeeding has increased significantly with the increase in the level of education, family income, and being an employee.

Keywords: *Breastfeeding, Income, Education, Employment.*

Introduction

Breastfeeding is the process of feeding human breast milk to an infant. It is the usual way to provide babies with the nutrients they need to ensure healthy growth and development in the future.[1] Worldwide almost 38% of babies are just breastfed during their first six months of life. The duration of breastfeeding is shorter in high-income countries than in those that are resource-poor.[2] In Iraq, the early initiation rate of breastfeeding has risen from 25.1% in 2006 to 43% in 2011, whereas the exclusive breastfeeding rate was only 20%. [3]

Breastfeeding is considered an important measure to secure optimal health and survival for children.[4] Breast milk is the optimal food for infants and its benefits are numerous, as they contain living components such as antibodies that fight infection, white blood cells, red blood cells, and antiviral agents.[5] Moreover, breastfeeding is a protective factor for chronic diseases that may occur later in life, such as diabetes, childhood asthma, obesity, high cholesterol, high blood pressure, and childhood leukaemia. As of intelligence and behavior in adulthood, it has been shown that breastfed infants achieve better results in the tests compared to infants who are formula-fed.[6]

The mothers likewise are no exception of breastfeeding benefits, it contributes to a lower risk of postpartum bleeding; maintains birth spacing; strengthens mother-infant relationship; and finally breastfeeding provides money and effort, as breast milk is ready and needs no preparation.[4] In addition, it protects against certain non-communicable diseases such as

heart disease, type 2 diabetes, breast cancer, endometrial cancer, and ovarian cancer.[6]

There is evidence showing that breastfeeding practices are influenced by many factors such as maternal age and higher parity. It has been shown that older mothers and higher parity are the strongest predictors of exclusive breastfeeding.[7,8] Socioeconomic status such as income, education, and employment also turn up affecting breastfeeding practices.[9] It has shown that rates of breastfeeding increase with high family incomes.[10] It was thought that parents, who are employed, have a higher level of education, and a higher income may have more positive attitudes towards breastfeeding [11] which in turn may lead to breastfeeding practices. Wherefore, the findings of this study would provide a database to the stakeholders in Iraq to design such an intervention programme to improve the practice of breastfeeding in the area with similar circumstances.

Method

Across-sectional study has been conducted at Pediatric General Hospital (PGH) in Kirkuk city over a period of seven months starting from January 2016 to the end of July 2016. The target population was mothers in Kirkuk city with children (< 24 months). Utilizing the sample size formula N= Z^2 x P x $(1-P)/ d^2$ for single proportion,[12] a 95% confidence level, a prevalence rate of 43%,[14] and a 5% allowable point of error, a sample size of 377 was arrived at. So, consecutive sampling was done on mothers who met the inclusion criteria from Pediatric General Hospital until the sample size was reached. Exclusion criteria were mothers who have not to breastfeed their babies due to barriers other than socioeconomic factors. A questionnaire was constructed to reach the purpose of the study. It consisted of three parts; the first part concerned with mothers' demographic attributes (age and parity), and maternal socioeconomic information (education, occupation, and income). The second part was supportive activities (visiting PHC regularly during pregnancy and participating in lectures regarding breastfeeding), and the last part was relating to breastfeeding practices. Family income was categorized as Low income (< 500000 ID), Adequate (500000-1000000 ID), and High income (> 1500000). The content validity the questionnaire was determined through a panel of ten experts. The questionnaire was piloted on 10 mothers who have been excluded from the final sample. The Statistical Package for Social Sciences software (SPSS, version 21) was used for data processing and statistical analysis. Data was analyzed through descriptive (frequency and percentages) and inferential statistics (Chi-square test). A P value of ≤0.05 was considered statistically significant.

More than half of mothers (63.1%) have aged 30 years and over, (69.2%) of them have more than one child, a vast majority of mothers (72.4%) have regularly visited primary health care center (PHCc) during antenatal period, and (67.1%) of them have received antenatal orientation about breastfeeding. A total of 288 mothers out of 377 reported being breastfed (Table 1).

A significant difference has been found between breastfeeding practices and some maternal data. These include age (p <0.001), parity (p 0.018), and antenatal lectures attendance (p 0.009). On the other hand, regular visit to (PHCc) during antenatal period has not affected breastfeeding practices (p 0.296).

Table 2: Association of breastfeeding practices with maternal socioeconomic status of (377) sample

N= number; %= percentage; P = level of probability ≤0.05

The findings of (Table 2) have been illustrated a highly significant association between breastfeeding practices and socioeconomic status of mothers. These include educational level (p 0.002), occupational status (p <0.001), and family income (p <0.001).

Discussion

Breastfeeding is considered as an ideal form of feeding in the neonate. It is a protective factor for both mothers and children because it contains antibodies that help children to fight microbial agents.[5] For mothers, it protects against uterine cervical and ovarian cancers as well as breast cancer.[6] Breastfeeding is influenced by several factors. The decision to breastfeed is associated with higher socioeconomic status.[9] A present study was designated to describe the influence of socioeconomic status on breastfeeding practices among mothers attending PGH in Kirkuk city. It used educational level, occupational status, and family income as indicators of socioeconomic status. It has shown a significant increase of the breastfeeding practice with an increasing level of

education and family income. This means uneducated women, and those with low income are usually less inclined to breastfeed their infants. The possible explanation for this finding is that uneducated mothers are at lower risk of social variables as a result of their contact with the community, and because of the lack of their health knowledge, they have fed their babies other than breast milk. This is because the mothers who have more education may understand the health benefits of breastfeeding.[14] This finding confirms previous similar studies,[10,15,16] while in contrast to others elsewhere.[17,18,19] This variance perhaps results from differences in the pattern of breastfeeding among women in different cultures. Another reason may be that mothers in those studies are more inclined to breastfeeding compared to other mothers. Furthermore, mothers' practices of breastfeeding have been affected by their occupation. It has shown mothers who work were more likely to breastfeed their babies than housewife mothers. This finding is coincide with that reported by other studies.[15,20] The explanation for this finding could be attributed to several reasons. First of all, in Iraq, a period of up to one-year maternal leave is given to female workers for taking care of their newborns. Second, during working hours, a nursing break of up to one hour is given for nursing mothers for the same reson.[13] The third reason is that parents, who are employed, have a higher level of education, and a higher income may have more positive attitudes towards breastfeeding.[11]

On the other hand, the current study also displays other maternal factors affecting breastfeeding practices. It has been shown that breastfeeding practices are higher among women who have an older age group. This finding is consistent with many studies.[7,21,22] A similar finding was observed for multiparous mothers, whereas the mothers who have more than one child are more inclined in practice to breastfeeding than those who have one child. This finding is also supported by other studies.[8,23] This could be attributed to mothers' experience of child rearing over the previous period. Moreover, mothers who have received antenatal orientation concerning breastfeeding are more likely to breastfeed their babies. This is mostly as a result of health education session they attended during antenatal visits. The classes are typically taught by well-informed educator in breastfeeding or lactation management. The information that has been giving for mothers during these classes are most often include certain problems related to ineffective breastfeeding and the benefits of breastfeeding to mother, baby, and society as well.[24]

In conclusion, socioeconomic status is responsible for such findings. Breastfeeding increased significantly with increasing level of education, family income, and being an employee. The study findings highlight the need for raising the level of women's education, expanding the chances for women to work can increase the income of the household which in turn participates in the financial stability for the families, and designing appropriate programmes for new parents to show the importance of breastfeeding and its benefits (e.g., social, psychological, and economic benefits) for mothers and babies in addition to showing the disadvantages of skipping breastfeeding.

Quantitative Assessment of Factors Affecting Visual Acuity by Changing the Luminance

Osama Q. Abdullah[1], Fadia W. Al-Azawi[2], Sara T. Hassan[3]

[1]Dijlah University College, [2]Al-Karkh University of Science, [3]Alrafidain University College

ABSTRACT

In today's deregulated, the world continues its voyage towards modernization, and there is a great demand for inventive in product and services development, Visual acuity measurement has become one of the most successful clinical tests of visual function, Visual Acuity (V. A) Commonly refers to the clarity of vision, in another dimension, although V. A. is an estimate of the visual system's ability to resolve the details. However, the estimates of Visual acuity are taken by evaluating and measuring the eye's ability to realize and resolve varying sizes of letters and shapes in Snellen's chart. More recently attention has focused on the luminance of the visual acuity chart while it is essential to consider the overall room illumination during visual acuity measuring. It has commonly been assumed that the rise in ambient room illumination decreases the size of the pupil. A smaller pupil increases the depth of focus furthermore reductions the peripheral light rays that entering into the eye. Thus, the reduced pupil diameter great less spherical deviation and other higher order aberration, such as coma aberration. A clinician may achieve an artificially better estimate of visual acuity in a brightly-lit examination room. The aims of this study is to determine the factors affecting Visual Acuity by changing the luminance. Fourteen patients aged 19 to 24 years were chosen. Monocular visual acuity patients were assessed under five different luminance levels (different colors), and V. A was measured in the patients with each room color. The results showed that there is a clear difference in the measurement of V. A when the light was changed from color to another. The visual acuity of patients was assessed using the five different levels of illumination.

Keywords: *Visual Acuity, luminance, Snellen chart*

Introduction

Visual acuity is an estimate of the visual system's ability to resolve fine details. Visual acuity estimates are taken by assessing and quantifying the eye's ability to recognize and resolve the letters of varied sizes and shapes[1]. There are numerous environmental factors which might influence the operator's performance within the control-room and cause errors. Conditions of work surroundings like sound, illumination, and heat have a crucial impact on people's attitudes, performance and behavior[2]. Visual performance is critical for control-room operators thanks to most of the activities in the process the information is done by the system of the human visual. Moreover, it had been found in studies that inappropriate illumination will increase the attention fatigue, reductions the performance, and eventually ends up in an incident. If environmental conditions, specifically illumination, cannot meet the individual's performance necessities, it'll cut back the quality of performance and result in the prevalence of errors[3-6]. Thus, making valid illumination is significant to AN individual's correct performance. Varied illumination factors (such as color temperature and intensity) have an effect on the individuals' visual and psychological feature performance[7].Varied factors like color distinction, illumination level, individual variations, viewing time, gazing and etc., Are in the result of visual performance[8].The individual's potency within the control-room is directly littered with visual performance. People would like sensible illumination within the control-rooms to possess AN acceptable vision[9]. During this study, the results showed that there's

a marked distinction within the measured optical intensity once ever-changing the space lightweight from color to a different color. Considering the potential disadvantages of measuring visual acuity below the bright area illumination with the traditional display, totally different intensities of sunshine with different wavelengths (traditional light, yellow light, red, green, and blue) were chosen and therefore the comparison for visual acuity among these sources of illumination was in deep trouble the identical patients. For this reason, this subject was chosen to attain this, the project to line the influence of adjusting brightness on visual acuity. Fourteen patients aged nineteen to twenty-four years were assessed. Monocular visual acuity patients were assessed underneath 5 totally different brightness levels (different colors), and V. A was measured within the patients with every area color. The results of the examination in patients showed that there's a transparent distinction within the mensuration of V. A once the sunshine was modified from color to a different. 2.0.

Materials and Methodology

Twenty-eight eyes of adults' students were examined in Dijlah University College/Optics techniques department/Refractive errors laboratory.

Essential colors were used to achieve this, the project as in the following tables and figures. These colors are different in colors which are related to wavelength, then energy [10].

The energy © of each color can be calculated using the Plank's equation:

$$E = h \upsilon = hc/\lambda \quad \ldots(1)$$

Where:

h: Plank's constant = $6.63*10^{-34}$ m^2 kg/s

υ: Frequency of the light.

C: Speed of the light in vacuum = $3*10^8$ m/s^2

ʎ: Wavelength of light (nm)

Table 1: The color spectrum used in this study

Color	Wavelength (nm)	E (e V)
Red	~ 700- 635	< 1.77
Yellow	~ 635 -590	2.14
Green	~ 590- 560	2.34
Blue	~ 520- 490	2.64

(d)

Figure 1: (a, b, c, and d): Examination room with different sources of light

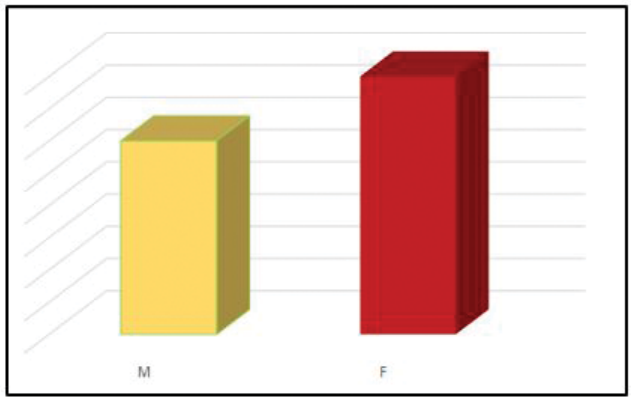

Figure 2: Percentage of the selected cases, according to gender

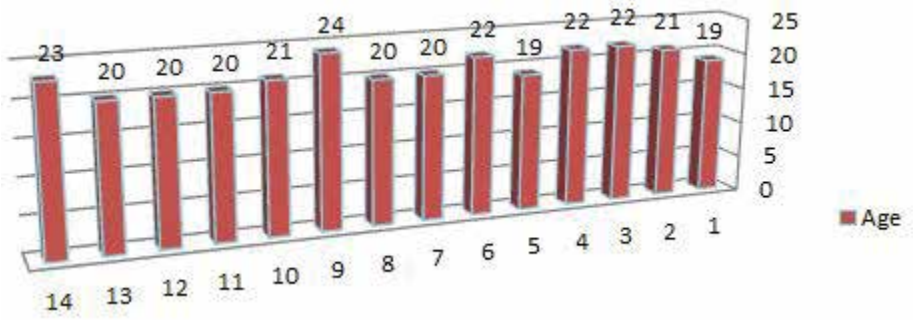

Figure 3: The age of the selected cases ranged between (19-24) years

Each patient was seated in front of the chart and the V. A is measured for each eye separately, first the right eye examined and the left eye closed by occluding then the right eye closed and the left examined.

The examination process repeated for every patient over a wide range of illumination (traditional, red, green, blue, and yellow) to study the effect of wavelength of each stimulus on the vision and to improve that one of the V.A. Problems its emphasis on fovia under one level of illumination furthermore one distance.

The examined patients selected randomly as the percentage shown in figure (2) 43% for male and 57% for females and them ages ranged between (19-24) years old as shown in figure (3).

Results & Discussions

The results obtained at the table (1) showed that there is an opposite relationship between the wavelength of the light and its energy. The red color which has the longer wavelength has the minimum energy while the blue light which has the minimum wavelength has higher energy.

The examination with eye chart is quite satisfactory, but this is obviously incomplete. It emphasizes on fovea vision, usually at one level of illumination in order to be complete, in this study, the effect of the illumination was studied over a wide range of illumination.

The results of this study show that correct illumination has a positive effect on an individual's performance and decreases the accident's occurrence and V. An affected by the room light; it's diverse in a dim room compare with that light one.

Conclusions

Studies showed that when there was a reduction in chart luminance, the width of the point spread function of the letter's image increased in the retina, as a result of the rapid fall off of the letter contrast, which in turn resulted in decreased visual resolution.

The investigate the consistency of visual acuity under different ambient room illuminations.

The findings of this study demonstrate that changes in luminance have an influence on VA that may contribute to test/retest variability.

Effect of Adding Probiotic with Different Levels of Citric Acid in Feed Supplementation to Laying Hens on Bacteria Content of Feed, Litter and Egg Shell

Rashid H. hameed Al-Dalawi[1], Qana Hussein ameen[1], Mahdi Salih Jasim[1]

[1]College of Agriculture, University of Kirkuk, Iraq; [2]College of Agriculture, University of Dayala, Iraq

ABSTRACT

Study conducted to determined effect of adding Probiotic (Iraqi Probiotic) with different levels of citric acid to Lohmann brown laying hens in order to know the effect of addition on the microbial content of the feed, litter and eggshell. The treatments were T1 without any addition (control), T2 (0.25) probiotic, T3, T4 and T5 add Probiotic each with a fixed level of 0.25% with levels 0.15, 0.30, 0.45% of citric acid sequentially. The Addition of probiotic with citric acid led to a significant decrease ($p < 0.05$) in both (Total count bacteria) and (Coliform bacteria) in feed and litter compared with the control treatment and the treatment of adding probiotic alone. The addition of either alone or with citric acid lead to a significant decrease in the total number of aerobic bacteria on the eggs product and no effect on the number of E.coli in the eggs product.

Keywords: *probiotic, citric acid, laying hens, feed, eggs shell, litter, bacteria Count*

Introduction

Poultry industry represented in last years quick developments in using various factors to increase productivity and these factors used are antibiotics to stimulate the growth, protection and treatment of domestic poultry from disease [(1)] However, this development has increased the animal's susceptibility to disease [(2)]. As well as the world orientation in recent years to prevent using of antibiotics to stimulate production [(3)]. Therefore, it was necessary to use alternative methods of antibiotics in breeding. From these substitutes have been use as Probiotic and acids including citric acid to stimulate growth and increase production of meat and eggs. as well as reduce the level of mortality by raising the immunity of the body as well as improving the conversion factor and protection against bacterial infection [(4)]. Probiotic is a living colonies of beneficial microorganisms, whether bacteria, yeast or fungus, which when introduced in sufficient quantities within the host, attached to the receptors located on the surface of the lining cells of the adrenal duct, thereby preventing the adhesion of harmful microorganisms [(5)] and [(6)]. Organic acids are a type of fatty short chain. Organic acids are naturally formed in plants as a result of metabolic processes and are found in different cells in varying amounts. For example, lemon fruits have a pH of about 2.5 due to the presence of citric acid (58 mg/mL). The acidity of the lemon fruits is due to the accumulation of this acid [(7)]. Organic acids have been used for many decades to preserve food and prevent the growth of pathogenic microbes [(8,9)] for the effectiveness of these acids in reducing the pH of the substances mixed to the level that affects the environment of pathogenic bacteria [(10)]. It has been used in the field of animal and poultry production as an effective and safe alternative to antibiotics used to stimulate growth, improve immunity and prevent the infection of many intestinal diseases and additives to feed and drinking water for domestic birds [(11)]. Adding of formic acid in level 0.5% to feed resulted in a reduction of pH to 6.62 compared to7.38 for control treatment, [(12)] study effect of adding Gallia acid (mixture of fumic acid, Formic, calcium propionate and Sorbic acid) by 1 g/kg feed, the preparation of bacteria *strptococcus Lactobacillus* in the intestines noticed a significant increase in the preparation of bacteria Lactococcus when adding the product compared to the control and thus enhance the role of the Probiotic when it used to promote production in poultry and the use of alternatives to additives antibiotics in poultry feed [(13)]. The aim of this study was to conduct the effect of adding Probiotic with organic acid to layer chicken ration on the bacterial count on feed, letter and egg shell.

Materials and Method

The experiment carried out in the field of poultry for 150 days by using of 195 Lohmann brown layers 20weeks old were rearing in cages and fed on a standard productivity diet (Table 1). The birds were distribute on five nutritional treatments

T1: (Control treatment) standard ration.

T2: Standard ration with 0.25% of Probiotic.

T3: Standard ration supplemented with 0.25% of Probiotic + 0.15 Citric Acid%.

T4: Standard ration with 0.25% Probiotic + 0.3 Citric Acid%.

T5: Standard ration with 0.25% Probiotic + 0.45% Citric Acid.

The Probiotic used is the Iraqi Probiotic, the microbiology was Lactobacilli, and Lactobacillus acidophilus, Bacillus subtitlis, and saccharomyces cerevisia yeast, Citric acid was 99% concentration.

Table 1: Ingredients using in diet and chemical composition of it

Composition	Percentage %
Corn	63.7
Soybean	26
Calcium	2.5
Die phosphate	7.5
Nacl	0.3
Chemical Composition	
Crude protein %	17
Energy k cal/kg	2740
Methionine%	0.140
Lysine %	0.92
Calcium %	3.45
Available phosphor %	0.63

- Mineral premix contained the following in milligrams per kilogram of diet: manganese, 120; zinc, 120; iron, 180; copper, 10; iodine, 2.5; Cobalt, 1.0.Vitamin premix contained the following per kilogram of diet: vitamin A, 13,200 IU; cholecalciferol, 4,000 IU; vitamin E, 66 IU; vitamin B12, 4.6 ug; riboflavin, 13.2 mg; niacin, 110 mg; pantothenic acid, 22 mg; vitamin K, 4 mg; folic acid, 2.2 mg; thiamine, 4 mg; pyridoxine, 8 mg; And biotin, 252 ug.3Selenium premix contained sodium selenite (Na2SeO3), roviding 0.3 mg/kg.
- Data expressed on a percentage of dry matter basis. Formulations Confirmed by proximate analyses

The samples of feed, letter and eggs collected every 30 days (5 replicates) by taking samples from different places of feed for each treatment after mixing well. The samples were placed in sterilized polythene bags. After that, 10 g of each sample was added and the saline solution was added in the sterile conditions and worked decays to 10^{-9} dilutions, and the same method was taken in taking samples from the mattress as samples of the mattress were taken from different places of each cage in which birds were breeding and samples were placed in sterile bags and worked the same dilutions. IN order to estimate the number of bacteria on the eggshell, the samples were collected by taking five eggs from each treatment, if there was no delay in collecting the eggs. The samples of each treatment were then placed in a sterilized bag and the solution was added 100 ml. Take 10 ml of suspension and dilute decimals until 10^{-9}. Bacterial content per cm^2 of egg surface was calculated. The spreading plating method [14] was followed by estimating both the numbers of coliform bacteria and the preparation of total bacteria, and the concentrations of these organisms were converted to logarithmic numbers of base 10 and expressed as Log10 cfu/gm for feed and letter. As for the bacterial preparation on the surface of the eggshell, it was expressed by Log10 cfu/cm^2 according to the method (15), using the following equation: $\mathbf{S = 4.68\ W^{2/3}}$

- Where S = the outer surface of the eggshell (cm^2) and W = the weight of the egg in grams.

To measure of Ph for feed, [16]. method used by use 1 g of feed per treatment, add 10 ml of distilled water, mix well, leave for 10 minutes at room temperature and pH were measure by pH meter. The data were analyzed using [17] using full random design (CRD) and the test of differences between coefficients using the[18].

Results and Discussion

The results of the statistical analysis in Table (2) showed that there was a significant effect ($p<0.05$) in the total bacterial count of the microbial content when adding the Probiotic with different amounts of citric acid

compared with the treatment of control and treatment of the addition of the Probiotic alone, Treatment of addition T5 was the lowest of the mean number of total bacteria followed by treatment T4 while the treatment T3 and T2 did not differ significantly from the control treatment. Table 2 also showed a significant decrease in colonic bacteria in the addition of the Probiotic with citric acid. The parameters T3, T4 and T5 showed the lowest values, which differed significantly from the control treatment without addition.

Table 2: Effect of the addition of the biocomponent with different levels of citric acid to the egg-white chickpea on the bacterial content of the egg-white chickpeas (5.65 log10 in m/g)

Treatments	Total number of aerobic bacteria	Number of E.coli
T1	7.39 ± 0.26	7.65 ± 0.65
T2	7.28 ± 0.19	5.31 ± 0.32
T3	6.98 ± 0.21	4.92 ± 0.72
T4	6.44 ± 0.05	4.63 ± 0.62
T5	6.15 ± 0.06	5.15 ± 0.43

Mean ± S.E

T1: (Control treatment) standard ration.

T2: Standard ration with 0.25% of Probiotic.

T3: Standard ration supplemented with 0.25% of Probiotic + 0.15%. Citric Acid.

T4: Standard ration with 0.25% Probiotic + 0.3%. Citric Acid.

T5: Standard ration with 0.25% Probiotic + 0.45% Citric Acid.

From this table we see that there is a significant decrease in the number of pathogenic bacteria. As the percentage of addition of citric acid increased to the Probiotic where the organic acid reduces the amount of harmful bacteria by reducing the pH when added to feed. Reducing the content Microbial, as the pathogenic microbes do not grow in the acidic medium. Which leads to the elimination of them and reduce their activity and reproduction through the destruction of the wall cell bacterial as well as disable the process of cloning the DNA of the cell and disorder in many physiological functions of the cell [19]. In contrast, beneficial bacteria thrive more in acidic media, making them grow, thrive and compete with harmful bacteria and microbes because of the constant competition between harmful and beneficial microbes. The results indicated in Table (3) that the addition of the Probiotic with alastric acid resulted in a significant decrease ($P < 0.05$) in the number of total bacteria of the letter. T5 and T4 were scored the lowest values for the average number of bacteria followed by treatment T3 while the treatment of addition of the Probiotic alone didn't different from the control treatment. It is also noted from Table (3) that the number of colonic bacteria has continued to decrease as we move towards the increase in the addition of organic acid to the Probiotic as recorded treatments T3, T4 and T5 significantly lower in the preparation of E.coli compared to the treatment of T1 and T2, due to the role of microbes in the Probiotic when the balance of these microorganisms within The gastrointestinal tract increases its ability to compete for food with pathogenic microorganisms, [20,21]. As well as its ability to secrete microbial growth agents, including Bactriocin, produced by Bifidobacterium, as effective bilogia compounds and inhibiting the growth of bacteria such as toxins, antibiotics, and bactericidal enzymes [22]. As well as the deadly and inhibitory effect of organic acid of pathogenic bacteria [23]. By reducing PH for the acid-sensitive cytoplasmic cytotoxicity, this will reduce the number of microbes present with glaucoma and thus will decrease its presence in the mattress of birds.

Table 3: Effect of the addition of the biocomponent with different levels of citric acid to egg white chicken eggs in the bacterial content of the chicken egg (log10 and L/g).

Treatments	Total number of aerobic bacteria	Number of E.coli
T1	6.99 ± 0.03	4.42 ± 0.04
T2	6.86 ± 0.13	4.29 ± 0.08
T3	6.78 ± 0.07	3.91 ± 0.04
T4	6.71 ± 0.1	3.67 ± 0.02
T5	6.62 ± 0.05	3.55 ± 0.05

Mean ± S.E

T1: (Control treatment) standard ration.

T2: Standard ration with 0.25% of Probiotic.

T3: Standard ration supplemented with 0.25% of Probiotic + 0.15%. Citric Acid

T4: Standard ration with 0.25% Probiotic + 0.3%. Citric Acid.

T5: Standard ration with 0.25% Probiotic + 0.45% Citric Acid.

From Table (4) we so that there is a significant difference between all additive treatments compared to the control treatment for the preparation of total bacteria on the eggshell and there was no significant difference between all treatments for the preparation of E.coli.

Table 4: Effect of the addition of the biocomponent with different levels of alastric acid to the brown chicken lemehannum in the bacterial content of the eggshell (log10 in C/cm²)

Treatments	Total number of aerobic bacteria	Number of E.coli
T1	7.61 ± 0.62	5.53 ± 0.63
T2	6.57 ± 0.61	5.36 ± 0.57
T3	6.55 ± 0.16	5.31 ± 0.05
T4	6.48 ± 0.04	4.74 ± 0.38
T5	6.43 ± 0.14	4.46 ± 0.15

Mean ± S.E

T1: (Control treatment) standard ration.

T2: Standard ration with 0.25% of Probiotic.

T3: Standard ration supplemented with 0.25% of Probiotic + 0.15%. Citric Acid

T4: Standard ration with 0.25% Probiotic + 0.3%. Citric Acid.

T5: Standard ration with 0.25% Probiotic + 0.45% Citric Acid.

From Figure (1), there is a significant decrease in the pH of the feed used for the addition of the Probiotic with citric acid compared to the addition of Probiotic alone and control treatment. The treatment T5 and T4 were fewer values for pH Followed by treatment T3 while no significant differences were observe between the addition of Probiotic alone and control treatment. The diagram below shows the value of the feed pH. We note that there is a significant decrease in the percentage of addition of citric acid.

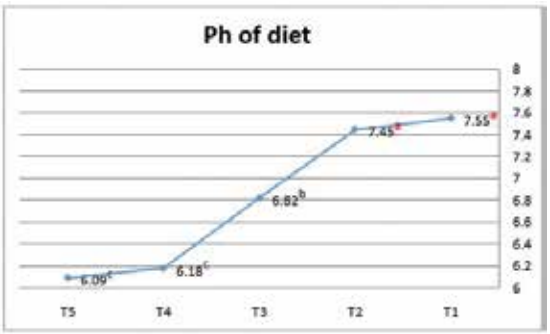

Figure 1: Effect of addition of Probiotic with different levels of acidic acid in pH () for white chick larvae

Conclusion

We consoled from this search that the addition of either alone or with citric acid lead to a significant decrease in the total number of aerobic bacteria on the eggs product and no effect on the number of E.coli in the eggs product.

Occurrence of MBLs and Carbapenemases among MDR and XDR *Acinetobacter baumannii* Isolated from Hospitals in Iraq

Safa Hasan Radhi[1], Alaa H. Al-Charrakh[1]

[1]Dept. of Microbiology, College of Medicine, University of Babylon, Hilla, Iraq

ABSTRACT

The current study was conducted to determine carbapenemase-producing *Acinetobacter baumannii* clinical isolates recovered from two hospitals in Iraq. A total of 540 different clinical samples were collected. Isolates were identified and Carbapenemase production were detected using MBL E-test, Modified Hodge's Test (MHT), and Modified Carba NP test. A total 30 *A. baumannii* isolates were obtained from clinical specimens. It was found that 73.3% isolates were carbapenem resistant. Out of 30 *A.baumannii* isolates, 22 (73.3%) isolates were confirmed to be MBL positive by MBL E-test method, 5(16.6%) by MHT, and 27 (90%) isolates by Modified Carba NP test. Results revealed that 21 *A.baumannii* isolates (70%) were found to be MDR and only 9 isolates (30%) were XDR. It can conclude that most of carbapenem resistant *A.baumannii* clinical isolates were MDR. The CNPt assay was the most reliable among phenotypic assays to detect MBL production.

Keywords: *Acinetobacter baumannii, MBLs, Carbapenemases, MBL E-test.*

Introduction

One of the greatest threats to modern medicine is the increasing prevalence of antibiotic-resistant bacteria, particularly Gram-negative bacteria[1-4]. One of these bacteria, *Acinetobacter baumannii*, has raised to prominence due to the international dissemination of multidrug-resistant lineages resistant to the carbapenem antibiotics[5]. Centers for Disease Control and Prevention (CDC) recognizes MDR *A. baumannii* as a source of global outbreaks especially due to its effectiveness in colonizing hospital environments and due to its increasing resistance to commercially available antibiotics [6].

Mechanisms of resistance in *Acinetobacter* strains include efflux pumps, β-lactamases, and modifications in porin proteins. Enzymatic degradation by β-lactamases is the most Prevalent mechanism of β-lactam resistance in *A. baumannii*. Serine oxacillinases and metallo-β-lactamases (MBLs) are β-lactamases with carbapenemase activity [7]. The prevalence of MDR *A. baumannii* strains have been increasing during recent years continually and causing of highly mortal hospital infections [8]. The increase in drug resistance of *Acinetobacter* to the most of antibiotics is resulting from abuse of antimicrobial agents[9]. Carbapenem resistance is now observed worldwide in *A. baumannii* isolates, leading to limited therapeutic options. Several carbapenem-hydrolyzing lactamases have been documented in *A. baumannii*. Lactamases from class B illustrate highly hydrolyzing activity of carbapenems [10].

The aim of this study was to investigate the characterization of Carbapenemase–Producing *A.baumannii* isolates recovered from two hospitals in Iraq.

Method

Sampling and study design: This cross sectional study was designed to investigate the characterization of Carbapenemase –producing *A. baumannii* isolates recovered from main hospitals in Babylon province, Iraq. A total of 540 different clinical specimens (burns, wounds, urine and blood) were collected from patients admitted to the out-patient clinics in Hillah Teaching Hospital and Babylon Teaching Hospital for Maternity

and Pediatrics at Babylon province, Iraq. These samples were collected during the period between January to June, 2018. Verbal consent was taken from each patient before sampling.

Isolation and Identification of A. baumannii: All clinical samples were streaked on MacConkey agar, Blood agar and Chrom agar. Isolates were identified to the level of species using biochemical tests (oxidase and catalase) and Vitek 2 system, in addition to the phenotypic characteristics of colonies on Chrom agar [11].

Determination of antibiotic susceptibility patterns: Thirty isolates of *A. baumannii* were selected for determination of antibiotic susceptibility patterns using modified Kirby-Bauer disc diffusion test (DDT) against the following antibiotics (CONDA-Spain): Ampicillin (AM), Pipracillin (PRL), Cefepime (FEP), Ceftazidime (CAZ), Cefotaxime (CTX), Aztreonam (ATM), Imipenem (IMP), Meropenem (MEM), Amikacin (AK), Gentamicin (CN), Tetracycline (TE), Doxycycline (DO), Ciprofloxacin (CIP), Trimethoprim- Sulphamethoxazole (SXT), Colstin (CT), Polymyxin B (PB). Results are interpreted according to guidelines recommended by CLSI guidelines [12]. Determination of MDR and XDR among *A. baumannii* isolates was done according to Magiorakos et al [15].

Phenotypic detection of Carbapenemases: All bacterial isolates that resistant to β -lactam antibiotic were tested for β- lactamase production by rapid iodometric method as described by Forbes et al. [11]. MBL production and Carbapenemase production by MBL E test method was performed as described by Behra et al. [13], Modified Hodge's Test (MHT), was performed as described by Lee et al. [14] and Modified Carba NP test was recommended by CLSI [12].

Results

Isolation of Acinetobacter baumannii: Results of distribution of different clinical samples showed that most samples obtained, were from burns (48.1%) while other samples distributed among samples of urine, blood, and wound (Table 1).

A. baumannii were isolated and identified depending on biochemical tests and Vitek 2 system, in addition to, cultural properties on Chrom agar medium. However, other species of *Acinetobacter* were also identified as (A. p*itti*, 2 isolates; and A. *calcoaceticus*, 3 isolates) depending on the appearance of red colonies on Chrom agar, in addition to Vitek 2 system.

Out of 540 clinical samples, only 30 isolates (5.5%) were belonged to *A. baumannii*. Out of 360 (66.6%) that showed positive cultures, 35 isolates were belonged to genus *Acinetobacter*. Only 30 isolates (8.3%) were belonged to *A. baumannii* (Table 1); out of which 29 (96.6%) isolates were obtained from Hillah Teaching Hospital and only one isolate (3.3%) from Babylon Teaching Hospital for Maternity and Pediatrics.

Table 1: Distribution of *A. baumannii* isolates among different clinical samples

Clinical sample type	No. (%) samples	No. (%) of *A. baumannii* isolates
Burn swab	260 (48.1%)	24 (9.23%)
Wound swab	30 (5.5%)	1 (3.33%)
Urine	100 (18.5%)	1 (1%)
Blood	150 (27.7%)	4 (%)
Total	540	30 (5.55%)

Regarding distribution of *A. baumannii* isolates among different clinical samples, results found that the majority of *A. baumannii* isolates recovered in this study was from burn units (24/260; 9.23%), and only 6 isolates were recovered from other clinical sites. Only one isolate (1%) was detected in urine samples (Table 1).

Antibiotic Susceptibility of A. baumannii isolates: The results showed that all *A. baumannii* isolates (100%) were able to produce β-lactamase using rapid iodometric method. They also exhibited different pattern of resistance to different antibiotics (Figure 1). All *A. baumannii* isolates (No.=30) demonstrated highest resistance to penicillins (carbenicillin and ampicillin) (100%), whereas they showed high susceptibility to piperacillin. A low resistance was detected (40%) among isolates to ceftazidime but they showed relatively high resistance (93.3%) to cefotaxime and cefepime. Results also revealed that *A. baumannii* isolates displayed relatively high resistance rate (73.33%) towards imipenem, and meropenem.

Aminoglycosides and quinolones resistance were variable among by *A.baumannii* isolates; (86.6%) to gentamicin and (50%) to amikacin, however, resistance to quinolones (ciprofloxacin) was detected as 20% among isolates.

Rates of resistance of our isolates to the remaining antibiotics were as follows: 12 (40%) to each of tetracycline and doxycycline, trimethoprim-sulfamethoxazole 18 (60%), Polymyxin B 15 (50%), and Colistin 18 (60%). For tetracycline, the resistance rate was 40%. The present study showed relatively low resistance level to polymyxin B (50%).

Results revealed that 21 *A.baumannii* isolates (70%) were found to be multidrug resistant (MDR) and only 9 isolates (30%) were XDR.

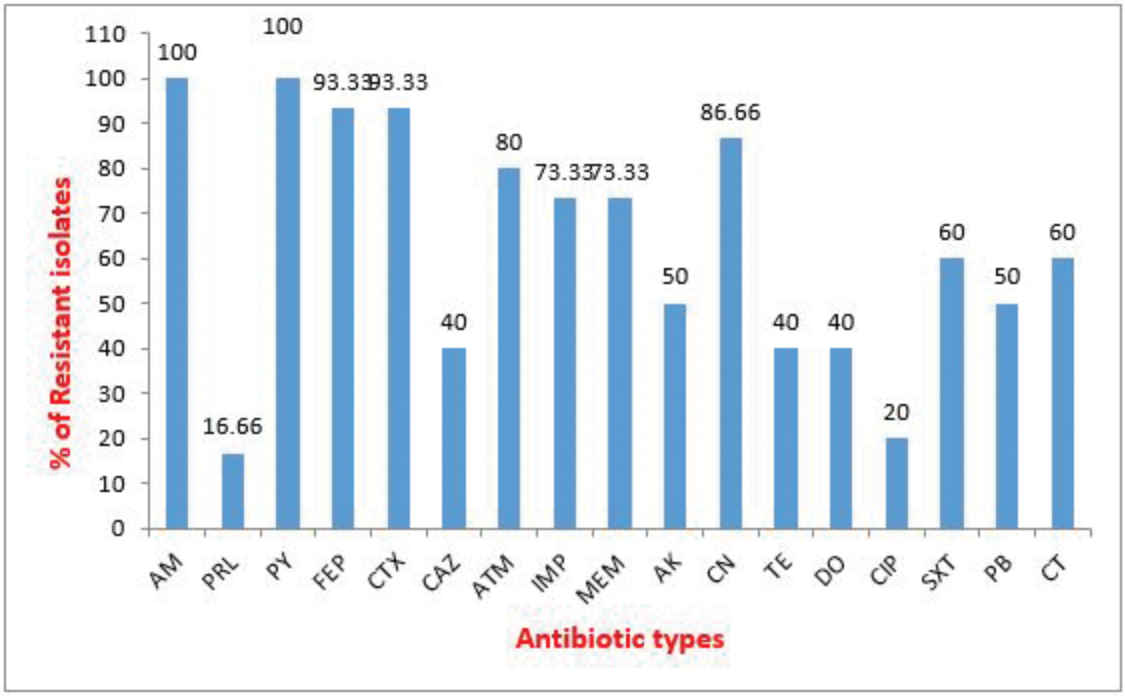

Figure 1: Antibiotic resistance pattern of *A. baumannii* isolates

Carbapenemase Production in A. baumannii: Metallo β-lactamases detection of *A.baumannii* isolates was performed by MBL E-test (Imipenem/Imipenem+ EDTA). Results found that 22 isolates out of 30 (73.3%) were positive to this test (Figure 2).

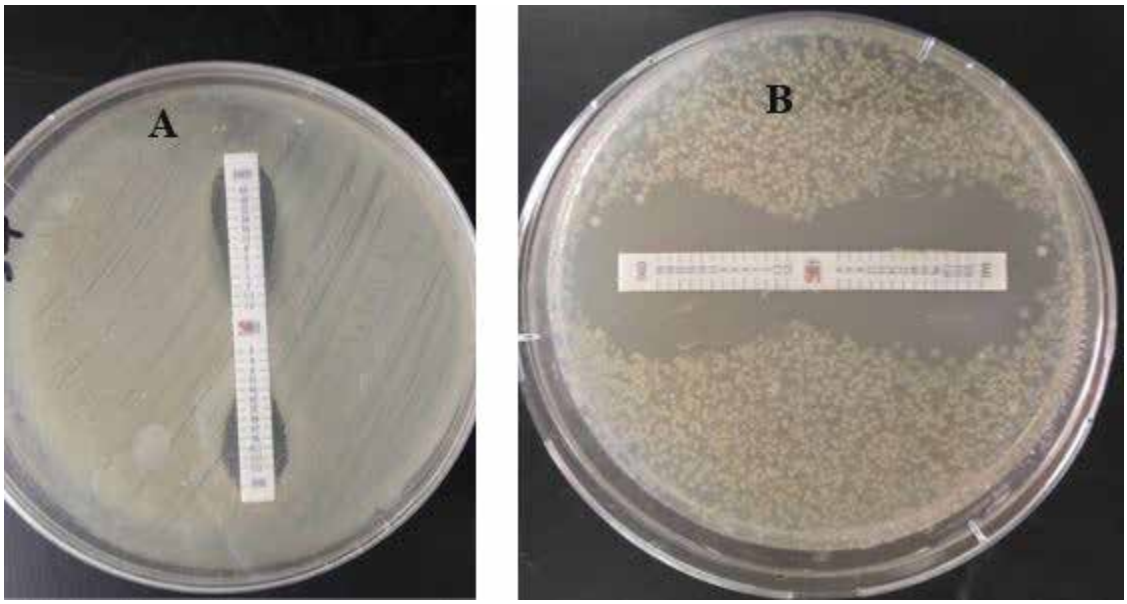

Figure 2: MBL-producing of *A.baumannii* isolate. A: *A.baumannii* BU1: B: *A.baumannii* BU28

In the modified Hodge's test, only five isolates of *A.baumannii* out of 30 (16.6%) displayed a clover leaf like indentation with imipenem disk indicating a positive result (Figure 3). In Modified Carba NP test, 27 (90%) of *A. baumannii* isolates were positive (Figure 4).

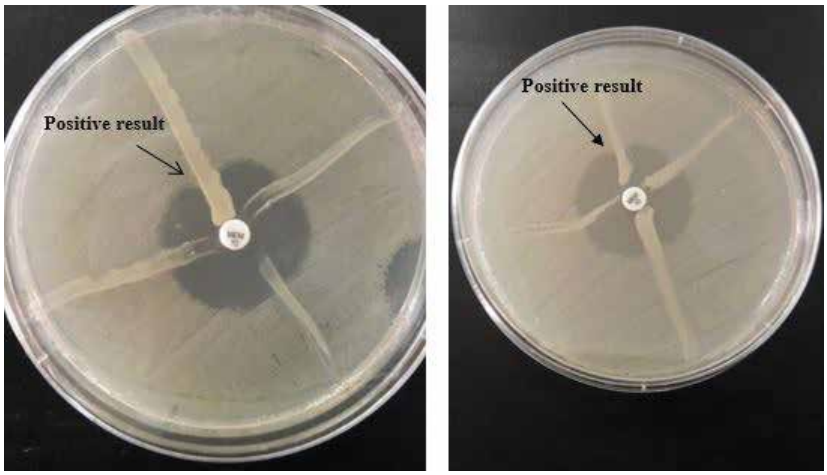

Figure 3: Modified Hodge's test (MHT)

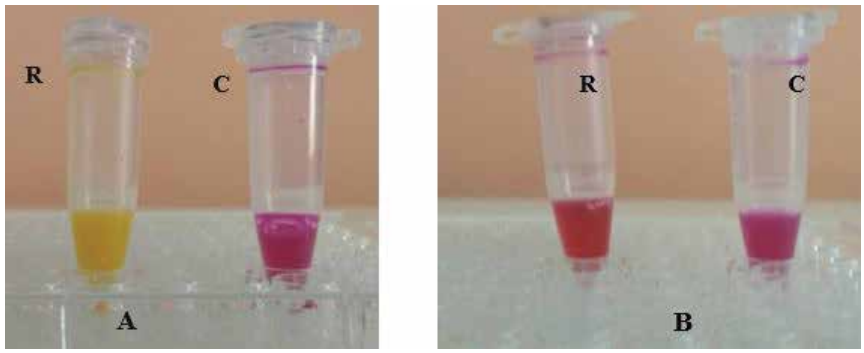

Figure 4: A: yellow color (Reaction tube) of carbapenemase-producing isolates *A.baumannii* BU1. B: Red color (control tube). non-carbapenemase-producing isolate *A.baumannii* BU28.

Only 5 *A. baumannii* (22.7%) isolates were able to produce the carbapenemase enzyme when detected by MHT and all the remaining isolates were carbapenemase negative (Table 2).

Regarding phenotypic detection of MBL using E-test, results found that 22 isolates (%73.3) were positive to this test. Comparing the results of this test with MHT, E-test has shown high positivity (73.3%) when compared to MHT, which showed a low positivity (22%), due to its false positive results (Table 2).

Carba NP test (CNPt) (CarbAcineto test) recommended by Nordmann and his colleagues was also used for detection of MBL *A.baumannii* producing isolates. Results found that 27 isolates of *A.baumannii* (90%) were positive to this test. This result makes CNPt is superior to other tests performed (MHT and MBL-E-test) that showed a relatively low positivity rate of 22% and 73.3% respectively (Table 2).

Table 2: Comparison of different methods for detection of carbapenemase producing *A. baumannii* isolates (No. = 30)

Detection Method	No. of isolates (%)	
	Carbapenemase Producer	Non-carbapenemase Producer
MHT*	5 (16.6%)	25 (83.3%)
Modified Carba NP test	27 (90%)	3 (10%)
MBL E test	22 (73.3%)	8 (26.6%)

*Modified Hodge test

Discussion

The isolation rate of *A. baumannii* from different clinical specimens was 8.3%. This result was also confirmed by several autors worldwide, who reported that the isolation rates of *A. baumannii* were 7.8%, 3.7%, 1.5%, and 0.76% respectively [16-19].

The reason for relatively high isolation rate of *A. baumannii* compared with the different studies mentioned above, may be due to that this study focused on selected samples that are well-known site of infections of this bacterium (Table 1). Other reason may be attributed to the use of a selective medium for isolation of *A. baumannii* (Chrom agar).

Results of distribution of different clinical samples showed that most samples obtained, were from burns. This perhaps resulted from ability of *A. baumannii* to survive for long periods of time in the hospital equipment's and capacity to acquire drug resistance this helps it in the spread of the infection [20].

Regarding isolation of *A.baumannii* from other clinical sites, only one isolate (1%) was detected in urine samples (Table 1). Nahar, *et al*. [21] reported that 3.1% of these bacteria were isolated from urine samples. This result shows that *A. baumannii* has relatively low prevalence in causing UTI.

Based on our findings, all *A. baumannii* isolates exhibited different pattern of resistance to several antibiotics. Al-Sehlawi *et al*. [22] noted that that all *A. baumannii* isolates were resistant to carbenicillin (100%) but half of them (50%) were resistant to ampicillin-sulbactam. High resistance to this class of antibiotics may be due to widespread use of these antibiotics in Iraqi hospitals.

The resistance of *A. baumannii* to cephalosporins in Iraq was recorded by several researchers AL-Kadhmi [23] reported that resistance rate of *A. baumannii* isolates to cefepime, ceftazidime and cefotaxime and were 100%. In Saudi Arabia, the resistance rates of *A. baumannii* to Ceftazidime was 91% [24].

Results of this study also revealed that *A. baumannii* isolates displayed relatively high resistance rate towards imipenem, and meropenem. The resistance of *A.baumannii* to Carbapenem was recorded by several authors in Iraq. Al-Harmoosh [19] reported that resistance rates of *A. baumannii* isolates to imipenem, and meropenem were 1% and 47%, respectively. The carbapenem resistance rates were lower when compared to the rates reported from another medical facility in Kuala Lumpur [25].

Resistance to Aminoglycosides by *A.baumannii* in this study was also reported by several authors worldwide [19,22,24].

Results of this study against ciprofloxacin was detected as 20% among isolates. Resistance to quinolones by *A.baumannii* was also reported by several authors worldwide. Alsehlawi *et al*. [22] found that resistance against ciprofloxacin was (91.6%). Result of resistance to trimethoprim-sulfamethoxazole was (60%) it came in dissparallel with study in Turkey by Kulah *et al* [26].

Based on our findings, the low rate of carbapenemase enzymes detected by MHT may be due to the fact that although this method is easy to perform, but occasional isolates may show false positive results [27].

In previous studies, using modified Hodge's test, several authors reported that 60%, 33.3%, and 53% of *A. baumannii* isolates, were confirmed as carbapenemase producer respectively [19,22]. Though CLSI does not advocate the use of MHT for detection of Carbapenemase production in non-fermenting gram negative bacilli, several authors have found MHT with Imipenem, EDTA and $ZnSO_4$ as a useful screening test for Carbapenemase production [28].

Regarding phenotypic detection of MBL using E-test, and comparing the results of this test with MHT, E-test has shown high positivity when compared to MHT which showed a low positivity due to its false positive results. Previously published data showed that E-test to be very sensitive for detection of antimicrobial resistance especially for MBLs[13,29]. One of the advantages of this technique can detect the MBL class (by supplemented inhibitor EDTA) and determine the resistance of organism to the carbepenems (Imipenem) simultaneously.

Detection of MBL *A. baumannii* producing isolates by Carba NP test (CNPt) showed high positivity (90%) of detected carbapenemase enzymes. This result makes this test is superior to other phenotypic assays used (i.e. MHT and MBL-E-test).

Conclusion

High isolation rate of carbapenem resistant *A. baumannii* (CRAB) was detected in this study. Most of them were recovered from burn unit. The CNPt assay was the most reliable among phenotypic assays to detect MBL production.

Conflicts of Interest: None of the authors have any conflicts of interest relevant to what is written.

Source of Funding: University funding was provided for: data collection, analysis, and interpretation; trial design; patient recruitment. No public funding was received.

Ethical Clearance: The study was conducted in accordance with the ethical principles that have their origin in the Declaration of Helsinki. The study protocol and the subject information and consent form were reviewed and approved by a local Ethics Committee.

The Effect of the Adding *Ganoderma Lucidum* Fungus Powder in the Production Performance for the Brown Japanese Quail Bird

Samawal S. Al-Tikriti[1], Abdul Haq Ismail Al-douri[1]

[1]Department of Animal Production, College of Agriculture, University of Tikrit, Iraq

ABSTRACT

This study was conducted in the poultry field belonging to the Department of Animal Production, College of Agriculture, University of Tikrit for the period from (29/8/2016 to 31/10/2016). The study aimed to investigate the effect of adding different levels of *Ganoderma Lucidum* powder in the production and physiological performance of the Japanese quail bird. It was used 160 birds from Japanese quail bird in the experiment (40 males and 120 females), with 16 weeks age. The experiment consisted of four treatments, each treatment contains 10 replicates and in each replicate is four birds (one male and three females). The birds were distributed randomly to the treatments, treatments were as follows: First treatment T1: a diet without adding the Ganoderma fungus powder (control). T2: a diet adding to it the Ganoderma fungus powder with the ratio of (0.5: 1000 g feed). T3: a diet adding to it the Ganoderma fungus powder with the ratio of (1: 1000 g feed). T4: a diet adding to it the Ganoderma fungus powder with the ratio of (1.5: 1000 g feed). The results showed that the addition of red Ganoderma fungus led to a decrease in the level of feed consumption for the second and third treatment compared to the control group. There was also a significant improvement in the feed conversion coefficient for the added treatments compared to the control group. A significant increase was also occurred in egg production and egg mass for the third treatment (1g/kg feed) compared to other treatments, while the fourth treatment was excelled in the traits of the average weight of the egg compared to the rest of the treatments.

Keywords: *Ganoderma Lucidum, Productive traits, Japanese quail bird*

Introduction

Fungi are similar to microorganisms, which grow like plants but without chlorophyll. Fungi depend on living organisms or other plants to feed them. The available information in literature showed that fungus was first identified by Greeks in early time and Romans who made them edible, toxic, and medicinal fungi[1]. The fungus is a thallophyte organism that spreads in different environments in wet and dry soil, fresh water, and in the air, and attacks many organisms, including plants, animals, and humans. It has a solid cellular wall identifying their shape except for Myxomycetes, which are usually immobile but have moving genital cells. Fungi are used in food and medicine. The fungus is called vegetarian meat, which contains a high percentage of protein. Some fungi are composed of monocellular and some of the Multicellular. The fungus consists of thallophyte, which is not characterized by roots, stems, and leaves but is organized into the strings known as Hyphae and Hyphae groups that form the body of the fungus is called Mycelium. Such these fungi are *Ganoderma Lucidum* fungus belonging to the *Polyporaceae* family, this fungus has popular names such as Mannentake, Holy Mushroom, Ling Chi, Ling Zhi Cao. The fungus is commercially cultivated in China, Japan, Malaysia, and the United States. It grows in Japan on wild plum trees but most of the supplies for the industry come from agriculture, and the *Ganoderma* fungus is a fungus with meaty texture with a shiny solid stalk and a cap that resembles a somewhat solid umbrella with yellowish color at first, they turn to scarlet red and maybe brown. This study was conducted to investigate the effect of *Ganoderma Lucidum* fungus on the productive and physiological traits for the Japanese quail bird as a laboratory bird[2].

Materials and Method

This study was conducted in the poultry farm belonging to the Department of Animal Production, College of Agriculture, University of Tikrit for the

period from (29/8/2016 to 31/10/2016). The study aimed to investigate the effect of adding different levels of *Ganoderma Lucidum* powder in the production and physiological performance of the Japanese quail bird. It was used 160 birds from Japanese quail bird in the experiment (40 males and 120 females), with 16 weeks age. The birds were bred in three-storeyed cages, with dimensions (40 x 40 x 40 cm) for one cage, the number of cages is 40 cage, where each cage was considered as a replicate. Water was provided by plastic Manhals with one Manhal per cage. The feed was provided by an external feeder of 150 g feed connected to the cage in such a way as to be easily separated for cleaning and to measure the remaining feed, with the rate of one feeder per cage. The experiment consisted of four treatments, each treatment contains 10 replicates and in each replicate is four birds (one male and three females). The birds were distributed randomly on the treatments, treatments were as follows: First treatment (T1): a diet without adding the Ganoderma fungus powder. T2: a diet adding to it the Ganoderma fungus powder with the ratio of (0.5: 1000 g feed). T3: a diet adding to it the Ganoderma fungus powder with the ratio of (1: 1000 g feed). T4: a diet adding to it the Ganoderma fungus powder with the ratio of (1.5: 1000 g feed).

Chemical Analysis of *Ganoderma* fungus Powder: The chemical analysis for the *Ganoderma* fungus of DXN Malaysia Company was used to estimate the amount of energy, protein, carbohydrate, fat and dietary fiber per 100 g as shown in Table (2).

Table 1: Chemical analysis for the Ganoderma fungus powder per 100 g.

Material	Amount
Energy	348 kcal
Protein	4.0 g
Carbohydrates	86.0 g
Fats	2.7 g
Dietary Fiber	0.9 g

The Studied Traits:

Egg Production: The eggs were collected at 9 am every day throughout the breeding period (9 weeks) and the average of total egg production was calculated during the period of the experiment.

Egg Weight: Egg weighed daily individually for each replicate using a sensitive balance (Citizrn type, Fr-H1200 Model), with accurately 0.01 (two digits after the point).

Produced Egg Mass: The produced egg mass and the percentage of egg production were calculated on the basis of H.D using the following equations:

The average of Egg mass = an average number of the produced eggs during a given period of time × egg weight (g).

Feed Consumption: The amount of feed consumption was calculated by weighing the feed remaining at the end of each week and subtract it from the feed provided at the beginning of the week to extract the daily average of feed consumption for the bird according to the following equation:

The daily average of feed consumption (g/bird)

$$= \frac{F}{X + 7 \times L}$$

F = feed consumed within a week.

L = number of live chicks at the end of the week

7 = Number of days of the week.

X = The total number of days in which the mortality chicks were fed.

Food Conversion Coefficient: The food conversion coefficient necessary to produce one gram of eggs was calculated according to the following equation:

Food conversion coefficient (g feed/g egg) = The daily average of feed consumption/the average of the produced egg mass (g/day).

Experimental data were analyzed using a completely randomized design (CRD) to study the effect of studied treatments on different traits. The significant differences between averages were compared using the Duncan Multiple Range Test[3], and The Statistical Analysis Software (SAS) was used in the statistical analysis[4].

Results and Discussion

Table (2) shows the average weight of the egg, it was noted a significant superiority of T4 on T3, while no significant differences between T4, T1 and T2. There were no significant differences between T1 and T4 with T3, The averages weights of egg amounted to (11.83, 11.45, 11.02, 12.03 g), respectively, while the traits of the egg production during the experiment period (60 days), T3 was excelled and showed significant differences with T1 and T2, while no significant difference was shown

with T4. There were no significant differences between T1, T2 and T4, the egg production amounted to (46.07, 47.16, 51.87, 48.83 eggs/birds) respectively, and the percentage of production on the basis HD amounted to (76.77, 78.61, 86.44, 81.38%), respectively. As for the trait of the daily egg mass, the second and third treatments were significantly excelled on the first treatment. No significant differences were found between them. No significant differences were observed with the fourth treatment. No significant difference was observed between the first treatment and the fourth treatment. The results of the third treatment were agreed with[5,6] in his study on the Japanese quail bird, where showed that the egg weight of the Japanese quail bird amounted to (11.00 g) while its results did not match the results of the first, second and fourth treatments. The results of the experiment did not agree with the results of in their study on the Japanese quail bird[7], where they found that the percentage of average egg production amounted to 68.97%. The reason for the improvement in the percentage of average eggs production on the basis of (HD) in the adding treatments for the *Ganoderma* fungus, where some of the materials directly affect the production and synthesis of Prostaglandins, the main material in its synthesis is the Arachidonic acid and other essential fatty acids, the survival it in the circulatory system and the Prostaglandins work to stimulate and manufacture the adenosine monophosphate (CAMP), because this reporter regulates or mediates the work of many peptide hormones that cannot penetrate the target cell wall but are associated with the receptors on the cell membrane and the complex hormone receptor, which indirectly activates an enzyme called Adenylate Cyclase, which converts the partial energy (ATP) Adenosine try phosphate to the CAMP inside the cell and this acts as a second reporter by indirectly activating other enzymes and proteins within the target cell, In the middle of which the work of several hormones, including the Luteinizing hormone (LH) and Follicle-stimulating hormone (FSH)[8]. The release of these two hormones led to stimulating the ovary and increases its activity in the formation of eggs and increasing egg production because of a positive correlation between the concentration of these hormones in blood plasma and egg production[9]. The regularity of secretion of LH hormone leads to the regularity of progesterone secretion from Granulosa Cells for mature follicles, leading to increased secretion of LH by positive feedback at the hypothalamus level, thereby increasing LH secretion, increasing ovulation, and increasing egg production[10]. Which lead to increasing the progesterone production, which is a precursor to estrogen, is important for the synthesis of the vitellogenin precursors and lipoproteins, and increasing the speed of transmission to the ovary, faster vesicle growth, and increase the ovulation[9].

Table 2: Effect of adding the Ganoderma fungus powder to the diet on the productive traits for the eggs of the Japanese quail

Productive traits	T1	T2	T3	T4
Egg weight (g)	11.83 ± 0.14 ab	11.45 ± 0.25 ab	11.02 ± 0.12 b	12.03 ± 0.17 a
Number of produced eggs (egg/bird)	46.07 ± 1.56 b	47.16 ± 0.31 b	51.87 ± 1.01 a	48.83 ± 0.29 ab
percentage of egg production (HD)%	76.77 ± 1.01 b	78.61 ± 1.05 b	86.44 ± 1.82 a	81.38 ± 1.12 ab
Eggs mass	9.63 ± 0.12 b	9.86 ± 0.09 a	9.83 ± 0.14 a	9.79 ± 0.08 ab

a,b in the row means significant differences at level ($p < 0.05$).

Table (3) indicates that the adding of *Ganoderma* fungus powder to the diet at different levels indicates no significant differences between the first, second, third and fifth weeks from the breeding period. The results showed a significant difference in the first treatment with the second, third and fourth treatments. The first treatment recorded the highest amount of feed consumption amounted to (29.14 g/bird/day). The results also showed significant differences between the first and fourth treatments compared to the second and third treatments in the sixth week, while the first, second and third treatments were significantly excelled on the fourth treatment in the seventh week. A significant difference was shown for the third treatment compared to the second treatment, while did not record significant differences between the third treatment and the first and fourth treatments in the eighth week. The final results of the breeding period showed a significant difference between the first treatment and the second and third treatments, while no significant difference was recorded

with the fourth treatment. where the first treatment recorded the highest percentage for feed consumption between the first treatment and the second and third treatments, while no significant difference was recorded with the fourth treatment where the first treatment recorded the highest percentage for the feed consumption between the treatments amounted to (28.76 g/bird/day), where indicated that the percentage of feed consumption for Japanese quail bird amounted to (24.40 g/bird/day), and did not agree with[10] found that the percentage of feed consumption for the Japanese quail birds amounted to (35.71 g/bird/day). The reason for the low feed consumption adding treatments compared to control to contain red Ganoderma fungus many active substances with more than 200 active substances, including organic germanium, Ergesterois, adenosyl, and polysaccharides, as well as containing it Ganoderic acids and triglycerides contained in the bright red cap components for the fungus, These substances are beneficial for cardiovascular, liver health. They also promote metabolism, inhibit tissue degradation, and make maximum use of nutrients and their metabolism for use in egg production. also indicated to that the chemical composition of the fungus contains a significant amount of crude protein, carbohydrates, raw fiber, raw fat, and low fatty acids, making it a valuable food component for use in poultry production[11].

Table 3: Effect of adding the Ganoderma fungus powder to the diet on the percentage of feed consumption (g) and the feed conversion coefficient for the Japanese quail bird.

Period (week)	T1	T2	T3	T4
1 – 2	24.82 ± 0.31	24.39 ± 0.53	24.39 ± 0.59	25.12 ± 0.31
2 – 3	26.51 ± 0.33	26.19 ± 0.59	26.36 ± 0.39	26.50 ± 0.34
3 – 4	28.11 ± 0.31	27.10 ± 0.67	25.46 ± 2.26	27.98 ± 0.48
4 – 5	29.14 ± 0.54 a	27.46 ± 0.49 b	27.60 ± 0.39 b	27.76 ± 0.33 b
5 – 6	31.53 ± 0.42	30.64 ± 0.67	30.64 ± 0.34	31.46 ± 0.36
6 – 7	28.44 ± 0.44 a	24.89 ± 0.85 b	25.86 ± 0.51 b	28.35 ± 0.61 a
7 – 8	31.12 ± 0.31 a	30.96 ± 0.56 a	31.86 ± 0.50 a	28.55 ± 0.60 b
8 – 9	30.41 ± 0.45 ab	28.81 ± 0.37 b	30.69 ± 0.89 a	29.74 ± 0.55 ab
1 – 9	28.76 ± 0.15 a	27.55 ± 0.35 b	27.86 ± 0.33 b	28.18 ± 0.20 ab
feed conversion coefficient	3.01 ± 0.09 a	2.92 ± 0.11 ab	2.77 ± 0.03 b	2.82 ± 0.14 b

a,b in the row means significant differences at level ($p < 0.05$).

Table (4) shows that there was a significant difference between T1 with T3 and T4 in the feed conversion coefficient. There was no significant difference between T1 and T2. The results did not show significant differences between T3 and T4 with T2, the averages of feed conversion coefficient amounted to (3.01, 2.92, 2.77, 2.82 g fed/g egg), respectively. The results of T3 were agreed with in his study on the Japanese quail bird, where the feed conversion coefficient amounted to (2.79 g fed/g eggs), while the results of the rest of the treatments did not agree with him. The improvement in the feed conversion coefficient and the increase in egg production lead to an increase in the mass of produced eggs compared to the number of feed grams. The reason is due to the fact that Ganoderma fungus contains many important nutrient elements and enzymes that increase nutrient elements availability within the digestive tract and thus increase the benefit of Feed consumption and turn it into eggs[12].

Conclusion

We consoled from this search that the addition of red Ganoderma fungus led to a decrease in the level of feed consumption for the second and third treatment compared to the control group. There was also a significant improvement in the feed conversion coefficient for the added treatments compared to the control group. A significant increase was also occurred in egg production and egg mass for the third treatment (1 g/kg feed) compared to other treatments, while the fourth treatment was excelled in the traits of the average weight of the egg compared to the rest of the treatments.

Effect of Non-pharmacological pain Management Methods on Reduction the Severity of Labor Pain in Primigravida Women at AL-Elwyia Maternity Teaching Hospital

Sarab Nasr Fadhil[1], Rabea Mohsen Ali[2]

[1]Assist. Instructor, [2]Professor, Maternal and Neonate Nursing Department, College of Nursing, University of Baghdad

Abstract

Objectives: To evaluate the effect of non-pharmacological practices on reducing level of pain between study groups during labor.

Methodology: A quasi-experimental study conducted on non-probability of (60) women (30) control and (30) study group whom admitted to Al-Elwyia Maternity Teaching Hospital suffering from labor pain for the period of (4th July 2018 through 24th October 2018). Descriptive& Inferential statistical analyses were used to analyze the data.

Results: The highest percentages of both groups were in age group (< 20) years, primary schools graduates, housewife, from "urban area", within low category of socioeconomic, at gestational age between (39 – 40 weeks +6day. With highly significant differences concerning reducing the severity of pain in (1st, 2nd, and 3rd) stages of labor among study and controlled groups at (P=0.000), (P=0.000), &(at (P=0.002) respectively.

Conclusions: The study concluded that are a highly significant differences concerning reducing level of pain in (1st, 2nd, & 3rd) stages of labor between study and control groups.

Recommendations: Need to develop training program to all midwives working in delivery room to upgrade their knowledge and skills about importance of using non-pharmacological methods to help them perform their role effectively in reducing level of pain for women during labor.

Keywords: *Effect, Non-Pharmacological, Labor Pain, Management, Primigravida.*

Introduction

The intensity of the pain experienced during labor is considered to be one of the most painful experiences in life. It is mainly dependent on stages of labor. At the onset of labor (in first stage) the pain is related to continuous contractions of the uterine muscle, dilation of the cervix, stretching of the perineal tissue and pelvic floor muscle, while at the second stage of labor the descent of fetus presenting part, fetus position, and pressure on bladder, bowel and the pelvic structure lead to intensify the pain. Also fear of birth process, anxiety, sense of control loss and stress all affecting on women's childbirth experiences and their perception towards labor. Therefore, the first priority in confirm a positive labor outcome and satisfying the physiological need of women is by effective labor pain management (1).

Methodology

A quasi-experimental study design was conducted on purposive sample, of (60) women (30) control group and (30) study group whom admitted to Al-Elwyia Maternity Teaching Hospital suffering from labor pain. Study implemented for the period of (4th July 2018 through 24th October 2018). Data collection will be gathered by application one of non-pharmacological strategies of pain relief methods include: (frankincense, jasmine,& olive oils), massage,body movement and change position (squatting, side-lying,& standing),breathing technique, and therapeutic touch),and by used questionnaire format which consisted of four parts, including demographic, reproductive characteristics, non-pharmacological methods the delivering woman received during labor and FLACC behavior scale to measure intensity of pain level. A pilot study was carried out between the 25th June 2018,

to 1st July 2018, on (10) women to determine the reliability of the questionnaire and content validity was carried out through the 12 experts. Descriptive and inferential statistical analyses were used to analyze the data.

Results

	Total	30	100	30	100	

(*) NS: Non Sig. at P>0.05; Testing based on a contingency coefficient (C.C.) test.

Table (2) shows that the highest percentage (53.5%) (56.7%) respectively for both study and control groups were at gestational age between (39 weeks – 40 weeks $^{+6day}$), and (53.3%) (66.7%) respectively for study and control groups have intact membrane status.

Table 3: Type of Practices Concerning Pain Management Methods Uses for Study group

No.	Items	No.	Yes		No		Order
			F	%	F	%	
1.	Frankincense Oil	30	9	30.0%	21	70.0%	1.0
2.	Jasmine Oil	30	7	23.3%	23	76.7%	2.0
3.	Side-Lying Position &Breathing	30	4	13.3%	26	86.7%	3.0
4.	Squatting Position	30	4	13.3%	26	86.7%	3.0
5.	Massage	30	1	3.3%	29	96.7%	4.0
6.	Massage &Standing position	30	1	3.3%	29	96.7%	4.0
7.	Therapeutic Touch &standing	30	1	3.3%	29	96.7%	4.0
8.	Olive Oil	30	1	3.3%	29	96.7%	4.0
9.	Breathing Technique	30	1	3.3%	29	96.7%	4.0
10.	Therapeutic Touch & side-lying position	30	1	3.3%	29	96.7%	4.0

Table (3) results show that " Frankincense Oil" method has recorded the high and first ordered method, and accounted 9 (30%), then followed with Jasmine Oil" method, and accounted 7 (23.3%), then followed with "Squatting Position, and Side-Lying Position &Breathing" methods, and accounted 4 (13.3%), Massage, Massage& Standing position, Therapeutic touch & Standing, Olive oil, breathing technique, & side lying position accounted 1(3.3%).

Table 4: Distribution of Pain Assessment in different Stages between studied groups using (FLACC behavioral scale) with Comparisons Significant

Stages of labor	FLACC behavioral scale category	No. and %	Groups		Total	C.S. (*) P-value
			Study	Control		
1st Stage	Mild	No.	0	0	0	C.C. = 0.647 P = 0.000 (HS)
		%	0.00%	0.00%	0.00%	
	Moderate	No.	30	2	32	
		%	100%	6.7%	53.3%	
	Sever	No.	0	28	28	
		%	0.00%	93.3%	46.7%	
	Total	No.	30	30	60	
		%	100%	100%	100%	
2nd Stage	Mild	No.	0	0	0	C.C. = 0.695 P = 0.000 (HS)
		%	0.00%	0.00%	0.00%	
	Moderate	No.	29	0	29	
		%	96.7%	0.00%	48.3%	
	Sever	No.	1	30	31	
		%	3.3%	100%	51.7%	
	Total	No.	30	30	60	
		%	100%	100%	100%	
3rd Stage	Mild	No.	30	20	50	C.C. = 0.408 P = 0.002 (HS)
		%	100%	66.7%	83.3%	
	Moderate	No.	0	6	6	
		%	0.00%	20.0%	10.0%	
	Sever	No.	0	4	4	
		%	0.00%	13.3%	6.7%	
	Total	No.	30	30	60	
		%	100%	100%	100%	

(*) HS: Highly Sig. at P<0.01; NS: Non Sig. at P>0.05; Testing based on a contingency coefficient (C.C.) test.

Table (4) results show that concerning 1st & 2nd stages the pain intensity level have recorded a moderate level in the study group, while sever level in controlled, then followed in the 3rd stage, all study cases 30(100%) has recorded mild level, while only 20(66.7%) in controlled group has recorded mild level, and the leftover has recorded moderate and sever, and they are accounted 6(20.0%), and 4(13.7%) respectively.

Discussion

Regarding to Socio Demographic Characteristic: (Table 1) The results show that the highest percentages (46.7%), (53.3%) respectively for both study and control groups are (< 20) years old. This finding is in agreement with a retrospective study which found that out of the (60) sample of primigravida women, the highest age groups were between (18-22) years that was (41.7%) and the lowest were found in the age group of (30-34) and they are accounted (11.7%) [2].The highest percentages (30%) (36.7%) respectively for both study and control groups are primary schools graduates. This finding is in agreement with study that finds that the women with low educational level will have minimum level of performance to cope with pain during childbirth process. While it was pointing that woman with higher level of educational ‘’such as college’’ was more perception to the childbirth preparation methods, presenting classes, and books reads to cope with labor pain [3]. The height significances in occupational status of wife, are “Housewives”, and they are accounted (93.3%) in both study and control groups, this finding is constant with the study that found unemployed women will have more free time in order to read book s, watch videos, and attend classes. Which all lead to a more positive childbirth experience [4]. The vast majority (90%) (86.7%) respectively of the both study and control groups were living at urban areas the researcher noted that although these women living in urban area and were have sufficient awareness that labor is painful, but there is lack of knowledge regarding the methods of non-pharmacological pain relief, and there advantages and disadvantages.

Reproductive Parameters: Table (2) Results show that the highest percentage (53.5%) (56.7%) respectively for both study and control groups were at gestational age between (39 weeks – 40 weeks +6day), these result are agreement with study that found that physiological factors such as uterine contractions, cervical dilation, and gestational age though essential parts of labor, are major contributors to labor pain[2]. the highest percentages (53.3%) (66.7%) respectively for both study and control groups have intact membrane status. These group of women artificial rupture of membrane were done for them to enhance progress of labor and increase cervical dilation,and this mean the women exposed to more painful than those with spontaneous rupture of membrane at term, and need to arrange for educating them about how copy with pain

Non Pharmacological Methods: The results of table (3) show that “ frankincense oil” method has recorded the highest and accounted 9 (30%), then followed with jasmine oil” method, and accounted 7 (23.3%), then followed with “squatting position, and side-lying position &breathing” methods, and accounted 4 (13.3%), finally, massage, massage and standing position, therapeutic touch and standing, olive oil, breathing technique, and therapeutic touch and distraction’’ are accounted 1 (3.3%). In this study noted that essential oils (Frankincense, jasmine, and olive) recorded the high number of uses and accounted 17(56.7%), because its promoting general relaxation, reduce anxiety and helpful to reduce labor pain, Then as observed in this study some women prefer changing positions which include squatting that accounted 4(13.3%) and side-lying position and standing which used as combine with other method. These positions help to speed labor by adding the benefits of gravidity and changing the shape of the pelvis in addition the position that women assumes have a profound effect on uterine activity and efficiency [5].Related to use breathing technique in this study one woman chose to apply breathing technique as alone be sit in bed and 4 of them use breathing technique with slid lying position and they are accounted 4(13.3) the researcher teaches woman how to apply this method based on evidence-based studies[6-8]. Relative to use of massage technique the results show that there are two women were choosing massage (one massage combined with standing position and other with side-lying position). The massage is one of the best non pharmacological therapies useful in labor. Because it has the potential benefits such as decreasing the intensity of pain. Relative to use therapeutic touch observed that there are two women chose therapeutic touch but in different way one therapeutic touch with standing position and another one use therapeutic touch with side-lying position.

Pain Assessment in Different Stages between Studied Groups Using (FLACC Behavioral Scale): In present study the researcher used FLACC behavior scale to measure the intensity of labor pain because the labor pain affects a woman's emotional control and it can be associated with fear that leads to a prolonged childbirth process and so mother are request for an unnecessary cesarean section[9]. In addition to that the intense and prolonged uncontrolled labor pain can cause long-term excitement imbalance and can psychologically disturb mother's health.[10],So that the researcher application some methods of non-pharmacological pain relief and reassess the pain level for study group, it was found that there are high significant at level of pain in two groups and in all labor stage as shown in table (4) show that concerning 1st & 2nd stages the pain intensity level have recorded a moderate level in the study group, while sever level in controlled, then in the 3rd stage, all study cases 30(100%) has recorded mild level, while only 20(66.7%) in controlled group has recorded mild level, and the leftover have recorded moderate and sever, and they are accounted 6(20.0%), and 4(13.7%) respectively. These findings are in agreement with study which measures the effects of breathing exercises on maternal pain during the second stage of labor revealed that the mean visual analog scale score of intervention group and control group were (88.2 ± 6.3) and (90.5 ± 7.0), respectively ($P < 0.001$). Based on this study, breathing exercises for women are effective in reducing the perception of labor pain, therefore the breathing exercises consider an effective method for labor pain management and lessening the duration of labor [7]. Another study which revealed that the primiparous women distributed in to two groups the (experimental and the control) group. Where the experimental group received a 30-min massage during the three phases of labor. Then the intensity of pain between the two groups was compared in the latent phase, active phase, and transitional phase. A t-test demonstrated that the massage group had significantly lower pain reactions in the latent, active and transitional phases [11]. Relative to change position a systematic reviews evidence several possible benefits for upright positions (squatting, sitting, chairs, kneeling, and birthing stools) in women without epidural anesthesia, such as a very small reduction in the duration of second stage of labor, when compared with supine positions [12]. Related to essential oils the effect on reduction of labor pain are consistent with the findings of study which assessed the effectiveness of jasmine oil massage, it is evident that the jasmine oil was effective in reducing level of first stage labor pain among primigravida women [13]. Furthermore, the use of touch therapy helps women maintain their sense of body integrity and increases the ability to their compatibility with the delivery [14].

Conclusions

The study concluded that there are a highly significant differences concerning reducing level of pain in (1st, 2nd, & 3rd) stages of labor between study and control groups.

Conflict of Interest: Nil

Source of Funding: Self

Ethical Clearance: Obtained from the

- Ministry of Health/Al-Russafa Health Directorate
- Ministry of Planning and Development Cooperation/ Central Statistical Organization Technique and Information.
- Al-Elwyia maternity teaching hospital.
- All laboring women participants in the research -have been approved before the questionnaire is started.

Recommendations

The study recommended developing training program to all midwives working in delivery room to upgrade their knowledge and skills about importance of using non-pharmacological pain management methods to help them perform their role effectively in reducing level of pain for women during labor.

Cholera Outbreak in Iraq, 2017

Shakir Mohsen Zgheir[1], Nabil Mansur Mustafa[1], Ali Abdalkader Ali[1], Jawad Al-Diwan[2]

[1]Communicable Diseases Control Centre, Iraq, Minstry of Health, [2]MBChB, MSc, FIBMS/FFPH, Department of Community & amp; Family Medicine, College of Medicine, University of Baghdad

ABSTRACT

Background: In Aug, 2017, Iraq as one of the Eastern Mediterranean Region countries experienced cholera outbreak. Iraq is a cholera endemic country with epidemics every 3-4 years. Poor services due to the wars and conflicts, the influx of internally displaced people reinforce many outbreaks in the last 10 years.

Aim of the study: To assess the Cholera Outbreak in Iraq, 2017

Method: We defined a case of Cholera as a patient with diarrhea that had a positive stool sample for vibrio cholera. Epidemiological investigations were carried for each case and their contacts was examined also the type of drinking water was determined.

Results: The total suspected cholera cases were 505. Most of the cases (98%) were inaba with a peak in W47 giving a case fatality rate of 0.6%. Generally, the diarrheal cases were in the middle and south of Iraq and the proportion of cholera cases was higher in those who use river, vehicle and other sources of water while most of cases occurred in autumn.

Conclusions: Provision of adequate and safe water supply besides other control measures should be in place to prevent further outbreaks. Epidemiological and laboratory evidence suggested that the water was the source of this outbreak.

Keywords: *Cholera, Iraq 2017, epidemics, water, endemic countries*

Introduction

Cholera is an infectious disease caused by ingestion of bacterium *Vibrio cholerae* with contaminated food or drinking water [(1)]. Only two serogroups (O1 and O139) cause outbreaks among many serogroups of *V. cholerae*. *V. cholerae* O1 has caused all recent outbreaks and the world now under the seventh pandemic, which started since 1961 in South Asia [(2)].

The disease is endemic in many countries and the discrepancy in the estimated burden of the disease may be related to the fact that many cases are not recorded due to weak surveillance systems, weak records and fear of impact on trade and tourism. The provision of safe water and sanitation is important in control of cholera transmission and other waterborne diseases [(2)].

In the Eastern Mediterranean Region, many outbreaks of cholera were reported from Afghanistan, Djibouti, Iraq, Pakistan, Sudan, Somalia and Yemen in the last decade [(3)].

Cholera is endemic in Iraq[(4)] and it was reported in 1820 for the first time in Basrah [(5)]. Iraq faced several epidemics during the last 5 decades all together due to underdevelopment and damage of infrastructures as a result of wars and conflicts. Shortage in provision of safe water in addition to bad sweage system, reinforce many outbreaks in the last ten years [(6)(7)].

Publishing on cholera epidemics in Iraq is scarce, therefore this report was carried out to highlight this problem, also to elucidate the picture of the epidemic and the factors potentiate the occurrence of the disease.

Aim of the study: To assess the Cholera Outbreak in Iraq, 2017

Material and Method

Data were collected from communicable diseases center (Minisry of Health) for the year 2017. Cholera case was defined according to WHO definition [8].

Laboratory Tests and Confirmation: Stool samples were collected in primary health care centres (PHCCs) and hospitals positive for *V. Cholera* is transferred to the Reference Laboratory at the Central Public Health Laboratory for confirmation. Each case was visited and interviewed by a team, their contacts were examined. Epidemiological investigation was carried out for each case (home visit for interview, examination of contact, type of water used and personal data).

Results

In year 2017, the first laboratory confirmed sporadic case of cholera was female 37 years old, lives in Baghdad Al Resafa/Al Kamaliya District which diagnosed in W22/ May. Then cases continued through Augest to December by a gradual occurrence of cases that progressed to an outbreak to register 505 (36.9%) cholera cases which confirmed by Central Public Health Laboratory/Iraq (CPHL) out of 1367 suspected cases. Most of the cases, 497(98.4%) caused by V. cholerae O1, El Tor, Inaba serotype while the remaining cases caused by V. cholerae O1, El Tor, Ogawa serotype, 8(1.58%). The peak was demonstrated at W47 (114 cases)**(Figure 1).**

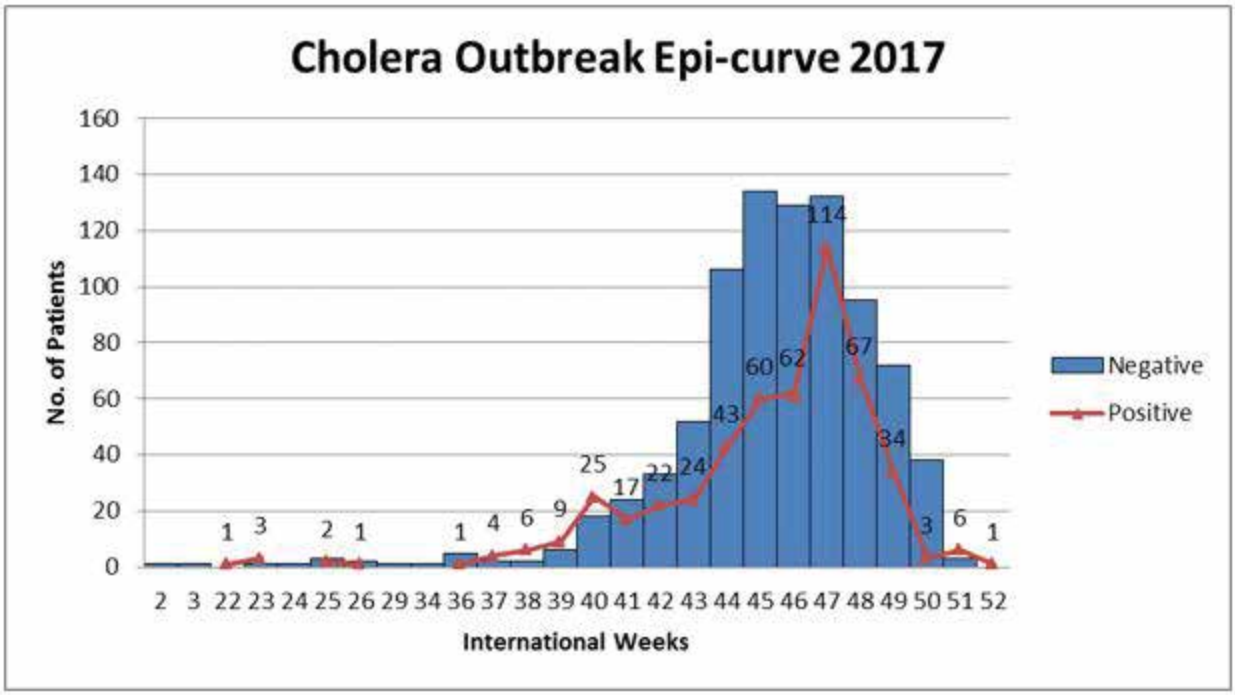

Figure 1: Epi-curve of cholera cases by international weeks

The overall rate was 1.33/100000 population and 3 patients with cholera died giving a case fatality rate 0.6%. Out of 505 cases, 254 were male (37.3%) giving male to female ratio 1.01:1.

The mean age was 31.5 ± 19.95 years old and ranged from 2 months to 90 years old.

Although the proportion of suspected cholera cases among females was higher than males [686 (50.18%) vs. 681(49.82%)], however, it showed no significant association between sex and cholera infection (χ^2=0.074, P=0.786). **(Table 1)**

Table 1: Distribution of cholera cases by gender, Iraq, 2017

Variable	Suspected	Positive
Gender	Total (N = 1367) No. (%)	Confirmed (n = 505) No. (%)
Male	681 (49.82)	254 (37.3)
Female	686 (50.18)	251 (36.59)

χ^2=0.074 , d.f =1, P-value = 0.786

The suspected cholera cases were distributed over 11 governorates out of 18 in Iraq. The higher number of diarrheal cases was in Baghdad Resafa and the lowest

was in Missan [706 (51.64) vs. 10 (0.37%)]. The highest proportion of cholera cases among diarrheal cases were in Kerbala while the lowest in Najaf as [66(98.51%) vs. 2 (5.88%)] respectively, whereas other governorates showed a percentage ranged between (10% to 67%), giving a significant association between cholera infection and governorate (P=0.000). **(Table 2)**

Table 2: Distribution of cholera cases by governorates, Iraq, 2017

Variable	Suspected	Positive
Health Directorate	**Total (N = 1367) No. (%)**	**Confirmed (n = 505) No. (%)**
Baghdad Resafa	706 (51.64)	265 (37.54)
Kerbala	67 (4.90)	66 (98.51)
Diwaniya	187 (13.68)	54 (26.88)
Babylon	207 (15.14)	59 (28.5)
Wassit	50 (3.65)	25 (50)
Missan	10 (0.73)	4 (40)
Kirkuk	15 (1.09)	3 (25)
Nineveh	47 (3.43)	5 (10.64)
Najaf	34 (2.48)	2 (5.88)
Baghdad kerkh	14 (1.02)	2 (14.29)
Muthana	30 (2.19)	20 (66.67)

χ^2=168.9,d.f =10,P-value = 0.000

Similarly, suspected cholera cases showed a significant association with the source of water being used along the study period (χ^2=32.8, P=0.000). As the highest proportion of suspected cases were found among those who used tab water and R.O, 60.79%(831). On the other, the proportion of cholera cases was higher among diarrheal cases that use the river, vehicle and other sources of water while the lowest in those used R.O water [9 (64.29%) vs. 60 (25.97%)] respectively, as shown in **Table 3**.

Table 3: Distribution of cholera cases by source of water, Iraq, 2017

Variable	Suspected	Positive
Source of water	Total (N = 1367) No. (%)	Confirmed (n = 505) No. (%)
Tab water	291 (21.29)	86 (29.55)
R.O.	231 (16.9)	60 (25.97)

Conted…

Tab water & R.O.	831 (60.79)	350 (42.13)
Others (river and vehicle water)	14 (1.02)	9 (64.29)

χ^2=32.8, d.f =3,P-value = 0.000

The highest proportion of cholera infection among diarrheal cases were in May while the lowest in July [2 (100%) vs. 0 (0.0%)] respectively, on the other hand the second highest percentage of infections among diarrheal cases was in September (64.18%). A significant association was found between the cholera occurrence and seasons as shown in **Table 4** (P=0.000).

Table 4: Distribution of cholera cases by months, Iraq, 2017

Variable	Suspected	Positive
Month	Total (N = 1367) No. (%)	Confirmed (n = 505) No. (%)
May	2 (0.146)	2 (100)

Discussion

The index case was diagnosed in W36/29August in Baghdad Risafa/Al Kamalea which followed by several cases from multiple governorates as an outbreak continued to W51/17December with total number cases 505. In 2007 outbreak, the total number of cholera cases were 4659 and most of cases were occurred in the north of Iraq while in the current study the number cases were 505 and most of them were occurred in the middle and south of the country this is because the outbreak may occur every 3 to 5 years [(4)].

The first case in 2007 an outbreak was diagnosed in Baghdad on W38/19 September in a study conducted

by Khwaif et al (2010) [5], alternatively in the current outbreak the first cholera case was diagnosed in Baghdad at the end of August 2017, whereas in 2015 the first case was diagnosed in Diwania/Gamas in September [9].

In this epidemic the serotypes were Inaba and Ogawa. In 2016 outbreak in which only 3 cases of Inaba were diagnosed, as well as in 2007, also Inaba was reported [5]. In Iraq two serotypes in which Inaba was dominant followed by ogawa,this confirmed by a study conducted by Saleh et al (2011) on 80 clinical samples from diarrheal patients in Iraq during the period 2007-2009 to explore bacterial isolates [10].

In the current epidemic the rate of cholera cases was 1.33/100000 population while in 2015 and 2016 the rate was 8.2/100000 and 0.01/100000 respectively [11,12] which explain that cholera can be seasonal or sporadic[2].

In fact in 2016, 38 countries reported 132121 cases which represent 23% drop in the number of cases reported compared with 2015 (172454 cases)[13], although WHO considered the officially reported cases represent only 5-10% of the actual number occurring annually worldwide[14] because various factors influence the underreporting such as weakness in the surveillance system, use of inappropriate case definitions, laboratory diagnostic capacities, and reluctance to report for fear of negative economic impact on trading and tourisim, in addition to limited registration in areas of conflicts [13].

CFR in this outbreak was 0.6% while the CFR in 2015 outbreak was 0.07% [11] and it is lower the CFR in Baghdad 2007 outbreak (2.2%) [5], in Camerone (6.1%) [15] and (>5%) in Zimbabwe [16]. In 2016, 38 countries reported cholera outbreak with CFR 1.8% (2420 death), of which 19 countries reported CFR > 1% while the overall CFR was 0.8% in 2015[13]. The low CFR in Iraq can be attributed to early detection and proper mangement of cases that prevent death.

In the current study the mean age was around 30 years old (31.5 ± 19.95 years), this result agreed with the results reported by Tamang et al (2005) a study conducted in Nepal on 148 patients with acute diarrhea showed that 46 patients (31%) were positive for V. cholerae O1 strains in which younger age group less than 30 years was mostly affected [17]. Similarly, a study conducted by Jabeen et al (2003) in Pakistan also showed that the mean age of patients infected with V. cholerae serogroup O1 was 23 years when compared with those infected with serogroup O139 their mean age as 40 years [18].

Also in the present study the highest percentage of suspected cholera cases was in age group 16-45 years 47.18% (645), which correspond to the results of study conducted in Mexico (2012) showed similar age distribution in which the greatest proportion of cholera in age group 25-44 years and those aged more than 65 years which interpreted to occupational exposure and eating habit [19].

Not all areas of Iraq served by tab water network, especially the remote and rural areas in which the people depend on rivers, streams and estuaries for domestic use and may be for drinking or served by vehicle water. There may be shortage in water provision and use electrical pumps to draw unsafe water from the old pipes that may be contaminated with sewage disposal net due to damge of both systems or contaminated with sewage stream in area not served by sewage net [5, 20].

The people may digging wells due to either shortage of tap water or unserved areas like outskirt and rural areas, which also considered unsafe because not tested bacteriolgicaly. Also, unplanned temporary camps for IDPs with shortage in provision of many standards for basic life as electricity, clean water and sewage [5]. Another explanation, that high population density in Urban areas and breakdown of water system and sewage disposal net have a great effect on spread of infection[16].

Iraqi Ministery of Environment in 2009 explain that the bacteriological contamination in water supply varies between governorates ranging between 2.5%-30% with average 16% which is beyond Iraqi National Driniking Water Standards and WHO Guidelines for Drinking Water permissible limit of 5% [20]. Around 250000 tones of sewage disposal thrown into Tigris river which contaminat the water sources and water nework [20]. Also, many houses in suburb and rural areas illegaly puncture the raw water transfer pipes for domestic use. Nowadays, many water filtration factories (R.O) were manged by people and they are not under supervision of Health control of Iraq MOH. These factories sail water to the families and not sure about its safety for drinking. Because of scarcity of water during dry seasons with reduction in provision even in the areas served. Many families with middle and low income, those living in poor and rural areas and IDPs in the camps depend on tab water but many people become gradually depend on R.O water [11].

The highest proportion of suspected cases was among those who use both tab water and R.O (60.79%) and followed by those who depened on tab water and those who used R.O, (21.29%) and (16.9%) respectively, as tab water may not be safe because there is no enough free chlorine in water or high turbidity that prevent chlorine function as the turbidity have a significant effect on the efficiency of chlorine as a disinfectant [21]. Also R.O water may be unsafe because it is not under the control of health authorities [11] and not tested physically, chemically and biologically.

Conclusions

1. The rate of cholera cases was 1.33/100000 population and the CFR was 0.6%.
2. Although the highest significant proportion of suspected cases were among age group 16-45years but the risk of infection decreased after 1 year of age.
3. Source of water is most important independent variable that were more likely increased the risk of cholera infection transmission, especially tab water and R.O water as well as the river's and other source water (vehicle water).
4. Cholera cases reported from 11 governorates out of 18.
5. The outbreak occurred in autumn and reached the peak on W47.

So we recommend the following

1. Strengthen the surveillance of suspected cholera cases specially active case detection.
2. Improve case management to decrease case fatality rate below 0.2%.
3. Increase orientation about the disease, especially in the autumn season.
4. Control of the environment by callobration with other menistries and health sectors that responsible for purification of water, safe food and good sanitation.
5. Health promotion by education of community at risk specially improving personal hygein.

ABSTRACT

Sepsis is the leading causes of morbidity and mortality in critical patients in many intensive care units. There were numerous parameter and biomarkers available to confirm the presence of sepsis**.** The aim of this study was to determine which one the parameter or biomarkers (white blood cell, CRP,procalcitonin and TNF-α) has a role as an outcome predictor in pediatric sepsis patient. This prospective cohort study was conducted in Pediatric Intensive Care Unit WahidinSudirohusodo hospital fromJanuari 2016untilMay 2017. A total of 108 sepsis patients were included. Plasma specimens were collected at admission, then the patients were being followed up for survived or non-survived. The diagnosis of sepsis is using the International Pediatric Sepsis Consensus 2005 criteria. Serum CRP,Procalcitonin TNF-α were measured using Enzyme Linked Immunosorbent Assay technique. Initial serumprocalcitonin level and TNF-α in non-survived children with septic were very significantly higher than those in the survived groupswith p=0.000 with OR2,46 CI(0,905-6,697) in procalcitonin and p=0.000 with OR 44,69 CI(5,749-347,36)in TNF-α**.** The initial serum level of PCT and TNF-α can be used as a predictor outcome of sepsis patient in children

Keywords: *WBC, CRP, Procalcitonin, TNF-α, Sepsis, Predictor*

Introduction

Septic shock is the primary cause of death in intensive care units (ICUs). With a mortality rate in excess of 50%, it results in more than 100 000 deaths a year in the United States.[1]Sepsis-induced organ failure leading to death appears to be due to the activation of a mediator cascade initiated by microbial components.[1,2]

Several biomarkers have been suggested for the early diagnosis of sepsis, including IL-1b, IL-8, TNF-α, and procalcitonin (PCT).[3] Located in the lower range in normal subjects, PCT, a calcitonin prohormone, increases significantly in patients with bacterial infections caused by a broad spectrum of gram-positive and gram-negative bacteria.[4] In three separate studies, the sensitivity of PCT in the diagnosis of sepsis was found to be 97%, 78%, and 85%, while WBC, CRP, and ESR levels did not have high accuracy in the diagnosis of bacterial infection in immunocompromised and neutropenia patients.[4]By measuring serum PCT, antibiotic therapy can be commenced or terminated to help doctors with the diagnosis of suspected sepsis. Compared with CRP and ESR levels, PCT levels are a better marker in diagnosing lobar pneumonia in children.[4]

PCT has been considered a reliable biomarker for differentiating sepsis from noninfectious systemic inflammatory response syndrome (SIRS).[5,6]

In the case of suspected sepsis, drug therapy is performed immediately after the patient'sadmission to hospital, as any delay in treatment can worsen the disease. However, delays can occur due to the lack of specific symptoms of sepsis or inaccurate microbial culture results. Blood cultures may be negative for various reasons, such as the use of antibiotics before hospital admission, which is common in our society, although the results of blood cultures are reported after at least 48 hours. They may also be negative in the early stages of SIRS and sepsis. Moreover, many organisms require

specific media and exclusive culture environments that are not available in most medical centers. However, microbial cultures do not reflect the host'sinflammatory responses nor do they detect organ dysfunction.[5]

TNF αcan cause intravascular thrombosis, inhibit muscle contractility of heart, lowers blood pressure (shock), vascular dilation, and plasma leakage which then lead to septic shock.Therefore, it is important to investigate the effects of cytokines as the prognostic value in patients with sepsis. [1]

Previous studies showed numerous biomarker also can determine the diagnosis in sepsis patients.[1]If we can predict the outcome of patients with sepsis earlier, thepatient can betreated more progressively, sothe mortality rate in patients with sepsis can be reduced. Based on the fact above, it needs an approach from biological parameter and biomarkers(WBC, CRP, PCT and TNF-α) to identify the role and prognostic value for sepsis.

Material and Method

This study included children aged 1 month to 18 years who were diagnosed with sepsis from December 2015 untilMay 2017 based on International Pediatric Sepsis Consensus of 2005, which was treated in the Pediatric Intensive Care Unit (PICU) WahidinSudirohusodo Hospital Makassar, Indonesia [21]. Samples are the entire population that meets the inclusion criteria. Inclusion criteria were patients with sepsis, age 1 month to 18 years, who was willing to sign an informed consent agreement. Exclusion criteria were patients with trauma, burns, malnutrition, malignancy, being received corticosteroid treatment and patients with immune deficiency

Written informed consent was obtained from all the patients and their guardians, and all the patients were examined clinically. Patients' characteristics, including their ages; sexes; temperatures; respiratory rates; heart rates per minute; systolic and diastolic blood pressures; alertness statuses at the time of admission and during hospitalization; underlying diseases.

Sepsis is SIRS caused by either a suspected or proven infection. This study used the the International Pediatric Sepsis Consensus 2005 criteria to diagnosis sepsis.

Five ml blood samples were used to measure PCT levels, CRP levels, TNF-α, blood cultures and CBC-Diff blood samples were taken.

After blood extraction, experiment should be conducted immediately as well. Samples may be stored at 2-8°C.Allowtheserumtoclotor 10-20 minutesatroomtemperature and centrifuge (at 2000-3000 RPM) for 20 minutes. Collect the supernatant carefully. When sediments occurred during storage, centrifugation should be performed again. Sample the assay, bring samples to room temperature. First, add prepared sample 40 µl standards and ELISA solutions. times. Add chromogen solution A and B. Incubate for 10 minutes at 37°Cforcolordevelopment. Thenaddstopsolution. Readthevaluewithin 10 minutes.

The data obtained are grouped into two groups of patients; survived and non-survived. Then, suitable statistic method was chosen to analyze the data, which was univariate and bivariate analysis, power=80%, α=0,05.Chi factor was used to determine the significance of predictor factor relationship with the outcome of survived and non-survived. Mann withney test is used compare the median initial serum of white blood cell, CRP,PCT and TNF-αlevel of the sepsis patient to the outcome survived or not survived if data not normally distributed. For normality test, Kolmogorov-Smirnov test was used. Statistical Analysis was processedbyusingSPSS 21

Results

An observational study with prospective cohort approach in108 sepsis patient sin childrenhas been conducte din Dr.Wahidin Sudirohusodo Hospital Makassarf rom Januari 2016 until May 2017.

The sample consisted of 40 sepsis and 68 with septic shock and then we observed for survived and non-survived. Fifty five sample in survived group consisted37 (52,1%) boys and 34 (47,9%) girls, while in 53 sample non-survived group consisted of 18 (47,4%) boys and 20 (52,6%) girls. Statistical analysis showed no significant difference between the two groups with p=0,59. The age was divided into ordinal. Statistical analysis showed that there wasno significant difference in age between the two groups with p=0.11 (Table 1). White blood cell (WBC), CRP, PCT and TNF-α was classified into ordinal. There were no significant difference in WBC,PCT and CRP between two groups, only TNF-α showed very significant difference with between survived and non-survived group with p= 0,000

Mann withney test is used compare the mean initial serum of white blood cell, CRP,PCT and TNF-α level of the sepsis patient to the outcome survived or not survived because they were not in normal distribution. (Table.2). Serum level of WBC in survived group the mean was 20077,53 mg/dL and range 3640 to 61730 mg/dL. While in non-survived group was 22050,57 mg/dL and range 3100 to 55200 mg/dL. Mann Whitney test results showed that there was no significant differences between the two groups with p=0.071

Serum level of CRP in survived group the mean was 45,27 mg/dL and range 0 to 238 mg/dLWhile in non-survived group was 68,70 mg/dL and range 0 to 289 mg/dL. Mann Whitney test results showed that there was no significant differences between the two groups with p=0.104

Serum level of PCT in survived group the mean was 16,00ng/ml and range 0 to 210 ng/ml. While in non-survived group was 44,26ng/ml and range 19 to 210 mg/dL. Mann Whitney test results showed that there was very significant differences between the two groups with p=0.000 with OR2,46 CI(0,905-6,697)

Serum level of TNF-α in survived group the mean was 429,77pg/ml and range 269,36 to 1009,17 pg/ml. While in non-survived group was 848,92 pg/mland range 231,11-1784,68pg/ml. Mann Whitney test results showed that there was very significant differences between the two groups with p=0.000 with OR 44,69 CI(5,749-347,36)

Discussion

The result so four research demonstrated thatPCTlevel and TNF-αin non-survived children withseptic were significantly higher than those in the survived groups.

This result similar withAygun F, that evaluated procalcitonin value is an early prognostic factor related to mortality in admission to pediatric intensive care unit, the result showed there was statistically significant relationship between PCT and TNF-α levels with MV support, NIV, inotropic drug use, mortality, AKI, hospitalization in the intensivecareunit,CRRT,andblood component transfusion.[7,8]

Performing procalcitonin and TNF-α test routinely in patients of sepsis can give rapid results in a day rather than the three to seven days required for bacterial culture and can act as surrogate markers of microbial infection. An increased of procalcitonin and TNF-α should be classified in higher risk of mortality and should be monitor and aggressive treatment started.[9,10,11]

At high levels, TNF-α induce pathologic abnormality of septic shock.[12] Results of previous studies have shown that TNF-α is a good marker for the diagnosis of sepsis, to assess the effectiveness of therapy, and prognosis of sepsis disease.[1]

Elevation of PCT levels usually occurs earlier during the course of infection than elevation of CRP levels, peaking at approximately 24 - 36 hours. Some studies of critically ill pediatric patients showed that the accuracy of PCT measurement in detecting bacterial infections is better than that of other markers, especially CRP. However, its sensitivity and specificity vary.[13,14]

In a cohort in an American tertiary hospital (78 children with criteria for sepsis and septic shock and 12 critically ill children without sepsis), persistently high PCT in children with bacterial sepsis was related to a poor outcome.[14,15,16]

In this study, white blood cell and CRP showed not significantly difference between 2 groups. CRP generally consider a nonspecific biomarker in sepsis.

C-reactive protein (CRP), one of the biomarkers that has been in longer use in pediatric sepsis, is a non-specific, acute-phase protein that increases 4-6 hours after exposure to an inflammatory trigger Its levels decrease rapidly with the resolution of inflammation and is usually high in invasive bacterial infections.[7,10] In a systematic review of CRP diagnostic accuracy for bacterial infection in non-hospitalized children with fever, the sensitivity and specificity of CRP were estimated at 77% and 79%, respectively. However, its predictive value increases with the number of serial measurements, thus rendering it possibly useful for therapeutic management. Serial measurements in which CRP levels remain elevated or increase after 48 hours of antibiotic therapy suggest treatment failure.[8]It is

worth remembering that CRP is not a specific biomarker for differentiating infection from inflammation or for identifying specific infectious agents. As in the case of other biomarkers, its use should always be associated with bedside clinical evaluation of patients, and other clinical decision-making criteria should always be used. When available, the use of CRP combined with other biomarkers including procalcitonin (PCT), IL-6 and IL-8 to increase its specificity in the diagnosis of infectionsand to assess changes in therapeutic approaches, including changes in antibiotic therapy, is also promising.[17,18]

Limitations of this study, we only examined the initial parameter and biomarker, not serially and we didn't analyzed the the outcome based on severity of illness. While the strength of this study is a prospective cohort design is used so that we can follow the effects of these prognostic factors

Conclusion

The initial serum levels of procalcitonin and TNF-α as the prognostic values for outcome in pediatric sepsis hopefully can be an additional reference, for more comprehensive sepsis treatment to prevent complications and deaths. Sepsis patients with initial serum levels of procalcitonin and TNF-α high, require a close monitoring. Further research needs to be done with the involvement of other factors are also associated with sepsis outcomes such as genetic polymorphism, and serial examination of the biomarker in patients with sepsis.

Reactive Thrombocytosis after Caesarean Section and Normal Vaginal Delivery: Implications for Maternal Thromboembolism and its Prevention

Suha Abduljaleel Wadi[1], Ahmed Rifat Shakr[1], Farah Muayyed Gebriel Shammas Youisif[1]

[1]Senior Specialist in Obstetrics and Gynaecology, Al-Elwiya Maternity Teaching Hospital, Baghdad, Iraq

ABSTRACT

Objective: To assess the duration and severity of reactive thrombocytosis after caesarean section and after normal vaginal delivery.

Design: A prospective study.

Setting: Al-Elwiya Maternity Teaching Hospital -Baghdad -Iraq.

Materials and Method: Seventy pregnant women who were admitted for delivery at Al-Elwiaya Maternity Teaching Hospital were recruited into the study, the platelets count was measured at the time of first visit in the antenatal period. The second sample was taken just before normal vaginal delivery or caesarean section, followed by postnatal blood samples on days: 3, 8, 12, 16, 20 and 24 for the measurement of platelets count. Seventy pregnant women were recruited and forty completed the study, twenty of whom were delivered by normal vaginal delivery and twenty by caesarean section. A random effects model was used to compare the platelets counts within and between the two groups (normal vaginal deliveries group and caesarean sections group) to assess the severity and timing of reactive thrombocytosis.

Results: Antenatally: there were no statistically significant differences in platelets count measurement in the first antenatal visit and the pre delivery visit between the two groups. There was a slight fall in the pre-delivery platelets count in both groups compared with first visit platelets count but this fall was not significant. Postnatally: I. in the normal vaginal deliveries group; the platelets count continued to fall until the third postnatal day, then it rose, reaching peak values, compared with first visit and pre-delivery values at days 8 and 12 of the postnatal period which was statistically significant. The mean platelets count decreased gradually thereafter. II. in the caesarean sections group; the platelets count gradually increased, the rise started from the third post-operative day reaching a significantly high value, compared with first visit and pre-delivery values at day 8 of the postnatal period. The platelets count peaked at days 12 and 16 of the postnatal period. The platelets counts remained significantly higher than the first visit and pre-delivery values for 24 days after the caesarean section.

Introduction

In vivo action of the clotting mechanism is balanced by limiting reactions that normally prevent clots from developing in uninjured blood vessels and maintain the blood in a fluid state. During pregnancy and early puerperium, this balance between coagulation and fibrinolysis is disturbed; towards hypercoagualability. The maintenance of normal haemostatic function requires the successful interaction of three main Components: Intact blood vessel wall, intact platelets

function system, intact plasma coagulation and fibrinolytic components [1]. Platelets are central to normal haemostasis and to all thromboembolic disease [2]; they appear to be necessary for the first phase of haemostasis i.e. the formation of the initial plug (temporary haemostatic plug)[1, 2]. Platelets are the smallest cellular elements present in human blood. They are granulated non-nucleated, 2-4 µm in diameter [1] with a concentration from 150,000-400,000/µL[2,3].

Patients and Method

This study was done in Al- Elwiya Maternity Teaching Hospital, Baghdad-Iraq. In cooperation with the Department of Haematology in the same hospital, during the period from the 1st of June 2017 to the 1st of August 2018.

Patients:

***Selection of patients:** Seventy pregnant women were recruited into the study during the antenatal visits to the antenatal care unit in the mentioned hospital. They had an age-range of 19-39 years (mean 31 years). Primiparous as well as multiparous women were included. The patients chosen were those who were committed to deliver in the mentioned hospital and agreed to take part in the study after explaining its aims to them. They had to comply with the following criteria: Gestational age was confirmed by history, clinical examination and ultrasonography done at 8-14 weeks of gestation. They had regular antenatal care, no major pregnancy complications, no history of essential hypertension or diabetes mellitus, no history of any medical disorder affecting the platelets count. The following pregnant women were excluded from the study: women with medical disorders affecting the platelets count such as thrombocytopenia, women with history of malignant disease and genetic blood disorders like antithrombin III deficiency. The following puerperal women were later excluded from the study: women who were delivered by instrumental delivery like forceps or ventouse, those who suffered from postpartum haemorrhage and those with anaemia.

***Questionnaire:** A questionnaire was made for each woman and it was in two parts: antenatal part and postnatal part. Serial blood samples were taken for the measurement of platelets count in the antenatal and in the postnatal periods.

Methods of samples taking from the patients: Seventy pregnant women who were admitted for delivery at Al-Elwiaya Maternity Teaching Hospital were recruited into the study, forty pregnant women completed the study, twenty of whom were delivered by normal vaginal delivery (NVD group) and twenty by caesarean section(CS group). the platelets count was measured at the time of first visit in the antenatal period. The second sample was taken just before normal vaginal delivery or caesarean section, followed by postnatal blood samples on days: 3, 8, 12, 16, 20 and 24 for the measurement of platelets count.

Statistics: A random effects model was used to analyze the platelets counts and to allow for the correlation between the repeated measures of platelets counts. The statistical significance of the difference between mean values was assessed by the student's (t) test probability value (p-value). Values of <0.05 were considered significant.

Results

Table 1: The mean & range of platelets counts of first visit and predelivery counts in the two groups

Time of blood sample taking	Normal vaginal deliveries group (mean & range of platelets counts) ($x10^9/L$)	Caesarean sections group (mean & range of platelets counts) ($x10^9/L$)	p-value (Caesarean sections counts compared with vaginal deliveries counts)
1st Visit	259.2 (157-393)	280.5 (145-385)	0.30
Pre-delivery	254.15 (138-384)	261.2 (136-370)	0.72
p-value (pre-delivery counts compared with 1st visit count)	0.81	0.32	

There were no statistically significant differences in the first visit and pre-delivery platelets counts between the two groups. There was a slight fall in the pre-delivery platelets count in both groups compared with 1st visit platelets count but this fall was not statistically significant (Table 1).

Table 2: The mean & range of platelets counts in the normal vaginal deliveries group

Time of blood sample taking	Normal vaginal deliveries group (The mean & range of platelets count x 10^9/L)	p-value compared with 1st visit platelets count	p-value compared with pre-delivery platelets count
Antenatal blood samples:			
1st Visit	259.2 (157-393)		
Pre-delivery	254.15 (138-384)		
Postnatal blood samples:			
Day3	250.2 (132-424)	0.2	0.3
Day8	373.55 (264-650)	0.000001 **	0.000001**
Day 12	378.3 (277-522)	0.000002 **	0.000003 **
Day 16	327.4 (235-420)	0.0003*	0.0002*
Day 20	321.6 (234-392)	0.0004*	0.0003*
Day24	291.5 (176-393)	<0.05*	0.04*

* Significant difference

** Highly significant difference (peak values)

In the normal vaginal deliveries group: The platelets count continued to fall until the third postnatal day, this fall was not statistically significant. The platelets count increased rapidly after the third postnatal day, reaching peak values at eighth and twelfth days of the postnatal period. These peak values were statistically significant compared with first visit and pre-delivery values. The platelets count exceeded the upper limit of normal range (400x10^9/L) in seven women (35%). The mean platelets count decreased gradually after the twelfth postnatal day (Table 2).

Table 3: The mean & range of platelets counts in the caesarean sections group

Time of blood sample taking	Normal vaginal deliveries group (The mean & range of platelets count x 10^9/L)	p-value compared with 1st visit platelets count	p-value compared with pre-delivery platelets count
Antenatal blood samples:			
1st Visit	280.5 (145-385)		
Pre-delivery	261.2 (136-370)		
Postnatal blood samples:			
Day 3	288.95 (148-421)	0.6	0.1
Day8	462.55 (269-635)	0.003*	0.002*
Day 12	537.15 (282-910)	0.0000002**	0.0000007* *
Day 16	542.3 (286-1107)	0.000003**	0.000001 **
Day20	475.95 (264-690)	0.005*	0.001 *
Day 24	430.3 (194-798)	0.002*	0.005*

* Significant difference

**Highly significant difference (peak values)

In the caesarean sections group: Reactive thrombocytosis began on the third post-operative day, but the rise was not significant. A significant high value of the platelets count was reached on the eighth post-operative day, compared with first visit and pre-delivery counts. Peak values of platelets counts were reached at twelfth and sixteenth post-operative days. These peak values were statistically significant higher levels, compared with the first visit count and pre-delivery count. The platelets counts remained statistically higher than the first and pre delivery values for 24 days of the postnatal period. So the rise in platelets count was continued for a longer period than in the normal vaginal deliveries group.

The platelets count exceeded the normal range (400xl0^9/L) in sixteen women (80%) (Table 3, Figure 1).

Table 4: The mean & range of platelets counts in the caesarean section group compared with normal vaginal delivery group

Time of blood sample taking	Normal vaginal deliveries group (The mean & range of platelets count x 10^9/L)	Caesarean sections group (The mean & range of platelets count x 10^9/L)	p-value (Caesarean section s counts compared with vaginal delivery counts)
Antenatal blood samples:			
1st Visit	259.2 (157-393)	280.5 (145-385)	0.31
Pre-delivery	254.15 (138-384)	261.2 (136-370)	0.73
Postnatal blood samples:			
Day3	250.2 (132-424)	288.95 (148-421)	0.09
Day8	373.55 (264-650)	462.55 (269-635)	0.01
Day 12	378.3 (277-522)	537.15 (282-910)	0.001*
Day 16	327.4 (235-420)	542.3 (286-1107)	0.0001*
Day20	321.6 (234-392)	475.95 (264-690)	0.00005*
Day24	291.5 (176-393)	430.3 (194-798)	0.005 *

* Significant difference

There was a greater rise in the platelets counts in the caesarean section group compared with the normal vaginal delivery group.

The platelets counts in women delivered with caesarean section were significantly higher than in women delivered normally from day 12 to day24 of the postnatal period (Table 4).

Table 5: The mean & range of platelets counts in the normal vaginal delivery group & caesarean section group (Summary of the results)

Time of blood sample taking	Normal vaginal delivery group (The mean & range of platelets counts (x10^9/L))	p-value (Vaginal deliveries counts compared with antenatal counts)	Caesarean sections group (The mean & range of platelets counts (x10^9/L))	p-value (Caesarean sections counts compared with vaginal deliveries counts)	p-value (Caesarean sections counts compared with antenatal counts)
Antenatal blood samples:					
1st **visit**	259.2 (157-393)		280.5 (145-385)		
Pre-delivery	254.15 (138-384)		261.2 (136-370)		
Postnatal blood samples:					
Day3	250.2 (132-424)		288.95 (148-421)

Day 12	378.3 (277-522)	0.000002*	537.15 (282-910)	0.001**	0.0000007*
Day 16	327.4 (235-420)		542.3 (286-1107)	0.0001 **	0.000001 *
Day20	321.6 (234-392)		475.95 (264-690)	0.00005**	0.001 *
Day24	291.5 (176-393)		430.3 (194-798)	0.005**	0.005*

* Statistically significant high value compared with 1st visit & pre-delivery platelets counts.

** Statistically significant high value compared with normal vaginal delivery group.

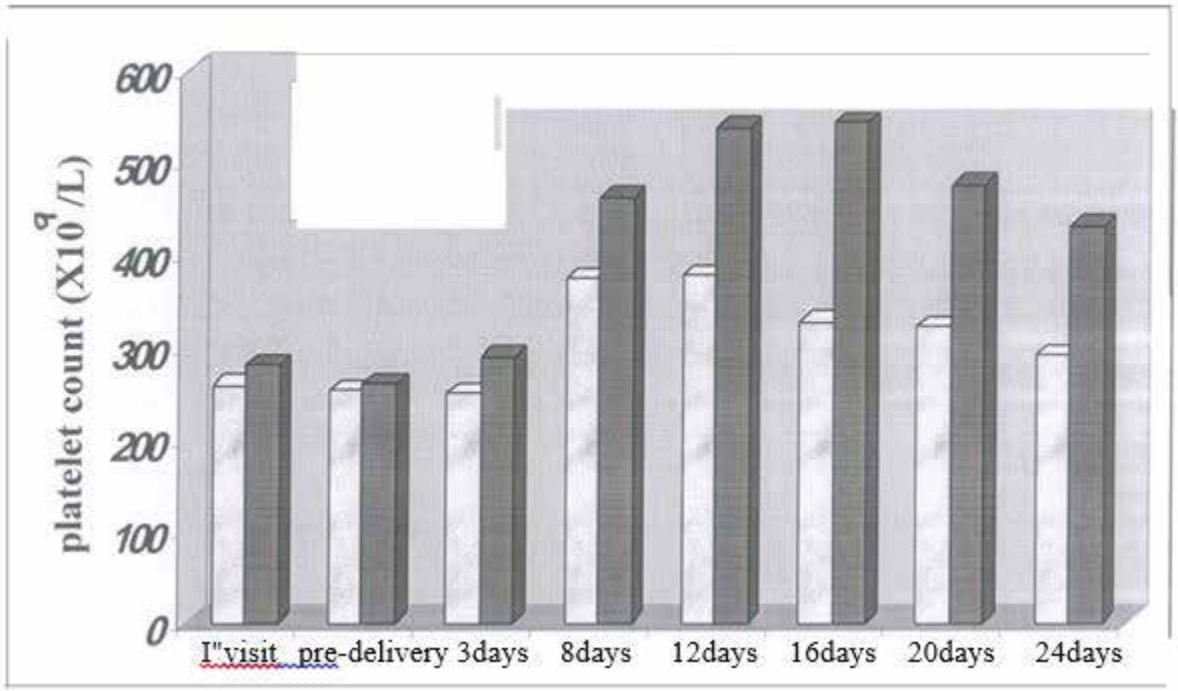

Fig. 1: Mean of platelets counts in the Normal Vaginal Deliveries group (NVD) and Caesarean Sections group (C-S)

Significant thrombocytosis occurred at days 8 and 12 after normal vaginal deliveries and caesarean sections. In the normal vaginal deliveries group, the mean platelets count decreased gradually thereafter. In the caesarean sections group, however, thrombocytosis continued till the sixteenth day. It stayed at significantly higher level than in the normal vaginal deliveries group for 24 days after delivery. The platelets counts in women in the caesarean sections group were significantly higher than in women in the normal vaginal deliveries group from day 12 to day 24 of the postnatal period (Table 5, Figure 1).

Discussion

Previous studies about this subject: Reactive (secondary) thrombocytosis (elevated platelets count > 450,000/µl and usually < 1,000,000/µl) [4]. P Saha, D Stott, R Atalla (2009) studied thrombotic changes during the postnatal period up to 6 weeks after delivery and assess the extent of risk period. In their study the mean platelets counts were low on predelivery days and rose sharply to a peak on day 11, and continued to be elevated until 25 days after delivery. The time to peak values is between (7-15) days, usually at a time when the patients are discharged from hospital. Their prospective study, showed that some women recruited antenatally in the vaginal delivery group required C-S. The coagulation parameters of women have been separately analysed in both groups (vaginal and cesarean), the result was that platelets counts and fibrinogen levels were significantly high till day 25 and 15 postpartum, respectively, after delivery (in C-S and VD groups). Reactive thrombocytosis that has been found to be a common occurrence during postpartum period is associated with an increased incidence of thrombosis. Increased fibrinogen is considered to contribute to hypercoagulable state as well. Also their study shows an exaggerated change towards hypercoagulability in cesarean sections group compared with vaginal deliveries group [5].

The overall incidence of VTE is approximately 1 in 1000 Maternities (Pregnancy and Puerperium) The puerperal period is the highest risk period for VTE, when it increases 20-fold [6]. The risk is greater in women who undergo c-section and is about 3 in 1000[7]. The risk was between 3-4 times higher for women who underwent an emergency (unplanned c-section) [8]. What is more important that the frequency of the thrombosis and the risk of fatal PE development are 10 times higher after cesarean delivery compared with normal vaginal deliveries in the

postpartum period (as observed by autopsies) [9, 10]. On the basis of the results of our study and other studies, it has been shown that the time of development of thromboembolic complications coincides with the time of significant reactive thrombocytosis, which was more prominent in the caesarean sections group. So there must be an association between reactive thrombocytosis and the increased incidence of thromboembolic complications, especially after operative delivery. Clinical presentation of postpartum VTE perceived to be rare and does not reflect the true incidence of silent venous thrombosis and many episodes of thrombotic events occur after discharge from hospital. Thrombosis and thromboembolism continue to be the leading cause of direct death in UK and the rate has not changed significantly, with a mortality rate of 1.01 per 100,000 maternities [11], despite wide spread use of thromboprophylaxis. There is a strong suggestion that inadequate thromboprophylaxis is a major cause of this preventable condition.

Conclusion

Our study data indicate that puerperium is a high-risk period for the development of TED. A significant thrombocytosis occurred at day 8 and day 12 after NDV and C-S. In NVDs group, the mean platelet count reaches peak values at 8th and 12th days of the puerperium and decreased gradually after the 12th postnatal days. In the C-Ss groups thrombocytosis continued till the 16th day. It stayed at significantly higher level than in normal vaginal deliveries group for 24 days after delivery. Such reactive (postpartum) thrombocytosis is associated with a hypercoagulable state and increase risk of TED and it is more prominent in the C-S group compared to the VD group where it extended up to 24 days postpartum. C-S was highlighted as the main risk factor for thromboembolism in the postpartum period. This could partly explains why the risk of puerperal thromboembolic events is about four times greater following C-S than following NVD and these events are more common ten days or more after delivery.

Recommendation

TE which is accepted as a complication, is a preventable one. Our recommendation is to consider anticoagulant prophylaxis for at least 21-25 days after delivery. Perhaps this would reduce the incidence of postpartum venous thrombosis and hence maternal morbidity and mortality. It is the task of the gynaecologic surgeon to identify patients at risk for development of a perioperative VTE and to apply the safest, most effective, and most cost-efficient method of prophylaxis to decrease the risk of thrombus development.

The Impact of Hormonal Replacement Therapy on Herpes Simplex Infection and Gingival Health in Post-Menopausal Women

Suzan Mohammed Abdul Raheem[1], Esra Hassan Abd Ali[2], Mahmoud M A Elian[3]

[1]B.D. S, M.Sc, Department, [2]M.SC, Ph. D., Dentistry College, Mustansiriyah University, Baghdad, Iraq; [3]BSc, H.D.D. MSc.

ABSTRACT

The fluctuating levels of sex hormones throughout menopause have an influence on oral health and periodontal disease. Deficiency of sex hormone during menopause and aging process mostly associated with local tissue and salivary flow changes make oral tissue more prone for infection. Few studies that assessed the rate of oral herpes simplex infection, bacterial growth and rate of gingivitis among postmenopausal women receiving Hormonal Replacement Therapy. So **aims** of study to assess the association of using the HRT and the incidence and recurrence rate of oral HSV infection, bacterial growth and gingivitis among post-menopausal women.

Subjects and Method: a cross sectional study carried out between 1st.oct.2017-1st.May 2018. Participants selected from private and outpatients' clinics of Dentistry College of Mustansiriyah University. Fifty -eight women in post-menopausal phase were selected randomly and categorized to two groups according to using the HRT. Frequency, severity of herpes simplex, relation of recurrence status to duration of using HRT, gingival index and bacterial growth were analyzed.

Results: Proportion of participants had mild, moderate and sever herpes simplex infection were 36.2, 34.5, 29.3% respectively. Proportion of subjects who are receiving HRT that reported sever herpes simplex infection and recurrence rate of >8 per year was significantly lower in comparison to non-user (18.4 vs.50%), (13.2 vs.45%) respectively. No significant association was found between severity or recurrence rate of HSV infection and duration of HRT use. Significant lower gingival index (GI) and bacterial growth (p=0.01 for all) with women who were on HRT (1.6 vs.2.8),(74.5 vs.127.3) respectively. The mixed bacterial isolate was reported with 55.2% of participants but no significant association found between type of isolate and status of using HRT and recurrence of HSV infection, in addition it has impact on gingival health of post-menopausal women

Keywords: *Herpes simplex infection, Hormonal Replacement Therapy, post-menapouse*

Introduction

The menopauses are considered an important phase as this physiological state result in adaptive changes at systemic and oral level [(1)]**.** Gums and teeth are mostly liable to any hormonal changes on post menopause and cant preserve a healthy equilibrium of useful and harmful bacteria within the oral environment [(2)]. Because oral mucosa comprises estrogen receptors, variations in hormone levels affect the oral cavity [(3)].

Herpes simplex virus (HSV) transferred through mucosal membrane and skin then spread to nerve tissues. The factors supposed to activate HSV not completely understood but endogenous factors such as immune deficiency, emotional stress and exogenous factors such as UV radiation were implicated [(4)].However, psychosocial stress is the most significant factor in the recurrence of lesions [(5)].

Certain types of bacteria promote viral disease symptoms, suggesting these bacteria may aid viral infection. Certain enteric viruses clarify how a bacterial constituent—attached or independent to the bacterium itself promotes the virus infection cycle [(6)]

Previously several studies were carried to assess the influence of (HRT) in adjusting periodontal circumstances

in postmenopausal women due to a potential connection between osteoporosis and periodontitis [7]. The HRT associated with a decreases of alveolar bone loss, but a number of researches failed to revealed an inverse relationship between alveolar bone density and periodontal disease. Additionally, some authors failed to establish positive effect for HRT on alveolar bone density[8]. There are conflicting results on the role of HRT on periodontal status in postmenopausal. While former research suggests that positive effects on periodontal status, a recent report challenges these results [9].

Hormonal Replacement Therapy has also been linked with decreased level of gingival bleeding. It has proposed that estrogen have an inhibitory influence on gingival inflammation by inhibiting mediators that includes IL-1, TNF-, IL-6, IL-1B, IL-8 and cellular mechanism of inflammation [10]. Conflicting findings about influence of HRT on probing pocket depth and attachment level [11].In several studies, the risk of tooth loss lowered among women who used HRT than those who did not [12]

The objectives of this study was to evaluate the rate, severity and recurrence rate of herpes simplex infection in addition to gingivitis and bacterial growth status in a group of post-menopausal women receiving HRT.

Materials and Method

Cross sectional study carried out from 1st Oct.2017to 1st May 2018, 58 women at postmenopausal phase were selected from outpatient clinic of Dentistry College of Mustansiriyah University and private clinics involved. The participants were categorized to two groups according to status of receiving the HRT. The participant received any immunosuppressive therapy, any medicine that affects the salivary flow, with any harmful habits such as smoking, chewing tobacco, alcohol etc. was excluded. All participants were examined looking for herpes simplex infection and asked about history of similar condition and it frequency per year. The frequency, severity and status of recurrence of herpes simplex infection and bacterial growth and their association with using of HRT were reported and stat. The gingival index also assessed and compared according to status of HRT use.

The growth of bacteria was assessed in two groups. The washing sample was diluted with sterile saline (10^{-1} -10^{-6}), the three last dilutions (10^{-4}- 10^{-6}) were cultured on BHI-A (Brain Heart Infusion Broth and Agar) for total bacterial count and on MSF-A for counting of oral streptococci and incubated at 370C for 24 hours. Triplicate plates were cultured for each dilution before and after chewing.

Statistical Analysis

SPSS version 23 was used for data entry and analysis. The appropriate tests (student T test and chi-square test) used to confirm significance. P <0.05 was considered significant

Results

The participants were categorized to two groups; 20(34.5%) was used HRT and 38(65.55) was didn't. The mean age was 50.6 ± 4.6 (range 48–61 years) for HRT+ group and 49.8 ± 3.6 (range 47–62 years) for the control group and this difference non-significant statistically (P=0.1).The clinical characteristics and type of isolate were summarized in table.1.

Table 1: Descrptive characteristics of studied group

		No.	%
status of HR	Mild	21	36.2%
	Moderate	20	34.5%
	Sever	17	29.3%
Frequency of recurrence of HS	<4	11	19.0%
	4-8	32	55.2%
	>8	15	25.9%
Type of isolate	Single	26	44.8%
	Mixed	32	55.2%

Our data indicated, there was significant association (p=0.005) between using the hormonal replacement and status of herpes simples as the frequency of subjects with moderate and sever status of herpes simples was lower with group who are receiving HRT in compare to control group as seen in table 2

Table 2: Association between severity status of Herpes simplex and status of using the HRT

		Using HRT				p-value
		Yes		No		
		No.	%	No.	%	
Severity status of herpes	Mild	19	50.0%	2	10.0%	0.005
	Moderate	12	31.6%	8	40.0%	
	Sever	7	18.4%	10	50.0%	

The results of current study showed that the proportion of subjects who were presented with high attack frequency (4-8 or >8/year) of herpes simplex significantly lower with group who were used HRT as seen in table 3.

Table 3: Association between frequency status of herpes simplex and status of using the HRT

		Using HRT				p-value
		Yes		No		
		No.	%	No.	%	
Frequency of recurrence/ year	<4	26	68.4%	5	25.0%	0.01
	4-8	7	18.4%	6	30.0%	
	>8	5	13.2%	9	45.0%	

The results revealed the was no significant association between type of growth in term of mixed or single isolate and status of using the hormonal replacement therapy as displaced in table 4.

Table 4: Association between type of isolate and status of using the HRT

		Using HRT				p-value
		Yes		No		
		No.	%	No.	%	
Type of isolate bacterial growth	Single	18	47.4%	8	40.0%	0.5
	Mixed	20	52.6%	12	60.0%	

The data showed there was no significant association between the duration of using the hormonal therapy and status of herpes simplex infection or frequency of recurrence (p=0.3, 0.7) respectively as showed in table.5.

Table 5: Association between duration of using the HRT, severity status and frequency of Herpes simplex infection

		Duration/year						p-value
		<2		2-4		>4		
		No.	%	No.	%	No.	%	
Severity status of herpes	Mild	0	0.0%	1	20.0%	1	20.0%	0.3
	Moderate	3	30.0%	2	40.0%	3	60.0%	
	Sever	7	70.0%	2	40.0%	1	20.0%	
Frequency of recurrence	<4	2	20.0%	1	20.0%	2	40.0%	0.7
	4-8	3	30.0%	1	20.0%	2	40.0%	
	>8	5	50.0%	3	60.0%	1	20.0%	

The results of current study demonstrated that the mean value of CFU colony forming unit of bacteria was significantly lower (p=0.01) with group of subjects who are using the HRT in compare to control group (127.3, 5.4) respectively as displaced in table 6.

Table 6: The mean value of CFU and GI according to status of using the HRT

	Using HRT	N	Mean	Std. Deviation	p-value
CFU	Yes	38	74.5	5.4	0.01
	No	20	127.3	6.7	
G I	Yes	38	1.6	0.7	0.01
	No	20	2.8	0.3	

The findings of current study showed there was no significant correlation between the duration of hormonal therapy used and CFU colony forming unit or GI gingival index as by using pearson correlation analysis.

Discussion

Menopause is usually followed by a number of physical changes in oral cavity therefor high prevalence of oral discomfort and changes could occur [13].Few studies focused on gingival changes and flow of saliva and other mucosal discomfort during and after menopause [14]

The results of this study show there was significant association between using the hormonal replacement therapy and decreasing frequency, recurrence, growth of and severity of herpes simplex infection as the results

revealed that the attack of herpes simplex 4-8 or >8/ year significantly lower with group who were used HRT. This relationship can be explained by the capability of HSV to create latent infection in autonomic ganglia that forcefully replicate or reactivate by physical, hormonal, or emotional stress that mostly improved with the using of HRT. [13].

The mean of GI and CFU of bacterial growth was lower with group who are receiving hormonal replacement therapy in compare to control group and this finding documente d that hormonal replacement therapy during menopause has positive impact on oral health but the exact mechanism behind that yet not well understood and further researches are recommended to highlight this association.

Studies had explained that negative life occasions are more dependably in the beginning or exacerbation of diseases and the association between significant negative life events and disease was mediated by the immune system. Studies has been shown that emotional stress can modify the immune system through the neural and endocrine systems in at least three different ways;- through the autonomic nervous system path way, through the release of neuropeptides and Through the release of hypothalamic and pituitary hormones[15,16], so the suggestion of using HRT in some way could modulate the immune response to stressful conditions that mostly associated with post menopause phase and reduce the incidence of viral infection and bacterial overgrowth

The behavioral mechanism supposed that people suffering from psychological illness may exacerbate poor health behaviors, such as smoking or drinking more frequently; consuming unhealthy diet and don not their oral hygiene. This behaviors leads to increased oral biofilm burden and decreased resistance of the periodontium to inflammatory breakdown. In an early study, adult subjects under financial strain and exhibiting poor coping behaviors were reported to be at increased risk for severe periodontitis [17]. Periodontitis patients with inadequate stress behaviors strategies were proposed to be at higher risk for severe periodontal diseases [18]

According to previous finding concerning the effect of stress in exacerbating the periodontitis status so it may effect in same manner and exacerbate the gingivitis status that could be reduced with using the HRT that mostly reduced the stress

Numerous studies showed that aging of human being is characterized by increased susceptibility to age-related diseases and, consequently, by the presence of multiple pathologies and comorbidities characterized by chronic processes, such as inflammation [19].

Many studies reveal that salivary pH, buffering capacity and flow rate play important roles in oral mucosal defense. When salivary flow rate is reduced, susceptibility to various oral diseases enhanced [20]. Some studies shown lower salivary flow rates in postmenopausal women, one was carried out by Parakh D et al [21], that reduction give route to poor oral hygiene and more susceptibility to oral physiological changes. A questionnaire study by Jansson and his co-workers (2003) [22] had been stated; there was more xerostomia among postmenopausal women who did not use HRT in comparison to those used hormonal therapy. The same authors proposed that some oral symptoms might be associated with estrogen deficiency, but oral symptoms do not develop immediately after menopause but some years later. It may also be that women with the severe symptoms decided to use HT and use of HT decreased their symptoms to the same level as in premenopausal women. The using of HRT could act in some way through increasing the salivary flow rate and that in turn could take part in minimizing the risk of oral infection in post-menopausal women.

In current study, we found that the salivary bacterial growth was lower with group of subjects that on hormonal replacement therapy while a study was conducted by Leimola-Virtanen R et al [23] that calculated salivary bacteria was found the HT seemed to have no effect on the amount of the total salivary bacteria in post-menopausal women.

Conclusion

The rate, recurrence rate and severity of herpes simplex infection was lower among postmenopausal women on hormonal replacement therapy.

[1]Physiotherapist, Biorehab Physiotherapy Centre, Kota Kinabalu, Sabah, Malaysia; [2]Clinical Coordinator cum Lecturer, [3]Lecturer, INTI International University, Nilai, Malaysia

ABSTRACT

Background and Objective: Violinists are commonly affected by neck pain a condition commonly associated with upper limb dysfunctions and there is limited information regarding the effects of neck pain on hand dexterity in violinists. The objective is to investigate if neck pain significantly affects tapping speed and the relationship between degrees of neck pain on tapping speed in violinists with neck pain.

Materials and Method: 34 violinists with neck pain (N = 23) and without neck pain (N = 11) were recruited. Tapping speed of the index-middle, middle-ring, and ring-little fingers of both hands were measured with HLTapper V.1.0 application. Analyses were done to identify significant differences in tapping speed between two groups; and to correlate degree of neck pain and tapping speed.

Findings: Significant difference in tapping speed of right middle-ring (RMR) finger between violinists with and without neck pain (p = 0.018). Strong negative linear correlation between degree of neck pain and tapping speed of RMR finger in violinists with neck pain was found (= -0.845, p = 0.001).

Conclusion: Tapping speed of the RMR finger may be affected by neck pain in violinists.

Keywords: *Neck Pain, Tapping Speed, Fine motor skills, hand dexterity in violinists*

Introduction

Upper limb dysfunction can borne from a variety of clinical conditions, neck pain has been cited as one of the most commonly associated issue.(1) Patients with neck problems were likely to present with upper limb disability; with the most classic example being upper limb pain, motor weakness, sensory deficits, and loss of function due to cervical radiculopathy.(2) In a study 79.6% of patients with non-specific neck pain reported that upper limb activities aggravated the neck pain thereby further cementing the statement that upper limb function is often impaired in association with neck pain disorders.(3)

Manual dexterity is defined as the ability to coordinate the fingers and to manipulate objects in a timely manner.(4) It is also the ability to integrate precision and speed with finely coordinated movements of the arm, hand, and fingers.(5) For musicians, playing a musical instrument often involves highly coordinated hand movements and profound digital precision and velocity.(6) The speed, fluency, & tempo required for musical performances of elite instrumentalists crowned musical expertise as the ultimate example of elite performance in complex hand dexterity, thus marking excellent fine motor skills as an essential component for musicians to perform well on their instrument.(7)

A musician's technique pertains to the way he holds the instrument, the force applied when playing, and the frequency of awkward static or dynamic postures. Static loading involves prolonged, sustained muscle contraction and stress across a joint, the surrounding soft tissue, and bony structures. On the other hand, dynamic load is

the force applied to the muscles, joints, and supporting structures by movements. [8] While the position of the left shoulder is relatively fixed, the left hand regulates the tone and pitch of the sounds produced by pressing the strings along the length of the finger board, in such a way that a higher pitched sound is generated when the string is pressed closer to the sound bridge, thus the position of the elbow, forearm, and wrist changes according to the required tone.[9] Here, stabilizing efforts from the neck and shoulder musculatures are needed to allow precision work in the hands and fingers when playing the violin. Thus, excessive overuse or misuse may cause fatigue of the stabilizing muscles, consequently resulting in neck pain and discomfort, possibly due to muscle spasms and nerve compression. [10] Another study found that violinists with unilateral neck pain showed less lower trapezius strength on the ipsilateral side compared to the contralateral side; likely due to the alteration of muscle usage between the upper trapezius and lower trapezius in stabilizing the violin due to pain.[11] Alteration of posture due to neck pain can be associated with difficulties in other regions, such as dexterity in the hands.[12]

Although musicians commonly report pain-associated decrease in fine motor skills, there is limited information regarding the effects of neck pain on hand dexterity in high string musicians.

Materials and Method

34 violin players (teachers, students, & performers) were recruited from University Malaysia Sabah, Sabah Institute of Art, & various music academies in Kota Kinabalu, Sabah upon approval from the relevant head of department or musical director of the aforementioned musical institutes. Inclusion criteria are, aged between 18 – 50 years old, playing the violin for at least two years and two hours per week. Has playing related non-specific neck pain (for symptomatic group) and does not have neck pain for the last 12 weeks (for control group). Whereas the participants are excluded if the, history of trauma or surgery to the neck, shoulder, arm, forearm, and hand, history of pregnancy (to avoid possible confounding factors such as pregnancy-related peripheral neuropathies e.g. carpal tunnel syndrome).

The subjects were recruited via convenience sampling from the aforementioned musical institutes. Group allocation was done according to the flow chart 1.1. Following that, the subjects answered the NPAD questionnaire. All participants provided written consent to participate in this study. Data collection was conducted over a period of six month from July 2018 to December 2018. Institutional ethical approval was obtained from the Research and Ethical Committee of INTI International University before proceeded with this study.

For the timed tapping test, the subjects were seated with their left forearm rested on a table, with the wrist neutral and relaxed. They were then asked to alternately tap each side of the rectangle with their index finger and middle finger as fast as possible for 10 seconds on the HLTapper V.1.0 application. They were then given a rest period of 30 seconds before repeating the test for two more times. The procedure is then repeated for the middle finger and ring finger; followed by the ring finger and little finger. The same test is done for the right hand as well. The number of taps performed per second are then recorded for each hand. After the above data have been recorded, group matching was performed and reassigned as depicted in the flow chart 1.1.

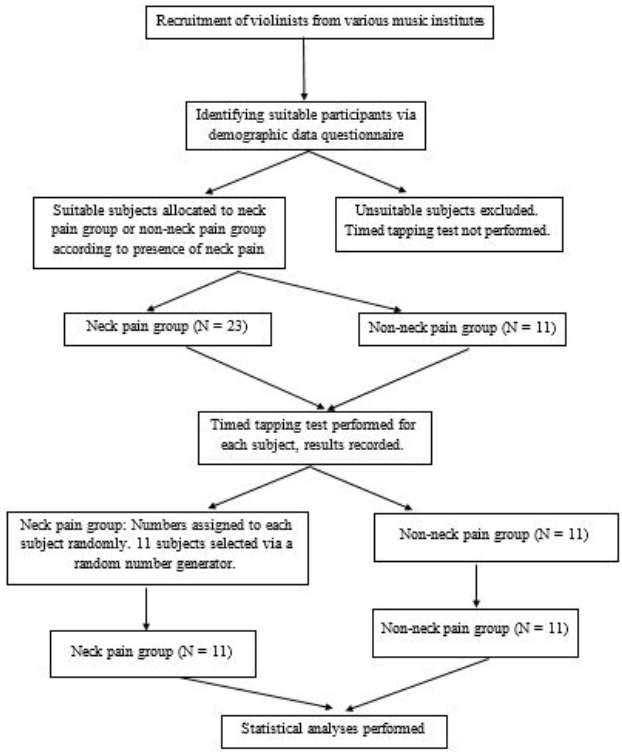

Figure 1.1 Flow chart of data collection

Findings

SPSS V.22 was used, with the alpha set at 0.05. Preliminary testing of sampling distribution showed that for tapping speed of all finger combination groups were normally distributed except for the right

middle-ring (RMR) finger combination of the neck pain group, as shown by their p-values in table 1.1. Thus, the independent T-test was performed to analyse the difference in tapping speed between violinists with neck pain and those without neck pain for all finger combination groups except for the RMR finger combination group where Mann-Whitney test instead. The Spearman's rho correlation coefficient was done to analyse the relationship between degree of neck pain and tapping speed.

Table 1.1: Tapping speed of all finger combination groups and their p-values

Groups / Finger combination	Neck pain group	Non-neck pain group
Right index-middle (RIM)	$p = 0.084$	$p = 0.200$
Right middle-ring (RMR)	$p = 0.026$	$p = 0.200$
Right ring-little (RRL)	$p = 0.200$	$p = 0.200$
Left index-middle (LIM)	$p = 0.200$	$p = 0.200$
Left middle-ring (LMR)	$p = 0.200$	$p = 0.200$
Left ring-little (LRL)	$p = 0.200$	$p = 0.200$

No significant between-group differences were found for age, gender, BMI, years of playing, total playing hours per week, and handedness ($p > 0.05$) in table 2.1.

Table 2.1: Sample characteristics and distribution of subjects

Demographics	Violinists with neck pain (N = 11)	Violinists without neck pain (N = 11)	p-value
Age (Year)	19 to 40 (Mean ± SD = 29.27 ± 7.54)	20 to 45 (Mean ± SD = 27.55 ± 8.29)	RIM: $p = 0.561$ RMR: $p = 0.294$ RRL: $p = 0.460$ LIM: $p = 0.667$ LMR: $p = 0.382$ LRL: $p = 0.540$
Gender (Male/ Female)	5/6	6/5	RIM: $p = 0.800$ RMR: $p = 0.889$ RRL: $p = 0.276$ LIM: $p = 0.519$ LMR: $p = 0.359$ LRL: $p = 0.267$
Body mass index	20.03 to 24.03 (Mean ± SD = 22.74 ± 1.34)	18.73 to 24.22 (Mean ± SD = 21.85 ± 1.92)	RIM: $p = 0.963$ RMR: $p = 0.873$ RRL: $p = 0.093$ LIM: $p = 0.251$ LMR: $p = 0.342$ LRL: $p = 0.789$
Years of playing (Years)	1 to 12 (Mean ± SD = 5.27 ± 3.36)	2 to 18 (Mean ± SD = 8.09 ± 5.00)	RIM: $p = 0.794$ RMR: $p = 0.604$ RRL: $p = 0.523$ LIM: $p = 0.190$ LMR: $p = 0.211$ LRL: $p = 0.755$
Total playing hours per week (Hours)	7 to 24.5 (Mean ± SD = 15.77 ± 6.25)	2 to 21 (Mean ± SD = 10.63 ± 6.82)	RIM: $p = 0.766$ RMR: $p = 0.493$ RRL: $p = 0.717$ LIM: $p = 0.639$ LMR: $p = 0.132$ LRL: $p = 0.366$

Conted…

Handedness (Right/ Left)	7/4	10/1	RIM: $p = 0.150$ RMR: $p = 0.285$ RRL: $p = 0.853$ LIM: $p = 0.572$ LMR: $p = 0.414$ LRL: $p = 0.076$

Analyses with the independent T-test found no significant differences in tapping speed of the RIM finger; RRL finger; LIM finger; LMR finger; and LRL finger combination groups of both hands ($p > 0.05$) between neck pain and non-neck pain groups. On the other hand, tapping speed of the RMR finger combination in neck pain group (Median = 8.20) differed significantly with a large effect size from the non-neck pain group (Median = 9.43), U = 28.5, z = -2.10, p =0.018, r = -0.633 using the Mann-Whitney test ($p < 0.05$).

Table 3.1: Mean tapping speed of both hands between neck pain and non-neck pain groups and their p-values

Groups / Finger combinations	Neck pain group	Non-neck pain group	p-value
RIM	10.70 taps/s	12.07 taps/s	$p = 0.068$
RMR	7.88 taps/s	9.29 taps/s	$p = 0.018$
RRL	6.32 taps/s	7.15 taps/s	$p = 0.211$
LIM	11.15taps/s	11.57 taps/s	$p = 0.617$
LMR	8.27 taps/s	8.95 taps/s	$p = 0.440$
LRL	6.38 taps/s	7.10 taps/s	$p = 0.282$

Spearman's rho correlation coefficient found a significant relationship between tapping speed of the RMR finger combination and the degree of neck pain, = -.845, p =. 001. This suggests a strong negative linear correlation between the two variables - indicating that as the degree of neck pain increases, the tapping speed of the RMR finger fingers decreases.

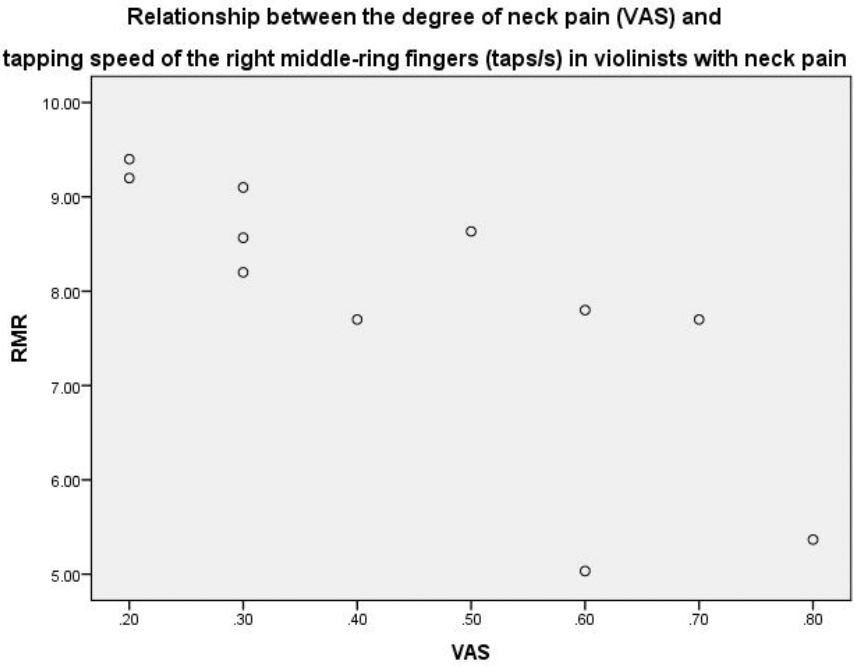

Figure 2.1: Relationship between the degree of neck pain (VAS) and tapping speed of the RMR fingers (taps/s) in violinists with neck pain

Discussion

The results of this study suggested that there were no significant differences in tapping speed in all the finger combinations between violinists with neck pain and those without neck pain except for the RMR finger combination, which demonstrated a significant difference of large effect size between the two groups. These results are in partial agreement with a study, which compared the sensorimotor function of violinists with and without neck pain to measure different motor aspects of the upper limb/hands. [7] The differences between the results of these studies may be due to the fact that the current study employs a timed alternate finger tapping method to assess the dexterity of the subjects, which is a more similar movement to those employed when playing a violin in comparison to the traditional way of assessing tapping speed by single finger tapping of the index finger; and thus may be more accurate than the latter in detecting significant differences in the tapping speed between two groups of subjects. Nonetheless, non-specific neck pain has been shown to have a significant impact on upper limb function, as indicated that 80% of patients with non-specific neck pain reported difficulties with upper limb tasks due to the pain.[3] The difference between this study and the current study is evident in the type of upper limb function studied – where Osborn and Jull examined gross movements such as lifting objects, gardening, and household chores; the present study examined fine and precision-oriented motor tasks of the hand and fingers. A similar interpretation can be drawn from results of a study by [13], which found that chronic mechanical neck pain populations had less accurate proprioception in the shoulder and wrist. Altered input from neck muscles secondary to pain and fatigue may affect sensory input to the central nervous system, consequently impairing upper limb proprioception and limit the performance of precision tasks. Furthermore, the results of the current study may also be explained by the fact that the structures of the right upper extremity is often placed under high levels of dynamic loading during playing. Here, the right upper extremity is used to produce larger range of motions compared to the left upper extremity during bowing movements, with the right shoulder placed in an increasingly abducted and internally rotated position depending on which strings are played. When musicians are required to play quickly and frequently under these conditions, accumulation of physical stress from dynamic loading can cause fatigue and micro-damage to the musculotendinous structures of the proximal stabilizing muscles and upper limb, ultimately resulting in pain, discomfort, and dysfunction.[9]

The current study also found that there was a significant, strong negative linear correlation between the degree of neck pain and tapping speed of the RMR finger among violinists with neck pain. These findings are in agreement with that of Osborn and Jull, which found a moderate to high correlation between the severity of neck disorder and level of upper limb disability – in that patients with more severe neck pain presented with more limitations in their upper limb function. However, the type of upper limb functions examined by Osborn and Jull differs from the current study, in the sense that Osborn and Jull studied recreational movements which involved gross motor function; whereas the current study examined fine motor tasks.

The first potential limitation of the current study is the selection of the measurement tool. As of now, there is no consensus regarding the most suitable outcome measure tool for assessment of hand dexterity in musicians. It future studies, perhaps an outcome measure tool that allows the musician to assume the exact basic position adopted during their musical performances may allow better analysis of the data, as this may minimize any carry-over effect from their experience with playing other instruments.

Conclusion

The study concludes that there is significant difference in tapping speed of the RMR finger combination between violinists with neck pain and violinists without neck pain. However, it also identified that no significant differences in tapping speed of the RIM finger; RRL finger; LIM finger; LMR finger; and LRL finger combinations between violinists with neck pain and violinists without neck pain. Furthermore, the current study also found that there is a significant and strong negative linear relationship between degrees of neck pain and tapping speed of the RMR finger in violinists with neck pain, in which tapping speed of the RMR fingers decreases as the degree of neck pain increases.

ABSTRACT

Background: Antimicrobials are among the most commonly used and misused of all drugs. The inevitable results of their common and widespread use has been the emergence of antibiotic-resistant pathogens, fueling an ever-increasing need for new drugs at a time when the velocity of antimicrobial drug development has slowed significantly, therefore aim of this study is reducing inappropriate antibiotic use which thought to be the best way to control resistance and reserve money spent for buying.

Material and Method: This descriptive study was held in the wards of Salah Aldin Teaching Hospital (STH), from (1-31) January 2017, the total number of collected sample is 1700 cases of inpatient were treated with antibiotics from a total of 2150 inpatient and only 647 cases in the pediatric wards who treated with antibiotics were included in the study. The study involved with determining the definite diagnosis, cause of admission, rational cost for using antibiotics and the duration of the treatment.

Results: Total numbers of cases who treated with antibiotics were 647 cases in pediatric wards only and the number of antibiotics which had been spent during that month as follow: 482 cephalosporins vials, 199 penicillins vials, 235 metronidazole bottols, 54 amino-glycosides, 35 glycopeptide, 31 Flouroquinolone, and 17 macrolides vials respectively as registered in the pharmacy books and wards (more than one antibiotic might be prescribed to one case). The total cost was 6194$ only in pediatric wards from a total 23929$ cost of antibiotics used in the whole wards of Salahaldin Teaching Hospital (STH).

Conclusion: The antibacterial agents are used in the wards of the hospital roughly, without differential tests and without any respect to the guidelines of judicious AB use to decrease the resistant. Cephalosporins are the most commonly used AB in all the five wards of STH, As well as the total cost of using AB in STH for only one month is about 23929 $, 6194$ in pediatrics. enormous amounts of AB used in STH can easily lead to serious problems of resistant infections, also huge amounts of AB dispensed for chest infections and GE (usually are viral in nature).

Keywords: *Antibiotics usage; Cost; Pediatric wads; Salahaldin Teaching Hospital.*

Introduction

An antibacterial are compounds or substances that kill or decelerate the bacterial growth. The discovery of antimicrobials is one of the most great and best medical achievements of the 20th century. Before the antimicrobial time, patients who contracted common infectious diseases developed significant morbidity or mortality. The discovery of penicillin in 1927, after that; the subsequent discovery of other antimicrobials, contributed to a considerable decline in mortality related to infectious disease during the next five decades. However, since 1980, the mortality caused by infectious diseases in the United States have begun to increase, to some extent due to increases in antimicrobial resistance[1,2]. So antimicrobial agents are among the most commonly used and misused of all drugs. The inevitable result of their common and wide spread use has been the emergence of antibiotic-resistant pathogens, fueling an ever-increasing need for new drugs at a time when the velocity of antimicrobial drug development has slowed significantly. Reducing inappropriate antibiotic use is thought to be the best way in resistance control [3].

Antibiotics have three principal uses: empirical therapy, definitive therapy, and prophylactic therapy.

When used as empirical therapy, the antibiotic(s) should cover all the possible pathogens, because the infecting organism has not been identified. Either combination therapy or, treatment with a single broad-spectrum agent may be employed. Once the infecting microorganism is identified, the course is completed with a narrow-spectrum, low-toxicity drug. Failures to identify the causative microorganism and to narrow the antibiotic spectrum thereafter are common misuses of antibiotics. The first consideration in selecting an antibiotic is whether it is even indicated, Diagnosis may be masked if therapy is started before appropriate cultures are obtained. Antibiotics are potentially toxic, and may encourage selection of resistant microorganisms. Of course, definitive identification of a bacterial infection before treatment is initiated often is not possible. In the absence of a clear indication, antibiotics often may be used if disease is severe and it seems likely that withholding therapy will cause failure to manage a severe or life-threatening infection[2,6].For definitive therapy, the course of therapy should be altered to a more specific and narrow-spectrum antibiotic once an organism and susceptibility have been identified [2,7].

Prolonged usage of empirical broad-spectrum coverage or multiple antibiotics should be avoided because it often is unnecessary, is costly, may select for antibiotic resistance against multiple agents, and may cause additional unfavorable effects due to the multiple agents. Inappropriately broad coverage often is continued because satisfactory cultures were not obtained before the initiation of therapy or because of the misconception that a broad-spectrum regimen is better than a narrow-spectrum regimen. Although reluctance to narrow therapy after a favorable initial response has occurred is comprehensible, the goal should be to use the most selectively active drug that produces the least unfavorable effects, which includes unfavorable effects on normal host flora[8]. The Centers for Disease Control and Prevention (CDC) has outlined a series of steps to reduce antibiotic resistance, including proper use of vaccination, thoughtful and proper use of indwelling catheters, early involvement of infectious disease experts, antibiotic choice based on local patterns of susceptibility, proper antiseptic technique to ensure infection rather than contamination, right use of prophylactic antibiotics in surgical procedures, infection control procedures to isolate the pathogen, and strict compliance to hand hygiene[2,9].Most viral diseases are self-limited and neither need nor respond to any of the currently available anti-infective compounds. Thus, antibiotic therapy of at least 90% of infections of the upper respiratory tract and many GI infections is ineffective[10].Antibiotic therapy too often is given in the absence of supporting microbiological data. Bacterial cultures and Gram stains of infected material are obtained too infrequently, and, when available, the results often are overlooked in the selection and application of drug therapy. Frequent use of drug combinations or drugs with broadest spectra is a cover for diagnostic imprecision[11].

Material and Method

The work is done in Salah aldin Teaching Hospital, cases are collected during January 2017, the samples are 1700 cases of inpatient treated with antibiotics from a total of 2150 inpatient case.

The cases are collected from the patients that are found in the hospital and from the files of the patients that still found in the hospital. The study involved with determining the definite diagnosis, cause of admission, rational cause for using antibiotics and the duration of the treatment.In this study, some parameters are involved such as: age, duration of treatment, type of the antibiotics and their dosage forms and changes in the treatment regimen.

Results and Discussion

We have seven major types of antibiotics (AB) that are always used in the wards of Salah Aldin Teaching Hospital (STH), these are Cephalosporins, penicillins, Metronidazole, amino-glycosides, quinolones, glycopeptides and macrolides respectively, and other antibiotics are used rarely. In this study, the type of antibiotics used can be shown by table (1).

Table 1: the use of antibiotics (AB)in the investigated cases

Types of antibiotics	In the whole wards of STH	in Pediatric Wards	Percentage % (total 1700 cases)
Penicillins	524	199	30.8%
Cephalosporins	1267	482	74.5%
Amino-Glycosides	137	54	8%

Conted…

Metronidazole	618	235	36.3%
Glycopeptide antibiotics	90	35	5.2%
Quinolones	78	31	4.6%
Macrolides	47	17	2.7%

Note: some patients received more than one antibiotic.

We found that from 2150 inpatient cases in the 5 wards of STH, 1700 cases were treated with AB and as shown by the table above; the most commonly used AB is cephalosporins and exactly the 3rd generation cephalosporin. Which is important to say that between these 1700 cases, we did not find any test for culture and sensitivity neither we find a gram stain or any differential tests for microbial growth. Also about 99% of the used AB in STH are of low quality which increases the duration of treatment, risks on the patient, and the risk of AB resistant.The total cost was 23929$ for the all antibiotics had been spent as registered in the pharmacy books and case sheets of the hospital,6194$ from the total cost for antibiotics were used by pediatric ward only.

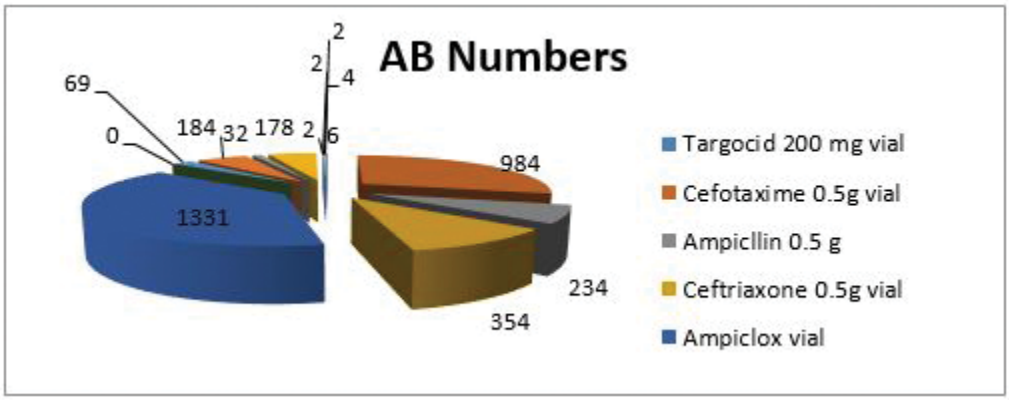

Figure 1: The use of AB for chest infections in the pediatric ward

Two- hundred seventy one cases in the pediatric ward were treated with AB for chest infection. As we can see from the figure (1), 1331 ampiclox vials had been dispensed for those case, 984 cefotaxime 0.5g vials, 234 ampicillin 0.5g vials, 354 ceftriaxone vials, 184 gentamicin 20 mg amp, and 178 vials of vancomycin vials. This enormous amounts from AB dispensed for 271 cases to treat chest infections and the duration ranges from 2 days to 7 days and we already know that 90% of these infections are viral in nature as documented in many clinical references(11,12,13)

The cost of this irrational use is about 3066$.

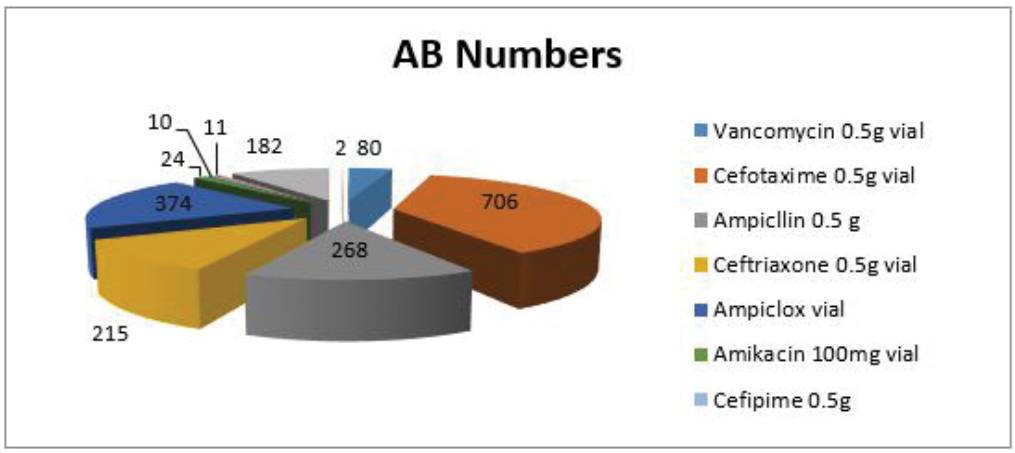

Figure 2: The use of AB for treating GE in the pediatric ward

Cases in the pediatric ward were treated with AB for Gastroenteritis (GE). Figure (2) reveals the total no. AB used for these cases.As we can see from the figure above, 706 cefotaxime 0.5g vial, 268 ampicillin vials, 215 ceftriaxone 0.5g vials, 374 ampiclox vials, 182 metronidazole bottles, and 80 vancomycin 0.5g vials were used in patients with GE. While almost references of medicine and clinical pharmacology document the fact that AB in GE will decrease the course of healing by not more than 1 day also that most of cases are viral in nature[8] (this agreed with Davidson's principles & practice 20th edition). The cost of this irrational use is about 1635 $.

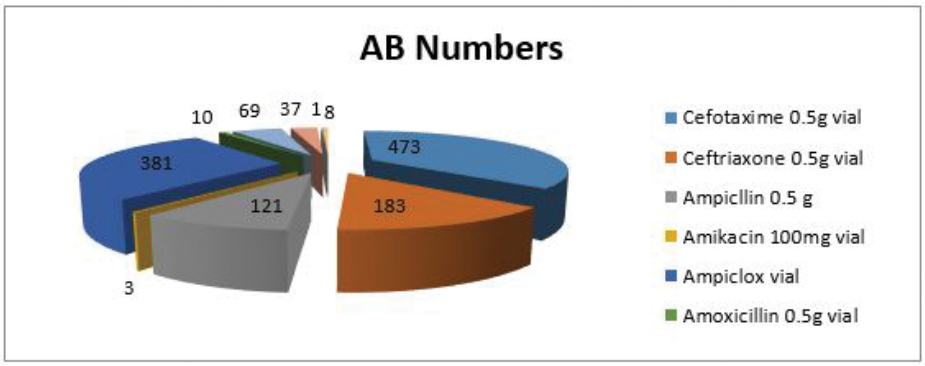

Figure 3: The use of AB for nosocomial prophylaxis in the pediatric ward

In the pediatric ward about 3.71 cases were received AB for nosocomial prophylaxis as shown in fig.(3), 473 cefotaxime vials, 183 ceftriaxone 0.5g vials, 121 ampicillin 0.5 g vials, 381 ampiclox vials, 37 gentamicin 20 mg amp, and 8 vancomycin vials were used for patients to prevent nosocomial infection.The chief complaints of these cases were anemia, blood transfusion, bone marrow aspiration, poor feeding, etc…..

Nosocomial AB prophylaxis should be used more cautiously with regarding culture and sensitivity tests.The cost of this use was about 821$

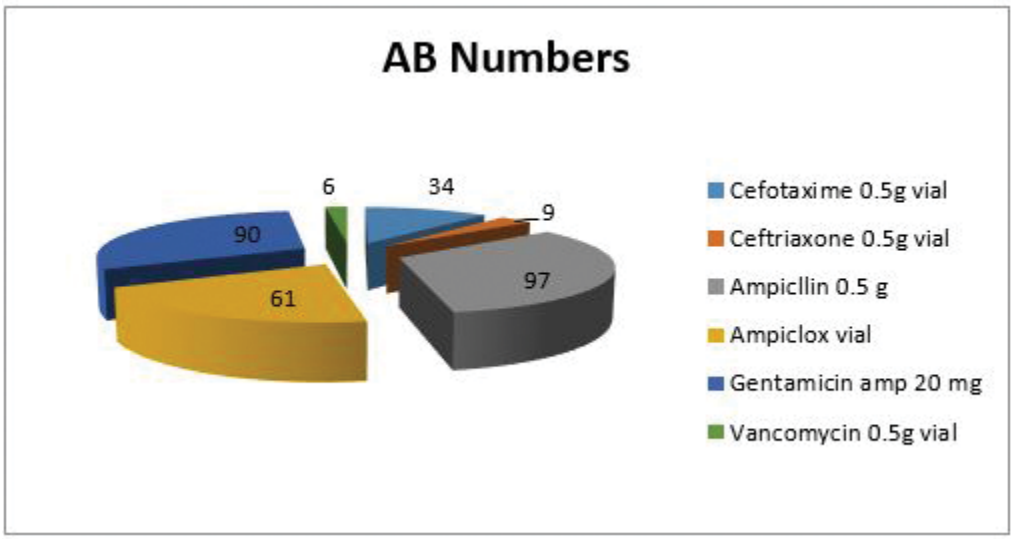

Figure 4: The use of AB in the pediatric ward for neonatal jaundice and post neonatal jaundice

Thirty -six cases in the pediatric ward were complaining from neonatal jaundice and post neonatal jaundice and received AB. Figure 4 reveals the total no. of AB used for these cases, As we can see from this figure, for only 36 cases, 97 ampicillin vials, 34 cefotaxime vials, 9 ceftriaxone vials (contra-indicated in neonatal jaundice[6] and this agreed with the British National formulary BNF), 61 ampiclox vials, 90 gentamicin 20 mg amp and 6 vancomycin 0.5g vials were used for this group of patients. While no specific indications were found for these cases and no support from the references for this use. Most of these cases not need AB therapy just phototherapy and we recommend that the patients who need AB should be selected. The cost was about 169$.

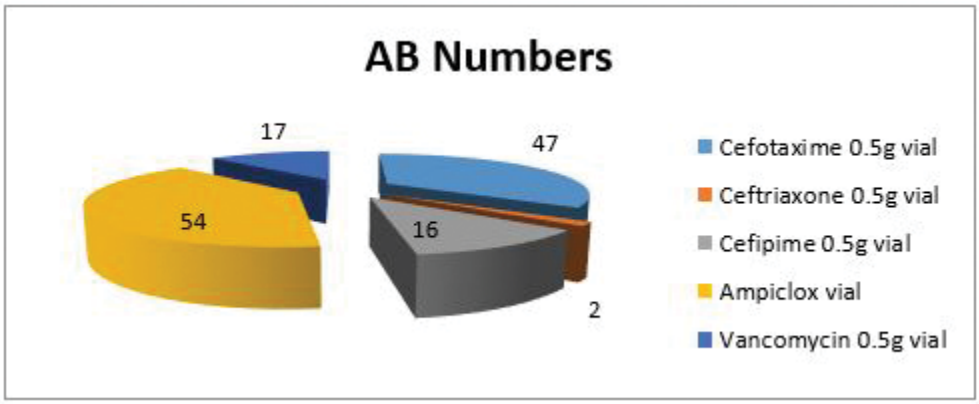

Figure 5: The use of AB for patients with febrile convulsion

Fourteen cases of febrile convulsions were treated with AB in the pediatric ward for the underlying cause. Figure -5 show reveals the total no. AB used for this group.As we can see from this figure, cefotaxime and ampiclox vials are the most commonly used also vancomycin vial found a place in these groups. Most of febrile illnesses caused by viral infections [6] (this agreed with reference 7,14) and the cost of this use is about 148$.

16 cases were treated with AB for croup(acute viral infection of the upper airway [1]).

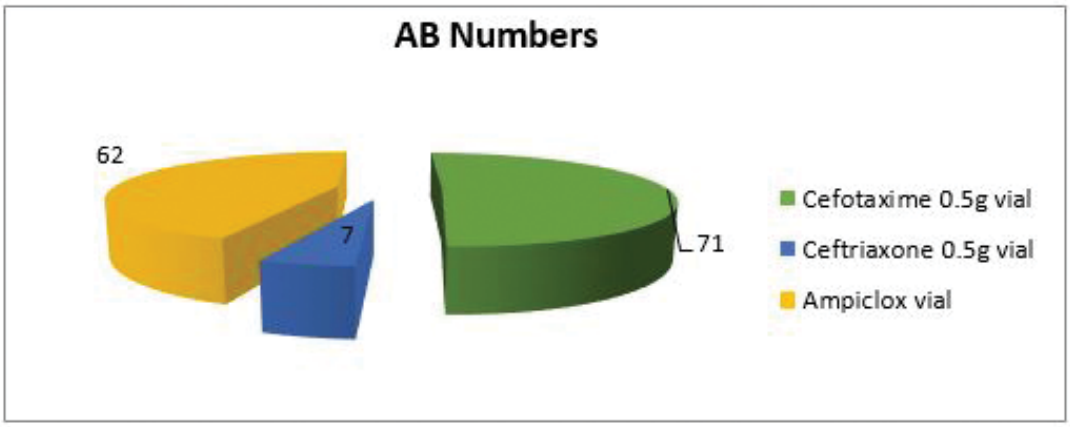

Figure 6: The use of AB for patients with croup in the pediatric ward

Figure 6 reveals the total no. AB used for these cases.As we can see from the figure below, for 16 cases with croup, 71 cefotaxime 0.5g vials, and 62 ceftriaxone 0.5g vial were used for these cases which most of them do not need AB treatment. The total cost for this use is about 45$.

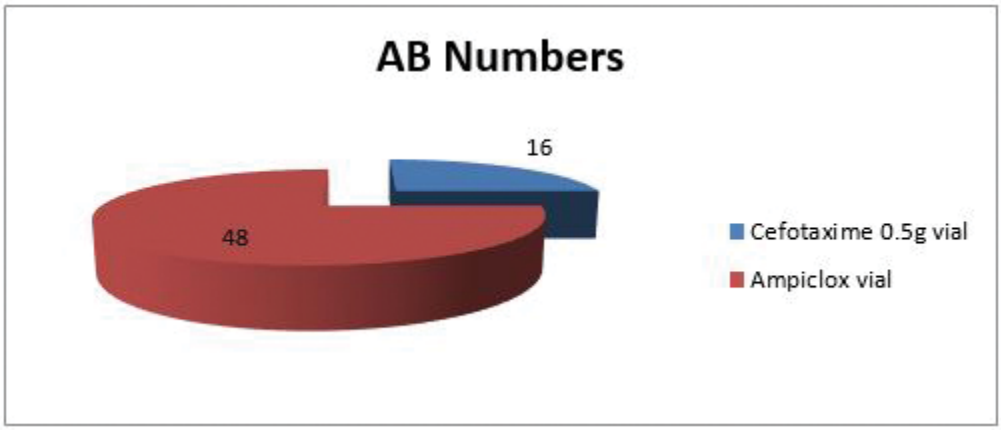

Figure 7: The use of AB for patients with kerosene poisoning

Five cases of kerosene poisoning in the pediatric group were treated with AB from the 1st day of admission. Figure 7 reveals the total no. AB used for these cases.AB in kerosene poisoning should not be used only if secondary bacterial infection occurs (this agreed with Karen etal.,2007)[6] The cost of this use is about 33$.

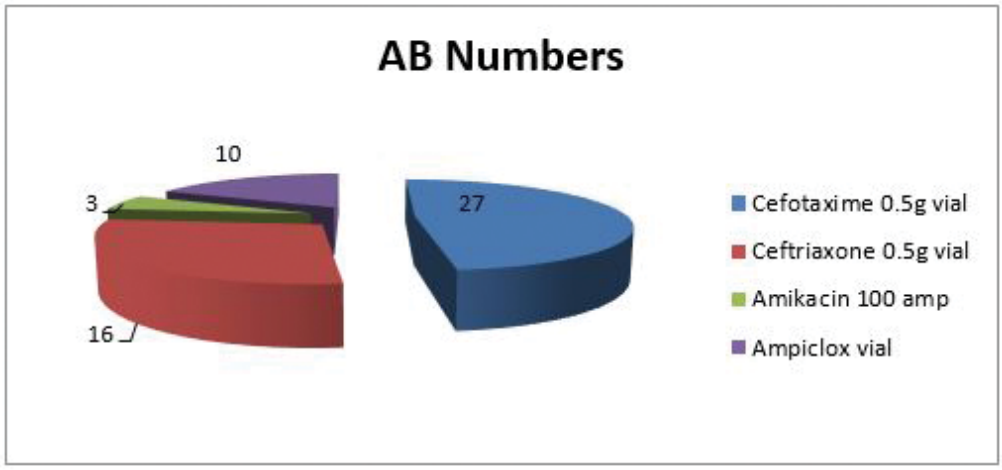

Figure 8: The use of AB in the pediatric for UTI

Nine cases were treated with AB for UTI in the pediatric ward. Figure 8 reveals the total no. AB used for this group. The total cost for this use is about 40$

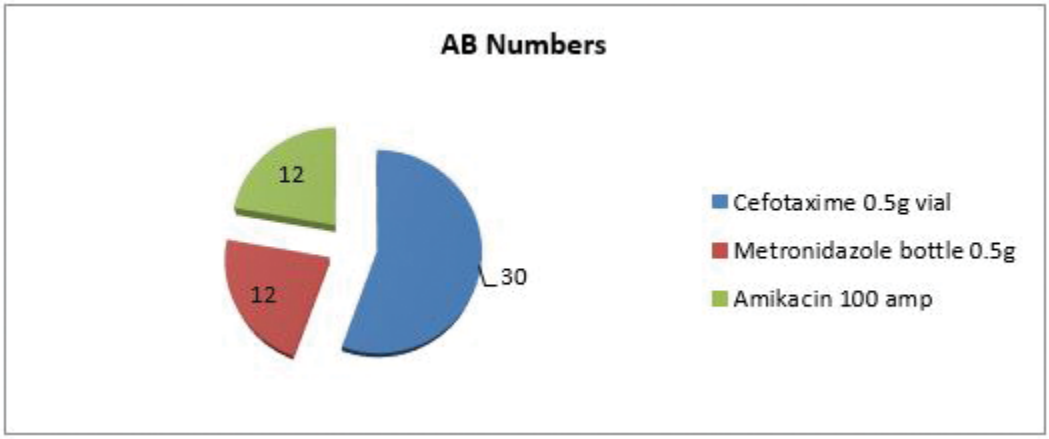

Figure 9: The use of AB for patients with septicemia in the pediatric ward

Two cases of septicemia were treated with AB. Also without test of culture and sensitivity. Total cost 42$

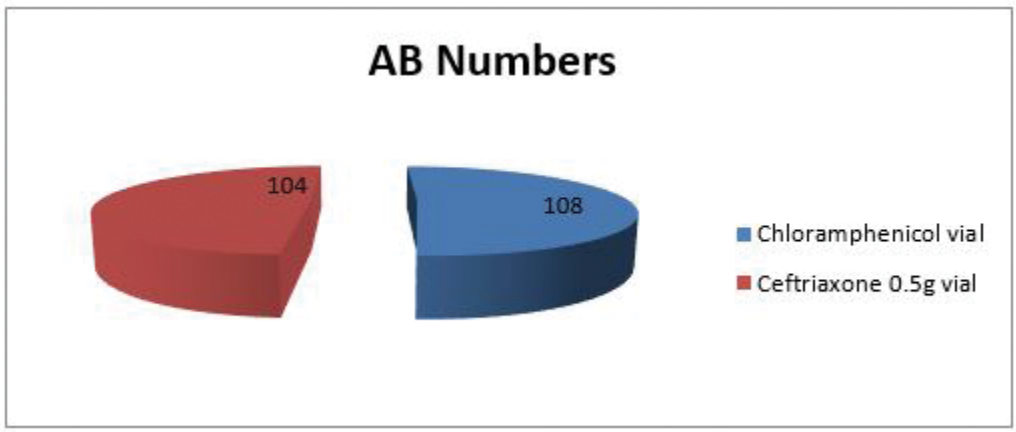

Figure 10: Chart about the use of AB for meningitis in the pediatric ward

Four cases were treated with AB for meningitis in the pediatric ward. Figure 10, reveals the total no. AB used for this group. The cost of this use is about 195$.

As we can see from this chart, 104 ceftriaxone 0.5 g vials with 108 chloramphenicl (1 g) vials were used for 4 patients and the duration were not less than 10 days. This reveals also how bad is the quality of these AB used in the hospital, while the use of top quality AB will decrease the cost, risk on the patient and risks of AB resistant (10,15,16).

Conclusions

1. The antibacterial agents are used in the wards of the hospital roughly, without differential tests and without any respect to the guidelines of judicious AB use to decrease the resistant.
2. Cephalosporins are the most commonly used AB in all the five wards of STH and namely the 3rd generation cefotaxime and ceftriaxone.
3. The total cost of using AB in STH for only one month is about 23929 $, 6194$ in pediatrics.
4. The enormous amounts of AB used in STH can easily lead to serious problems of resistant infections
5. Huge amounts of AB dispensed for chest infections and GE (usually are viral in nature), also many patients with jaundice, and CRF received AB may be contraindicated to their cases.

Acknowledgments

We would like to express our great appreciation to Salah aldin Teaching Hospital, for help me in collecting the cases of this search.

Education Conducted By Pharmacist in Improving Hyperlipidemic Patient Adhearance

Vidia Arlaini Anwar[1], Delina Hasan[2], Sesilia Andriani Keban[3], Yardi Saibi[2]

[1]Stikes Kharisma Persada Pamulang; [2]Pharmacy Study Program at UIN Syarif Hidayatullah, Jakarta; [3]Faculty of Pharmacy, Pancasila Univeristy

ABSTRACT

The adhearance is one of the keys for successfulness of drug therapy. Low adherence is often found in long time drug use, one of them is hyperlipidemic patients. This study aimed to investigate the effect of pharmacist education intervention on patient compliance and their lipid plasma level. The research design was quasi-experimental nonequivalent group control and perspective. The study was conducted on hyperlipidemic at Port of Jakarta hospital. The number of samples was determined by using Krejcie and Morgan tables which yielded 44 respondents/patients. Compliance is measured by an MMAS questionnaire. The control and intervention groups were given leaflet containing drug information and gave the patient the opportunity to ask questions. The results showed that there was no significant difference in patient characteristics in terms of gender, age, education and dependent ($p < 0.05$) except on the distance characteristics ($p > 0.05$). Patient compliance increase in the intervention group differs significantly from the control group in the second and third periods of measurement ($p < 0.05$) while the compliance improvement in the control group occurred in the third period of measurement ($p < 0.05$). The plasma cholesterol level decreases significantly differences between intervention from the control group at the third measurement ($p<0,05$). It can be concluded that pharmacists' education either in the form of leaflets with verbal explanations or in leaflet alone can improve patient compliance with their medications where the improvement is faster achieved by pharmacist intervention in the form of a leaflet with a verbal explanation. Pharmacist education is also able to decrease patient plasma cholesterol level.

Keywords: *compliance, pharmacist education, hyperlipidemic*

Introduction

Based on basic health research data 2013 showed 35.9% of Indonesia's population aged ≥ 15 years with abnormal cholesterol levels (based on NCEP ATP III, with cholesterol levels ≥ 200 mg/dl), where women were more than men, and cities were more a lot compared to the countryside. Some provinces in Indonesia such as Nangroe Aceh, West Sumatra, Bangka Belitung, and Riau Islands have a prevalence of hyperlipidemia ≥ 50% [1]. Data from the Double Study of the Faculty of Medicine, University of Indonesia (2009) showed that the results of the measurement of lipid profiles in 490 study respondents obtained 290 people (59.2%) among them in a state of hyperlipidemia[2].

World Health Organization (WHO) 2013 reported that the highest prevalence of total blood cholesterol in Europe (54% for both sexes), followed by America (48% for both sexes). Africa and Southeast Asia have a low percentage of 22.6% and 29.0% respectively. High cholesterol is estimated to cause 2.6 million deaths (4.5%) and 29.7 million disabilities each year [3]. Hyperlipidemic patients include patients who need long-term therapy, which usually correlates with low levels of adherence to drug use as reported in several publications[4]. One study found that after nine months of statin therapy, only 56% of patients continued to take treatment and this percentage continued to decline after the first year[5]. The level of adherence of patients who use lipid-lowering drugs on average is 50%, with about 2/3 of patients remaining obedient on the first year of treatment[6].

These patients need special attention by pharmacists in accordance with pharmaceutical service standards. The provision of education or drug information services is the obligation of pharmaceutical staff regulated in the decision of the health minister of the Republic of Indonesia number 72MENKES/SK/X/2016.

Compliance is one of the keys to success in achieving an optimal therapeutic outcome. It is hoped that education and counseling by pharmacists can improve patient compliance[8–9].

Method

The method used in this study is a quasi-experimental non-equivalent control on hyperlipidemic patients who were outpatient at Jakarta Port Hospital on the period of August - October 2017. Sample were all populations that met the inclusion criteria: Patients who came to the pharmacy installation during August - October 2017; diagnosed with hyperlipidemia in their medical records and received treatment with antihyperlipidemic drugs, patients with complete and clearly legible medical records.

The technique of getting samples is by consecutive sampling. The number of samples was determined by Krejcie and Morgan[11]. Samples were divided into 2 groups of 44 people each; the first group was the control group, while the second group was the intervention group. To enter the sample into the control or intervention group was determined by multiples of 5, ie the first 5 patients were included in the control group while the next 5 patients were included in the intervention group, and so on until the number of the two sample groups was sufficient. The research instrument is a compliance questionnaire refers to the MMAS [12] method.

Result and Discusion

A. Sosio-Demographic Respondent Characteristics:

The socio-demographic characteristics of the respondents in the control group and the intervention group included gender, age, education, the distance of house (residence) and dependents (costs) as shown in table 1. It can be seen that based on sex category, the majority of respondents in the control group and the intervention group were female respondents, that is as many as 25 (56.81%) for the control group and 30 (68.18%) for the intervention group. The results of the statistical test showed that there were differences in the distribution of the sex group of the control group and the intervention but the difference was not significant ($p = 0.271 > 0.05$). Basal metabolic rates for men are 10 percent higher than women. Therefore, women tend to convert food into fat more, whereas men tend to convert food into muscle and reserve energy ready to use. Muscles burn more fat than other cells. Because women have fewer muscles, women have a smaller chance to burn fat.[13]

Based on the age category, most respondents in the control group and intervention group were 35 (79.55%) for the control group and 29 (65.91%) for the intervention group. The results of the statistical test showed that there were differences in the distribution of the control group and intervention age categories but these differences were not significant ($p = 0.151 > 0.05$). The number of hyperlipidemic patients at >55 years is far greater than the age group below. The risk of hyperlipidemia increases with age. The weakness of the body is known to increase with age and predominantly accumulates in the area around the abdomen. LDL levels decrease with age and conversely LDL levels increase[14].

Based on the education category, the majority of respondents in the control group and intervention group were respondents with high school education, which were 25 (56.82%) for the control group and 24 (54.55%) for the intervention group. The statistical test results showed that there was a difference in the distribution of the control group and intervention education categories but the difference was not significant ($p = 0.612 > 0.05$). The higher the level of education of a person, the higher his awareness of efforts to maintain his health. This may be the cause of the highest number of patients at the high school level.

Based on the category of distance house (residence) with the hospital, the majority of respondents in the control group were long distance as much as 8 (18.18%) and the most intervention group was close distance as many as 36 (81.82%).

b.	Cash	4	9,09	5	11,36	
	Total	44	100,00	44	100,00	

The results of the statistical test showed that there were differences in the distribution of dependents in the control group and intervention respondents, but these differences were not significant (p = 0.725> 0.05).

B. Description of Respondent's Compliance

Table 2: Percentage of patients based on the level of compliance per period between two

No.	Level of compliance	Period 1		p	Period 2		p	Period 3		p
		Control	Intervention		Control	Intervention		Control	Intervention	
1.	Low	90,91	81,82	0.188	84,09	63,64	0,023	52,27	0,00	0,000
2.	Medium	9,09	11,36		15,91	29,55		47,73	34,09	
3.	High	0,00	6,82		0,00	6,82		0,00	65,91	

The question of the respondent's compliance as many as eight questions. Table 2 shows the level of compliance of the respondents of the two groups for each period. The highest level of compliance of the respondents in the two groups was respondents with a low level of adherence of 90.91% for the control group and 81.82% for the intervention group. The percentage of high adherence level categories is 0% for the control group and 6.82% for the intervention group. Differences in compliance between two groups of respondents were statistically

tested with the Mann Whitney test and the results as shown in table 2. It can be seen that in the first period there were no significant differences in adherence between the two groups of respondents indicated by the significance value of 0.188 (p value> 0, 05). In the second and third periods of measurement, statistical analysis showed that there were significant differences in adherence between the two groups as indicated by a significance value smaller than 0.05. This means that in the second and third period, verbal education conducted by pharmacists has been able to have an effect on respondents' compliance in using drugs prescribed by doctors.

Low compliance is a problem in the long-term treatment of patients for chronic non-infectious diseases and for long-term infectious diseases such as tuberculosis and HIV-AIDs. Patients of this group need to get priority for health workers including pharmacists in the form of counseling [15].

The results of this research indicate that pharmacist education affects the compliance of hyperlipidemic patients in taking cholesterol drugs. Interventions carried out by pharmacists in the form of consultations with patients where the pharmacist discusses the management of medication that will be undertaken by the patient including lifestyle changes. Pharmacists also provide patients with some material related to the treatment of patients [21].

The pharmacist's intervention in the form of education carried out at the beginning of the patient came to the pharmacy to redeem their medication, then performed again when the patient came back. At two repeated measurements, there was an increase in compliance in intervention patients [23]

Effects of interventions carried out by pharmacists as outlined previously are summarized in the following table:

Table 3: Percentage of patients based on changes in the level of compliance per period Intervention group

No.	Level of compliance	Intervention (2-1)		p	Intervention (3-2)		p
		Period 1	Period 2		Period 2	Period 3	
1.	low	81,82	63,64	0,003	63,64	0,00	0,000
2.	medium	11,36	29,55		29,55	34,09	
3.	high	6,82	6,82		6,82	65,91	

Table 3 shows changes in adherence and statistical test results to see the differences in the intervention group. Total of patients with high levels of adherence is greatly increased.

The statistical test used is a paired sample t-test. The results of this statistical test are presented in table 5.6. It can be seen in table 5.6 that for the pharmacist education intervention group it has shown the effect of the second period of measurement indicated by p <0.05.

From the statistical test as seen in table 4, the change in adherence in the second period of measurement was not significant which was indicated by a significance value of 0.083 (> 0.05). Changes in adherence in the third period of measurement were seen to be significant in the third period of measurement marked by a p-value <0.05 (0,000). This finding is in line with the report in a literature review which explains that the intervention provided is only in the form of written information that is not very efficient if given to patients who receive treatment for the long term[25].

Table 4 : Percentage of patients based on changes in the period of meeting rates Control group

No.	Level of compliance	Control (2-1)		p	Control (3-2)		p
		Period 1	Period 2		Period 2	Period 3	
1.	Low	90,91	84,09	0,083	84,09	52,27	0,000
2.	Medium	9,09	15,91		15,91	47,73	
3.	High	0,00	0,00		0,00	0,00	

Conclusion

Pharmacist education (leaflet and verbal) can improve patient adherence in using the drug in the first and second months after the intervention, which was indicated by a significant difference between the intervention groups to the control group (p <0.05). Giving leaflets that contain drug information requires a longer time to improve patient compliance with drug

use, which is indicated by a significant difference in the compliance of the control group in the second month of measurement ($p < 0.05$).

Suggestions

Education for hyperlipidemic patients should be continued and even intensified. It is necessary to measure plasma lipid levels in addition to total cholesterol levels with the consequence of increasing research costs.

Grateful Greeting

Thank you to those who have helped this research

The Effect of Exercise Technique Altering with Use Heavyweight Rackets in the Development of Concentration (Sodium, Potassium) in the Blood and Smash Skill for Player's Badminton

Wissam Salah Abdul Hussein[1], Abeer Ali Hussein[1], Ebtighaa Mohammed Qasim[1]

[1]University of Kerbala/The College of Physical Education and Sports Sciences, Iraq

ABSTRACT

The skill of beating is one of the most important offensive skills in the game of badminton, through which the player can decide the point in his favor, and given the diversity of the use of skills at one point and the speed of the large brush requires us as researchers to find the best technique to develop this skill, so researchers used The method of exercise altering dimensions and trends and different altitudes in addition to the use of different weights and weights of some of them are heavy and some of them are lighter, and researchers try to know this method on the concentration of functional alterings in blood and whether there was a burden and effort on the muscle.

The aim of the research was to prepare a special exercise in the style of the altering exercise and using burdens loaded with badminton. To study the effect of the altering exercise method using the weight-laden binders in the concentration of sodium (potassium) in the blood and to develop the skill of smash of the player's badminton. The search for the altering exercise method in the overloaded bats has a positive effect on the concentration of sodium (potassium) badminton. The researchers used the experimental approach to design a single group with pre and post testing in order to suit the nature of the problem and achieve the research objectives. The sample of the research represented the entire research community and they are players of the province of Babylon for the season 2018 - 2019 and the number of (4) players, which means researchers used the method of comprehensive inventory of all members of the community.

The most important conclusion was that the altering exercise technique helped to develop the crushing skill of the feather. There was a marked improvement in the concentration of salts of blood (sodium and potassium), but within the natural information in the upper direction due to the use of exercise loads in the experimental group. The most important recommendations are the need to pay attention to the training altering during the educational units because it is best to deal with the skills of badminton, which falls within the open circuit system. And the need to use different and varied exercise technique commensurate with the skills required to perform.

Keywords: *exercise technique altering, sodium, potassium and blood.*

Introduction

The expansion of the technique of learning motor skills invites researchers to carefully choose the appropriate method for the conditions of the learning environment, such as the type of effectiveness, age, level of scientific and educational sample, and their physical and skill preparation, and that developing the abilities of the players depends heavily on how they interact with and respond to the educational method followed. The need to know the teacher and the trainer for more than one of the technique of exercise because otherwise it remains in the ability to deal with players is very limited so the use of more than a method of learning gives the opportunity for the coach and player to upgrade the educational process.[1]

We have been able to develop our concepts of the training process as a competitive trend in the field of sports and to take strides towards the construction of

valuable scientific concepts to impose Scientific Interest.[1] Since badminton is an individual game practiced by both sexes and most of its skills fall under the open circuit system, during which the development of the skill level of the learner.[2]

The skill of smash is one of the most important offensive skills in the game of badminton, through which the player can decide the point in his favor, and given the diversity of the use of skills at one point and the speed of the large brush requires us as researchers to find the best technique to develop this skill, so researchers used The method of the altering exercise dimensions and trends and heights of various and different in addition to the use of different weights and weights of some of them are heavy and some of them are lighter, and researchers try to know the effect of this method on the concentration of functional altering in blood and was there burden and effort on the muscle.[3]

Therefore, the importance of research is to benefit from the technique of altering exercise using different weights and their effect on the concentration of salts (sodium - potassium) in the blood and skill smash for the players badminton.

Research Aims:

1. Prepare exercises in a modified exercise method and using burdock burdens.
2. To identify the effect of the method of the altering exercise using burdens in the concentration (sodium - potassium) in the blood and develop the skill of smash of the players badminton.

Hypothesis:

1. The method of exercise altering with use heavyweight rackets concentration (sodium, potassium) in the blood and develop the skill of smash of the players badminton.

Research Methodology and Field Procedures

Research Methodology: The researchers used the experimental approach to design a single group with pre and post testing in order to suit the nature of the problem and achieve the research objectives.

Search Community and Sample: The sample of the research represented the entire research community and they are players of the province of Babylon for the season 2018 - 2019 and the number of (4) players, which means researchers used the method of comprehensive inventory of all members of the community.

Means, Tools and Devices Used:

- A terrace at the height of 1 m (2) homemade
- Badminton court number (2) - Number of (10) homemade
- Electronic Stopwatch (2) Chinese Made
- Badminton Rackets No. (14) type (Yonex)
- Badminton balls (40) Plastic and natural feathers (Yonex)
- String Number (15) Type (impact) - Jumping ropes Number (10) Type (Yonex)
- Plastic columns at heights (cm -170 - 180 cm - 2 m) Number (2) for each measurement
- Homemade cords with length (10 m) - Loaded rackets - Complete laboratory tools for the purpose of drawing blood from the sample - Loaded rackets

Tests used and their descriptions:

Test the crushing skill of the front crushing: [4]

Purpose of the test: measure the accuracy of the crushing skill of the front crushing

Required tools: feather benders, natural feathers, additional lists (213cm) height, rubber rope, data registration form, feather court designed with test design. As in Figure (1).

Performance Description: The player stands in the designated place (X) and sends the badminton sent to him from an interview area ( ) With a strong crushing blow trying to drop it in the top-level area provided that the feather passes over the net and from under the rope behind the grid at a distance of 60 cm and the height of (213cm) and the player performs (10) attempts with the observation of the force of the strike.

Performance Evaluation:

1. The degree is given according to the place of fall of the feather.
2. If the feathers do not cross over the net and under the rope or fall outside the designated areas, they shall be given zero.

3. Feather that lies on the line between the two regions given the highest degree
4. Degrees Divided by Regions (1-2-3-4-5).
5. The final grade is the total of the degrees of attempts (10) which is (50) degree.

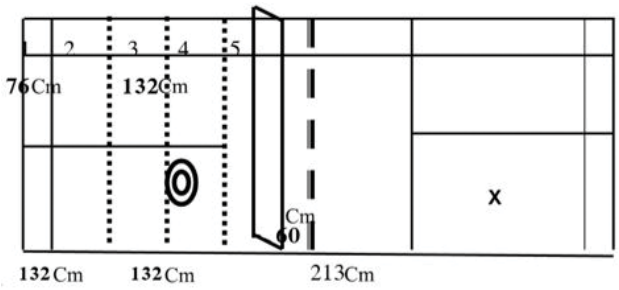

Figure 1: Shows the layout of the badminton court to test the overwhelming frontal impact

Test of sodium and potassium: It was agreed with a scientific laboratory licensed health to take a sample of blood for the players of the province for the purpose of conducting the necessary analysis to know the ratios of sodium and potassium.

Pre Tests: The researchers conducted the pretests on 1/2/2019 in the closed hall in the district of Mahaweel - Governor of Babel, and blood samples were taken for the players and the test of the overwhelming beating of the feather.

Special exercises used in research: Through the experience of field researchers in the field of badminton and relying on Arab and foreign sources, I performed various exercises (Appendix 1). These exercises were organized to suit the members of the sample and the level of training. Based on the principle of changing the parameters of one skill, and height and distances using a racket different from the weight of the real racket, and took part of the main section and the rate of (20) minutes and two units per week. The course was divided into (9) training units.

Posttests: The researchers carried out the post tests on 1/3/2019 in the closed hall in the district of Mahaweel, the province of Babel. Blood samples were taken for the players and the test was carried out by the crushing blow. Under the same circumstances as the pretest.

Results

Presenting the results of the pre and post-test tests of the sodium and potassium test group and the crushing batting skill.

Table 1: Show calculate the values of the mean, the standard deviation, and the calculated Wilcoxon values for the tests pre and post and experimental group

Skill	Units	Pretest		Posttest		Wilcoxon values	Level of significance	Type of significance
		Mean	SD	Mean	SD			
Sodium test	Mall	140	2.3	149	3.11	2.21	0.02	Sig.
Potassium test	Mall	4.5	0.41	5	2.70	2.22	0.03	Sig.
Front smash	Grade	21	3.11	29.4	4.99	2.21	0.01	Sig.

Sample size = 4 below the level of significance (0.05).

Table (1) shows that there are statistically significant differences, since the values of the significance level were less than the value of the significance level (0.05). This indicates that there are differences and for the benefit of the post-test. This is due to the exercise method used by the researchers.

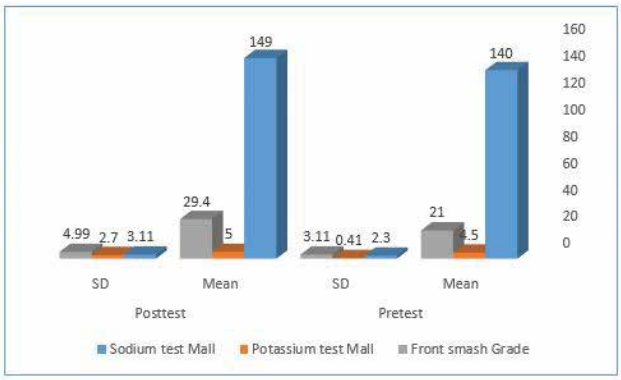

Figure 2: Show the differences between the computational circles and the post deviations of the pre and post tests

Discussions

The researchers attribute the difference between the pre-test and the post-test of the experimental group to the exercises used in the training modules and the use of training technique in accordance with the learned skill type. The use of the exercises prepared for the skills studied and applied in the altering exercise method. The explanation, presentation, guidance, instructions and feedback were The great effect on the development of the experimental group in the post-test, where the correct organization of the exercises used, which took all the skill forms and different parameters and different (power-speed-distance-time) Experimental group members have developed a variety of mobility programs for one skill, increasing the chances of success of the skill when performing on the field. The teacher or trainer is designed for the learning environment, which creates educational systems, achieves the goals of the educational unit and prepares educational situations.[5]

Wrisberg (2000) points out that the use of motor forms for one skill develops the generalized motor program and improves the player's performance despite different measures for the program itself. The development of the locomotor program is enhanced when the player exercises wide variations of movements and the same class of movement.[6]

The increase in the sodium and potassium altering due to their direct association with the increase of muscular and nervous activity due to physical exertion (effort of the game), and the increase in the concentration of mineral salts (sodium, potassium) due to the impact of physical exertion, which was characterized by the extreme intensity that the player during the game and work Functional devices lead to the balance of mineral salts in the body so this is an increase within normal limits. [7] "The permeability of metal ions leads to an imbalance in the distribution of mineral salts on both sides of the fibroblast membrane causing muscle contractions ". [8]

Conclusions

1. The technique of the altering exercise helped to develop the skill of beating overwhelming feather.
2. The use of heavy speculators helped increase the accuracy and strength for the overwhelming blow to the plane
3. There is a marked improvement in the concentration of salts of the blood (sodium and potassium), but within the natural information in the upper direction as a result of the use of heavy weights in the exercise of the experimental group.

Evaluate the Level of Application of Sports Marketing Practices for the First Iraqi Football Clubs

Yaseen Ali Khalaf[1], Ibrahim Younis Waga[1]

[1]University of Anbar, College of Physical Education and Sport Science, Iraq

ABSTRACT

The present paper aims to identify the role of sports marketing in developing the performance of the administrative corporations of the Iraqi football Premier League clubs. A survey descriptive method has been used due to its relevance to the research problem and aims. The sample is composed of members of the administrative corporations of the Iraqi football Premier League clubs for the 2017 - 2018 season. The total sample consisted of (101) members elicited from 19 sports clubs; it was selected in a deliberate manner, as it is representative for the whole sample according to three variables (job status, academic qualification, and years of experience in administrative work). It was found that the measure of sports marketing was accepted and expressed in terms of sports marketing practices from the point of view of employees in the football Premier League clubs, and that all staff members have a positive attitude towards sports marketing. It was recommended that it is needful to benefit from the scale of sports marketing and apply it to different samples and raise the grants offered to sports clubs to carry out their various activities and achieve their marketing objectives and to conduct studies and research in the field of marketing sports in Iraq and its novelty and modernity of this field in Iraqi sports sector.

Keywords: *Evaluation, sports marketing and practices.*

Introduction

Sports marketing has been considered as one of the main areas on which sports institutions in the world rely. Hence, it is considered as the most successful option able to ensure the sustainability of the economic recovery that can cover sports activities as well as the financial profit that contributing to the growth and development of these institutions in line with the goal. Therefore, this field has witnessed a gradual development and became more widespread and diversified in the present time as it included various methods, such as marketing of advertising rights, television marketing and marketing of tournaments and players and as well as the provision of internal and external services to the consumer represented by the public. This area has become an administrative and economic system that has imposed itself through positive financial returns. Therefore, 'marketing is an art of successful management process, which affects the society in general and the sports community in particular'.[1]

The significance of the research stems from its role in highlighting the reality of the process of marketing sports from the point of view of the members of the governing corporations of the Iraqi football Premier League clubs via evaluating the application of sports marketing practices to reflect the reality in the field of marketing and the need to develop and identify the imbalances to increase the administrative awareness within the sports institutions to ensure the development of sources of financial financing facilities for the marketing process. There is lack of sports marketing plans within the sports institutions due to the difficulties and financial crises that affect sports marketing plans within the sports institutions. They prevent most of the Premier League clubs in Iraqi football from implementing their programs and activities planned in the required form. Due to the lack of significant financial resources in this area because sports marketing is still new in Iraq, such institutions do not depend on sports marketing to improve their resources and annual financial plans and do not move consistently. In addition, sports clubs rely directly on government grants offered by the Ministry of Youth and Sports and the Iraqi Olympic Committee to cover the annual activities, which call to the level of ambition, in addition to some donations from businessmen.

Research Aims: To know the role of sports marketing and its importance in developing the performance of the governing bodies of the Premier League football clubs in Iraq.

Research Methodology and Fieldwork Procedures

Research methodology: The researchers used descriptive method of survey to suit the nature of the problem and achieve the research objective.

Sample and its design: The sample included 101 members of the administrative corporations from 19 Premier League football clubs for the 2017-2018 season, which was divided into and the sample was selected by the deliberate search as in Table (1) as they represent all categories of the sample according to the variable (job status, qualification, years of experience in administrative work).

Measuring Tool: In order to identify the status of sports marketing in the Iraqi football Premier League for the (2017 - 2018) season, the researchers used the Sports Marketing Scale (Yaseen Ali Khalaf 2018) applied to the Iraqi environment consisting of seven areas and 62 statements. The correcting process of this scale is based on the five-way Likert method of alternatives (fully agree, agree, neutral, disagree, do not agree).[2]

Applying the Scale: The scale was applied to the research sample composed of 101 participants of the administrative corporations; the scale was distributed for the period from 1/7/2018 to 2/8/2018. After completing the implementation steps, the researchers collected the data and arranged it in tables pending statistical processes to complete the research aim.

Data Analysis and Discussion

The researchers relied on the percentages shown in table (2) to interpret the results of participants' responses.

Table 2: Percentages and levels of the scale fields

S. No.	Category	Level
1.	80 % and above	Very high
2.	70% - 79%	High
3.	60% - 69%	Medium
4.	50% - 59%	Low
5.	Below 50%	Very low

Participants' responses for all fields of the scale by functional variable:

Table 3: Show the mean, standard deviations and percentages of the scale Variabless by function variable

Total	251.7	15.92	81.20	241.2	22.32	77.79	240.4	26.06	77.54	248.3	25.44	80.08
Level	Very high			High			High			Very high		

Participants' responses to all areas of the scale by function variable: The results of the tables (3) show that the total score of the responses of the sample members for all the fields of the scale according to the variable of the functional status were close despite the differences in their positions. The variable (head) was in the lead with (81.20%) categorised as very high. The variable (member) came in the second position with a percentage of (80.08%) and a very high rating. The variable (vice president) occupied the third position with (77.79%) and a high rate. Finally, the variable (secretary) came in the last position by percentage (77.54%) with a high rating.

These results indicate that all participants of the application sample in the functional variable had a positive attitude and full awareness towards sports marketing and its importance, because of the material and moral support that help in developing the sports movement of the Premier League football clubs in Iraq. They go in line with Mohamed Sherif's (2004) study, which has been one of the most important findings of the study, in that the concept and importance of sports marketing for the council members of the boards of sports clubs was a positive concept, as they all understand this concept and important role in the development of sports.[3]

Huda Hassan Al-Khaja's (2000) study showed that the weakness of the level of sports marketing can be ascribed to the fact that the sponsor companies do not provide adequate financial support for sports clubs as well as fear of most businessmen to invest in sports.[4]

Participants' responses on all fields of the scale according to the variable of the scientific qualification

Table 4: Show the mean, standard deviations and percentages of the scale fields by scientific qualification

Variables	Diploma and below			Bachelor			Master and Phd		
	Mean	SD	Percentage	Mean	SD	Percentage	Mean	SD	Percentage
Laws and Regulations (Legal Dimension	39.56	2.35	79.13	39.25	2.3	78.50	43.55	5.32	87.09
Administrative dimension	33.37	3.65	74.14	33.45	2.31	74.33	33.37	3.37	74.14
The economic dimension of sports marketing	30.32	1.23	75.80	31.25	1.25	78.11	32.65	2.310	81.62

Conted…

The technical dimension of sports marketing	40.26	4.32	89.47	37.36	5.34	83.01	37.36	2.021	83.01
Technical (technological) dimension of sports marketing	29.33	2.35	83.78	26.58	2.35	75.92	28.35	1.004	81.01
The Social) dimension of sports marketing	39.35	3.21	87.45	36.25	3.001	80.54	33.24	3.47	73.85
The media dimension of sports marketing	41.12	2.31	82.24	41.12	4.31	82.24	42.21	5.321	84.42
Total	253.32	19.43	81.71	245.25	20.88	79.11	250.72	22.812	80.87
Level	Very high			High			Very high		

Participants' responses on all fields of the scale according to scientific qualification: The results in table (4) show that the total score of the responses of the sample members on all fields of the scale according to scientific qualification were close despite differences in scientific qualifications. This may be due to the laws of elections in federations and clubs, which require the availability of scientific qualifications for members of the Union and the club regardless of the positions they will occupy. The (High diploma) variable occupied the first position (81.71%) and at a very high level of education, followed by a (MS + PhD) variable with a (80.17%) percentage and at a very high rate. The (Bachelor) variable came in the last position with a percentage of (79.11%) and a high level of appreciation.

These results indicate that the strategies towards marketing sports of all members of the application sample in are not influenced by their scientific qualifications. This can be attributed to the fact that they were interested in developing the sports movement in Iraq by activating the sports marketing practices within sports clubs. Deficiency in facilities, such as sports halls prevented these clubs from achieving positive financial returns, which are considered one of the most important aspects of investment in sports institutions. Hassan Ahmed Al Shafei (2006), who claimed that one of the main axes of investment in sports institutions is the infrastructure and the need to have the necessary facilities and tools and devices to promote sports investment in sports institutions, confirmed this. This encourage sports investment in sports institutions.[5]

Samir Abdelhamid (1999) emphasized that the importance of using the concept of marketing in sports institutions is the high contribution rates of businessmen and the increase of financial support plays a significant role in achieving the objectives of the administrative body of the union and the club.[6]

Participants' responses according to variable years of experience in administrative work

Table 5: Show the mean, standard deviations and percentage percentages of the scale fields according to variable years of experience in administrative work

Variables	(1-5) years			(6-10) years			(11-15) years			16 years and above		
	Mean	SD	Percentage	Mean	SD	Percentage	Mean	SD	Percentage	Mean	SD	Percentage

Total	243.91	23.194	78.68	256.7	25.195	82.80	250.1	24.576	80.67	248.87	17.96	80.28
Level	High			Very high			Very high			Very high		

Participants' responses on all fields of the scale according to variable years of experience in administrative work: The results in table (5) show the total score of the responses of the sample members on all the fields of the scale according to the variance of the years of experience in the administrative work. The (1-5 years) variable showed 78.68%, the (6-10 years) variable had 80.87%, and the (16 years and over) variable had a percentage of 80.28%. After comparing these percentages against the percentages adopted by the researchers in order to interpret the results Responses of the sample to the scale As in Table (2) above, it was found that a variable (6-10) years obtained first place at a very high level of estimation, followed by a second variable (11-15 years) at a very high level, followed by the third rank variable (16 years and over) at a very high level, while ranked fourth and last variable (1-5) years at a high level.

These results indicate that the experience in administrative work was not significantly affected by sports marketing practices for the employees of the Premier League football clubs in Iraq. However, the orientations of the experts who occupied the three highest positions were fairly close to each other and relatively less difference from the results of the fourth and final variables (1-5) years. The researchers attribute these results to the fact that the experienced centers of the three advanced centers are able to develop solutions, proposals and future perspectives on sports marketing as a result of their success and failure experience gained through participation in local and international sports competitions, and watching the sports marketing practices in those countries, especially the developed countries in this field. This means that all employees of sports clubs of different years of experience in the administrative work emphasize the need to exploit sports marketing by their various institutions to promote the sports movement in Iraq and keep pace with the development in developed countries. This is consistent with one of the most important findings of Jamal Mustafa Zuhairi's (2010) study that "The marketing process must be carried out in accordance with plans developed in advance by persons with high levels of experience to suit the developments and developments and the global situation in the field of sports marketing.[7]

Conclusions

1. The scale of sports marketing has been accepted and reflected sports marketing in terms of sports marketing practices from the viewpoint of the employees of the Premier League football clubs in Iraq.
2. All employees of the Iraqi football Premier League clubs have a positive attitude towards

sports marketing, but the grants allocated by the Ministry of Youth and Sports and the Iraqi National Olympic Committee do not cover their needs and affect the implementation of planned activities.

3. The 'Years of experience in administrative work' variable (1-5 years, 6-10 years, 11-15 years, 16 years and over) had the highest high results for all fields of the scale.
4. The 'scientific qualification' variable (diploma and less, bachelor's, master's degree, and doctorate) has achieved very high results for all fields of the scale and less than variable years of experience in administrative work.
5. The 'functional' variable (head, vice president, secretary, member) has good results for all fields of the scale and less than the variable of scientific qualification and years of experience in administrative work.

Knowledge, Attitudes, and Behavior of Pregnant Women in Preventing of Pregnacy Complication and Childbirth: Application Study of Yudhia Model

Yudhia Fratidhina[1], Nina Herlina[2], Desri Suryani[3], Yandrizal[4]

[1]Departement of Midwife Politeknik Kesehatan Kementerian Kesehatan Jakarta III; [2]Department of Midwife Gunadarma University; [3]Politeknik Kesehatan Kementerian Kesehatan Bengkulu; [4]School of Health Sciences Tri Mandiri Sakti Bengkulu

ABSTRACT

The high of maternal mortality rate (AKI) largely caused by a lack of knowledge and bad behavior of pregnant women on high risk pregnancy treatment.This condition had impact the high maternal mortality while childbirth.

The purpose of this study was to apply model participatory asset community development research in action for pregnant women through mentoring on prevention of pregnancy complication and childbirth. The study was done by using approach quasi experiment approach with the pre-post test design was 83 respondents. The application of this model at community done by YUDHA model.

The result showed that knowledge score before applying model was 41.20 after applying 70,55, the attitude score before applying was 20.62 after applying model was 40.56, while the behavior score before applying model was 30.50 and after applying was 70.48. YUDHIA model statistically could improve knowledge (p= 0.000), attitude (p=0.000) and behavior of pregnant women (p=0.000) compared before getting mentoring.

The research conclusions that YUDHIA model could increase knowledge, attitudes and behavior of pregnant women on prevention of pregnancy complication and childbirth.

Keyword: *pregnant women, pregnancy, chlidbirth*

Introduction

Maternal Mortality Rate (MMR) is one of the important indicators of the level of public health and able to be used in the monitoring of pregnancy-related deaths. This indicator is affected by general health status, education, and services during pregnancy and childbirth[1]. The direct causes of maternal mortality for more than 90% were a result of obstetric complications, mainly of childbirth complications. Pregnancy complications were obstetric emergencies that cause the death of the mother and fetus. Pregnancy complications included hypertension and pre-eclampsia, anemia, placenta previa, and diabetes[2]. While childbirth complication is difficult childbirth (dystocia) that causes a disease. Childbirth complications include premature rupture of membranes, premature childbirth, abnormal fetal position.

Based on the Indonesian Demographic and Health Survey (IDHS) in 2012, MMR in Indonesia was high, at 359 of 100,000 live childbirths. This figure increased compared to MMR in 2007 which was at 228 (MOH RI, 2010). Meanwhile, the 5th global target of the MDGs (Millennium Development Goals) is reducing MMR to 102 in 2015. Based on reports from the Provincial Health Office of Banten, the highest MMR was in Pandeglang. Complications of pregnancy and childbirth in Pandeglang district caused 34 cases of maternal mortality in 2013, 14 cases for bleeding, 8 for hypertension during pregnancy, 4 for infection, and 9 for prolonged childbirths and other cases[3].

One strategic move is improving the knowledge, awareness, and motivation toward improved behavior for the prevention of complications of pregnancy and childbirth. It is able to be conducted through the empowerment and participation of family or community. Empowerment goal is to increase the capacity and capability of society to be able to recognize the encountered problems, explore and exploit the available resources, as well as show their existence clearly[4]. One of the efforts to improve maternal health status and reduce maternal mortality rate (AKI) in Pandeglang district is through improving knowledge, attitude, and behavior of pregnant women in prevention of pregnancy and delivery complication, through application of Participatory Asset Model of Community Development Research In Action (YUDHIA) model which involves the community in solving the problem.

YUDHIA models are expected to address issues related to the incidence of complications of pregnancy and childbirth in the community in the prevention of pregnancy and childbirth complication. This study was conducted in order to identify the aspects of Model Participatory Asset Community Development Research in Action (YUDHIA).

Method

This study was a quasi experimental research with pre- post test design. Place and time of study in District Cimanuk in July-November 2016 (5 months). The population was all pregnant women of trimester II and III in Cimanuk sub-district, Pandeglang Regency, Banten Province. The population of pregnant women was 800 person. The sample was taken using simple random sampling method in pregnant mother of trimester II and III around the work area of Puskesmas (Public Health) in Cimanuk Sub-district, Pandeglang Regency, Banten Province, fulfilling inclusion and exclusion criteria, 83 respondents. Questionnaires are used as a means of collecting data. Before the quesioner is used the reliability test and the validity of the questionnaire are used. Data obtained in the form of knowledge, attitude and behavior of pregnant women. Statistical analysis using chi square.

Result and Discussion

Knowledge of pregnant women: Scores of respondents's knowledge variable about the prevention behavior of pregnancy and childbirth complications were presented in Table 1.

Table 1: Knowledge of Pregnant Women Before and After Assisting YUDHIA Model

Variable	N	Mean	Median	SD	Min-Max	P
Pre	83	41.20	50	7.22	30-60	0.001
Post	83	70.55	60	6.30	54-80	
Value of difference: 29.35						

Source : Primary data, 2016

Knowledge analysis of pregnant women who followed the assistance of YUDHIA Model resulted the average knowledge of pregnant women at first measurement 41.20 with deviation standard 7.22, minimum value 30 and maximum 60. While at second measurement gived the average knowledge of pregnant women was 70.55 with a standard deviation was 6.30, a minimum value was 54 and a maximum was 80. There was an increase of respondents's knowledge score before and after assistancing YUDHIA model was 29.35. Statistical analysis indicated that YUDHIA assistance had a significant effect (p=0.001) on the change of pregnant women's knowledge in the job area of Pandeglang Regency. This study showed that the implementation of the YUDHIA model significantly changed the level of knowledge of pregnancy and childbirth complication. These results were in line with studies conducted in the UK, that the midwives knowledge increased significantly after receiving obstetric training[5].

In the pretest, the average score of respondents knowledge was only 41.20 (SD 7.22). It got into the category of low knowledge, meaning less than 50% of knowledge about pregnancy and childbirth complications which was known by the respondents. Knowledge of bleeding was the most familiar to the respondents. Studies which conducted in Uganda showed results that were not much different. Only one third of respondents knew at least three danger signs in the phases of pregnancy, childbirth, and postpartum. Among them most respondents said that bleeding during

pregnancy and swelling of the hands and face were signs of danger during pregnancy[6].

Knowing the signs and symptoms of pregnancy and delivery complications will make responders more anticipated and prevented for mitigating the impact of pregnancy and childbirth complications by reducing the first two and late three if the health facility was ready to treath the complications[6]. The socialization about obstetric danger was key to finding health services for obstetric emergencies and in find prevention or promotion efforts during pregnancy and childbirth. So the lack of awareness of dangerous signs will be related to the lack of preparation to conduct childbirth normally as well as preparedness to face complications[7]. Assuming that all pregnancies were at risk, the mother should be aware of the signs of dangerous complications of pregnancy, childbirth, and postpartum.

Efforts to increase this knowledge was able be conducted with health promotion, both orally, in writing and audio. One of the latest approaches in improving knowledge and outcome of birth is Centering Parenting. Centering Parenting was a model that involving groups of 6-7 mother-babies together to get treatment for the first year. Through nine sessions, medical officers provided care and also provided information on health, infant development and baby-mother safety issues. The program integrated three major components of care, namely health, education, and support in-group assessment[8].

Attitude of Pregnant Woman: Changes in attitude of respondents before and after assisting YUDHIA model were shown as follows.

Table 2: Attitude of Pregnant Women before and After Assisting YUDHIA model

Variable	N	Mean	Median	SD	Min-Max
Pre	83	20.62	20	5,85	11 – 33
Post	83	40.56	40	6,23	34 – 55
Value of difference		19.94			

Source : Primary data, 2016

The average attitudes of pregnant women in the first measurement was 40.56 with a standard deviation of 5.85, the minimum value was 11 and maximum was 33. While in the second measurement obtained the average attitude of pregnant women was 40.56 with a standard deviation was 6.23, the value minimum was 34 and maximum was 55. There was an increase in attitude scores of respondents before and after assisting YUDHIA Model, the point was 19.94. The statistical analysis showed that YUDHIA assistance had a significant effect (p = 0,001) on the change of attitude of pregnant woman in work area of Pandeglang Regency.

This study showed that assisting YUDHIA Model significantly improved pregnancy attitudinal score on pregnancy and childbirthcomplications. Changes in attitudes was observed in this study were more prevalent on items about pregnancy screening. Research in Jordan showed there were as many as 91% of respondents who had a positive attitude to perform pregnancy checks during the emergence of alarm signs of pregnancy [14]. Unfortunately this study did not observe respondents's attitudes toward the danger of pregnancy. A study in Argentina showed that only 30% of pregnant women had a positive attitude associated with mild bleeding, dizziness, and vomiting- gag. The rest assumed that these signs were normal (negative attitudes), as delivered by the family and the environment around pregnant women. With a positive attitude toward pregnancy alert will trigger positive behavior in pregnancy examination and prevention of complications[9].

One that influences respondents's attitudes toward pregnancy and childbirth complications was maternal education, husband education, and education from health workers[10]. All three factors were able to increase awareness about the danger signs of pregnancy more than twice. It suggested that more exposure to information about complications, will enhance attitudes so it gave an effect on decision making during pregnancy and childbirth[11]. While information/promotion about pregnancy complications and delivery informations to pregnant women which was provided by health workers will greatly affect the attitude of the mother. Furthermore, these attitudes will affect the behavior of pregnancy examination. It will be very important in detecting pregnancy complications and providing advice to pregnant women and families on timely follow-up examinations[12].

Behaviour of Pregnant Women: An overview of scores changes in pregnant women's behavioral associated with the prevention of pregnancy and childbirth complications is shown in the following table.3

Table 3: Behaviour of Pregnant Women Before and After Assisting YUDHIA Model

Variabel	N	Mean	Median	SD	Min-Max
Pre	83	30.50	32	8.52	18-54
Post	83	70.48	70	8.32	55-80
Value of Difference		39.98			

Source : Primary data, 2016

The analysis result of pregnant women's behaviour who followed YUDHIA Model assisting got the average of pregnant women's behavior on first measurement (before, assistance) 30.50 with standard deviation 8.52, minimum value 18 and maximum 54. While in second measurement got the average behavior of pregnant mother (after assistance) was 70.48 with standard deviation of 8.32, minimum score 55 and maximum 80. There was an increase in score of respondent behavior before and after assistance YUDHIA model of 39.98. The statistical analysis showed that YUDHIA mentoring had significant effect (p=0,001) on the change of pregnant women's behavior in Pandeglang Regency. After YUDHIA Model was conducted, there was a significant change in the prevention behavior of pregnancy and childbirth complications. The results of this study were in line with study in Garut, West Java, that after receiving P4K training, the behavior of childbirth was led in health personnel.

Assisting YUDHIA Model was conducted intensively for 3-6 months until the mother maternity. In this assistance process, pregnant women received continuous education and strengthening from cadres about the signs of pregnancy complications. In addition, the promotion of childbirth in health personnel continues to be done. It is able to increase the knowledge of the respondents about the complications and ultimately changed their behavior, one of which is performing birth in midwife. By access, the community in Cimanuk Sub-district had the financial ability to deliver to health personnel. Although there were some who could not afford, but it could be overcome by the existence of saving maternity. In addition, with the availability of waiting homes, pregnant women who were in the village furthest from the health center able to wait in the waiting house that had been provided.

The pretest-postest presentation was conducted to determine whether or not the influence of assisting YUDHIA Model toward knowledge, attitudes, and behaviors prevention of pregnancy and delivery complications. So that assisting YUDHIA Model on prevention of pregnancy and childbirth complications able to be used by pregnant women as a guideline to prevent pregnancy and childbirth complications. The YUDHIA model was conducted by involving health workers (midwives), families, cadres, and the community. All the elements that played a role need to get assistance to better understand the concept and role in implementing this YUDHIA model. In addition,assistancewas also provided to equate common goals, it is to form behaviour pregnancy and childbirth complications that finally able to be prevent complications of pregnancy and childbirth.

The involvement of cadres and communities in this model was very appropriate. Based on the results of systematic review, cadres proved able to deliver the message of preventive intervention of maternal and child health problems in developing countries and poor countries. Because the cadres was able to deliver the message directly to the target audience ie mother, using the cultural and habitual approaches that apply in the community[13].

Conclusion

YUDHIA model was implemented through the process of assisting pregnant women by cadres. This assisting wasconducted from the second or third trimester of pregnancy to the maternity. As a tool in assisting pregnant women, the cadre was equipped with YUDHIA Model module. Assisting YUDHIA model significantly improved knowledge, attitude, and behavior to prevent pregnancy and childbirth complications.

Some recommendations that able to be delivered related to pregnancy and childbirth complications, for example in overcoming the limitations of human resources in the field of health and limited health facilities in Assisting YUDHIA model with empowerment approach and full participation of local asset-based communities is an intervention strategy in an effort to reduce maternal mortality. Assisting YUDHIA model able to be used in assisting village midwife duties in the early detection and prevention of complications of pregnancy and childbirth

Conflict of Interest: The authors declare that there is no conflict of interest.

Negeri Sembilan, West Malaysia; [3]Program Department of Physiotherapy, Lovely Professional University, Phagwara, Punjab

ABSTRACT

Background: It is important to quantify postural misalignment to provide effective treatment. Web-plot digitizer software (WPDS) was developed for analysis of posture angles. However, the reliability of this software in quantifying head posture angles is not known.

Study Design: Repeated-measure study.

Method: A total of 31 participants were recruited. Head posture angles were measured using Photogrammetry method and analyzed using WPDS. Intra-rater evaluations were performed twice by a rater with a period of three weeks' interval. Three raters reanalyzed all the photographic data for inter-rater reliability.

Results: High level of reliability was demonstrated for intra-rater analysis in participants with and without neck pain with ICCs ranging from 0.92 to 0.99 (SEMs: 0.10 to 0.88; CV: 1.65 to 10.77). The inter-rater reliability between three raters was also high (ICCs: 0.98 to 0.99).

Conclusions: Excellent intra and inter-rater reliability was demonstrated using WPDS. WPDS can be used in clinical setting for head posture assessment.

Keywords: *Reliability; head posture angles; Web plot digitizer software.*

Introduction

Forward head posture (FHP) is one of the most common abnormal posture associated with neck pain[1,2]. FHP can be characterized as an excessive anterior translation of the head in a sagittal plane[1]. These postural malalignments can lead to an imbalance between cervical and shoulder synergists, predisposing musculoskeletal injuries[2].

Therefore, correction of abnormal posture is crucial. Effective management includes postural assessments which can inform the intervention selection[3]. Clinically, FHP assessment is mostly performed by observation in which it is widely dependent on clinical experience and subjective interpretation of the examiner[4,5]. Moreover, studies have shown that existing method of postural assessment have poor accuracy and low reproducibility between observers[6].

Objective measures to assess FHP includes 3D motion analysis, electromagnetic, optical devices and surface topography are known to be more precise and reliable[8]. However, these techniques are mostly laboratory based, costly and time consuming[4,7]. There is a need for a feasible and reliable tool to measure FHP.

Digital photographs has been used to measure FHP[4,7,9,10]. This method has been reported to be relatively cheap, easy and fast[6,8,10]. Photograph method has also

been demonstrated to have good intra rater reliability in measuring neck postural angles with interclass correlation coefficients (ICCs) of 0.56 to 0.89 and 0.93 to 0.99 respectively[11].

Accordingly, postural assessment software has been developed to determine postural angles[7]. There are several FHP assessment software's which are available such as Alcimage, All Body Scan 3D, Biotonix, Corporis Pro, Fisiometer Posturogram, Physical Fisio, and Software of Posture Assessment[12]. One of the limitation of these software's are it requires special technical skills to operate, operating instructions are not in English and the software's need to be purchased[12].

In addition, the reliability of these software's are not reported[12]. Thus, there is a need to have a reliable FHP software to measure postural malalignment.

A software that will be useful is probably Web-Plot Digitizer Software (WPDS). WPDS is a window based, open resource application distributed under the General Public License Version 3 that has a scientific tutorial which can work with a variety of plots and images[13]. Nevertheless, the reliability of the WPDS has not been studied.

Therefore, the aim of our study is to assess reliability of WPDS in measuring head postural angles in adults with and without Non Specific Neck Pain (NSNP).

Method

Participants: A repeated measure study design was adopted. A total of 31 participants were recruited by convenience sampling method. The inclusion criteria for participants without neck pain were those who have not experienced neck pain for the past six months. The exclusion criteria include congenital diseases with musculoskeletal impairments and balance disorders.

The inclusion criteria for participants with neck pain were those present with complain of neck pain for the past 3 months or more. Whereas, the exclusion criteria for neck pain participant includes presence of any neurological symptoms, congenital diseases which could modify the musculoskeletal systems and balance disorder. Prior to data collection, all participants were given explanation about the study purpose, and informed consent was obtained.

Equipment: Photographs were taken from lateral view using a computer web-camera (Logitech C310, HD, 1280 X 720). The camera was supported on a tripod and placed at a distance of 1.5 meters away from the line marking the position of a participant. Landmarks were placed on the floor to ensure the same positioning[9]. The camera lens axis was placed perpendicular to the sagittal plane of the participant at the height that corresponded with seventh cervical[14]. The C_7 markers was placed in the center of the lens to reduce parallax error [14]. The captured images were imported to WPDS to calculate the FHP. The FHP angle was calculated by constructing the lines from one landmark to the other. The following variables were analyzed for measuring FHP angle as in the Figure 1:

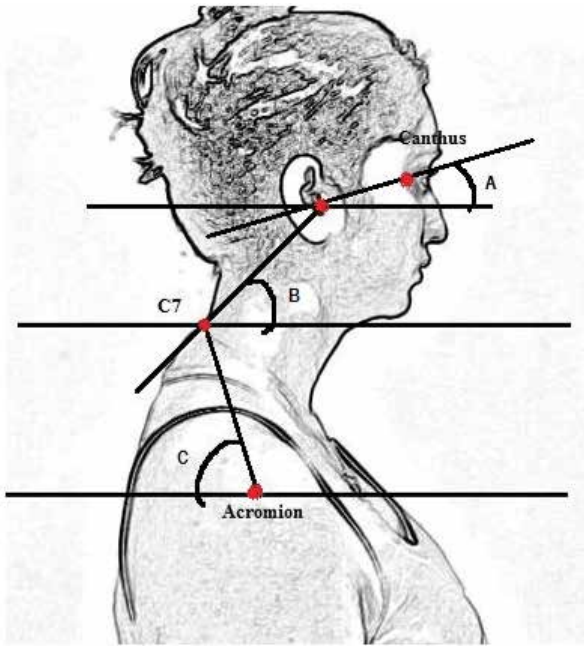

Figure 1: Sagittal head tilt (A),Craniocervical angle (B), and Shoulder angle (C).

Procedure

All the participants were instructed to stand comfortably in an upright position and to look straight ahead to a distant point at eye level before each photograph was taken[16]. Two reference frames for feet placement were placed on the floor to limit the variability associated with participants' positions. Before taking the photographs, the anatomical landmarks of the participants were palpated and marked by the same experienced physiotherapist using colored adhesive tape [15]. With these landmarks, the FHP angle were calculated[15].

Three physiotherapist who were not regular users of WPDS were invited for inter-rater reliability analysis. Prior to the analysis, the raters were orientated about how to use the software.

Data Analysis

Data was analyzed using statistical software package SPSS (Version 22.0). The primary rater analyzed all the photograph images twice with a period of three weeks' interval. Intra-rater reliability was examined using intraclass correlation coefficients (ICC), standard error of measurements (SEMs) and coefficient of variation (CV). For inter-rater evaluation of WPDS, three raters analyzed the photograph images by calculating the postural angles independently.

The results of ICC values were classified as poor for 0 to 0.40; moderate for 0.40 to 0.75; and excellent for 0.75 to 1.00[17]. The SEMs was used to investigate different sources of variation in test scores[18]. The measure is considered reliable if the SEMs is less than 5%[18].

The CV is described as the estimation error of measurement when usually the repeated measures are performed. The measure is considered reliable if the CV is lesser than 15%[18]. CV is calculated based on the formula in which, CV = (SD/X) 100

The Bland – Altman plot was calculated to evaluate the agreement between two trials of measurement. The trial measures should lie between the probabilities of 95% for a good, reliable measure[18].

Results

All participants completed the trials and the data was normally distributed. The mean and standard deviations of participants' characteristics are as depicted in Table 1. The ICC, SEMs and CV of the postural angles of participants are shown in Table 2. The intra-rater reliability were excellent with ICCs ranging from 0.92 to 0.99 (Table 2). The SEMs and CV were between 0.10 to 0.88 and 1.65 to 10.7 respectively. These results suggest a high level of intra-rater reliability in the postural angle measurements.

Table 1: Descriptive characteristics of participants

Participants	Without neck pain (n = 15) Mean (SD)	With neck pain (n = 16) Mean (SD)
Age	24.6 (6.36)	24.5 (13.4)
BMI	22.5 (8.50)	24.9 (8.12)

Table 2: Intra-rater reliability analysis of postural angles

Posture Angles	Without neck pain			With neck pain		
	CV	SEMs	ICC(95% CI)	CV	SEMs	ICC (95% CI)
SHA	10.12	0.36	0.97 (0.93 – 0.99)	10.77	0.76	0.92 (0.79 – 0.97)
CCA	2.42	0.20	0.98 (0.96 – 0.99)	1.65	0.10	0.99 (0.98 – 0.99)
SA	6.35	0.88	0.96 (0.90 – 0.98)	3.46	0.30	0.98 (0.96- 0.99)

SHA: Sagittal Head Tilt angle; CCA: Craniocervical angle; SA: Shoulder angle.

The Bland-Altman plot for measurement of first trial and second trial in participant without neck pain for sagittal head angles shows the mean difference of -0.2 with a confidence interval (CI) of upper limit 4.3 and lower limit -4.0 respectively (Figure 2). Cervical angles had a mean difference of 0.17 with CI of upper limit 3.4 and lower limit -3.0 respectively and shoulder angle revealed the mean difference of 1.4 with a CI of upper limit 10.5 and lower limit -7.6 respectively. The Bland-Altman plot for measurement of trial 1 and trial 2 in participants with neck pain for sagittal head angle revealed the mean difference of 0.3 with CI of upper limit 6.0 and lower limit -5.4 respectively, cervical angle with the mean difference of 0.3 with CI of upper limit 2.0 and lower limit -1.5 respectively, and shoulder angle with the mean of 0.9 with CI of upper limit 5.5 and lower limit -3.5 respectively. Visual analysis of all the plots showed that all the measurement differences were in between the ± 2SD, indicating that the scores of both the measures had acceptable agreements.

The inter-rater reliability between three raters demonstrated high level of reliability (Table 3). The ICCs for inter-rater ranged from 0.98 to 0.99 demonstrate

excellent reliability between raters. The SEMs ranged from 0.08 to 0.40 and CV ranged from 0.02 to 0.06 which demonstrated high inter-rater reliability. Therefore, the results suggest that the WPDS is reliable in measuring postural angle.

Table 3: Inter-rater reliability analysis of postural angles

	Angle	Rater 1 Mean (SD)	Rater 2 Mean (SD)	Rater 3 Mean (SD)	CV	SEMs	ICC (95% CI)
Without neck pain	SHA	15.94 (8.13)	16.57 (7.98)	16.57 (7.98)	0.06	0.10	0.99 (0.98- 0.99)
	CCA	47.02 (7.49)	47.77 (7.65)	48.18 (7.70)	0.02	0.08	0.99 (0.98 - 0.99)
	SA	52.43 (13.06)	51.73 (13.01)	53.95 (15.00)	0.05	0.40	0.98 (0.96 - 0.99)
With neck pain	SHA	18.89 (5.46)	19.21 (5.28)	19.10 (5.69)	0.05	0.09	0.99 (0.97 - 0.99)

	SA	50.08 (10.56)	48.34 (9.77)	49.66 (11.06)	0.05	0.32	0.98 (0.96 - 0.94)

Without Neck Pain **With Neck Pain**

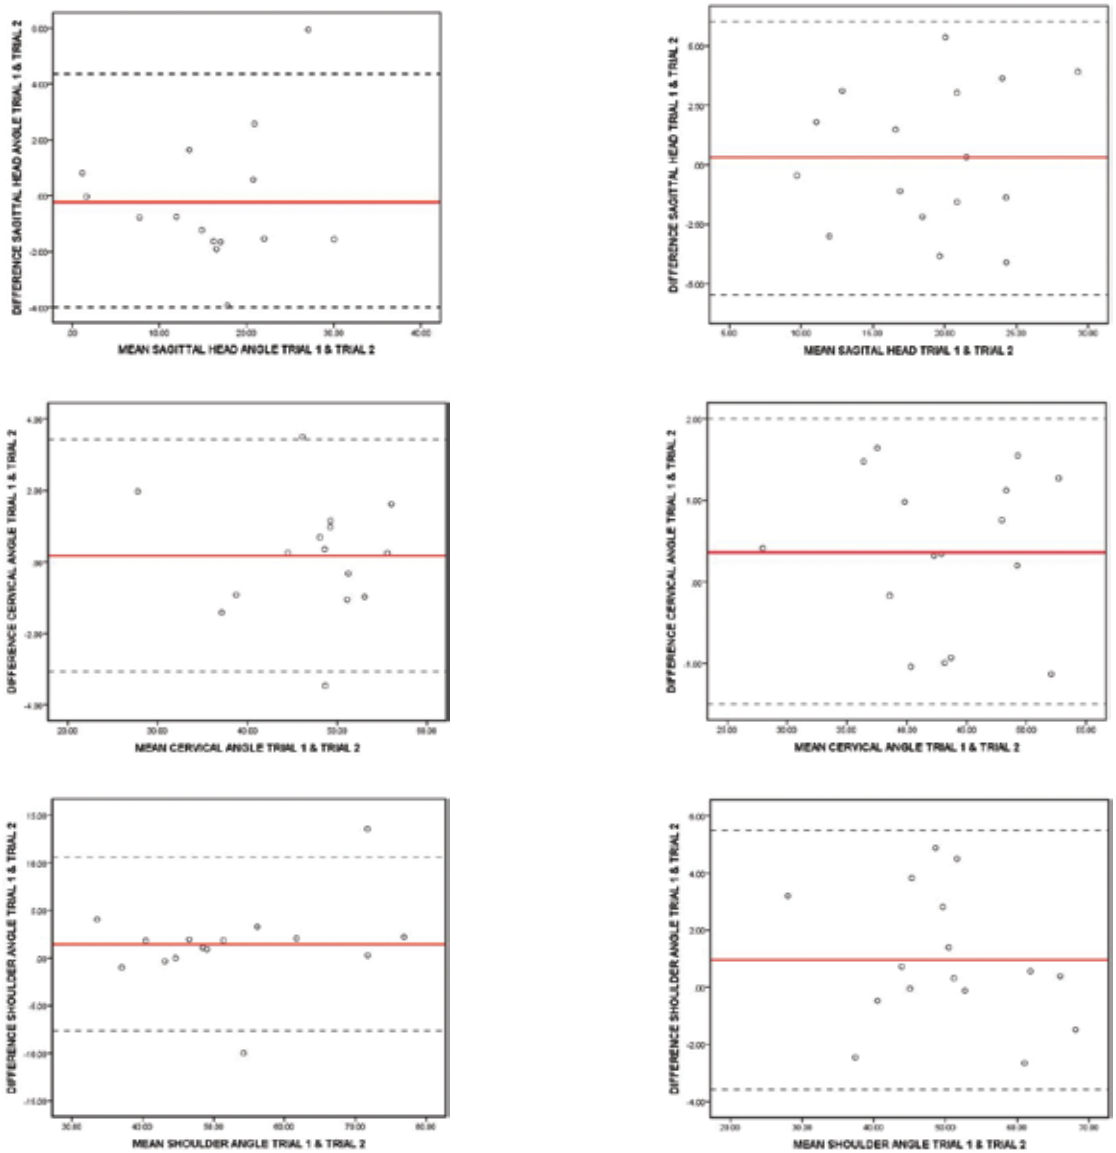

Figure 2: Bland-Altman plot of two different trials

Discussion

In our present study we examined the intra and inter rater reliability of WPDS in measuring head posture angles. The results demonstrated that the intra and inter rater of WPDS in measuring head posture was excellent.

Inter-rater reliability of WPDS was found to be excellent. These results were further supported with the findings of Bland-Altman plots, indicating that the two trials in both participants with and without neck pain had acceptable agreements. Inter-rater reliability results of posture assessment using another similar software, postural assessment software (PAS) showed that the values of 44.8% and 34.5 % respectively between rater 2 and 3 were non acceptable whereas the other raters had showed an acceptable reliability values[7].

Inter-rater agreement in using such techniques could have been influenced by many factors, including experience and training of the raters on the usage of software. It is noteworthy, that usage of WPDS does not require an experience computer user as it's easy to operate. Similarly, inter-rater reliability of fibre angles from ultrasound images were found to be excellent (ICCs: 0.94 and 0.97)[19]. These results could have been influenced by recall bias in identifying the points on the images.

An excellent intra-rater reliability of WPDS was also demonstrated in our present study. The results of SEM and CV were small and in the acceptable ranges suggesting good measurement precision. These results are consistent when compared to a previous study reporting sagittal photographic spinal posture assessment which demonstrated excellent reliability [10].

One of the factors that could have influenced the reliability of postural angles using WPDS is the accuracy of palpations. Marker placements can result in errors leading to high variability in measurements[10]. However, error from difference in palpations were controlled by getting only one experienced physiotherapist to do so throughout the study.

The anatomical landmarks were marked using colored tape to reduce the variability of measures. The quality of the photographs were also assured by using same trained person to capture the image for the analysis by the raters. We deduced that the inter-rater variability in our study would have been mainly from the selection of the points in constructing the lines from one landmark to the other for measuring the angles.

Another factor that could affect the reliability of the study is perspective error[20]. In the present study perspective error was controlled by minimizing the rotational angle of neck by keeping the optical axis perpendicular to the postural angle.

Positioning of the head and the use of instruction to a participant is also known to affect the measurements[7]. Alteration in neck positioning may cause incorrect visualization of the markings. Whereas, the use of instruction to a participant can highly influence the human movements and position. In regard to this, the error related to positioning of head and instructions to participants was minimized in our study by ensuring standardized positioning of the participants by providing a clear and detailed instructions.

Results from previous studies have supported the usage of software as an accurate method in the measurements postural angles for clinical use[5,10,21]. The reliability of a measurement system used clinically or in research must be established in order to ensure that the error involved in measurement is small enough to detect actual changes in what is being measured[12]. Our study results showed excellent reliability as we used stringent methods and was based on the guidelines for reporting reliability and agreement studies (GRASS).

The limitation of the present study is that for the inter-rater reliability of measuring head postural angles using WPDS, we limited the analyzing to the photographic images. However, from the results of the intra-rater reliability we speculate that the reliability will remain to be excellent. Another limitation is that the validity of measuring postural angles using WPDS was not performed as it was beyond the scope of this study. Future studies should explore examining intra and inter day intra-reliability of measuring using WPDS and its concurrent validity.

Conclusion

Excellent reliability of WPDS in measurements of FHP was demonstrated in our study. Hence, we recommend the use of WPDS for prevention of FHP as a screening tool and management in clinical practice as it is reliable, easy and simple to be used.

Proton Pump Inhibitor to the Hepatic Cirrhosis Patients with Hematemesis Melena: A Retrospective Study

Zakiyah[1], Didik Hasmono[1], Muhammad Noor Diansyah[1], Christiawan Ardianto[1]

[1]Department of Pharmacy, Faculty of Pharmacy, Universitas Airlangga, Jl. Dharmawangsa No.4 - 6, Airlangga, Gubeng, Kota SBY, Jawa Timur 60286

ABSTRACT

Background: The Proton Pump Inhibitor (PPI) can be given as supportive therapy in hepatic cirrhosis patients with hematemesis melena during treatment at the hospital. However, the use of proton pump inhibitor therapy as a supportive therapy for hepatic cirrhosis patients with hematemesis melena has not been widely used in hospitals.

Objective: This study aims to determine the pattern of use of proton pump inhibitor (PPI) in patients with hepatic cirrhosis with hematemesis melena in the hospital.

Method: This study is a retrospective descriptive non-experimental. Sampling was obtained from secondary data medical records of patients that diagnosed hepatic cirrhosis with hematemesis melena. The variables observed were patients with hepatic cirrhosis with hematemesis melena such as age, gender, type of drug, dose, route of use, the frequency of administration, duration of drug administration, and clinical symptoms.

Results: The most widely used PPI was omeprazole with intravenous route with a dose of 1x40mg and 2x40mg (61.54%), oral omeprazole route with a dose of 2x20mg (7.69%), intravenous route pantoprazole with a dose of 1x40mg and 2x40mg (5.13%), and intravenous lansoprazole route with a dose of 1x30mg and 2x30mg (48.72%).

Conclusion: The pattern of using proton pump inhibitor therapy in hepatic cirrhosis patients with hematemesis melena is different in each patient.

Keywords: *proton pump inhibitor, hepatic cirrhosis, hematemesis melena, treatment pattern*

Introduction

Cirrhosis is ranked twelfth as the cause of death in adults worldwide with a prevalence of 1.8% [1]. According to a report by a government hospital in Indonesia, the mean prevalence of liver cirrhosis is 3.5% of all patients treated in the Internal Medicine ward, or a mean of 47.4% of all liver disease patients treated. Comparison of the prevalence of cirrhosis in male: female is 2.1: 1 and the average age is 44 years [2]. Cirrhosis is a diffusion process characterized by fibrosis and changes in normal liver structure to abnormal nodules. Hepatic cirrhosis can be caused by many conditions, including; consumption of alcohol, hepatitis B and C viruses, immunological disorders, hepatotoxic substances [3]. Hepatic cirrhosis can result in complications of hematemesis melena caused by an aneurysm of the veins that leads to upper gastrointestinal bleeding [4].

Proton Pump Inhibitor (PPI) is a supportive therapy given to patients with hepatic cirrhosis with hematemesis melena [5]. PPI works to suppress stomach acid by the mechanism of inhibiting proton pumps which prioritize the resistance of H +/K + -ATPase to the gastric mucosa [6]. Some research data shows that PPI-class drugs are better than H2-receptor antagonists in acid suppression [7]. The advantage of using PPI is due to its superiority

in maintaining gastric acidity. Research data show that stomach acid disrupts clotting formation, increases platelet disaggregation and fibrinolysis. Therefore, inhibition of gastric acid and increased gastric acid pH will improve clotting stability and reduce the incidence of bleeding [8,9]Fleming TR. A multiple testing procedure for clinical trials. ... (2010. Commonly used PPI class drugs are esomeprazole, lansoprazole, omeprazole, rabeprazole, and pantoprazole [10].

The use of PPI in the long term has the potential to cause hypergastrinemia by 50-100% and will increase gastric acid secretion after long-term use of PPI. The results of a systematic review of the evaluation of acid hypersecretion showed that there was a rebound after the use of PPI for 8 weeks [11]. Other side effects that occur in PPI use include diarrhea, abdominal pain, constipation, nausea, vomiting, and bloating [12]. Based on the description above, the use of PPI in patients with hepatic cirrhosis with hematemesis melena still needs to be studied further because it is possible for DRP (Drug Related Problems).

Materials and Method

This study uses a non-experimental or observational with the descriptive retrospective design. Subjects in this study were patients diagnosed with hepatic cirrhosis with hematemesis melena who received PPI therapy in the inpatient room of Airlangga University Hospital Surabaya city for the period of January 2014 to December 2016. Where the subject was determined by the Time-Limited Sampling method by means of each patient who fulfilled Research criteria were included in the study during a certain period of January 2014 to January 2015. Data collection for this study was carried out retrospectively. Where research data is obtained from medical records of patients treated with the diagnosis of hepatic cirrhosis with hematemesis melena from January 2014 to January 2017 which is then put together into the collecting sheet. Data observed includes; patient profile (medical record number, patient identity, hospital entry and date of discharge, complaints and final diagnosis, disease history and treatment history, and laboratory data and clinical data) and profile of therapy data (type of drug, dose, frequency of administration, route of administration, and duration of therapy). Data analysis was based on data obtained from the Medical Health Record (RMK) of hepatic cirrhosis patients with hematemesis melena. Data obtained from data collection sheets are put together into the main table and then processed statistically and analyzed descriptively in the form of tables, diagrams, graphs or narratives.

Results

PPI Treatment Profile: From the results of the study, hepatic cirrhosis patients with hematemesis melena who received therapy shown in Table 1.

Table 1: PPI therapy profiles based on PPI Types

PPI Drugs	Amount	Percentage (%)
Omeprazole	24	61,54
Lansoprazole	13	33,33
Pantoprazole	2	5,13
Total	39	100,00

Profile of route of use, dose, and frequency of PPI therapy used can be seen in Table 2.

Table 2: Routes, dosages, and frequency of PPI therapy

PPI Drugs	Route	Frequency & Dose	Amount	Percentage (%)
Omeprazole	i.v	2.dd.40 mg	23	58,97
	i.v	1.dd.40 mg	1	2,56
	p.o	2.dd.20 mg	3	7,69
Pantoprazole	i.v	2.dd.40 mg	1	2,56
	i.v	1.dd.40 mg	1	2,56
Lansoprazole	i.v	2.dd.30 mg	13	33,33
	i.v	1.dd.30 mg	6	15,38

Note: *) One patient can receive more than one medication for treatment

In the use of PPIs, each patient gets a different duration of treatment depending on the clinical effects caused by each patient can be seen in Table 3.

Table 3: Duration of PPI usage

PPI Drugs	Duration	Amount	Percentage (%)
Omeprazole	< 4 weeks	27	69,23%
Lansoprazole	< 4 weeks	19	48,72%
Pantoprazole	< 4 weeks	2	5,13%

The profile of the substitution of type, dose, and route of PPI in hepatic cirrhosis patients with hematemesis melena can be seen in table 4.

Table 4: Profile of PPI type, dosage and route replacement

Substitution Profile		Amount	Persentase (%)
Drugs Substitution			
Pantoprazole (2x40 mg)/iv	Lansoprazole (1x30 mg)/iv	1	2,56
Omeprazole (2x40 mg)/iv	Lansoprazole (2x30 mg)/iv	3	7,69
Lansoprazole (2x30 mg)/iv	Omeprazole (2x40 mg)/iv	1	2,56
Doses Substitution			
Omeprazole (2x40 mg)/iv	Omeprazole (1x40 mg)/iv	1	2,56
Lansoprazole (2x30 mg)/iv	Lansoprazole (1x30 mg)/iv	2	5,13
Route Substitution

Identification of *Drug Related Problem* (DRP): Potential interactions can be seen in Table 6.

Table 6: Potential drug interactions

PPI Drug	Other Drug	Drug Interactions	Amount	Percentage (%)
Omeprazole	Furosemide	Furosemide can increases hypomagnesia effect from omeprazole	4	10,26

Patients with hepatic cirrhosis with hematemesis melena potential interactions between PPI therapy and other drugs occur in the interaction of omeprazole with furosemide which can increase hypomagnesia.

Discussion

In the results of this study, the types of PPIs used were omeprazole, lansoprazole, and pantoprazole. Omeprazole is the most therapy used by patients with hepatic cirrhosis with hematemesis melena in hospitals because omeprazole has a more cost-effective price because it is registered with the Social Security Organizing Agency (BPJS), so many patients use omeprazole. There was no significant difference in effectiveness between omeprazole and lansoprazole at standard doses. When the frequency of administration added to twice a day, omeprazole is better for inhibiting gastric acid at night than lansoprazole [13]omeprazole and lansoprazole provide effective acid suppression and equal healing and symptom relief in patients with GERD. Despite this, controversy exists as to the efficacy of available proton pump inhibitors in the control of gastric acidity. AIM: To assess the efficacy of omeprazole 20 mg vs. lansoprazole 30 mg and omeprazole 40 mg vs. lansoprazole 30 mg in intragastric pH control. METHODS: Study I: 12 Helicobacter pylori-negative volunteers (mean age 33 years. Pantoprazole in standard doses has the same effectiveness as omeprazole in inhibiting proton pumps [14]. Omeprazole is most frequently used by the intravenous route because the oral route of omeprazole has acid degradation in the digestive tract [15]. In this study, omeprazole was administered at a dose of 2x40 mg daily and 1x40 mg daily intravenously and given a dose of 2x20 mg per oral. daily. Lansoprazole is given at a dose of 1x30 mg daily and 2x30 mg daily, for pantoprazole given at a dose of 1x40 mg daily and 2x40 mg daily. Standard dose was omeprazole 1x40 mg daily, lansoprazole 2x30 mg daily and pantoprazole 1x40 mg daily omeprazole 2x40 mg daily [16]arrived at after careful consideration of the evidence available. When exercising their judgement, professionals are expected to take this guideline fully into account, alongside the individual needs, preferences and values of their patients or service users. The application of the recommendations in this guideline are not mandatory and the guideline does not override the responsibility of healthcare professionals to make decisions appropriate to the circumstances of the individual patient, in consultation with the patient and/or their carer or guardian. Local commissioners and/or providers have a responsibility to enable the guideline to be applied when individual health professionals and their patients or service users wish to use it. They should do so in the context of local and national priorities for funding and developing services, and in light of their duties to have due regard to the need to eliminate unlawful discrimination, to advance equality of opportunity and to reduce health inequalities. Nothing in this guideline should be interpreted in a way that would be inconsistent with compliance with those duties. Gastro-oesophageal reflux disease and dyspepsia in adults: investigation and management (CG184.

The type of PPI given in less than 4 weeks, namely omeprazole, lansoprazole, and pantoprazole, provided that patients can get more than one type of PPI. The use of long-term PPI with a potential of hypergastrinemia increases gastric acid secretion by 50-100% after long-term use of PPI [11]. The results show that there were patients receiving PPI substitution from pantoprazole 2x40 mg iv. daily to lansoprazole 1x30 mg iv. daily. Pantoprazole has a t½ that is longer than lansoprazole (t ½ = 1 hour) which is 2 hours [17]Helicobacter pylori infection, gastrooesophageal reflux disease, nonsteroidal anti-inflammatory drug (NSAID. Therefore, the substitution is appropriate because it reduces the time to suppress stomach acid due to the development of clinical symptoms. In addition, there was one patient who received PPI substitution from omeprazole 2x40 mg iv. daily and one of the patients that received lansoprazole 2x30 mg iv. also get dose substitutions to lansoprazole 1x30 mg iv. daily, this dose substitution was also appropriate due to the development of Clinical symptom, so there is no need for high doses or intravenous use. For route substitution, namely omeprazole iv. to omeprazole 2.dd.20 mg PO, daily. This replacement can be caused because the patient's condition has begun to improve because oral administration is not always possible in critically ill patients or with decreased awareness [18].

PPI substitution of omeprazole 2.dd.40 mg iv. daily to lansoprazole 2.dd.30 mg iv. daily, this substitution caused by the ability of lansoprazole in binding to protein by 98%, that leads to longer suppression effect of gastric acid [19]. The substitution is expected to compensate for the clinical symptom with longer gastric acid suppression effect from lansoprazole. After that, the substitution of lansoprazole 2.dd.30 mg iv. daily to omeprazole 2.dd.40 mg daily, this substitution is based

on omeprazole ability as the fastest PPI group that reach peak serum concentration [20].

Other therapies given for hepatic cirrhosis patients with hematemesis melena which are most widely given in this study are antibiotics including cefotaxime, antifibrinolytics namely tranexamic acid, sucralfate, vitamin K, and laxatives including lactulose. There is an ulcer in the upper gastrointestinal tract and also caused damage to the Kupfer cells of the liver and if accompanied by ascites it could trigger SBP. Therefore hepatic cirrhosis patients with hematemesis melena are given antibiotics as infection prophylaxis. Cefotaxime is the most widely administered antibiotic because cefotaxime is the third generation of a cefolosporin class which has a very broad working spectrum, stronger antibacterial activity and relatively lower side effects [21].

Administration of tranexamic acid which is an antifibrinolytic group aims to reduce or stop active bleeding [22]. Tranexamic acid can reduce upper gastrointestinal bleeding and stabilize the patient before endoscopic treatment [23]we found that tranexamic acid may reduce mortality. The present review includes updated searches of randomised trials on tranexamic acid versus placebo, cimetidine or lansoprazole. To assess the effects of tranexamic acid for upper gastrointestinal bleeding. Electronic searches (The Cochrane Library, MEDLINE, EMBASE, Science Citation Index. In this study patients were also given Vitamin K, this is intended to help the blood clotting process. Lactulose is given to prevent constipation in these patients and to prevent the chance of toxic substances to pass from the intestine to the liver which in turn can cause hepatic encephalopathy [24]. Patients also are given sucralfate, this therapy aims to cure esophageal ulcers. This drug has a protective effect on mucosa including stimulation of mucous prostaglandins. In addition, sucralfate can directly absorb bile salts [25].

Identification of drug-related problems is carried out on several things such as dose suitability, route of administration, and risk of drug interaction. The selection of route, dose, and type of PPI is based on several factors including the sensitivity of each individual patient in reducing the clinical symptoms, pharmacoeconomics, and consideration of clinical symptoms. PPI therapy in hepatic cirrhosis patients with hematemesis melena can lead to Drug-Related Problems. The DRP observed at RMK is DRP related to drug interactions. In this study, it was possible to interact between omeprazole and furosemide. Drug interactions occur with moderate severity. Long-term PPI use can cause hypomagnesia, and furosemide can cause an increased effect of hypomagnesia from omeprazole [20]. In this study, plasma magnesium levels were not tested to determine the incidence of hypomagnesia.

Conclusion

The most frequently used of PPI Drugs in hepatic cirrhosis patients with hematemesis melena is omeprazole in intravenous route. Drug Related Problems (DRP) that occur in PPI treatment and other drug therapies in patients with hepatic cirrhosis with hematemesis melena have found potential interactions between the PPI such as omeprazole with furosemide.

ABSTRACT

Background: Alveolar bone regeneration can be guided by the application of a collagen protein coupled with neuroinductive protein, following tooth extraction.

Aim of the study: The present study was designed to evaluate the radiologic, histologic and histomorphometric aspects of socket healing in extraction site received placental collagen with brain-derived neurotrophic factor(BDNF), compared with control site that healed spontaneously.

Materials and Method: Twelfth *Sprague-Dawley* male rats were subjected for a surgical tooth extraction of upper central teeth of both sides. The right side be the control one as the socket healed spontaneously. while left side be the experimental site, as tooth socket treated with 1µL of placental collagen with 1µL of BDNF. The rats were scarified at 2 and 4 weeks post extraction. Socket healing was examined radiographically and histologically.

Results: Experimental site illustrates trabecular bones formation between the peripheral and central regions of the sockets at 2 weeks and increment of bone formation was observed, filled most of socket at 4 weeks with reepithelization recognized at the surface. Radiographical view shows radiopaque that comprising 50% to 74% of the overall area of the socket and was assigned a score of 3 with a high p value in comparisum to control.

Conclusion: The present study, high lighted on osseo-inductive effect of the local application of placental collagen with BDNF in socket healing.

Keywords: *alveolar bone,bone regeneration,socket healing,BDNF,collagen protein,tooth extraction*

Introduction

The alveolar socket walls undergo a physiological changes and remodeling process with a variable molecular interaction events after tooth extraction. Different socket preservation techniques and materials have been proposed to facilitate healing.[1,2]Most of techniques consist to fill the alveolar socket with different enhancing materials that act as stimulants or scaffolds for bone growth and initiate epithelization of the braked mucosa.[3,4,5]

The use of the collagen matrix could be a clinical option to preserve post-extraction ridges especially when an improvement in soft tissue quality is desired.[6] Many experiment were done to analyze processes involved in the incorporation of Bio- Collagen in host tissue during healing following tooth extraction.[7,8,9]

Brain-derived neurotrophic factor reported to be involved in differentiation and proliferation of non-neuronal cells, such as endothelial cells, osteoblasts that have been recognized to be also involved in regulating tissue formation and healing in skeletal tissues. [10]Also, this neurotrophin can enhance expression of osteogenic factor, BMP-2, as well as the major angiogenic factor,vascular endothelial growth factor VEGF that promote bone formation and enhance vascularization, and healing of the injury site. [11,12]Therefore, the present study is the first report on the application of placental

collagen coupled with brain-derived neurotrophic factor as enhancing material for bone regeneration and socket healing.

Materials and Method

Animals: Twelfth *Sprague-Dawley* male rats aged (10–12-week) and weight (250–300 g) were kept in the animal department of (National Center of Drug Control and Research/Iraq) at a constant humidity and temperature of 23°C according to the National Council's guide for the care of laboratory animals.The rats were subjected for a surgical tooth extraction of upper central incisors (right side was considered as control site, that tooth socket healed spontaneously,while left side(experimental site) received 1µL of placental collagen with 1µL of BDNF

Materials

- Placental Collagen protein (N0. C-7521,SIGMA P).

  A lyophilised powder that can be reconstituted in sterile water at 1 mg/ml.

- Lyophilised BDNF protein 10µg (ab9794)/ Abcam,the protein was reconstitute in water to a concentration of 0.01mg/ml.

Method

Surgical Procedure: After anesthetizing the animal by general anesthesia the upper left and right central incisors extracted by simple extraction without trauma. The left socket treated with a combination of 1µL placental collagen and 1µL of BDNF as experimental site, while the right one left without treatment (control). The two sockets were sutured with black silk suture.Rats were sacrificed at 2 and 4wk post-extraction for the analysis of the extraction sites. (n=6 in each group at different sacrificed time point)

Radiographic Examination and Grading: Clinical radiographic examination was used to evaluate the degree of bone mineralization (DBM) in the extraction sockets during healing.The semiqualitative grading system used for radiographically examining DBM was based on the following parameters at 10× magnification: (a) sections with no evidence of radiopacity were assigned a score of zero; (b) a radiopaque area comprising less than 25% of the overall area of the socket was assigned a score of one; (c) a radiopaque area comprising 25% to 49% of the overall area of the socket was assigned a score of 2; (d) a radiopaque area comprising 50% to 74% of the overall area of the socket was assigned a score of 3; and (e) a radiopaque area comprising 75% or more of the overall area of the socket was assigned a score of 4. Each section was scored by 2 independent examiners.[13]

Histological Examination and Assessment: The premaxilla were resected cutting till the end of dental canal, fixed in 10% buffered formalin, decalcified in 10% formic acid, dehydrated and embedding in paraffin wax then serial cut 5µm cross section and stained with Hematoxylin and Eosin.

All these sections were examined under light microscope to evaluate the healing of extraction wounds.

In addition, histomorphometry was used to assess the amount of new bone formation, by estimation of trabecular separation (Tb.Sp, in microns) in different portions of socket healing(coronal,middle and apical), each section was evaluated by 2 independent examiners at 10x.

Results

Histologic examinations revealed an absence of inflammatory cells in all studied sites, whereas bone formation and epithelization varied in the experimental compared to control and according to different periods.

At 2 week post extraction period, histological feature for control site shows bone trabeculae coalesce peripherally with bone socket. Radiographical view shows radiolucent in the socket with some radiopacity present along the wall of the extraction sockets. While experimental site illustrates trabecular bones formation between the peripheral and central regions of the sockets. Radiographical view shows mixed of radiolucent and radiopaque filled the middle portion with substantial amount of detectable calcification that present in the extraction sockets, lamina dura still intact and visible. Figures(1,2,3)

At 4 week healing period, histologic description for control site shows trabecular bone at central and peripheral portions of the socket that confirmed by radiographic film that illustrates mixed view of radioopacity and radiolucent with detectable calcification. Epithelization was not recognized for control.

For experimental site, histologically, shows new bone filled most of socket with fibrous tissue over it. Reepithelization appears at the surface. Radiographical view shows radiopacity filled most of apical, middle and coronal portions of the socket with lamina dura disappeared partially. Figures(4,5,6)

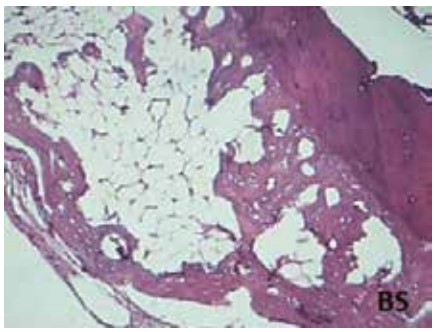

Figure 1: Alveolar socket for control at 2 week duration shows bone trabeculae coalesce peripherally with bone socket.H&Ex10

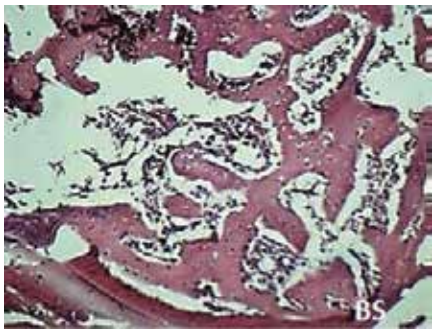

Figure 2: Alveolar socket for experimental at 2 week duration shows trabecular bones formed between the peripheral and central regions of the sockets. H&E x10

Figure 3: Conventional radiographic view after 2 week illustrates Control (right)side with some radiographically detectable calcification was present along the wall of the extraction sockets,while exp.(left) side shows a substantial amount of radiographically detectable calcification was present in the extraction sockets
Note: lamina dura still intact and visible.

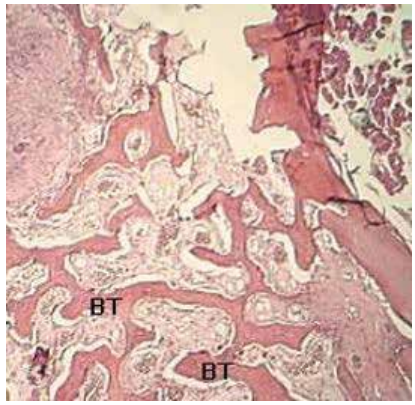

Figure 4: Alveolar socket for control at 4 week duration shows trabecular bone(BT) at central and peripheral of the socket.H&Ex10

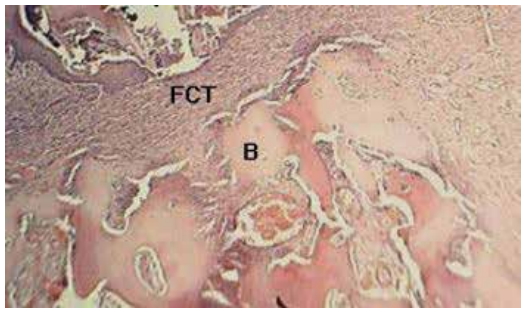

Figure 5: Alveolar socket for exp. at 4 week duration shows new bone(B) filled most of socket with fibrous tissue(FCT) over it.H&Ex4

Figure 6: Conventional radiographic view for both sides control and experimental of socket 4weeks duration shows radioopacity and radiolucent . In experimental side shows more radiopacity and include most of apical, middle and coronal portion of socket.
Note: partial disappear of lamina dura internally in experimental side

Statistic Analysis

Results show less record for trabecular separation measurement in experimental site in comparisum to control.And in the apical portion for both studied sites

in comparisum to other portions.Moreover, trabecular separation measurement decreased as the period proceed in both control and experimental sites with a high significant P≤0.01Value.Tables(1,2)

Radiographic Grading Score: Radiopaque area comprising 25% to 49% of the overall area of the socket and assigned score, 2 that recorded in 4th week of control and in 2nd week for experimental site. Whereas, radiopaque that comprising 50% to 74% of the overall area of the socket, assigned a score 3, was recognized in experimental site at 4th week post operatively with a high p value in comparisum to control. Table(3)

Discussion

Socket healing is a complex physiological process involving a coordinated interaction of hematopoietic cells, immune cells within the clot plug, in conjunction with development of new vascular bud and bone cell precursors. Multiple factors regulate healing at molecular events, which affects different stages in the osteoblast, endothelial,epithelial lineages during multiple processes such as migration, proliferation, chemotaxis, differentiation and protein synthesis.[14,15]

In present findings the experimental site illustrates trabecular bones formation in the peripheral and central regions of the sockets and bone formation was observed, filled most of socket at 4 weeks with reepithelization of braked mucosa,these results may related to the use of placental collagen which is a protein that's an important building block for bone and made the scaffold of the bone. Moreover,collagen also, promote a regenerative response including its effectiveness for acceleration of osteoblasts growth, [16] its potential role in preserving osteogenic potential of mesenchymal stem cells[17], and its ability to enhance angiogenesis.[18]

Mesenchymal stem cells MSCs differentiate directly into osteoblasts, which secrete an osteoid matrix to form bone, [19]as illustrates in 2 week duration of socket healing. Furthermore, application of neurotrophin (BDNF) effects on vascular endothelial growth factor VEGF that promote bone formation and enhance vascularization, therefore,the present study records score 3 for radiographic grading of experimental site which indicated for the enhancement of newly bone formation and accelerate of socket healing. [20,21] Thus, bone formation and reepithelization process that detected in experimental site depend, in part, on the presence of placental collagen and in part to the role of the combined BDNF.

Conclusion

Our preliminary results suggest that the association placental collagen plus BDNF may be a valuable method for socket healing.

Study the Effect of *Lycium barbarum* Polysaccharide on Bone and Thyroid Gland in Hyperlipidemic Healthy Male Albino Rats

Heba A. Abd-Alsalam Alsalame

College of Education for Pure Science, University of Kerbala, Iraq

ABSTRACT

The aim of the study was to determine the protective role of *Lycium barbarum* Polysaccharide against the development of osteoporosis and hypothyroidism induced by high cholesterol diet in male albino rats, 45 male albino rats were grouped into three sets. The first group (G1) was fed with normal diet and considered as a control group. The second group (G2) was fed 2% cholesterol-enriched diet for three months to induction of hypercholesterolemia, while The third group (G3) was fed 2% cholesterol-enriched diet +100mg/kg of *Lycium barbarum* Polysaccharide (LBP). Blood samples were withdrawn after starvation of the animals at night, after the end of three months, 5 ml of blood was withdrawn from the heart to measure the following parameters: concentration of total cholesterol (TC), High density lipoprotein (HDL), Low density lipoprotein (LDL), Very low density lipoprotein (VLDL), Triglyceride (TAG), Alkaline Phosphatase (ALP), phosphorus (p+), Calcium (Ca+), Parathyroid Hormone (PTH), Thyronine (T3), Thyroxin (T4) and Thyroid stimulating hormone Hormons(TSH). Rats in G2 had significantly greater levels of TC, TAG, LDL, and VLDL compared to G1, while the picture was an opposite direction in the levels of HDL. G2 rats had significantly greater levels of PTH, calcium and phosphorus, while ALP levels were significantly reduced compared to that observed in G1 rats. Levels of thyroid hormones (T3, and T4) were significantly decreased, while the TSH levels were significantly increased in the G2 rats compared to that of G1 rats. Rats in group 3 did not reveal any significant changes in all measured biomarkers comparing to that values measured in G1. It is concluded from the present study that hyperlipidemia increases osteoporosis risk and causes thyroid dysfunctions and confirms the protective role of the *Lycium barbarum* Polysaccharide against osteoporosis risk and maintain thyroid dysfunctions in male albino rats.

Keywords: *Lycium barbarum, Polysaccharide, bone, thyroid gland, male, albino rats.*

Introduction

Hyperlipidemia, a wide term, also called hyperlipoproteinemia or lipemia is the condition in which one of the serum biomarkers of lipid profile is elevated. These biomarkers involve triglycerides (TAG), total cholesterol (TC), and low-density lipoprotein cholesterol (LDL)[1]. Hyperlipidemia is formed due to the potential lack of lipid metabolism or transport of plasma –derived lipids or a disturbance in both generation and degeneration of lipoproteins2.

Hyperlipidemia is now recognized that can be seriously detrimental as a main risk factor for fatty liver, atherosclerosis and stroke[1]. Osteoporosis and cardiovascular disease are the two main diseases related to increase the risks of illness and death in the senility population. Hyperlipidemia, result from many factors like increased dietary consumption or genetic mutations, such as in deficiency of LDL receptor, has pernicious effects on the blood vessels, such as progress the calcification of blood vessels. In hyperlipidemia, much of LDL particles pass to subendothelial space cross the endothelial barrier, where they are convert by reactive oxygen species that created by macrophages and adjacent smooth muscle cells[3]. In human osteoporotic bone a same process happen, the particles of oxidized lipoprotein accumulate in the perivascular subendothelial spaces[4]. Many cells in the bone like Osteoblasts having the ability to modify of lipoproteins particles[3], and produce of lipid oxidation in the bone marrow of hyperlipidemic mice[3,4].

Lycium barbarum L. is one of the Chinese materia medica (CMM) that plays many biological roles. These biological roles may have come from its components that include polysaccharides, zeaxanthin, and cerebroside, betaine, *p*-coumaric acid, and β-sitosterol. Specifically, polysaccharides derived from *Lycium barbarum* (LBP) have been suggested to have influences on different physiological processes such as glucose regulation, antioxidant system, and immunity, antihyperlipidemia, antihypertension, and anticancer[5,6]. Recently, many studies indicated that LBP has antioxidant property which may mitigate the potential DNA damage. Therefore, the current study was conducted to test the efficiency of LBP on hyperlipidemia by focusing on bone parameters and thyroid gland hormones.

Materials and Method

Experiment Design: A total of 45 male albino rats were equally grouped into three sets. The first group (G1) was fed with normal diet and considered as a control group. The second group (G2) was fed with 2% cholesterol-enriched diet for three months to induction of hypercholesterolemia; the third group (G3) was fed with 2% cholesterol-enriched diet +100mg/kg of LBP.

Blood samples were withdrawn after starvation of the animals at night, after the end of three months, when 5 ml of blood was withdrawn from the heart. The blood was then placed in clean plastic tubes, especially the non-containment of anticoagulants. At a speed of 3000 cycles/minute for 15 minutes to measure some of the following parameters: concentration of total cholesterol (TC), High density lipoprotein (HDL), Low density lipoprotein (LDL), Very low density lipoprotein (VLDL), Triglyceride (TAG), Alkaline Phosphatase (ALP), phosphorus (p+), Calcium (Ca+) Parathyroid Hormone (PTH), Thyronine (T3), Thyroxin (T4) and Thyroid stimulating hormone Hormones (TSH).

The concentration of cholesterol, was measured according to method[8], the determination of the concentration of HDL was done by enzymatic method[9]. While LDL was measured according to the Friedewald equation. VLDL concentration can be calculated by dividing the value of TAG by (5)[10], The concentration of triglycerides by enzymatic method was estimated according to the method[11]. ALP, p+, Ca+, PTH, T3, T4 and TSH concentrations were measured by Kits using Enzyme-Linked Immunosorbent Assay (ELISA) using the Axiom Minireader ELISA Reader.

Statistical Analysis: Results were statistically analyzed by using the SPSS program and the correlation coefficient was tested by means of the analysis of variance by complete randomized design (CRD). The least significant difference (L.S.D) was used to show the significance of the results[12].

Results and Discussion

Levels of TC, TAG, LDL, and VLDL were significantly higher among males in G2 compared to G1, while the picture was an opposite direction in the levels of HDL. Hoverer, all these measured biomarkers were not significantly changed in G3 rats compared to that observed in G1 rats (see table 1)

G2 rats had significantly greater levels of PTH, calcium and phosphorus, while ALP levels were significantly reduced compared to that observed in G1 rats. Levels of thyroid hormones (T3 and T4) were significantly decreased, while the TSH levels were significantly increased in the G2 rats compared to that of G1 rats. However, Rats in group 3 did not reveal any significant changes in all measured biomarkers comparing to that values measured in G1.(see table 2,3). any.

Table 1: Effect of Cholesterol at the level of TC, HDL, LDL, VLDL and TAG in serum of male rabbits

Groups / Parameters	(G1)	(G2)	(G3)
TC (mg/dl)	126.26 ± 5.14	163.18 * ± 4.28	130.10 ± 4.41
HDL(mg/dl)	35.41 ± 1.39	26.21 * ± 0.96	36.51 ± 1.08
LDL (mg/dl)	91.31 ± 2.54	102.0 * ± 3.46	94.65 ± 3.14
VLDL (mg/dl)	25.25 ± 0.92	32.63 * ± 1.05	26.02 ± 1.03
TAG (mg/dl)	139.34 ± 4.85	142.59 * ± 5.13	140.74 ± 4.91

Mean ± standard error, *= significant difference

Present study demonstrated that the high cholesterol diet has led to boost the levels of TAG, TC, LDL and VLDLC and down regulated the HDL levels. These results are agreed with many experimental tudies[13]. Excrescent intake of cholesterol results in elevation of serum cholesterol concentration by down regulating LDL receptor synthesis by increase intake of LDL by LDL receptor which leads to elevation of blood cholesterol concentration[14]. Increase levels of lipids oxidative damage has been suggested to be a mediator driving the osteoporosis. In bone, many of bioactive oxidized lipids such as the derived pre osteoblasts and oxidized low-density lipoprotein (oxLDL) could negatively interfere with several differentiation processes of osteoblast[15]. In addition, these molecules may also suppress the differentiation of preosteoblast and mesenchymal stem cells[16]. In the current study, HDL levels were significantly decreased in G2 group, suggesting that hyperlipidemia may have caused elevation of LDL and TG together with increasing risk. Serum levels of HDL were inversely related to risk. This result agreed with[17].

Table 2: Effect of Cholesterol at the level of ALP, p+, Ca+ and PTH in serum of male albino rats

Groups / Parameters	(G1)	(G2)	(G3)
ALP(U/100 mL)	18.11 ± 4.38	12.34 * ± 0.48	16.48 ± 1.03
P+(mmol/L)	4.42 ± 2.23	5.36 * ± 1.54	4.72 ± 1.86
Ca+(mmol/L)	2.59 ± 0.17	3.61 * ± 0.24	2.58 ± 0.91
PTH(PG/Ml)	582 ± 10.34	675 * ± 9.91	597 ± 10.13

Mean ± standard error, *= significant difference

In this study we also confirm that, the high fat diet lead to hyperparathyroidism in rats, by the elevation the concentration of PTH, Ca+ and P+. The calcium measurement in the rats with high fat diet may be pseudohypercalcemia as the result of the turbidity of serum riches with fats[18]. Hyperparathyroidism may result from resistance of renal PTH which leading to retention of phosphate or a change in the calcium-sensing receptor. This may be a negative feedback response due to elevation the concentration of PTH[19]. On the other hand, the down regulation of PTH receptor could be due to detrimental effects of oxidized lipids on bone cells especially the osteoblasts [20]. The increased levels of ALP observed in the current study may indicate that diet with high quantity of cholesterol could have had negative impacts on bone functions. It may have also reduced bone formation and promoted bone resorption[21].

Levels of T3 and T4 were significant decreased and there was an increase in the level of serum TSH in treated group compared with the control group. In hypothyroidism, the effects of thyroid hormone on the expression of LDL receptor and absorption of cholesterol exceed the effects of the cholesterol synthsised by hepatic cells[24]. Greater levels of serum lipids levels in these rats with hypothyroidism are agreed with many studies[25,26]. The abnormality of lipid in hypothyroidism could be linked to the changes observed in serum TSH levels

Table 3: Effect of Cholesterol at the level of T3, T4 and TSH in serum of male albino rats

Groups / Parameters	Rats provided with normal diet (G1)	Rats provided with 2% cholesterol-enriched diet (G2)	Rats provided with 2% cholesterol-enriched diet plus 100 mg/kg LBP (G3)
T3	143.86 9.04 ±	127.83 * 4.28 ±	139.97 4.63 ±
T4	51.05 ± 3.72	22.48 * ± 4.19	48.73 4.51 ±
TSH	1.61 ± 0.21	* 4.62 1.04 ±	1.98 0.28 ±

Mean ± standard error, *= significant difference

Historically, LBP has been used as a source of antioxidant that scavenges the potential effects of reactive oxygen species and in turn minimizing the possible oxidative damage. [27]. The effect of LBP on cholesterol riches diet has been tested in rats in order to evaluate its influence on TC, its LDL, HDL and TAG levels. Rats fed

with LBP and cholesterol were distinguished by increased HDL concentrations and decreased concentrations of TC, LDL and TAG compared with cholesterol enriched rats[28]. This study agreement with many studies[29] which get similar results supported the supposition that supplementation of LBP has a positive effect on the serum lipid by decreasing TC and TAG concentrations. Other study demonstrated that the hypolipidemic effect of LBPs was seen on the hyperlipidemic rabbits. In these animals, LBPs have significantly reduced the s total cholesterol and TAG and increased the HDL-C levels after 10 days of treating with LBPs, LBPs also exhibit effective antioxidant activities against hyperlipidemia. The data from that study highlighted the hypolipidemic and antioxidant effects of LBP [30].

Conflict of Interest: This research is a personal non-profit work and there is no conflict of interest.

Source of Funding: None.

Ethical Clearance: Ethical clearance was obtained from the Faculty Scientific Committee (College of Education for Pure Science, University of Kerbala, Iraq) to Study the effect of Lycium barbarum Polysaccharide on bone and thyroid gland in hyperlipidemic healthy male albino rats.

Effect of Exposure Biochinin-A During Gestation Stage on HoxA10 Gene Expression and Histological Change in Uterus of Healthy Female Rats

Huda A. Najy[1], Ayyed H. Hassan[1]

[1]College of Veterinary Medicine, University of Kerbala, Karbala, Iraq

ABSTRACT

The aim of this study is to estimate effect of exposure BC-A during gestation stage onHoxa10 mRNA expression with histological change in uterus of female rats. This study include Sixty mature female rats were meted with thirty males after making sure all female rats get pregnant. Sixty pregnant females were divided for 5 groups each groups contain 12 female rats as fallowing (control negaative, control positive, 25mg/kg, 50mg/kg, and 100mg/kg) B.W, during gestation in 12th,14th,16th, and 18th *utero* –exposure to BC-A. The pregnant rats were allowed to deliver F1 pups. Adult F1femle rats were also mated with male. HoxA10 mRNA expression was measured by using RT-PCR procedure. Our result found the HoxA10 mRNA expression level were increased more in dose 100 mg/kg B.W. in uterus of female rats compared with doses 25,50 mg/kg B.W. and control groups of F1 mature rats. While, there were histopathological changes generally including uterine hyperplasia, cystic endometrial hyperplasia (CEH), congestion and bleeding in the myometrium and enlargement in the cells lining uterine gland with reduce the number of uterine gland. In conclusion: The BC-A is exposure to during embryonic growth in uterus leads to changes in the level of gene expression of HoxA10 gene. As well as, lead to change in histological of uterus, which affects the reproductive health.

Introduction

These days, as the responsibility on endocrine disturbance were different combinations of compositions of blend that numerous antagonistic influenced the humans and animals or descendants by means of cooperate with endocrine disturbance[1]. Endocrine upsetting are exogenous substance that meddle with hormones combination, digestion, or activity. Furthermore, some of them could epigenetic modification of DNA that can be transmitted to the accompanying ages. The embryo is touchy to any change of hormone condition[2]. Biochanin -A an isoflavone phytoestrogens present in red clover that was a specifically agonist at ER-β estrogens receptor[3]. Perinatal presented to phytoestrogens nourishment could be affecting on ovarian cells in the develop rodents become a few initiation material since[4]. Biochanin An, a non-steroidal estrogen present in plant, dietary-inferred biochanin A mixes show different estrogenic and antiestrogenic consequences for estrogen-related quality articulation, recommending quality explicit guideline[5]. The hox quality family coordinates appropriates morphological improvement and tissue separation along all the key hub of the embryo[6]. HoxA10 quality is the organogenesis of mullerian regenerative tract. HoxA10 is communicated in the uterine epithelium, stroma and muscle. In situ hybridization of HoxA10 mRNA uncovers solid articulation in the uterus, however no articulation in the fallopian tube, cervix or vagina[7]. In Hox A10 quality – a quality is vital for uterus advancement, it is fascinating to take note of that hoxa10 DNA methylation was not adjusted in grown-up mice treated with same of phytoestrogen, it features the incredible defenselessness of the baby and the presence of basic formative window for the epigenetic impacts of EDC[8]. Presentation to estrogenic synthetic substances

amid fetal life disturbs female conceptive tract developmental[9]. The impacts of formative introduction to phytoestrogen on uterine morphology and function[10]. By adjustment in endometrial stromal morphology[11]. Notwithstanding local differentiation, the endometrial epithelium experiences glandular morphologensis to shape spread glandular structures in endometrial stroma. These cell and provincial separation stroma. These cell and territorial separation forms are stunningly delicate to interruption by steroid hormone singling[12].

Materials & Method

Animals of the Study: The experimental animal model selected for present study is (Rattus Norvegicus) rats were obtained from the Laboratory Animal Unit, College of Medicine, University of Baghdad, Iraq. They were 16 to 18 weeks old with an average body weight (200-250gm) for females and (250-300gm) for males. The animals were clinically healthy, kept under hygienic conditions and air-conditioned room. The light system was 12/12 hrs light/dark cycle;25 ± 5 C° with a relative humidity of 50 ± 5%. Food & water were offered daily, the animals were accommodated to the laboratory Collage of Veterinary Medicine, University of Kerbala, Karbala, Iraq conditions for 30 days before beginning of experiment for acclimation then randomly divided into four groups comprising 12 animals for each group as the following:

G1: Female Rats were given DMSO (IP) & served as control negative

G2: Female Rats were given Estradiol (IP) at dose 5mg/kg B.W & served as control positive.

G3: Female Rats were given Biochinin-A(IP)at dose of 25mg/kg B.W

G4: Female Rats were Biochinin-A (IP) at dose 50 mg/kg B.W.

G5: Female Rats were given Biochinin-A(IP)at dose of 100 mg/kg B.W.

The tested compound is Biochanin-A(BC-A): The test chemical used in this experience is BC-A acquirement from Sigma Chemical Company, USA[13].

Tissue sample: For histological analysis of the uterus to organize the architecture changes and for assessment of mRNA expression level of target gene (HOX10 A):

1. **Histological examination:** The tissues were promptly fixed in formalin (10%). After fixation, tissues were handled in common way and implanted in paraffin for consequent histological examination of uterus. The histological area was assessed by a pathologist earlier learning of BC-A given to creatures done according to[14].
2. **Tissue preparing for expression level of HOX10A gene:** The tissues were placed quickly in normal slain then freezing in -20 c°. Total RNA extraction :Total RNA were extracted from rat uterus horn by using Accuzol Total RNA Extaction Reagent(Bioneer, Korea) and done according to[15].

Primers: Two primers were used in this study, first primer used for 18S gene as Housekeeping gene and second primer used for **HOXA10** gene as target gene. These primers were obtained from[16], the primers used in quantification of gene expression using qRT-PCR techniques based SYBER Green DNA binding dye, and supported from (Bioneer, Korea) company.

Table 1: The Primers and their sequences

Primer	Sequences		(G-C) Amplicon size
HOXA10	F	5′-AACAGTAAGCCTCTCGGA-3′	50 bp
	R	5′-TGCTTCGTGTAAGGGCAGC-3′	57 bp
Housekeeping 18s	F	5′TAAGTCCCTGCCCTTTGTACACA-3′	47 bp
	R	5′GATCCGAGGGCCCTCACTAAAC-3′	59 bp

RT-PCR protocol: Get ready GoTaqR 1-Step RT-qPCR Reaction Mix as a response blend that involvement: Go TaqR 1-Step RT-qPCR Master Mix, CXR dye, nuclease - free water and Go Script™ RT Mix. Conclude the numerous of control and experimental reactions in the assay according to[17].

Static analysis of qRT-PCR: the information consequences of q RT-PCR for target and housekeeping quality were broke down by relative evaluation quality articulation levels (fold change) Livak method that explained by[18].

	Test	Calibrator (cal)
Target gene	CT(target, test)	CT(target, cal)
Reference gene	CT(ref, test)	CT(ref, cal)

Calibrator sample:

ΔCT (calibrator) = CT (ref, calibrator) – CT (target, calibrator)

Test sample:

ΔCT (Test) = CT (ref, test) – CT (target, test)

ΔΔCT= ΔCT (test) – ΔCT (calibrator)

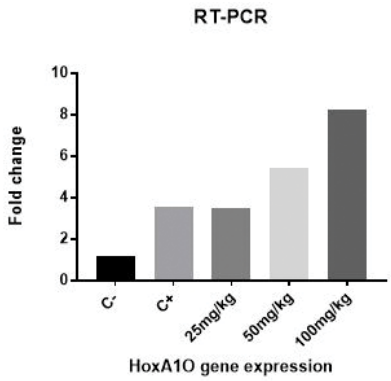
Fold change = 2-ΔΔCT

Ratio (reference/target) = 2CT (reference) – CT (target)

So, the relative expression was divided by the expression value of a chosen calibrator for each expression ratio of test sample.

Results

Reverse transcriptase real-time PCR results presented that HOXA10 mRNA expression level were increased more than in dose 100mg/kg female rats compared with doses 25mg/kg,50mg/kg and control group of female mature rats. The results of this calculations offered the relative expression is (8.229) fold higher in alternative in dose 100 mg/kg. While, in dose 50 mg/kg (5.419) .and in dose 25 mg/kg the fold change (3.449) than in control positive higher (3.557). Fold is lower in control negative (1.152).in table (4-2-6). Again, in time at which all the alternative dose of BC-A produces increased in hoxa10 gene expression Treated groups and with each of other groups, a matter which contribute to significant differences at (P≤0.05).



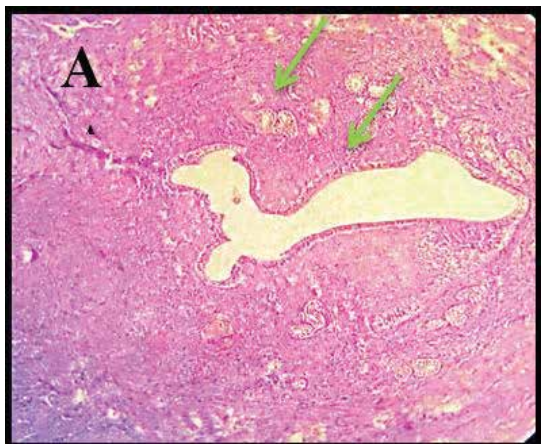


Fig. 1: Effect of BC-A exposure on uterine HOXA10 expression was measured by relative RT-PCR in different dose of BC-A utero-exposure

The effect of BCA on female Uterus Histology: The uterus of rat perinatal treated with BC-A in doses (25 mg/kg,50mg/kg,100mg/kg) B.W. there was histopathological changes generally including uterine hyperplasia, cystic endometrial hyperplasia (CEH), congestion and bleeding in the myometrium and enlargement in the cells lining uterine gland with reduce the number of uterine gland.

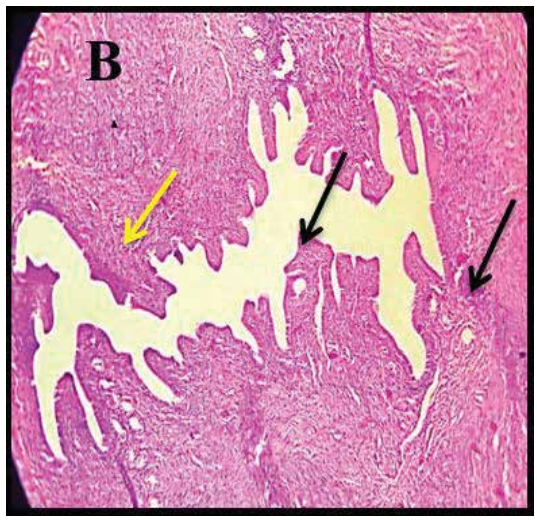

Fig. 2

A: Light micrograph of histological changes in normal uterus of female rats (green arrows) shows normal in cells lining endometrium and uterine gland. H&E, 10x.

B: Light micrograph of histological changes in uterus of female rats perinatal exposed to BC-A in 100mgkg B.W shows the (yellow arrow) uterine hyperplasia in endometrium of uterus. (black arrow) cystic endometrial hyperplasia (CEH). H&E, 10x.

C: Light micrograph of histological changes in uterus of female rats perinatal exposed to DES control positive. shows (black arrow) enlarged cell lining uterine gland. H&E,10x.

D: Light micrograph of histological changes in uterus of female rats perinatal exposed to BC-A in 25mg/kg B.W shows the (yellow arrow) uterine hyperplasia in endometrium of uterus (black arrow) enlarged cell lining uterine gland. H&E, 10x.

E: Light micrograph of histological changes in uterus of female rats perinatal exposed to BC-A in 50mgkg B.W, (black arrow) cystic endometrial hyperplasia (CEH). H&E, 10x.

Discussion

In this present study, we have been researched that effect of the BC-A (phytoestrogens) on hoxa10 gene expression in uterine during gestation stage to fetus in vitro life's results in changed in reproductive dysfunctional via changing HoxA10 expression. In present study have been alteration in HoxA10 expression in various doses due to effect of BC-A, the higher dose 100mg/kg cause uterine histology, hypertrophy and disrupt female fertility. The HoxA10 is important for continuing adult expression in stroma, muscle, uterus and epithelium gland also in normal development of mullerian duct[19]. The HoxA10 was activated by steroid hormone when bind to endometrial receptor that lead to regulation cell differentiation, it caused on endometrium responsive to embryonic development[20]. The HoxA10 is a basic of development immure mesenchymal cell to endometrial tissue[21]. Estrogen is a potent promster of HoxA10 gene through stimulation of stroma and endometrial during control steroid hormones during development stage[22]. The growth and development of female fetus is very sensitive to any components or compounds estrogens[23]. The exposure to BC-A during pregnancy effects on development and growth of uterus and this similar when treated neonataly or during pregnancy to DES[24]. The HoxA10 gene expression during exposure to BC-A to BC-A appears to associated with uterine dysfunction. Gene expression is assign of hormonal imbalance. The histologic evaluation of uterus[25]. In the present study where exposed perinatal to BC-A in different dose (25,50,100) mg/kg B.W. We have been shown the bad effect of BC-A on the activity of estrogen leading to dysfunction in female reproduction system. Light micrograph of histological changes of the uterus rat perinatal treated with BC-A in doses (25 mg/kg,50mg/kg,100mg/kg) B.W. there were histopathological changes including cystic endometrial hyperplasia (CEH), bleeding in the myometrium uterine, hyperplasia, congestion and enlargement in the cells lining uterine gland with reduction the number of uterine gland with enlargement of cell lining uterine gland and uterine hyperplasia in endometrium. The incidence of uterus lesions was described, and this is in accordance with the recent data on the potentially carcinogenic alterations in female reproductive tissues caused by decrease pre-natal doses of xenoestrogen[14]. The exposure to DES during critical stages of pregnancy lead to reprogramming of uterus and this responsible

for changes in the level of estrogen during a lifetime[26]. The exposure to BC-A during uterine organogenesis cause changes in level of DNA and increases the gene expression of estrogen receptors as ERβ in the endometrium[27]. This may increase height of endometrial epithelia[28].

Conflict of Interest: This research is a personal non-profit work and there is no conflict of interest.

Source of Funding: None.

Ethical Clearance: Ethical clearance was obtained from the Faculty Scientific Committee (College of Veterinary Medicine, University of Kerbala) to Study the effect of exposure biochinin-A during gestation stage on HoxA10 gene expression and histological change in uterus of healthy female rats.

ABSTRACT

Background: There is an increase of forward head posture among university students due to faulty posture in their daily activities. Age, gender, usage of computer and smart phones are one of the contributing factors of forward head posture.

Methodology: This cross-sectional study was conducted to determine the prevalence of forward head posture and to investigate the associated risk factors that contribute to the development of forward head posture. 188 participants were recruited in the current study with pre-defined inclusion and exclusion criteria. The participants were screened with demographic questionnaire, followed by the cervical angle measurement using photography method. Then, the angle measurement was analyzed using web plot digitizer (WPD) software.

Results: 67 % of participants were identified with forward head posture while 58.5% were not aware of forward head posture. Only computer and smart phones showed significant association with forward head posture.

Conclusion: There is a need of intervention and education on awareness of good posture especially with increased usage of computer and smart phones in recent days.

Keywords: *forward head posture, computers, smart phones, risk factors, university students*

Introduction

Forward head posture has been identified as the displacement of the head anteriorly with cranio-vertebral angle lesser than 50 degrees. [1,2] While the head displaced forward, the centre of gravity also shift and consequently, causes the upper body to shift backward with the shoulder slumped. [3–5] Sustaining the head in this forward posture for prolonged period of time has been associated with the development of other musculoskeletal disorders such as 'upper crossed syndrome', which leads to reduction of lordosis in lower cervical and kyphosis of upper thoracic vertebra. [6,7] In the long run, this may cause shortening of muscular fibers muscles involving the atlanto-occipital articulation, overstretching of muscles around joint and leads to chronic neck pain. [8]

In a study among university students in Pakistan, prevalence of 63.96 % of forward head posture were reported. [1] Whereas in another study among dental staff, 85.5 % reported of forward head posture. [9] In another study among healthy subjects, 66 % reported of forward head posture and they fall under the age range of 20-60 years old. [10] The increase of forward head posture at alarming rate especially among young adults is worrisome. Nevertheless, there is no evidences on the prevalence rate of forward head posture among students in Malaysia. Hence, there is a need for a study to determine the prevalence of forward head and an early intervention in preventing the faulty posture.

There are many factors that could contribute to the development of forward head posture such as age[10], gender [11–14], frequency of physical activity [15,16], occupation [4], usage of computer and smartphones [4,17] and others. However, there is lack of literature addressing the prevalence of forward head posture among university

students in Malaysia. Besides, no studies have examined all the associated risk factors together that influence the development of forward head postures. Thus, the aim of the current study is to determine the prevalence of forward head posture and to investigate the associated risk factors that contribute to the development of forward head posture among university students.

Methodology

Subjects: A cross-sectional study was conducted to determine the prevalence of forward head posture among university students. This study was conducted among four private universities in Klang Valley, Malaysia with total of 188 participants thru convenience sampling method. The participants were selected with predefined inclusion and exclusion criteria. Selected participants were between the age of 18 to 30 years with good general health. Participants with history of cervical and shoulder fracture or trauma, cervical surgery, functional or structural scoliosis, bone cancer or had excessive thoracic kyphosis were excluded from the study. [18–20]

The first author briefed the study methodology to the participants and written informed consent was obtained prior to the study. The Research Ethics Committee of INTI International University, Malaysia approved the study.

Procedure: The participants were given a demographic questionnaire that includes, age, gender, BMI, usage of computer and smart phone daily as well as the awareness towards forward head posture. The C7 spinous process was palpated and identified with a marker which was attached over its midpoint of the most prominent part. The participants were then instructed to stand at their comfortable stance and not allowed to shift their body weight from one foot to another. Participants were required to flex and extend the head for three times and then look forward while resting in a comfortable position. [18]

Participant's cervical angle were analyzed by taking a photo from the sagittal view. The measurement was standardized as the distance from the participant's shoulder tip to the center of the camera were set at 30cm in standing position. [20] The photos were transferred to the computer and analyzed using Web Plot Digitizer (WPD) software, an open resource, used to retrieve quantitative data from images (http://arohatgi. info/WebPlotDigitizer/). The cervical angles were quantified according to previous study angle measurement methods with a virtual line was drawn between the midpoint of tragus to C7 spinous process and a horizontal line through the spinous process of C7 using WPD software **[Figure 1].** [19,21] Forward head posture was indicated with high decrease in the cervical angle measurement.[22–24].

Figure 1: Reading from WPD software represents craniovertebral angle when two indicator lines were aligned with pin markers (seventh cervical [C7] vertebra spinous process) and tragus

Statistical Analysis: Data were analyzed using statistical software package SPSS (Version 21.0, Chicago, IL, USA). The data were normally distributed based on the Shapiro-Wilk test. Descriptive statistics were used to examine the prevalence and awareness on forward head posture among the university students using frequencies. A Chi-square test was employed to investigate the relationship between forward head posture and risk factors such as age, gender, computer and smartphone usage daily.

Results

Prevalence and Awareness of Forward Head Posture: In the current study, 67% participants were identified with forward head posture. Based on the WPD analysis, the highlighted green group indicates participants with minimal or non-FHP (≥55º cervical angle) whereas the red group indicates severe FHP with <50º of cervical angle. Participants with moderate FHP falls under cervical angle 50º - 54º of CV angle **[Figure 2]**. The results also reveal that 58.5% participants were not aware about the forward head posture. The mean (SD) of the participant's age were 20.12 (2.19).

Forward Head Posture and Age: The age distribution was shown in **Figure 3**. Results revealed that most of the participants with forward head posture were aged between 18-21 (45.2%). The results of the Chi-square demonstrated that there was no significant association between age and forward head posture ($p = 0.625$).

Forward Head Posture and Gender: The number of male and female participants was 74 and 114. The

prevalence of forward head posture (moderate and severe category) among male and female participants was 67.57% (50/74) and 66.67% (76/114) respectively. The results show that the prevalence of forward head posture among male participants is slightly higher than female participants. The Chi-square analysis demonstrated no significant association between gender and forward posture (p = 0.991).

Forward Head Posture and Usage of Computer Daily: The prevalence of forward head posture (moderate and severe category) among the participants of computer use daily between 1 to 5 hours were 41.9% (44/105), 6 to 10 hours were 98.3% (59/60), 11 to 15 hours were 100% (21/21) and more than 15 hours were 100% (2/2) respectively. The use of computer of more than 6 hours per day have shown high number of forward head posture prevalence. The Chi – square analysis demonstrated significant association between duration of computer use daily and forward head posture (p = 0.000).

Forward Head Posture and Usage of Smart Phone Daily: The prevalence of forward head posture (moderate and severe category) among the participants of smart phone use daily between 1 to 5 hours were 23.38% (18/77), 6 to 10 hours were 95.16% (59/62), 11 to 15 hours were 100% (41/41) and more than 15 hours were 100% (8/8) respectively. Similar to computer usage, smart phone usage of more than 6 hours per day also shows high number of forward head posture prevalence. There is a significant association between smart phone usage and forward head posture (p = 0.000).

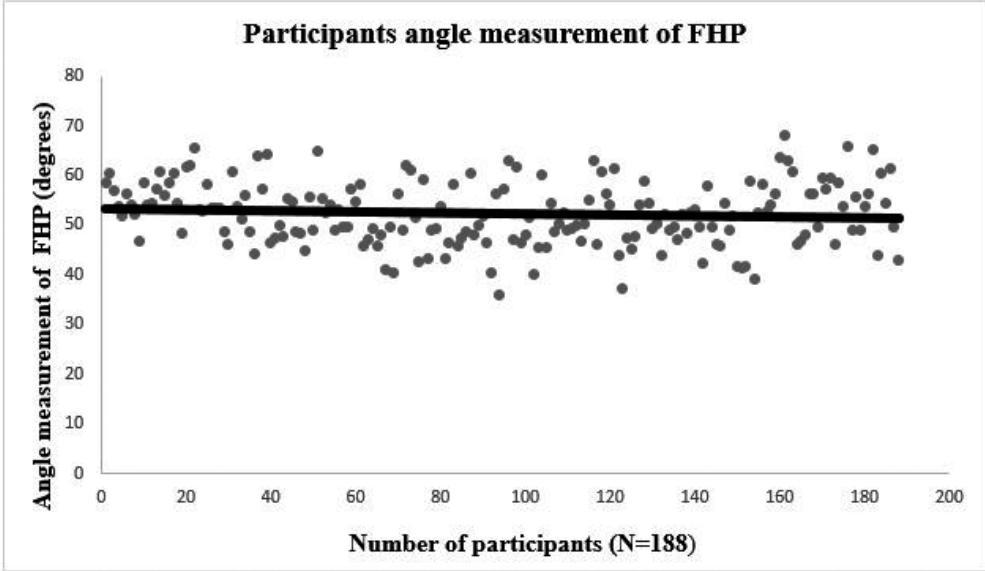

Figure 2: Scatter Plot showing CV angle of each participants

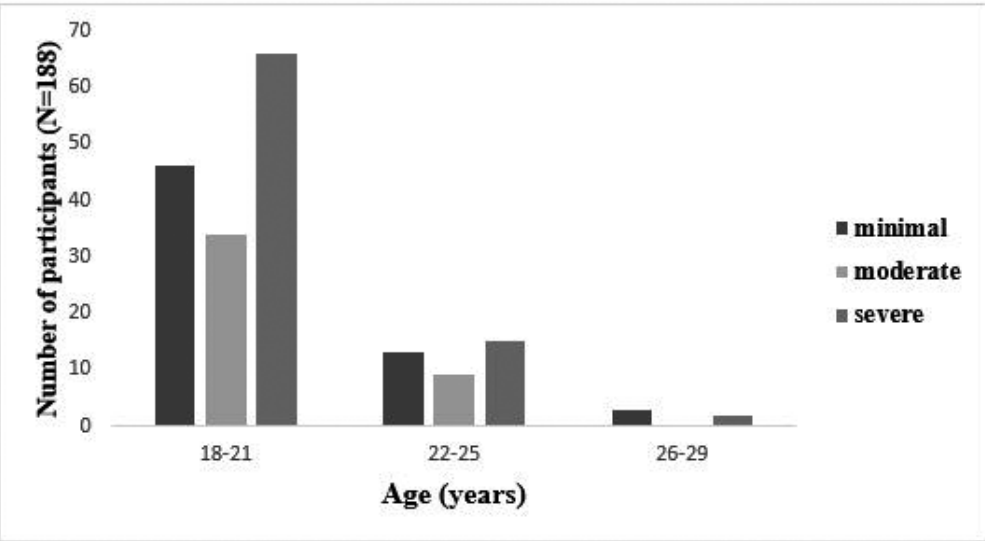

Figure 3: Age distribution of participants

Discussion

The prevalence of forward head posture among 188 university student in the current study is 67% whereas 58.5% of student reported not aware of forward head posture. In another similar study conducted by Arfa et al. among 197 students from four universities in Pakistan, the prevalence of forward head posture was 63.96%. The same study concluded that the high prevalence among the university student could be possibly due to high usage of computers and faulty postures during lectures.[1]

The current study reveals no significant association between forward head posture and age, although a high percentage of 45.2% of participants aged between 18 – 21 reported of forward head posture. This could be possibly due to the usage of computer and smart phones more in this university age range compared to others. [10] There is a significant relationship between computer and smartphone usage with forward head posture in our current study. Previous study has stated that with the increase usage of computers located below eye sight for prolong period of time causes exaggerated anterior curve in lower cervical vertebra and exaggerated posterior curve in upper thoracic vertebra establishing the forward head posture. [4,25] These symptoms are more prominent with the increase of smart phones usage among youth. [4] In the long run, with the protrusion of head forward and shift of centre of gravity anteriorly consequently will lead to posture imbalance and reduced motor control ability of the individuals.

The usage of smart phone in a sustained, static posture with an unsupported arm could induce misalignment of neck and shoulder. ([17]) This is being further explained where the usage of small monitors of smart phones with the device held on the laps causing the individuals to position their head down, increasing the muscle activity in the cervical extensors and eventually triggering muscle fatigue. [26] In fact, many previous studies have also reported positive association between the usage of computer and smart phones with forward head posture similar to our study. [17,26,27] Therefore, the current study emphasizes the importance to create an awareness on the correct posture and consequences of forward head posture in the long run as prolong use of computer and smart phones may induce changes in cervical and even the thoracic and lumbar spine posture.

The limitation of current study is the generalization duration usage of computer and smart phone in the questionnaire as in if the students used the devices for social media, assignment used, entertainment or gaming purpose in the questionnaire. Future studies should examine the responsiveness of the WPD software in longitudinal study for better accurate reliable result. The ability to identify the cervical angle might differ time to time, thus, future studies focusing over the same participants over a length period of time is suggested.

Conclusion

A high prevalence of forward head posture has been identified in the current study among the university student. The current study also indicates a significant association between the computer and smart phone usage with forward head posture. The significant forward head posture differences between these students needed to be intervened as it may affect the health in future. This study, hence, provides evidence for existing data and further emphasize the importance of good posture education and physical exercises for the students.

ABSTRACT

In this new era of globalization, Business organizations around the world are struggling to develop effective quality measurement parameters, and strategies to survive in competition, and to achieve customer satisfaction, business organizations such as hospitals must be able to understand the needs, desires and expectations of customers and be able to create value. This study aims to explore the value of patients according to Bugis Philosophy at the Regional Public Hospital in South Sulawesi. The study was conducted at 4 hospitals in 4 regency where the majority of the population were ethnic Bugis namely Siwa Regional Public Hospital WajoRegency, LamadukellengRegional Public Hospital SengkangRegency, TenriawaruRegional Public Hospital Bone Regency and AndiMakkassau Hospital Pare-Pare City in South Sulawesi Province. The research method is qualitative. The results of this study indicate that identification of customer needs in terms of health care services is good even though medical devices are not complete. The underlying reason for patients to choose treatment is mostly because the distance is close enough, good and complete health services, and referral factors from the health center.Health services that should be available in hospitals are improving health services that are prime for all aspects both in terms of nurse care and doctor's vision.The types of services or other supporting facilities needed are still lacking, and presumably the hospital allows families to come to visit even though briefly. The conclusion of this study is that patients' needs related to health services from all aspects are classified as not running optimally because it is caused by several factors such as lack of health human resources (expert doctors), incomplete health equipment, and other supporting facilities that are not yet available. (Marenrengperru') between families within the scope of the region it is advisable to maintain the existing bugis values without violating the rules that apply within the scope of the hospital.

Keywords: *Value, patients, Regional Public Hospital, Bugis Philosophy,*

Introduction

In this new era of globalization, business organizations throughout the world are struggling to develop effective measurement tools for quality measures, and strategies for survival in competition.[1] With increasing competitive competition in the global economy, profitability, requiring more than good products and services, a business must provide customers with unforgettable satisfaction. [2] The health industry is considered to be one of the most challenging sectors in the face of increasing pressure in the health sector, and the introduction of new technology needs attention in its implementation.[3]

On the one hand, the development of information technology makes people more intelligent and demands superior service quality.[4] This is also influenced by the number of service options presented which are marked by the development of the hospital industry. Modern hospital management systems must provide *customer focused services*, which means that the hospital must be able to understand the needs, desires and expectations

of customers and creating valuein providing services in order to achieve satisfaction and be able to survive competition.[5]

The results of research show that trust in satisfaction is smaller than the indirect effect of trust in satisfaction through customer value. This is also supported by the results of research conducted by Indrianty which shows that the dominant variable to increase the lifetime value of customers for the public is the brand equity value for public hospitals, while those in private hospitals do not show a significant difference. [6,7]

South Sulawesi Province which has various tribes and languages including ethnic and Bugis languages. Bugis language is one of the language groups spoken in the Bone area to Pinrang, Sinjai, Barru, Pangkep, Maros, Pare – Pare,Sidrap, Wajo, Soppeng, this language is the language most used by the people of South Sulawesi.In Bugis tribal culture there are three things that can give an idea of the culture of the bugis, namely the concept of *ade, sirinapesse*and the symbolism of the bugis is the silk sarong.[8]

Bugis ethnics that have theideology*Siri Na Pecce* which include the existence of the nature of *Sipakalebbi*(sip*k*lEbi) which is horizontal mutual respect including *Ada Na Gauk(ad ngau)*namely words according to deeds, *Teppe* (tEpE) namely belief, acknowledging self-servant*Sipakatau* (sipktuuau) namely mutual respect, mutual respect as servants (humanity), *Mamase* (mmes) which is friendly in speaking, always showing affection, *Malempu(*mlEuuPu) u are honest, honest,*macca*(mc), which is smart, smart *MarenrengPerru* (mereREpru) which is faithful, symbolizes a very close family relationship.[9]

Based on the above, cultural aspects need to be considered in providing daily services at the Hospital. This study will explore the needs of patients according to value through the service experienceof ethnic Bugis patients at the South Sulawesi Regional Public Hospital. The focus of the research lies in exploring the needs of patients for the Regional Public Hospital in South Sulawesi based on local wisdom, namely Bugis philosophy.

Materials and Method

Type of research used is descriptive qualitative research with anapproachethnographic. Samples were taken based on the minimum number of needs with the technique of collecting data with indepth interviewsand observationsfor inpatients during November-December 2018 as informants.

Results

A. Characteristics of Informants The: Number of informants was 32 people from 4 Regional Public Hospitals in South Sulawesi, consisting of 13 male and19 female. In this research the theme was compiled based on the purpose of the research, namely identifying customer needs in accordance with the philosophy of Bugis in this case the patient with ethnic Bugis in several Regional Public Hospitals in South Sulawesi Province.

B. Identification of Customer Needs

a. for Health Workers in

1. **SiwaRegionalPublicHospital,WajoRegency:** Experience informants on services provided by health workers both doctors and nurses while being treated at the Regional Public Hospital of WajoRegency. From the interviews, some opinions were conveyed by the informants, most of whom said that the services provided by doctors and nurses at SiwaRegional Public Hospital were good and they served quickly and friendly even though the medical devices were not complete but still made patients feel comfortable.
2. **TenriawaruRegional Public Hospital, BoneRegency:** Experience of informants on the services provided by health workers both doctors and nurses while being treated at the Tenriawaru Regional Public Hospital in Bone Regency. From the results of the interviews, several opinions were conveyed by the informants, namely all informants said that the services provided by doctors and nurses were good and they served kindly and quickly.
3. **LamadukellengRegional Public Hospital, Sengkang Regency:** Services provided by doctors and nurses are good and they serve fast, responsive, friendly and polite especially the doctors and nurses are diligent to visite, even though the ICU is not conducive because visitors are smoke-free in the ICU, but do not reduce patient satisfaction at the hospital. From the results of the interviews, several opinions were conveyed by the informants.

4. **AndiMakkassau Hospital, Pare-Pare City:** From the interviews most of the informants said that the given at AndiMakkassau Hospital, Pare-Pare City is pretty good and they serve quickly.

b. Reasons for Selection of the Hospital as a place Treatment

1. **Siwa Regional Public Hospital in WajoRegency:** The underlying reason for informants to choose SiwaRegional Public Hospital as a place of treatment is mostly because it is close to home, good service, complete specialist doctors and referral factors from the Puclic Medical Center.
2. **Tenriawaru Regional Public Hospital Bone Regency:** The underlying reason for the informant was to choose Tenriawaru Regional Public Hospital mostly because they already had experience in the hospital, besides also because of the complete medical doctors, complete medical devices, good service and due to reference factors.
3. **LamadukellengRegional Public Hospital, Sengkang Regency:** The reason for choosing LamadukellengRegional Public Hospital, SengkangRegency for treatment is because the distance is quite close, good service, complete specialist doctors, friendly nurses, and complete health services. The following is an interview quote about this.
4. **AndiMakkassau Hospital, Pare-Pare City:** The reason underlying the informant for choosingAndiMakkassau Hospital of Pare-Pare City for treatment is because the distance is quite close, good and complete health services, a complete specialist doctor, and already classified as type B which is certainly one of the referral center hospitals.

c. Health services that should be available at the Hospital

1. **SiwaRegionalPublicHospital,WajoRegency:** Health services that should be available in hospitals are improved health services for all aspects. From the interviews, some opinions were conveyed by the informants, most of whom said that the health services that should be provided by doctors and nurses at SiwaRegional Public Hospital were the improvement of primary health services related to doctors being more patient to patients and visite time in the morning.
2. **TenriawaruRegional Public Hospital, Bone Regency:** Health services that should be available at the hospital are improved health services for all aspects. From the interviews, some opinions were conveyed by informants, most of whom said that the health services that should be provided by doctors and nurses at the TenriawaruRegional Public Hospital were the improvement of their main health services related to doctors being more patient and visite time in the morning.
3. **LamadukellengRegional Public Hospital, Sengkang Regency:** Health services that should be available in hospitals are to improve the quality of excellent health and nursing health services and maintain performance. From the interviews, some opinions were conveyed by informants, most informants said that health services should be provided by doctors and nurses in LamadukellengRegional Public Hospital, Sengkang Regency, whose quality of health and nursing services was related to doctors as much as possible to visit patients, quickly and responsive in serving other than that the hospital tightened the rules regarding smoking bans for buyers.
4. **AndiMakkassau Hospital Pare-Pare City:** Health Services what should be available at the hospital is improving the quality of excellent health services and increasing care for nurses. From the results of the interviews obtained several opinions conveyed by informants namely Most of the informants said that health services should be provided by doctors and nurses in theAndiMakkassau Hospital of Pare-Pare City is to improve the quality of health and nursing services.

d. Patient Experience During Care at the Hospital

1. **SiwaRegionalPublicHospital,WajoRegency:** Various patient experiences during hospitalization are very diverse. From the results of interviews conducted, some experiences were conveyed by informants,

namely informants who said that the experience of patients related to the services provided while being treated at SiwaRegional Public Hospital is more attention to the equipment available at the hospital so that everything functions properly such as oxygen cylinders

2. **TenriawaruRegional Public Hospital, Bone Regency:** Patients' experiences while being treated in hospitals are very diverse. From the results of interviews conducted, some experiences were conveyed by informants. Some informants said that the experience of patients related to the services provided during treatment at the Tenriawaru General Hospital was the doctor's lack of attention to visit the patient, besides the visiting hours at the hospital were good so does not interfere with the patient's resting hours, and one informant said that the hospital should not differentiate services between Health Insurance (*BPJS*) patients and general patients.
3. **LamadukellengRegional Public Hospital, Sengkang Regency:** Various experiences of patients while being hospitalized are very diverse. From the results of interviews conducted, some experiences were conveyed by informants, namely patient experience related to the services provided while being treated at LamadukellengRegional Public Hospital, Sengkang Regency, good service and able to maintain the quality of existing health services and improved for all aspects both in terms of nurse care, doctor's vision, and visiting hours are tightened
4. **AndiMakkassau Hospital Pare-Pare City:** Various patient experiences while in hospitalization is very diverse. From the results of interviews conducted, some experiences were conveyed by informants, namely the experience of patients related to the services provided while being treated at theAndiMakkassau Hospital of Pare-Pare City, a good service and able to maintain the quality of existing health services and improved for all its main aspects nurses and applicable rules can be applied properly.

e. Types of services or other supporting facilities needed by

1. **Siwa Regional Public Hospital, Wajo Regency:** Various suggestions related to the types of services or other supporting facilities needed but not yet available in hospitals, especially SiwaRegional Public Hospital so far are still lacking, and hospitals should complete facilities so that patients feel more comfortable while being treated. From the results of interviews conducted, most of the informants said that other types of services/supporting facilities needed at the SiwaRegional Public Hospital were still lacking so far, and the hospital should complement these facilities.
2. **Tenriawaru Regional Public Hospital, Bone Regency:** Various suggestions regarding the types of services or other supporting facilities needed but not yet available in hospitals, especially TenriawaruRegional Public Hospital, BoneRegency has so far been quite good and already complete and make patients feel comfortable.
3. **Lamadukelleng Regional Public Hospital, Sengkang Regency:** Various suggestions regarding the types of services or other supporting facilities needed but not yet available in hospitals, especially LamadukellengRegional Public Hospital, Sengkang Regency, so far have been quite good, and the hospital should complete facilities such as water supply and additional care rooms stays can be given barriers such as curtains so that patients feel more comfortable while being treated in LamadukellengRegional Public Hospital, Sengkang Regency
4. **AndiMakkassau Hospital, Pare-Pare City:** Various suggestions regarding the types of services or other supporting facilities needed but not yet available at the hospital especially AndiMakkassau Hospital, Pare-Pare City as far as this is good enough, it's just that the hospital should equip facilities such as fans or air conditioners need to be added and cleanliness is maintained so that patients feel more comfortable while being treated byAndiMakkassau Hospital, Pare-Pare City**.**

Opinions related to the extended family who came to visit (MarenrengPerru') (mereREpru)

1. **Siwa Regional Public Hospital, WajoRegency:** Opinions of informants regarding large families who came to visit and there were limits to visiting hours were considered good enough, only the hospital allowed the families who came to visit all of them even though briefly because of mutual caring between families was still high (Marenrengperru') (mereREpru).
2. **TenriawaruRegional Public Hospital, Bone Regency:** Opinion of the informants related to the extended family who came to visit and there are limits to visiting hours as far as This was considered considered to be lacking, it was better for the hospital to add visiting hours and it would be possible to allow the families who came to visit even though for a while because of mutual caring between families (Marenrengperru') (mereREpru).
3. **Lamadukelleng Regional Public Hospital, Sengkang Regency:** Opinions of informants regarding large families who came to visit and there were limits on visiting hours were considered good enough so far, only the hospital allowed families to come to visit take turns because the sense of mutual care between families is still high (Marenrengperru') (mereREpru), besides that patient guards can be added according to the patient's situation and condition.
4. **AndiMakkassau Hospital Pare-Pare City:** Opinions of informants regarding large families who came to visit and there were limits to visiting hours were considered good enough so far, only the hospital would allow the families who came to visit all of them while they were still visiting hours, do not be too tightened on the rules of the visiting hours because the sense of mutual care between families is still high (Marenrengperru') (mereREpru).

Conclusion

Conclusion of this study is at the South Sulawesi Provincial Regional Public Hospital, namely SiwaRegional Public Hospital, WajoRegency, TenriawaruRegional Public Hospital, Bone Regency, LamadukellengRegional Public Hospital, Sengkang Regency and AndiMakkassau Hospital, Pare-Pare City needs of patients related to health services from all aspects classified as not yet running with optimally because it is caused by several factors such as lack ofS health human resources (expert doctors), incomplete health equipment, and other supporting facilities that are not yet available. In addition, because of the still high value (Marenrengperru') (mereREpru) between families within the region, it is advisable to maintain existing bugis values without violating the rules that apply within the scope of the hospital.

ABSTRACT

This study is a design and development-based research which intends to develop a module specifically to be implemented on adolescents to help enhance their emotional competence and also to test the content validity of the module. Seven professionals with experience in dealing with adolescent emotional issues were recruited to validate the module. A rating scale based on this is constructed to be evaluated by the professionals. The overall validity was calculated based on the percentage of agreement between the professionals. The Emotional Competency Module received an overall validity rating of 85.6%. Therefore, there is evidence that shows that this module is suitable to be implemented to enhance the emotional competency level of adolescents.

Keywords: *Emotion competency, Emotional Competency Module, validity*

Introduction

A recent study on adolescent delinquency found that adolescents with better emotional intelligence had lower levels of delinquency[1]. Numerous social problems happen today that start from less serious cases such as coming late to school, skipping class, breaking rules, followed by serious cases such as disobeying teachers, smoking, participating in illegal racing, gangsterism, bullying and more serious cases such as involving in sexual activities, pregnant out of wed lock, baby dumping and rape that has been reported by the mass media almost every day[2].

Research Background: From the year 2009 to 2013, the Malaysian Welfare Department revealed that there are a total of 23,950 male and 1828 female offenders[3]. The Department of Statistic Malaysia reported that Malaysian adolescent population from the age of 10 to 19 years old was estimated to be 5.5 million while the population of Malaysian youths aged 15–25 years old was estimated to be around 5.2 million and approximately 19% of the total population[4]. Although, the number of delinquent juveniles is not high, the number is still alarming and significant enough to simply let this go. In addition, this does not include the number of hotspot schools identified in Malaysia with many delinquent behaviours detected among their students. These delinquent behaviours are such as drug abuse, smoking, vandalism, bully among many others. Hence, a module is developed to help to address these issues among adolescents. Many studies showed that emotional intelligence programmes or trainings were effective in many facets such as positive emotional intelligence shifts and others behaviors [5] enhance emotional intelligence through expressive writing and deep breathing, increase emotional intelligence in adolescents with emotional and behavioral problems.[6]

Problem Statement: We keep observing adults saying these common labels for adolescents these days such as 'disobedient', 'incorrigible', 'unruly' or 'ungovernable'. These social illnesses faced by young generations demand the governable attention of various individuals as there is a link between their current behaviour and the potential for delinquency and future involvement in criminal activities[7]. Recently, there are many studies conducted based on experimental design that implemented training or intervention to develop emotional intelligence. However, very little researches

have been done on emotional intelligence module development in Malaysia. Therefore, this study intends to fill up the gap by developing a module specifically to be implemented on adolescents to help enhance their emotional competence.

Research Objective: This study aims to develop an emotional competency module for adolescents and to test the validity of the module to be implemented for adolescents in Malaysia. Hence, the research objectives for the study are as stated:

i. Is there any content validity evidence for Strategy 1: Self-Awareness?

ii. Is there any content validity evidence for Strategy 2: Self-Management?

iii. Is there any content validity evidence for Strategy 3: Social Awareness?

iv. Is there any content validity evidence for Strategy 4: Relationship Management?

Literature Review

Emotional intelligence is a combination of competencies that allows an individual to be aware of, to understand and to be in control of their own emotions, to recognize and understand the emotion of others, and to use this knowledge to foster their own success and the success of others[8]. A person who can manage their behaviours, face changes, can solve problems, capable of building good relationships with others during worrying situations and can communicate with others are those with high EQ[9]. The current study follows the Goleman's Emotional Intelligence Theory. Although Goleman's theory is more applicable within organization setting but his theory focuses on a wider area in an individual's emotional intelligence. His theory includes the four constructs of emotional competence which are self-awareness, self-management, social awareness and relationship management. Therefore, the module is mainly constructed using the Goleman theoretical framework.

Meanwhile, findings from a survey showed that many higher education students agreed that financial support lead to stress and that a module to deal with emotional problems was necessary [10]. Besides, 86% of the students at the university mentioned that a module is needed to address the emotional issues that university students are facing.

Other emotional problems intervention studies managed to maintain the positive effects and prevent violence among adolescence in terms of use of aggressive strategies to resolve conflict was significantly reduced[11] whereas emotional competence were found to be significant predictors of changes in perceived stress, mental health, somatic complaints and vigour and confusion[12].

Methodology

This study is a design and development research. An Emotional Competency Module was developed for adolescents. Hence, to check for the content validity, the module was sent to be validated to 7 professionals with experience in dealing with emotional issues among adolescents and also in developing modules[13] [14]. According to Yaghmale (2003), having around 5 to 10 field experts is more suitable to measure the content validity[15].

Research Sampling: The samples of this study consisted of 7 professionals with experience in handling adolescents with emotional or/and delinquent behaviours. Five of them are counselling or psychology lecturers from Sultan Idris Education University, National University Malaysia, International Islamic University Malaysia and Putra University of Malaysia. Meanwhile, other experts who were recruited worked at a setting in which they have to deal with adolescents behaviours. Some of them include a counselling teacher at a secondary school, a Welfare Department Assistant Officer and a psychology officer at a juvenile delinquent rehabilitation center.

Research Instruments: There are three criterias for checking for validity of items which are, a) The content measures what it's supposed to measure, b) The items do not underrepresent the content required, c) Items represent what the researcher meant to measure[16]. A rating scale based on this is constructed to be evaluated by the experts. This rating scale was back-to-back translated and underwent face validity before it was given to the experts.

Data Analysis

An inter-rater reliability analysis for the 7 experts ratings was conducted. The results showed that the reliability of the experts ratings was high. A descriptive analysis was conducted based on the percentage of rating

for each activity as well as the overall module by the experts. The results are stated in the research findings. A validity rating of 70% for the content validity of a module is considered high[17][18].

Research Findings

Table 1: Content validity analysis results of module activities

Activity: Theme		Total Score	Percentage of Validity (%)
Theme 1: Self-Awareness		**342**	**81.43**
1	The Emotional Brain: Psycho-biology of emotions	55	78.57
2	Emoticons: Understanding emotions	56	80.00
3	ABC: Emotion rationalization	57	81.43
4	This Is Me: Self-acceptance	57	81.43
5	Triple Vision: Self-efficacy/Resilience	56	80.00
6	The Best Version of Yourself: Self-esteem	61	87.14
Theme 2: Self-Management		**507**	**80.48**
1	Emotional Map: Emotion regulation	57	81.43
2	Breathing Technique: Controlling emotions	58	82.86
3	POP!: Stress management	52	74.29
4	Pressure Cooker: Stress management	59	84.29
5	Time Flies: Stress management/Time management	55	78.57
6	My Spiritual Coping: Stress management	56	80.00
7	Progressive Muscle Relaxation: Stress management	57	81.43
8	Weigh Me Up: Self-motivation	57	81.43
9	Move It!: Self-motivation	56	80.00
Theme 3: Social Awareness		**281**	**80.29**
1	One Day: Social responsibility	56	80.00
2	Empathy: Empathy	58	82.86
3	Colourful Emotions: Empathy	59	84.29
4	Life Tree: Social respect	55	78.57
5	Colours of Malaysia: Social respect	53	75.71
Theme 4: Relationship Management		**286**	**81.71**
1	Sherlocking: Communication skills	55	78.57
2	Let's Win: Assertive skills	58	82.86
3	Maze Runner: Teamwork	56	80.00
4	Rabbits and Hyenas: Dealing with criticism	60	85.71
5	Sorry Sorry: Emotion expression	57	81.43

Table 1 shows that all the module activities has a high percentage of content validity results. Overall, the 'POP!' activity in the self-management theme received the lowest percentage of validation rating which is 74.29% whereas 'The Best Version of Yourself' activity which focuses on enhancing self-esteem received the highest rating which is 87.14%. Obtaining 70% for the content validity of a module is considered high[19]. Hence, all the activities are accepted and presumed to be effective in enhancing the self-awareness, self-management, social awareness and relationship management skills of participants.

Table 2: Overall module validity analysis results

	Overall Module Content Validity Results	Percentage
1	This module covers for the target population.	**84%**
2	This module can be implemented successfully.	**88%**
3	Time allocated to the individuals to complete the module was sufficient and appropriate.	**80%**
4	The emotional competence of the adolescent was enhanced after the completion of the module.	**88%**
5	This module is capable of enhancing the emotion competence.	**88%**
	Total Content Validity	85.6%
	Inter-rater reliability (α = 0.606)	

Based on Table 2, a high validity of 85.6% for the overall module was calculated. Hence, it can be concluded thus far in the research that the module developed is appropriate to be implemented to enhance adolescents' emotional competence.

According to inter-rater reliability the α = 0.606, indicate that there was fair agreement among the rater analysis on the module contents.

Discussions, Implications And Suggestions

The development of this module can aid the Malaysian Youth Policy that helps prepare youths to lead the nation by empowering their emotional competency skills. Besides, the module will also be a tool for psychologists or counsellors as well as other mental health professionals to implement this module for adolescents identified with emotional competency issues. Numerous social problems happen today that start from less serious cases such as coming late to school, skipping class, breaking rules, followed by serious cases such as disobeying teachers, smoking, participating in impulsive behaviors that has been reported by the mass media almost every day [20]. It is quite challenging to handle such numerous number of adolescent involving in problems in Malaysia. In accordance to this, many areas related to adolescent delinquency problems have been investigated by researchers[21]. The Emotional Competency module is developed to meet the challenge to work with vulnerable youth to develop their emotional health. The four main emotional domains are used to assess the emotional competency levels of adolescents in this study, and the valid and inter validity shown the higher (85%) of validity score. The contents of the module are valid with the inter reliability of experts (0.90). activities are most useful and inspire way to practically build up the emotional competency skills[22]

Findings provide evidence that the Emotional Competency Module is suitable to be implemented for adolescents to help enhance their emotional competence level. This is also similar to the Emotional Intelligence Module (EeiM) which also revealed good content validity[23]. Future suggestions for the research would include that testing the module on a wider scale whereby adolescents' population from different background such as juvenile delinquency center, international secondary schools and private institutions can become the participants. Besides, this module can certainly be modified for use for differently abled adolescents.

Conclusion

The Emotional Competency Module has a high validity of 85.6% for the overall module which shows that it is suitable to be used for the adolescent population in Malaysia. Hence showing evidence that the Emotional Competency Module can help enhance the emotional competence of adolescents.

Community Led Total Sanitation (CLTS) in Cikupa Village and Teluknaga Village in Tangerang, Indonesia

Devi Angeliana Kusumaningtiar[1], Gisely Vionalita[1]

[1]Department of Public Health, Faculty of Health Sciences, Universitas Esa Unggul

ABSTRACT

Diarrhea incidence in Indonesia is 423 per 1000 population in 2006. Increased diarrhea cases in one area can be controlled by sanitation approach. One of the Ministry of Health programs to improve Indonesian health status is Community Led Total Sanitation (CLTS). Teluknaga and Cikupa Health Centers have differences in the number of diarrhea cases. In addition and geographical conditions. This study used observational quantitative study with cross sectional study design. In this study, there was no intervention. Study sample consisted of 200 respondents (100 respondents in Cikupa village and 100 respondents in Teluknaga village). This study used random sampling. One household will be chosen by one respondent to be interviewed. Analysis of the data used independent t-test. The results showed that mean of CLTS for the Teluknaga village and variable was -32.50 with standard deviation was 0.383. While, the mean of CLTS for Cikupa village was 44.14 with a standard deviation was 0.398. According to Mann Whitney test above showed that p-value was 0.000 $<\alpha = 0.05$. It meant that there was significantly different in CLTS between Cikupa and Teluknaga village, Tangerang. Implementation of CLTS in urban and rural areas has been still different. However although there were differences, it has been still a big and complex challenges. In addition, required varied methods, tools and approaches. Latrine subsidy in households was long-term production by government support.

Keywords: *Sanitation, Diarrhea, CLTS, Environmental, Indonesia*

Introduction

Sanitation development challenges in Indonesia are community social culture and behavior. They are accustomed to defecating in any place, especially to water bodies which are also used for washing, bathing and drinking water. In addition poor hygiene and sanitation have been still much. Study by The Indonesia Sanitation Sector Development Program (ISSDP) in 2006 showed that 47% of people behave defecation into rivers, fields, ponds, gardens and outdoors.

WHO states that waterborne disease deaths reach 3,400,000 people per year, and diarrhea is the biggest cause of death, 1,400,000 people per year. The cause of death is poor sanitation and water quality. Diarrhea is an endemic disease and also a potential outbreak disease in Indonesia that often causes death. In 2015 there were 18 outbreaks of diarrhea that spread in 11 provinces, 18 districts/cities with a total sufferers was 1,213 people and 30 deaths (CFR 2.447%)[(1)]. Based on cumulative data from 43 Primary Health Care in Tangerang District, 2014, it was found that the percentage of diarrhea cases of all ages increased since 2011 to 2014. The highest cases of diarrhea in 2011 were 40.19%, in 2012 cases increased to be 42.67%, in 2013 increased to 43.72% cases and in 2014 also increased to be 51.34% cases[(2)].

Increased diarrhea cases in one area can be controlled by sanitation approach. One of the Ministry of Health programs to improve Indonesian health status is Community Led Total Sanitation (CLTS). CLTS is a government program to strengthen efforts to accostume clean and healthy lives, prevent the spread of environment-based diseases, improve community capacity, and implement government commitments to improve access of drinking water and basic sanitation sustainably to achieve SDGs[(3)].

The CLTS National Strategy is a reference for planning, implementation, monitoring and evaluation related to CLTS. Health sanitation is closely related to community culture. In an effort to foster community participation must be considered also the community socio-cultural conditions. To involve the community in development efforts, especially in the health sector that will bring better results is if the process use educative approach that is trying to raise awareness in the community through increasing knowledge by considering local social culture.

Ministry of Health Indonesia stated that the lowest percentage who implemented CLTS was DKI Jakarta Province 1.87% and Banten Province 24.44%, while the highest percentage who implemented CLTS were Special Region of Yogyakarta Province 93.84%[4].

Teluknaga and Cikupa Primary Health Care are located in Tangerang, Banten Province. Primary Health Care Teluknaga is a primary health care that has an ISO certificate and has been cases of diarrhea that fall into the top 10 diseases in the primary health care area, while the Cikupa is a primary health care that did not have an ISO certificate and for cases of diarrhea does not fall into the top 10 diseases. In addition, based on geographical conditions, Cikupa Village is an administrative area, close to industries, factories, shops and roadside resident, the condition is crowded and has sufficient facilities and infrastructure. Meanwhile, Teluknaga Village has a population whose livelihoods are mostly fishermen, located on the coast, and the area has many fish ponds. This differences is predicted due to the house and surrounding environment has not been health requirements, no sewerage, and littering behavior and communities PHBS has been still lacking[2]. Based on these problems, important to study about Community Led Total Sanitation (CLTS) Differences between Cikupa and Teluknaga, Tangerang District.

Methodology

This study was used observational quantitative study with cross sectional study design. In this study, there was no intervention. Study sample consisted of 200 respondents, 100 respondents in Cikupa village and 100 respondents in Teluknaga village. Sample collected used random sampling. Each family head who was recorded at the household where the data was collected will be chosen one respondent. The respondent criteria were sought as a family decision maker, a husband or wife. Then, the respondent will be given a questionnaire on community led total sanitation that will cover five pillars. Data analysis used an independent t-test analysis to determine CLTS differences between Cikupa and Teluknaga village.

Result

Description of 5 pillars CLTS implementation in Cikupa and Teluknaga Village as bellow:

Table 1: Description of CLTS in Cikupa dan Teluknaga Village, Tanggerang (respondents)

CLTS Implementation	Dwelling			
	Cikupa		Teluknaga	
	Good	Poor	Good	Poor
Open defecation free (ODF)	50	50	9	91
Hand washing with soap	79	21	24	76
Household drinking water and food management	42	58	26	74
Safekeeping of household waste	33	67	16	84
Safekeeping of household liquid waste	7	93	3	97

According to Tabel 1, the highest proportion of handwashing with Soap in Cikupa Village was good. While in the Teluknaga Village, the highest proportion of household drinking water and food management properly was good.

Table 2: Description of Average CLTS in Cikupa dan Teluknaga Village, Tanggerang

	Dwelling	N	Mean ± SD
STBM	Teluknaga Village	100	32,50 ± 0,383
	Cikupa Village	100	44,14 ± 0,398

Based on the table 2 showed that the mean of CLTS for the Teluknaga village variable was -32.50 with a standard deviation was 0.383. While, the mean of CLTS for Cikupa village was 44.14 with a standard deviation was 0.398.

Furthermore, it was conducted normality test first for bivariate analysis. Results of the normality test showed that distribution was not normal with p-value 0.000 $<\alpha = 0.05$. Then, non-parametric statistical tests were used using Mann-Whitney U.

Table 3: CLTS Differences in Cikupa dan Teluknaga Village, Tanggerang

	Dwelling	N	Mean	p-value	95% CI
STBM	Teluknaga Village	100	-11.640	0.000	-12.729 - -10.551
	Cikupa Village	100			

According to Mann Whitney test above showed that p-value was 0.000 <α = 0.05. It means significantly different of CLTS between Cikupa and Teluknaga Village.

Discussion

Incident cases of diarrhea in Cikupa Village were lower than Teluknaga village. In Cikupa Village, diarrhea cases were not included in the top 10 diseases however in Teluknaga Village, cases of diarrhea had been still in the top 10 diseases. Then, study result showed that there were differences in CLTS between Cikupa Village (low diarrhea cases) and Teluknaga village (high diarrhea cases). Study was conducted in Nyando in 2008, where diarrheal disease was found to be a major cause of morbidity and mortality among children under five, especially in rural and suburban communities in the district. Thus, diarrhea contributes 87% and 48% for child morbidity and mortality[5].

Requirement of sewage disposal that met to health rules were not polluting the soil surface, do not contaminate surface water, do not pollute soil water, dirt could not be open so that it could be used as a vector for laying eggs and breeding[6]. Factors that encourage indiscriminate disposal of fecal activities include low socio-economic levels, insufficient knowledge in environmental health, and poor habits in disposal of feces that are passed down from generation to generation. Build latrines depending on i) pre-existing social context factors, ii) socially intensive processes initiated by CLTS, iii) CLTS fosters the confidence to be able to build and rebuild toilets, and iv) CLTS communicates its benefits to health latrine[7]. When the community has succeeded in making changes and declares its environment free of open defecation free (ODF), the further challenge is to maintain these conditions so as to ensure that no single member of the community returns to practice open defecation free (ODF)[8].

According to observations, there has been still many respondents who behave less for pillars 1 to stop defecate at any place. It was because the community behavior was difficult to change, it seen from the community who already have latrines but still have defecation behavior in the river. This was in line with study stated that CLTS was an approach for long-term problems for a sustainable national planning framework with the implementation of CLTS promotion in schools, preparing cadres who follow CLTS, the implementing CLTS's cost included facilitation and installation of latrines cost by own resources, CLTS advocacy in churches and mosques, motivating children as a key role in using latrines in their homes[9].

Removing human waste (feces and urine) properly and maintaining personal hygiene could maintain health. If waste was not maintained and disposed incorrectly and unsafe, it could be affected to human health and caused serious diseases such as diarrhea, dysentery, typhoid, cholera and other types of infectious diseases. These health problems could be prevented if more effort was conducted for changes personal hygiene behaviors, such as handwashing properly, waste disposed properly, and using clean toilets with easy access to clean water sources[10].

Based on pillar 2 about handwashing with soap showed that behavior of handwashing with soap in Teluknaga village was lower than Cikupa village. Based on the observations to the respondents who have lack behavior of handwashing with soap, they have only washing hands with water without soap and lacking of respondent's knowledge regarding to important times for washing hands. Washing hands with water was more less effective in removing diseased germs from the hands than washing hands with soap. Hand washing using soap was one of the most effective and inexpensive ways to prevent diarrheal disease which mostly cau ses death in children. Washing hands with soap after using the toilet or helping children with bowel movements and before handling food could reduce the level of diarrhea, cholera and dysentery about 48 -59%[11].

Household drinking water and food management which was to be the pillar 3 of CLTS showed that the proportion of poor behavior in Cikupa village was 58% and the in Teluknaga village was 74%. Food must be

managed well and properly in order to prevented health problems and benefit for body. A good way to manage food was by applying the principles of food hygiene and sanitation. Household food management, although in small scale or on a household scale must also applying the food principles of sanitation. A good hygiene sanitation principles included sorted food ingredients, stored food ingredients, processed food, stored cooked food, transported food, served food[3].

Safekeeping of household waste which was to be pillar 4 of CLTS showed that the proportion of lack behavior in Cikupa village was 67% and in the Teluknaga village was 84%. Based on observations, it showed that both of two villages there have not been sorting organic and inorganic waste and did not dispose of garbage every day. Still found trash around the river and gardens proved that people's awareness have been still lack for littering impact.

Waste was a source of disease and a breeding for disease vectors such as flies, mosquitoes, rats, cockroaches. Garbage could be pollute the soil also and caused comfort and aesthetic disturbances such as unpleasant odors and unsightly views. Therefore waste management was very important to prevent disease transmission. Trash must be available, trash must be collected every day and disposed of in temporary shelters. If it was not reached by the service of garbage disposal to the final shelter, it could be carried out by eliminating the waste by stockpiled or burned[12].

Household liquid waste management (pillar 5) showed that the proportion was poor in the Cikupa village (93%) and Teluknaga village was 97%. Observations showed that in both village, it has been still poor for safekeeping household liquid waste. It seen from inundated and uncovered drains in almost these villages. Stagnant liquid waste could be a disease vectors source, including public faucets or lavatories. Domestic liquid waste must be disposed properly following to appropriate standards of waste disposal. Domestic liquid waste usually was not an extreme waste hazard to the environment except it was disposed incorrectly that could be impacted to surface water or shallow ground water.

The last and very important step in the waste management process was disposal that must be carried out in an eco-freindly. Rwanda city that liquid waste management was company's responsibility, however the government was also developing guidelines on how disposal activities should be carried out. This study stated that "Every liquid waste, especially from hospitals, clinics, industries and any other hazardous liquid waste must be collected, cared for and changed in a way that does not reduce the environment to prevent, eliminate or reduce adverse effects on human health, resources nature, flora and fauna[13].

The traditional approach to rural sanitation is based on two assumptions. The first assumption is that people do not know about sanitation and hygiene, but if they are educated they will change their behavior. The second assumption is that people will use the toilet if they are given assistance to build it. However, these two assumptions are often proven wrong. Research shows that knowledge of health risks associated with poor sanitation does not always trigger behavior change. Furthermore, the proportion of latrines built with subsidies has never been used but as storage rooms, animal shelters. The traditional approach also focuses on individual households rather than encouraging the whole community to take collective action to clean the environment[14][15][16]. Interventions focused on clean water, sanitation and hygiene have been shown to have an impact on the incidence of diarrhea from many studies conducted[17].

Conclusion

Implementation of CLTS in urban and rural areas has been still different. However although there were differences, it has been still a big and complex challenges. In addition, required varied methods, tools and approaches. Latrine subsidy in households was long-term production by government support. Thus, the problem of this study was people behavior who quite difficult to change in implementing CLTS.

Competing Interst: This research is part of Ministry of Research Technology and Higher Education (RISTEKDIKTI) Indonesian's funding, thus, there is no competition in conducting this research.

Etchical Clearance: The study was approved by the Ministry of Research Technology and Higher Education (RISTEKDIKTI) Indonesian

The Prevalence of Explained and Unexplained Subfertility—A Case Study: Kirkuk City (Iraq)

Eman I Fathi

Department of Obstetrics and Gynecology, College of Medicine, University of Kirkuk, Kirkuk, Iraq

ABSTRACT

Infertility refers to the inability of a sexually active non-contracepting to get pregnancy in a one year. The diagnosis of explained infertility is performed via standard fertility investigations, which encompasses: assessment of ovulation, semen analysis and tubal patency test. The infertility is considered as an unexplained when the standard fertility evaluation fails to identify an abnormality. This study aims to determine the prevalence and main causes of subfertility. In this study, a multicentre survey is carried out at the infertility centre at the Azadi teaching hospital in Kirkuk, Iraq during the period January 2016 – October 2018. For this aim, 1023 patients are involved in this case-control study: where the females are ranging in age from 18 to 45 years. The results show that (55.35%) have primary subfertility, whereas (44.5%) have secondary subfertility. Additionally, (44.5%) and (75.65%) have primary and secondary subfertility respectively. Furthermore, (75.65%) are explained while unexplained subfertility cases are found in (24.34%). The main causes of female subfertility: 46.64% are ovulation disorders, (21.18%) are primary and (21.18%) are secondary. Besides, out total (774 explained) patients, there is (15.24%) has tubal causes, (6.84%) are primary and (8.39%) are secondary. Moreover, in (20%) the cause is due to male factor, (12.4%) are primary and (7.62%) are secondary. Additionally, in (1.16%) of subfertility is caused by endometriosis, (0.09%) and (0.03%) is primary and secondary subfertility respectively. (16.92%) have multiple disorders found in both partners. Also, in explained subfertility in (63%), the females were responsible for the subfertility, male factor alone is in (20%), (52.66%) are primary and (47.33%) are secondary. Finally, regarding male factor subfertility, the outcomes shows follows: azoospermia in (7.1%), asthenozoospermia in (21.93%), (55.48%) has oligospermia, (8.38%) has oligo-terato-asthenozoospermia and (7.1%) has teratozoospermia.

Keywords: *Infertility, azoospermia, oligospermia, asthenozoospermia, teratozoospermia*

Introduction

Subfertility is a worldwide concern can be either primary or secondary. Primary subfertility is defined as inability to achieve pregnancy after one year of regular intercourse while secondary subfertility is defined when there is a preceding pregnancy irrespective to the outcome. It implies that the processes leading to conception have occurred successfully and so has a better prognosis[1]. The World Health Organization (WHO) anticipated that (60-80 million) couples around the world currently are subjected to have subfertility[2][3]. It varies across regions and expected to affect (8-12 %) of couples[4]. It may also be classified as explained in which there is one or more causes of subfertility and others are unexplained in which all the basic investigations including tests for ovulation assessment, tubal patency, hysterosalpingography, laparoscopy and seminal fluid analysis were normal[5]. In the cases mentioned above, abnormalities are likely to occur, however, it cannot be identified by current methods. There are many reasons which are as follows: 1) the releasing of the eggs could not be at the optimum period of fertilization which may not enter the fallopian tube. 2) the eggs can be reached by sperm which may prevent fertilization. 3) Distribution of transporting of the zygote. 4) Fails in implantation[6]. It is well known

Corresponding Author:

Email: faithfathi@yahoo.com

that the quality of the egg is crucial and the eggs of females in advanced maternal age have reduced capacity to achieve successful fertilization. Furthermore, in some women with unexplained infertility, another reason fertility complications could arise from polymorphisms in folate pathway genes[4][5]. Therefore, unexplained infertility is not the main reason. However, it is a relative inability to get pregnancy, and lots of these patients may be imagined without getting any treatment[7].

It may be appropriate to investigate and treat those patients with less than one-year history of subfertility when they have obvious features which can lead to subfertility such as patients with endocrine problems like severe PCOS, hypothyroidisim or hyperthyroidisim, female age more than 35 years or cases diagnosed as endometriosis before marriage[8]. There is some other term in subfertility which is called fecundability which means the probability of having a pregnancy within one menstrual cycle[9]. Female age and duration of subfertility is the most important predictor of the outcome. It is well known that the fecundity is reduced with aging, it is usually decreasing in 32-years old, then, it will fall dramatically in 37 [10][11]. In the other hand, the rate of the natural monthly fecundity can be about (25%) in ranging 20-30 years of age which reduces to under (10%) upper the 35 years old. Furthermore, both the female and male factor are involved and account approximately for 35% [12]. In over 5800 couples in 25 counties, WHO identified that more than 85% of infertility among African females was subjected to infection comparing with 30% in females worldwide[13]. This means that there is the different demographic distribution of the causes of subfertility. Accordingly, this work is also aiming to investigate the existing surveys on the causes of the prevalence of subfertility and proportion of couples in order to obtain a medical help for fertility problems in Kirkuk city in Iraq[14].

Patients and Method

To estimate the prevalence and main causes of subfertility, a multicentre survey was conducted over 3 years and 9 months from (January 2015–October 2018) in Kirkuk subfertility clinic of Azadi teaching hospital. 1023 couples in this region, who consulted a practitioner for primary or secondary subfertility during this period were included in the study. patients who were involved in the research, the female age was ranging between 18-45, and male age was between 18-55 years, patient with primary infertility had never get pregnancy, while secondary subfertility include any patient had at least one time in which pregnancy test was positive whatever the outcome, whether it ended to full term pregnancy or ended as early abortion, to all patients the main basic investigation of subfertility were done including hormonal profile (FSH, LH, TSH, Prolactin hormones were estimated at the second day of the cycle, and progesterone level was measured between day 21 -29 according to the patients cycle, all female patients had test for tubal patency (HSG) which was done 2 days after finishing her period, transvaginal ultrasound was done on day 2 and day 13 to assess ovulation, and seminal fluid analysis was done after 3 days of abstinence.

Results

The study shown in the following tables. In Table (1), it is shown that among 1023 patients, 567 patients (55.35%) have primary subfertility among that primary subfertility 311 (30.4%) of the patients were between (18-30) years age, 198 (19.35%) their age was between 31-39 years, 58 (5.6%) were between 40-45. At the same time from total cases (1023) it was found that 456 (44.5%) have secondary subfertility, 261 (25.5%) their age was between (18-30), 163 (15.9%) their age was between (31-39), 32 (3.1%) patients their age was between (40-45). In Table 2 three fourth from the total number of cases 774 (75.65%) were explained while unexplained subfertility cases were found in one fourth 249(24.34%) of the couples surveyed. In Table (3) result shows that the main causes of female subfertility were ovulation disorders 361 (46.64%), 197 (25.46%) were primary and 164 (21.18%) were secondary. Out of 1023 total patients (774 explained) there was 118 (115.24%) had tubal causes, 53 (6.84%) were primary, and 65 (8.39%) were secondary. In 155 (20%) the cause of subfertility was only due to male factor 96 (12.4%) was primary and 59 (7.62%) were secondary. 9 (1.16%) patients had endometriosis, 7 patients (0.09%) was primary and 2 (0.03%) secondary subfertility. 131 (16.92%) had multiple disorders in which the cause was found in both partners. Out of 774 cases (explained subfertility), the females were responsible for subfertility in 488 (63%) which means that more than half of the cases of explained subfertility were only due to female causes, and male factor alone was in 155 (20%), which mean around one-fifth of explained subfertility was

due to male factor alone. 257 (52.66%) were primary, and 231 (47.33%) were secondary as shown in Table 3. Regarding male factor subfertility, out of 155 patients with male factor subfertility, azoospermia was found in 11 (7.1%), 34 (21.93%) patients the cause of male factor was asthenozoospermia, 86 (55.48%) oligospermia, 13 (8.38%) had oligo-terato-asthenozoospermia, and teratozoospermia in 11 (7.1%) patients.

Table 1: Distribution of primary and secondary subfertility according to female age

Age groups	No of patients	Types of subfertility			
		Primary		Secondary	
		No.	%	No.	%

Discussion

WHO has reported in[1], in developing countries, 25% of couples are found to be infertile. Additionally, the organization stated that the prevalence of females has kept as it is from 1990 to 2*010. In 2010, US CDC reported that the prevalence rate of infertility was 10.9% where the rate has demonstrated variations across parts of any country[2]. It is worth mentioning that abnormalities are possible to present; however, they can not be detected via current methods. In this study, we found that the prevalence of unexplained subfertility reached 24.34% similar to US prevalence rate (the unexplained infertility rate was about 25% of infertile couples)[8]. Furthermore, we found that the rate of male subfertility is 23.25%. This rate is less than what has obtained in India where the malefactor prevalence was between (40- 50%) and impacts of 7% of all males[12].

The incidence of pathological subfertility is difficult to determine precisely, especially for male factor due to our social culture which always defends men against women resulting in delay or underestimating the diagnosis of the male element. In some cultures, subfertility bears a sense or stigma of being declined by the couple. Additionally, therefore, subfertility causes a noticeable disillusionment[15]. It is well known that the subfertility reasons vary with geographic and socioeconomic variation[11]. Deprivation, starvation and mass migration due to war in Iraq, especially in Kirkuk city in the last 4 years. Furthermore, the high cost of infertility investigation and treatment and non-availability of them in government hospital make patients unable to attend private infertility clinic. On limit resources, the infertility places a large burden by seeking helps for widespread couples.

The results demonstrated that 63% from total 774 patient with explained subfertility was due to pure female causes. Also, 46.64% have anovulation and 15% tubal causes. This finding is similar to study done in England where it was found that 50% are female causes, 25% is due to anovulation and 25% are caused by tubal problems. In the literature, the studies showed that the woman causes are ranged between 25-37% of the infertility worldwide. The larger proportions in Southeast Asia and Sub-Saharan Africa are mainly caused by tubal factor[13], other 20% male and 16.92% combined causes. The reason of these findings is due to restricted sexual relation within a marriage relation only. Additionally, the low level of sexual transmitted disease in Iraq is because of the country religion is Islam which prohibits the sexual relations between the unmarried couples.

In Sub-Saharan Africa[16], primary infertility is less common than secondary infertility, where most often the outcome of untreated STIs or complications from pregnancy/birth[14]. Since the 1980s, there was an increasing in infertility rates about 4%, and most of them are due aging[15]. It is well known that the females become less fertile as they grow old. For instance, females in 35 years old get pregnant after three years of regular unprotected intercourse. Nevertheless, only 77% women in 38 years old get pregnant after three years of regular intercourse. In the UK, in infertile couples, male factor infertility rate reaches 25%, and another 25% remains as unexplained infertility[17]. On the other hand, 10% of couples in Sweden who seek for children are infertile[18]. Additionally, male factor, female factor, and both side factors have equally rate (about 33%) of infertility in all these cases[18].

Conclusion

We concluded that there are differences in the causes of the subfertility in different areas in the world. Several reasons are behind this finding which can be as follows:

Religious points.

The age of marriage.

Poverty.

The differences in the national resources in each country which can support subfertile people.

Conflict of Interest: The authors have no financial, consultative, institutional, and other relationships that might lead to bias or conflict of interest.

Source of Funding: The authors have no sources of funding, so it is self-funding research.

Ethical Clearance: We declare that the study does not need ethical approval.

ABSTRACT

The quality of water used for daily needs affects human health. Some people in Banjarmasin use the PDAM Bandarmasih water and some use Martapura River water. One of the infection signs is the increases of white blood cell, includes neutrophil, monocyte, eosinophil and lymphocyte. The aims of this study was determine the differences of neutrophil, monocyte, eosinophil and lymphocyte count between Martapura river water consuments and Bandarmasih Local Water Supply Utility consuments in Banjarmasin. This study was an analytic observational with a cross sectional approach. Sample selection used purposive sampling technique. The result showed that neutrophil, monocyte, eosinophil and lymphocyte count average level of 30 consuments of Martapura River water were 54.03%, 7.43%, 3.2%, 34.8%, respectively; and neutrophil, monocyte, eosinophil and lymphocyte count average level of 30 consuments of Bandarmasih Local Water Supply Utility was 54.9%, 7.53%, 4.39%, 32.8%, respectively. Statistical analysis with unpaired t-test showed that there wasn't any difference of neutrophil, monocyte, eosinophil and lymphocyte.count between Martapura River water consuments and Bandarmasih Local Water Supply Utility consuments (p=0.723, p=0.822, p=0.623%, p=0.318) in August 2018 period.

Keywords: *river water consuments, local water supply consuments, immunity, leukocytes*

Introduction

The river flow in the Province of South Kalimantan, especially the City of Banjarmasin, is used for various activities. The percentage of river water use by the people of the Alalak River to clean their houses is 95%; to water the plants 92%; to bath 77%; to wash the clothes, the cooking utensils, and the eating utensils 74%; and forthe ablution 1%.[1]

The more the activity of the people on the riverside grows, the higher the level of pollution in the waterdue to the direct household waste thrown away to the water.[2]The huge amount of waste disposalinto the river will make the quality of water worse.As many as 34% of the people around the river in Banjarmasin throw feces directly into the river and 64% use traditional septic tang (*cubluk*) that do not meet the requirements of good sanitation, causing the surrounding environment to be polluted. It is very possible to find many bacteria, viruses, and parasites in polluted water.[3]The bacteriological test of river water in Berangas, Barito Kuala showed that the MPN values of *Coliform* and *E. Coli* are respectively 29 and 0 MPN/100 ml. The MPN value of *Coliform*dropped to 18 MPN/100 ml in the river water which has been given alum.

Another cause of river water pollution in the city of Banjarmasin is the disposal of domestic waste and factory waste into the river.[4] As the population increases, the effortsto fulfill the water needs are increased through the Local Water Company (PDAM). The clean water in the city of Banjarmasin is supplied by the PDAM Bandarmasih through the process of coagulation-flocculation, filtration, sedimentation and disinfectation. Chlorineisa disinfectant commonly used by PDAM.[5]This substance is capable of killing pathogenic bacteria and protozoa in the water and inhibiting the growth of moss.[6]The existence offreechlorine compound in the distribution of water permitted by PERMENKES 2010is 0.2-0.5 mg/l.[7]

The microbiological quality of water provided by PDAM Bandarmasih is proven to be good through the analysis of the quality of customers clean water of Water Treatment Plant (IPA)zone 1 PDAM Bandarmasih on

the period of June-July 2018, the amount of *E. Coli* and the total of *Coli* is 0 per 100 ml of water in the sample thatmeets the drinking water requirements.[8]

Neutrophils together with monocytes are phagocytic cells and are the first immune cells to respond during infection to fight bacteria.[9] Eosinophils play a role in allergic and parasitic infections.[10] Whereas lymphocytes are able to produce the body's defense components against foreign objects that have been specifically identified. There are B lymphocytes that function in humoral immunity and produce antibodies in the blood, and T lymphocytes as cellular immunity that does not produce antibodies, but works directly to destroy specific foreign objects with chemicals.[9,10]

The poor water quality, especially microscopically, increases the risk of infection for its users, one of which is an increase in the number of leukocytes. Based on the description above, a study was conducted to determine the differences in the number of neutrophils, monocytes, lymphocytes and eosinophils of Martapura River water users with water users of PDAM Bandarmasih.

Research Materials and Method

The implementation of this study was using an observational analytic cross sectional method. The population of this study is the people using the water from Martapura River on Ray Street 17 RT. 02 Berangas District with a total population of 155 people and the people using the water from PDAM Bandarmasih on Maluku Street RT. 05 Pasar Lama District with a total population of 176 people for daily needs in Banjarmasin City in August 2018.

Results

The Shapiro-Wilk test showed that the data on the number of neutrophils and lymphocytes of river water user group and PDAM water user group spread out normally. The data onthe number of eosinophils and monocytes were not normally distributed, hence data transformation was carried out. After all data were normally distributed, it was followedby hypothesis testing with unpaired t, the results showed that there were no statistically significant differences in the number of neutrophils, monocytes, lymphocytes and eosinophils between the two groups of research subjects with *p* values of 0.723, 0.822, 0.623 and 0.318.

Discussion

The average number of each cell type is almost entirely within the normal range, both in the group of the river water users and thegroups of the PDAM water users.Only the average number of eosinophils of PDAM water users has increased from the normal value (4.39%). The statistical results showed that there were no significant differences in the number of neutrophils, monocytes, lymphocytes and eosinophils between the two groups of respondents, this could be due to the two groups of respondents giving direct treatment of water to be used, namely deposition, alum and boiling which could interfere with the sustainability of the pathogenic bacteria in the water thereby reducing the risk of infection for users. In addition, the use of soap, toothpaste and other cleaning agents can kill pathogenic microorganisms because they are antibacterial.

The river water used by the people on Ray Street 17, Berangas for daily activities, especially kitchen needs is always accommodated and given the alum which functions as a floculator where its activities are to agglomerate pollutants such as industrial residues, metals, and microorganisms and are known also as an antibacterial[11].Alum can inhibit the bacterial growth. The concentration of alum as much as 1% makes gram-positive bacteria experience a death phase, and the concentration of 2% causes the death of gram-negative bacteria.

The disposal of soap and detergent waste into the river results to aworse quality of river water. However,

alum can reduce detergent levels by absorbing dyes and other pollutants, and alum is effective in reducing iron levels in water.[13]

Particularly for drinking water, besides being given alum, it can also be boiled. The bacteria and the other pathogens in the water that go through a cooking process to 100°C for 5-10 minutes will disappear.[14]

The water needs for the daily activities of people in Maluku Street, Pasar Lama are fulfilled with the water from PDAM Bandarmasih. The water has been given chlorine as a disinfectant. The results of qualitytest of PDAM water (table 2)are in accordance with the standard, where one of the indicators, known as the value of water turbidity, is not more than 5 NTU. It is because the high value ofturbiditywill reduce the disinfection activity during the processing of water purification.[15] The disinfection will work effectively if the free chlorine in the water amounts to between 0.2-0.5mg/l, if the disinfectation is less, it will not be effective, andif it is more, it will be carcinogenic.[16]

The disinfection process of water from PDAM Bandarmasihis proven to be good, according to the lab results in June 2018 showing that the MPN values of *Coliform* and *E. Coli*are 0 per 100 mL.[17] Therefore, the water flow that reaches the people's houses is of good quality and free of pathogenic microorganisms. This is in accordance with the results of the study that the average number of neutrophils, monocytes and lymphocytes using PDAM water on Maluku Street, RT02, Banjarmasin is in the normal range.

In addition to the direct treatment of water used, people in both locations also use soap for bathing, washing dishes and other eating utensils, and toothpaste for brushing their teeth. One of the ingredients contained in toothpaste is flour which is antibacterial. The use of toothpaste with flour has been proven to be effective in killing bacterial colonies.[18,19] The antibacterial content found in toothpaste is baking soda (sodium bicarbonate). Baking soda is alkaline which can neutralize the pH of the oral cavity, so that it can inhibit the bacterial metabolic activity. Baking soda also has hypertonic activity which later results in hypotonic content of water-losing bacteria which will make the bakery cells become dehydrated and can eventually destroy the bacteria.[20,21]

Ordinary soap (not antibacterial) can reduce 50% of pneumonia in infants and 53% of diarrhea in children under 15 years old.And there is no significant difference between antibacterial soap and ordinary soap in its effectiveness in killing bacteria.[22]

Although there were no statistically significant differences between the neutrophil counts of the two groups of respondents, there were variations in the number of respondents between the two groups of respondents. This was probably due to the differences in the environmental characteristics of the two research locations. Maluku Street is a market area with dense environmental characteristics. The houses and the merchant stalls are located side by side on both sides of the road with a large number of local people and market visitors.An environment with a huge amount of population and a minimum amount of air ventilation can increase the density of germs or bacteria.[23] The people around such location have a higher risk of exposure to bacteria. Meanwhile, on Ray Street 17, Berangas District, it looks cleaner.

Gender also affects the number of leukocytes. In this study, the number of female respondents in the group of river water users (19 people) was less than the female respondents in the group of PDAM water users (23 people). The immune response of women is faster to respond toinfectioncompared to the immune response of men. When an infection occurs, a woman's immune system recognizes and destroys pathogens that enter the body more quickly than men.[24]

Conclusion

Based on a study of the difference in the number of leukocytes ofusers of water from Martapura Riverand users of water from PDAM Bandarmasih, it was concluded that the average numbers of neutrophils and monocytes, lymphocytes and eosinophils of the people using the water from Martapura River in August 2018 were 54.03%, 7.43%, 34.8% and 3.2%. The average numbers of neutrophils, monocytes, lymphocytes and eosinophils of the people using the water from PDAM were 54.9%, 7.54%, 32.8% and 4.39%, respectively. The statistical results showed no significant differences between the average number of neutrophils, monocytes, lymphocytes and eosinophils ofthe water usersof Martapura Riverand the water users of PDAM Bandarmasih.

ABSTRACT

Background: Many endometrial cancer patients will undergo a comprehensive lymphadenectomy despite having disease confined to the uterus with low percent of lymph node metastasis, resulting in prolonged operating time, additional cost, and potential side effects, sentinel lymph node (SLN) procedure has been evaluated in Endometrial Cancer and has emerged as a possible middle solution to overcome under treatment of high risk patients or over treatment of low risk patients.

Method: This is a cross sectional non randomized, prospective study, non-comparative study with the purpose of determining rate of SLN detection at Egyptian National Cancer Institute, Cairo University for patients presented with early endometrial carcinoma.

Results: 46 patients have SLN using blue dye. 32 case injected with methylene blue (69.6%) and patent blue injection was in 14 cases with (30.4%). SLN was detected in 39/46 cases with detection rate (84.8%). With failure of detection in 7/46 cases with failure rate (15.2%), false -ve rate 16.7% and test sensitivity is 84.3% with NPV 97.1% and accuracy 97.4%. No false positive cases present in this study this means that False +ve rate 0%, specificity 100% and PPV 100%.

Conclusion: SLN using Blue dye is very simple especially in low resource countries but is associated with low detection rate and false negative rate. As surgeons gain experience in SLN mapping for endometrial cancer and achieve detection rates of 90% or greater, with a combined decrease in false-negative rates.

Keywords: *blue, dye, endometrial, lymphadenectomy, lymphedema*

Introduction

Endometrial cancer is the most common malignancy of the female reproductive tract worldwide, in Cairo National Cancer Institute registry, it is the third most common gynecological cancer constituting 23%, with median age is 60 years. [1]

The uterus is midline structure, its lymphatic drainage likely to be bilateral mainly along obturator, iliac, caval and paraortic nodes. Also parametrium and presacral areas are at risk. This pattern of spread needs complete staging with pelvic and paraortic lymphadenectomy.[2]

Histological grade, depth of myometrial invasion, lymph node metastasis are the most important prognostic factors of endometrial cancer. [3] Thus FIGO group recommends pelvic lymphadenectomy to stage patient disease and assess lymph node status, whereas GOG group recommends systematic pelvic and paraortic lymphadenectomy which is associated more morbidity. [4]

Surgical staging by total abdominal hysterectomy, bilateral salpingo-oophorectomy and pelvic lymphadenectomy was agreed by most surgeons as standard of care for patients with grade 2 and 3 endometrioid cancer as well as patients with clear cell and papillary serous tumors. [4, 5]

Patients with grade 1 endometrioid cancer some of them are staged appropriately others are not staged according to surgeon assessment during surgery. This increased concern about over treating low risk group of patients who may have prolonged survival especially when complete regional lymphadenectomy is done which may have long term effects and morbidity. [6, 7]

Sentinel lymp f symptomatic lymphedema, bleeding, increase operative time and cost. [8]

Aim of the Work: To detect the accuracy and sensitivity of colorimetric method of SLN in staging of endometrial cancer, to evaluate the feasibility of SLN to stage patients with early endometrial cancers.

Patients and Method

This cross-sectional study was conducted on endometrial cancer patients presented to National Cancer Institute, Cairo University, Egypt

Inclusion Criteria: Stage IA histological grade 2 and 3 endometrioid adenocarcinoma, clear cell and papillary serous carcinoma, Stage IB endometrial carcinoma, Stage II endometrial carcinoma.

Exclusion Criteria: Patients with grade 1 endometrioid adenocarcinoma, stage III and IV disease, and patients with allergy to blue dye.

Study Design: This non-randomized, prospective, non-comparative study for determining the SLN detection rate by histopathological examination, anatomical distribution of SLNs.

Method used for SLN in Endometrial Cancer Cases: Cervical injection of blue dye 2-sided at 3 and 9 o'clock, 4 ml used in a combined superficial (1-3 mm) and deep (1-2 cm) cervical injection, fundal injection with 2 ml of blue dye has been also used in number of cases with cervical injection.

Procedure: After anesthesia patient cervix was and 22-gauge spinal needle was used to inject blue dye into cervix at 3'oclock and 9'oclock for each side 2ml of dye (1 ml superficial from 1-3mm depth and the other 1 ml deep 1-2cm cervical depth). Immediately following cervical injection surgical field prepared, abdomen was opened and 2ml of blue dye was injected subserosal in uterine fundus, field prepared and abdomen was packed for surgery till 10 minutes after fundal injection and about 25 minutes after cervical injection, it was estimated that it might take up to 30 minute for tissues to absorb blue dye and to be taken by lymphatic vessels to turn lymph node blue. Surgery was proceeded as routine and started with pelvic lymphadenectomy for which visual identification of colored or blue nodes were searched for and identified, its anatomical site was reported, and such node excised separately and sent separately for histopathological examination, then surgery was completed as standard (total abdominal hysterectomy, bilateral salpingooophorectomy and standard pelvic lymphadenectomy). None identified SLN or failed mapping was reported, and surgery also completed as standard.

Results

46 patients with endometrial carcinoma meeting selection criteria underwent SLN procedure in endometrial carcinoma using colorimetric method using either methylene blue (69.6%, n=32/46) or patent blue (30.4%, n=14/46) cervical (34.8%, n=16/46, injection site 3 o'clock and 9 o'clock superficial and deep) and or cervical and fundal subserosal injection (65.2%, n=30/46). Their mean age was 57.9 years with range (51-69). All patients (100%) have been surgically done through laparotomy and all have preoperative pathology endometrial carcinoma. 67.4% (n=31/46) of patients had less than myometrial invasion and 32.6% (n=13/46) had more than half myometrial invasion. Mean time to detect SLN defined as time from dye injection till visualization of dye colored node (SLN) was 30 minutes with range (20–40) minutes. The detection rate was calculated as the number of patients with at least one detected pelvic colored SLN divided by the total number of patients who underwent SLN mapping. SLN was detected in 84.8% (n=39/46) of cases. Location of detected colored SLN included obturator group (59%, n=23), internal iliac group (23.1%, n=9), paracervical (15.4%, n=6) and external iliac group (2.6%, n=1), bilateral detection was reported in 33.3% (n=13).

All SLNs were examined histopathologically and the uterus examined for myometrial invasion, grade of carcinoma, LVSI and pelvic lymphadenectomy examined histopathologically for lymph node metastasis.

Pathological nodal metastasis had been detected in 12.8% (n=5/39) of examined SLNs, and in 15.2% (n=7/46) of standard postoperative pelvic

lymphadenectomy. Postoperative less than half myometrial invasion was detected in 67.4% (n=31/46) patients while 32.6% (n=15/46) patients had more than half myometrial invasion. Pathological grading of endometrial carcinoma showed 11 case (23.9%) as G I, 33 case (71.7%) as G II and 2 cases (4.3%) as G III.

Diagnostic Accuracy of SLN: One case of detected SLNs have negative histopathological examination and their associated standard pelvic lymphadenectomy was proved to be positive for nodal metastasis which means that false -ve rate was 16.7% and test sensitivity was 84.3% with NPV 97.1% and accuracy 97.4%. No false positive cases were detected in this study meaning that False +ve rate was 0% with specificity 100% and PPV 100%. Significant higher LN positivity with myometrial invasion more than half '6/9' than those with less than half myometrial invasion '1/30' was detected (40% vs. 3.25; P=0.003). LN positivity in grade II and III (20%) versus no positive LN with grade I (0%) has been found (P=0.107). Out of 7 cases with undetected SLN, one case proved to have +ve nodal involvement on pathological diagnosis which means failure rate of 14.3%.

Discussion

LN metastasis affects management of endometrial cancer and usually indicates a poor prognosis. [9, 10] Thus, surgical staging with pelvic LN dissection is recommended for all high-risk endometrial cancer patients. However, most patients with endometrial cancer don't not have LN metastasis making lymphadenectomy and its drawbacks major concern, many surgeons perform selective lymphadenectomy based on pre or intraoperative findings. As the decision to perform LN staging often is based on the individual surgeon's experience there is a lot of bias.

The challenge is to identify accurate surgical technique to stage endometrial cancer and avoid unnecessary morbidity and procedure that give information about nodal status while avoiding the potential for over treating low-risk patients and undertreating patients with metastatic disease. [11]

Burke et al.[12] published the first report on identification of SLNs in endometrial carcinoma in series of 15 patients they occluded the tubes with clips and injected isosulfan blue into the subserosal myometrium of uterine fundus at 3 midline sites, dye uptake was observed in 67% of cases with false negative rate of 50%.

Holub et al. [13] and Gien et al. [14] reported similar detection rate of 61.5% and 56% respectively using the same technique of burke et al. [12] Niikura et al. [15] in their series of 28 patients injected radioactive tracer around the tumor under direct visualization by hysteroscopy the day before surgery, SLNs was identified using gama probe and removed the detection rate was 82%. Fersis et al. [16] reported only a 50% detection rate. Bats et al. [17] used cervical injection of the dye with a detection rate of 80%. Holub et al. [18] used a combination of cervical and subserosal fundal injections of blue dye and reported detection rate 80%. Our results of blue dye injection in cervical and subserosal showed comparable detection rate of 84.8%.

El-Agwany et al. [19] reported detection rate 86% in series of 30 patients with early endometrial cancer having blue dye injection cervical and fundal subserosal, and 93% detection rate in series of 30 patients with hysteroscopic injection of blue dye. Barlin et al. [20] in a study of 498 endometrial cancer patients who received blue dye cervical injections, SLN was identified in 81% of patients. The SLN correctly diagnosed nodal metastases in 40/47 patients who had at least one SLN mapped, for a 14.9% false-negative rate. Youssef, et al. [21] studied 20 cases with fundal injection of blue dye and reported a detection rate for the SLN of 85% and a failure rate of 15%. Altgassen et al. [22] reported 92% detection rate using blue dye injection fundal subserosal in series of 20 patients. Vidal et al. [23] reported a 62% detection rate in a series of 66 patients with cervical injection of blue dye with sensitivity 86% and NPV 98%. Mais et al. [24] reported a 62%detection rate in a series of 34 patients with cervical injection of blue dye with sensitivity 50% and NPV 85%. Lopes et al. [25] reported a 78%detection rate in a series of 40 patients with cervical injection of blue dye. Holloway et al.[26] reported 76%detection rate in a series of 200 patients with cervical injection of blue dye with sensitivity 98% and NPV 99%.

An acceptable SLN detection rate varies among literature, but a detection rate of 80- 90% or greater is preferred. Khoury-Collado et al.[27] studied 115 patients with endometrial cancer to determine the SLN detection rate and how many SLN mapping cases a surgeon

needed to perform to reach the 90% benchmark. During the early phase of the study an SLN was identified in 78% of cases with 2 false-negatives, while during the late phase an SLN was identified in 94% of cases with no false negatives. Detection rates increased from 77-94% (P=0.033) during the 2 periods, with surgeon experience (≥30 cases) playing an integral role.

SLN mapping can play a more prominent role in LN assessment and staging in early-stage endometrial cancer. For now, the standard in many practices continues to include a comprehensive lymphadenectomy versus no nodal assessment. Further prospective studies are needed in order to assess the role of SLN biopsy in endometrial cancer.

Conclusion

SLN procedure using blue dye is very simple especially in low resource countries but is associated with low detection rate and false negative rate. Cervical injection technique may be promising procedures for sentinel node mapping. In a setting in which hysteroscopic skills are lacking, cervical injection should be the preferred way to sentinel node identification.

Inorganic Nitrogen Salts in Fibrinolytic Enzyme Production from *Bacillus Megaterium BM 9.1* with Solid State Fermentation

Mukti Hapsari[1], Achmad Toto Poernomo[1], Amiruddin Prawita[1]

[1]Pharmacy Department, Faculty of Pharmacy, Airlangga University, Jl. Airlangga No 4-6, Airlangga, Gubeng, Surabaya city, Jawa Timur

ABSTRACT

Background: The use of fibrinolytic enzymes is necessary as a thrombolytic agent in the treatment of vascular disorders. Most fibrinolytic enzymes are obtained from fermented food bacteria.

Objective: This study was conducted to determine the effect of inorganic nitrogen salt against the production of fibrinolytic enzyme from *Bacillus megaterium BM 9.1*.

Method: This experimental study was first conducted on *Bacillus megaterium BM 9.1* from coastal waters which were overgrown with mangrove trees. Media preparation used consisted of 3 types, namely nutrient agar, nutrient agar with the addition of inorganic nitrogen salts (KNO_3, $NaNO_3$, $(NH_4)2SO_4$ and NH_4Cl) and agar with addition of inorganic nitrogen salts (KNO_3, $NaNO_3$, (NH4) $2SO_4$ and NH_4Cl).

Results: From 9 media that have been treated, 100% of them positive in producing fibrinolytic enzymes. Nutrient Agar (NA) + KNO_3 is the best medium with the highest Fibrinolytic Index (IF) mean, which is 5.60 ± 0.087. Determining the optimum concentration of potassium nitrate does not mean the highest concentration are having the high influence. The optimum fibrinolytic activity of *Bacillus megaterium BM 9.1* are found at 2% potassium nitrate concentration.

Conclusion: Fibrinolytic enzymes can be easily found from some fermented foods, especially the *Bacillus (genus Bacillus)*. *Bacillus megaterium BM 9.1* in the inorganic nitrogen salts is one of the agents that produce fibrinolytics enzymes which can be used as a therapy for fibrinolytics agents.

Keywords: *Bacillus megaterium BM 9.1, Inorganic nitrogen salts, fibrinolytic activity, solid state fermentation*

Introduction

Every day the body carries out a homeostasis process. When bleeding occurs will prevent thrombus formation, that is formed will clog the blood flow that carries oxygen to the tissue so that the blood flow stops, as a result the tissue is not getting oxygen supply. If the thrombus in the blood vessels moves to the brain, oxygen cannot reach the brain and a stroke occurs. Stroke can be treated using thrombolytic agents. One of the thrombolytic agents that are widely used in the treatment of vascular disorders is fibrinolytic enzymes[1–3].

Sources of fibrinolytic enzymes can be obtained from bacteria, fungi, algae and animals[1]. Bacteria are the group that produces the most fibrinolytic enzymes. Most bacteria that can produce fibrinolytic enzymes are from *Bacillus*, *Streptococcus*, *Staphylococcus*, *Vibrio*, *Paenibacillus Chryseobacterium Pseudomonas*. Some of them are Bacillus subtilis which is produces sodiuminase, *Streptococcus hemolyticus* which is produces streptokinase and Staphylococcus aureus which is produces staphylokinase[4–6]

Previous study it was found that *Bacillus vallismortis Ace02* isolated from traditional Korean fermented foods and *Bacillus amyloliquefaciens CD-4* were isolated from douchi fermented soybeans (traditional Chinese food) capable of producing fibrinolytic enzymes[7,8]. In addition, cotton cake and wheat bran as nitrogen sources of *Bacillus cereus NS-2* and *Bacillus megaterium KSK-07* isolated from Kisk, traditional fermented food from Egypt have produced fibrinolytic enzymes[9,10].

The use of Solid State Fermentation for protease and amylase production by thermophilic bacteria, Bacillus sp. BBXS-2 has been done and had been contain fibrinolytic enzymes[11]. Most of the nitrogen available in nature is ammonia (NH_3), nitrate (NO_3-), or nitrogen gas (N_2). Almost all prokaryotes can use NH_3 as their nitrogen source, many also can use NO_3-, and some can use organic nitrogen sources, such as amino acids[12]. Nitrogen is very important in the growth of bacteria. This is because nitrogen will be metabolized to produce amino acids, nucleic acids, proteins and cell wall components[13].

Bacillus megaterium BM 9.1 is a microorganism from the Bacillus group, which is still in one genus with *Bacillus subtilis* which was isolated from mangrove forest[14]. Where almost all genus bacillus is used as fermented foods there is a content of fibronolytic enzymes. Thus, this study was conducted to determine the effect of potassium nitrate (KNO_3), ammonium chloride (NH_4Cl), sodium nitrate ($NaNO_3$) and ammonium sulfate (NH_4) $2SO_4$ on *Bacillus megaterium BM 9.1.*

Materials and Method

***Bacillus* Microroganism, *Bacillus megaterium BM 9.1*:** Similar to many proteolytic enzymes originated from microorganisms, most fibrinolytics also originate from the genus Bacillus microorganisms[15]. Study of experiment microorganism[16] that were used in this study are Bacillus megaterium BM 9.1 that been isolated from the mangrove ecotourism coast of Wonorejo Surabaya, Indonesia.

Media Preparation and BM 9.1. enzyme production: The media that been used in this study for culturing *Bacillus megaterium BM 9.1* consists of 3 types of media as follow, nutrient agar with addition of inorganic nitrogen sources (KNO_3, $NaNO_3$, (NH_4) $2SO_4$ and NH_4Cl) and agar with addition of inorganic nitrogen sources (KNO_3, $NaNO_3$, (NH_4) $2SO_4$ and NH_4Cl). All of the media were put in each test tube that consist of 8 mL and 12 mL and sterilized by autoclave at 121ºC for 30 minutes.[17,18].

Production of Fibrinolytic Enzymes in inoculated media: The production of fibrinolytic enzymes uses the solid-state fermentation method. The media consists of a based layer and seed layer. The first based layer was made by using 8 mL of fibrinolytic enzyme production media which from three variations of nutrient agar media which were included in the petri dish and evenly distributed. While the seed layer is made with 12 mL of fibrinolytic enzyme production media[19].

Fibrinolytic activity with Fibrin Plate. Test media for fibrinolytic enzyme activity were incubated at 37 ° C for 24 hours. Bacteria that produce fibrinolytic enzymes will provide a clear zone around the hole. The clear zone diameter is measured by using the calipers and determined by its fibrinolytic index[20].

Results

First, the growth of *Bacillus megaterium B.M 9.1* in various media for producing Fibrinolytic Enzymes ai observed. After an incubation period of 24 hours at 37 ° C there is a growth of bacterial colonies in various media that producing fibrinolytic enzymes. Then to determine the fibrinolytic enzyme activity it can be measured by the fibrinolytic index. The fibrinolytic index is measured by comparing the clear zone formed on the fibrin plate to the diameter of the well.

Figure 1: *Bacillus megaterium BM 9.1* culture on *nutrient agar* + potassium nitrate

Figure 2: Fibrin plate activity from nutrient agar + ammonium chloride media

From Figure 2, which is one example of the growth of *Bacillus megaterium B.M 9.1* bacteria on nutrient agar + potassium nitrate, a clear zone is observed in this media. Figure 4 also shows that the diameter of the clear zone in the fibrin plate activity of the nutrient agar + ammonium chloride is wider than the diameter of the well. This clear zone formation shows the activity of fibrinolytic enzymes around the media. Complete results from 7 media with the combination of nitrogen sources from inorganics salts produces a clear zones, which means that there are fibrinolytic enzymes in each medium. Each medium replicated three times with phosphate buffer pH 7.4 as the negative control agent.

Table 1: Observation results of fibrinolytic enzyme activity on various inorganic nitrogen salts

Production Media		Clear zone diameter (mm)	Fibrinolytic Index (FI)
Nutrient agar	1st	18,30	4,58
	2nd	18,35	4,59
	3rd	18,30	4,58

Furthermore, similar observations were made on the production of fibronolytic enzymes and optimum inorganic nitrogen sources with different concentrations. The activity test procedure is repeated again from the culture stage and following the stages that are appropriate to the previous procedure. All media produce clear zones in the fibrinolytic index. Likewise, the most significant concentration of KNO_3 on the activity of fibrinolytic enzymes is found in the 2% potassium nitrate.

The results of statistical analysis using one way ANOVA resulted in differences in fibrinolytic activity of various inorganic nitrogen salts. With the value of F count 83,085> F table 5,32. The differences in data

must have a normal and homogeneous distribution. In accordance with the results of one way anova in fibrinolytic activity at various concentrations of KNO_3 it also produced differences.

The results of the post hoc test analysis shows that Nutrient Agar (NA) + potassium nitrate has the significant differences on the production of fibrinolytic enzymes with means difference is higher than the other treatment groups. This result is supported by the homogeneous subsets test results which shows if NA + potassium nitrate has the significant effect with a value of 22.4. Whereas the 2% KNO_3 media has the significant differences on the production of fibrinolytic enzymes with means difference is higher than the other treatment groups.

Discussion

The study was conducted on *Bacillus megaterium BM 9.1* that isolated from the Eco Wisata Mangrove Coast Wonorejo, Surabaya city, Indonesia[14]. The results from this study is to determine the effect of inorganic nitrogen salts on the production of fibrinolytic enzymes and to determine which inorganic nitrogen salts that have the significant influence against the production, then fibrinolytic enzyme production media with added inorganic nitrogen salts are made with solid fermentation method.

In fibrin plate, 4 wells were made using sterile holes with a diameter of 0.4 mm. Substances from fibrinolytic enzyme production medium was inoculated into a well on the fibrin plate media. Phosphate buffer pH 7.4 is used as a negative control. The fibrin plate media was incubated for 24 hours at 37 ° C. The addition of methylene blue to the media aims to clarify the formation of clear zone, this is because fibrin is colorless. The clear zone of the fibrin plate media indicates the ability of the enzyme to degrade the fibrin substrate and its diameter which is formed in accordance with the potential of its fibrinolytic activity[21]. Degradation of fibrin by fibrinolytic enzymes into soluble amino acids causes the formation of clear zones.

Enzyme production is influenced by several factors, such as media, temperature, pH, activators and inhibitors [22]. A good medium for bacterial growth is a medium that containing carbon, nitrogen and minerals. Nutrient Agar (NA) is a standard medium for culturing and as metabolite production media for *Bacillus sp.* In another case, LSD analysis concluded that the Nutrient Agar (NA) + potassium nitrate had the greatest influence on the production of fibrinolytic enzymes. Potassium nitrate, ammonium chloride, ammonium sulfate and ammonium nitrate that have been used as nitrogen source for Bacillus sp. The results show the maximum growth rate and production of enzymes found in the media with potassium nitrate as its nitrogen source [23].

After determining the most effective inorganic nitrogen salts for the production of the fibrinolytic enzyme from *Bacillus megaterium BM 9.1*, then the optimum concentration of potassium nitrate for the production of the fibrinolytic enzyme *Bacillus megaterium BM 9.1* will be determined. After the comparison, the higher concentration potassium nitrate was accompanied by an increase in fibrinolytic activity of *Bacillus megaterium BM 9.1*. The optimum fibrinolytic activity of Bacillus megaterium BM 9.1 are achieved at 2% potassium nitrate, but at 2.5% potassium nitrate concentration the production rate is decreasing. This can be caused by two things. First because along with the increase in concentration there is also an increase in the amount of nutrients, so the bacteria growth rate will increase and the products of the metabolites produced are enzymes, will also increase. But the higher concentration of nutrient not always accompanied by an increase in activity, because an excessive amount of nutrient may lead to death of bacteria.

Second, there is a feedback inhibition mechanism. At feedback inhibition, the first enzyme activity in the biosynthetic pathway is inhibited by the end product of the pathway. The first reaction in the biosynthetic pathway produces an intermediate product used by the next enzyme as a substrate. Thus, inhibition of enzyme activity in the first reaction can stop the formation of intermediate products used for the formation of the final product [24,25]. Finally, the statistical test using one way anova showed a significant difference between the concentration of potassium nitrate and the activity of the fibrinolytic enzyme of *Bacillus megaterium BM 9.1*. Increased potassium nitrate concentration (% b / v) also causes an increase in fibrinolytic activity.

Conclusion

All inorganic nitrogen salts increases the production of the fibrinolytic enzyme *Bacillus megaterium BM 9.1*. The best nitrogen source from inorganic nitrogen salt for the production the fibrinolytic enzyme of *Bacillus megaterium BM 9.1* is potassium nitrate. With the

optimum concentration of 2% b / v. So that the *Bacillus megaterium BM 9.1* with inorganic nitrogen salts can be used as one of the therapies as fibronolytic agents.

Ethical Clearance: The research process involves participants in the survey using a questionnaire that was accordant with the ethical research principle based on the regulation of research ethic committee. The present study was carried out in accordance with the research principles. This study implemented the basic principle ethics of respect, beneficence, nonmaleficence, and justice.

Relationship Exclusively Giving Mother's Milk with Growing Baby

Mustamin Mustamin[1,2], Chatarina Umbul[3], Shrimarti Rukmini Devy[4], Rudy Hartono[2]

[1]Doctoral Candidate of Health Sciences, Faculty of Public Health, Airlangga University, Indonesia; [2]Department of Nutrition, Makassar of Health Polytechnic, Indonesia; [3]Department of Epidemiology, Faculty of Public Health, Airlangga University, Indonesia; [4]Department of Health Promotion, Faculty of Public Health, Airlangga University, Indonesia

ABSTRACT

Breast milk is the best nutrient for infant especially for the newborn. Nutrition in breast milk has benefits for improving infant's growth and development. The infant are expected to be the successor of the nation that has competitiveness and high productivity by getting the best nutrition in the breastmilk. This research aims to determine the relationship of breastfeeding with infant's growth and development in Sudiang Raya District Makassar City. This research is an analytic with cross sectional study design. The population were all the infant aged 6-12 months in Sudiang Raya distric as many as 192 infants. Total sample were 78 infant. The results showed that the exclusive breast feeding was high (66,7%) compared to the non-exclusive breast feeding (33,3%). Based on data analysis found that there were a significant relationship between breastfeeding and infant's growth based on BB/U index with ρ: 0,000, PB/U index with ρ: 0,001 and BB/PB index with ρ: 0,010. There were also a significant relationship between breastfeeding and infant's development with *ρ: 0,000. Giving breast milk to the infant can increase growth and development so that it can improve their health status.*

Keywords: *breast milk, infant, growth, development*

Introduction

Based on data from the 2013 basic health research for the city of Makassar, breastfeeding <1 hour was 63.6%, breast milk for the past 1-6 hours was 20.5%, who gave breast milk for the last 7-23 hours was 1.5%, breastfeeding for the last 24-47 hours was 7.7% and the last ≥48 hours was 6.8%[2,5,9].

Growing and developing are two things that have different meanings. Growth and development is a continuous process that occurs since conception and continues into adulthood. Therefore, in the process of reaching this age the child must go through various stages of growth and development[15,16,18].

Data from the Ministry of Health of the Republic of Indonesia (2006) in Kholifah (2014), there are 16% of children under five in Indonesia who experience general developmental disorders. Whereas UNICEF (2011) data in Fauzia (2015), there are 27.5% or 3 million children under five who experience motor development disorders. This shows an increase in the number of toddlers who experience general developmental disorders which include gross motor development disorders, fine motor skills, hearing loss, intelligence and delayed speech.

Based on the description of the low rates of exclusive breastfeeding, the importance of the benefits of exclusive breastfeeding and the number of patients with growth disorders in Indonesia which continues to increase, the authors are interested in examining the "relationship between breastfeeding and infant growth in the Sudiang Raya area of Makassar City".

Material and Method

This study is an analytical study with a cross sectional study design. This research was conducted in the Sudiang Raya Urban Village in February-June 2017.

The population in this study were 192 infants aged 6-12 months. The sample was chosen by random sampling method and selected 78 babies.The instrument used was the Pre Development Screening Questionnaire, digital scales and fixation boards[12].

The type of data collected consists of two types, namely primary data and secondary data. Primary data is data obtained from respondents through observation and interview activities.

The primary data collected is as follows:

1. Respondent and family characteristics including name, age, date of birth, parent's name, address of parents, work of parents, education of parents, tribes of parents and religion of parents obtained through interviews.
2. Providing breast milk to babies obtained through interviews directly with the mother of the baby.
3. Baby growth which includes data on body weight and body length of the baby. Body weight data was measured using weight scales and body length data was measured using a fixation board conducted directly by the researcher towards the respondent.
4. Development of infants is assessed based on the suitability of development based on the age of the baby at that time. Developmental screening uses the form of the Pre Development Screening Questionnaire conducted by researchers on parents, closest people or baby caregivers.

Meanwhile, secondary data obtained in the form of the number of babies, schedules and locations of posyandu were obtained through the Sudiang Raya Health Center in Makassar City.

Data on body weight and body length were processed using the WHO Antro application that displays the nutritional status of the sample[2,3,5,14,15].

Data from the sample development interviews were assessed manually based on scoring from the Pre Development Screening Questionnaire form[7,9,10]. Data analysis using SPSS with the chi square test

Findings

Characteristics of Respondents

Table 1: Characteristics of Respondents

Characteristics	n[1]	%
Baby age		
6-8 month	56	71,9
9-12 month	22	28,1

Conted…

Baby Gender women	41	52,6
administration of breast milk Exclusive	52	66,7
Father's age 19-30 years	43	55,1
Mother's age 19-30 years	58	74,3
Fathers's education Graduated from high school	52	66,7
Mother's education Graduated from high school	50	64,1
Father's occupation private employees	29	37,2
Mother's occupation housewife	70	89,7

$n^1 = 78$

Based on age, it was found that infants who were sampled were generally aged between 6-8 months as many as 56 infants (71.9%). According to gender, it is known that babies are generally female, as many as 41 babies (52.6%) and exclusively breastfed as many as 52 babies (66.7%)

It is known that mothers of babies generally aged between 19-30 years are 58 people (74.3%). While the baby's father is generally aged 19-30 years as many as 43 people (55.1%). he majority of parents' education is graduating from high school. The mother of a baby with high school education graduated as many as 50 people (64.1%) and father of a baby with high school education as many as 52 people (66.7%). Mother's work as a housewife is 70 people (89.7%), while the baby's father works as a private employee as many as 29 people (37.2%).

Administration of Breast Milk

Table 2: History of Administration of Breast Milk to Infants Aged 6-12 Months

Administration of breast milk	Total	
	n[1]	%
Exclusive	52	66,7
Non Exclusive	26	33,3

Based on the results of research conducted in the Sudiang Raya area of Makassar City in infants aged 6-12 months, it was found that 52 infants (66.6%) received exclusive breastfeeding and 26 exclusive breastfeeding (33.4%).

Relationship between Giving Breast Milk with Baby Growth

Table 3: Relationship between Giving Breast Milk with Baby Growth

Good nutritional status	Administration of breast milk				p
	Exclusive		Non Exclusive		
	n	%	n	%	
good nutritional status	51	73,9	18	26,1	0,000
body length according to age	50	74,6	17	25,4	0,001
body weight according to body length	52	70,3	22	29,7	0,010

The chi-square test results of the relationship between breastfeeding and infant growth based on index body weight according to age and body length according to age with a value of ρ = 0,000, body length according to age index with a value of ρ = 0.001 and index body weight according to body length with a value of ρ = 0.010. According to the results of the study, infants who were exclusively breastfed had normal nutritional status based on the body weight according to age index of 51 infants (98.1%) and those who were not exclusively breastfed 18 infants (69.2%) had good nutritional status. Based on body length according to age index, 50 infants (96.2%) had normal body length and were given exclusive breastfeeding and 17 babies (65.4%) had normal body length but were not given exclusive breastfeeding. Meanwhile, based on the body weight according to body length index all infants fed exclusively breastfed had normal nutritional status while 22 infants who were not given exclusive breastfeeding (84.6%) had normal nutritional status and 4 infants (15.4%) among them were thin.

Relationship between Breastfeeding Mother and Baby Development

Table 4: Relationship between Breastfeeding Mother and Baby Development

Baby development	Administration of breast milk				ρ
	Exclusive		Non Exclusive		
	n	%	n	%	
Corresponding	49	84,5	9	15,5	0,000
Not corresponding	3	15	17	85	

The results of statistical analysis prove that there is a significant relationship between breastfeeding and infant development in the Sudiang Raya area of Makassar City with a value of p = 0,000. Infants who were exclusively breastfed were 52 babies (66.7%), 49 infants (94.2%) of whom had development according to their age and 3 babies (5.8%) had inappropriate developments. Meanwhile, of the 26 babies (33.3%) who were not given exclusive breastfeeding as many as 17 babies (65.4%) had inappropriate development and 9 babies (34.6%) had the appropriate development.

Discussion

Mother's milk (ASI) is the best food for newborns, breast milk should also be given as early as possible when the new baby is born. Breastmilk given to babies after birth until the fourth or seventh day contains colostrum which is a liquid that is rich in protein and functions to fight infection, thereby reducing morbidity and even mortality. The provision of ASI can also help the survival of babies, especially families from low socio-economic groups by helping to alleviate the family's economic burden and improve the quality of life for babies from poorly maintained sanitation environments.

Based on the results of research conducted in the Sudiang Raya area of Makassar City in infants aged 6-12 months, it was found that 52 infants (66.6%) received exclusive breastfeeding and 26 exclusive breastfeeding (33.4%). The provision of exclusive breastfeeding to infants is higher than that of infants who are not given exclusive breastfeeding according to previous studies. Previous research conducted in the working area of the health center in Tamalanrea, Makassar, also stated that more groups were given exclusive breastfeeding, namely 29 respondents (56.9%) compared to non-exclusive breastfeeding groups, namely 22 respondents (43.1%)[19,20,21]. Growth is a quantitative change in the form of an increase in the number, size, dimensions of cells, organs and individuals. Not only changes in physical size of the body but also the structure of organs and brain[18,19].

Based on the results of statistical analysis states that there is a significant relationship between breastfeeding and infant growth in the Sudiang Raya area of Makassar City based on the index body weight according to age, body length according to age and body weight

according to body length. The chi-square test results of the relationship between breastfeeding and infant growth based on index body weight according to age with a value of ρ = 0,000, body weight according to age index with a value of ρ = 0.001 and index body weight according to body length with a value of ρ = 0.010.

This is in accordance with previous research where there was a significant relationship between exclusive breastfeeding and the growth of 6-month-old infants in the Working Area of Berseri Pangkalan Kerinci Health Center, Pelalawan Regency. Likewise with the research which states that exclusive breastfeeding affects the nutritional status of infants [9,10,11,14].

Giving intake other than breast milk for infants under 6 months of age can increase the risk of infectious diseases and trigger malnutrition. This is because the provision of intake other than breastmilk cannot be properly digested by the intestines of the newly developing baby and the non-sterile manufacturing process can mediate the entry of infectious disease-causing bacteria[4].

Development is a change that occurs quantitatively and qualitatively, increasing the ability of the body's function to be better and predictable which is an interpretation of maturation or maturity. Changes in development occur in gross motor function, fine motor, cognitive, language, emotional and behavioral development as a result of development that is influenced by the environment[1,3,4].

The results of statistical analysis prove that there is a significant relationship between breastfeeding and infant development in the Sudiang Raya area of Makassar City with a value of p = 0,000. Infants who were exclusively breastfed were 52 babies (66.7%), 49 infants (94.2%) of whom had development according to their age and 3 babies (5.8%) had inappropriate developments. Meanwhile, of the 26 babies (33.3%) who were not given exclusive breastfeeding as many as 17 babies (65.4%) had inappropriate development and 9 babies (34.6%) had the appropriate development.

The results of this study are in line with research conducted in July (2015) where there was a significant relationship between exclusive breastfeeding and exclusive breastfeeding on the development of children aged 3-12 months in which 25 infants (41.7%) who were exclusively breastfed had normal development.

Optimal child growth is influenced by three basic needs. The three basic needs are ASUH in the form of fulfilling children's basic needs in the form of intake such as breastfeeding and monitoring growth, ASIH in the form of fulfilling children's emotional needs such as love and treatment from people around their environment and ASAH obtained through the learning process[20,21].

Conclusion

1. Based on the body length according to age index, 96.2% had normal body length exclusively breastfed and 65.4% had normal body length but were not given exclusive breastfeeding. Meanwhile, based on the body weight according to body length index all infants who were given exclusive breastfeeding had normal nutritional status (100%) while 84.6% of infants who were not given exclusive breastfeeding had a normal nutritional status and 15.4% were thin.
2. Infants aged 6-12 months who are given exclusive breastfeeding in the Sudiang Raya area of Makassar City have a development that is in accordance with their age of 62.8%. Meanwhile, infants who were not given exclusive breastfeeding and had an inappropriate development of 65.4%.
3. Giving breast milk to infants aged 6-12 months in the Sudiang Raya area of Makassar City has a significant relationship to the growth of infants with ρ: 0,000 for index body weight according to age, ρ: 0,001 for display body according to age index and ρ: 0,010 for index body weight according to body length index.
4. Giving breast milk to infants aged 6-12 months in the Sudiang Raya area of Makassar City has a significant relationship to the development of infants with ρ: 0,000.

Conflict of Interest: There was no conflict of interest at the time this research was conducted.

Source of Funding: This study received independent funding and assistance through the Makassar health polytechnic Risbinakes fund of the Ministry of Health of the Republic of Indonesia.

Ethical Clearance: Before the research was conducted, researchers obtained ethichal clearence from the ethics commission of health research at the Makassar Health Polytechnic.

ABSTRACT

Smoking is a serious threat to global health, around 1.3 billion tobacco users have nearly 6 million people who die each year due to diseases that arise from tobacco use. Smoking behavior not only can trigger NCDs *(Non-Communicable Disease)* but it also has an effect on economic problems, the more cigarettes consumed, the higher the costs that will be incurred due to health care and the cost of death due to diseases that arise from smoking behavior. Comprehensive smoking behavior problems which are caused not only by psychological and pharmacological factors but also social and environmental needs a community approach to control these behaviors.

This study aims to collect and analyze articles related to the application of community models in an effort to control smoking behavior. The design used is the *literature review*, articles are collected using search engines such as *ProQuest*, BMC Public Health, Google Scholar and *Plos One*. Criteria article used was published in 2007 -2017. Based on the collected articles, the result is found that the community-based approach can be applied in the context of controlling smoking behavior as an effort to move the community and to modify the social environment that can support the creation of behavioral changes and to control smoking behavior.

Keywords: *Smoking Behavior, Community Approach, Control smoking*

Introduction

Smoking behavior has becomes a people's lifestyle, compared to rural areas, smokers in urban areas are more numerous, this is because urban residents or urban communities have very high social movements[1.] Smoking remains a serious threat to global health, around 1.3 billion tobacco users, nearly 6 million people die each year from diseases arising from tobacco use[2,3.] Tobacco use causes excessive health costs and loss of one›s productivity[3.] About 80% of the 1.3 billion smokers worldwide live in low and middle income countries, where the burden of disease and death from tobacco use are the biggest problem in the country[3.]

Based on data from the Global Adult Tobacco Survey (GATS) in 2015 from 22 countries there were 879 million smokers with a total of 721 men who smoked and 158 women who smoked[2]. If there is no serious prevention in inhibiting the growth of smoking behavior, in the 21st century, there will be 1 billion people die of illness due to smoking. It can be concluded that, the higher the consumption of cigarettes the higher the mortality rate[4.]

The problem given of smoking behavior is a comprehensive problem because it is caused not only by psychological factors such as the presence of comfort when smoking, and addiction due to addictive substances contained in cigarettes, but also there are social and environmental factors that have an important role in shaping a person›s smoking behavior, so what is done is not enough to approach individually but in a community.

Handling community-based smoking behavior has been carried out in various countries starting from the implementation of non-smoking regional policies, interventions by providing counseling, and various smoking cessation programs[5,6]. Nierkens (2013) revealed that community-based interventions to overcome the problem of tobacco use are more effective by combining family values[7]. Helping smokers to quit without creating an environment that supports them to quit will be difficult for a smoker and can cause them to relapse. Whereas community-based intervention has a framework that shows that individuals, interpersonal, community, organization and government have an influence on individual health status and can overcome several factors that form smoking behavior simultaneously[8]. Therefore, the handling of community-based smoking behavior is considered effective in overcoming the problem of smoking behavior. Based on the background above, the authors are interested in discussing "community model applications in an effort to control smoking behavior".

Method

The method used in writing this article is a literature review. That is a search for literature conducted using an online database that provides free journal articles in PDF format: ProQuest, BMC Public Health, Google schooler and Plos One. In the initial stages of searching for journal articles, around 400 articles from the Year 2007 to 2017 were obtained. Exploration and identification of articles that have relevance will be compiled. Of these, only about 95 articles are considered relevant.

Results

Based on the results of the articles collected and the analysis of the authors, it was found that smoking behavior was caused by things that were multi cause. Smoking does not necessarily become a person›s daily activities. There are various kinds of factors that influence a person to become a smoker that is starting from lack of knowledge related to the dangers of smoking to health, low education, weak economy, influence of parents, influence of friends, influence of advertising, influence of substances in cigarettes, psychological influences and cultural influences[9-20] .

The most important thing on a problem of smoking behavior that their exposure to smoke by people around who do not smoke, especially mothers and children are usually known as SHS (Secondhand *Smoker).* The higher the number of active smokers, the higher the SHS (Second Hand Smoker) will be. This prompted the Government to issue a policy related to the protection of SHS such as prohibiting smoking in certain places and in vehicles with children[21-24]. Therefore, to handle and control the behavior of smoke, which is quite alarming, many countries implementing strategies that can touch the biggest factor causing the increase of smoking behavior that social environmental factors by implementing a strategy based on community.

Forms of community-based smoking behavior control are carried out by various countries, namely the application of assessed smoke-free policies can decrease my smoking prevalence, exposure to SHS and health issues that arise from smoking[24]. Brazil is one of the success stories that has succeeded in reducing deaths arising from tobacco. A policy strategy called «The Sim Smoker Policy Simulation Model» developed in Brazil has succeeded in overcoming the problem of smoking. The policy model adopted is starting with raising the price of cigarettes, strict restrictions on cigarette advertisements and health warnings, the existence of laws or rules for non-smoking air and increasing smoking cessation programs[25].

Other policies in the form of increasing tobacco tax, intervention in packaging tobacco products, campaigns through mass media and prohibitions on cigarette advertising at the point of sale, can effect smoking attitudes and behavior[24.26]. In America, various media lift isseu related dangers of smoking on health, the efforts of the media to support the advocacy process and help policy makers easily to employ the new area without smoke and to shape public opinion in order to pro-restaurant and non-smoking bar[27].

Along with the development of the times, increasingly developing technology is used as a medium for delivering information to a broad audience. In New Zealand, using a social media program is called «Online Smoking Cessation Social Network». The program helps the wider community to obtain information regarding the dangers caused by smoking and guide smokers to stop smoking[28].

In Indonesia one form of community-based intervention that has been proven to be able to control

smoking behavior, namely being in a bone-bone village. Bone-bone Village in Enrekang District, South Sulawesi Province is a clear proof of the success of overcoming the problem of smoking with a community-based approach. The information obtained related to the dangers of smoking for themselves and surrounding people, aroused the heart of one of the Public Figure, namely the Village Head to deal with smoking behavior in his village. The strategy used by conducting a survey previously was related to the community›s opinion about cigarettes and then together with other community leaders, they drew up a plan and invited the community to participate to jointly determine the area of smoke-free Bone-bone Village[29].

Discussion

Smoking behavior has become the lifestyle of today's society from a variety of elements either old, young, poor or rich. Smoking has a major impact on the environment that is unhealthy and has a worse impact on the overall health of the community[30]. Smoking behavior is not only detrimental to the health of the smoker itself but also the people around him. Viewed from any angle the cigarette remains negative. The more a person smoked the more death and the emergence of the risk of disease NCD›s (Non-Communicable Disease).

The World Health Organization in the Ottawa Charter through the International Conference on Health Promotion in 1986 has provided a framework clearly as an approach to changing people›s behavior towards better public health by developing health-minded public policies, create an enabling environment, strengthen community action or movement, develop individual skills, and reorient the health care system[30,31].

Given the smoking behavior of the world community is very alarming, one of the efforts of the WHO (World Health Organization) to overcome the current tobacco problem is to invite each country to implement the MPOWER strategy[3]. The strategy MPOWER question are: **M**onitoring of tobacco use and prevention policies, **P**rotect from tobacco Smoker, **O**ffer help to quit tobacco use, **W**arn about the dangers of tobacco, **E**nforce bans on tobacco advertising, promotion and sponsorship, **R**aising taxes on tobacco. Referring to this MPOWER strategy, several countries make community-based smoking behavior control programs.

Community refers to a group of people who share a sense of social identity, general norms, values, goals, and institutions[32]. A community is based on geographical boundaries (environment, city, or other place), social identity and interests (ethnic groups), or sharing political responsibility[33,34]. Various studies reveal that the handling of community-based smoking behavior is effective in dealing with smoking behavior in certain groups[7,35]. Community -based interventions not only take place in society, but also important in guiding into a characteristic.

The following are three principles in community-based interventions; Community-based interventions are guided by an ecological framework, where individuals, interpersonal, community, organization, and government factors are believed to influence individual health status, efforts by community-based programs to overcome several factors, either simultaneously or sequentially[8]. Community-based interventions are designed to meet community desires and membership-based interventions. Communities usually begin with needs assessment and developing relationships with community leaders who understand the strengths and problems of the community. The third characteristic of community-based interventions is community participation. Community participation refers to the process by which individuals and families take an active part in discussions and activities to improve people›s lives, services, or resources.

Community-based intervention by relying on community participation is considered capable of overcoming multi-causes health problems. The community-based approach recognizes that health problems have several causes, requiring several interventions to influence individual behavior and simultaneously changing the social, political and economic environment based on local health conditions[8]. Applying a community-based approach shows that the role of family or community leaders influences smokers to stop smoking and reduce exposure to Secondhand Smoker (SHS). In this case, community participation in an environment where a smoker is located can influence a smoker to quit[35].

Conclusion

Community-based interventions are considered effective in overcoming the problem of smoking

behavior because, the problem of smoking behavior is a comprehensive problem caused not only by psychological factors but also by social or environmental factors. Community-based interventions place more emphasis on community participation which refers to the process by which individuals and families take an active part in discussions and activities to improve people›s lives by continuously controlling smoking behavior. With a community approach, we are able to create an environment that supports changes in one›s smoking behavior. Further research needs to be done by considering the implementation of community-based smoking behavior control for marginal areas with special characteristics.

Level of Type L Metacrylate Acid Copolymer as Microparticle Matrix Improves *Lactobacillus casei* Protection against Gastric Acid

Ayun Dewi Rahayu[1], Dwi Setyawan[1], Sugiyartono[1]

[1]Department of Pharmacy, Faculty of Pharmacy, Universitas Airlangga, Jl. Airlangga No.4 - 6, Airlangga, Gubeng, Surabaya, East Java, Indonesia

ABSTRACT

Background: *Lactobacillus casei* is a probiotic that has an ability to protect the intestine, but is damaged due to the acid pH in the stomach. A system is needed to provide protection. Probiotic microencapsulation can provide protection against *Lactobacillus casei* by increasing the levels of methacrylic acid copolymers.

Objective: The aim of this study is to determine the effect of type L methacrylic acid copolymers as microparticle matrix on the protection system of *Lactobacillus casei* against acidic atmosphere.

Method: *Lactobacillus casei* probiotic microparticles were made from three formulas using matrix type L methacrylic acid copolymers with levels in formulas I, II, and III, each of which was 0.50%; 0.75%; and 1.00% by spray drying technique at 120°C inlet temperature.

Results: Moisture content decreased with the increasing levels of methacrylic acid copolymers from formulas I, II and III with 10.05% ± 0.49; 9.77% ± 0.19 and 7.45% ± 0.11 respectively. In determining particle size, the results increased simultaneously with the increasing levels of methacrylic acid copolymers in formulas I, II and III, which were 3.29 ± 0.07; 3.79 ± 0.06 and 4.34 ± 0.13 respectively.

Conclusion: Increasing the level of L type methacrylic acid copolymer as a matrix can increase the protection capability of *Lactobacillus casei* microparticles against gastric acid.

Keywords: *Probiotics, Lactobacillus casei, spray drying, capolymer.*

Introduction

Probiotics is possible to change the microbial balance in the intestine as a first aid for hosts [(1)]. Probiotic bacteria can maintain intestinal health, help absorb food, produce vitamins, prevent the growth of pathogenic bacteria, and increase host immunity [(2)]. Probiotics must be able to get through stomach acid and reach intestine in the amount of 106-107 cfu/ml in order to provide benefits for the host [(3,4)]. *Lactobacillus casei* is a lactic acid bacteria that has antibacterial effects, immunomodulatory effects, and can be beneficial for the health of the digestive system [(5,6)]. *Lactobacillus casei* has an action target area in intestine, but can be damaged by an atmosphere of stomach acid [(7)]. The development of drug delivery systems aims to minimize the occurrence of drug degradation, prevent harmful side effects of drugs, and increase bioavailability and accumulation of drug fractions in desired body parts [(8)]. One development of drug delivery systems is to use microparticles as carriers of active ingredients. The process of making microparticles is by using microencapsulation [(9)].

Type L methacrylic acid copolymer is an anionic polymer which has been commercially used as an enteric coating for delivery of oral drugs, in which the drug will be released into the intestine that has an alkaline environment [(10)]. Matrix levels are related to the

Gubeng, Surabaya, East Java, Indonesia 60115

density and wall thickness of the formed microparticles. In addition, the high matrix content has an effect on increasing the viscosity of the matrix solution and will increase the thickness of the microparticle wall. The density and wall thickness of the microparticles increase the protection power of the microparticles against stomach acid [3,6,11].

Spray drying technique is a technique of forming microparticles by dissolving or suspending probiotics into a solution or melt polymer and trapped in the form of particles [9]. Formation of microparticles from spray drying is done by hot air flowing resulted in water evaporation that occurs faster [9,12]. The research using spray drying with an inlet temperature of 98º C resulted in the morphology of the microparticles which did not meet and the water content was still high. Based on the description above, a study was conducted to obtain the right type L methacrylic acid copolymer which can provide protection power from the *Lactobacillus casei* microparticles to an optimal gastric acid atmosphere. In this study the spray drying method was used at an inlet temperature of 120ºC.

Method

This was a laboratory experimental study. The materials used were *Lactobacillus casei* from the Center for Food and Nutrition Studies at Gajah Mada University, Yogyakarta, Indonesia, type L methacrylic acid copolymers, Sodium hydroxide (NaOH), de Man Ragosa Shorpe (MRS), Agar medium, sterile Phosphate Buffer Saline (PBS), Potassium phosphate (KH2PO4), Potassium chloride (KCl), Aquadem free of CO2 and sterile Aquadem.

Identification of type L methacrylic acid copolymers: Examination of L-type methacrylic acid copolymers with FTIR spectrum was carried out using KBr pellet technique. As much as 1 mg of the substance with 100 mg KBr was mashed homogeneously, then put into a vacuum dryer, then molded with a hydraulic press until a thin translucent plate was obtained. From the results of the examination, the specific wave number values of the compounds analyzed were obtained. Specific wave numbers obtained stated the presence of certain groups of structures of compounds analyzed [13].

Preparation of *Lactobacillus casei* Probiotic Bacteria Starters: Ingredients of de Man Ragosa Shorpe (MRS) medium of 5.22 grams of broth were weighed and dissolved into 100 ml sterile aquadem, then stirred until homogeneous. The solution was heated by slowly heating to boil, for one or two minutes. After being homogeneous, the solution poured into a test tube container of 10 ml and sterilized at 121ºC for 15 minutes. *Lactobacillus casei* from main stock culture was bred by taking one Ôse of bacteria and then put in 1 ml of sterile saline and vortexed until it was cloudy. Then, put in 10 ml of MRS sterile broth and dishwasher at 37ºC for 48 hours. Furthermore, it was taken as much as a few Ôse and swiped on a sterile slant and incubated at 37ºC for 48 hours to become a starter of *Lactobacillus casei* which was ready for use. Culture of probiotic bacteria can be used for a maximum of 1 month at 4ºC storage. If the culture stored more than 1 month, probiotic bacteria need to be rejuvenated.

Optimization of *Lactobacillus casei* Growth Time: As much as 5.22 grams of MRS broth were weighed and dissolved in 100 ml sterile aquadem, and then stirred until homogeneous. Once it become homogeneous, the solution was poured into an erlenmeyer container and sterilized at 121ºC for 15 minutes. The MRS medium of sterile broth was added with one Ôse starter of *Lactobacillus casei* and incubated at 37ºC. Samples were taken at 0, 4, 6, 8, 12, 16, 18, 24 and 48 hours to check pH and the number of *Lactobacillus casei* colonies by determining the Total Plate Count (TPC) of each growth time.

Examination of pH of *Lactobacillus casei* suspension carried out by *Lactobacillus casei* culture in MRS broth was taken for 10 ml at each time of growth. Then, the measurements were carried out using a calibrated pH meter using standard buffer solutions. Determination of TPC was carried out by 1 ml *Lactobacillus casei* suspension mixed with 9 ml sterile phosphate buffer saline (PBS with pH = 7.4) and vortexed. A 1:10 dilution was carried out in 10 series dilutions using sterile PBS, each dilution was piped as much as 1 ml to be inserted into a tube containing 10 ml MRS so that the sterile was then vortexed and poured into a plate. The plate was shaken until the sample was evenly dispersed. After the MRS medium solidified, the plate was incubated at 37ºC for 48 hours.

***Lactobacillus casei* Microparticle Formulation**

Table 1. Design of Lactobacillus casei microparticle formula

No.	Materials	Function	FI	FII	FIII
1.	Bacterial Suspension: *Lactobacillus casei*	Active ingredients	109 *cfu*/ml	109 *cfu*/ml	109 *cfu*/ml
	Sterile aquadem	Solvent	ad 250 ml	ad 250 ml	ad 250 ml
2.	Matrix solutions:				
	Acid copolymers type L methacrylate	Matrix	5 grams	7.5 grams	10 grams
	MRS *broth*	Nutrition	5 grams	5 grams	5 grams
	Sterile aquadem	Solvent	ad 750 ml	ad 750 ml	ad 750 ml

Note:

F I: Formula with 0.50% type L methacrylic acid copolymer

F II: Formula with 0.75% type L methacrylic acid copolymer

F III: Formula with 1.00% type L methacrylic acid copolymer

Levels of type L methacrylic acid copolymers on F I, II, and III were made from a total of 1000 ml.

Protection Test of *Lactobacillus casei* Microparticles against Gastric Acid: Test solution was prepared, i.e. acid solution of pH of 1.2 and pH of 7 of phosphate buffer saline solution. Acidic solution of pH of 1.2 was made by mixing 50 ml of 0.2 M KCl solution with 85 ml 0.2 M HCl solution and added aquadem to volume of 200 ml. Phosphate buffer saline of pH of 7 was then made with a composition of 50 ml 0.2 M KH2PO4 mixed with 25 ml 0.2 M NaOH solution and added aquadem to volume of 200 ml. In addition, the calculation of viable bacteria using the Total Plate Count method was incubated at 37ºC for 48 hours. Three-time replications were performed for each formula.

Results

Optimization of Lactobacillus casei Growth Time: The results of *Lactobacillus casei* pH and ALT log tests showing the amount of viability of germs at each incubation time are presented in Table 2.

Table 2: Results of *Lactobacillus casei* pH and ALT log examination at each incubation time

0	8.87	9.5	9.49	9.29 ± 0.36
4	8.62	9.85	8.97	9.15 ± 0.63

Conted…

6	11.28	11.56	9.42	10.75 ± 1.16
8	9.66	9.36	9.47	9.50 ± 0.15
12	12.54	11.07	12.76	12.12 ± 0.92
16	11.17	11.58	11.73	11.49 ± 0.29
18	10.48	10.71	10.55	10.58 ± 0.12
24	10.09	10.72	9.99	10.27 ± 0.40
48	9.48	10.49	9.46	9.81 ± 0.59

From the pH test results, it was found that there was a decrease in pH from the growth time of 0 hours until the growth time of 12 hours. In 12 to 18 hours, the pH was stable and then an increase in pH was occurred. Based on the results of these tests, it can be seen that the optimum time for *Lactobacillus casei* (the end time of the exponential phase or the beginning of the stationary phase) occurred for 12 hours.

Protection power Test Results of *Lactobacillus casei* Probiotic Microparticles on Gastric Acid Atmosphere

Table 3: Test of Protection power Test of *Lactobacillus casei* Probiotic Microparticles on Gastric Acid Atmosphere

Formula	Replication I	Replication II	Replication III	Mean ± SD
ALT log after Spray Drying				
I	6.45	7.06	7.04	6.85 ± 0.35
II	6.35	7.49	6.89	6.91 ± 0.58
III	7.68	7.30	6.83	7.27 ± 0.45
ALT log of *Lactobacillus casei* in a microparticle after being exposed to an acidic atmosphere				
I	6.46	6.19	6.25	6.30 ± 0.14
II	6.68	6.72	6.45	6.62 ± 0.15
III	7.05	7.22	7.14	7.14 ± 0.09
Protection of *Lactobacillus casei* in microparticles against acidic atmosphere (%)				
I	94.31	90.36	91.24	91.97 ± 2.07
II	96.72	97.30	93.39	95.80 ± 2.11
III	96.97	99.31	98.21	98.17 ± 1,17

From these data, it can be seen that the increase in matrix levels of type L metacrylate acid copolymers (0.50%, 0.75%, and 1.00%) can increase the percentage of protection power in the *Lactobacillus casei* microparticles.

Discussion

Increased matrix levels used can cause an increase in the thickness and density of the matrix wall. The higher methacrylic acid copolymer causes more hydrogen bonding carboxylic groups to be formed and will increase the density of the microparticle wall [(14)]. The density and wall thickness of a high microparticle causes an increase in the protection power of the microparticle against stomach acid [(3)].

The mixture of *Lactobacillus casei* suspension with matrix solution and MRS was carried out by microencapsulation using spray drying method and the pre-adaptation process was firstly carried out. [(15)]. The three microparticle formulas produced had a moisture content (MC) higher than the required content of probiotic microparticles which was not more than 4% [(16)]. The moisture content of spray drying microparticles can be influenced by the inlet temperature. An increase in inlet temperature can cause a decrease in moisture content [(17)].

The difference in matrix levels will affect the characteristics of the probiotic microparticles that are formed. Probiotic microparticles that meet the characteristics of probiotic microparticles range from

1-1000 µm, ideally less than 100 µm. [3,18]. Entrapment efficiency is carried out to determine the amount of probiotics coated in microparticles and show the content of probiotics as active ingredients [19]. Factors that influence entrapment efficiency are include solubility of the polymer in solvents, matrix content, and solvent removal rate. [1]. High matrix levels will increase the protection of probiotics against temperature.

Spray drying is a single closed system process that can be used for a variety of materials. The medicinal ingredients are dissolved or suspended into suitable solvents containing polymers. The solution or suspension is atomized into the drying chamber and the microparticles are formed as atomization droplets which are dried by hot air. The results are highly influenced by the nature of the material. Microparticle parameters, such as particle size and solvent residue levels, are influenced by instrument settings, such as inlet temperature, feed flow rate, air spray flow, and aspirator flow. Parameter optimization is done through trial and error [19]. The use of spray drying in the probiotic industry is limited because of the high temperatures during the process can reduce the viability of probiotics.

The size of probiotic microparticles of formula I, II and III increased with the increase in the matrix content of type L methacrylic acid copolymers used. This can occur because the increase in matrix levels causes an increase in wall thickness so that the size of the microparticles is larger [3]. Increased levels of L-type methacrylic acid copolymers on each formula showed significant differences in the particle size of the *Lactobacillus casei* microparticles formed. The protection power of probiotic microparticles against acids is the ability of probiotics in the form of microparticles to survive during the acidic atmosphere of the stomach.

Conclusion

Increased levels of type L methacrylic acid copolymers from 0.50%; 0.75%; and 1.00% as a matrix can cause an increase in the protection power of *Lactobacillus casei* microparticles against stomach acid. The formula with 1.00% type L metacrylate acid copolymer was a formula with the highest protection power for *Lactobacillus casei* microparticles against stomach acid.

Ethical Clearance: The research process involves participants in the survey using a questionnaire that was accordant with the ethical research principle based on the regulation of research ethic committee. The present study was carried out in accordance with the research principles. This study implemented the basic principle ethics of respect, beneficence, nonmaleficence, and justice.

Conflict of Interest: The author reports no conflict of interest of this work.

Source of Funding: This study is done with individual funding.

The Influence of Tell Show Do Method Based on Individualized Educational Program (IEP) to the Tooth-Brushing Behavioural Change among Slow Learner Children in Bukittinggi, Indonesia

Febrian[1], Ghina Ukhtia Fajrani[1], Arymbi Pujiastuty[1]

[1]Faculty of Dentistry, Andalas University, Jl. Perintis Kemerdekaan No. 77 Padang, Sumatera Barat, Indonesia

ABSTRACT

Objectives: Slow learner children are the largest population of children with special needs in Indonesia, including 80.64% have poor oral hygiene caused by inappropriate tooth-brushing. An advance learning method needs to take behavioural change of children's tooth brushing habit. This study aims to investigate the Tell Show Do Method based on Individualized Educational Program (IEP) affected the behavioral changes of tooth brushing among slow learner children in elementary school Bukittinggi, Indonesia.

Method: This was a quasy experimental study with one group pre-test and post-test design. Total of 32 slow learner children, grade 4-6 were included in this study. Data was analyzed by using Paired McNemar test.

Results: The latest behavioural change on cognitive, affective and psychomotor became different into good category. Hence, there is significant difference before and after counselling (p=0,000). So, it is concluded that Tell Show Do Method based on Individualized Educational Program (IEP) affect behavioural changes regarding tooth brushing among slow learner children in elementary school Bukittinggi, Indonesia.

Keywords *: Counselling, Tell Show Do, IEP, Slow Learner, Behavioural Change*

Introduction

Dental Caries is one of the most common oral hygiene issue in the world, including in Indonesia. One of the main factor is inappropriate of tooth brushing technique. According to RISKESDAS 2013, only 2,3% people in Indonesia use correct method of tooth brushing.[1] It may affect oral hygiene neither healthy person nor children with spesial needs. This study concerned about slow learner children.[4] Slow learner children are a group of children with IQ of 70-90 (slightly below average) without mental retardation. Fourteen percent children in Indonesia are slow learner and 80,64% of them have poor oral hygiene.[1]

Education and counselling could improve children oral hygiene.[3] There is a need of early counselling with proper method according to their ability, mainly in children with special needs. Slow learner children are categorized into children with special needs, but they can learn something as long the given method is a proper method. So thus proper education and counselling method for this population is needed.

One of the method of pediatric dentistry is Tell Show Do method.[6] Tell Show Do is the most effective non-pharmalogical techniques use by pediatric dentist.[7] This method is done by telling, introducing, and showing dental hygiene procedure to children. Information can be delivered verbally with language that easy to understand, and also by giving the children opportunity to observe and apply the given information.[6,8] Study by Arun Sharma and Rishi Tyagi in India in 2011, suggested that Tell Show Do method showed positive impact and very effective to modify children behavior.[9]

Slow learner children need special technique, unlike normal children.[10] Individualized Educational Program (IEP) is a program made to serve children with special needs. This program is adjusted for each individual, according to their ability, method, and learning speed so one can understand the given subject. In other word, this learning technique gives children chance to learn based on their ability so thus we can maximize their ability as well.[10] In Indonesia, this program was commonly used as an educational program to serve children with spesial needs including slow learner children. Whereas combination of Tell Show Do method to IEP is a new innovation that was never been done before. So, this study aims to investigate Tell Show Do based on IEP with behavioural changes on tooth brushing, among slow learner children.

Materials and Method

This was a quasy experimental study with one group pre test- post test design. Pre test was done at the beginning of the study by using a questionnaire, and respondents were given treatment using Tell Show Do based on IEP. Before counselling, first step to do was recognized the characteristics of slow learner children and grouped based on the results of that assessment. Then, counselling given individually with Tell Show Do method. At the end, evaluated the effect of counseling using post test with the same questionnaire. This study took place in Al Azhar Elementary School Bukittinggi, West Sumatera, Indonesia on February 2018. Fourth-sixth grade slow learner students were recruited. Data was analysed using Paired McNemar to investigate signification of each behavioural domain including cognitive, affective, and psychomotor, and considered significant if $p < 0,05$.

Results

Tabel 1: Differences of behaviour domain before and after counselling using Tell Show Do method based on IEP (n = 32)

Behavior Domain	Before Counselling				After Counselling				P value
	Good		Poor		Good		Poor		
	n	%	n	%	n	%	n	%	
Cognitive	12	37,5	20	62,5	30	93,75	2	6,25	0.000
Affective	11	34,37	21	65,63	30	93,75	2	6,25	
Psychomotor	10	31,25	22	68,75	29	90,63	3	9,37	

Based on table 1, frequency distribution of good categories increased after counselling. Before counselling, almost respondent had poor category to use tooth-brushing technique in cognitive, affective and psychomotor domain (62.5%, 65.63%, 68.75%) respectively. On other hand, cognitive, affective and psycomotor domain decreased in poor category after counselling with 93.75%, 93.75%, 90.63% respectively. So, there were significant difference of behaviour change before and after counselling using Tell Show Do method based on IEP with p value 0,000.

Discussion

Study showed that there were behavioural changes of tooth brushing among slow learner children after counselling using Tell Show Do method based on IEP observed by behavioural domain including cognitive, affective, and psychomotor. Firstly, counselling with the method of Tell Show Do based on IEP was done by recognizing the characteristics of slow learner children. Secondly, children with the same characteristics were classified into the same group. Then, they were given counselling on each group by using the Tell, Show and Do method gradually. Counselling in each group was different, depending on the level of children's ability, so it can be absorbed quickly or even takes a long time. Hence, this method is called by IEP.

The cognitive level was changed significantly due to counselling design according to the level of children's ability. The results of this study similar to the theory by the American Academy of Pediatric Dentistry (AAPD) claimed that the Tell Show Do method can changes children's knowledge of dental health care because of clearly explanations to children about the dental health

procedures at the "Tell" stage and shown the procedure to make them easier to understand at the "Show" and "Do" stage.[11] The significant change of the cognitive level in this research was also caused by appropriate service education to slow learner children with IEP. The results of this study is similar to Budiyanto et al in 2013 stated that the IEP is an efficient program to provide knowledge in children with special needs and can be absorb well. The program is implemented individually on each slow learner children according to the level of ability.[12]

In affective level category after counselling, there were significant changes to better affection than before counselling caused by education process of knowledge could produce good attitude. It also supported by Notoatmodjo 2010, respondent with good cognitive level also had good affective level too.[3]

Significant change of psychomotor level toward to good category because the counselling not only giving raw material at Tell and Show stage, but also giving opportunity to practice direct knowledge among slow learner children. Meanwhile, Do stage can stimulate their motor skills in brushing action. The children's motor skills can be stimulated by practical activities of their knowledge. Its supported by the AAPD in 2015 stated that the Tell Show Do method can give children the opportunity to try out their own procedures more precisely at the Do stage, so it more easily to understand and implement the procedure.[11]

Thus, the behavioural improvement was due to children's awareness to change their behaviour through health counseling.[1] Tell Show Do method can be used in behavioral management in pediatric dentistry.[6,8,13] This study similar to Arun Sharma and Rishi in India, suggested that Tell Show Do method had positive effect and can be used on behavioural management in pediatric dentistry.[9] Tell Show Do also can be used to explain oral hygiene to children with special needs. Not only verbal information and easy language, but also method enables children to observe and apply their knowledge under supervision.[14]

Tell Show Do method in this study was done through IEP. Study showed learning through IEP increased behavioural changes of tooth brushing among slow learner children. This was in accordance with theory by the ministry of education and cultural in 2013, suggested IEP could serve children with special needs.[13] Blackwell et al in United States argued that IEP was an appropriate and an effective program for children with special needs because it was adjusted with individual needs.[15] Ruble et al from United States also argued that IEP was the only program compatible to treat children with special needs due to children's needs and education based on their interested and understanding.[16]

Conclusion

Tell Show Do method based on Individualized Educational Program (IEP) has significant correlation with behavioural change on tooth brushing among slow learner children in elementary school Bukittinggi, Indonesia.

Ethical Clearence: Taken

Conflict of Interest: There is no conflict of interest of this study.

Hyperglycemic and Hypertension are Major Component of Metabolic Syndrome that Caused Circulatory Morbidity in Hajj Pilgrims

Iche Andriyani Liberty[1,2], Nasrin Kodim[2], Mukaramah[2]

[1]Department of Public Health and Community Medicine, Medical Faculty of Sriwijaya University, Palembang, Indonesia; [2]Department of Epidemiology, Public Health Faculty of Universitas Indonesia, Depok Indonesia

ABSTRACT

Hajj is a community that needs special attention, the series of worship activities during in the holy places in Makkah and Madinah must be supported by physical and mental prime. One of the health problems has related to circulatory disease. This study presents the impact of metabolic syndrome (hyperglycemic, hypertension, and obesity) that caused circulatory morbidity in Indonesian Hajj Pilgrims. The design study is Retrospective Cohort, conducted on 152,429 Indonesian pilgrims departing in the Hajj season 2016/1437H sourced from The Siskohatkes data of the Ministry of Health of the Republic of Indonesia. The prevalence of metabolic syndrome (hyperglycemic, hypertension, and central obesity) on Indonesian pilgrims 1.6% and significant differences were found in all characteristic: sex, age, employment, and education, BMI, istitha'ah, and smoking behaviour. Hyperglycemic had greater HR than hypertension and central obesity with HR of 2.06 (1.63-2.60) adjusted by BMI, smoking, age, and sex as a risk of inpatient care. While, hypertension had greater HR than hyperglycemic and central obesity with HR 2.04 (1.99-2.09) adjusted by smoking, age, and sex as a risk of outpatient care in the holy places in Makkah or Madinah. Regulation for additional history of drugs consumed on screening of pre-existing disease before departure is needed.

Keywords: *hyperglycemic, hypertension, Mets, hajj, morbidity*

Introduction

Metabolic syndrome (MetS) is a complex disorder characterized by abdominal obesity, impaired glucose metabolism, atherogenic dyslipidemia and hypertension.[1,2] A systematic review of epidemiologic data from the Middle East reports a prevalence of MetS in men of 20.7-37.2% and 32.1-42.7% in women. Increasing trend of circulatory disease followed by ignored active health policies to control the risk factors, but studies are available that discusses the risk factors of circulatory disease has not been found, especially that associated with metabolic syndrome. [1,3, 4]

Circulatory disease, which is customarily defined as those causes of mortality and morbidity with International Classification of Diseases 10th revision (ICD10) codes I00-I99 (or equivalently the International Classification of Diseases 8th or 9th revision (ICD8, ICD9) codes 390–459). Major types of circulatory disease are Arteriosclerosis, Cardiac valve diseases, Cardiac arrhythmias, Cardiomyopathy, Cerebrovascular disease (CeVD), Hypertensive disease, Ischemic heart disease (IHD), Pericarditis.[3]

Hajj is a community that needs special attention. the series of worship activities during in holy places in Makkah and Madinah must be supported by physical and mental prime. One of the health problems facing the congregation is related to circulatory disease. Blood glucose, triglyceride, HDL, LDL, cholesterol, blood pressure, and physical anthropometry such as weight and height and abdominal circumference are some of the variables that can be an indicator of cardiometabolic risk and have been measured before pilgrims leave. Hajj

pilgrims who are large populations are expected to become populations representing the community in providing predictive values related to metabolic syndrome and their impact on circulatory morbidity that are major problems and causes of major deaths worldwide.

Method

Study Design and Study Protocol: This study used secondary data SISKOHATKES 2016 with Retrospective Cohort Study design, conducted on all Indonesian pilgrims departing on the Haj season 2016/1437H. The target population of all Indonesian pilgrims departing during the Hajj season 2016 and recorded in the initial examination SISKOHATKES 2016. Population study has 152,429 pilgrims in 2016 who conduct medical tests.

Measurements and Calculations: Before departure, all Indonesian pilgrims are required to visit a government health facility for a medical examination and to receive a pocket book that outlines their health condition. Clinical identification of patients with the features of MetS was based on the criteria proposed by the NCEP-ATPIII (National Cholesterol Education Program Adult Treatment Panel III). Patients were considered to have MetS when three of the following five criteria were met: 1) waist circumference ≥ 102 cm in men and 88 cm in women; 2) fasting hyperglycemic ≥ 110 mg/dL or using diabetes medications; 3) triglycerides ≥ 150 mg/dL or taking triglyceride lowering agents; 4) HDL cholesterol < 40 mg/dL for men; < 50 mg/dL for women or taking cholesterol-lowering agents; and 5) hypertension (systolic blood pressure ≥130 diastolic blood pressure ≥85) or using antihypertensive medication. Body mass index (BMI) was calculated as weight (kg) divided by height (m) squared (kg/m^2). The criteria used to define overweight were underweight (<18.5); Normal weight (18.5 -24.9kg/m^2); Overweight (25.0-29.9kg/m^2); Obesity Grade I (30.0-34.9kg/m^2); Obesity Grade II (35.0-39.9kg/m^2); and Extreme Obesity as BMI of ≥40 kg/m^2. Based on the Regulation of the Minister of Health of the Republic of Indonesia Number 15 of 2016 on Istitha'ah explained that the ability to perform the pilgrimage physically, mentally and provision.

Statistical Analysis: Processing and analysis were performed using statistical program STATA 15. Univariate analysis was performed to see the distribution of each variable and parameter estimation of the variables presented in tables, and bivariate analysis using Chi Square test. Multivariate analysis using Cox Regression to determine the hazard ratio of cardiometabolic factors on the impact of morbidity from cardiovascular disease. Before the variable entered in multivariate analysis, first tested proportional hazard. The test is conducted to determine whether the candidate variables has a proportional hazard over time or not.

Findings

All 15,429 Indonesian pilgrims were aged 18 years or more. where the prevalence of metabolic syndrome was 1.6% (2,450 pilgrimages). Most pilgrims had metabolic syndrome were female 1.8% and aged 50-59 years (Table 1). The prevalence of Mets (hyperglycemic, hypertension, and central obesity) on Indonesian pilgrims 1.6% and significant differences were found in all characteristic: sex, age, employment, and education, BMI, istitha'ah, and smoking behavior. Majority pilgrims with Mets were female (1.8%), aged 50-59 years (2.15%), military/police (2.0%), low education (1.7%), extreme obesity (3.0%), not qualified temporarily of istitha'ah (2.8%), and did not smoking (1.7%).

Table 1: Indonesian Hajj Pilgrims Characteristic and Metabolic Syndrome

Variables	Mets		Total	P-value
	Yes (n = 2,450)	No (n = 149,979)	(n = 152,429)	
Sex				
Female	1,563 (1.8%)	83,156 (98.2%)	84,719	0.000
Male	887 (1.3%)	66,823 (98.7%)	67,710	
Age				
<40 years	42 (0.3%)	14,749 (99.7%)	14,791	0.000

Table 2 from multivariate analysis with cox regression showed the results obtained that hyperglycemic had greater HR value than hypertension and central obesity with HR of 2.06 (1.63-2.60) adjusted by BMI, smoking, age, and sex. This means that pilgrims who before departure have clinical considents with hyperglycemic have a risk of 2.06 times to have circulatory disease and hospitalized (inpatient care) while performing the pilgrimage in the holy places in makkah or madinah.

Tabel 2: Multivariate Analysis of Associated Mets and Inpatient Care Caused of Circulatory Disease

Variables	Inpatient Care		Total (n=152,429)	HR 95% CI	p-value

Discussion

MetS is an increasingly common cause of morbidity and mortality and has been reported with many postulated pathophysiologic diseases. Prevalence of metabolic syndrome is high among Asians and is rising, particularly with the adoption of modernized lifestyle.[2] The most commonly associated with insulin, along with proinflammatory, prothrombotic, and low grade oxidative status.[5] In this research, age and sex has associated with Mets and in multivariable analysis, age is confounding variable. With respect to age, MetS prevalence rates were higher in older, relative to younger, elderly subjects; however, this difference was nonsignificant. In general, the prevalence of MetS increases with age.[6]

Aging is one of the diverse and functional that occurs from time to time. These terms also affect biological functions after reaching their maximum potentials. During aging, sex steroid hormone is reduced and sex hormones that bind globulin increase, the rate of decrease in free hormone levels. Therefore, the reproductive and non-reproductive actions of sexual steroid hormones decreased significantly. However, there are major differences in the prevalence, timing of onset and severity of many conditions such as metabolism and disease, which are different from men and women and protective roles. [7,8]

There is more evidence that different sex is important in epidemiology, pathophysiology, treatment and results in many diseases include hyperglycemic. Increased insulin secretion is observed in both sexes, both of which have sufficient compensation to approach the normal curve, derived from the control of normal weight on the subject. Insulin sensitivity disorders and insulin secretion are equally strong and similar in both sexes. The evidence is confirmed as well as introducing age and BMI as covariates into the entire population: that is, insulin sensitivity decreases with increasing BMI in the same rate for men and women in all categories of glucose tolerance; while insulin secretion increases with BMI on a faster rate in men, it is better to compensate for the increase insulin resistance. This trend may partly explain why, in general, women are better at insulin sensitivity than men in normoglycemic states. This may be related to sex hormones and their receptors, different body fat distributions and associated biomarkers, such as higher adiponectin. Estrogen shows a protector effect of cell apoptosis, stimulates the beta cell secretion and increased insulin sensitivity with antidiabetic effects mainly described to ERα.[9]

Meta-analysis of prospective cohort studies found in populations with MetS defined by NECP have a significantly higher risk of incident stroke than those without MetS and higher in women compared with men, which was in agreement with a few studies.[10] Proper identification of Mets in hypertension can provide better predictions of poor cardiovascular events and models that can be used for specific factors.[11]

Each component of the MetS is an independent risk factor for cardiovascular disease, together producing a wide spectrum of vascular and cardiac diseases.[12] Each component of cardiovascular disease, related to the spectrum of cardiovascular conditions including microvascular dysfunction, coronary atherosclerosis and calcification, cardiac dysfunction, myocardial infarction, and heart failure.[13]

The obesity relationship observed with hypertension makes the body work exploring the causes and effects of obesity on the heart. Chronic weight gain and adiposity can lead to significant neurohormonal changes and adaptation to the cardiovascular system. These changes include activation of the renin angiotensin-aldosterone system, changes in adipocytokines levels, and proinflammatory cytokines, and sympathetic nervous system activation. Activation of the sympathetic nervous system may contribute to increased heart rate, renal sodium retention, blood volume circulation, ventricular end (preload), cardiac output, and or blood pressure. [9,13,14]

Hajj is the largest annual religious ritual in the world, and also an obligation to be carried out at least once in the lifetime of every physically, psychologically and financially able Muslim.[14] Pilgrims with hyperglycemic should avoid exposure to heat and use protective footwear during hajj rituals. The mass-collection treatment in Hajj can be optimized by increasing the patient's knowledge of performing the pilgrimage at a younger age, doing monitoring of hypertension, blood glucose, and screening of pre-existing comorbidities. Maintaining weight, abdominal circumference, lipid profile within the optimal limit by continuing to perform regular physical activity and consumption of low-calorie foods, high fiber, and do not smoke is needed before pilgrims perform the pilgrimage.

Adherence to antihypertensive and antihyperglycemic consumption is also needed for blood pressure and blood glucose of pilgrims remain controlled before and during the pilgrimage. For healthcare providers it is necessary to immediately formulate regulation for additional history recording of drugs consumed by pilgrims during initial health check prior to departure. In order for the formulation of the drug to be consumed by the congregation appropriately to obtain blood pressure and controlled blood glucose.

The Determinant Factors of Child's Immunization Status: A Cross Sectional Study on the *Dayak Pitap* Tribe in the District of Balangan Indonesia

Ida Hastutiningsih[1], Oedojo Soedirham[2], M. Bagus Qomaruddin[2], Boerhan Hidayat[3]

[1]Doctoral Student of Public Health Program, [2]Lecturer, Department of Health Promotion and Behavior Science, Faculty of Public Health, [3]Professor of Medicine, Department of Pediatric, Faculty of Medicine, Airlangga University, Surabaya, Indonesia

ABSTRACT

Background: Even if the immunization coverage in a region is high, but the unimmunized child gathered in one location, then the benefit from herd immunity developed will not be gained by the child in that location so the risk for outbreak vaccine preventable diseases is high. So in order to solve this problem, it is important to reach this under vaccinated population and increase the child's immunization status of the population. The aims of this research were to describe the immunization status and its determinant factors that influenced the child's immunization status of *Dayak Pitap* tribe in the district of Balangan Indonesia

Method: A cross sectional study conducted in May to June 2018 which included the interview using a questionnaire with the mother of 12 – 35 month old child in all house hold in *Dayak Pitap* tribe. The independent variables were the mother's education level, the mother knowledge about immunization, the history of mother immunization status during pregnancy and the childbirth attendant and the cultural determinant namely the *aruh* ritual, the *papantang* and the use of the *samban*, whereas dependent variable was the child's basic immunization status. The uni-variable analysis and logistic regression analysis employed as the research analysis method.

Result: The complete child's immunization status coverage was 48%. The determinant factors that significantly influenced on the child's immunization status were the mother immunization knowledge level (p=0.000), the history of mother immunization during pregnancy (p=0.033), the history of birth attendant (p=0.000) and the using of *samban* by the children (p=0.012).

Conclusion: In order to gain the better child's immunization status coverage of the *Dayak Pitap* tribe, it is important to develop combination interventions to give better knowledge about immunization to the mother with the tailor made material, promote birth attendant labor and reach the pregnant mother for immunization.

Keywords: *Child immunization, indigenous tribe, cultural determinant*

Introduction

One of the purposes of immunization is to develop herd immunity in the community that can make all the children get benefit from the protection, including not immunized children and children who had already immunized but failure in developing antibody that can be caused by the child condition such as virus and bacterial infection[(1)], the nature and condition of the vaccine itself[(2)] "ISBN":"1873-2518 (Electronic[(3)] and the abnormalities of the immune system such as the *hypogammaglobulinemia,* other genetic factors and other causes that still poorly understood [(4)]. In order to develop the herd immunity, high uptake of fully immunized children must be obtained. The problem is every country

has population groups that are not fully immunized that have a consequence in the risk of vaccine-preventable disease outbreak.

Actually, in case there is a child, who is getting an infection of vaccine preventable diseases, but the high uptake of immunization has been obtained and the herd immunity has been developed, the other children will be protected because the spread of the infection had already blocked. However, this only works if unvaccinated child is scattered across geographical areas. If the unvaccinated child is gathered in one location, such as in the *Dayak Pitap* tribe, diseases can cause large outbreaks – even if the region or province or national vaccination coverage is high.

In this purpose, it is important to make sure that the immunization coverage in the remote areas is also high. However, based on the preliminary study that conducted in *Dayak Pitap* on January to March 2017, the fully immunized children coverage of the *Dayak Pitap* tribe was only 34.3% and from the in depth interview conducted with the traditional leaders, the *balian* (the traditional spiritual leader/traditional healers) and other community members, the reason for this low uptake of fully immunized children was probably because of the community belief about the causes of illnesses which are natural causes (heat, cold, rain), spirit of ancestor causes, shamanism causes, breaking taboos causes and other supra natural causes. This belief, therefore has an implication on the initiatives that they use to prevent illness, namely always conducted *aruh* ritual, not violate *papantang* and the use of a *samban* for their children. So besides the factors that have commonly stated as the determinant factors of the immunization coverage, in the *Dayak Pitap* tribe, the cultural factor such as *the aruh ritual, the papantang* and *the samban* probably also has a contribution in determining the child immunization coverage.

The *aruh* ritual is a ritual that conducted regularly by the *Dayak Pitap* tribe across the human life cycle and the rise cultivation cycle. The ritual filled with many kinds of sacred activities and materials, offerings and also rhythm that accompany the spell of the mantra and dance of the *balian* as the traditional spiritual leader. The absence of conducting the *aruh* ritual believed by the community can cause misfortunes and illnesses. The *papantang* or taboo is a form of oral prohibition to do something because it's against the culture and community tradition, although there was no legal or customary sanction for the violator. The violation of *papantang* also believed by the community can cause misfortunes and illnesses. A *samban* is a kind of amulet that worn as a necklace by the child after conducting a sacred ritual and believed can protect children from illnesses.

This research conducted in the *Dayak Pitap* tribe that settles in the slope of *Meratus* highlands in *Tebing Tinggi* sub districts of *Balangan,* South Kalimantan Province, Indonesia. Although this tribe registered as Hinduism which is called *Hindu Kaharingan,* very little aspect of Hinduism exists in their everyday lives. They still maintain their belief and culture as *animism* and *dynamism* tribe.

Hence, the aim of this paper is to describe the immunization status and its determinant factors that influenced the child's immunization status of *Dayak Pitap* tribe in the district of Balangan Indonesia.

Material and Method

This analytic observational quantitative research employed by a cross sectional design. The analysis unit was the household of *Dayak Pitap* tribe that had a 12 – 35 month old child. Data collected from all households that had a 12 – 35 month old child in May to June 2018 using a questionnaire. The respondent was the mother of 12 – 35 month old child.

The independent variables were the mother's education level, the mother knowledge about immunization, the history of mother immunization status during pregnancy and the childbirth attendant and the cultural determinant namely the *aruh* ritual, the *papantang* and the use of *samban*, whereas dependent variable was the child's basic immunization status.

Data analysis using the univariable analysis to describe the distribution of frequency and proportion of independent and dependent variables and logistic regression analysis to analyze the influence of independent variables toward the dependent variable.

Results

1. **Socio-demographic characteristics of respondent and children of *Dayak Pitap* tribe:** The majority of mother in Dayak Pitap were in 20 – 29 years old interval (60%) and had primary educational level (42%) and 90% were farmer. Their immunization

knowledge level mostly was low (68%). Most of the mother had only one child (44%) with higher female distribution (54%). 66% of the mother did not complete their immunization during pregnancy and 46% assisted by the traditional birth attendant when delivered their babies.

2. Immunization Status of 12 – 35 month old child of *Dayak Pitap* tribe

Table 1: Immunization Status of 12 – 35 month old child of *Dayak Pitap* tribe

Village	Number of Child 12 s/d 35 month old age	HB0	BCG	DPT-HiB-HB			Polio				Measles	Fully Immunized Children	
				1	2	3	1	2	3	4			%
Ajung	23	14	19	18	14	11	22	15	13	11	13	8	34,8
Iyam	10	4	8	6	6	4	9	8	6	5	8	2	20,0

	birthattendant	-18,525	12,718	1	,000
	aruh	-12,487	,642	1	,423
	papantang	-12,174	,016	1	,899
	samban	-14,944	5,556	1	,018
Step 2	educationlevel	-12,225	,101	1	,750
	knowledgelevel	-18,489	12,630	1	,000
	historyofmotherimmunization	-14,204	4,061	1	,044
	birthattendant	-19,402	14,457	1	,000
	aruh	-12,749	1,149	1	,284
	samban	-15,103	5,859	1	,015
Step 3	knowledgelevel	-19,169	13,889	1	,000
	historyofmotherimmunization	-14,241	4,033	1	,045
	birthattendant	-19,405	14,361	1	,000
	aruh	-12,810	1,172	1	,279
	samban	-15,306	6,163	1	,013
Step 4	knowledgelevel	-19,340	13,060	1	,000
	historyofmotherimmunization	-15,070	4,520	1	,033
	birthattendant	-19,405	13,189	1	,000
	samban	-16,003	6,386	1	,012

Based on the table above, the dependent variables that significantly influenced the independent variables were the mother immunization knowledge level (p=0.000), the history of mother immunization during pregnancy (p=0.033), the history of birth attendant (p=0.00) and the using of *samban* by the children (p=0.012).

Discussion

The complete child immunization coverage in the *Dayak Pitap* tribe was 48%, still far from the Indonesian Heatlh Ministry target i.e. 92.5%. The highest coverage was in Kambiyain village i.e. 88.9% and the lowest was in Iyam village i.e. 20%. The highest immunization dose coverage was Polio1 i.e. 48% and the lowest dose coverage was DPT-HiB-HB3 i.e. 29%.

Based on the data analysis conducted, the independent variables that significantly had influenced on the child immunization status of *Dayak Pitap* tribe were the mother immunization knowledge level, the history of mother immunization during pregnancy, the history of birth attendant and the cultural determinant namely the use of *samban*. Whereas the mother education level and the cultural determinant namely the *aruh* ritual and the *papantang* were not significantly influenced the child immunization status.

Many research have shown that the mother immunization knowledge correlated with the child immunization status [(5)(6)(7)] and influenced the child immunization [(8)(9)]. Other research also shown that the mother with good immunization knowledge has 2.21 probability to fully immunized their children compare with the mother with poor immunization knowledge [(10)].

In this case, develop an intervention to increase the mother immunization knowledge with the combination with the other interventions still promising in order to increase the fully immunized child coverage.

The other determinant factor that significantly influenced the child immunization status in the *Dayak Pitap* tribe was the use of *samban*. Using some kind of amulet both for protection and curing not only known in *Dayak Pitap* tribe but also widely known in many traditional cultures such as in Narsinghdi district in Bangladesh [(11)], in Bedouin tribes of the Negev Southern Israel, Middle East [(12)], in Gaddis of Bharmour Himachal Pradesh, India [(13)] and most of tribal communities worldwide especially for the children[(14)].

Even if the using of *samban* significantly influenced the child's immunization status, the intervention of this cultural variable is not easily formulated and need further research. Intervention with poor knowledge about the culture itself can result in negative consequences and can lead to worse health outcome. However, based on this research, health professional known that the using of *samban* was significantly influenced the child's immunization status of the *Dayak Pitap* tribe.

The history of mother immunization during pregnancy and birth attendant also significantly influenced the child's immunization status. These two variables actually correlated with the present of the care for pregnant women and labor that usually provided by the midwife.

As states by the WHO and other references, immunization is one of the most successful and cost effective health intervention achievement, has saved countless of children's lives and increased health status in the world [(15)(16)(17)(18)(19)(20)(21)]. However, virus and bacteria do not respect border, if the disease still circulate in any part of the world the risk of outbreak still remained. In order to give all protection to all children the high uptake of fully immunized children must be obtained all over the world and to reach the under vaccinated, immunization programs need to develop tailored intervention to overcome the existing barriers.

Conclusions

The child immunization coverage of the *Dayak Pitap* tribe was 48%, lower than the Indonesian health ministry target i.e. 92.5%. The determinant factor that significantly influenced the child's immunization status of the *Dayak Pitap* tribe were the mother immunization knowledge level, the history of mother immunization during pregnancy, the history of birth attendant and the cultural determinant namely the use of *samban*.

Hence, in order to gain the better child's immunization status coverage of the *Dayak Pitap* tribe, it is important to develop combination interventions to give better knowledge about immunization to the mother with the tailor made material, promote birth attendant labor and reach the pregnant mother for immunization.

The Use of Diuretic Drugs in Heart Failure Patients

Lolla Junny Avianda[1], Didik Hasmono[1], Meity Ardiana[1], Ruddy Hartono[1]

[1]Departement of Pharmacy, Faculty of Pharmacy, UniversitasAirlangga, Jl. Airlangga No.4 - 6, Airlangga, Gubeng, Kota SBY, JawaTimur 60115

ABSTRACT

Background: Heart failure can reduce the rates of expectations and quality of life. In the last few decades, the management of this disease has developed continously, including in pharmacological therapy. Diuretic is a class of drugs that is often used as a choice for heart failure patients. The pattern of diuretics usage needs to be observed further. Because if the use of diuretics is not appropriate, it potentially leads to drug related problems that affect patient management.

Objective: This study aims to examine the pattern of use of diuretics in heart failure patients who are undergoing treatment in hospital hospitalization units.

Method: This is a descriptive and retrospective study, using medical record data for heart failure patients who received diuretic therapy in the patient room at the hospital. Sampling method used the time limited sampling.

Result: Total patients who met the inclusion criteria were 50 patients, dominated by male (68%). The age of patients, most of them were in the age group 61-70 years (32%). The most widely used diuretics were the single dose furosemide (50%) and combination dose furosemide and spironolactone (36%). There was no drug related problem (DRP) in the drug interactions and undesirable side effects.

Conclusion: Most diuretic therapies for heart failure patients who were hospitalized at the hospital, were according to the available guidelines.

Keywords *: heart failure, drug related problem, diuretics*

Introduction

Heart failure is a disease that increase a morbidity and mortality rates. This disease weakens and reduces the expectations rates and quality of life. In this era, heart failure become an important health issue. Heart failure results in 12 to 15 million outpatient visits per year. It becomes the most common reasons for hospitalization in patients over the age of 65 years. Typical symptoms in heart failure are labored breathing when the patient is in a rest and activity, fatigue, leg edema. [1–3]

In general, it can be said that over the past 50 years, there have been three different eras related to the management of heart failure. The earliest era, known as the non-pharmacological era, focused in its treatment on fluid restriction. Then followed by the pharmacological era, that found an increasing use of inotropes and diuretics and the discovery of vasodorators, and the discovery of posterior drugs related to the neurohormonal pathway. Along with all technological developments, new drugs are approved to improve significantly the prognosis of heart failure patients. In addition, a new era also immediately gave rise to regenerative therapy. [1,4-7]

In pharmacological therapy, one of the choices is using diuretic drugs. Diuretics are drugs that can increase urine flow rates, but clinically diuretics also increase the excretion rates of Na^+ (natriueresis) and Cl-, which is the accompanying anions. Diuretics have often been used as management of the heart failure symptoms for many years. Because diuretics interfere

a sodium retention by increasing urine sodium and free water clearance. The purpose of diuretics usage is to relieve the heart failure symptoms by reducing an excess volume without causing intravascular volume depletion. Diuretic classification is based on various ideas such as workplace (loop diuretics), efficacy (high-ceilling diuretics), chemical structure (thiazide diuretics), similarity of work with other diuretics (thiazide-like diuretics), effects on potassium excretion (potassium-sparing diuretics). [8–10]

The most commonly diuretic that used for congestive heart failure is loop diuretics such as furosemide which is given IV in doses of 40 mg, followed by oral use if it takes 20-80 mg / 24 hours. In most patients with loop diuretics can achieve sufficient diuresis to relieve congestive symptoms, but when diuretic resistance arises, fluid management may be complicated and potentially damaging. The pattern of diuretic usage in heart failure patients still needs to be studied more because of the possibility of improper use of therapy and the potential of drug related problems occur that affect the management of heart failure patients. [11–14]

Method

The study that conducted was non-experimental or observational research, that was a descriptive retrospective. The study material used health medical record data in patients with a diagnosis of heart failure who received diuretic therapy in the hospital inpatient room.

Specified sample inclusion criteria were patients with heart failure and receiving diuretic therapy with or without complications. Furthermore, on the exclusion criteria, namely heart failure patients during the therapy period, the patient died, or is referred to another hospital and forced home.

Research samples were recorded on the data collection sheet, including: patient profile (name, gender, age, weight / height, address); date of hospital admission, date of hospital discharge, and medical record number; diagnostics, laboratory data, and kinetic data; Disease history, treatment history, and complaints experienced; The variables of diuretics that given to patients include type, dosage, and route of administration.

Data analysis was done by calculating the number of patients and grouping patients based on patient demographics, types of diuretics used and complications or comorbidities. In addition, it is necessary to know the use of other drugs to determine drug interactions in heart failure patients.

The sample collection was done with the time limited sampling method. Data was collected in the medical medical record room at Hospital of Bhayangkara H.S Samsoeri Mertojoso, Surabaya Indonesia. Data analysis was carried out based on data obtained from the patient's medical record. Then the data obtained from the data collection sheet was entered into the main table and then processed and analyzed descriptively in the form of tables or narratives.

This research had been reviewed by the Health Research Ethics Commission of Bhayangkara Hospital Surabaya and has been declared ethical.

Results

Based on the results of the study, it was found 50 patients who qualified the inclusion criteria and were dominated by male sex (68%). Furthermore, most of patients in the age group 61-70 years (32%). The most complaints that patients had experienced were breathing problems, chest pain and edema. In objective data, the diagnosis of heart failure was most evidenced through supporting data in the form of chest X-ray, ECHO and EKG. The history of the most comorbidities in heart failure patients was hypertension (32%) followed by coronary heart disease, diabetes mellitus with hypertension, and only diabetes mellitus.

Patterns for Usage of Heart Failure Drugs

Profile of the use of heart failure drugs: The most widely used drugs is the diuretic group, as many as 66 frequency of use.

Table 1: Profile of the use of the group of heart failure drugs

Groups of drugs	Frequency of usage
Cardiac Glycosides	5
ACE Inhibitor	18
ARB	16
B Blocker	26
Diuretics	66
Nitric	28

Note: *) One patient can receive more than one medication for heart failure during treatment

Type of Diuretics: The highest usage of diuretic drugs is furosemid with 50% a combination of furosemide and spironolactone (36%). And the the following type of diuretics mostly used are

The highest use of diuretic drugs is furosemide (50%), then followed by a combination of furosemide and spironolactone, spironolactone, combination hydrochlorothiazide and furosemid, and combination of hydrochlorothiazide and spironolactone, which their values are 36%, 10%, 2% dan 2%.

Dosage of Diuretics: The use of diuretic doses is divided into the use of single doses and combination doses which will be presented in detail in the table below.

Table 2: Single dose of diuretics

Type of diuretics	Dose regimentation	Frequency
Furosemide	2,5mg/ hour pump	2
	10mg/hour pump	9
	1x20mg IV	1
	2x20mg IV	4
	3x20mg IV	1
	1/2x40mg p.o	1
1x40mg p.o		7
Spironolactone	1/2x25mg p.o	1
	1x25mg p.o	4

Table 3: Dosage of diuretic combination

Regimentasi dosis			Frequency
Furosemide	Spironolactone	Hydrochlorothiazide	
5mg/hour pump	1/2x100mg p.o	-	2
	1x100mg p.o	-	1
	2x25mg p.o	-	1
	-	2x25mg	1
10mg/hour Pump	1x25mg p.o	-	3
1x20mg IV	1x25mg p.o	-	2
2x20mg IV	1x25mg p.o	-	1
3x20mg IV	2x25mg p.o	-	1
	1x25mg p.o	-	1
1x40mg p.o	1x25mg p.o	-	3
2x40mg p.o	1x25mg p.o	-	3
-	1x25mg p.o	1x25mg p.o	1

Diuretics Route: The most therapeutic route of diuretics is oral.

Table 4: Diuretics route

Diuretics route		Frequency	Percentage (%)
Furosemide	Intravenous pump	19	27
	Intravenous	11	16
	Per oral	14	20

Conted…

Spironolactone	Per oral	24	34
Hydrochlorothiazide	Per oral	2	3

Note: *) The number of routes given above is not the same as 50 patients, because in one patient can get a single diuretic therapy or combination diuretic therapy

Diuretic Therapy Monitoring: Monitoring of diuretic therapy is conducted with electronic serum monitoring.

Table 5: Diuretic Therapy Monitoring

Patients using diuretic therapy	Frequency	Percentage (%)
Serum electrolyte monitoring was carried out	29	58
Serum electrolyte monitoring was not carried out	21	42

Identification of Drug Related Problem (DRP)

Drugs Interaction: The percentage of possible drug interactions in heart failure patients is not equal to 100% because not all patients experience potential drug interactions.

Table 6: Drugs Interaction

Type of Drugs	Interacted with	Mechanisms of Drugs Interaction	Frequency	Percentage (%)
Furosemide	Amiodaron	Causes an increase in ventricular arrhythmias	3	6
	Digoxin	Increases digoxin toxicity	5	10
Spironolactone	Potassium chloride	Causes hyperchalemia	3	6
	ACE Inhibitor	Causes hyperchalemia	2	4

In the use of furosemide with digoxin monitoring**,** therapy of furosemide with digoxin was monitored more than 4 patients (80%) rather than those who were not monitored as many as 1 patient (20%). And then heart failure patients who used spironolactone therapy with ACE-I contained 2 patients with 1 patient who did not carry out serum electrolyte monitoring (50%).

Side effects of drugs: In this study was found no drug side effects occurred in heart failure patients.

Discussion

From the data shows the heart failure patients who were undergoing hospitalization, complaints a shortness of breath and chest pain. Dyspnea or shortness of breath can result in pulmonary blockage or systemic hypoperfusion due to left ventricular failure. Patients usually experience various symptoms that associated with systemic fluid accumlation which are known to be venous blockages, associated with right ventricular failure ie peripheral edema. This usually occurs in areas that depend on the body, such as the ankle (Edema pedal) for outpatients or sacred areas to sleep in the patient's bed. Bowel or stomach blockages can also appear, but it does not lead to characteristic signs unless proven to be open ascites. In right ventricular failure it is also possible to find the pulmonary hypertension. [15]

The status of heart failure can be seen from medical support data such as echo, chest X-ray and ECG. The medical support data above is related to completing the diagnosis of heart failure, where ecocardigraphy is the most useful method in evaluating systolic and diastolic dysfunction. Chest X-ray is also an important component in diagnosing heart failure such as showing cardiomegaly. An electrocardiogram should be performed on all patients suspected of heart failure. [16]

From the results study above, patients who were diagnosed with heart failure were in the age range 61-70 years. The diagnosis of heart failure manifests most commonly in adults that over 60 years. The incidence of heart failure increases with age, and reaches 1% per year in people over 65 years old. [15,17]

The most common history of comorbidities in heart failure patients is hypertension. One factor that contributes to the development of primary hypertension is a physical disorder involving the renin-angiotype-aldosterone system (RAAS) and natriuretic hormone. Furthermore, the second most common comorbid disease is diabetes mellitus. Changes in structure that show a concentric left ventricular remodeling as a characteristic of diabetes.. [15]

The results showed the classification of drugs used in heart failure patients that mostly consumed, is a diuretic. Other classes of heart failure drugs used are glycosides, ACE inhibitors, ARB groups, β inhibitors and nitrate groups. The diuretic drugs used are hydrochlorothiazide (thiazide diuretic), furosemide (loop diuretic), and spironolactone (potassium-sparing diuretic). These uses are either single or combination doses. In this study, the single dose of furosemide was given due to its higher diuresis and natriuresis efficiency. Whereas, the combination of furosemide and spironolactone is given because potassium-sparing diuretics are weak diuretics when used singly but it cause potassium retention, so they are usually given with loop diuretics to prevent hypokalaemia. [16,18,19]

The loop diuretic is a diuretic group which has the same ability to block the symporter Na^+ -K^+ - $2Cl^-$ in the raised portion of the Henle loop diuretic. This drug is given orally to reduce peripheral edema and pulmonary edema in moderate to severe stage of heart failure. Loop diuretics are effective in patients with reduced kidney. [18.20]

In the administration route of furosemide in heart failure patients is more given by pump than by intravenous or per oral method. Continuous intravenous administration of furosemide is indeed simpler, more effective, and a method to accelerate diuresis in certain patients. The administration of furosemide to patients depends on the clinical symptoms of the patient.[21]

Problems that related to the use of potential diuretic drugs in the heart failure, one of which is related to drug interactions. In the study showed that potential drug interactions occured between furosemide and amiodarone. Concomitant administration of drugs that can cause hypokalaemia and hypomagnesemia and increase the ventricular arrhythmias, including tachycardia.[22]

Other potential interactions was a combination of furosemide with digoxin. Cardiac glycosides inhibit sodium and potassium ATP-ase, which is associated with the transport of sodium ions and potassium ions acrossing the myocardial cell membrane. This is related to an increase in the availability of calcium ions that associated with contractions from cells. The loss of calcium is caused by diuretics, exacerbates potassium loss from myocardial cells, thereby increasing the activity and toxicity of digitalis. [20]

Other potential drug interactions occur between spironolactone and KSR. The effects of spironolactone and potassium compounds are additives, which can cause hypercalemia. In addition, spironolactone and ACE inhibitor groups also has the potential to cause reactions. ACE inhibitors can inhibit aldosterone which results in potassium retention, so it is expected to maintain adosterone potassium antagonists, such as spironolactone which causes hypercalemia.[20] In many patients that use combination therapy, the serum electrolyte was monitored. However, in this study was found no actual drug interactions. Furthermore, on the issue of other potential drug interactions is drugs side effects. In this study there were not found a patient that experienced the diuretic side effects.

Conclusion

Most of the usage of diuretic therapy in heart failure patients in inpatient installations, had been in accordance with existing guidelines. In this study, there was no Drug Related Problem (DRP) of diuretics usage.

Conflict of Interest: There is no conflict of interest in this study

The Antibacterial Activity of Kersen Leaves (*Muntingia Calabura)* Extracts against *Aeromonas Hydrophilia;* in Vitro Study

Onny Kurnia Sari[1], Wahyu Tjahjaningsih[1], Sudarno[1]

[1]Faculty of Marine and Fisheries, Universitas Airlangga, Dharmahusada Permai No.330 street, Mulyorejo, Surabaya, East Java (60115), Indonesia

ABSTRACT

Background: *Aeromonas hydrophila* is one of opportunistic bacteria that capable causing disease in fresh water fishes. The outbreak of diseases in fresh water fishes become an important issue in fish farming. Antibiotics can be used as therapy for those problems. But the usage of antibiotics can cause the bacterial resistance and side effects of medications. The usage of antibiotics in fish farming also can trigger the water polution.

Objective: The aim of this study was to observe the antibacterial activity of kersen leaves *Muntingia calabura* extracts against *A. hydrophila* with in vitro study and to determine the minimum concentration the extracts that inhibit the bacterial growth and its ability to kill the bacteria.

Method: There was nine group consisted the extracts with various concentration, as 50%, 25%, 12,5%, 6,25%, 3,12%, 1,56%, 0,78%, positive control group with chloramphenicol, and negative control group with dimethyl sulfoxide (DMSO) 10%. Those extract was soaked in bacterial culture and incubated for 24 hours.

Result: The young kersen leaves extracts had stronger antibacterial activity against *A. hydrophila,* compared to the old kersen leaves. Minimum Inhibition Concentration (MIC) of the extracts was at concentration of 50% and Minimum Bactericidal Concentration (MBC) was at concentration of 12,5%.

Conclusion: Kersen leaves extract has antibacterial activity against *A. Hydrophila* by in vitro study.

Keywords: *Aeromonas hydrophilia, Muntingia calabura, leaves extract, fish farming*

Introduction

Outbreak of disease is one of the obstacles that often occur in fish farming. *Aeromonas hydrophila* is an opportunistic bacterium, the cause of disease in various types of freshwater fish. These bacteria attack the internal organs of the fish through the digestive tract or the skin of fish that have not been injured. This occurs because the fish are stressed due to density or increase in extreme environmental temperatures. The bacterial infection, that caused by *A. hydrophila*, is better known as Motil Aeromonas Septicemia (MAS). The symptoms of this disease are ulceration, erythrodermatitis, hemorrhagic septicemia, red disease, and prominent scales [(1)].

One of the natural products that can be utilizded as natural medicine is kersen. Kersen is a small fruit, that well known and healthy, produced from trees that have many benefit [(2)]. Kersen plant is easily found on the roadside as shades and it has good ability in adaptation. Kersen leaves contain various bioactive compounds, such as flavonoid, saponins, triterpenes, and tannins [(3)]. The study by Fariestha (2018) shows the methanol extract of kersen leaves had antibacterial activity against gram positive bacteria, that is *Staphylococcus aureus* [(4)].

Based on some statements above, the antibacterial activity of kersen leaves extracts were tested to observe its ability to inhibit the growth and kill gram negative bacteria, *A. hydrophila*, which can threaten the success of fish farming. The experiment was done by extracting the leaves of kersen, then followed by doing an antibacterial activity test with the disk diffusion test and

streak method to determine the antibacterial activity of kersen leaves extract to *A. hydrophila*.

Materials and Method

Equipment: The equipment that used in this experiment such as blender, digital scales, oven, reaction flasks, rotary vacuum evaorator, autoclave, test tubes, tube rack, measuring pipette, petri dish, bunsen burner, Ose needle, micropipette, glass stirrer, laboratory tweezer, and ruler.

Materials: The materials in this study were pure isolates of *Aeromonas hydrophila*, that obtained from the Juanda Quarantine Hall, Surabaya, young kersen leaves (that the leaves color is light green), old kersen leaves (that the leaves color is dark green), methanol, Whatman filter No. 1, aquadest, dimethylsulfoxide (DMSO) 10%, barium chloride (BaCI) 1%, sulfuric acid (H_2SO_4) 1%, physiological saline (NaCl), chloramphenicol, Whatman disk paper No.42, trypticase soya agar (TSA).

Preparation of Mc Farland 0,5 ($1,5x10^8$ sel/ml) solution: Mc Farland solution preparation was done by mixing 0.05 ml of barium chloride ($BaCl_2$) 1% and 9.95 ml of sulfuric acid (H_2SO_4) 1% in a test tube. Then it was shaken until a turbid solution formed. This turbidity is used as the standard turbidity of bacterial suspension tests

Kersen leaves extract preparation: Kersen leaves extract was diluted with dimethyl sulfoxide (DMSO) solvent 10%. DMSO solution functions as a solvent that quickly seeped into the epithelial extract without damaging the cells. DMSO solution is often used in the medical and health research [5].

Before the test tube was being used, it was labeled according to the concentration of the solution. The concentration of the solution were 50%, 25%, 12.5%, 6.25%, 3.12%, 1.56%, 0.78%. The preparation of solution with concentration 50% was done by mixing 4 grams of kersen leaves extract with 4 ml DMSO 10% in the test tube, stirred with a glass stirrer until homogeneous. For the solution with concentration 25% was carried out by mixing 2 ml of solution with concentration 50% and 2 ml DMSO 10%, then stirred until homogeneous.

The preparation of the other solution with lower concentration was done by mixing 2 ml of the solution from the previous test tube and 2 ml of DMSO 10%. After the last concentration of 0.78% was obtained, a 2 ml solution from the test tube 0.78% was taken and discarded because it was not used [6]. The positive control group was using 2 ml of chloramphenicol, while a negative control group was using 2 ml of DMSO 10%. Chloramphenicol is often used for the treatment against *A. hydrophila* and has strong efficacy in inhibiting the growth of *A. hydrophila* [7].

Minimum Inhibitory Concentration (MIC) with difusion methods: Before the Minimum Inhibitory Concentration (MIC) test of kersen leaves extract was done, the preliminary experiment was carried out to determine efficacy of young and old kersen leaves extract against *A.hydrophila* [4]. The efficacy test of antibacterial activity carried out using disk diffusion test. The extract that used in prelimenary experiment was kersen leaves extract with concentration 100%.

Figure 1: The efficacy test of antibacterial activity of young and old kersen leaves extract. Explanation: Arrow sign = inhibitory zone

Minimum Inhibitory Concentration (MIC) with disk difusion methods: The paper disks were soaked in kersen leaves extracts with various concentrations. After ± 15 minutes, paper disks were taken aseptically using laboratory tweezers, then aerated in room temperature ± 3 minutes until dried. Paper disks were placed and slightly pressed onto the surface of the bacterial media (one medium was given one disk paper). All tested media were incubated at 28º C for 24 hours and the inhibitory zones were measured using a ruler. The minimum inhibitory concentration (MIC) was measured by subtracting the overall diameter of the paper disks and inhibitory zones with the diameter of the disk paper[8].

Minimum Bactericidal Concentration with Streak Method: Minimum Bactericidal Concentration (MBC) with streak method was carried out to determine the bactericidal ability of kersen leaves extract. The test was carried out by adding 1 ml of liquid isolate of *A. hydrophila* with a density of 10^7 cells/ml into each extract solution and the control group, then it was homogenized. The mixture of bacteria colony and the solution was taken using Ose needle and streaked to TSA plates, then incubated at 28ºC for 24 hours. If the bacteria was occurred in TSA plates, it shows that the extract solution did not have ability to kill the bacteria. If there is no presence of bacteria in TSA plated, it shows the extract solution had ability to kill bacteria [9].

Results

Table 1: Minimum Inhibitory Concentration (MIC) of Kersen leaves extract

No.	Concentration of young Kersen leaves extract	Diameter of inhibitory zone (mm)
1.	0,78%	0
2.	1,56%	2
3.	3,12%	5
4.	6,25%	6
5.	12,5%	9
6.	25%	14
7.	50%	15
8.	Positive control (chloramphenicol)	20
9.	Negative control (DMSO 10%)	0

The young kersen leaves extract at concentration of 0.78% shows no inhibition zone was seen. That was meant the extract with concentration of 0.78% could not inhibit the growth of *A. hydrophila*. The antibacterial activity of young kersen leaves extract was seen at concentration of 1.56%, characterized by the presence of inhibitory zones around the disk paper. The higher concentration of young kersen leaves extract, the larger the inhibitory zone that appeared around the disk paper [10]. Chloramphenicol was used as a positive control, while the negative control using DMSO 10%. In positive control group shows a very large inhibitory zone that was 20 mm, while the negative control group did not show any antibacterial activity, so there was not found any visible inhibitory zone around the disk paper. The results shows that the minimum inhibitory concentration of young kersen leaves extract that approaching positive control was the extract at concentration 50%.

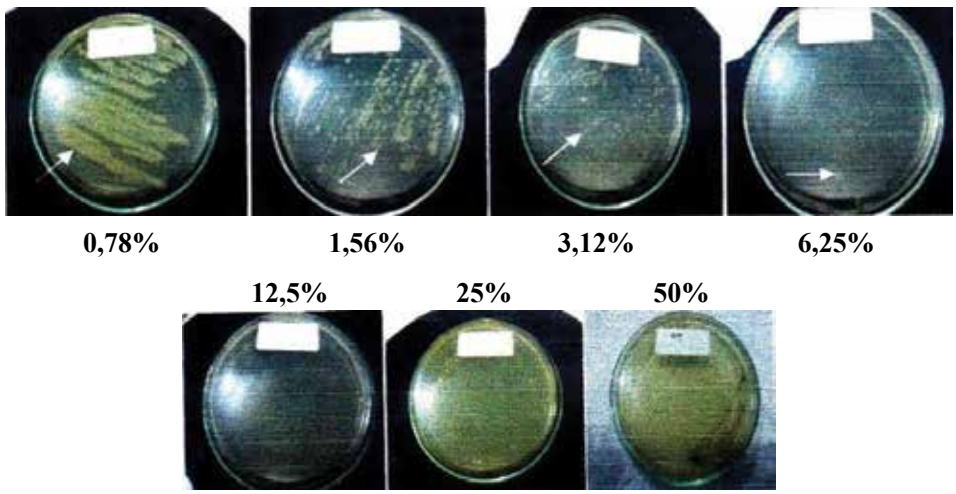

Figure 2: Minimum Bactericidal Concentration (MBC) of young kersen leaves extract. Explanation : Arrow sign = *A. hydrophila* bacterial colony

Figure 2 shows the growth of *A. hydrophila* is indicated by an arrow sign. In TSA plate with a concentration of 12.5%, 25%, and 50%, there was no bacterial growth. That shows at these concentration young kersen leaves extracts had ability to kill bacteria. It can be concluded, the minimum concentration of young kersen leave extract which can kill *A. hydrophila* is 12.5% [11].

Discussion

The results of this study shows that the bacteria that the identified bacteria are *A. hydrophila* (Table 1). In Figure 1, reddish-colored bacteria shows the bacteria is gram-negative and rod-shaped bacteria. *A. hydrophila* was gram negative bacteria, facultative anaerobes, rod shaped in 0.3-1.0 x 1.0-3.5 µm which moved with flagellum, had fermentative oxidative characteristic [12]. Catalase, H_2S, indole, β-galactosidase, oxidation occurs, but not on ornithin, decarboxylase and or phenylalanine, deaminase. There was a positive result, but it did not occur in the methyl red test[13]. In bacteria culture was done, the bacterial colonies on the media appeared creamy on agar media.

Table 1 shows the higher of concentration of kersen leaves extract, the greater its ability to inhibit bacteria growth. The positive control group used chloramphenicol

treatment, because it is often used for the treatment of infection caused by *A. hydrophila* and very strong inhibits the growth of *A. hydrophila* [13]. The negative control group used DMSO, because its properties are neutral and does not damage cells [5].

Raho and Benali (2012) states in their research that the provisions that indicate the antibacterial strength of chloramphenicol as followed the inhibitory zone <12 mm indicated weak, 13-17 mm indicated medium, and > 18 mm indicates as very strong [11]. The results in this study shows the chloramphenicol had antibacterial strength that very strong, it resulted in 20 mm of diameter inhibitory zone. Whereas the MIC test results of kersen leaves extract when compared to chloramphenicol were included in medium categoriy, it resulted in 15 mm of diameter inhibitory zone. Young kersen leaves extract at the concentration of 0.78% shows no inhibitory zone, because the concentration was very low, so it was not able to inhibit the growth of *A. hydrophila* [14].

The content of flavonoids on the extracts resulted in inhibition bacterial growth. The action of flavonoids as antibacterial is by releasing transduction energy towards the cytoplasmic membrane of bacteria and inhibiting bacterial motility. In addition, tannin compounds also play a role in inhibiting bacterial growth. Tannin compounds can interfere cell permeability because it has ability to shrink cell walls or cell membranes [15].

The Minimum Bactericidal Concentration (MBC) is defined as the lowest concentration that capable of killing bacteria. It determines the concentrations of the extracts that provide clear zones without microbial growth in the agar media by visual observation [16]. In this study, that was not found any bacterial growth in agar media with the extract at a concentration of 12.5%. Tannin and saponin compounds increase antibacterial effect.

The extract at concentration < 6.25% did not have the ability to kill bacteria, but only inhibit the bacterial growth, as evidenced by the presence of colonies that weee still growing. The smaller concentration of the extracts, there were more colonies that appeared. Saponin compounds have the ability of lowering the surface tension of the cell walls. So when the surface tension is disturbed, the antibacterial substances will enter easily into the cell and disrupt the cell metabolism until the bacterial death occurs [17].

Conclusion

The kersen leaves extract had antibacterial activity against *A. hydrophila,* by in vitro study. The minimum inhibitory concentration of kersen leaves extract that approaching the positive control group was 50%, with a 15 mm of diameter inhibitory zone, in 24 hours incubation period. The minimum bactericidal concentration of kersen leaves extract against *A. hydrophila* bacteria was 12.5% in 24 hours incubation period.

Ethical Clearance: The research process did not involve any participants for object, instead only use diffusion method with kersen leaves and aeromonas bacteria. The process of research has been following principle based on the regulation of research ethic committee. This study implemented the basic principle ethics of respect, beneficence, nonmaleficence, and justice.

Conflict of Interest: The author reports no conflict of interest of this work.

Source of Funding: This study is done with author's funding only,

Could the Severity of Infected Gingiva in Pregnant Woman Affect the Quality of Life?

R. Darmawan Setijanto[1], Novia Setyowati[1], Taufan Bramantoro[1], Achmad Aghasy[1]

[1]Departement of Dental Public Health, Faculty of Dental Medicine, Universitas Airlangga, Surabaya, Indonesia

ABSTRACT

Background: Observation carried out in early 2016 to a number of pregnant women in Community Health Center Surabaya found that more than 80% of pregnant women had infected gingiva or gingivitis. Pregnant women are susceptible to oral and dental disease. Oral heath problem could impact on oral health-related quality of life, includes physical pain, physical disability, psychological discomfort, functional limitation, and social disability.

Objective: The aim of this study was to analyze the influence of severity level of infected gingiva on oral health-related quality of life of pregnant woman.

Method: A cross-sectional study was conducted in 10 Community Health Centers Surabaya and involved 106 pregnant women. All of participants were examined regarding their severity level of infected gingiva, also answered the quality of life questionnaire.

Result: Lower quality life of pregnant woman were observed in woman presenting more severe infected gingiva level.

Conclusion: Oral health-related quality of life of pregnant woman were influenced by the severity level of infected gingiva.

Keywords: *gingivitis, pregnancy, quality of life, woman*

Introduction

Pregnant women have higher prevalence of gingivitis than non-pregnant women[1]. Pregnancy gingivitis affects 25-100% of pregnant women and occurs during 2nd to 8th month of pregnancy[2]. Indonesian Dental Association has recorded prevalence of pregnancy gingivitis 75-90% worldwide, meanwhile in Indonesia it is up to 5-10%[3,4]. In early 2016, initial survey upon pregnant women conducted at Community Health Center Surabaya found that more than 80% pregnant women had gingivitis. During pregnancy, progesteron level in body could be 10 fold higher than normal level. This kind of condition potentially increases certain pathogenic bacteria growth that lead to gingivitis[5].

There are several factors which could influence susceptibility of pregnant woman to gingivitis, such as gestational age, nutritional status and the presence of systemic disease i.e diabetes mellitus. Gestational age is associated with susceptibility of pregnancy gingivitis because of hormonal change such as an increase of estrogen and progesterone as gestational age increases[6]. Poor nutritional status of pregnant woman could decrease immunity against various diseases, particularly infectious disease. Malnutrition or poor nutritional status has synergistic relationship with infection, which means malnutrition deteriorates infectious disease, and infection deteriorates malnutrition[7]. Any changes in immune system and estrogen and progesterone level in 40% of pregnant women lead to gingivitis during pregnancy[5,8,9].

Chronically and untreated pregnancy gingivitis could increase risk of premature birth and low birth weight (LBW) [10]. This is emphasized by National Health Survey 2002 which showed that 77% of pregnant women with gingivitis have preterm labor. In addition, in a study reported by Retroningrum 2006 carried out in Kariadi Hospital Semarang showed that pregnancy gingivitis had risk factor of low birth weight (LBW) as 8,75 times higher than those without gingivitis[11].

Gingivitis as oral health problem frequently occurs during pregnancy could impact on individual well-being such as physical pain, physical limitation and psychological discomfort. Impact of oral health condition on quality of life is evaluated and defined as Oral Health-Related Quality of Life (OHRQoL). United States Surgeon General's report defined oral health-related quality of life as a multidimensional concept that describe oral health–related comfort during eating, sleeping and involving in social interaction. Acharya et al stated that periodontal disease in pregnant woman lead to poor oral health-related quality of life[12].

According to previous study, it has been found impact of gingivitis during pregnancy on oral health-related quality of life, but the lack of available data about that in Indonesia is the underlying reason to investigate correlation between severity level of pregnancy gingivitis and oral health-related quality of life of pregnant woman.

Material and Method

This study was analytical observational quantitative study with cross sectional study design, aiming to investigate correlation between risk factors and effect. The samples were chosen using cluster random sampling method, resulting of 106 pregnant women as respondents in 10 Community Health Center Surabaya. All the procedures in this study were conducted according to the approval of Ethical Commission.

This study had inclusion and exclusion criteria. Inclusion criteria included: (1) pregnant woman without dental calculus; (2) never have gingivitis before pregnancy; (3) without systematic disease, such as diabetes mellitus; (4) pregnant woman on early first trimester, late first trimester, early second trimester, late second trimester, early third trimester, and late third trimester; (5) regularly consuming high-fiber containing food (vegetables and fruits). Exclusion criteria of study included: (1) pregnant woman with dental calculus; (2) with history of gingivitis before pregnancy. (3) with systemic disease, i.e diabetes mellitus. (4) irregular high-fiber containing food (vegetables and fruits) consumption.

This study employeed questionnaire form as instrument to know respondents data and Oral Health Impact Profile (OHIP-14). Also, gingival index form to assess severity level of gingivitis. Oral Health Impact Profile (OHIP-14) questionnaire form have been modified spesifically to know level of oral health-related quality of life of pregnant woman. Before questionnaire modification, translation of instrument had been done first. After translating instrument of oral health-related quality of life of pregnant woman, researcher did validity and reliability test. During validity and reliability test, questionnaire instrument was distributed with cluster random sampling to pregnant women in Maternal and Child Health (MCH) Clinic, Community Health Center Surabaya.

Questions in questionnaire of oral health-quality of life consisted of 7 dimensions, as follows: 1. Dimension of functional limitation; 2. Dimension of physical pain; 3. Psychological discomfort; 4. Physical disability; 5. Psychological disability; 6. Social disability; 7. Handicap. In that questionnaire, respondent would be asked how frequent they had gum impairment during pregnancy using Likert scale. The choices of answer of questions in oral health-related quality of life of pregnant woman questionnaire were "very often", "fairly often", "sometimes", and "vever" with score as 1, 2, 3, and 4, respectively. The higher the score, the better the quality of life.

Selected pregnant women were given informed consent as their approval to participate as study sample. After that, intraoral examination was done using periodontal probe and mouth mirror to see the severity level of gingivitis in respondents, and recorded on gingival index. This study received ethical approval from Ethics Committee Faculty of Dental Medicine, Universitas Airlangga. For analysis, distribution table was used with percentage as confirmation. Present study employeed correlation test to analyze correlation between pregnancy gingivitis and oral health-related quality of life of pregnant woman.

RESULT

In this study, characteristics of pregnant women in Community Health Center Surabaya had been known, such as: age, level of education, employement status, monthly income, gestational age and maternal mid-

upper arm circumference (MUAC). In terms of age, mean age of pregnant woman was 28 years, most of them aged 24-32 years (59.5%). Majority of respondents had ever attended level of education minimum Senior High School (67.9%). Most of them (68.9%) were unemployeed. Monthly income of respondents was under five million rupiahs (97.2%). Most respondents examined in Community Health Center belonged to low and moderate economic class, and 50.9% had third trimester of gestational age with mean age approximately 24 years. Majority of MUAC were 23.5 cm (88.7% of total respondents), and mean MUAC was 28 cm. It showed that most pregnant women in Community Health Surabaya had good nutritional status.

Oral hygiene level of pregnant women (68.9% of total respondents) was classified as moderate with mean score by 2.4. Also, 47.2% of total respondents had moderate severity level of gingivitis, and mean score of gingival index was 1.3. Moderate level of gingivitis possibly could decrease oral health-related quality of life of pregnant woman, thus results in low OHIP-14 score.

Table 1: Value of correlation coefficient and significance level of pregnancy gingivitis on each item of Oral Health Impact Profile-14

Dimension	Item	Correlation coefficient (r)	Significance level (p)
Functional limitation	Difficulty in pronouncing any words	- 0.047	0.631
	Sense of taste impairment	- 0.226*	0.020
Physical pain	Painful aching on gum	- 0.187	0.055
	uncomfortable to eat any foods	- 0.134	0.171
Psychological discomfort	Feeling self conscious	- 0.175	0.073
	Feeling tense	- 0.082	0.405
Physical disability	Unsatisfactory diet	- 0.199*	0.041
	Interrupted meal	- 0.283*	0.003
Psychological disability	Difficult to relax	- 0.253*	0.009
	A bit embarrassed	- 0.078	0.428
Social disability	Difficulty in doing usual jobs	- 0.197*	0.043
Handicap	Totally unable to function	- 0.167	0.086

Tabel 2: Value of correlation coefficient and significance level of pregnancy severity on oral health-related quality of life of pregnant woman

Variable	Correlation coefficient (r)	Significance level (p)
Quality of life score (OHIP-14)	- 0.327*	0.001

Table 1 shows that there is correlation between severity level of pregnancy gingivitis and oral health-related quality of life of pregnant woman particularly in dimension of functional limitation, physical disability, psychological disability, and social disability.

Table 2 shows that there is significant correlation between severity level of pregnancy gingivitis and oral health-related quality of life of pregnant woman. This is negative correlation which means the higher the severity level of gingivitis, the lower the quality of life, and vice versa.

Discussion

As presented on study result, the severity level of pregnancy gingivitis in Surabaya according to Loe & Silness gingival index was moderate, and oral hygiene status was classified as moderate. On third trimester of pregnancy, estrogen and progesterone level increases, thus vascularization and blood vessel permeability of gingiva is also increased[13]. The presence of debris and calculus is overresponded by gingiva that leads to gingival inflamation, redness and easily bleeding. It shows that hormonal factor could worsen plaque bacteria as local factor[14].

Pregnancy gingivitis is one of oral diseases that frequently affects pregnant woman particularly on 2nd to 8th month of pregnancy[2]. This is confirmed by present study result that demonstrated 54 of 106 pregnant woman had gingivitis on third trimester of pregnancy. Pregnancy

gingivitis could present some clinical manifestations which may influence daily activities and quality of life[15]. One of instruments used to assess oral health-related quality of life is *Oral Health Impact Profile* 14 (OHIP – 14). OHIP – 14 is a multidimensional concept which describes comfort during eating, sleeping, and socially interacting[16]. According to the present study result, mean score of oral health-related quality of life of pregnant woman in Community Health Center Surabaya was fairly good.

The presence of oral health impairment may impact significantly on physical, psychological and social well-being, thus influences quality of life. Impairment in oral cavity such as periodontal disease e.g life-threatening impairment on gingiva may contribute to preterm birth and low birth weight, influence respiratory disease, gastrointestinal, stress and decrease immune system againts infection[17,18]. The presence of gingival problems may lead to stress, therefore it could make patient afraid, anxious, having painful aching and discomfort. If it is untreated, quality of life will be influenced[17].

In this study, the severity level of pregnancy gingivitis had influence on quality of life particularly in dimension of functional limitation, physical disability, psychological disability, dan social disability. Dimension of functional lmitation includes sense of taste impairment, thus appetite is decreased. Decreased appetite will infuence intake of vitamin A and fiber which is highly required by pregnant women, particularly fruits and vegetables, consequently in addition to promote gastrointestinal disorder, of course it will impact on comprehensively maternal and fetal health[17].

Dimension of physical disability includes discomfort in eating any foods, which means the higher the severity level of pregnancy gingivitis, the more uncomfortable in eating any foods, and vice versa. Beside physical disability, severity level of pregnancy gingivitis also impact on meal process, which could lead to interrupted meals. It shows that the higher the severity level of pregnancy gingivitis, the more frequent they have interrupted meals. Impairment in dimension of functional limitation and physical disability is caused by clinical manifestation of pregnancy gingivitis such as gingival enlargement on papilla of one or two teeth that may interfere mastication[19]. It is crucial for pregnant woman to maintain oral health in order to masticatory function keep maintained, thus nutrition intake, dental and overall health of pregnant woman are maintained in good condition[20].

Dimension of psychological disability includes being difficult to relax, which means the higher the severity level of pregnancy gingivitis, the more difficult pregnant woman relaxed. Bleeding gingiva is one of discomfort that commonly occur during pregnancy. This condition is normal and not life-threatening, but for most of pregnant women it may cause anxiety so that they are difficult to relax[21]. Gingival enlargement particularly in anterior region as clinical manifestation of gingivitis may also impact on psychological aspect[22]. Gingival problems will impact on communication process because oral structure is the important part of verbal and non-verbal communication, hence it may influence self image and ability to survive and build social relation[17].

Dimension of social disability includes difficulty to do usual jobs, which means the higher the severity level of pregnancy gingivitis, the more difficult pregnant woman to do usual jobs. Gingival problems may cause pain and discomfort during activities, thus it could decrease work productivity[17]. The severity level of pregnancy gingivitis has significant correlation with oral health-related quality of life of pregnant woman. Therefore, if the severity level of pregnancy gingivitis is high, oral health-related quality of life of pregnant woman will be low, and vice versa.

Conclusion

Based on study result and discussion, it has been known that there is negative correlation between the severity level of pregnancy gingivitis and oral health-related quality of life of pregnant woman, which means the higher the severity level of gingivitis, the lower the quality of life and vice versa.

Age and Education Distribution Patterns of Working Mothers on Dental Health Behavior in Preschool Children in Mid-Class Society

Isnawati[1], R. Darmawan Setijanto[2], Taufan Bramantoro[2], Dinda Dewi Zalinda[3]

[1]Master Program in Dental Health, Faculty of Dental Medicine, Universitas Airlangga, [2]Department of Dental Public Health, Faculty of Dental Medicine, Universitas Airlangga; [3]Department of Health, Vocational Faculty, Universitas Airlangga

ABSTRACT

Background: Dental caries is a common disease in children which if left untreated, it may affect weight, growth and the quality of life in childhood. The behavior of parents, especially mothers, affects the children's oral health, because mothers aside of being the decision maker for the children, they also have careers.

Objective: This study aimed to analyze the relationship between age and education of working mothers on dental health behaviors in pre-schooled children aged 5-6 years.

Method: This was a cross-sectional study, involving working mothers who have children aged 5-6 years in Banjarbaru, South Kalimantan. The number of respondents was 101 working caregivers, that was chosen by means of a cluster random sampling technique. The data were obtained through interview and questionnaire. The results were analyzed statistically using logistic regression test with a significance value of $p<0.05$.

Results: There was no significant relationship between age and education of working mothers on dental health behaviors in preschoolers.

Conclusion: The age and education of working mothers are not related to dental health behavior in preschool children in Banjarbaru South Kalimantan.

Keywords: *age, education, mother behavior*

Introduction

The World Health Organization (WHO) stated that 60-90% of school children worldwide suffered from caries[1], a common disease which if untreated, it may affect weight, growth, and quality of life, especially in childhood[2]. Basic Health Research in 2013 stated that dental and oral health in Indonesia remained quiet apprehensive. The high prevalence of dental and oral health problems was found in South Kalimantan Province (36.1%), making it the second highest after South Sulawesi (36.2%)[3]. Previous research, analyzing the relationship of dental caries with the quality of life in school children aged 5-7 years in Landasan Ulin Sub-district, Banjarbaru, South Kalimantan proved the average of primary tooth suffering dental caries as many as 9 teeth per children[4]. Parents have main role in providing the information and encouraging a healthy living. The knowledge, beliefs, and attitudes of parents affect oral health, eating habits and the health behaviors of children[5]. Parental behavior, especially mothers, affects the oral health of children because mother acts as a primary caregiver and the ultimate decision maker[6,7]socioeconomic status, oral health behaviors of children and their parents. Oral health status of children was examined. The parent and their children oral health relationship were tested using regression and correlation analysis. Results. About 222 parents and

children participated in the study. There was a significant relationship between history of having dental problems in parents and dmft index in their children (P = 0.01).

The Central Bureau of Statistics in Banjarbaru, South Kalimantan, stated that in 2015, 62.45% of women worked as a bureaucrat. Women working in the public sphere for economic and social motivation; to increase family income and not depend on husband[8], while the social motivation are education level, free time, seeking for experience and self-actualization[9]. The socio-economic status of the family greatly affects the family's need compliance to achieve a prosperous standard of living and maximum health[10].

Working women in Banjarbaru are classified to middle-class society for having a fixed income and well educated. Middle-class society is a social class with occupation and fixed income, modern society which is economically prosperous, and well-educated and considered as an important person by the surrounding society[11]. Health behavior is formed by three main factors; predisposing factors, namely knowledge, attitude, belief, values, age, education, occupation, and family economic status. The second are supporting factors are the physical environment, health facilities and infrastructure and health program. The last is supporting factor of the attitudes and actions of health workers or others who become role models[12].

The purpose of this study was to analyze the relationship between age and education of working mothers on the dental health behavior of preschool children aged 5-6 years in Banjarbaru, South Kalimantan.

Method

The study was approved by the Medicine Health Research Ethical Clearance Commission (016/HRECC. FODM/III/2018). Each respondent who participated in the study had consented to voluntary informed consent. Respondents in this study were educated working mothers aged 21-40 years.

Research Design: This cross-sectional study was conducted on 101 working mothers in Banjarbaru. Sampling was done by cluster random sampling. Sample criteria were mothers who worked and had preschool children aged 5-6 years. Data was obtained using questionnaires. Instrument behavior consisted of 6 statements that contained the behavior of mothers in the dental health of preschool children aged 5-6 years. Each answer was given with a score of 0-1.

Statistical Analysis: Data were analyzed using SPSS 16 for Windows. Nonparametric Descriptive Statistics used logistic regression with the level of significance value was <0.05.

Results

There were two independent variables, age and education, and one dependent variable, the behavior of the dental health of the mother. All variables can be seen in Table 1. There were 33 (32.7%) working mothers aged 21-30, 68 persons with age 31-40, 22 persons (21.8%) with low education, and 79 persons (78.2%) with high education. Analysis using SPSS version 16 Software for Windows showed that there was no significant relationship between educated working mothers' age on dental health behaviors of a preschooler. The results can be seen in Table 2.

Table 1: Distribution of age and education of working mothers in Banjarbaru

Variables	Category	Total	Percentage
Age of caregiver	21-30 years	33	32.7
	31-40 years	68	67.3
Education of caregiver	Low	22	21.8
	High	79	78.2
Total		101	100

	Good	21.2	39.7			31.8	34.3		

Mother's behavior in telling children to clean teeth after every meal had no significant relationship with age (p = 0.945, OR = 0.963) and education (p = 0.647, OR = 1,348). At the age of 21-30 years old, mother's behavior on dental health was mostly bad as much as 78.8% with low level of education equal to 81.8%, whereas at age 31-40 years old, mother's behavior on dental health was mostly bad as much as 77.9% with high education level of 77.2%. Mother's behavior in telling children to clean teeth before bedtime had no significant relationship with age (p = 0.574, OR = 1.294) and education (= 0.468, OR = 1.467). At the age of 21-30 years old mother's behavior toward dental health was mostly bad as much 60.6% with low education level equal to 63.6%, whereas at age 31-40 years old, mother's behavior to the dental health of child was mostly bad as much 51.5% with the higher education level of 51.9%. The behavior of mothers to clean the teeth every morning after breakfast and the night before bed had no significant relationship with age (p = 0.55, OR = 1.313) and education (p = 0.591, OR = 1.32). At the age of 21-30 years old, mother's behavior toward dental health of children was mostly good as much as 51.5% with low education level of 50%, whereas, at age 31-40 year, majority of mother behavior to dental health of child was mostly good as much as 60.3% with education level high of 59.5%. The behavior of mothers who let children eat a snack every day had no significant relationship with age (p = 0.635, OR = 0.802) and education (p = 0.869, OR = 0.998). At the age of 21-30 years old, mother's behavior toward dental health of children was mostly good as much as 63.6% with low education level equal to 63.6%, whereas at age 31-40 years old, mother's behavior to dental health of child was mostly good as much as 57.4% with high education level of 58.2%. Mother's behavior in telling children to use toothbrush and toothpaste every day had no significant relationship with age (p = 0.684, OR = 0.75) and education (p = 0.999, OR = 0.000). At the age of 21-30 years old, mother's behavior toward dental health of children was mostly good as much as 90.9%, although they had low education, Whereas, at age 31-40 years old, mother's behavior to dental health of children was mostly good as much as 81% with high education level equal to 58.2%. The mother's behavior of having a mouthwash after eating had no significant relationship with age (p = 0.063, OR = 2.676) and Education (p = 0.625, OR = 0.758). At the age of 21-30 years old, mother's behavior toward dental health was mostly bad as much as 78.8% with a low level of education equal to 68.2%. Whereas, at age 31-40 years old, mother's behavior to the dental health of children was mostly good as much as 60.3% with the high education level of 65.8%.

Discussion

According to the literature, behavior building is affected by attitude and knowledge, which can be gained from both formal and non-formal education[13]. Previous studies stated that education level reflect knowledge and skills to make health behavior choices[14,15]. The mothers' dental health behavior is an important factor in building the children's dental health behavior[6,14]socioeconomic status, oral health behaviors of children and their parents. Oral health status of children was examined. The parent and their children oral health relationship were tested using regression and correlation analysis. Results. About 222 parents and children participated in the study. There was a significant relationship between history of having dental problems in parents and dmft index in their children (P = 0.01). Education may have various impact on individual, depend on personality, social environment, culture, and perception. Besides, education also increase the career opportunity. The working environment in public sector has high pressure that may induce stress, and affecting a person behavior, hence, behavior is more influenced by personality of a person than the level of

education[16,17]. The result is in accordance with previous research which showed that the level of education does not affect the working mother's behavior toward the dental health of preschool children aged 5-6 years. Education is a program to develop personality and abilities that last a lifetime. The higher education, the easier the person to receive information. The more information that comes in, the more the knowledge gained. Knowledge is very close to education, so it is expected that someone with higher education will have better knowledge, including health care[12,18].

Table 2 showed that the mother's behavior toward child's dental hygiene is not correlated to education. Lack of knowledge and access to information, causing a person to have limited knowledge about the hazard of unhealthy behavior so less motivation to adopt healthy behavior[16]. Learning process may enhance professional skills and specific knowledge that are still relevant to general knowledge[19]. Education plays an important role in caries prevention. Parents with higher education had more concern to the oral health of children, that make them have a better oral health behavior[20,21]. Behavior is the biggest factor affecting one's health. Developmental psychology states that the age of 18-40 years is an early adulthood. As getting older, the maturity and strength of a person will be more mature in thinking and work[22]. Danang and Irdawati stated that age is one of the factors that influence mothers to be able to run the role of optimal care. The age of the mother or the parent who has reached maturity in thinking and being able to properly educate and nurture the child will be able to reach the stage of development according to his time[23,24].

Working mother's behavior towards spending more time at work than at home. This causes the mother to have little time with the children so that the oral hygiene practice of children is sometimes neglected because of the activities. Based on the data obtained, it was shown that the mother who worked in the city of Banjarbaru, South Kalimantan aged 21-40 years old had high education. Supposedly, with age, a person has better knowledge about dental and mouth health, so that the practice of oral hygiene is also good. However, in this study different things were obtained that the age and level of education had no relationship with the behavior of working mothers on the dental health behavior of preschool children aged 5-6 years in Banjarbaru, South Kalimantan. Working mothers have high stress because of their work[16,17]. Exhaustion after work tends to make mothers do not care about the dental and oral health of children. This is in accordance with the results of a study that states that good knowledge was not always directly proportional to the pattern of parenting[6,24–26]socioeconomic status, oral health behaviors of children and their parents. Oral health status of children was examined. The parent and their children oral health relationship were tested using regression and correlation analysis. Results. About 222 parents and children participated in the study. "There was a significant relationship between history of having dental problems in parents and dmft index in their children (P = 0.01", meaning that although the mother has a good knowledge about oral health, it does not necessarily make her have a good attitude to apply the knowledge.

Conclusion

Age and education of working mothers do not affect dental health behaviors in preschool children aged 5-6 years in healthcare prevention and maintenance efforts. However, the personality of the caregiver affects this behavior. Caregivers who work tend to have a high level of stress so that after coming home from work, the behavior that appears is the behavior as it is, meaning not so concerned about the dental health of children.

Relationship between Behavior and the Use of Personal Protective Equipment to Pesticide Consumer Farmers in Tonrong Rijang Village Baranti District Sidenreng Rappang District

Zaenab[1], Ashari R[1], Nurmin[1]

[1]*Health Polytechnic of Ministry of Health in Makassar, Indonesia*

ABSTRACT

Agriculture is one of the most important areas. However agricultural life is closely related to the use of pesticides that can cause health problems. To minimize health problems is one effort that can be done with the use of a complete Protective Tools. The type of research used is an analytical survey with Cross Sectional approach with the population of rice farmers in Tonrong Rijang Village Baranti Subdistrict Sidenreng Rappang Regency as many as 334 HH with sample 67 HH. Determination of the number of samples in this study was determined by using Cluster method and data retrieval was done using Random Sampling Method. Data processing is done by using *Chi Square test* with SPSS 25, Microsoft excel, and Microsoft word. The results of this study explain that farmers with high knowledge level of 44 people (66%), who have high Protective toolsusage as many as 21 people (31%) and who have the use of PPE while as many as 23 people (34%). Farmers with a moderate level of knowledge of 23 people (34%), who had high Protective toolsusage of 7 people (11%) and those with PPE were 16 (24%). Farmers who have a high attitude (good) as many as 55 people (82%) who use high Protective toolsas many as 21 people (31%), while those using PPE were as many as 34 people (51%). Farmers who have moderate attitude (less good) as many as 12 people (18%) who use high Protective toolsas many as 7 people (10%) and who use PPE while as many as 5 people (8%). Based on result of chi square test that obtained is *p value* 0,173 (p value> 0,05) on knowledge and *p value* 0,2 (p value> 0,05) at attitude. So it can be concluded that there is no relationship between behavior with the use of personal protective equipment on pesticide user farmers in Tonrong Rijang Village Baranti Sub-District Sidenreng Rappang.

Keywords: *Farmer, Personal Protective Equipment, Knowledge, Attitude*

Introduction

Agriculture is one of the most important fields in fulfillment of a need for a society where Indonesia is an agricultural country that is predominately live in agriculture. The number of farmers reached 40% of the total workforce in Indonesia or about 46.7 million. With the growing population every year, people start to think to improve the results of its production in the agricultural sector, one of the ways they are the pesticide use to decrease the disruptor factors of production such as pests. [6].

Massive use of pesticides can cause health problem mainly on farmers sprayers. One of the impacts caused due to the use of pesticides are poisoning on rice farmers. One of the efforts to prevent pesticide poisoning on farmers is by the use of complete Protective self tools, such as masks, work clothes, boots, and gloves. [8]

The World Health Organization (WHO) said that the negative impact of pesticides for public health is highly toxic and dangerous. Direct contact with this acute toxicity risk pesticides or chronic. Headache, nausea, vomiting and so forth even irritation on the skin and blindness are symptoms of acute poisoning from pesticides. Data from the World Health Organization

Email: zainab@poltekkes-mks.ac.id

(WHO), 1-5 million cases of pesticide poisoning occur in workers in the agricultural sector where the majority of cases occur in developing countries that 20,000 inhabitants got fatal effect due to the use of pesticides[3].

Materials and Method

1. **The location of the research:** The location of the research conducted in the village of Tonrong Sub-district Baranti Flint District Sidenreng Rappang. The area of Tonrong village of Flint around 340 ha/m² with 1,318 inhabitants with 338 families.
2. **Population and Sample:** The population in this research is the entire rice farmers in the village of Tonrong Sub-district Baranti Flint District Sidenreng Rappang which is 334 Family. Determined using the method of Cluster and Data retrieval is performed using a Random Sampling Method based on the Joseph Muri Suharsimi Arikunto method[1] [4]. Sample were taken from 20% of the total population. Because the population is more than 100 people in the village of Tonrong Flint with calculation as follows:

- Dusun Mattonrong Salo : 191 KK
- Dusun Tonrong Rijang : 143 KK
  - 191 KK x 20 % : 38 KK
  - 143 KK x 20 % : 29 KK +

67 KK

3. **Data Analysis:** Data analysis was done using the table along with the discussion and concluded by using the Chi Square test using SPSS with 25, Microsoft excel, and Microsoft word.

Discussion

1. **The relationship between knowledge of the farmers with the use of protective tools:** Based on the results of the study indicate that there is no significant relationship between knowledge with the use of protective toolson farmers in the village of Tonrong Sub-district Baranti District Sidenreng Rappang. It is based on the results of a test of chi square p is the value obtained 0.173 (p value 0.05 >). The results of this research shows that most farmers had a high level of knowledge 44 people (66%) and moderate level of knowledge are 23 people (34%). Where a Farmer has a high level of knowledge as much as 44 people (66%), which have a high use of Protective toolsas many as 21 people (31%) and who have moderate use of the Protective toolsare 23 people (34%). Farmers who have a moderate level of knowledge as much as 23 people (34%), which have a high use of Protective toolsas much as 7 persons (11%) and who have the use of the Protective toolsare as much as 16 people (24%).

   The results of this study are inconsistent with research Faris Khamdani [5] about the relationship between Knowledge and attitudes with the use of the tool of self protector Spray Pesticides on farmers in the village of Angkatan Kidul 2009 obtained a result that respondents who have less knowledge and do not wear full personal protection as much as 32 people or 94.1%, while respondents who have a knowledge of good and simply not wearing full personal protection a number of 13 people or 28.3%. Respondents with less knowledge and wear full personal protection is 2 persons or 5.9% while the respondents had the good knowledge and enough wearing Protective toolspeople or 71.7%.

   The results of this research in line with the Shobib research[7] about the relationship between knowledge and attitudes with the practice of using Protective toolsthemselves at the peasant pesticide users in the village Curut Penawangan Kec years 2013 from Grobogan Regency the results of statistical tests knowledge with practice obtained p value 0,658 (p > 0.05) showed no meaningful relationship between knowledge with practice of using Protective toolson farmers users of pesticides. Behavior or practices of farmers in the use of the Protective toolsinfluenced many factors, although the good farmer's knowledge of the use of Personal Protection when interacting with pesticides, but in practice it may not be appropriate, the availability of the protective tools, comfort, season and weather that did not allow, and it because follows the behavior of people or fellow farmers, so knowledge is not necessarily influential or relate to a person's behavior or practices.

   In this study the majority of farmer > 50 year old with working period of >10 years and most of the farmers did not finish Elementary School and some of them have to high school education level. Farmers who did not finish elementary school most have moderate knowledge levels, while farmers who had education up to secondary school have a high knowledge. Farmers who

have moderate knowledge are (farmers who did not finish elementary school) most of them do not use the complete self protective tool, whereas farmers who have the knowledge are farmers who have high education up to Secondary School Upper Intermediate mostly use Protective toolsthemselves. This shows that formal education provides a major influence in the open insight and understanding of the new values that exist in the environment. Someone with a high level of education will be easier to understand the changes that occur in their environment and the person will absorb those changes if the feel is beneficial for him. Someone who never attended formal education estimated will more easily accept and understand about health messages through this extension as well as the mass media [5].

Farmers ' knowledge need to be improved in order to pay more attention to the use of protective self, especially about the negative effects or dangers that can be caused from pesticides if they do not use Protective toolsthemselves, provide guidance and simulation about the use of Protective toolsthemselves with good and true, such as hats, masks, gloves, long sleeve shirt, long pants and boots and danger from not using protective tools and the need for protective about the posters themselves at the peasant must be used in order to remind farmers and farmers ' awareness of the importance of safety and health in the work.

2. **The relationship between Attitude with the use of Protective toolsfrom Pesticide Users in the village Tonrong Rijang:** Based on the results of the study indicate that there is no significant relationship between the attitude to the use of protective tools to pesticide users on farmers in the village of Tonrong Rijang Sub-district Baranti District Sidenreng Rappang. It is based on the results of a test of chi square p is the value obtained by 0.2 (p value 0.05 >). The results of this research shows that most of the farmers have a high attitude that as many as 55 people (82%) and moderate were 12 people (18%). Where a Farmer has a high attitude towards the use of the protective tools. Protective toolshigh user by as much as 21 people (31%), while the use of moderate user as many as 34 people (51%). Farmers who have an attitude of moderate (less good) that uses high protective toolsas much as 16 people (10%) and the use of the protective toolsas many as 5 people (8%). Although most farmers have high attitude towards the use of protective tools, they still don't use protective toolsthemselves in action. There is still lacking of using protective tools. So it can be seen that attitude does not necessarily reflect one's actions or the actions of someone often at odds with his attitude.

The results of this research are consistent with 2013 Shobib research [7] about the relationship between knowledge and attitudes with the practice of wearing Protective toolsin the village of Curut Penawangan Kec years 2013 from Grobogan Regency the results of statistical tests attitude with practice obtained p value 0,902 ($p > 0.05$) showed no meaningful relationship between attitude with the practice of wearing protective toolsto farmer that is pesticide users.

The results of this research are also in line with the research of Usman Rifai [6] about factors associated with compliance with the use of Protective toolsthemselves at the rice farmer in Dukuh Sodong Village Semarangtahun Town Mijen Subdistrict Purwosari 2017. From the statistics, there is no relationship between the attitude of compliance with the use of Protective toolsbecause in Dukuh Sodong.They assume that the wearing of protective tools can be interfere with work as well as the uncomfortable feeling while using protective tools.

Attitude is a tendency to hold actions against an object, with a way of stating the existence of signs for enjoying or not enjoying the object. Attitude is just part of human behavior. Attitude is a reaction or response is still closed from someone's response to a stimulus or object. The attitude shows in the real connotation of congruency reaction to certain stimuli in everyday life is the emotional nature of the reaction against the social stimulus[5].

This research show that the attitude of farmers in using protective tools is good, but despite the attitude of farmers already well there are several factors that affect the use of Protective Tools, such as comfort in work. Most of the farmers are not using protective gloves namely self as much as 59 respondents or 88% because farmers feel

uncomfortable while working (mix and spray) wear gloves. The hand is one of the important aspects that need to be protected because farmers use the hands to take, mixing and spraying of pesticides, the use of gloves may also reduce the risk of entry of pesticides from the skin, as many as 54 respondents or 81% do not use boots in the works because it feels uncomfortable, besides the weather factor also affects the rainy season will be very hard work by wearing boots, and as many as 51 respondents or 76% did not wear a mask because it feels stuffy or difficulty breathing when spraying pesticides and the unavailability of the mask should be used.

In this study the majority of farmers have time work > 10 years and some farmers have time work ≤ 10 years. Farmers work with > 10 years have a high attitude (good) on the use of protective tools so well with farmers who have working period ≤ 10 years also has a great attitude towards the use of protective tools themselves. However, both farmers with a working period of >10 years or farmers with work that has ≤10 years high attitude in the use of protective tools themselves mostly have usages that are self protective tool in terms of are not use protective tools themselves. This shows that although the farmer who has a long working period though, that have experience in doing his job has not been able to implement the full use of Protective tools in protecting himself when doing spraying.

Conclusion

There is no relationship between the behavior with the use of protective tools themselves on rice farmers in the village of Tonrong rijang Sub-district Baranti District Sidenreng Rappang, where p value = 0.173 (p value 0.05 >) on knowledge and p value = 0.2 (p value 0.05 >) on attitude.

Conflict of Interest: In this study between researchers and research subjects did not have a conflict of interest, because subjects did not have personal or informal relationships with researchers.

Source of Funding: The source of funds in this study came from self funding in 2018.

Ethical Clearance: The ethics of this study were obtained from the Ethics Commission for Health Research, Health Polytechnic of Ministry of Health in Makassar, Indonesia.

ABSTRACT

A laboratory is a place to carry out experiments. Working in a laboratory means having zero chance to perform reckless behaviors in performing or using equipment and materials provided in a laboratory. A laboratory as a place with high chances of hazard occurrence is required to be examined by implementing Hazard Identification Risk Assessment Determining Control (HIRADC) analysis, which also an essential element in occupational safety and health management system due to the fact that it relates to the endeavor to prevent and control hazards used to determine the objectives and intentions of occupational safety and health. HIRADC analysis in this research is expected to reduce hazard risks that are likely to be discovered in laboratories. This research is performed in 2 nutrition laboratories in the Faculty of Public Health, Universitas Airlangga. The data used are the primary data obtained from observation. The results show that there are 15 hazard identifications from two identified laboratories. The highest hazard level is medium-risk, which consists of 3 hazard identifications. Risk controls need to be continuously implemented in order to control hazards that might be occurred.

Keywords: *laboratory, HIRADC, hazard*

Introduction

A laboratory is a place to carry out an experiment. Working in a laboratory requires cautious behavior in treating or using equipment and materials in the laboratory. This is intended to scale down the possibility of occupational accidents in a laboratory. Amongst of the potential hazards that are likely to happen in a laboratory are fire, poisoning, and equipment damage.[1]

Everything that contains danger is fundamentally sustained by the risk management to control hazards that can potentially cause several risks in occupational safety and health to prevent unwanted occupational accidents comprehensively, planned, and structured under a well-managed system. The number of hazard aptitude is determined by the possibility of the occurrence of the incidental accidents as well as by the severity it may cause.[2]

According to the International Labour Organization (ILO), 2.78 millions of workers are reportedly dead each year due to occupational accidents and occupational illnesses. Approximately 2.4 million (86.3%) of these deaths are caused by occupational illnesses, while more than 380,000 (13.7%) are caused by occupational accidents.[3] Referring to the data provided by National Social Security (re BPJS Ketenagakerjaan), the number of occupational accidents in Indonesia is still massive. In 2015 alone, 110,285 cases of occupational accidents were disclosed, while in 2016, 105,182 cases were detected. In addition, until August 2017, National Social Security attained the number of 80,392 cases of occupational accidents.[4]

The big number of accidents must not be underestimated. A laboratory as a workplace in which several of hazard risks can be discovered must have control to reduce the number of occupational accidents in Indonesia. OHSAS 18001 is one of occupational safety and health management systems with an international

standard that aims to provide safety for workers from unwanted matters that might arise from workplaces or working activities itself. In accordance with the requirements given by OHSAS 18001 clause 4.3.1, an organization must set a procedure and conduct Hazards Identification, Risk Assessment, and Determining Control, which also known as HIRADC.[5]

A laboratory as a place with high risk of danger should also be carried out by HIRADC (Hazard Identification Risk Assessment Determining Control) analysis that roles as an indispensable element in occupational safety and health management system since it directly relates to the prevention and hazard control used to determine the objectives and intentions of occupational safety and health. The carried out HIRADC analysis is expected to reduce hazard risks that might arise in a laboratory.

Method

Study Population and Analysis: This research implemented observational approach and cross-sectional. The data were analyzed descriptively by elaborating the hazard potentials in the area in which the research was conducted to obtain risk assessments and determining controls. This research was carried out in Nutrition Laboratories of Faculty of Public Health, Universitas Airlangga Surabaya, namely the Laboratory of Nutrition Processing and the Laboratory of Biochemistry and Nutrient Processing Analysis. These locations were chosen as the locations of the research due to the fact that there had not been similar research carried out. The variables used in this research were the working activities in the laboratories, hazard sources, assessment, and risk control. The data gathered from this research are known as the primary data, which were obtained by observation. In addition, the results of the observation were presented in the form of narration and table before analyzed descriptively to draw a conclusion.

Risk Assessment: There are three main focuses in HIDARC, namely the attempt to perform hazard identifications and its characteristics, which is followed by filling up the assessment, risks of existing hazards, and last, recommending control endeavors that are likely to be executed.

Hazard identification is done to monitor high-risk workloads and underline the hazards related to certain equipment. Hazards in a working environment can be categorized into three major groups, for instance, health hazards, safety hazards, and environment hazards.[6] After that, evaluate risks whether the risks are acceptable or not is measured. To measure the score level of the risk, it is important to understand two main components, namely Likelihood, and Severity.The criteria to assess Likelihood can be seen in Figure 1, while the criteria to assess Severity are presented in Figure 2.

LIKELIHOOD(L)	EXAMPLE	RATING
Most Likely	The most likely result of the hazard/ event being realized	5
Possible	Has a good chance of occurring and it is not unusual	4
Conceivable	Might be occur at sometimes in future	3
Remote	Has not been known to occur after many after	2
Inconceivable	Is practically impossible and has never occurred	1

Source: **Department of Occupational Safety and Health Malaysia** *(2011)*

Figure 1: Likelihood Criteria

SEVERITY(S)	EXAMPLE	RATING
Catastrophic	Numerous fatalities, irrecoverable property damage and productivity	5
Fatal	Approximately one single fatality major property damage if hazard is realized	4
Serious	Non-fatal injury, permanent disability	3
Minor	Disabling but not permanent disability	2
Negligible	Minor abrasions, bruises, cuts, first aid type injury	1

Source: **Department of Occupational Safety and Health Malaysia** *(2011)*

Figure 2: Severity Criteria

After obtaining the severity level of risks, the control to suppress the risk level to become as low as possible is likely to be done.[7]

Result

According to the observation, in the Laboratory of Biochemistry and Nutrient Processing Analysis, five items of hazard identifications as displayed in Table 1 were discovered.

Table 1: Hazard Identifications in the Laboratory of Biochemistry and Nutrient Processing Analysis

No.	Activity	Hazard Source
1.	Food nutrient analysis (mixing food ingredients with reagents)	Acid reagent and concentrated base (heated up to 400° C in a fume hood)
		Heat from the fume hood
2.	Biochemistry analysis (mixing reagents and human body sample)	Reagents (Acid and strong base with high concentration)
		Droplets from human (blood, urine, saliva, hair)
3.	Biochemistry and nutrient analysis practices with a minor accident	No First Aid kit in the laboratory

Table 2: Hazard Identifications in the Laboratory of Nutrition Processing

No.	Activity	Hazard Source
1.	Peeling and cutting food ingredients to be processed	Sharp food ingredients
		Knife
		Bacteria
2.	Washing food ingredients and utensils	Bacteria
3.	Cooking foods on a stove and deep fryer	LPG
		Heat
		Hot oil
4.	Cooking foods using a microwave	Heat
		Electricity
5.	Cooking foods using an oven	Heat
6.	Food processing practices with a minor accident	No First Aid kit in the laboratory

The hazard sources discovered in both laboratories contribute to risk accidents and diseases caused by the work done in both locations. Referring to the terms proposed by AS/NZS 4360, in order to correctly measure the risk level of each hazard, the assessment of two components, Likelihood and Severity, from point 1 to 5 based on the possible risk occurrences needs to be done.[7] The information is presented in Table 3 and Table 4.

Table 3: Likelihood and Severity of the Laboratory of Biochemistry and Nutrient Processing Analysis

Hazard Source	Risk	Likelihood	Severity	Risk Level
Acid and concentrated base reagent (heated up to 400° C in a fume hood)	Fluid exposed to the skin	1	3	Low
	Fumes inhaled and enter the respiratory tract	2	3	Moderate
Heat from a fume hood	The heat from the heating devices exposed to the hands	1	2	Low
Reagents (Acid and strong base with high concentration)	Fluid exposed to the skin	1	3	Low
	Fumes inhaled and enter the respiratory tract	1	3	Low

Conted…

Droplets from human (blood, urine, saliva, hair)	Droplets exposed to the skin tissues	1	1	Low
	Droplets swallowed or inhaled and enter the human body	1	2	Low
No First Aid kit in the laboratory	Injuries cannot be treated with First Aid and caused more severe wounds	2	3	Moderate

Table 4: Likelihood and Severity of the Laboratory of Nutrition Processing

Hazard Source	Risk	Likelihood	Severity	Risk Level
Sharp food ingredients	Sliced by sharp food ingredients	1	2	Low
Knife	Hands sliced by a knife	2	2	Low
Bacteria	Food contaminated by bacteria	1	1	Low
Bacteria	Food ingredients and utensils contaminated by bacteria	1	1	Low
LPG	Exploding and fire	1	4	Low
Stove heat	The heat from the stove or heat-conductor utensils exposed to the hands	2	2	Low
Hot oil	Hot oil exposed to the hands	2	2	Low
Food heat	Hot food products (burn) exposed to the hands	2	2	Low
Electricity	The electric shock when connecting the cable to the socket	1	2	Low
Oven heat	Hot oven and food products (burn) exposed to the hands	2	2	Low
No First Aid kit in the laboratory	Injuries cannot be treated with First Aid and caused more severe wounds	2	3	Moderate

The following step to be performed is assessing risk levels by alluding the risk matrix as shown in Figure 3. The meeting point of Likelihood and Severity is the one that determines whether the risk level belongs to a low, moderate, or high level. Moreover, in elaboration, if the meeting point of Likelihood and Severity is in the green area, it can be presumed that the risk level is low. However, if the meeting point is in the yellow area, it is considered as moderate and high if it belongs to the red area.[7]

Source: **Department of Occupational Safety and Health Malaysia** *(2011)*

Figure 3: Risk Matrix

The high-risk level requires immediate actions to control hazards in accordance with five hierarchy controls. The moderate-risk level, on the other hand, compels designed approach in hazard controls as well as executes alternative plans if needed. Additionally, for the low-risk level, the hazards are still likely to be accepted and not in need of further control. [7]

Discussion

Hazard Identification

1. **The Laboratory of Biochemistry and Nutrient Processing Analysis:** In the hazard identification discovered in the Laboratory of Biochemistry and Nutrient Processing Analysis, it was settled that the reagent is the main hazard in the laboratory. Other than that, the reagent liquid is believed to be dangerous if exposed to the human body. Moreover, the reagent needs to be heated. Thus, it can be presumed that beside the reagent liquid that originally contains chemical matters, instruments and utensils with high temperatures as well as fumes from the reagent heating process are also undoubtedly alarming. Unfortunately, the subjects who perform such tests seem to underestimate the consequences and resulting to inhale the alarming fume.

   Other than food substances, the Laboratory of Biochemistry and Nutrient Processing Analysis also evaluates the biochemistry taken from the human body as the sample, for instance, blood, urine, saliva, and hair. Those samples are considered as hazards since they can transmit diseases. Therefore, it can be stated that doing activities in a laboratory means living close to danger, according to the survey conducted by Education Bureau in 2011/2012 regarding accidents in school laboratories in 401 middle schools which enlisted the reported 348 cases of laboratory accidents. From the survey, the results showed that 328 people were injured, with the percentages of 39.1% of grazes, 37.6% of minor burns, 8% of accidents on the eyes, and 7.2% of exposure to chemical substances.[8] First Aid kit needs to be stacked to anticipate minor accidents. However, regrettably, there is no First Aid kit spotted in the Laboratory of Biochemistry and Nutrient Processing Analysis.

2. **The Laboratory of Nutrition Processing:** In the Laboratory of Nutrition Processing, activities to process foods are the main activities performed. The processing equipment that is most likely to cause danger is a knife, providing it has a sharp side that can be a cause of grazes. Additionally, stoves and ovens in high temperatures that can cause burns and LPG that may explode. Other than that, food ingredients such as pineapples, shrimps, and fish can also be considered as the potential hazard sources. If food ingredients are contaminated with bacteria due to unclean washing process or un-fresh ingredients, the bacteria itself may transfer to the laboratory workers. Moreover, heated oil is presumably causing accidents, for example, hands splashed by hot-temperature oil. The Laboratory of Nutrition Processing, unfortunately, does not provide First Aid kit, resulting in minor accidents cannot be immediately treated.

Risk Assessment

1. **The Laboratory of Biochemistry and Nutrient Processing Analysis:** The average hazard level discovered in the Laboratory of Biochemistry and Nutrient Processing Analysis is the low-risk level, providing the occurrences hardly arise when doing such activities in the laboratory. Even so, the score of 2 in Likelihood aspect is given for fumes inhaled when processing food ingredients and untreated minor accidents due to the absence of First Aid kit in the laboratory.

   As for the Severity aspect, the average point given for the Laboratory of Biochemistry and Nutrient Processing Analysis is 3. Likewise, the risk of droplets exposed to skin tissues causing blisters, bruises, wounds, and worries resulting those hazards be given the Severity point of 1. As for the risk of hands exposed to the heat from a fume hood and droplets swallowed, the hazards be scored 2 points of Severity aspect since it may cause non-permanent disabilities.

   From the elucidation above, it can be concluded that there are only two hazards that are considered as moderate, namely fume reagents inhaled during food nutrient analysis and the absence of a First Aid kit.

2. **The Laboratory of Nutrition Processing:** The danger of processing equipment in the Laboratory

of Nutrition Processing such as knives, stoves, and ovens be given the score of 2 in Likelihood aspect. The same score is also given to hot oil, food heat, and the absence of First Aid kit. The explosion of LPG and electric shock accident records are nowhere to be found, causing both hazards to be given the score of 1 in Likelihood aspect.

For the Severity aspect, the highest score of Severity, 4, is attained from the explosion of LPG since it may be resulting in fatal injuries and the damage of properties. In contrast, the lowest Severity score is obtained by the bacteria in food ingredients and processing equipment, which each gets a score of 1. The Severity level with the score of 3 is only spotted in the risk caused by the absence of First Aid kit. As for the other hazards, the score given is 2 due to the fact that it does not cause any severe injury.

In broad, it can be stated that all hazard risks in the Laboratory of Nutrition Processing on average, attained the score of the low-risk level. Hence, one point that cannot be ignored is the absence of First Aid kit, which belongs to the moderate risk level.

Risk Control

Control actions are needed to prevent occupational accidents that can result to fatal injuries.[9] Amongs of the actions that can be executed are:

a. Administering briefing concerning on the proper and safe experiment instructions before each experiment (Standard Operating Procedure of the experiment and Experimental Instructions)

b. Administering briefing on how to properly and safely process food ingredients

c. Administering briefing on how to properly use knives or hazard-possible instruments that it can be safely used by the users

d. Administering briefing on proper personnel and equipment hygiene sanitation

e. Making regulations to wear Personal Protective Equipment (*APD)* such as rubber gloves, masks, goggles, and a laboratory coat

f. Placing LPG that are far from flammable substances and in a stable temperature

g. Procuring First Aid kits as needed to treat minor injuries caused by minor accidents when doing activities in the laboratory

h. Procuring Personal Protective Equipment, such as heat resistant gloves to minimize the possibility of hand exposed to hot equipment

Some of the elaborated suggestions above are reckoned to be considered in order to control hazards in laboratories to prevent occupational accidents and severe occupational illnesses.

Conclusion

The Laboratory of Biochemistry and Nutrient Processing Analysis and the Laboratory of Nutrition Processing in the Faculty of Public Health, Universitas Airlangga come with different types of hazards. The Laboratory of Nutrition Processing has more potential hazards (10 hazards) than the ones in the Laboratory of Biochemistry and Nutrient Analysis (5 hazards). Nonetheless, the risk levels discovered in the Laboratory of Biochemistry and Nutrient Analysis in moderate-level are reported more with the number of two, obtained from the risk of inhaling reagent fumes while analyzing food substances and the absence of First Aid kit in the laboratory. On the other hand, the Laboratory of Nutrition Processing only has one category of moderate-risk level: the absence of First Aid kits. Thus, it can be assumed that both Nutrition Laboratories in the Faculty of Public Health are considered quite safe inasmuch as no high-risk level of hazards discovered. As a matter of fact, only a few are scored a moderate-risk level. However, risk controls are still essential to be done in order for the hazards to be controlled.

ABSTRACT

The application of Occupational Health and Safety is an important aspect that should be applied in a laboratory unit. Laboratory is a unit used to apply the theories taught in class and also as a means to study the academic activists. A laboratory is a facility that has potential hazards both directly and indirectly. Potential hazard is commonly referred to all sources, situations, or activities that could potentially cause injury (accident) or occupational diseases. Potential hazard causes not only an injury or occupational diseases caused in working, but can result in losses of material and environment for the surrounding communities such as fire, explosion or pollution due to the laboratory activities. Hazard in the laboratory is often not realized by those who are in the laboratory. This is due to the absence of assessment standards and poor socialization or learning about the potential hazard that make it is necessary to identify the level of hazard in a university laboratory. The object of this research study was laboratory of Department of Occupational Health and Safety at Faculty of Public Health, Universitas Airlangga, Surabaya. This research study was an observational research because the researcher only did observations without giving treatment. The research design used in this research study was a cross-sectional study because the research study was conducted at one particular time. The tool used to analyze risk was HIRADC (*Hazard Identification Risk Assessment Determining Control*). There were ten hazards that exist in the laboratory. The source of hazards were seen from the attitude at work, materials, and equipment, environment and the way of working. The results of the research study found that the risk level in the laboratory of OHS (Occupational Health and Safety) Department of Occupational Health and Safety Universitas Airlangga was 60% (low). The control could be done through the engineering control, administrative control, and the use of personal protective equipment (PPE).

Keywords: *Hazard Identification Risk Assessment Risk Control, Hazard, Risk analysis*

Introduction

Workplace certainly has the potential hazard that can cause accidents. One of the workplaces is the laboratory. Educational research unit, hereinafter referred to as laboratory, is academic support unit in educational institutions, in the form of closed or open spaces, permanent or movable, systematically managed for testing, calibration and/or production activities on a limited scale, by using equipment and material based on certain scientific methods, in the context of implementing education, research study, and/or community service (Permenpan RB Number 03 Year 2010). Laboratory is managed by technicians or laboratory staff known as Educational Laboratory Institutions.[3]

Educational Laboratory Institutions are positions that have scope, duties, responsibilities, and authorities to conduct management of educational laboratories occupied by Civil Servants with rights and obligations given in full by authorized officials. In the laboratory, there are rules and orders that must be obeyed by each laboratory user.

The existing regulations in Indonesia related to the implementation of Occupational Health and Safety are

Law Number 1 Year 1970 on Occupational Health and Safety. Government Regulation Number 50 Year 2012 on Implementation of Occupational Health and Safety Management System. It states that the Occupational Health and Safety Management System applied must be in accordance with the national policy of Occupational Health and Safety Management System. OHS Management System includes the establishment of OHS policies, OHS planning, implementation of Occupational Health and Safety plan, monitoring of Occupational Health and Safety, evaluation of OHS performance, and reviewing and improving the performance of OHS.[5]

Entrepreneurial or Education Laboratory Institutions at least conducts an initial review of Occupational Health and Safety conditions such as hazard identification, risk assessment, and risk control. Risk assessment and risk control or commonly known as HIRADC is a method of the OHSAS 18001:2007 standard. Organizations in conducting hazard identification and risk assessment must pay attention to the scope, nature, and time to ensure the method is proactive and provide identification, priority and risk documentation, and application of controls as needed.[2]

The Global Estimates Fatalities reported that 6,000 workers worldwide had lost their lives every day due to accidents and work-related illnesses/occupational diseases. Based on the data from Social Insurance Administration Organization (BPJS), number of accidents remained in high each year. In 2015, there were 110,285 cases of occupational accidents. In 2016, as there were 105,182 cases of occupational accidents with cases decreased by 4.6%. Meanwhile, currently the number of occupational accidents in Indonesia is around 80,392 cases.[7]

Workplace accidents can be caused by mistakes and negligence in the use of machinery or the equipment in the workplace, disobeying the work procedures, lack of job training, unavailability of occupational health and safety equipment. As well as the workplace accidents that occur in the laboratory.

Department of Occupational Health and Safety, Faculty of Public Health is a leading educational facility and is very supportive of the academic community in developing research study, so that it always striving to increase and improve the best quality of all facilities in it.

Working in laboratory unit of Occupational Health and Safety or working in other laboratory has various hazards. Workplace accidents that occur can not be separated from the hazards that exist both physical, chemical, biological, ergonomic, and other hazards. The occupational accidents are high electrical tension, scratches, contracting diseases, punctured by lancet, and others. Occupational accidents in laboratory unit of Occupational Health and Safety must be identified, analyzed, and controlled to prevent the workplace accidents.

Therefore, this research study aims to analyze the risk of hazards using the Hazard Identification Risk Assessment Risk Control in laboratory unit of Occupational Health and Safety as an effort to prevent and control the risks of occupational accidents and occupational diseases to the laboratory users.

Material and Method

This research study was an observational research because the researcher only did observations without giving treatment during the research study. The research design used in this research study was a cross-sectional study; the data collection was carried out in a certain period of time.

The data analysis of this research study was descriptive because the researcher only described the process and data collected without analyzing the relationships between variables. The tools used in this research study were *hazard identification, risk assessment,* and *risk control.*

This research study only used primary data obtained through interviews and observations. Interviews were carried out to the laboratory staffs who were responsible for the laboratory unit of OHS or referred to as the Education Laboratory Institutions. Observations were made to obtain information related to work performed, sources of hazard, existing risks, and risk control efforts that had been made. The results of data collected and analyzed were presented with narrative text and HIRADC tables.

Finding

The laboratory unit of OHS, Department of Occupational Health and Safety, Universitas Airlangga had various activities; activities that had a source of hazard and would pose a risk to Occupational Health and Safety. The HIRADC method was used as a first

step that could be used to prevent the occurrence of risks that could cause workplace accidents. The first step was Hazard identification was performed on ten laboratory activities in the laboratory unit of OHS. The ten laboratory activities identified the hazard of each activity performed.

The next step was risk assessment of each hazard. Risk analysis was performed with qualitative methods by assessing aspects of opportunity or likelihood and severity which were then evaluated using a risk matrix as referred to the *Australian Standard/New Zealand Standard (AS/NZS 4360: 2004)*[1].

Risk assessment was conducted when laboratory activities began. The source of hazard had ten risks. There were six risks with a low category, three risks with a medium category, and one risk with a high category. The results of the risk assessment based on the calculation of likelihood and the severity which was converted using the risk matrix table, will be used as the next step, that was determining control.

Risk control had been performed by the laboratory staff on hazards or risks from each laboratory activity based on the findings or events occurred. By trying to compare the results of the risk assessment with the control efforts, then it will be known what attempts were still less effective. Therefore, hazard control can be performed using a hazard control hierarchy, namely elimination, substitution, engineering control, administrative, and the use of PPE (personal protective equipment.

1. **Hazard identification:** Activities conducted in laboratory unit of OHS had a variety of potential hazards such as the use of electrically powered equipment, the up and down of the bench, the use of sharp materials, the use of mouthpieces, non-functioning of water wash, and equipment cluttered or not placed properly. Potential hazard of using electrically powered equipment could cause electricity issues that were not in accordance with the MCB, so that the electricity could be interrupted, which might cause short circuit, or fire.

   Physical fitness practicum activities had potential hazards when the bench going up and down. If going up and down a bench happened in an incorrect position, it could cause muscle pain. Then, if the bench did not have strong feet, it could also cause accidents.

   At the time of the blood chemistry test using lancet, cotton, and capillary tube, these objects could transmit other people's blood from the remaining blood. In addition, the lancet could cause punctured or scratched skin due to the sharp lancet.

   At Laboratory unit of OHS, at the time of delivering the materials, the chair used was not ergonomic because it did not have a backrest and a right armrest. In addition, the chair used did not have a cushion on the buttocks.

   Water wash in laboratory unit of OHS could be used. This might cause the chemical that splashed into the eyes could not be washed easily. Therefore, these chemicals could cause irritation.

   Then the equipment in laboratory unit of OHS was in a mess condition and was not placed in the proper place. So, the equipment could be dropped, damaged, or lost.

2. **Risk Assessment:** After identification of hazard was performed, the source of hazard or potential hazard would have a risk impact. The risk impact was categorized into three categories, those were low, medium, and high category. The three categories were derived from calculations that refer to AS/NZS 4360:2004[1].

   Risk = Likelihood × Severity

   Based on the results of the risk assessment, there were ten risks. There were six risks with low category, three risks with medium category, and one risk with high category.

   Low-risk categories were the risk of injury and unable to perform the first aid, disease transmission through saliva or blood, eye irritation, time efficiency, and equipment damage. The risk with the medium category was the occurrence of severe injuries, the occurrence of symptoms of MSDs (*musculoskeletal disorders*), and falling equipment could injure another person. Then, for a high-risk category, that was electric shock or fire due to a short circuit.

Table 1: Risk Analysis and Risk Level

No.	Activity	Sources of Hazard	Risk	Risk Analysis		Risk Total	Risk Level
				L	S		
1.	Scratched sharp end of the room sides. Cut during practicum.	Equipment/sides of the room that could cause injury.	Unable to perform the first aid in case of accidents and injuries become more severe.	4	1	4	Low
2.	Falling down on the bench at the physical fitness laboratory.	When doing practicum, the practitioner can be negligent and lead to accidents.	Causing serious injury. Not yet happened but can happen at any time.	2	3	6	Medium
3.	The use of equipment with electric power When the learning process conducted, it is often interrupted.	Electric current is not in accordance with MCB (Miniature Circuit Breaker).	Electricity off when practicum is conducted. It can cause fire.	2	5	10	High
4.	Using someone else's mouthpiece that has been used in Pulmonary Physiology Laboratory.	When doing practicum, the practitioner can neglect to put the transducer used, not directly disposed in the place provided for disposal.	Transmission of disease through saliva.	2	2	4	Low
5.	The use of lancet, cotton, and capillary tube in blood chemistry laboratory after use.	Punctured by someone else's lancet. Exposed to other people's blood from cotton and capillary tube.	Transmission of blood-borne diseases.	1	4	4	Low
6.	*Air wash* does not work or often die	When getting foreign object in the eye	Eye irritation.	1	3	3	Low
7.	Wooden seating/ wooden benches are too old and many are not sturdy/strong.	Less ergonomic chair. Fell from the chair.	Symptoms of MSDs.	5	1	5	Medium
8.	Place the goods/tools above the cabinet (administration room).	Tool or item dropped when taken.	Injuring the person who took the tool item.	5	1	5	Medium
9.	Place a tool that can still be used and cannot be used as one.	Enable chemical reactions between tools.	Rust occurrence. Material loss. Time efficiency when searching.	4	1	4	Low
10.	The tool can not be used properly or damaged.	Do not know whether the tool is functioning properly or not.	Tool damage.	4	1	4	Low

3. **Determining the Controls:** Determining control in laboratory unit of OHS had been performed but the determining control was still not effective. This was because the laboratory staff did not conduct former HIRADC; they only looked at risks that could be observed by the eye but not thoroughly. The HIRADC method could help the existing determining controls and which risk could be prioritized to be controlled first.

   Determining control applied a control hierarchy. At low-risk category, determining control efforts could be done by elimination, that was eliminating or separating equipment which was not usable and could still be used. Besides that, it was also performed administratively, such as the procurement of equipment and the placement of first aid kit in accordance with PER.15/MEN/VIII/2008, Yellow Trash Bag (B3) was placed beside the spirometer.[4]

   Laboratory staff supervised the practicum by controlling the provision of Safety Box. Laboratory staff administered the place of the practicum, Laboratory staff proposed to procure a pump so that the water could be supplied to the laboratory room and the water wash functioned properly and the recapitulation sheets existed when the tools were used. Hence, if it did not function properly, calibration could be done immediately.

   Risks with the medium category was controlled by administrative way such as Making rules or SOPs for those who would enter the laboratory area; printed and put in front of the entrance (prohibition of eating, drinking, using cellphones when not needed, the use of PPE, and the use of tools). Add SOPs and rules in each lab chapter in the General Practicum Guide. For example, conditions that are permitted as a *role model* had to be in a healthy condition, not fasting, and menstruate. It needed provision of bearings on wooden chairs, repairment for the chairs that were felt to be less sturdy such as the addition of nails and so on. Replacement also needed to be performed for the seats/chairs that were truly not feasible, and also applying and maintaining 5R (Concise, Neat, Clean, Care, and Diligent).

   Whereas the high-risk category was performed using elimination, that was MCB replacement in the laboratory and performing routine checks every month.

Conclusion

Risk assessment using HIRADC in laboratory unit of OHS had various sources of hazard. There were ten potential hazards from laboratory activities.

The ten potential hazards may pose different risks. There were three categories of risk assessment, those were low-risk category, medium-risk category, and high-risk category. The results of the risk assessment had ten risks. There were six risks with low-category, three risks with medium-category, and one risk with high-category.

Determining control efforts performed followed a hierarchy of controls, those were elimination, substitution, engineering control, administrative control, and the use of PPE.

ABSTRACT

This article discusses the effects of a gluten-free diet on the human body suffering from various diseases (celiac disease, autism, allergies). The article highlights both the positive and negative effects of a gluten-free diet on the human body. In addition, the article provides a brief overview of gluten-free food technologies (confectionery, bakery products).

Keywords: *gluten, gluten-free diet, celiac disease, gluten-free foods, bakery products, technology*

Introduction

A gluten-free diet which is also known as the GFD is a kind of diet that firmly eliminates gluten. While gluten is the combination of different types of proteins that are specifically found in wheat and all the products related to wheat. It is also found in products like barley, oats, and rye. Gluten is contained not only in all baked products, wheat bread, pasta and macaroni products, but also in all kinds of foods made with the addition of wheat flour as a thickener - for example, semi-finished products, sauces and ketchups. The term "gluten" is applicable to a combination of simple prolamin (rich in proline), called "gliadins", and glutelin (rich in glutamine), called "glutenins" the cereal proteins[1].

Table 1: Content of gluten in different type of flour[2]

Type of flour	Protein content in 100g	Gluten content in 100g
Wheat flour	10 – 14 g	3.0 – 5.0 g
Barley flour	11 – 12 g	2.2 – 2.8 g
Rye flour	9 – 10 g	2 – 2.5 g
Oat flour	10 – 11 g	2 – 2.2 g
Millet	10 – 11 g	1.5 – 1.7 g
Dinkel wheat	10-15 g	0.3 – 1.0 g

The presence of specifical oats in a gluten-free diet is questionable because it can be dependent on the cultivar of oat and also the repeated cross-contamination through other gluten-containing cereals could be the reason of this[3]. A specificity of gluten protein is that it has a very low quantity nutritional as well as biological value. Research says that the presence of grains that specifically consist of gluten is not necessary for the human diet. On the other hand, an unstable amount of food, as well as an improper section of gluten-free replacement foodstuffs, could be the reason for nutritional deficiencies. Nutritional difficulties can be prohibited with the help of accurate dietary education[4].

Celiac disease (gluten-sensitive enteropathy) is a disease caused by the inability of the intestine to digest gluten from cereals. Celiac disease can occur in various clinical forms, not always explicitly. In fact, there are latent or hidden, clinically unexpressed and without obvious symptoms, monosymptomatic forms or forms with all intestinal and extraintestinal, clinical symptoms. It is not yet determined the method of preventing the development or treatment of celiac disease. Therefore, only a gluten-free diet is the only therapy that can ensure good health for people affected by celiac disease[5,6].

Benefits of a Gluten-free diet: One of the biggest benefits of a gluten-free diet is that it is helpful to improve the level of energy at a higher rate. There are various forms of gluten intolerance and also it has numerous severities but those don't have adverse effects

on the health of the human body. A gluten-free diet is also helpful to overcome the management of Autism. Autism is a mental disorder that usually takes place in the child of age two or less than that. For the treatment of this disorder, different therapies are recommended and a Gluten-free diet is also suggested by the doctor[7].

According to research it is also observed that a gluten-free diet is helpful to reduce weight however evidence for this claim is less but research says it is useful to diminish weight. A gluten-free diet is also helpful to absorb nutrients from the diet. By the absorption of nutrients, cellular activity of human body is improved so it can be beneficial for the human body. Gluten is the special kind of protein that is linked with the high intensities of swelling in the body that can be the ultimate source of a high level of oxidative stress in cells. The cells that are under oxidative stress can be the reason for cancerous changes[8].

Inflammation is the process that happens at the very first stage of many cancerous variations. In this case, the immune system might be inhibited instantaneously and incapable to take care of cancerous fluctuations in the very first stage. A gluten-free diet is also helpful to improve the overall immunity of the body. There are most of the diseases of heart and blood vessels that are caused just because of the inflammation and Gluten-free diet is helpful to reduce the inflammation so ultimately reduces the risks related to heart diseases[9].

A gluten-free diet also helps to reduce allergies. Gluten bigotry also establishes externally, as repeated occurrences that look like dermatitis that comes under the common occurrences. Though these can be managed with the help of application of contemporary anti-itch ointments, using an ointment is a much-recovered idea to avoid the rashes in the initial place. Urticaria is the type of allergy and also known as hives happens commonly in individuals with gluten allergies. So these types of allergies can be controlled with the help of a gluten-free diet. According to research, this diet is also helpful to improve fertility and risk of spontaneous miscarriages can also be controlled by a Gluten-free diet[10].

Some other positive impact of a gluten-free diet includes fewer headaches as well as less joint pain. Nutritional difficulties can be prohibited with the help of accurate dietary education that can suggest either to take a gluten-free diet or not. However, a strict gluten-free diet can also have some negative effects on the human body and these are as follows.

Negative effects of a Gluten-free diet: According to research, it is estimated a gluten-free diet has not enough quantity of fiber in the overall diet so it can be the reason for constipation. Whole wheat and food related to that has a huge quantity of gluten and these are also the major sources of fiber. On the other hand, gluten-free food consists of potato, tapioca as well as white rice that don't have the adequate quantity of fiber as per the requirement of the human body. Diet consist of fiber, though indigestible, plays an essential role to reduce the level of constipation. It is also helpful for keeping the bowel movements regular as well as soft. To prevent constipation while taking a gluten-free diet it is also very important to take the adequate quantity of food that is rich from the fiber.

Gluten-free including different types of grains, brown rice, quinoa as well as millet, fruits, vegetables, seeds, and nuts don't have an adequate quantity of fiber so causes constipation[11]. According to research, it is found that the people who are taking a gluten-free diet face the issue of nutrient deficiency[12]. There are lots of gluten-containing foods including the bread; cereal, as well as pasta and these, are richer form vitamins as well as a mineral. These are also helpful to fulfill the demand of human freedom that is lacked in a gluten-free diet. So the fact is gluten-free forms of these kinds of foods are less probable to be exhilarated. Just because of this human body face the deficiency of B vitamins and iron[13].

To evade such kind of deficiencies, there is a need to eat a balanced diet and also the person must take a multivitamin supplement[14]. There are some undesirable things that happen with the body while taking a gluten-free diet. These include less gas, bloating as well as diarrhea. So by taking a gluten-free diet digestive system of human body is disturbed and within 6-8 months effects can be adverse than before[15]. So these are some negative effects of a gluten-free diet on the human body.

Technology and formulation of gluten free food products: Currently, the production of gluten free food products, in particular confectionery products, is of particular concern in worldwide. One of the methods of production is to use in the formulation of flour of minor types as the main raw material.

The patent[16] describes the method of production of gluten free cake. The method involves following processes: churning margarine and granulated sugar to

form a homogeneous mass within 10-15 minutes. Then adding eggs and salt and mixing for 20 minutes. Sifted cornmeal and rice flour, starch and baking powder are gradually added to the finished mass. Next, candied fruits and grinded lemon are added. The molding is carried out in the treated non-stick coating form. Muffins are baked at 200 °C for 20-25 minutes and cooled to room temperature. The method of production allows to obtain gluten free cake with balanced amino acid composition and enriched with dietary fiber.

The authors[17] developed the technology and formulation of gluten free wafers. It comprises, wt.%: rice flour 12.0, buckwheat flour 48.0, sugar 18.4-19.0, fat component 8.0-10.0, chicken egg 3.3 -3.7, invert syrup 2.4-2.7, salt 0.3-0.5, drinking soda 0.3-0.5, ammonium salt 0.1-0.3, potato starch 2.0 -3.0, drinking water up to 100. The ratio of rice and buckwheat flour is 1:4. The proposed wafers is aimed expanding the range of gluten-free flour confectionery products and the possibility of using them in the nutrition of patients suffering from celiac disease, due to increased nutritional value and the lack of gluten.

Zharkova et al.[18] developed gluten free bread formulation and method of production. This method for the production of gluten-free bread includes the preparation of dough from gluten-free raw materials containing corn starch, granulated sugar, edible salt, baker's dry yeast, vegetable oil, thickener. Then the molding and baking process is performed. The gluten-free raw materials additionally contain amaranth flour, and xanthan gum is used in the following ratio, wt%: amaranth flour 18,5-29,3; corn starch 18.1-29,9; granulated sugar 2,1-2,2; dry yeast 0,31-0,326; xanthan gum 0.19-0.25; vegetable oil 2,47-2,48; table salt 0,745-0,761; water - the rest. The invention provides improved quality and nutritional value and expanded of the range of gluten-free products.

Another gluten-free bread production method includes kneading dough from a gluten-free mixture, water, sunflower oil and yeast. Gluten-free mixture contains the following ratio of components, wt.%: corn starch 51,5-56,5; rice flour 20.0-25.0; soy protein 9.7-10.0; salt 0.8-1.0; granulated sugar 2.0-2.5; food citrus fibers Herbacel AQ Plus 1.2-1.5; lecithin Lezi Pro90S 2.0-3.0; rowan powder (fruit/husk) 3.0-8.0. Gluten free bread baked by this method has brighter, harmonious taste and smell, improved structural and mechanical properties, high microbiological stability during storage[19].

Kozubayeva and Yegorova developed the gluten free cakes from amaranth flour. Amaranth flour was mixed with corn or rice flour and added to the dough in the form of a homogeneous mixture in the range from 5.0% to 25.0% of the total amount of flour according to the recipe. It was shown that the use of corn and amaranth flour in the ratio (10.0–12.5%): (90–87.5%) or rice and amaranth flour in the ratio (15.0–17.5%): (85.0–82.5%) allows to receive cakes products of the standard quality. Developed new cakes contain lower simple carbohydrates, but higher content of dietary fibers, easily digestible proteins and essential fatty acids compared with available on the market cakes[20].

Comparing Lower Grades and Higher Grades Astrocytoma in Three Age Groups: by CD133 Antibody

Zainab Zahid Saadoon[1], Huda Mahdi Al-Khateeb[1], Khitam Abdul-Razak Alkhafaji[1]

[1]College of Medicine, University of Baghdad; Iraq–Baghdad

ABSTRACT

Brain tumors are heterogeneous in nature and current studies reveal that aggressive behavior and recurrence of the tumor are led by brain tumor stem cells (BTSCs) This stem cells compartment demands distinct study to provide new therapeutics lines targeted against it. From the many markers that annotate BTSCs, is CD133, the first marker used to identify BTSCs and regarded as the protein which confers resistance and virulence of the tumor.

Aim of Study: Using CD133, to identify BTSCs by immunohistochemistry in paraffin sections of different grades of astrocytoma, distributed in to three different age groups then, compared with each other. We aimed to check the change in number of CD133-positive cells between grades and between ages, to confirm that CD133 is a real representative for the actual increase in virulence across grades and ages.

Materials and Methods: 121 paraffin blocks are collected from the archives of specialty surgery hospital in Baghdad and processed for immunostaining with CD133, then quantified to calculate number of positives and comparing the results between different grades and different ages.

Results: We obtained increased in number of positives of CD133 by ascending from lower grades towards higher grades in the three age groups; however, when we compared the same grade in between the 3 groups, we saw there was increase in expression from the children to the adult and then decrease in the older, the adulthood show the most increase. The ascending manner of the expression is no longer demonstrable across the age groups, that's the older group show lower expression than the adults despite being more virulent clinically. This mean that CD133 doesn't stand alone as a candidate for representation of the virulence in age group ≥50 years old.

Keywords: *astrocytoma, grades, ages, CD133, virulence*

Introduction

Most of the brain tumors develop the ability to resist the treatment and/or the recurrence after surgical removal [(1)], this demand more researches on the underlying causes. Emergence of the brain tumor stem cell (BTSCs) hypothesis [(2)], suggests that brain tumor mass consists of heterogeneous cell populations and only a relatively small fraction of cells in the tumor, termed brain tumor stem cells (BTSCs), have the ability to proliferate and self-renew expansively [(3, 4)]. BTSCs are thought to be the driving factor for intratumoral heterogeneity, cancer metastasis [(5)] and the cause for resistance to radiotherapy/chemotherapy, so targeting them will lead to tumor regression [(3,4)]. Thus, the presence of distinct compartments in a tumor demand distinct identification and analysis, thereby treatments [(6).] CD133 represents an important cell surface marker of the BTSCs as the capacity for tumor cell self-renewal and proliferation exclusively resides in the minority CD133⁺cell fraction [(2)]. Moreover, CD133-positive BTSCs represent the cellular population that confers glioma radio resistance and could be the source of tumor recurrence after radiation [(7, 8, 9)]. CD133 is the first recognized member of the prominin family, it's a pentaspan transmembrane glycoprotein,

with 865 amino acids and five transmembrane domains [10]. From a clinical viewpoint, identification of BTSCs by CD133 has substantial implications clinically, as these cells "need to be eliminated in order to offer long-term disease free survival" [11]. The analysis of the BTSCs quantity by CD133 may provide novel perception into patient prognosis that may then guide the aggressiveness of therapy [2]

In our study, we investigated the expression of CD133 by BTSCs niches, in four grades astrocytoma in three age groups and compared the positives in between the grades and ages, to correlate the expression change with the grading of the tumor and with aging of the patients. This comparison checked if they went parallel with each other as the virulence increases, and checked if the CD133 expression can be used to measure the prognosis and the virulence of the disease as long as the grading and the aging do, and to see if the grading has a strong effect on its expression or/and if the aging has this effect. In this study, each group has four grades I, II, III, IV except the group of older patients begins with grade II, as we couldn't find grade I for this group.

Materials and Method

121 Specimen blocks of brain tumors was collected from blocks archives of pathology department/Specialty Surgery Hospital, after taking the consents from all attributed institutes. Paraffin blocks specimens were filtered according to inclusion criteria: primary astrocytoma, diagnosed according to WHO classification 2007, then categorized equally into the four grades of astrocytoma I, II, III, IV (except the older group we couldn't find grade I for this age) and distributed into 3 age groups, (childhood (0-18), early and middle adulthood (19-49 years) and older "late adulthood and elderly" (50-80). Each subgroup has 11 samples. Exclusion criteria: any brain tumors other than astrocytoma, any secondary brain tumors, recurrent brain tumors and any tumors that treated previously by radiotherapy or chemotherapy were all excluded. Samples were stained by H and E and immunostained by CD133. For immunohistochemistry, marker used was Polyclonal Anti- CD133 (MBS355164) (My Biosource) Detection kit [including the secondary antibody and chromogen] is (Ready-to-use IHC/ICC kit (Biotin free), One-Step HRP Polymer anti-Mouse, Rat & Rabbit IgG with DAB) # MBS841593 (My Biosource). For marker dilution, 1/300 was used diluted with Tris Base Saline (TBS). Washing done with (TBS/TritonX). Antigen retrival was done by Citrate buffer/Tween 20 at 100 C°, for 15 min. Protein block and hydrogen peroxide were applied then primary antibody; after that detection kit with dab.

Statistical Analysis: Eleven samples were counted for each grade. Five random images of each sample were counted by Aperio imagescope version 12.3.2.8013 (Leica). The mean percentage of the number of positives was calculated and reported as the mean then eleven samples were counted as such and statistically evaluated. The numbers were compared in between the different grades in the same group and in between the three groups for the same grade. Analysis of data was carried out using SPSS-25 (Statistical Packages for Social Sciences- version 25). The significance of difference of different means (quantitative data) were tested using Students-t-test for difference between two independent means or ANOVA test for difference among more than two independent means. Tukey's test used for calculating the significance between each two variables. Statistical significance was considered whenever the P value was equal or less than 0.05.

Results

Table 1: Reveals the number of positive cells immunostained by CD133 antibody, among four grades astrocytomas distributed in three groups children (<18y), adults (18-49y) and older (=>50y)

Astrocytoma Grade	Number of positive (NP) of CD133 immuno-labelling			P value
	Children (<18y)	Adults (18-49)	Older (=>50)	
Grade I	237195 ± 102974 (91357-381996)	604519 ± 132826 (387079-865519)	-	0.0001#
Grade II	484648 ± 140631 (307303-786582)	1000909 ± 340913 (576147-1763458)	825748 ± 288176 (352546-1235639)	0.0001*
Grade III	834223 ± 386767 (416248-1590931)	1596705 ± 276710 (1186986-2136518)	1314618 ± 357221 (801179-1912214)	0.0001*

P value	0.0001*	0.0001*	0.003*	
-Data were presented as Mean ± SD (Range)				
*Significant difference among difference independent means using ANOVA test at 0.05 level.				
#Significant difference between two independent means using Students-t-test at 0.05 level.				

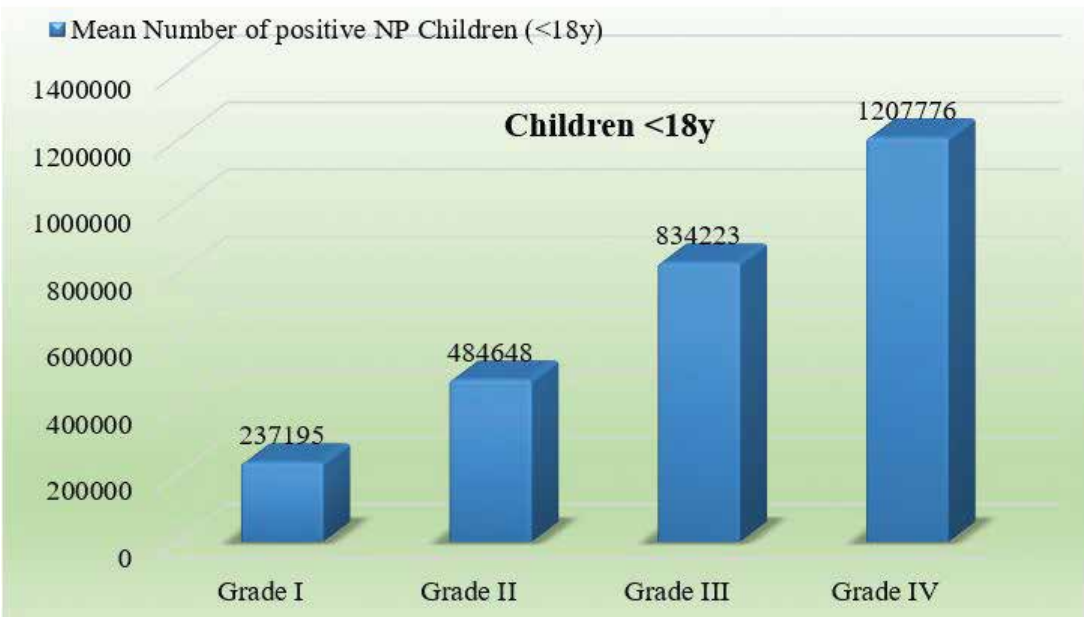

Figure 1: Comparing grades in children group reveals: increase in the no. of positivity whenever we go up from lower grades towards higher grades of astrocytoma. All the grades show high significance in changes when compared with each other

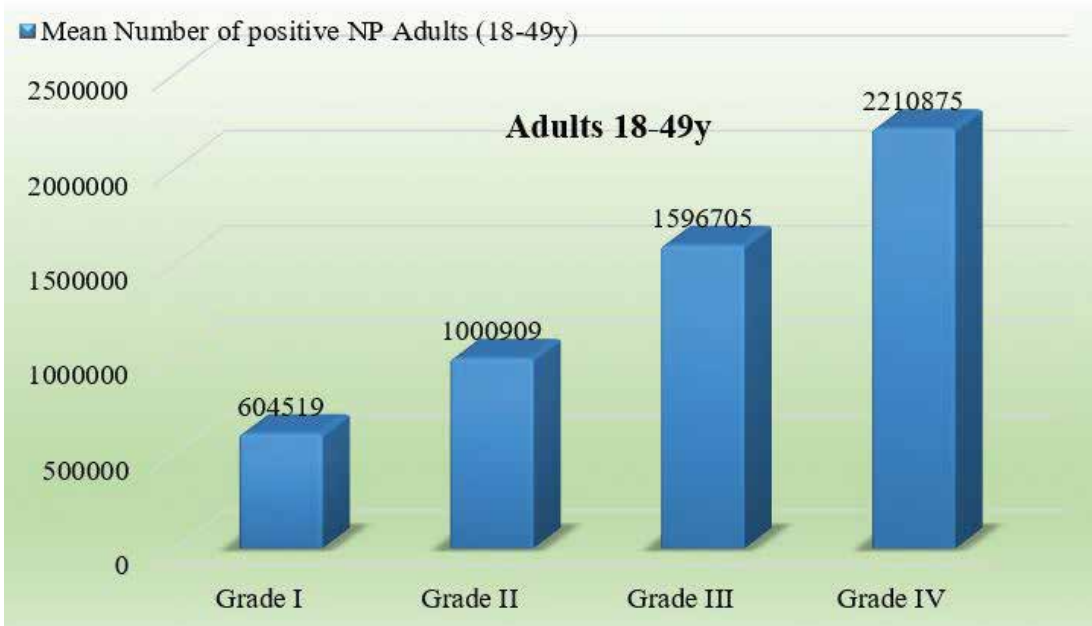

Figure 2: Comparing grades in adult group reveals: increase in the no. of positivity whenever we go up from lower grades towards higher grades of astrocytoma. All the grades show high significance in changes when compared with each other

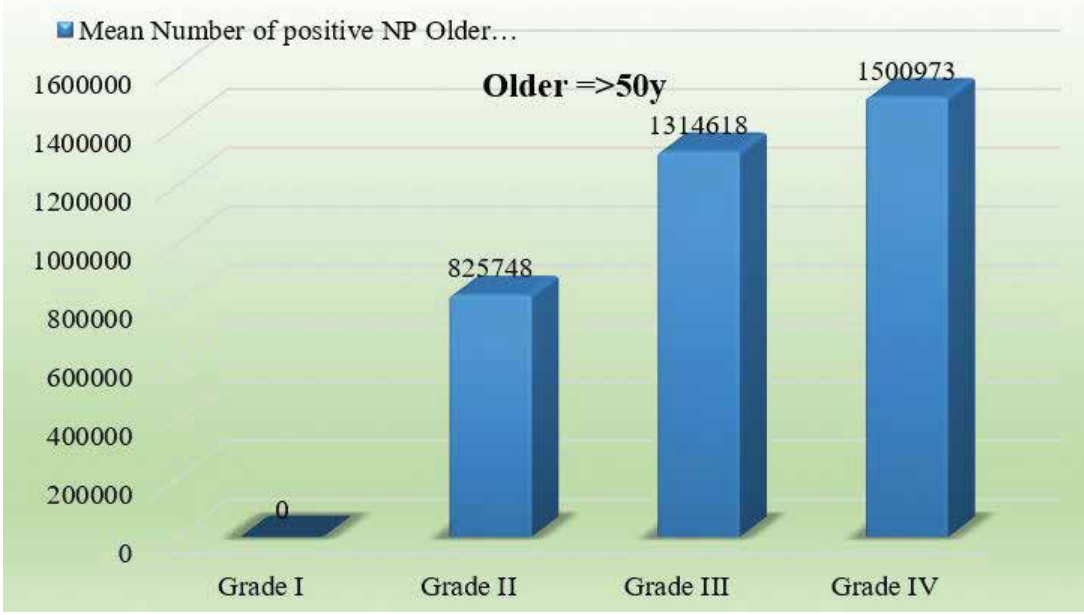

Figure 3: Comparing grades in the group of older reveals: increase in the no. of positivity whenever we go up from lower grades towards higher grades of astrocytoma (we couldn't find grade I for the older group). All the grades show high significance in changes when compared with each other except the grade III, IV show no significance

Discussion

We demonstrated: an increase in number of positivity whenever we go up from lower grades towards higher grades of astrocytoma in all groups (children, adult, and older groups), the number and intensity of cells expressing CD133 increases dramatically. All the grades show high significance in changes when compared with each other in the same group (p value was very significant except for grade three and grade four for the older group Fig 3). This goes with [12], who stated the expression of CD133 increases with grades; however, the latter conducted the study without segregating age groups for the grades and includes tumors other than astrocytoma like oligodendroglioma, which did not exclude the bias of different histology; in addition, it uses frozen section instead of paraffin sections. Our results also go with [13], however the latter conducted the study on different types of glioma not pure astrocytoma. Our results were inconsistent with [14] who describe no correlation between CD133 and grading of the glioma although the latter conducted the study by expression with immunofluorescence and without age groups and the study included secondary glioma in addition to different glioma types. The results were also inconsistent with [15], who proposed the percent of expression was in opposite to the grades; however, they found the Methylation of the CD133 promoter was associated with the grade of the tumor. Use of different procedure and different CD133 antibody clones might explain the difference between our findings and the results obtained in other studies. Another explanation was use of different tissue fixation methods. In other studies, cryosections were used to stain CD133, whereas we used formalin-fixed paraffin sections. As CD133 represent the virulence of the tumor [10, 16, 17], CD133 can be considered as virulence index of astrocytoma across the grades. Many studies stated that the increased in tumor aggressiveness and the bad prognosis go with increasing the grades [18, 19, 20]. From our results, this may be attributed to the increase in CD133 expression concomitantly. Other studies stated that the aggressiveness and the bad prognosis increase with aging [21, 19, 22, 23], however, the latter studies differentiate between elderly and younger through different virulent factors. In our study, when we compared expression of CD133 in between the three age groups for the same grade, there was increase in expression from children to adult then decrease again in older (table 1). One study [24] stated that CD133 expression has no relation with age, however the latter study analyzed CD133 gene by RT-PCR not by immunohistochemistry. All the grades demonstrate more increase in the adult group than the other two groups (table 1, Figure 1, 2, 3). The expression decrease again in the older group. In contrary to that, the

virulence increases with increase the age as described by [21, 19, 22, 23] and one of the favourable prognostic factor in astrocytoma is being less than 50 as illustrated by [25, 21, 26, 27], who all described the prognosis of age less than 50 is more favorable over the older age. Thus, we suggest CD133, as a virulence factor, cannot be solely representative to virulence in the age≥50, as it did not go parallel with age-dependent virulence. The age profile of the astrocytoma grades before 50 and after 50 years old, may carry in its molecular analysis another distinction other than CD133. This might further suggest that any type of therapy in this particular age group must take in consideration another virulent factors and renders the CD133 alone as defective candidate for the reflection of the virulence at ≥50 years old age

Conclusion

Based on the expression of CD133 protein by immunohistochemistry, we suggest an association between CD133 expression, and the increased in the grading of astrocytoma from low to high grade, this association is proportional, and this might explain the very different clinical course of the different grades of astrocytoma regarding the increased in virulence. This might help also when drawing a therapy destined against the BTSCs, taking in consideration the grading of the tumors. However, the situation was different when expression was compared with increase in the age. Different expression of the CD133 have been obtained in successive age groups and astrocytoma in older group ≥50 years, despite being more aggressive clinically than the astrocytoma in adults aging<50, the decrease in CD133 expression suggest that this aggressiveness might be attributed to other factors other than CD133 alone, as it does not reflect the real difference in aggressiveness. Beyond this, our results of CD133 expression across the ages might set for a difference base between age 50 and below and revealed interesting insights into astrocytoma differences across the grades and across the ages and therefore represents a valuable resource for future studies.

Differences in Growth of Children with Autism and Normal in Surabaya, Indonesia

Dewi Setyowati[1], Budi Prasetyo[2], Dominicus Husada[3]

[1]Doctoral Program, Faculty of Medicine, Universitas Airlangga, Surabaya, Indonesia; [2]Department of Obstetrics and Gynecology, [3]Department of Child Health, Faculty of Medicine, University of Airlangga Dr. Soetomo Hospital, Surabaya, Indonesia

ABSTRACT

Background: Children with syndrome spectrum disorder wherein danger of a compromised dietary intake and biological process standing that might impact growth over each the short and long run. Children and youth with a disability were deemed to be at greater risk of obesity due to lower levels of physical activity, inappropriate behaviors associated with their disability, medication and related chronic health conditions.

Aim: To evaluate the growth status of children who were diagnosed with ASD in comparison with healthy controls.

Method: This research was a cross-sectional analytic study using questionnaire instruments to guardians and also direct measurements to respondents. The number of respondents for the group of children who have autism was 30 children and normal groups of children as many as 60 children. The independent variables in this study were children, autism and socio-economic, while the variables depend on body weight according to age, height according to age and head circumference according to age. This data was analyzed using the Mann Whitney U test.

Results: The results of the study of 30 children with autism and 60 normal children obtained a percentage of children suffering from autism and normal children in the same good nutritional status as many as 76.67%. Height according to age for children suffering from autism in normal conditions is 66.66% and normal children are larger 83.33%, while for head circumference according to age children with autism and normal children are 100% normal. After statistical tests using SPSS 23 with $\alpha = 0.05$, $p = 0.987$ was found for body weight according to age, $p = 0.650$ for height according to age and $p = 1$ for head circumference according to age.

Conclusion: There was no difference in body weight, height, and head circumference according to age between children with autism and normal so that it could be said that children who have limitations in this case autism have normal growth like other children.

Keywords: *Autism, Body weight, Height, Head circumference, Growth.*

Introduction

Autism spectrum disorder (ASD) was a neurodevelopmental disorder defined by deficits in social interaction and communication, yet as restricted, repetitive or stereotypic behavior, with Associate in Nursing onset before three years older[1–3]. Children with syndrome spectrum disorder wherein danger of a compromised dietary intake and biological process standing that might impact growth over each the short and long run. The restricted body of revealed analysis addressing this concern has been contradictory and inconclusive to this point[1,4]. Children and youth with a disability were deemed to be at greater risk of obesity due to lower levels of physical activity, inappropriate behaviors associated with their disability, medication and related chronic health conditions [2,5].

Centers for Disease Control and Prevention (CDC) found that US boys were almost five times more likely to receive an ASD diagnosis than girls, indicating that approximately one in 42 boys is currently diagnosed with ASD [4]. Patients with ASD may also suffer from the leaky gut syndrome, which was caused by inflammation of the intestinal mucosa and abnormal bacterial overgrowth leading to a disorder of bowel motility [6–8]. Two factors that were known to be risks in ASD and potentially influence growth were food selectivity behavior and gastrointestinal health status. Selective dietary intake could play a significant role in the growth status of children with ASD. Children with ASD were more likely to have food selectivity and feeding issues resulting in challenging behaviors surrounding food intake than their typically developing peers[1,2,9,10]. Food selectivity continues to be highly reported in children with ASD and was simply defined as the consumption of an abnormally limited variety of food[1,11]. This behavior affects food choices, which, in turn, could affect nutritional status and growth. For children with food selectivity behavior, a refusal to consume one or more food groups is common, and anxiety and tantrums could be associated with the introduction of new foods [1,12].

Anthropometric measurements, including height, weight, and head circumference were an effective method of evaluating dietary intake, growth status and nutritional status in children with ASD[1]. As noted, the effects of gastrointestinal symptoms and food selectivity could lead to inadequate dietary intake, resulting in abnormal anthropometric measurements [1,6,13]. In some studies, no differences in BMI were reported between children with ASD and their typically developing peers, whereas other studies have reported higher rates of underweight children with ASD compared to their typically developing peers. For these reasons, we chose to evaluate the physical status of children with ASD by means of detailed dietary evaluation and anthropometric assessment. The present study aimed to evaluate the growth status of children who were diagnosed with ASD in comparison with healthy controls.

Method

The type of this research used analytic observational research that used a case-control research design. This study compared between the case group and the control group. This research was conducted in the special school of Chakra, Agca autism and normal children who were in Ceria, Diponegoro, and Darmahusada Children's Kindergarten. The inclusion criteria for the autism group in the study were autistic children who had not entered adolescence (women <12 years, men <14 years) and guardians of autistic children who were willing to become research samples, while the exclusion criteria were autistic children suffering from congenital abnormalities and other diseases which affects growth and autism children who were not in place when measuring growth. In the control group had the inclusion criteria for normal children who had the same age range as autistic children and guardians of normal children who were willing to be the study sample, while the exclusion criteria were normal children suffering from congenital abnormalities and other diseases that affected growth and normal children who were not in place when measuring growth. The sampling technique used in this study was using saturated sampling or census means that the entire population was examined, this applies to the group of children with autism. However, for the control group using the random sampling method. The independent variables in this study were children, autism and socio-economic, while the dependent variable was body weight according to age, height according to age and head circumference according to age. This data analyzed using the Mann Whitney U test.

Result

Table 1: Characteristics of participant

Characteristics	Autism		Normal	
	Frequency (n)	Percentage (%)	Frequency (n)	Percentage (%)
Age (years old)				
>2-3	1	3.33	1	1.67
>3-4	1	3.33	2	3.33
>4-5	6	20	7	11.67

Conted…

>5-6	12	40	24	40
>6-7	8	26.67	17	28.33
>7	2	6.67	9	15
Gender				
Boy	21	70	42	70
Girl	9	30	18	30
Income				
<Regional minimum wage (standard)	4	13.33	10	16.67
> Regional minimum wage (standard)	26	86.67	50	83.33
Nutrition intake based on recall food method 24				
Deficient	24	80	8	13.33
Good	6	20	52	86.67

In this study, the study sample was boys less than fourteen years old and women less than twelve years old. In this study, it is also known about the income of parents who have an average parent's income above the Regional minimum wage(standard) and nutritional intake for children because they were considered to provide an important role in the growth of children. The method used in determining the amount of nutrient intake was using the 24-hour recall food method so that it known the amount of nutrition eaten.

Growth : The growth of children in this study was grouped into three according to the main purpose of looking for differences in growth which were classified into body weight, height and head circumference per age. The results of the growth of autism and normal children could be seen in table 2.

Table 2: Distribution samples based on the growth of autism and normal children

Characteristics	Autism		Normal		p value
	Frequency (n)	Percentage (%)	Frequency (n)	Percentage (%)	
Body weight per age					
Severe thinness	1	3.33	0	0	0.986
Thinness	2	6.67	5	8.33	
Normal	23	76.67	46	76.67	
Overweight	4	13.33	9	15	
Height per age					
Severe short	5	16.67	0	0	0.650
short	8	26.67	2	3.34	
Normal	17	56.67	50	83.33	
Tall	0	0	8	13.33	
Head circumference per age					
Normal	30	100	60	100	1

Based on the table above, it was explained that there was no difference between the group of autistic children and the normal ones. Body weight in both groups was dominated by normal results, height and head circumference of both groups also within normal limits.

Discussion

Our first hypothesis was that children with ASD would have significantly lower anthropometric values, but this is no confirmed by our results. There was no consensus

among previous research comparing the anthropometric values of children with ASD and TD children found that prevalence of overweight and obesity was significantly higher among young children (2–5 years of age) and adolescents (12–17 years of age) with ASD compared with the matched controls. However, for ages 6–11 years, no prevalence differences were found [13]. Children aged 2–5 years with ASD had more overweight and obesity and children aged 6–11 years had more underweight than theNHANES-matched cohort [14].

The exact reason why the weight would be unhealthy among children with ASD was not clear. Among schoolchildren of the age studied herein, growth was highly sensitive to the balance between energy intake and total energy expenditure. However, the energy intake estimates in children with ASD and TD children were similar [13,15]. Likewise, ASD and TD groups could present different patterns of growth throughout the time life. In any case, although BMI was an important indicator of a healthy weight, it was not necessarily a good indicator of nutrient status[7,13]respectively. We chose to fully evaluate the nutritional and growth status of children with ASD and their typically developing peers given the limited amount of data available regarding this topic, incomplete work in prior datasets, and the conflicting results that have been reported to date

Parents of children with ASD reported a greater prevalence of food refusals based on the texture of food, mixtures, brand, shape, and taste/smell than did TD children. Contrary to expectations, a similar prevalence of food refusal based on temperature, foods touching other foods, and the color was found between children with ASD and TD children. Parents of children with ASD reported more reasons for food refusal, with over one-third of parents reporting refusal based on three or more characteristics of food [10]. Gluten-free/casein-free and lactose-free diets are followed by some children with ASD. Because children who adhere to these diets restrict all dairy products [9].

One such eating pattern, selective eating, was characterized by a diet that lacks variety and has been associated with inadequate consumption of foods low in energy density such as fruits and vegetables, lean protein-rich foods, and foods high in fiber. Although not uncommon in typically developing children, selective or "picky" eating appears to be more prevalent in children with autism spectrum disorders and may persist beyond the early childhood period. Children with ASD who exhibit food selectivity have been found to have sensory sensitivity with concomitant aversions to specific colors, smells, temperatures, and textures, and preferences for energy-dense foods. Thus, children with ASD who exhibit sensory sensitivity may be predisposed to diets with a limited variety that was high in energy-dense foods and low in fruits, vegetables, and fiber, putting them at increased risk for overweight and obesity[3,11–13,16].

There was no evidence of statistical interaction between any of the dietary patterns and BMI z-score with autism status [12]. According to the anthropometric data, there was no difference in body weight, height, and head circumference according to age between children with autism and normal. The results of the present study showed no significant differences between both groups regarding the contribution of energy intake from dietary carbohydrate, protein, and fat in daily diets. Also, no significant differences between both groups in relation to energy, carbohydrates, and fats intake were observed. Furthermore, children with autistic disorder showed significant low protein intake and high fiber intake compared to healthy controls. Overall, the results of the present study indicate that anthropometric measurements of children with ASD are similar to those of healthy peer controls. There were no significant differences in measurements of height, weight and head circumference across participants in this study.

Conclusion

There was no difference in body weight, height, and head circumference according to age between children with autism and normal, so that it could be said that children who have limitations in this case autism have normal growth like other children. Further research was needed to determine the acceleration of growth in both groups and the factors that influence it. Comprehensive physical and anthropometric assessment should be completed for all children with ASD in a primary care setting as a baseline measurement to evaluate the need for referral for more specialized evaluation and potential intervention on a case-by-case basis

Functional Outcome after Conventional Open Discectomy for Patients with Herniated Lumber Disc: One Year Follow Up

Mohammed Hassan Razoki

Consultant Orthopaedic Surgeon, Department of Orthopaedics, College of Medicine, University of Kufa, Iraq

ABSTRACT

Introduction: Lumber disc herniation is a common and frequently occurring disease. Conventional discectomy is in use for decades, and it has got a curative effect for treatment of disc herniation which will not respond to conservative treatment.

Aim of the Study: The current study aimed to evaluate the functional outcome after (12 month) of conventional discectomy for the management of patients with lumber disc herniation.

Patient and Method: A prospective study done in the period between October 2015 and February 2018 on 78 patients (40 males and 38 females) their mean age 37.6 years (range21-65) was diagnosed with sciatica caused by single level lumber disc herniation (LDH) and underwent open discectomy. Each patient was followed up for one year regarding their functional outcome, using the Oswestry disability index.

Results: The means of the total oswestry low back pain scoring scale after 6 months, and 12 months of management were significantly decreased compared to mean before management (60.7% versus 38.1%, P=0.004; and 60.7% versus 24.7% respectively).

Conclusion: Conventional open discectomy is still a good method for treatment of lumber disc herniation.

Keywords: *Lumber disc herniation, conventional discectomy. Oswestry Disability Index*

Introduction

Lumber disc herniation (LDH) is the most common diagnosis among the degenerative abnormalities of the lumbar spine (affecting 2 to 3% of the population, and it is the principle cause of spinal surgery among adult population. [(1).]. The natural history is generally favourable, with improvement of symptoms in 75% of patients after 4 weeks [(2).]Although most patients relieved from symptoms without surgical treatment, there is a consensus for operating on selected patient with persistent radicular pain after 2-6 months. [(3)]

Surgical discectomy gives earlier relief of symptoms, enabling patient to return to their work and other daily activities more rapidly.[(3)]

Conventional classical operation (laminectomy/ laminectomy with discectomy) is in use for decades; however in 1977 microdiscectomy technique was performed for lumber disc herniation.. [(3)]

The advantage of open discectomy is that there is more accumulated experience with it, no additional endoscope or microscope is needed, and the duration of learning curve and of the operation is shorter.. [(4)]

The last decade has seen an evolution of minimally invasive spine surgery with

new technological developments. Minimally invasive spine surgery is thought to decrease postoperative pain and allow quicker recovery by limiting soft tissue retraction and dissection. Advances in microscopy, tissue

retractors, and specialized instruments have enabled surgeons to perform procedures through small incisions. As with the open approach, the goals of the minimally invasive approach are to adequately decompress the involved neural elements, stabilize the motion segment, and/or realign the spinal column according to the needs of the individual patient [5]

In 1997 tubular retractors and the endoscope was first introduced and later adapted to incorporate the operative microscope [6,7]. These techniques allow for enhanced visualization through a small skin incision, and they cause minimal disruption to the posterior muscles. As a result, patients spend less time in the hospital and are able to mobilize quicker, ultimately leading to high patient satisfaction and significant cost savings. [8,9]

Several recent studies have compared conventional open discectomy with microdiscectomy to find if there are any significant differences by using either method. In this study we want to find the functional outcome after one year for patient who underwent conventional open discectomy. In future we hope when the operative microscope become available that we will do comparative study for the functional outcome after doing open discectomy versus microdiscectomy.

In this study we used the Oswestry Disability Index (ODI) [10] (also known as the Oswestry Low Back Pain Disability Questionnaire) to evaluate the functional outcome postoperatively. It is extremely important tool that researchers and disability evaluators use to measure a patient's permanent functional disability. The test is considered the 'gold standard' of low back functional outcome tools

Patient and Method

Patient and Study Design: Seventy eight patient (40 males and 38 females) diagnosed with sciatica caused by lumber disc herniation (LDH).conventional open discectomy done for them during the period from October 2015 to February 2018. Each patient was followed up for one year after the surgery regarding t functional outcome.

The patients included in the study had single level disc herniation with radiculopathy proved by MRI, with no history of previous back surgery.

Scoring System: The scoring system that had been used to evaluate the functional outcome of the patients in this study is the Oswestry Disability Index (ODI) which is also known as (Oswestry Low Back Pain Disability Questionnaire). [10]

The score was calculated for each patient in the study (in regard to all of its variables: pain intensity, personal care, lifting, walking, sitting, standing, sleeping, sex life if applicable, social life and travelling) at the preoperative period (the day before the surgery), and recalculated during the periods of the follow up which had been selected in the current study (6 months and 12 months) postoperatively.

Surgical Procedure: Preoperatively lumber spin MRI and AP and LAT plain X ray of lumbar spine were taken. Informed consent was taken from all the patients included in this study. Surgery was done under general anaesthesia, patient placed in a prone position with the abdomen free to reduce the intraoperative venous bleeding. The proper level was determined by fluoroscopy. A 5-8 cm.mid line incision and facia incision done, and the paravertebral tissue retraced using deep retractors. In most cases flavectomy and arcotomy of the lamina above the disc level was done. Carful mobilization of the dural sac and the nerve root medialy before evacuating the herniated disc. This might involve entering the disc space, or just removing a free sequestrated disc fragment (sequestrectomy).After checking the epidural space, the layers were appropriately closed.

Follow up: All patients discharged from the hospital after 2-3 days with instruction of free movement in bed with assisted walking for few steps until day ten where the stitches were removed. After 2-3 weeks they can return to their light daily activities. The follow up continue and after six months all the patient were re-evaluated using the Oswestry disability score. The same thing done for all the patients after 12 months. All the data about the patients and the results of the ODI were analysed accordingly.

Statistical Analysis: The data analyzed using Statistical Package for Social Sciences (SPSS) version 25. The data presented as mean, standard deviation and ranges. Categorical data presented by frequencies and percentages. Paired t-test (two tailed) was used to compare different ODI scores pre and postoperatively among study groups. A level of P – value less than 0.05 was considered significant.

Results

The total number of patients in this study was 78. All of them were diagnosed as having lumber disc herniation and treated by conventional open discectomy.

The general characteristics and variables regarding the patients are shown in table (1). The age was ranging from 21 to 65 years with a mean of (37.6) years and standard deviation (SD) of ± 7.3 years. The patients aged ≤ 50 years were (67) (85.89%), and those above (50) were (11) (14.10%). Females were 38 (48.7%) and males were 40 (51.2%). For occupation; 44.9% were housewives, 19.2% free jobs, 14.15%employee, 8.89% farmers, 7.7 %retired, and 5.1%drivers. The table show that the right sided disc herniation is little bit more than the left. It also shows that 50% of the patient has herniation at L4/L5 level, and about 45% have herniation at L5/S1 level.

Table 1: General characteristics and variables of the patients

Variable	No. = (78)	Percentage %
Age(21-65)		
Mean(37.6)		
≤ 50	67	85.89%
> 50	11	14.10%
Gender		
Male	40	51.28%
Female	38	48.71%
Occupation		
Housewife	35	44.9%
Free job	15	19.2%
Employee	11	14.1%
Farmer	7	8.89%
Retired	6	7.7%
Driver	4	5.1%
Side		
Right	42	53.84%
Left	36	46.15%
Level		
L5/SI	35	44.87%
L4/L5	39	50%
L3/L4	2	2.56%
L2/L3	2	2.56%

Total Oswestry Low Back Pain Scoring Scale: Comparison of total ODI Score before operation and after; 6 months, and 12 months of management (table 2). It shows significant improvement after 6 and 12 months from the operation, 60.7% versus 25.2 %, (P=0.001); and 60.7% versus 21.4% (P=0.001) respectively).

Table 2: The results of ODI preoperatively, 6months, and 12 months postoperatively

variable	ODI% Mean ± Std. Dev	P Value
preoperatively	60.7 ± 5.62	0.001
6months postoperatively	25.2 ± 10.42	0.001
Reduction of ODI/6months	35.5	
Preoperatively	60.7 ± 5.62	0.001
12months postoperatively	21.4 ± 3.69	0.001
Reduction of ODI/12months	39.3	

Discussion

The prevalence of symptomatic herniated lumber disc is about 1-3%in Finland and Italy. About 19/27% of people without symptoms have disc herniation on imaging.[11]

Lumber disc herniations are the most common causes for working –age individuals to undergo lumbar spine surgery. [12].

The surgeon according to his training and his experience can chose (for surgical treatment of lumber disc herniation) any method like microdiscectomy, endoscopic microdiscectomy or the classical operation (laminectomy/laminectomy with discectomy).

Several questionnaires are available to help measure the functional status of a patient, the ODI is the most commonly used outcome-measure questionnaire for low back pain in a hospital setting [13].

As seen from our results using the ODI there was a great improvement in the functional out come after conventional open discectomy. Statistically there was significant decrease in the score (P < 0.05).

Most of the studies shows a significant improvement of the ODI postoperatively, but there was no significant differences whether we use conventional open discectomy or microdiscectomy [1,3,4,14,15].

Cagatay et. al. [4] in their paper on 519 patients compare the outcome of functional results between patients treated by open discectomy and others treated by microdiscectomy, concluded that "the long term results in both groups were similar and the choice of either method depend on the experience".

Xiaosheng et. al.[14] also compare the two methods; they found that both methods obtain the same satisfactory results. The advantages of microdiscectomy are that it is minimally invasive method, with less blood loss, short time, short hospitalization, with fewer medical expenses.

Andreas et. al... [3], also found no significant difference in the functional outcome between two methods.

Kovačević et. al. [15] compared standard lumber discectomy with microdiscectomy and concluded that there in no particular advantage of either technique in terms of functional outcome. But they also found that there was significant lower recurrent disc herniation and higher reduction of leg pain in case of microdiscectomy.

Luis et. al. [1] concluded that the clinical results were similar after 2 years by using either surgery. They were in favor of early surgery because recovery is faster and surgery is economically favorable since it enables early return to work.

George et. al. [16] did analysis of results of surgery of over 39.000 patients and found that all the patients had 79% good/excellent results, and none of the operative procedures gave a different outcome.

Table (3) is to compare between different studies regarding age and gender of patient who underwent open discectomy.

Table 3: Age and gender of different studies

Study	Total No.	Age (range)	Mean age	Male	Female
Present study	78	21-65	37.6	40 (51.28%)	38 (48.77%)
Cagatay et. al. [4]	276	27-67	44.8	176 (63.8%)	100 (36.2%)
Xiaosheng et.al. [13]	225	15-79	46	127 (56.44%)	98 (43.55%)
Kovačević et. al. [14]	111	17-75	44.9	57 (51.35%)	54 (48.64%)

The table shows that the mean age group in this study was 37 years while in the other studies was about 45-46 years. Our study also shows that the number of patients above 50 years were(11) and represent (14.10%) of the whole group. These results give us an idea about epidemiology of lumber disc herniation in the population, were this disease is less common in older people. Jo Jordan et.al. [11], found that the highest prevalence of lumber disc herniation is among people aged 30-50 years.

Daoyou et. al. [17] concluded that a decrease of LDH with aging occur in the elderly. This is because the volume and inflammation of the nucleus gets lesser since degeneration lead to atrophy of the nucleus with the aging. Thus, the pressure from the nucleus will become gradually less, with the result being lower incidence of annulus injury and occurrence of lumber disk herniation, especially after 80 years old [17].

In almost all the studies the males are predominantly affected by LDH than females and this is probably because males involved in more "hard working" types of jobs. [4,11,14,15]. Yet our study shows the highest percentage of female patients among other studies. The explanation for that is that about 50%of housewives in the group are "farmers" coming from rural areas around city of Najaf.

Regarding the levels predominantly affected, our study shows that 94.87%of the cases have disc herniation at L4/L5 and L5/S level. The same findings seen by Jo.Jordan et al[11], Cagatay et al. [4], and dauyo et.al. [17]where the results where 95%, 93.47%, and 95% respectively, with L4/L5 more predominant.

Conclusion

Conventional lumber open discectomy is still a good method for treatment of lumber disc herniation.

Conflict of Interest: No conflict of interest

Source of Funding: None

Compliance with Ethical Standerds: Informed consent was obtained from all individuals participant included in the study.

Early Complications Following Bipolar Hemiarthroplasty as Primary Treatment for Displaced Femoral Neck Fracture in Elderly Patients

Mohammed Hassn Razoki[1], Adnan Essa Elkelaby[1]

[1]Department of Orthopedics, College of Medicin, University of Kufa

ABSTRACT

Femoral neck fracture is one the most important traumatic event in elderly patients. The objective of this study is to assess the incidence of early complications following bipolar hemiarthroplasty for management of displaced femoral neck fractures in elderly patients.

Patients and Method: This is a prospective study of 60 patients 60-90 years old (37 female and 23 male) with displaced femoral neck fracture who underwent bipolar hemiathroplasty with a follow up period ranged from 12-22 months. Several variables including age, gender, medical comorbidities, type of fracture,complication mortality and Harris Hip score were assessed.

Results: There were four cases of infection, two cases of dislocation, eighteen cases anterior thigh pain, two cases of DVT and two mortality. The average HHS decrease with increasing age of the patients. There was no significant intraoperative complications but there was postoperative complicaions.

Conclusions: Bipolar hemiarthroplasty through posterior approach seems to be a good option for primary treatment of displaced femoral neck fractures in elderly patients with few complications.

Keywords: *Hemiarthroplasty, femoral neck fracture, complications.*

Introduction

Femoral neck fracture is one of the most important traumatic event in the elderly, because of its high rate of complications [(1)]. Femoral neck fractures occur most frequently in elderly female patients following fall from standing height and may be associated with osteoporosis. Undisplaced femoral neck fractures account for 15% of these fractures in elderly and are usually treated with internal fixation. There are several surgical options for displaced femoral neck fractures with regard to patient's age, functional status and cognitive function. In this group of patients, reduction and internal fixation is associated with significant complications. Therefore, hip arthroplasty is the treatment of choice. The appropriate intervention was selected based on individualized patient assessment and planning[(2)].

In United Kingdom, over 300 000 patients are admitted to hospital with fragility hip fractures every year [(3)]. The incidence of these fractures is 2-3 times more in females as compared to male population [(4)]. Hip fractures account for around 20% of the surgical fractures. Femoral neck fracture account for approximately 50% of all fractures of the hip region [(5)].

The incidence of proximal femoral fractures tends to increase among the elderly as mean lifespan continues to increase. Hip fracture rates are highest in Northern and Central Europe, moderate in North America, and at the lowest in south Asia and Africa. For each decade after 50 the risk of hip fracture double and the worldwide incidence is predicated to rise from 1.7 million in 1990 to 6.3 million in 2050 [(6)]. Hip fractures are associated with 30 % mortality at one year and a profound temporary, sometimes permanent impairment of independence and quality of life [(3, 7, 8)].v

Patient and Method

This prospective study conducted on 60 patients (37 female and 23 male) with displaced intracapsular femoral neck fracture (Garden type 3 and 4), all treated by bipolar himiarthroplasty from January2016 to November 2017. The follow up period ranged from 12-22 months.

They were 60 - 90 years of age with mean of (74.2). Thirty-nine patients have right hip fracture (65%), in twenty-one patients the left hip was involved (35%).

The time interval between the injury and bipolar hemiarthroplasty varies from two to seven days.fracture occure in48 patient after fall while 7 sustained RTA and 5 had twisting injury.

Method

The patients were investigated for fitnes for anesthesia.

Assessment for the general health of the patients with medical consultation if needed.

Analgesia and enoxaparin (LMWH) in prophylactic dose was given to the patients. LMWH stopped 12 hours before surgery and return back after 12 hour.

Informed written Consent was taken.

Surgical Technique: All patients were operated under spinal anesthesia and given 1-gram ceftriaxone intravenously one hour before skin incision. All patients were operated through posterior Moor approach by the same surgical team.

The patient was securely fixed in the lateral decubitus position with the operated side uppermost.

The skin incision starts 10 cm from the PSIS and directed laterally and distally posterior to the posterior edge of greater trochanter and extends for 10 or more cm, parallel to the shaft of femur.

The fascia lata was exposed and incised in line with skin incision. Gluteus maximus muscle splitting in proximal incision then occurred.

Retraction of the gluteus maximus muscle reveals the back of greater trochanter overlying by trochanteric bursae. Special care is taken in order to not injure the sciatic nerve. In most cases, the sciatic nerve have to be identified and protected.

Blunt dissection will usually remove the trochanteric bursa. Internal rotation of the hip makes external rotator more stretch and obvious and displaces their insertion away from the sciatic nerve. The external rotator and piriformis tendon now tagged with a stay sutures so that they well be re-attached at the end of the procedure. After that, they are transected near their insertion and reflected backwards to protect sciatic nerve.

The capsule now seen and incised longitudinally or mainly by T-shaped incision exposing the fractured femoral head and neck.

The fractured head then removed by corkscrew with transecting ligmentum teres and measured to determine the appropriate size.

After that, the femoral canal preparation performed. Then filling the femoral canal by cement using cement gun and then insert the cemented prosthesis and waiting for setting and finally reduction done.

Assessment of the size of prosthesis and the stability of hip then done. Suturing in layers (joint capsule, external rotator, piriformis, fascia lata, skin) with suction drain and finally dressing.

Fig. 1: Preoperative x-ray of the hip

Fig. 2: Postoperative x-ray of the hip

After Care: The patients instruct to lie supine with abducted and externally rotated lower limbs.

An antibiotic regimen with ceftriaxone 1gm IV once daily for 3 days then change to oral antibiotic in form of Augmentin 1000 mg twice daily for 7 – 10 days, low molecular weight heparin (enoxaparin 4000 IU once daily) for thirty days in addition to analgesia in form of paracetamol vial 1g three times daily and tramadol ampoule on need administered postoperatively.

We advise patient to start movement of normal limb and ankle movement of operated limb as early as possible and as tolerated in addition of calf massage by relatives, elastic stocking. Patients were mobilized on the second postoperative day using a walker frame. AP radiograph of the operated hip performed after mobilization (second postoperative days), 14 days postoperatively (at time of stiches removal), and then as indicated. The suction drain removed after 24-48.

The patient continued on partial weight bearing for 4-6 weeks then turned to full weight bearing accordingly

Fellow up: The patients were followed for any complication at second week, fourth week, second month, six month and 1 year.

All data were collected and analyzed according to Harris Hip Score(9)

Results

There were 60 patients in our study. their age varied from 60 to 90 years old (mean 74.2).Sex distribution showed female predominance (37 female and 23 males) forming 61.67% and 38.33% respectively.

There was at least one comorbid condition in 36 patients. Cardiovascular disease was the most common comorbid condition in our patients.

In our study there was not any significant intraoperative complications.17 patients needed blood transfusion intraoperative while 11 pt. receive blood in the ward (1 unit of blood). No intraoperative mortality was observed. The duration of surgery ranged from 45-60 minutes (the mean is 52.5), post-operative length of stay 2-4 days, In 1 year follow up we have :

Four cases had wound infection (6.67%) discovered at time of stiches removal

Three cases was superficial infection responding well to parenteral then oral antibiotic therapy and one was deep infection need surgical debridement and extraction of bipolar and finally received THR.

Two cases had posterior dislocation (3.33%).

Eighteen cases had anterior thigh pain (30.00 %) which was mild to moderate.

Two cases had DVT (3.33%) which treated conservatively.

Two cases of death (3.33%).

Table 1: Harris Hip Scores of Patients in the studied group

Harris Hip Scores	Pt.	%
Excellent (90-100)	11	18.33%
Good (80-89)	37	61.67%
Fair (70-79)	7	11.67%
Poor (< 70)	5	8.33%

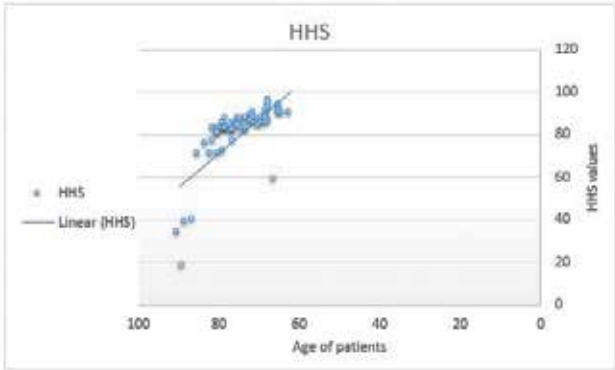

Fig. 3: Relationship of HHS and age of the patient

This figure show the decrement of HHS with increasing age of the patients.

Table 2: Show the relationship (P-value) between complications and age, gender, Type of fracture, medical comorbidities, and blood transfusion

Variables	Complications				
	Infection	Dislocation	Anterior thigh pain	DVT	Death
Age	0.0007227	0.8624	0.293	0.0009	0.4793
Gender	0.5778485	0.0701	0.0171	0.7353	0.2643
Type of fracture (Garden classification)	0.8697328	0.3308	0.4604	0.3308	0.0056
Presence or non of comorbidities	0.0939334	0.7737	0.3087	0.2475	0.2475
Blood transfusion	0.0269024	0.1283	0.8249	0.1283	0.1283

Discussion

Elderly ambulatory patient with Garden's type III and type IV, better treated by prosthetic head replacement or total hip replacement. This is because old people must be active and got up without delay to prevent complications. [10,11,12].

Using a prosthesis in a fresh femoral neck fracture allows immediate weight bearing and returns of elderly patients to activity and help to avoid complications of recumbency. It also eliminates avascular necrosis and nonunion as a complications of femoral neck fractures. It also reduces the reoperation rates compared to internal fixation. [13,14].

The complications of persistent pain and protrusio acetabuli with unipolar hemiarthroplasties have led many surgeons to choose a bipolar system. The lack of biological fixation of the non-textured stem inserted without cement may cause long-term thigh pain. The biarticular design of the bipolar system is thought to be associated with less acetabular wear than unipolar prostheses. A suggested but unproved advantage of the bipolar design is improved stability of the prosthesis and resistance to dislocation. [15,16].

In this study, we had 4 cases of surgical site infection(SSI) (6.67%), three superficial infection treated conservatively. The fourth was deep refractory infection not responding to conservative management, it ended with THR.,

Shah et al. [17]., Lu-Yao G et al.[18], and Saberi.[19] reported incidence of SSI as 0.1%, 1.7% and45%. In this study, we found that there was significant relationship between SSI and age of patients *P*-value (0.0007), presence of DM *P*-value (0.0004) and receiving blood transfusion *P*-value (0.0269).) . Kaye et al[20]. in their article (the effect of increasing age on the risk for surgical site infection) proved that increasing age in adult has often been identified as a risk factor for SSI.

In their study Lu-Yao G et al.[18] found that patients with DM had a higher SSI than those without DM (5.6% vs. 3.7%) Kim et al [21] found significant relationship between allogeneic blood transfusion and SSI following hip and knee arthroplasty. The incidence was 2.88% vs 1.74% for the transfusion and non-transfusion group respectively) On the other hand, we found no relationship between infection and each of gender of pt., type of fracture and presence of comorbidities other than DM.

We had 2 case of posterior dislocation in our studied group (3.33%) which happened 6 – 8 week postoperatively when patients start full weight bearing and both cases treated by open reduction under spinal anesthesia.

For the same complication, Rajak et al. [22],Mandanat et al. [23]. and Kim et al[24]. reported 3%,5.6% and 3.8 % respectively.

This dislocation rate may be attributed to compromising the strong posterior capsule during posterior Moore approach making the hip more vulnerable to dislocation. There was insignificant relationship between dislocation and our comparable variables.

There were 18 cases of anterior thigh pain (30.%) which was mild to moderate (according to simple pain score)[9], they respond well to rest or simple analgesics in form of paracetamol or NSAIDs.

Also Rajak et al. [22]. reported 30% cases of pain of which 20% mild pain and 10% moderate pain, while Vincent et al [25]. reported the 24.6% rated as moderate to severe in their series. We found significant relationship between anterior thigh pain and gender *P*-value (0.0171), while there was insignificant relationship between anterior thigh pain and other variables.

We reported two cases of DVT (3.33%).while Lee et al[26]. reported incidence of (2.7%). Mazen et al[27]. reported higher incidence which was(11.8%). We found significant relationship between DVT and age of the patients *P*-value (0.0009), while there was insignificant relationship between it and other variables.

There were two cases of death, which represent about (3.33%). One of them died after three weeks of operation and the other one died six weeks postoperatively.

Rajak MK et al. [22]. had no mortality in their series of 30 patient while Rödén M et al [28] reported (9.3%) mortality in their 100 patient.

We found significant relationship between mortality and type of fracture *P*-value (0.0056), while there was insignificant relationship between it and other variables.

The mean Harris Hip Score result in our study was 80.6 which was comparable to other studies such as that of Rajak et al. [22] (83.1) and Mouzopoulos et al) [29].

(83.7. HHS decrease with increase ages of the patients as seen in this paper.

Conclusion

Bipolar r hemiarthroplasty through posterior approach seems to be a good option for primary treatment of displaced femoral neck fractures in elderly with few complications.

Assessment of the Anterior Talofibular Ligament(ATFL) Thickness in Chronic Stroke Patients by Ultrasound

Mohammed Hassn Razoki[1], Nada Rida Alharis[2], Haider Kadhim Hussain[2]

[1]Department of Orthopedics, [2]Department of Radiology, College of Medicin, University of Kufa, Iraq

ABSTRACT

Stroke is one of the commonest diseases affecting people world - wide. Spastic equino varus foot is one of most common disabling deformities observed among hemiparesis patients. The aim of the study is to compare ATFL thickness on the affected and unaffected sides of chronic stroke patients with that of healthy individuals using ultrasonography.

Method: Comparative case-control study carried out between October 2017 to September 2018. There were 77 chronic stroke patients (46 males and 31 females) , matched 154 healthy individual (90 males and 64 females).

The thickness of the anterior talofibular ligament(ATFL)was measured using ultrasound.

Results: The mean thickness of ATFL in stroke cases was significantly higher (2.74 ± 0.25 mm) than the mean thickness of ATFL in control group (2.34 ± 0.22 mm) , while the mean ATFL thickness was significantly higher in both affected and unaffected sides in stroke cases than mean thickness in the control group. Within the stroke cases the mean ATFL thickness was significantly higher in the affected than unaffected side, while in control group, there was no significant difference between both sides.

Conclusion: Chronic stroke patients had thicker ATFL on the affected side than unaffected side & both sides were thicker than the group healthy control.

Introduction

Anterior talofibular ligament (ATFL)is one of the most biomechanically important ligament of ankle, it is also the most frequently and often first to be injured as a result of abnormal inversion stress[(1)]. The average width of ATFL is 7.2 mm and average length is 24.8 mm long [(2)]. The anterior talofibular ligament limits the anterior displacement of the talus and plantarflexion of the ankle. Only in plantarflexion the ligament comes under strain[(3)].

Following stroke patient may develop hemiparesis, which can have a profound effect upon walking ability[(2,4)]. Spastic equinovarus foot (SEVF) is one of the most common disabling deformities observed among hemiplegic patients. SEVF deformity has four main causes[(5,6)]. The first is spasticity of the calf muscles (soleus, gastrocnemius, tibialis posterior, flexor digitorum and flexor hallucis longus muscles) , responsible for SEVF in the stance phase of gait. The peroneus longus and brevis muscles may also be spastic (often with clonus), but such spasticity is useful to limit the varus and stabilize the ankle. Secondly, the spastic muscles have a tendency to remain in a shortened position for prolonged periods, which, in turn, results in soft-tissue changes and contractures, leading to a fixed deformity. Thirdly, weakness of the ankle dorsiflexor muscles (tibialis anterior, extensor digitorum and hallucis muscles) as well as the peroneus longus and brevis muscles is often emphasized by triceps spastic co-contraction and/or contracture. The weakness also affects the triceps surae muscles, leading to a lack of propulsion at the end of the stance phase of gait.

Lastly, an imbalance between the tibialis anterior and the peroneus muscles leads to varus of the hind-foot in the swing phase, as peroneus activation must compensate for physiological varus positioning related to contraction of the tibialis anterior. In such a case, the foot will be placed in an unstable varus position during the swing phase and at the beginning of the stance phase[7]. The incidence of equinovarus deformity of the foot in adult stroke patients has been reported to vary between 10% and 20% [2].

Equinovarus deformity can increase the chance of fall,as the feet tend to drag over the floor during swing phase[8]. Recovery of walking ability by addressing the ankle-joint deformity helps patients with stroke to regain independence in daily life, and is one of the main rehabilitation training goals[9]. Fortunatly, ankle-foot orthoses have been used successfully to correct equinovarus deformity after stroke[10]. However little was written about the effect of equinovarus deformity on ATFL in patient with post stroke hemiplegia. The aim of this study is to compare between the anterior talofibular ligament (ATFL) thickness on the affected and unaffected sides of chronic stroke patients with that of healthy individuals using ultrasonographic study.

Patients and Method

Patients and Study Design: This comparative case control study was carried out on 77 patients from October 2017 to September 2018. There were 77 chronic stroke patients, matched with 154 healthy individual. The selection of patients (chronic stroke patients) and control group was done according to inclusion and exclusion criteria, where chronic stroke is a period starting six months after initial stroke. All patients and controls were referred from orthopedics and rehabilitation unite after fully diagnosis of chronic stroke patients by clinical examination and imaging modality.

The study group included 77 chronic stroke patients (46 males and 31 females) , mean age (60.2 ± 9.8) , mean BMI (26.20 ± 4.3) matched with 154 healthy control group (individuals without disorders of the ankle or had no surgical intervention of the lower limbs) (90 males and 64 females) , mean age (59.9 ± 9.6) mean BMI (26.7 ± 3.78).

Inclusion Criteria: The events of stroke (hemorrhagic or ischemic stroke) at least 6 months, who have developed weakness on one side with abnormal gait.

Exclusion Criteria

1. Previous botulinum toxin injection to gastro-soleus muscles
2. Event of post stroke period ankle injury.
3. Fixed ankle contracture.
4. Previous surgical intervention of the lower limbs.

Method

All the patients and control group underwent gray scale sonography to measure thickness of anterior talofibular ligament (ATFL) using a linear probe (7 - 12 MHz GE VOLUSON E8 ultrasound machine) and was done by same radiologist.

Measurements was taken as the patient in a supine position with the ankles in neutral or slight plantar flexion. A longitudinal image of the ATFL was scanned with the transducer placed in a slightly oblique direction from the anterolateral aspect of the lateral malleolus to the peak of the talus.

The hyper echogenicity of the two bony landmarks made them easy to be identified the ligament. The normal ATFL was depicted as hyperechoic bundles on sonography. ATFL thickness was measured halfway between the two bony landmarks of the ankle. All sonographic measurements were taken in the plane perpendicular to the long axis of the ligaments for standardization and reproducibility of the measurements. The thickness of the ligaments was measured two times, and the mean values were recorded as shown in figure (1).

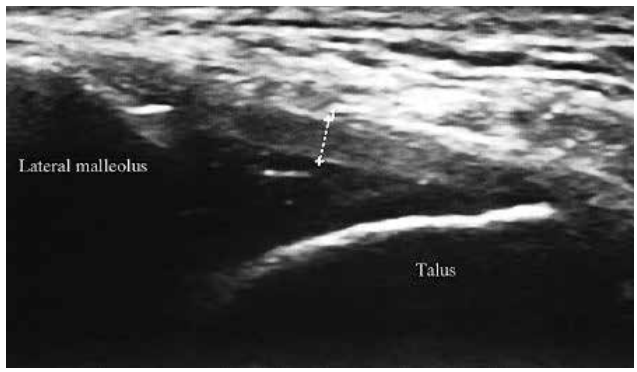

Figure 1: A musculoskeletal ultrasound image of the anterior talofibular ligament and thickness measurement (49)

Results

A total of 77 chronic stroke cases and 154 controls were enrolled in this study, both groups were almost matched for age and gender, where the mean age was 60.2 ± 9.8 in patients and 59.9 ± 9.6 in controls, (P > 0.05). Males were almost dominant in both groups represented 59.7% and (58.4%) among stroke cases and controls, respectively, (P > 0.05) . The mean body mass index (BMI) was 26.20 ± 4.3 in stroke cases and 26.7 ± 3.78 in controls with no significant difference, (P > 0.05).

History of diabetes mellitus was relatively more frequent in stroke cases, contributed for 32.5% while it was reported in 23.4% of controls, however, the difference was statistically insignificant, (P> 0.05) . Hypertension was also more frequent in stroke cases than controls, 54.5% and 43.5%, respectively with no statistically significant difference (P > 0.05) (table 1).

Table 1: Demographic characteristics of the studied group

Variable	Statistic	Group		P Value
		Stroke cases (N = 77)	Controls (N = 154)	
Age (years)	Mean ± SD*	60.2 ± 9.8	59.9 ± 9.6	0.85
Range (years)		83 - 37	82 - 37	
BMI (Kg \ m2)	Mean ± SD*	26.20 ± 4.3	26.7 ± 3.78	0.43
Range (Kg \m2)		32 - 20	33 - 20	
Sex	Male n (%)	46 (59.7)	90 (58.4)	0.82
	Female n (%)	31 (40.3)	64 (41.6)	
History of diabetes Mellitus n (%)		25 (32.5)	36 (23.4)	0.14
History of Hypertension n (%)		42 (54.5)	67 (43.5)	0.11

Among the stroke cases, right side was affected in 43 (55.8%) cases and the left side in the remaining 34 cases (44.2%). Tthe disease duration of stroke cases ranged (6 – 36) months with a mean of 18.8 ± 10 months.

The comparison of mean ATFL thickness of stroke cases and controls revealed that ATFL was significantly thicker in stroke cases than controls; the mean ATFL thickness was significantly higher in both affected and unaffected sides in stroke cases than controls, 2.74 ± 0.25, 2.52 ± 0.27 and 2.34 ± 0.22 mm respectively, Furthermore, within the stroke cases the mean ATFL thickness was significantly higher in the affected than unaffected side, (P. value < 0.001). (tables 2) and (figure 3.2).

Table 2: Results of ANOVA multiple LSD (least significant difference) comparison of ATFL thickness of stroke cases and controls

Comparison	Mean difference	Standard error	95% Confidence Interval of the difference	P. Value
Affected vs. unaffected side	0.219	0.039	0.142 – 0.296	< 0.001
Affected side vs. controls	0.398	0.031	0.331 – 0.465	< 0.001
Unaffected side vs. control	0.179	0.033	0.112 – 0.246	< 0.001

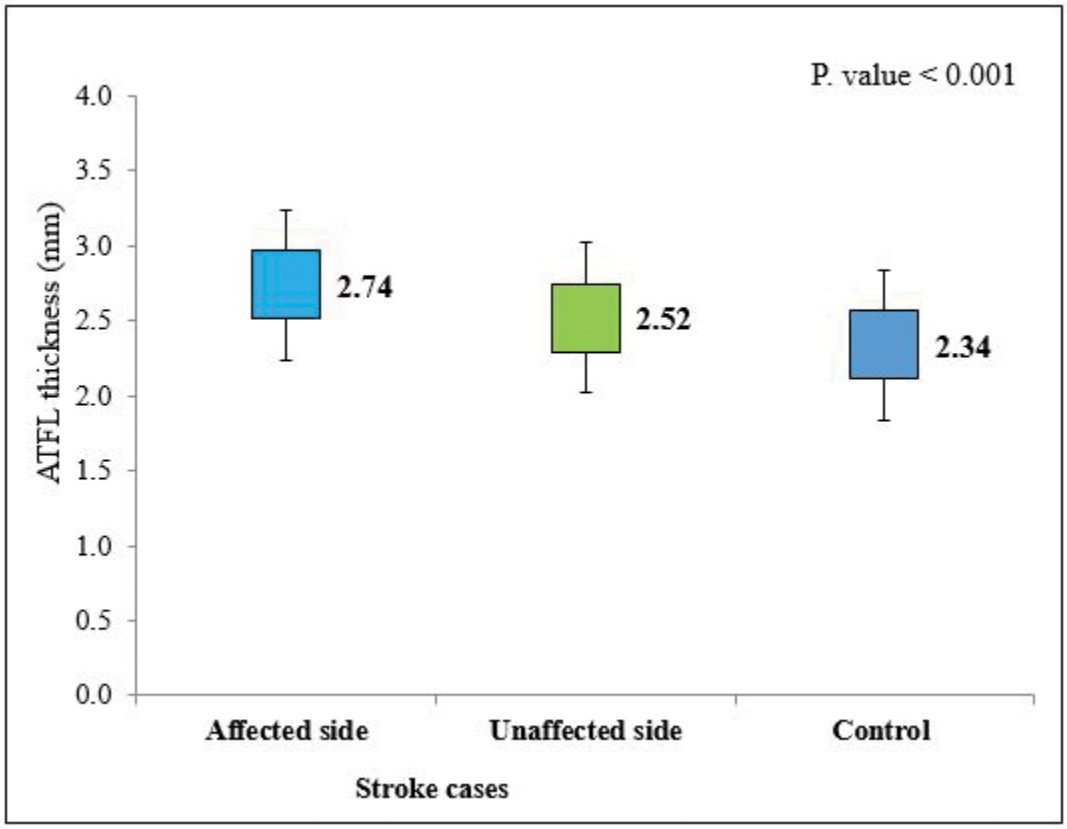

Figure 2: Graphical comparison of mean ATFL thickness of stroke cases and controls

To assess the possible effect of demographic variables in both stroke cases and controls on the ATFL thickness, inter-correlation was performed for these variables against the ATFL thickness in affected and unaffected side (table 3), the results of these correlations revealed that the ATFL thickness not affected by the demographic characteristics of the stroke cases, in all comparison, (P>0.05).

Table 3: Correlation matrix of the ATFL thickness with demographic characteristics of stroke cases (N = 77)

Variable	Statistic	ATFL thickness affected side(cm)	ATFL thickness unaffected side
Age	*R*	0.05	0.08
	P. value	0.65	0.52
Sex	*R*	0.01	-0.05
	P. value	0.96	0.68
BMI	*R*	0.19	-0.12
	P. value	0.11	0.30
Diabetes Mellitus	*R*	-0.17	-0.09
	P. value	0.14	0.43
Hypertension	*R*	0.08	-0.13
	P. value	0.49	0.25
Disease duration	R	0.07	0.12
	P. value	0.56	0.31

Similarly, the inter - correlation was performed in control group, (table 4), and the results of these correlations were also statistically insignificant, (P > 0.05).

Table 4: Correlation matrix of the ATFL thickness with demographic characteristics of controls (N = 154)

Variable	Statistic	ATFL thickness affected side(cm)	ATFL thickness unaffected side
Age	*R*	0.044	0.044
	P. value	0.58	0.57
Sex	*R*	0.11	0.13
	P. value	0.17	0.17
BMI	*R*	0.041	0.41
	P. value	0.62	0.62
Diabetes Mellitus	*R*	0.026	0.031
	P. value	0.75	0.71
Hypertension	*R*	0.049	0.047
	P. value	0.55	0.57

Discussion

Stroke is one of the commonest diseases affecting people world - wide, chronic stroke patients with weakness on one side have higher risk of fall and ankle ligament injury, equino varus deformity is the result of abnormal activity in multiple muscles, it occur in 20 % of patients with stroke. Although most studies have focus on gait patterns of stroke patients, the presence of an equino varus foot was not specified, subcategorization of gait patterns would be helpful in developing and delivering more targeted treatment.

Ultrasound is now widely used for the assessment of the tendon and ligaments abnormalities, healthy ligaments contain high level of collagen with a structural orientation. Changes to ligaments as a result of disease and injury can give rise to a spectrum of damage, the mildest form is interstitial tearing of collagen fibers in which the ligament may be elongated and lax. Ultrasound is one of the most sensitive tools to diagnoses the injury of ligaments and other soft tissues and quantify the ligament integrity[11].

Ultrasound could be used to evaluate thickness and type of the injury of the ATFL[12]. It has been shown that ultrasound has high sensitivity and specificity for chronic ATFL tear, Advantages of using musculoskeletal ultrasound include cost - efficiency, shorter examination time, and the ability for real - time and dynamic imaging. It also utilizes no ionizing radiation and is portable, as well as widely available[13].

Furthermore, dynamic sonography (during externally applied stress) has the potential to identify ligament [11].

In the present study, it has been shown that the mean thickness of ATFL in stroke cases was significantly higher than the mean thickness of ATFL in control group and the mean ATFL thickness was significantly higher in both affected and unaffected sides in stroke cases than the mean thickness in control group. In addition, in the stroke cases the mean ATFL thickness was significantly higher in the affected than the unaffected side, while in control group there was no significant difference of the mean ATFL thickness between both sides.

Yildizgoren, M. et al [14]. studied (38) patients with chronic stroke and (38) normal control group and to the best of our knowledge this is the only available research that investaged ATFL thickness in patients with post stroke hemiparesis. He found that chronic stroke patients have a thicker ATFL on both the affected and unaffected sides, compared with healthy individuals (2.75 ± 0.41, 2.42 ± 0.30, 2.35 ± 0.19 mm) respectively. This is consistent with our study which showed that the mean ATFL thickness was significantly thicker in both affected and unaffected side in stroke cases than mean thickness in control groups (2.74 ± 0.25, 2.52 ± 0.27 and 2.34 ± 0.22 mm) respectively.

It can be postulated that these findings may be due to several factors. Hemiplegic patients often have inadequate ankle dorsiflexion due to loss of motor control, spasticity of the gastrocnemius soleus or the invertor group, and/or ankle contracture[14]. Because a ligament is a highly organized fibrous tissue, its mechanical properties are directionally dependent on stress, an increased thickness of the ATFL reflects morphologic changes that occurred secondary to the ankle injury[14].

The viscoelastic characteristic of ligaments is the gradual increase in ligament deformation over time under a constant load. Recruitment of collagen fibers may be important for resisting gradual deformation of the ATFL under a constant load, and the ATFL is thickened on the affected side [14].. The stabilization of the ankle in a neutral position reduces the load on the ATFL and prevents ankle torsion.

The use of ultrasonography can aid in early detection of the affected ligaments, thus helping to prevent ankle deformity.

In this study hypertension, diabetic mellitus and disease duration had no significant effect on ATFL thickness.

Conclusion

ATFL is thicker on the affected side than the unaffected and both of them are more thick than in the feet of control group.

Classroom Control Patterns and its Relation to the five major Factors of the Personality of Sports Education Teachers in Babil Governorate

Aied Kareem Abdaun[1], AbdulrhmanGhadhab AL-SAADI[2], Haedar Sami Mohammed[1]

[1]AL-Qasim Green University, Department of Sport, Babel, Iraq; [2]AL-Nahrin University, Department of Sport, Baghdad, Iraq

ABSTRACT

This study investigates the physical level of classroom control differed by the five major factors of personality? Are there gender differences between the patterns of classroom control according to the five major factors of the personality? Is there a relationship between the patterns of classroom control and the five major factors of the personality of the physical education teachers? The objectives of the research are to construct and codify the scale of the patterns of classroom control and to prepare and apply the scale of the five major factors of the personality as well as the extraction of the standards and levels for the scale of class control patterns.

Keywords: *prepare, regulate, classroom control patterns, five major factors, personality.*

Introduction

The Introduction and Importance of Research: The school is one of the most important institutions of the Ministry of Education in which the student's personality is formed, his ethics are refined, and knowledge which will be his weapon in the future is learned. It is the cornerstone through which the student reaches his goals and it provides him with all means of success according to the rules and regulations.[1,2] One of the most important components of the school environment is the classroom. Its management is both an important and difficult task. It is an important part of the work of the teachers of physical education [3, 4]. The physical education teacher is the main supervisor of the classroom and is directly responsible for the implementation of the educational process.[5]

The classroom control is one of the bases upon which to achieve the educational objectives of the educational process and its success, and its role is not only to raise the level of academic achievement for students, but also to contribute to their moral and social development, so the control is an educational process that requires control of behavior, passions and emotion under the leadership in order to achieve a specific goal, it is considered a psychological and social needs which the educational process seeks to develop it for students [6].

One of the models that described the personality is the model of the five major factors of the personality, which contains five dimensions through which the difference in personality is explained based on each prevalent dimension among the teachers of physical education, and it gives us a description of individual differences among teachers.

The importance of this research is to identify the patterns of classroom control practiced by teachers of physical education, the five major factors of the prevalent personality, and the relationship between the patterns of classroom control and the five major factors of the personality of the physical education teachers. [7]

The Research objectives

1. To construct and codify the scale of the patterns of classroom control for physical education teachers in Babil Governorate.
2. To prepare and apply the scale of the five major factors of the personality for the physical education teachers in Babil Governorate.
3. The extraction of the standards and levels for the scale of class control patterns of physical education teachers in Babil Governorate.

4. To identify the level of the classroom control patterns for physical education teachers in Babil Governorate.
5. To identify the relationship between the classroom control patterns and the five major factors of the personality for physical education teachers in Babil Governorate.
6. To identify the gender differences between the classroom control patterns for physical education teachers in Babil Governorate.

The Research Methodology and Field Procedure

The Research Methodology: The researcher used the descriptive approach in the method of survey studies. The standard studies are suited to the process of building and codifying standards which corresponds to the nature of the current study.

The research Community and Sample: The research community and its sample of physical education teachers in Babil Governorate have been identified. Their number was (759) of which (582) were male teachers and (177) were female teachers. The size of the research samples was (455) representing a percentage of (59.94). The sample of reconnaissance was (30) teachers, construction sample was (190) teachers, codifying sample was (190) teachers while the number of the application sample was (200) teachers.

The research tools and used equipment: The current research tools include: 1- Sources and references 2- Questionnaire form 3- Laptop.[16]

Table 1: Shows the five major factor scale articles for personality according to dimensions

The dimension	The Positive articles		The negative articles	
	The Articles	Total	The Articles	Total
Neurosis	6,11,21,26,36,41,51,59	8	1,16,31,26	4
Extraversion	2,7,17,22,32,37,47,52	8	12,27,42,57	4
Openness to experience	13,28,43,53,58	4	23,33,38,48,3,8,18	7
Acceptability	4,19,34,49	4	9,14,24,29,39,44,54,59	8
Conscientiousness	60,50,40,35,25,20,10,5	8	15,30,45,55	4
		33		27

The correction key was according to the 5-Likert scale, where the tester obtains the following answers when responding the articles of the scale as shown below:

Table 2: Shows the degree of response on the scale of the five major factors for personality

The Articles	Strongly Agree	Agree	I have no opinion	Disagree	Strongly Disagree
The Positive	5	4	3	2	1
The negative	1	2	3	4	5

Determining the validity of the five major factor scale articles for personality: The researcher presented the (60) articles of the scale to (7) experts and specialists. The researcher used the test (Ka-2) to identify the valid and invalid articles. The results showed the validity of all articles where the calculated (Ka-2) value of (7) was greater than the tabular value (3.84) with (0.05) significance level and (1) degree of freedom. The experts agreed to keep the answer alternatives as mentioned above **(8).**

Procedures for controlling the scale of the patterns of classroom control: For the purpose of achieving the objectives, there must be a tool to measure the patterns of classroom control based on scientific bases and appropriate to the Iraqi environment. After studying the relevant researches and scales like studying [7, 8], the researcher has taken the following steps:

Define the Objective and purpose of the scale: The aim is to construction and codify the scale of classroom control patterns and its purpose is to identify the prevalent classroom control pattern of the research community represented by physical education teachers in Babil Governorate.

Steps of constructing the Scale: A good test should be prepared to include the whole curriculum in a balanced manner. The Steps of constructing the Scale are:

Determine the fields of scale: Seven dimensions were presented to experts and specialists showing the validity of the dimensions (patterns) of the democratic, chaotic, punitive and authoritarian. The dimensions (patterns) of (preventive, therapeutic, reprehensive) were excluded because the calculated (Ka-2) values are less than the tabular value (3.84) which was below the significance level (0.05) and degree of freedom (1).

Presentation, analysis and discussion of results: The five major factor scales and the classroom control patterns have been applied to the application sample of (200) teachers representing a percentage of (26.35%). When the data were processed statistically, the number of male and female teachers who were categorized by the five major factors of the personality was determined. The number of democratic pattern male teachers was (55) and female teachers was (27. The number of punitive pattern male teachers was (20) and female teachers was (3), whereas the number of the authoritarian pattern male teachers was (22) and female teachers was (7). The number of the chaotic pattern male teachers was (53) and the number of female teachers was (13). On the scale of the five major factors of the personality. There were (51) male teachers on the neurosis factor and (5) female teachers. There were (20) male teachers and (10) female teachers on the extraversion factor and the openness to experience there were (21) male teachers and (7) female teachers. There were (15) male teachers and (17) female teachers on the conscientiousness factor, and there were (43) male teachers and (11) female teachers on the vigilant conscience factor. By this we have achieved the **second research objective** which is (the preparation and application of the scale of the five major factors of the personality of the teachers of sports Education in Babil Governorate).

Table 3: The Statistical description of the scale of the classroom control patterns according to the five major factors of the personality

The patterns	Total number	Number of articles	The hypothetical median	Minimum value	Maximum value	Arithmetic median	Standard deviation	Standard error	Skaewness
Female Teachers									
Democratic	27	13	48.00	37.00	59.00	47.41	6.53	0.26	0.45
Punitive	3	11	35.00	33.00	37.00	34.67	2.08	0.20	0.23
Authoritarian	7	10	34.00	31.00	37.00	35.43	2.44	0.92	0.79
chaotic	13	11	43.50	40.00	47.00	43.77	2.13	0.59	0.62
Total	50	45	192.50	166.00	219.00	185.12	9.19	0.73	0.87
Male Teachers									
Democratic	55	13	35.50	23.00	48.00	40.29	4.95	0.67	0.32
Punitive	20	11	44.50	34.00	55.00	42.35	5.72	0.28	0.51
Authoritarian	22	10	45.00	40.00	50.00	44.36	2.90	0.62	0.49
chaotic	53	11	38.50	30.00	47.00	38.08	4.50	0.62	0.33
Total	150	45	152.00	138.00	166.00	152.17	8.14	0.66	0.08
The Total Scale									
Democratic	82	13	41.00	23.00	59.00	42.63	6.43	0.71	0.27
Punitive	23	11	44.00	33.00	55.00	41.34	5.97	0.25	0.48
Authoritarian	29	10	40.50	31.00	50.00	42.20	4.77	0.89	0.43
chaotic	66	11	43.50	30.00	47.00	39.20	4.72	0.58	0.30
Total	200	45	178.50	138.00	219.00	160.41	11.43	1.23	0.79

It appears that the arithmetic median hypothesis of the scale of the classroom control patterns which were extracted from the achieved degree and its value (178.50) is the largest achieved arithmetic median which was (160.41). The arithmetic median achieved for the teachers (152.17) is greater than the hypothetical median of (152.00) and is not Influential. We also see that the arithmetic median of female teachers is equal to (185.12) and is smaller than the hypothetical median which was (192.50).

Normative Levels of the Classroom control Patterns Scale: Three normative levels were determined. both levels are good and weak (15.73%) The average level reached a rate of (68.27%) Of the area under the normal distribution curve, where it appeared to us that the level of teachers is average but the misses and the sample as a whole were weak, representing (38.67%) For teachers and (54%) For misses and (73%) For the sample as a whole of the research community as shown in the below:

Table 4: Shows the standard levels and percentage of the test of the classroom control patterns

The scale of the classroom control patterns	Sample number	Weak 15.73%		Average 68.27%		Good 15.73%	
		Number	%	Number	%	Number	%
Females	Categories	166 -183		184 – 201		202 – 219	
	50	27	54	15	30	8	16
Males	Categories	138-147		148-157		158-176	
	150	45	30	58	38.67	47	31.33
The sample as a whole	Categories	138-165		166-193		194-221	
	200	146	73	42	21	12	6

The relationship between the classroom control patterns and the five major factors of personality: The researcher used the simple correlation coefficient (Pearson) and the results were as follows:

Table 5: Shows the correlational relationships between the classroom control patterns and the five major factors of personality

The classroom control patterns Personal factors	The Democratic	The punitive	The authoritarian	The chaotic
Neurosis	0.06	0.63	0.51	0.11
Extraversion	0.45	0.09	0.12	0.13
Openness to experience	0.10	0.13	0.08	0.05
Acceptability	0.57	0.10	0.11	0.14
Conscientiousness	0.12	0.54	0.49	0.07

As shown above, it is found that the relationship between the Neurosis, the punitive and authoritarian pattern is statistically significant as well as the extraversion with the democratic pattern is statistically significant, the acceptability was a statistical significant with the democratic pattern while the conscientiousness was a statistical significant with the punitive and authoritarian pattern because the value of Sig was less than significant level (0.05).

Discussion of Results

After the standard levels of the scale have been extracted, the level of classroom control for the research sample as a whole was (weak) at (73%). As for the female teachers, the level is also weak at (54%) The male teachers were at an average level of (38.67) and this is a good indicator of their classroom control, especially as we know that this result may be due to the environment that provides male teachers with a degree of control over the students and that their abilities are suitable for the work of controlling the classroom. As for the differences between male and female teachers, the significant for female teachers in the democratic and chaotic pattern was higher and the reason for this result that female teachers are mothers before everything, they are dealing with their emotions and they are not cruel with the students regardless of their gender, As for male teachers, they have

the advantage in the punitive and authoritarian pattern, as mister is hard on students when they violate the rules and regulations. As for the differences in the fields of classroom control patterns, it was found that differences are random except the preference of the democratic pattern on chaotic, and authoritarian on chaotic also, The democratic pattern was the best pattern, as it was represented by (82) teachers, followed by chaotic pattern which was represented by (66) teachers.

Conclusion

By presenting, analyzing and discussing the results, the researcher reached the following conclusions:

1. The scale of the classroom control patterns has been codified for physical education teachers.
2. The common personality factors were revealed, the neurosis and the Conscientiousness factors were common for male teachers, and the acceptability and Conscientiousness factors were common for female teachers.
3. The patterns of classroom control were revealed and the dominant patterns for male teachers were democratic and chaotic, and for female teachers were punitive and authoritarian.
4. Three levels were extracted on the scale of the classroom control (good, average and weak)
5. The female teachers' level was weak, and the female teachers were average, and the sample as a whole was weak.

The Recommendations: In light of the researcher's conclusions, he recommends the following:

1. Teachers need to learn about ways to distance them away from authoritarian and punitive patterns.
2. The need to prepare courses to help teachers of physical education on how to practice classroom control patterns.
3. The need for teachers of physical education to know the modern patterns of classroom control and its impact on the process of learning in the classroom.

Effect of Speed Training Technique in Determining the Effectiveness of Creatine and Phosphorus for Advanced Volleyball Players

Amal Sabeeh Salman Al-Tamimi

University of Diyala, Faculty of Basic Education, Department of Physical Education and Sports Sciences

ABSTRACT

The importance of research is to maintain the production of energy and non-disbursement in a large way and it is only through the right and appropriate training, including the method of increasing speed and thus put the scientific information for trainers on the importance of maintaining the production of energy for players through the implementation of this training and testing.

This study aimed to prepare the training of increasing speed in determining the effectiveness of creatine and phosphorus for advanced volleyball players. Also, to Identify the impact of high intensity training in determining the effectiveness of creatine and phosphorus for advanced volleyball players.

This study concluded that, the technique of speed training is especially important in the production of energy after decomposition of creatine and phosphorus during the appropriate training. Also, Experimenting with appropriate training and investigating the facts of speed and its importance in the volleyball game in the production of energy through the control of creatine and phosphorus also, this study recommendations that, adopting the method of training of increasing speed is especially important in the production of energy after decomposition of creatine and phosphorus during appropriate training. Also, the need to emphasize the experimentation of appropriate training and investigating the facts of speed and its importance in the game of volleyball in the process of energy production through control creatine and phosphorus.

Keywords: *Speed training technique, creatine phosphorus volleyball players*

Introduction

Human Health The most important thing that is sought in scientific research and how to raise the functional variables to the best using either necessary nutritional supplements or exercise activities that work on functional changes that raise the health offenders of the human. **(1)**

When functional changes and energy production are related to the exercise of any physical activity here, we need to be precise in dealing with the methods of training in a true scientific way as they control the energy production necessary to complete the game and achieve good results in the game in practice.(2)

The game of volleyball is characterized by speed in the implementation of basic skills both in defense or attack and during periods of the game, which lasts more than two hours in some cases, which requires the player to maintain its speed and strength without falling during that period, it must be training in a manner that can control the discharge necessary energy for performance. (3)

Therefore, the method of increasing speed, which ranges from speed to slow to the maximum speed, is sometimes more controlled by functional changes physiological, including creatine and phosphorous necessary in dealing with energy. (4)

The power out of the (ATP) needs constant compensation of energy during sports activity through creatine phosphate, which is one of the sources of energy and stock in the cells of the body because of its impact on the phenomenon of extending the body and fills the shortage of energy sources during physical performance.**(5)**

Hence, the importance of research is to preserve the production of energy and non-drainage in a large way and it is only through the right and appropriate training,

including the method of increasing speed and thus we put a scientific information for trainers on the importance of maintaining the production of energy for players through the implementation of this training and testing.(6)

Increasing Speed Training Method: It is a modern sports training method that helps the athlete to increase the speed of performance gradually from easy to difficult and thus avoid sports injuries in addition to the development of special speed of the game, this is what (Amarullah Ahmed Al-Bassati, 1998)"1" confirm it. ((This method is the gradual increase of running speed from (jogging to running) to the enemy at full speed and then rest in walking and improves this type of training both speed and strength). (7)

Blood creatin is an important indicator to measure the amount of physical effort, as it changes after physical exertion. Creatine changes to creatinine after loss of water molecule. The normal values of creatine in the blood for healthy people are about 0.5 - 0.9 mg/100 ml serum)(8).

There is about 98% of muscle creatine in the form of phosphocrytin (CP), which is a high energy source in muscles) (9).

Phosphate has the ability to bind in reverse with many enzymatic systems and other essential compounds of metabolic processes and is related to the functions of ATP, ADP and phosphocrytin, which produce energy. (10).

2-Research Problem: The energy spent by the player suits the specificity of the game and the training which the player exercises to win and the good results. In the absence of proper training with the system of energy exchange will not raise the level of the player with the effort and sure to drop the level and not to win.

And through the humble experience of the researcher as a player and specialist in the science of physiology found that experimentation is an important factor in investigating the scientific facts of the quality of the training and its physiological impact, so it is necessary to know each method of training and its specialties in upgrading the functional side and energy production in the body of the player, including creatine and phosphorus, Perhaps not studied in terms of physiological and specificity of the game, including the game of volleyball. (11)

Therefore, the researcher decided to study this problem by identifying the effect of the technique of increasing speed in determining the effectiveness of creatine and phosphorus for advanced volleyball players.(12)

Research Goals:

1. Prepare the training of increasing speed in determining the effectiveness of creatine and phosphorus for advanced volleyball players.
2. To identify the effect of high-intensity training in determining the effectiveness of creatine and phosphorus for advanced volleyball players.
3. To identify the differences between the results of (pre/post) (Before/After) tests in determining the effectiveness of creatine and phosphorus for advanced volleyball players.
4. To identify the differences between the control and experimental groups in determining the effectiveness of creatine and phosphorus for advanced volleyball players.

3-Research Hypotheses:

1. There are significant differences between the results of (pre/post) (Before/After) tests and for the benefit of post (After) test in determining the effectiveness of creatine and phosphorus for advanced volleyball players.
2. There are significant differences between the control and experimental groups and for the benefit of the experimental group in determining the effectiveness of creatine and phosphorus for advanced volleyball players.

Material and Method

Research Areas:

Human Field: Volleyball team players in the Faculty of Basic Education/Diyala University.

Spatial Field: the Faculty of Basic Education/Diyala University and Shams laboratory for pathological analysis in Baquba Al-Jadida/Tabu Street.

Time Zone: Duration from 3/12/2018 to 13/2/2019.

Field Procedures:

Research Methodology: The researcher used the experimental method with the sample of the controlled and experimental groups to suit the solution of the research problem and achieve its objectives.

Research Community and Its Sample: The research community is identified in a deliberate manner for the volleyball players of the applicants who represent the volleyball team in the College of Basic Education/ University of Diyala and their number are (20) players.

After that, 12 players were selected from the main team, who continued the training and the participants in the tournaments. The sample was randomly divided into two groups (controlled and experimental groups), so that the number of each group was 6 players and the sample formed 60% of the original society.

The sample was homogenized within the group by using the difference coefficient and the equivalence of the two groups using the (t) test as in Table (1).

Table 1: Demonstrates the homogeneity and equivalence of the control and experimental groups

Level of significance	Calculated t-value	The experimental group			Controlled group			Measurement	t
		Coefficient of variation	SD	M	Coefficient of variation	SD	M		
Not significant	0.013	2.013	3.61	179.25	2.042	3.66	179.22	Length/cm	1
Not significant	0.378	2.915	2.5	85.74	2.1	1.79	85.22	Weight/kg	2
Not significant	0.021	17.381	0.077	0.443	16.063	0.071	0.442	L/U Creatine	3
Not significant	0.14	3.598	0.113	3.14	3.555	0.112	3.15	L/U phosphorus	4

The Schedule (t) value at the freedom level (10) and the level (0.05) = 1.812

Information Collection Methods

Means of Data Collection:

1. Arabic references.
2. Exploration experience.
3. Measurements used.

Instruments and Tools Used:

1. Needle to draw blood samples.
2. Bottles to save blood samples.
3. Centrifuge
4. Cool Box to save blood samples with all requirements for obtaining ratios.
5. Optical analysis device
6. Electronic blood pressure device.
7. six (6) Volleyballs.
8. Medical balance.
9. regulated volleyball playground.
10. Metric tape measure.

Field Research Procedures:

Determining Research Variables: Based on the researcher's humble experience and review of sources and references, the variables that the researcher considers necessary were identified as follows:

1. Creatine.
2. The phosphorus.

Exploration Experience: The researcher conducted an exploratory experiment on 3/12/2018 on the same research sample. The required exercises were applied for the purpose of rationing the training load used according to the method of increasing the speed and creating the measurements required for measures, and the purpose of the experiment was to:

1. Knowing the required equipment and tools.
2. Knowing the right time.
3. Knowing the obstacles facing the researcher in the future.
4. The regulation of exercises and the calculation of the appropriate size by the quality of training high intensity and low intensity.

Measurements and method of procedure used: The researcher carried out the pre (before) measurement on the members of the research sample after the performance of a high intensity training unit and then the blood was withdrawn by 5 cm cubic by a specialist pre and post (before and after) the training curriculum of the research sample and laboratory treatment for measuring creatine and phosphorus through laboratory treatment.

Field Experience:

Pre (Before) measurement: The pre (before) measurement was conducted on 17/12/2018.

Main Experience and used Training: After learning the conditions and components of load for the method of training, increasing speed, a set of exercises for the technical performance of volleyball was developed and applied in this method, which is determined by the intensity of the training and ranges (90-100%).

The exercises were implemented in the main section of training units of the trainer during the special number period at a rate of (3) units per week and for two months (24) training units.

The size of the load was determined according to the intensity set. The rest was based on pulse return (120-130 bpm) and time was calculated to rest during the pulse. The application of the exercises was from 18/12/2018 to 12/2/2019.

Post (after) Measurement: The post-measurement is carried out on 13/2/2019.

Statistical Method

Using (spss) system with statistical treatments and to find the following:

1. Arithmetic mean (M).
2. Standard deviation (SD).
3. The difference coefficient.
4. Test (t) for interrelated samples.
5. Test (t) for independent samples.
6. Percentage.

Results and Discussion

By noticing and observing Table (2) and (3) we can see significant differences in controlled and experimental groups in pre/post measurements. This is an evidence of improvement in the physiological variables under study, including creatine and phosphorus, which are important in conserving energy sources. This is due to the training that is used and positively influenced by the physical loads that saved the energy production through correct analysis For the important compounds creatine and phosphorus "to decompose the chemical bonds in phosphocrytine resulting in the emission of energy that reproduces ATP. [15]

As the regularity of the sample in the training and the use of additional loads of the set, this is consistent with the statement by Karima Ahmed Fattouh, "The regularity in the training program lead to the creation of some physiological variables of the body as a manifestation of adaptation to the nature of that activity. [13]

Table (4) shows differences between the controlled and experimental groups and for the benefit of the experimental group, in which the researcher considers to be due to the increased training technique used as a method of handling high stress intensity and affecting the process of energy production. As the responses and changes that occurred during the application of this training course, which led to the events of a state of real-time and cumulative adjustment of the increase in the amount of muscle compounds in the recovery, and this cycle increases the energy stocks within the muscles working after the combination of compounds to form a phosphocrytine compound (CP).Which is reflected in the increase in the proportion of stocks of energy sources to be an important factor in the events of speed as it is the first key to the operation of energy systems after (ATP) because of the very low amount of energy funding to the working muscles[14], which led to the body to consume compound (CP) due to physical performance. The increased level of serum creatine phosphate (CP) in the muscle changes particularly in sports activities that require high performance and short-term durability in order to ensure the reconstruction of ATP [14]."

Table 2: Shows the pre/post (t) value of the controlled group

Level of significance	Calculated (t) value	The standard error	Post (after)		Pre (before)		Measurements
			SD	M	SD	M	
significant	5.333	0.015	0.021	0.522	0.071	0.442	L/U Creatine
significant	2.272	0.044	0.023	3.25	0.112	3.15	L/U phosphorus

The Schedule (t) value at the freedom level (5) and the level (0.05) = 2.015

Table 3: Shows the pre/post (t) value of the experimental group

Level of significance	Calculated (t) value	The standard error	Post (after)		Pre (before)		Measurements
			SD	M	SD	M	
significant	4.269	0.078	0.241	0.776	0.077	0.443	L/U Creatine
significant	3.66	0.112	0.146	3.55	0.113	3.14	L/U phosphorus

The Schedule (t) value at the freedom level (5) and the level (0.05) = 2.015

Table 4: Shows the post (t) value of the controlled and experimental groups

Level of significance	Calculated (t) value	Experimental group		Controlled group		Measurements	t
		SD	M	SD	M		
Significant	2.351	0.241	0.776	0.021	0.522	L/U Creatine	1
Significant	4.545	0.146	3.55	0.023	3.25	L/U phosphorus	2

The Schedule (t) value at the freedom level (10) and the level (0.05) = 1.812

Conclusions and Recommendations

Conclusions: Throughout the results, the researcher concluded the following:

1. The technique of growing (increasing) speed training is especially important in the production of energy after decomposition of creatine and phosphorus during the appropriate training. [12]
2. Experimentation an appropriate training and investigating the facts of speed and its importance in volleyball in the process of energy production through the control of creatine and phosphorus.

ABSTRACT

Background: Bonding of orthodontic brackets of fixed orthodontic appliance by using acid etch technique was first introduced in 1955. LED-based light sources posses many benefits as minimal heat generation. There is a new generation of LED light cure corporate with three different intensities (standard, high power and extra power). **Objective:** this study was aimed to evaluate the effect of increasing intensity and decreasing duration of LED light on shear bond strength and adhesive remnant index of metal orthodontic brackets.

Materials and Method: Sixty healthy extracted maxillary premolars were divided into three groups of twenty teeth for each, group (I) cure with a standard LED light curing (1000mW/cm2) for 10 seconds, group (II) cured through a high-intensity LED curing light (1400mW/cm2) for 8 seconds, group (III) cured with a extra high-intensity LED curing light (3200mW/cm2) for 6 seconds. The teeth mounted in acrylic resin, Shear bond strength test was done. Then, adhesive remnant index (ARI) was evaluated. Data were analyzed by one-way analysis of variance ANOVA test and LSD, and Fisher exact test.

Results: The results showed that there were statistically significant differences among the study groups. The maximum value of shear bond strength was for group III (17.834 ± 0.367) and the minimum shear bond strength value was for group I (8.888 ± 0.307). ARI scores showed a statistically significant differences among groups, with a high tendency toward score 1 and score 0 in all three groups.

Conclusion: High intensity LED light with low curing duration has advantage of increasing bond strength in addition to reducing chair time taken for curing procedure and enamel cleaning following de-bonding procedure without any effect on the enamel integrity.

Keywords: *LED lights, shear bond strength, ARI, orthodontic brackets, maxillary premolars, chair time.*

Introduction

Bonding of orthodontic brackets of fixed orthodontic appliance by using acid etch technique was first introduced in 1955 [1], as just auto-polymerizing materials were obtainable at that time [2]. With introduction of light-cured adhesives, these materials became widely accepted among orthodontists since they provide ample working time to accurately locate the orthodontic bracket on the enamel surface, to clean any overflow material, ease of use and allow immediate insertion of archwire [3]. In the last several years, various light-cured devices have been introduced including Tungsten-quartz halogen curing units (TQH) [2,4], Halogen light-curing units [5], argon laser, xenon plasma arc and solid-state light-emitting diodes (LED) technology [6]. These devices vary in their energy source, light intensity and wavelength [7,8]. With TQH technology just 1% of the over-all energy input is used for light emission and generated as heat with residual energy [9]. The Halogen bulbs units supply 400-900 mW/cm2, and need 40-second light curing per situate to become sufficient polymerization of adhesives [10]. Argon laser or plasma arc light curing devices are costly, complicated and of relatively large size [11].

The use of light curing LED units of gallium nitride blue light-emitting diodes in orthodontics was firstly suggested by Mills [12].Following that time, more efficient LED devices had developed in order to increase performance of photo-activation and

reduce polymerization time, so this will decrease chair time, offering more comfort to patient and fulfilling professional requirements [2, 7,13]. LED-based light sources posses many benefits as minimal heat generation, this reduced temperature because LEDs have a lifecycle over 10,000 hours ineffective of significant degradation in light output [14], small size, ergonomic, less weight, low power consumption, reduced noise generation, longer life source of radiation, light emission spectrum with most dental photo-initiator techniques using camphoroquinone as the di-ketone absorber, with the greatest absorption in the blue section of the visible light spectrum at a wavelength of 470nm [2,5,7,13,15]. Also, the LED lights are resistant to shock and vibration and do not need filters to produce blue light [2,16]. LED lights can succeed optimum result of clinical bonding with inferior curing time when compared with the conventional curing system [17-19]. For all these positive characteristics, the technology of light-emitting diode is presently the most popular method of light curing for orthodontic bracket bonding [2,15,20,21].

It is imperative to remember that high strength of bond values are inherently critical, as they can cause enamel breakages during removing of the brackets [22, 23,24]. The ARI index gives an idea about the effect of shear bond strength on the tooth.

There is a new generation of LED light cure corporate with three different intensities (standard, high power and extra power). The purpose of this study was to evaluate the effect of three different light intensities with different time exposure in vitro on shear bond strength and ARI of metal orthodontic brackets as to whether they allow more curing time reduction without reducing shear bond strength or they do not. In addition, study their effects on the ARI.

Materials and Method

Teeth Samples: Sixty extracted human maxillary first premolars were gathered from two orthodontic clinics. The teeth were cleaned off debris and saved in normal saline solution in a closed container at room temperature (22°C ± 3) and normal saline replaced continuously to avoid bacterial growth until the time of bonding procedure.

The inclusion criteria of samples included: no caries, no cracks, no visible decalcification and or hypoplastic areas (teeth were examined by using light curing unit).

Before bonding procedure, all buccal surfaces of the teeth were cleaned and then polishing with non-fluoridated pumice for 20 seconds. Teeth were irrigated with water spray for 10 seconds and then dried with triple air syringe for 10 seconds before mounting procedure. Thereafter, the teeth distributed randomly into three groups of 20 teeth in every group.

Mounting Procedure: The investigator used large fissure bur to do a retentive groove in the teeth to enhance the teeth keeping within the acrylic blocks serrated all teeth. Then, the teeth were vertically mounted in a block made from self-cure acrylic; hence, the crown was uncovered and the buccal view was directed to be parallel to the surveyor analyzing rod. Thus, the applied force would be at 90^0 angle to the bracket-tooth interface [22].

Etching and Bonding: The whole buccal surfaces of all teeth were etched with the 37% phosphoric acid gel (Etching agent, Resilience; Ortho-Technology; Fl/USA) for 20 seconds. Later, teeth were washed with copious water and dried for approximately 20 seconds until the enamel appeared chalky white. Subsequently, a primer was applied with a cotton applicator on etched buccal surface (Sealant resin, Resilience light cure adhesive; Ortho-Technology; Fl/USA). Maxillary first premolar stainless steel brackets were bonded to the teeth usage adhesive paste (Resilience light cure adhesive; Ortho-Technology; Fl/USA), positioned the bracket on the buccal surfaces of the tooth in the desired position with minimum force and following placement pushed firmly in order to be positioned accurately. After that, clean excess of adhesive paste flow out from under the bracket with a sharp scalar. Resin was cured by using Valo Ortho LED curing light (Ultradent, South Jordan, UT) (Figure 1) at the same light-tip distance (10mm) with the following procedures:

Group I: 20 teeth were cured with a standard LED curing light (1000mW/cm2) for 10 seconds, 5 seconds from medial surface then 5 seconds from distal surfaces.

Group II: 20 teeth were cured by a high-intensity LED curing light (1400mW/cm2) for 8 seconds, 4 seconds from medial surface then 4 seconds from distal surface.

Group III: 20 teeth were cured with a extra high-intensity LED curing light (3200mW/cm2) for 6 seconds, 3 seconds from medial surface then 3 seconds from distal surface.

Light intensities of VALO device was examined by using a radiometer (Demetron, Kerr Corporation, Orange, Calif) to confirm the manufacturer light intensities values before starting the study.

Figure 1: Valo Ortho LED curing light

Shear Bond Strength Test: Using a testing universal machine (model 4411; Instron, Norwood, MA, USA), at cross-head velocity about (0.5mm/min) via testing machine (Figure 2).

Specimens positioned in acrylic resin were prepared in a way that the brackets were perpendicular to the shear blade. All study groups were submitted to the shear bond strength test with placing the tip of active shear blade on the superior portion of the bracket base (Figure 3), and the force was directed to the bracket–tooth interface by a blade at a cross-head velocity of 0.5mm/minute till the bracket detached.

The maximum force applied for de-bonding the bracket from tooth surface was recorded in Newton (N). The readings were gained in kgf (Kilogram-force), changed into N (Newton), then the shear bond strength was determined by dividing the force by bracket surface area, with average surface area of the bracket base was (12.4mm^2), so the shear bond strength measured values in MPa.

Adhesive Remnant Index Assessment: Following the debonding procedure, the debonded enamel area of teeth and the brackets were checked by using a stereomicroscope with magnification of X20 (Olympus, Tokyo, Japan) in order to evaluate the ARI and at the same time carefully examine the integrity of enamel surface. Depending on ARI scores as determined by Artun and Bergland [25].

Score 0 = the enamel free from any adhesive remaining.

Score 1 = the enamel contain less than half of adhesive.

Score 2 = the enamel contain more than half of adhesive.

Score 3 = whole the enamel covered with the adhesive remaining.

Figure 2: Instron machine

Figure 3: Shear bond test

Statistical Analyses: Statistical analyses were performed using ANOVA test and LSD test to figure out any statistical difference in shear bond strength values of the three light intensities. The difference in ARI scores between the three groups was examined by Fisher exact test. The significance levels depended on statistical analysis as follows: (0.05≥P>0.01) considerably significant, (0.05 ≥ P>0.001) highly significant and (P>0.05) non-significant.

Results

Descriptive statistics for measured shear bond values of three groups were demonstrated in Table (1). The mean shear bond strength (measured in MPa), standard deviation (SD) and statistical comparisons for three groups were showed in Table (2).

The statistical analysis of the results using One-way analysis of variation (ANOVA) was related to determine any significant differences for values among groups. The ANOVA test showed that there were statistically significant differences among the three groups. The highest mean ± SD shear bond strength value was for group III (17.834 ± 0.367) MPa; whereas the lowest value was for group I (8.888 ± 0.307) MPa. Also the LSD test showed that there were statistically significant differences among the groups (Table 2).

The comparison of ARI scores of the three light intensities showed statistically significant differences, with a high tendency toward score 1 and score 0 in all three groups (Table 3). Examination of enamel surface of each tooth showed normal enamel surface without detachments or cracks.

Table 1: Descriptive statistics of shear bond strength values (MPa) for the three studied groups

Groups	Mean	SD	Minimum	Maximum
Group I	8.888	0.307	**8.412**	**9.427**
Group II	14.277	0.441	**13.810**	**14.872**
Group III	17.834	0.367	**17.087**	**18.310**

Table 2: Comparison of the shear bond strength values (MPa) among the three studied groups

Groups	Mean (MPa) ± SD	95% CL	P value	LSD*
Group I	8.888 ± 0.307	8.668-9.108	P≤0.001	2.763
Group II	14.277 ± 0.441	13.961-14.593		
Group III	17.834 ± 0.367	17.572-18.097		

*LSD= 2.763 (Any difference in means of any two groups greater than 2.763 is considered significant)

Table 3: Comparison of ARI scores among the three studied groups

Groups	Score 0	Score 1	Score2	Score3
Group1	7(35%)	8(40%)	4(20%)	1(5%)
Group2	7(35%)	9(45%)	3(15%)	1(5%)
Group3	8(40%)	9(45%)	3(15%)	0(0%)

Group 1 viz Group 2: Fisher Exact Test = 2.715, df=1 P-value =0.007**

Group 1 viz Group 3: Fisher Exact Test = 7.077, df=1 P-value =0.000**

Group 2 viz Group 3: Fisher Exact Test = 2.264, df=1 P-value =0.024*

** Highly significant. * Significant.

Discussion

Orthodontic patients request for premium orthodontic with brackets, but orthodontists are still concerned about their bond strength. So the study tried to get better and easier ways to bond the brackets used in fixed orthodontic appliances. Different recent advancements have been made to develop shear bond strength, these advancements have focused on getting better bond strength, shortening bonding time, minimizing bonding steps number, and reducing the remnants of adhesive after debonding without effect on enamel surface of the teeth.

With provision of LED lights in the markets, the manufacturers are continuously developing new LED devices with increased light intensity to reduce curing time, which subsequently reduces clinical chair time[26, 27].

These improvements have moved to create the superior bonding strength, at the same time must maintain enamel surface during treatment and after de-bonding.

There is a new generation of VALO-LED light (Ultradent Products Inc.) with three different light intensities mode and suggesting curing times for both metal and ceramic brackets (Table 3).

Table 3: VALO-LED light modes and suggesting curing times

Variables	Standard	High power	Extra power
Power (Mw/cm^2)	1000	1400	3200
Time (sec.)	1×10	2×4	2×3

Bracket debonding during treatment course can occur due to low shear bond strength [28], which will delay treatment and cause discomfort to the patient. Reynolds suggested that the lowest shear bond strength level would be about (5.6-7.8) MPa nearly for all different orthodontic tooth movements [29]. According to Reynolds lowest level, the three studied groups above the minimum shear bond level.

The present study can be considered the first study that investigated this new generation of VALO-LED light available in the Iraqi market**.**

The obtained results demonstrated that the mean shearing bond strengths of Group I, Group II, and Group III were 8.888, 14.277, and 17.834 MPa, respectively. The outcome of present study showed that there were significant differences among the three studied groups. Group I showed the lowest shear bond strength, while group III had the highest value.

ARI scores were compared among the three groups using Fisher exact test which showed significant differences and, at the same time, all three groups showed high tendency toward score 1 (40-45%) and score 0 (35-40%), which indicated that in all three groups, the adhesives mainly adhered to bracket bases not to enamel surfaces but without effecting the enamel integrity.

These results indicated that using this new generation of VALO-LED light allows increasing the shear bond strength which is the most important objective of orthodontists and at the same time reducing the time waste during curing procedure. Additionally, preserving enamel integrity throughout the orthodontic treatment and following de-bonding and reducing enamel cleaning time following de-bonding procedure, which will result in benefits to both orthodontists and patients at the same time.

Conclusion

High intensity LED light with low curing duration has the advantage of increasing bond strength in addition to reducing chair time taken for curing procedure and enamel cleaning following de-bonding procedure without any effect on the enamel integrity.

Comparative Study between Muscle-Split Versus the Classical Muscle-Cut Subcostal Incision for Open Cholecystectomy

Awni Ismail Sultan[1], Khalid Khairi Hussein[1]

[1]Department of Surgery, College of Medicine, Tikrit University, Salah Al-Deen, Iraq

ABSTRACT

Introduction: Many incisions have been advocated and used for open cholecystectomy. The right subcostal incision is commonly chosen, in which abdominal wall muscles divided in the line of incision. The aim of this study is to unreveal whether muscle splitting incision for open cholecystectomy affects operative duration and blood loss, postoperative pain, duration of hospitalisation, then subsequent local complications namely, wound infection and incisional hernia compared with the traditional rectus muscle dividing open cholecystectomy.

Methodology: Analytic study included adult cases (n=120) that were undergone a right-sided subcostal incisions for open cholecystectomy, who were not candidates for laparoscopic approach or those were converted to open version. They were randomly divided into two groups (n=60 each) depend on the operation type *viz*. classical muscle-cut subcostal incision (MCSI) group and same length, muscle-split subcostal incision (MSSI) group. Patients were examined for operative time (calculated from starting incision till closure of skin), intraoperative blood loss, postoperative pain (using the visual analogue score), and length of hospitalization. Six weeks postoperatively, all incisions were followed, and any case of surgical site infection or incisional hernia was reported.

Results: Regarding operative variables, the operative time is more in group MSSI (92.7min) with less blood loss (12.3ml) than that in group MCSI (86.4 min) with more blood loss (28.6ml). The postoperative pain is significantly less in group MSSI as compared to MCSI depending on visual analogue score, as the following: day 1 (3.44 Vs. 1.56), day 2 (1.78 Vs. 0.90), and day 3(1.18 Vs. 0.76). Six weeks postoperative follow up showed that 11 patients as 7(11.6%) in group MCSI, and 4(6.6%) of group MSSI) developed surgical site infection; all were treated as outpatient cases. Besides, 4 patients as 3 patients (5%) in group MCSI, and only 1case (1.6%) of group MSSI developed incisional hernia requiring surgical repair.

Conclusion: Muscle split subcostal incision is quite suitable for uncomplicated open cholecystectomy with less operative blood loss, less postoperative pain, earlier discharge, and less postoperative complications, namely wound infection and incisional hernia.

Introduction

The laparoscopic cholecystectomy is now considered as the "gold standard" technique for the management of gallstone disease[1]. However, open cholecystectomy still widely performed especially for cases not appropriate for laparoscopy[2], those converted to open approach, or wherever facilities for laparoscopy are unavailable especially in developing countries[3,4]. Many incisions have been advocated and used for open cholecystectomy, and the right subcostal incision is

commonly chosen[5,6]. It is the muscle division, which is supposed to be responsible for postoperative pain and the resultant local and systemic effects[7].

Theodore Kocher[8] originally described the subcostal incision; it affords excellent exposure to the gall bladder and biliary tract and can be made on the left side to afford access to the spleen[8.] It is of particular value in obese and muscular patients and has considerable merit if diagnosis is known and surgery planned in advance[9]. The subcostal incision is started at the midline, about 2-5 cm below the xiphoid and extends downwards, outwards and parallel to and about 2.5cm below the costal margin[7]. Extension across the midline and down the other costal margin may be used to provide generous exposure of the upper abdominal viscera. The rectus sheath is incised in the same direction as the skin incision, and the rectus muscle is divided with cautery; the internal oblique and transversus abdominis muscles are divided with cautery[7,10]. Special attention is needed for control of the branches of the superior epigastric vessels, which lie posterior to and under the lateral portion of the rectus muscle. The small eighth thoracic nerve will almost invariably be divided; the large ninth nerve must be seen and preserved to prevent weakening of the abdominal musculature. The incision is deepened to open the peritoneum[7,11].

In the recent years, many surgeons have advocated the use of a small 5-10cm incision in the subcostal area for cholecystectomy which is known as mini cholecystectomy. This incision is similar to the Kocher's incision except for the length of the incision[12]. The major advantages of this incision are lesser postoperative pain, early recovery from the surgery and return to work and good cosmetic results[13]. But a disadvantage is less exposure, which can be dangerous in cases of difficult anatomy or lot of adhesions and chances of injury to bile ducts or other structures[14,15]. It is the muscle division, which is supposed to be responsible for postoperative pain and the resultant local and systemic effects[16].

This study was undertaken to know whether the muscle splitting technique for open cholecystectomy affects operative duration, blood loss, postoperative pain, and encourages early mobilization with a reduction in hospital stay, and whether it relates to surgical site wound infection or hernia compared with the traditional rectus muscle dividing open cholecystectomy.

The aim of this study is to reveal whether muscle splitting incision (MSSI) for open cholecystectomy affects operative duration and blood loss, postoperative pain, duration of hospitalisation, then subsequent local complications viz. wound infection and incisional hernia compared with the traditional rectus muscle dividing open cholecystectomy.

Materials and Method

Patient's Enrollment: This study has been conducted at the Kirkuk General Hospital, for the period from December 2016 to August 2018. The patients (n=120) with ages ranging between 20-60 years, who were either contraindicated for laparoscopy, or those were converted from laparoscopic to open procedure. Their written informed consent was taken before operation. Classical muscle-cut subcostal incision (MCSI) group was included 42 females and 18 males. While, the same length muscle-split subcostal incision (MSSI) group includes 39 females and 21 males. All patients with features of acute cholecystitis or jaundice, diabetic patients and those on chronic steroid use were excluded from the study.

All patients were investigated for confirmation of diagnosis and anesthetic fitness. Patients were randomized in two groups, muscle splitting (MSSI) and muscle dividing (MCSI) groups and except for the manner in which anterior abdominal wall was dealt with, the cholecystectomy was otherwise standard and same for both the group. Incision length was kept less than 12cm.

Surgical Procedure: A transverse subcostal incision was used in all cases. Anterior rectus sheath was divided in the line of the incision. Rectus muscle was cut along the line of incision in a muscle cutting group, but in muscle splitting group rectus muscle was split bluntly in the line of its fibers approximately 2.5 cm to the right of linea alba. Rectus muscle was then retracted medially and laterally to expose the posterior rectus sheath which was then divided vertically and peritoneal cavity entered in both of the groups. Intraoperatively, the following parameters were measured: the operative time calculated from the start of incision till the end of surgical operation, and the amount of blood loss by weighing the blood-soaked mops and swabs both before and after the procedure.

Postoperatively, we used visual analogue score (after explaining it to patients) with 10 degrees to evaluate the severity of postoperative pain, both at the night visit and

at the next morning visit. We also notified the duration of hospital stay. Then, we followed the cases for six weeks to check for signs of severe surgical site infection and incisional hernia. Both groups were compared, and the results assessed statistically.

Results

Patients were divided into two equal groups (60 patients in each). In the group Demographics of patients were comparable in each group as shown in Table 1.

Table 1: Demographics of Patients in Both Groups

	Females	Males	Mean age (years)	P value
MCSI	42	18	41.6	0.07
MSSI	39	21	42.8	0.08

Regarding operative findings, the mean operative time in general was higher in group MSSI (92.7min), than in group MCSI (86.4min), while the mean blood loss was much higher in group MSSI (12.3ml vs. 28.6ml), see table below.

Table 2: Operative time and blood loss in both groups

	Mean Operative Time (min)	Mean Operative Blood Loss (ml)
Group MCSI	86.4	28.6
Group MSSI	92.7	12.3
P value*	0.001	0.001

Used two-sample t-test*

Postoperative pain was assessed for 3 days following surgery, and was noticed to be higher in group MCSI than group MSSI, as following day 1 (3.44 Vs. 1.56), day 2 (1.78 Vs. 0.90), and day 3 (1.18 Vs. 0.76) as shown in Table 3.

Table 3: Mean visual analogue score for postoperative pain in both groups

Postoperative Days	Visual score in MCSI	Visual score in MSSI	P value*
1	3.44	1.56	0.001
2	1.78	0.90	0.001
3	1.18	0.76	0.001

Used two-sample t-test*

We reported earlier hospital discharge for patients in group MSSI, that 49 patients (81.6%) were discharged at the second postoperative day, in comparison to only 13 patients (21.6%) in group MCSI.

Most patients with group MCSI 28(46.6%) were discharged on the 3rd postoperative day, while only 9 patients (15%) from group MSSI left the hospital on that day. On the other hand, the 4th postoperative day, all the remaining patients from both groups were discharged home, as follows 19 patients (31.6%) and 2 patients (3.3%) from groups MCSI and MSSI, respectively.

Table 4: Number of patients fit for discharge in both groups

Postoperative Days	MCSI	MSSI	P Value*
2nd	13(21.6%)	49(81.6%)	0.001
3rd	28(46.6%)	9(15%)	0.006
4th	19(31.6%)	2(3.3%)	0.001

*Chi-square test was used.

Six weeks postoperative follow up showed a lower incidence of surgical complications in group MSSI. Surgical site infection occurred in 7 patients (11.6%) in group MCSI, vs. 4 cases (6.6%) in group MSSI, while incisional hernia documented in 3 patients (5%) in group MCSI, vs. just 1 patient (1.6%) in group MSSI, as shown in Table 5.

Table 5: Six weeks postoperative complications in both groups

	MCSI	MSSI	P value*
Wound infection	7	4	0.38
Incisional hernia	3	1	0.32

Chi-square test was used*

Discussion

In the present study observed that the blood loss in group MCSI is more than group MSSI, but with less overall postoperative time. Muscle cut is associated with division with all segmental blood vessels, and muscle fibers[7]. This may explain the increased blood losses. Regarding shorter operative time in group MCSI, it's likely due to the better access and view gained by muscle cutting[8,16], which may be reflected in a shorter duration required to accomplish the surgery.

The patients of group MSSI experienced less postoperative pain than those in group MCSI. Decrease in pain is mainly attributed to the splitting of rectus muscle rather division of muscle. When muscle is cut, many segmental blood vessels and nerves get divided which in turn make muscle spasm and leads to pain[7,16]. Merrill attributed less pain to intact vascularisation and innervation of the muscle with splitting incision[3].

Baguley also reported that muscle splitting technique appears to be superior in terms of postoperative pain and discomfort to the muscle dividing method[16]. Other authors reported similar results in regard to less pain and even less postoperative analgesics requirements. Many authors reported that the mean postoperative analgesic doses required for each patient is significantly less[12].

Patients were considered fit for discharge when they had no respiratory problem, moved bowel, no need of regular intake of analgesics, took food and drugs orally and were ambulatory[7]. In our study, 49 patients (81.6%) were discharged at second postoperative day, in comparison to only 13 patients (21.6%) in group MCSI. Thus group MSSI patients were fit for discharge earlier as compared to group MCSI patients. This was mainly because of less pain and early mobility.

Less postoperative pain encourages early ambulation, earlier discharge from hospital and faster return to work[17]. Baguley et al.[16] reported that 100% patients of muscle splitting group were fully mobile by day 3 as compared to 75% patients with muscle dividing group[16]. In this era of concern for the expense of health care delivery, strategies that reduce the length of hospitalisation and decrease duration of disability stimulate tremendous interest among the medical and lay communities. The muscle splitting incision is superior to muscle dividing incision in term of less pain, early mobility, less physiological alteration, decreased morbidity and hospital stay[7,14].

Wound infection was shown to be more common in group MCSI, most likely due to haematoma collection following blood vessels division, besides local ischemia that ensues. Wound infection is probably an important risk factor for the development of incisional hernia and wound dehiscence[8]. The local nerves divided by the cut through incisions increase the possibility of having postoperative incisional hernia[17]. Generally speaking, transverse and oblique incisions seem to cause less wound dehiscence than the midline and paramedian incisions[18]. Yet, as the subcostal incision has an oblique medio-proximal direction, it tends to cut most nerves, segmental blood vessels and muscle fibres perpendicularly. The partial denervation of the abdominal wall ensues with permanent muscle weakness and numbness[7]. Burger et al[8], found that muscle-split abdominal incisions cause less risk for wound dehiscence than their muscle cut surgical wound versions[8].

Conclusion

The muscle split subcostal incisional can be suitable for uncomplicated open cholecystectomy, with less blood loss, less postoperative pain, earlier discharge from hospital and less postoperative wound infection and less incisional hernia as compared to classical muscle cut subcostal incision.

ABSTRACT

Background: Intrauterine growth restriction (IUGR) is a complex placental vascular disease with augmented perinatal morbidity and mortality caused by various fetal, maternal as well as placental factors. This study was conducted to find any association of whichever placental histo-morphometric findings to encounter any sole placental based issues influencing fetal growth and development, which might be derived from neither fetal nor maternal basis giving consideration for any probable analogous problem for prospect pregnancies.

Method: Placentas of 100 IUGR newborns (group-I) and another 100 from normal body weight newborns (group-II) were obtained between 2nd of February of 2018 and 31th of January 2019 to be studied histometrically for the number of: nuclei of syncytiotrophoblast cells, syncytial knots, chorionic terminal villi, blood vessels, and the perimeter and surface area of the villous sections, all were statistically evaluated.

Results: Morphometric data confirmed that placentas of group-I had significant higher number of syncytiotrophoblasts nuclei, knots, terminal villi, blood vessels, terminal villi perimeter and cross-sectional surface area than group-II.

Discussion: Encountered placental histological changes for idiopathic IUGR newborns raised suspicion it was caused by pure placental factors and could be compensation to adjust the functional requirement during placental insufficiency.

Conclusions: Newborns with idiopathic IUGR could be resulted from pure placental factors which might be ascertained by histological assessment of placental tissues.

Keywords: *Idiopathic IUGR, Placenta, Terminal villi perimeter, Terminal villi cross surface area, Syncytial knots.*

Introduction

Intrauterine growth restriction (IUGR) is still a significant problem worldwide [1], and problematical placental vascular disease ensuing a low birth weight and/or preterm delivery with increased perinatal morbidity and mortality [2-4]. IUGR may be originated by various feto-maternal and/or placental factors [2-5].

The placenta is the least celebrated human appendage, yet an attractive model for global medical investigations[6&7]. As placental growth is imperative in the ultimate health of the mother and her fetus, a complete knowledge about placental structures and physiology is surely required [8 & 9].

After birth, the placenta could be regarded like an investigational animal for wide assortments of making inquiries [10]. Nevertheless, it is the merely organ

recognized to be produced in parenthood, then gets a distinctive fate[11].

About its constitution; placenta has tissues, in cooperation, from mother and fetus. The embryonic surface, chorion, which is created by trophoblasts, whereas the maternal surface is referred to as decidua basalis. The trophoblasts take in cytotrophoblasts along with syncytiotrophoblasts that build the chorionic villi collectively to offer an exchange plane course. Thousands of chorionic villi branching numerous times to be soaked in maternal blood lakes for transmission of gasses and nutrients [12 &13].

Material and Method

This work was carried out through Department of Anatomy, College of Medicine, Al-Mustansiriyah University, in assistance of Department of Gynecology and Obstetrics at Fatima Al-Zahraa Administrative Hospital, Al- Khadhraa Private Hospital and Al-Yarmook Teaching Hospital in Baghdad, Iraq. Permitted by the confined scientific committee of each of these medical institutes. A total of 200 mothers, along with their newborns and placentas were incorporated in this study. These mothers were admitted to delivery room for normal vaginal deliveries at these hospitals. All were chosen at term pregnancy (of 38-40 weeks), and non-smoker apparently healthy and normal women, according to their history, clinical assessments, laboratory tests and ultrasound check. Fetal state also was verified by Doppler ultrasonic exam. Any mother had difficult or delayed labor and any postpartum maternal death also had been ruled out from this work. A verbal consent was gained from each mother to be a component of this work. All fetal IUGR was considered to be idiopathic, given that there were no apparent maternal or fetal basis.

Placentas were divided into two groups. Each group consisted of 100 newborns with everyone own placenta. The 1st group holds placentas of infants having idiopathic IUGR (Group-I), whereas the 2nd group embraced placentas of infants having normal average body weight (Group-II), which was regard as the control group.

Placentas were right away examined grossly after being expelled, and tissues were taken from the central part of cotyledon at half way between the fetal surfaces and maternal and at middle of the widest diameter extending from the insertion of umbilical cord to the periphery of placenta [11 &12]. Every block was roughly 1×1×1 cm and was organized for schedule paraffin section to be fixed and stained by haematoxylin and eosin. Then, from every tissue block five sequential sections of about 5 μm thicknesses were obtained and inspected histologically by light microscopy [14&15]. Morphometric histological data were gained using computerized program specifically, *Motic Image Plus 3*, at different magnifications, and the estimated data of 6 histological parameters were taken randomly from 5 fields achieved from the center and four corners of each specimen, then images were imprisoned in high clarity using the built-in camera to obtain mean number of the followings parameters: (1) nuclei of syncytiotrophoblasts, (2) syncytial knots, (3) chorionic terminal villi and (4) cross-sectioned blood vessels of the villous core. Then after, three randomly selected terminal villi having dissimilar sizes "small, medium and large" were considered in every section and the following two factors were anticipated: (5) mean perimeter of the villous sections in μm and (6) mean villous surface area in 1 μm^2.

The estimated data were deliberated as mean ± Standard deviation (SD), then by means of "Paired Samples T- test" with the program namely "*Statistical Package for Social Sciences* SPSS Statistics Version 25". Statistical significance of the comparable variables were evaluated and p value was equal or less than 0.05[16].

Results

The morphometric data obtained from tissue images at 400× magnification revealed the followings: As shown in table 1 and figure 1, firstly, the nuclei of the coating syncytiotrophoblasts zone of IUGR group (Group-I) were significantly more packed than the control group (Group-II), forming nearly a continuous layer enveloping core of the villi. Secondly, the number of syncytiotrophoblast knots at the peripheries of villi was significantly superior in group-I too. Thirdly, group-I have significant higher number of chorionic terminal villi than group-II. In addition, there were significant more villous connective tissue cells and fibers, allowing diminutive intervillous spaces surrounding these villi. Furthermore, the number of blood vessels inside the core of villi was also significantly higher in group-I than group-II with extremely significant statistical difference. Lastly, the mean perimeter and cross-sectional surface area of the terminal villi was significantly higher in group-I too as in table 1 and figures 2 & 3 respectively. All mentioned mean differences between the groups were statistically highly significant with p value extremely less than 0.05.

Table 1: No. of Syncytiocytotrophoblast's nuclei, no. of Syncytiocytotrophoblasts knots, no. of villi and no. of blood vessels in placental tissues of fetuses having IUGR (group-I) and fetuses having normal wt. (control/group-II).

	Histological parameters	Groups	N	Mean ± SD	p value
1.	No. of Syncytiocytotrophoblast's nuclei	Group-I (IUGR)	100	14.567 ± 4.419	0.0001
		Group-II (Control)	100	9.132 ± 3.411	
2.	No. of Syncytiocytotrophoblasts Knots	Group-I (IUGR)	100	2.014 ± .337	0.0001
		Group-II (Control)	100	0.912 ± .276	
3.	No. of Villi	Group-I (IUGR)	100	11.209 ± 5.117	0.0016
		Group-II (Control)	100	9.132 ± 3.978	
4.	No. of blood vessels	Group-I (IUGR)	100	6.311 ± 1.402	0.0001
		Group-II (Control)	100	4.576 ± 1.236	
5.	Perimeter of the villi in µm	Group-I (IUGR)	100	143.612 ± 41.022	0.0001
		Group-II (Control)	100	112.004 ± 19.643	
6.	Sectional surface area of the villi in μm^2	Group-I (IUGR)	100	11345.674 ± 236.127	0.0001

Discussion

Placenta is still an imperative matter of interest for medical researches [8&9], so it was preferred in the existing study. It is considered to be as a mirror for the fetal intrauterine state [17]. The vital triangle consisted of mother, fetus and placenta is regarded as an active balanced milieu, hence, any harm to one of them would surely influence the others [18&19]. So many previous studies had documented that a pure placental factor was the solitary cause in some IUGR cases [20].

Normal birth-weight neonates were considered to be the control group [21&22]. In this revision cases of IUGR due to apparent maternal and/or fetal factors were kept out, hence the included cases of IUGR were considered to be purely due to placental sources. Histological and morphometric studies of human placentas were looked upon by many researchers just as a meandering approach to study the histo-physiology of pregnancy [23]. This study

included three varieties of villi, depending on previous comparable work [23]. The program "Motic Image plus 3" which was used in this study, was exceptionally useful to quantify the asymmetrical and compound constitutions of the terminal chorionic villi pictures, and evaluate the data in a mathematically balanced method. Tissue samples were obtained just from the cotyledon just at midway between the fetal and maternal surfaces and in the middle of largest diameter between the cord insertion and periphery, since this practice was used by other workers, to stay away from any structural tissue variation between subchorionic and parabasal regions[24&25].

By examination of haematoxylin and eosin stained samples of mutually groups: Table 1 and figure 1 shows the syncytiocytotrophoblast's nuclei number was found to be increased in group-I, which might be as a compensatory means to tolerate placental insufficiency [26]. It had been stated that there is a higher syncytiocytotrophoblast's nuclei number in cases of stillbirth, poor fetal outcome and low birth weight [27&28]. Also augmented number of syncytial knots in group-I similar as results noticed in pre-eclampsia, toxaemia of pregnancy and idiopathic intrauterine growth retardation [29]. Profusion of syncytial knots are usually regarded as an indicator of oxidative stress in consequence of deprived fetal circulation [28]. The greater number of larger terminal villi containing more connective tissue cells and fibers in group-I which possibly be caused by diminished fetal villus perfusion producing activation and proliferation of fibroblasts within villous stroma [28 & 30]. The increased number of blood vessels in placentas within the villous core of group-I, which was regarded as a placental compensatory response to recover chronic low down blood perfusion and hypoxia [29 & 30]. Table 1 and figure 2 showed that the mean of perimeters of villous sections was increased in group-I which represented the feto-maternal substitution surface mimic what is seen in placentas of diabetic pregnant mothers [31]. Table 1 and figure 3 illustrated larger cross-sectional surface area, in placentas of group-I. This surface area signifies the crossing point for substitution between fetal and maternal flow, therefore, it is a milieu of medical investigate till now [29]. The instantaneous data in group-I were comparable to that of interruption in placental tissue maturation and they were just as compensatory mechanisms to get better placental function [29 & 31]. It might be concluded here that idiopathic IUGR, with the presence of apparently average healthy mothers, could be due to pure placental factors which might be ascertained by histological assessment of placental tissues.

Such study was assumed to view a number of morphometric histological microscopic modifications in the placenta, in casing of wholesome placental cause of IUGR in order to take care of the future pregnancy and to prevent as much as possible such similar IUGR condition for maintenance of fetal and mother optimal wellbeing as well as decreasing neonatal loss. Moreover, this instant results might confirm the idea of existence of a remarkably related ***"birth triangle***"; formed of fetus, placenta plus mother [32].

Evaluation of Polycystic Ovarian Syndrome Women as a Result of Clomiphene Treatment

Zainab Abdul wahed Naji

MSc, Clinical Biochemistry, Al Iraqia University, Baghdad, Iraq

ABSTRACT

Polycystic ovary syndrome (PCOS) is a disorder that affects a woman's hormone levels Clomiphene citrate is used generally as an initial treatment. In the present study, LH, FSH, testosterone, progesteron and oestrogen were analysed for the women undergoing clomiphene in Iraq. Total 73 infertile PCOS women (age ranging from 19-33) were enrolled in the study and they were divided into 3 groups depending on the clomiphene treatment where, group 1 patients (n=21) were given 50mg, group 2 (n=23) were given 100mg and group 3 (n=28) were given 150mg dose of clomiphene. The serum leutinizing hormone and testosterone found to be decreased after treatment, while follicle stimulating hormone and estrogen showed the opposite trend. When various parameters are studied such as ovary size, number of follicles, endometrium layer, it was found that, ovarian size after treatment they are decreased but did not show any significant difference.

Keywords: *Polycystic ovary syndrome, clomiphene, leutinizing hormone, testosterone*

Introduction

Infertile women about 20-40% are having ovulatory disorders and PCOS is the most common cause of ovulatory dysfunction, which represents approximately 70% of cases[1,2]. Clomiphene citrate is used generally as an initial treatment[3]. Clomiphene citrate utilization shows discrepancy between the high rates of ovulation (60-85%) and the much low rates of conception (20-40%) per cycle[1,4]. In case of pregnancies where we use clomiphene citrate, 7-13% shows multiple gestations[1,2,4]. The women taking Clomiphene citrate shows certain common side effects such as 20% vasomotor symptoms, 5% adnexal tenderness, 3% nausea, 1% headache, and rarely blurring of vision of scotoma[2]. The ovarian hyperstimulation syndrome (OHSS) incidence in patients treated with clomiphene citrate is rare, but it may lead to multiple follicular development with OHSS risk and in patients with PCOS shows multiple pregnancies[1,5].

The polycystic ovary syndrome (PCOS) approximately accounts for 75% of the cases and is the commonest cause of anovulatory fertility[6]. In the patients with PCOS the first agent to be introduced in general practice for ovulation induction is clomiphene citrate (CC) and is still considered the first therapeutic option for PCOS[7]. The choice of clomiphene is because relatively safe nature, can be administered easily, and is inexpensive. It is important to know that the first line treatment is diet and exercise[8-10]. Women with PCOS shows various metabolic disorders including increased serum levels of luteinizing hormone (LH), testosterone, and prolactin which could influence women health in long term[11-13]. The clomiphene citrate with an injection of human chorionic gonadotropin administration is one of the most common therapies[14]. In women with PCOS clomiphene is used to improve ovarian function, menstrual pattern and glucose metabolism[15-16].

Estrogen compounds and clomiphene have structural similarity which may have negative effect on endometrial thickness[16-17]. For the treatment of infertility in male clomiphene citrate is most commonly prescribed. In the hypothalamus and pituitary, clomiphene citrate which is synthetic nonsteroidal drug which acts as an antiestrogen and competitively binds to oestrogen receptors. The normally low levels of oestrogen on the male hormone axis are blocked which results in increased secretion

of GnRH, FSH and LH. These hormone's enhanced output increases testosterone production and sperm production[18]. In the present study, LH, FSH, testosterone, progesteron and oestrogen were analysed for the women undergoing clomiphene in Iraq.

Material and Method

Enrollment of the Patients: Total seventy three infertile patients (age 19-33) with polycystic ovary syndrome (PCOS) were enrolled in the present study. Oral consent was obtained before enrollment.

Treatment of Clomiphene: The enrolled patients were randomly divided into three groups on the bases of their clomiphene treatment. The patients were given Clomiphene at various doses such as 50mg (n=21), 100mg (n=23) and 150mg (n=28).

Blood Collection and its Separation: The blood was collected before (pre-treatment sample) and after (post-treatment sample) treatment to check its effect. The collected samples were centrifuged at 3000 rpm for 10 minutes, and serum was separated within 30 minutes from the time of blood collection. Serum was aliquots in an Eppendorf tube and frozen in the deep freeze at -40°C.

Serum of all patients was subjected for the estimation of the luteinizing hormone and FSH estimation. The estimation of Testosterone, progesteron and oestrogen were carried out as per manufacturer's instructions (VIDAS® system, Biomerieux, Italy).

Statistical Analysis: The results were represented as mean ± Stand error (n=21). The data were processed in the Microsoft excel program and graphpad prism 5 (version 5.01).

Results

In the present study we took total 73 infertile patients with age ranging from 19-33. These all patients are suffering with polycystic ovary syndrome (PCOS). These are divided into 3 groups depending on the clomiphene treatment where, group 1 patients (n=21) were given 50mg clomiphene, group 2 (n=23) were given 100mg and group 3 (n=28) were given 150mg dose of clomiphene. The blood was collected before (pre-treatment sample) and after (post-treatment sample) treatment to check its effect. Luteinizing hormone, FSH, Testosterone, progesteron and oestrogen from blood Serum of all patients was studied. The serum leutinizing hormone and follicle stimulating hormone are determined it is found that before treatment the LH levels were high which fall after the treatment and they shows significant level of difference. As the concentration of clomiphene is increased level of LH shows difference i.e. low value. It shows that high concentration of clomiphene (150 mg) shows high level of significance.

When serum FSH was determined we can find that FSH levels were low before treatment and which increases after treatment. The clomiphene concentration at 150 mg shows increase in FSH levels but show non-significant difference. When LH and FSH ratios are calculated together clomiphene concentration at 150 mg shows good results i.e. lowered level of both LH and FSH, and hence shows significant level of difference.

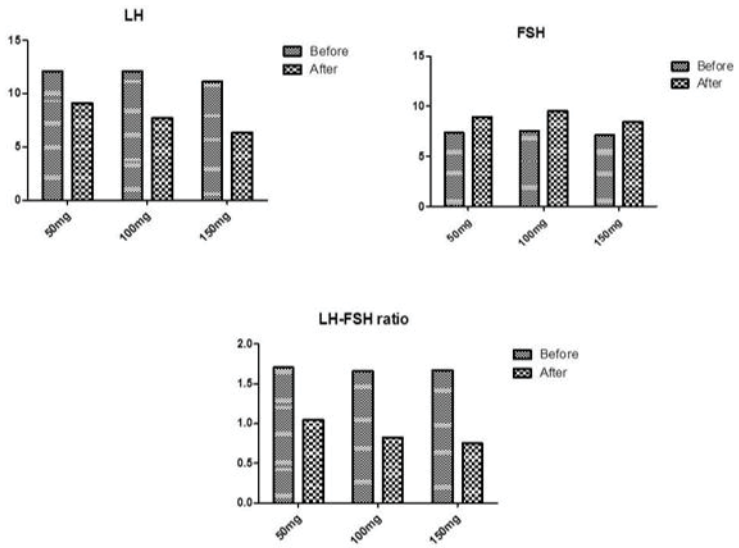

Figure 1: Serum LH and FSH levels and their ratio

We also analyzed the testosterone, progesterone, oestrogen levels, we found that before treatment the testosterone levels were high, which get lowered after the clomiphene treatment, which showed significant difference. The oestrogen levels were low before treatment which are increased after treatment, where concentration of clomiphene did not show any significant difference but after treatment if compared to before treatment, all the concentrations shows significant difference level.

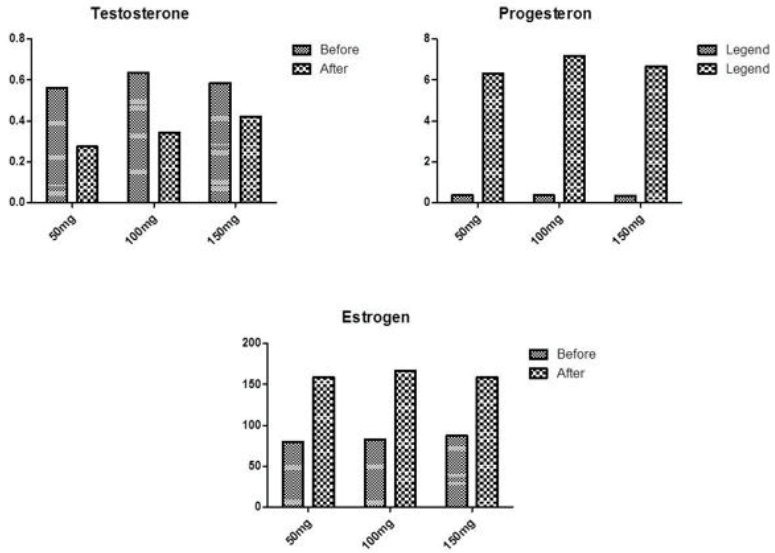

Figure 2: Serum testosterone, progesterone and estrogen levels

When various parameters are studied such as ovary size, Number of follicles, Endometrium layer, it was found that, ovarian size after treatment they are decreased but did not show any significant difference. When number of follicles is determined before and after treatment it showed significant difference. Endometrium layer when determined showed non-significant difference level.

Table 1: Effect of various concentrations of clomiphene on ovary size, number of follicles and endometrium layer

Parameter	Treatment	50mg	100mg	150mg
Ovaries size	Before	17.14 ± 1.19	16.06 ± 1.12	15.39 ± 1.59
	After	14.25 ± 1.79	14.01 ± 1.81	13.64 ± 1.63
Number of follicles	Before	13.90 ± 1.86	13.13 ± 1.35	13.71 ± 2.08
	After	18.33 ± 1.15	17.47 ± 0.94	17.53 ± 0.744
Endometrium	Before	4.29 ± 1.10	3.52 ± 1.47	4.14 ± 1.11
	After	6.45 ± 0.57	6.58 ± 0.95	6.4 ± 0.70

Discussion

In the present study total 73 patients with age ranging from 19-33 were selected. All these patients are suffering with polycystic ovary syndrome (PCOS). These are divided into 3 groups, group 1 patients (n=21) were given 50mg clomiphene, group 2 (n=23) were given 100mg and group 3 (n=28) were given 150mg dose of clomiphene. Further blood samples are drawn and tested for serum FSH, LH levels and testosterone, progesterone and estrogen levels are determined.

In the present study, we found nonsignificant difference in FSH and significant difference in LH. Where, Sheikh-El-Arab et al[19] found significantly higher values of FSH (p-0.02), and had significantly thicker endometrium (p-0.02). Rebecca et al[20] found that significant increase in LH and FSH levels in the clomiphene citrate group if compared with control group (P<0.01: P<0.02). Serum thyroid levels in CC-treated group is higher as compared to the placebo group (P<0.01).

Safeer et al[21] found that serum testosterone showed highly significant increase (P<0.05), serum FSH showed non- significant increase which is same like present study report. Gonzales et al[22] showed highly significant increase in the testosterone serum level (P<0.05), and increase in mean serum level of FSH (P<0.1).

Shekoufeh et al[23] found that, in some experiment group FSH significantly reduced if compared to control and in group (p<0.001). The results also showed that estrogen level was increased significantly in all groups (p<0.001). Also, the progesterone levels in all groups decreased significantly if compared to control (p<0.001). Kerin et al[24] and Dicky et al[25] also found similar results like present study.

Ethical Clearance: The blood was collected from AL_ Numan hospital after their investigation. Oral consent was taken before enrolled the patients in the study.

Variance Analysis of Acute Myocardial Infarction Clinical Pathway in The Era of National Health Insurance

Fadlia Fardhana[1], Kurnia Sari[2], Atik Nurwahyuni[2]

[1]Post Graduate Student of Public Health, Department of Health Policy and Administration, [2]Department of Health Policy and Administration, Faculty of Public Health, Universitas Indonesia

ABSTRACT

Acute myocardial infarction (AMI) was responsible for 7.4 million deaths worldwide and could cause complications, disability, productivity loss with high cost. Since Indonesia has implemented the National Health Insurance, cost efficiency in maintaining clinical practice quality is needed. Clinical pathway is a tool for maintaining quality of clinical process and cost by setting intervention based on time and sequence. Analysis of variance was carried out to evaluate the implementation of clinical pathway. Data from medical and billing record were reviewed and analyzed by Clinpath Evaluation Tool version 2.0. Characteristic of patient, average utilization of medical treatment and clinical tests, and drugs utilization were obtained from this tool. Hospital has played a good role in maintaining quality of health services. This can be seen from the accordance between clinical practice and clinical pathway in majority of the medical treatments and drugs administration. Average length stay was 4.65 days with the median of 6 days, and this was close enough with clinical pathway. Administration of oxygen and isotonic fluid were the highest average utilization in clinical practice. Nitrate and anti-platelet were the major drugs used in medication. Wide variations only occurred in laboratory tests (variation: 86.96%) and should be evaluated, considering variation could affect quality of services and moreover on the cost of treatment.

Keywords: *clinical pathway; myocardial infarction; implementation pathway; variance analysis.*

Introduction

As Indonesia has been entering the era of National Health Insurance in 2014, the quality of health services while maintaining cost efficiency became one of the biggest issues in health care delivery. The National Health Insurance in Indonesia introduced new health care financing policy from fee for service to case-based scheme. This financing method was called Indonesian Case Base Group (INA-CBG) tariff and based on the Minister of Health Regulation number 52 and 64, 2016. INA-CBGs uses codification system from diagnosis and clinical procedure or clinical pathway from certain disease[1,2].

The new Health Insurance in Indonesia brought challenge to health care provider. Health care provider needs to use resources efficiently to reduce service's cost while still maintain the quality in patient care. Clinical pathway is one of the most popular disease management tools to overcome this problem[3]. Clinical pathway provides sequence and timing of healthcare practitioner's intervention to achieve outcome therapy with optimal efficiency[4]sequencing and timing of interventions by healthcare professionals for a particular diagnosis or procedure. It is a relatively new clinical process improvement tool that has been gaining popularity across hospitals and various healthcare organisations in many parts of the world. It is now slowly gaining momentum and popularity in Asia and Singapore. Clinical pathways are developed through collaborative efforts of clinicians, case managers, nurses, and other allied healthcare professionals with the aim of improving the quality of patient care, while minimising cost to the patient. Clinical pathways have been shown to reduce unnecessary variation in patient care, reduce delays in

discharge through more efficient discharge planning, and improve the cost-effectiveness of clinical services. The approach and objectives of clinical pathways are consistent with those of total quality management (TQM. Research in Hong Kong and Singapore stated that the implementation of clinical pathway for AMI impacted the decreasing length of stay variation, mortality rate, and complication rate[4]sequencing and timing of interventions by healthcare professionals for a particular diagnosis or procedure. It is a relatively new clinical process improvement tool that has been gaining popularity across hospitals and various healthcare organisations in many parts of the world. It is now slowly gaining momentum and popularity in Asia and Singapore. Clinical pathways are developed through collaborative efforts of clinicians, case managers, nurses, and other allied healthcare professionals with the aim of improving the quality of patient care, while minimising cost to the patient. Clinical pathways have been shown to reduce unnecessary variation in patient care, reduce delays in discharge through more efficient discharge planning, and improve the cost-effectiveness of clinical services. The approach and objectives of clinical pathways are consistent with those of total quality management (TQM.[11]. Other research also found that implementation of clinical pathway can decrease clinical practice variation and cost of treatment[5,6]acute myocardial infarction (AMI.

Acute myocardial infarction (AMI) is one of the manifestations of coronary heart disease (CHD) and part of cardiovascular diseases (CVDs). Cardiovascular diseases were the cause of 31% deaths globally and 17.7 million people were estimated to die from CVDs in 2015. Among the 17.7 million, 7.4 million deaths were caused by coronary heart disease[7]. In Indonesia, coronary heart disease is the highest cause of death, which was the cause of 14.2% deaths in 2016[8]. Coronary heart disease became the global burden and also impacted the economy. In United States, myocardial infarction caused 1.1 million hospitalizations and costed at least US$ 450 billion[9]. Besides death, AMI can cause complications, disability, and productivity loss[10].

Clinical pathway should be evaluated constantly to maintain quality from the healthcare provider. Variance analysis could be used to evaluate and analyze the implementation of clinical pathway. Variance is clinical practice deviation from the standard in clinical pathway[12]. Deviation in this study includes variation of length of stay, timing of intervention, and drugs administration. The purpose of this study is to present clinical practice variance for acute myocardial infarction as basic evaluation of the clinical pathway.

Material and Method

This research was conducted in private hospital in Bogor. Data were collected prospectively from medical record and billing unit from October 2016 to March 2017. Medical record and billing unit in hospital provided patient's data recapitulation digitally, and then the recapitulated data became the data source in this study. Date of birth, sex, payment method, and date of patient's admission and discharge were gathered from medical record. Doctor specialist visit (frequency of doctor's visit), medical treatment, laboratory test, radiology, and drugs administration were gathered from billing record.

All inpatient acute myocardial infarction with code ICD-10 I21.9 were included in this study. An exclusion criterion was an inpatient that had secondary diagnosis. All data recapitulations were analyzed by Clinical Pathway Evaluation Tool version 2.0. This tool is in public domain. The information that can be obtained from this tool were characteristic of patient (age, sex, payment method, and length of stay), average utilization of medical treatment and clinical tests, and drugs utilization. Analysis variance were carried out by comparing average utilization and standard clinical pathway in hospital.

Result

General Characteristic: There were 233 patients with acute myocardial infarction from October 2016 to March 2017. Patients that had secondary diagnostic were excluded and 10 patients were left to be analyzed. Among 10 patients, 8 patients were male (80%) and 2 patients were female (20%) with the average age of 60.2 years old (range from 42-75 years old). 90% patients choose National Health Insurance as their payment method and 10% patients payed privately. Average length of stay (ALOS) was 4.65 days with the median of 6 days (range from 2-7 days).

Medical Treatment Utilization: Utilization can be interpreted as the amount of clinical practice that were given to all patients from patient's admission to discharge

or per one period of care. Medical treatment variation was cardiopulmonary resuscitation. The highest average utilization was administration of isotonic fluids and the lowest was ECG diagnostic, which were 14.8 and 1.0, respectively. Other average utilization of medical treatment can be seen in Table 1.

Table 1: Medical Treatment Utilization

Medical Treatment	Utilization according to the clinical pathway	Average Utilization in clinical practice
ECG diagnostic	1.0	1.0
Oxygen delivery	3.0	7.6
IV isotonic fluid	7.0	14.8
ECG serial	5.0	5.3
Specialist's visit	7.0	6.5
Vital sign monitoring	7.0	3.9
Cardiopulmonary resuscitation	-	0.1

Drugs Utilization: The main principal for AMI medication is to restore blood flow in blood vessel to the heart as soon as possible. Drugs that were used according to the clinical pathway were drugs from classification of nitrate, anti-platelet, anti-coagulant, statin, beta blocker, ACE inhibitor, angiotensin receptor blocker (ARB), anti-depressant, and anti-inflammatory steroid. Beside drugs that were included in clinical pathway, patients were also given other drugs such as gastroprotective drugs, drugs for diabetes, antibiotic, anti-hypertensive and diuretics. This study only included patients that did not have secondary diagnosis, but evidently there were still some other drugs that were given to patients. Average utilization for medication was presented in Table 2.

Table 2: Drugs Utilization

Drugs Classification	Utilization according to the clinical pathway	Average Utilization in clinical practice
Nitrate	+	28.5
Anti-platelet	+	17.0
Anti-coagulant	+	3.1
Statin	+	3.0
β-blocker	+	2.3

Conted…

Angiotensin Receptor Blocker (ARB)	+	1.1
Anti-anxiety	+	3.1
Laxative	+	0.8
Gastroprotective drugs	-	2.1
Diabetes drugs	-	1.5
Antibiotic	-	0.4
Anti-hypertensive	-	0.5
Diuretics	-	0.6

Laboratory and Radiology Utilization: The laboratory test that was included in clinical pathway was only troponin test. Troponin test was used as diagnostic test to diagnose AMI. But according to data, laboratory tests that were received by patient were not only troponin test, but also routine blood test, creatinine, urea nitrogen (BUN), glucose test, test for Na, K and Cl, HDL, LDL, total cholesterol, SGOT and SGPT. Radiology was not included in clinical pathway, but there was radiology utilization for thorax. Laboratory and radiology average utilization are presented in Table 3.

Table 3: Laboratory and Radiology Utilization

Laboratory	Utilization according to the clinical pathway	Average Utilization in clinical practice
Troponin T	1.0	0.6
Blood test	-	1.0
Creatinine	-	0.6
BUN	-	0.6
Glucose test	-	0.6
Na, K, Cl	-	0.2
HDL and LDL	-	0.4
Total cholesterol	-	0.4
SGOT and SGPT	-	0.2
Thorax	-	0.2

Discussion

AMI is caused by reduction of blood flow to the heart. Reduction of blood flow was caused by atherosclerosis and vasoconstriction[13]. Average Length stay (ALOS) for

AMI patient in hospital was in the range of 6-7 days. In this study, ALOS was 4.65 days with the median of 6 days. ALOS was shorter than length of stay in clinical pathway, but from the median, it can be indicated that most patients were treated in hospital for around 6 days, and this was in accordance with the clinical pathway. The compliance for length of stay was 70%. Average utilization of specialist's visit was 6.5 meanwhile the average length of stay was 4.65. This means that specialist could visit patient more than once per day.

AMI can be detected by analyzing troponin. Troponin is a biomarker that will increase in blood level in myocardial ischemic condition. Patients with chest pain for 20 minutes or more and wasn't getting better after the nitroglycerin was delivered, were suspected to have AMI. Patients then will get ECG diagnostic to decide immediate treatment[9,13,14]. In clinical pathway, AMI was detected by chest pain, ECG, and troponin. ECG diagnostic should be done once but troponin test was conditional in the first day of patient admission. Average utilization of ECG diagnostic and troponin test were 1.0 and 0.6. If every patient received ECG diagnostic and troponin test for one time, then the average utilization should be 1.0 in the first day admission. The compliance of ECG diagnostic was 100%, while compliance of troponin test was 66.67%. The variance of troponin test occurred because there were patients who took troponin test in second day of admission while in clinical pathway, patient could not take troponin tests in the second day of admission.

During treatment, vital sign and ECG should be monitored every day until the patient is discharged. Average utilization for vital sign and ECG were 3.9 and 5.3, respectively. This indicates that some patient got ECG monitoring for more than once per day. This was likely because AMI patients were treated in ICU or HCU room and need to be monitored closely. Oxygen and isotonic fluids also were administered during treatment. Oxygen should be administered for the first three days since admission and the rest days were conditional. Meanwhile isotonic fluids should be administered every day until the patient is discharged. Average utilization for oxygen administration was 7.6 and average utilization for the first three days ranged from 1.3 to 3. This signifies that oxygen administration was in accordance with the clinical pathway, and oxygen was delivered for more than once per day. Average utilization for isotonic fluid was 14.8, with the range from 0.2 to 4.2 per day. Administration of isotonic fluid was also in accordance with the clinical pathway and each patient was administered with it at least once per day.

Drugs for AMI patients were delivered during patient's stay and after the patient's discharge. Major treatment for patient during hospital stay was the combination of anti-platelet aspirin, nitrate and statin. Anti-platelet $P2Y_{12}$ inhibitor (e.g. clopidogrel) and anti-coagulant can be added as major treatment for patients depending on patient's condition. Morphine and β-blocker also considered to be delivered for relieving chest pain[13,14]. In AMI clinical pathway, patients got combination of dual anti-platelet (aspirin and $P2Y_{12}$ inhibitor), anti-coagulant, and statin as major treatment and it is slightly different from the literature. Drugs from the classification of ACE inhibitor, ARB, β-blocker, nitrate, morphine, laxative, and anti-depressant were for conditional utilization. Meanwhile drugs that were given after the patient was discharged were dual anti-platelet, nitrate, statin, ACE inhibitor, ARB, or β-blocker.

The highest drug utilization was drugs from nitrate and anti-platelet classification, which were 28.5 and 17.0, respectively. Anti-coagulant (utilization 3.1) and statin (utilization 3.0) were the third and fourth highest but their total utilizations were far from nitrate and anti-platelet. From the utilization, it can be indicated that this result was different than clinical pathway. Dual anti-platelet, anti-coagulant, and statin should be the highest utilization because they should be administered to patients every day until the patient is discharged. ALOS was 4.65, therefore if patients at least received drugs once per day, drugs utilization should be 4.65. But from the result, drug utilization for anti-coagulant and statin did not reach 4.65 and this means that patients did not receive anti-coagulant and statin every day. Drugs utilization might be different than the clinical pathway, but actually in accordance with literature. Literature stated that nitrate could be given as major treatment, and practically nitrate was highly given to patient.

There were patients who received gastroprotective drugs, antibiotics, diabetes drugs, and anti-hypertension and edema drugs. These drugs were not listed in clinical pathway therefore it is considered as variations. Furosemide was known as medication for heart failure. Heart failure was usually caused by myocardial damage and the consequence of arrhythmia or other ventricular

complications. Alongside with other anti-hypertensive drugs such as amlodipine, furosemide also used for hypertensive patients[13,15,16]. This study only included patients who did not have secondary diagnosis, but practically there were patients who received anti-hypertension, edema, antibiotics and diabetes drugs. This means that there were patients who had diabetes, hypertension or heart failure and infection during treatment in hospital.

As for gastroprotective drugs, there are literature that stated using these drugs for handling adverse drugs reaction. Adverse effect of anti-platelet drugs is an increased risk of bleeding, commonly in gastrointestinal (GI) tract. Gastroprotective drugs such as proton pump inhibitor (e.g. pantoprazole and omeprazole) can be used to ameliorate GI tract[17,18]anesthesiologists encounter many patients who are receiving drugs that affect platelet function as a fundamental part of primary and secondary management of atherosclerotic thrombotic disease. There are several antiplatelet drugs available for use in clinical practice and several under investigation. Aspirin and clopidogrel (alone and in combination. This was possibly the main reason for the use of gastroprotective drugs in some patients.

There were a lot of variations in laboratory test. AMI clinical pathway only included troponin test, but practically other laboratory tests were given during patients stay in hospital. Laboratory variations included routine blood test, creatinine, urea nitrogen, glucose test, Na, K, Cl, HDL, LDL, total cholesterol, triglyceride, SGOT and SGPT. Variations in laboratory test reached 86.96%. There was also utilization in radiology, which was thorax. Radiology was not included in the clinical pathway therefore thorax was considered as variation.

Conclusion

Hospital has played a good role in maintaining quality of health services. This can be seen from the accordance between clinical practice and clinical pathway in majority of medical treatment and drugs administration. Wide variations only occurred in laboratory tests, where the variation reached 86.96%. This variation should be evaluated considering variation could affect the quality of services and moreover on the cost of treatment. This is because maintaining quality and cost are very important for the continuity of private hospital, especially in this Indonesian National Health Insurance era.

Indoor Particulate Matter (PM_{10}) and Health Risk on Junior High School Students in Depok

Sasnila Pakpahan[1], Bambang Wispriyono[1]

[1]Department of Environmental Health, Faculty of Public Health, Universitas Indonesia, Depok, West Java, Indonesia

ABSTRACT

Poor indoor air quality is found to be related to the prevalence of respiratory disorders in children. School aged children spend 6-8 hours in classroom. Therefore, air quality and its health risk in classroom need to be considered. In this study, we measured the level of PM_{10} in three junior high schools and its health risk assessment. The mean level of indoor PM_{10} in three schools were 0.215 mg/m^3, 0.075 mg/m^3, 0.229 mg/m^3 respectively. The level of indoor PM_{10} in two schools was higher than outdoor. The exposure of PM_{10} in two schools was estimated to inflict health risk therefore it needed to be maintained at a safe threshold of 0.142 mg/m^3. This study concluded that indoor air quality in all junior high schools was poor and estimated to inflict health risk on students.

Keywords: *PM10; health risk; school; student*

Introduction

Indoor air pollution is found to be higher than outdoor and associated with various respiratory diseases. The high rate of indoor air pollution is related to around 2 million deaths in developing countries and 4% of global disease burden. Poorly ventilated rooms cause indoor and outdoor pollutants to accumulate indoors from time to time[1,2]. Nowadays, humans spend most of their time indoors[2-4]. One common indoor air pollutant is PM_{10}. The level of health risk due to PM_{10} exposure in classrooms is found to be associated with the prevalence of respiratory disorders such as asthma, wheezing, bronchitis, lower respiratory tract infections, and impaired lung function in children[3,5-8]. In addition, exposure to particulate matter was also reported to affect lung development in children[9-11].

In Depok, the prevalence of asthma (6.4%) was found higher than the province and national. Particularly, the prevalence of asthma in the 5-14 years old children was 4.6%[12]. Children are susceptible to air pollution due to higher respiratory frequency and physical activity, also development of the respiratory system related to puberty[1,13]. This group spends 65-90% indoors, including 6-8 hours in classroom[1,14,15]. Classrooms tend to have four times higher occupancy density than offices, inadequate ventilation, and building conditions increase the risk of more polluted air. Identification and control of indoor pollution will reduce both short and long-term health impacts[1,14,16]. Hitherto, there has not been research on PM_{10} exposure and its health risk on students of junior high school in Indonesia. Therefore, it is important to study the exposure of PM_{10} in schools and its health risk on students of junior high school to encourage environmental health management in school that suits student characteristic.

Method

Health risk assessment was conducted by referring to the *Risk Assessment and Management Handbook* 1996[17,18]. The sampling locations were 10 classrooms and three fields from three junior high schools, randomly selected. The concentration of PM_{10} was measured using DustTrak™ II Aerosol Monitor 8532 for one hour each point. The size of ventilation openings and classroom

were measured. A survey of 357 junior high school students was conducted to obtain data of body weight, height, and activity pattern that represent the population of junior high school student in Depok. The weight and height was also measured. The activity pattern was collected through questionnaires to obtain the frequency of exposure and duration of exposure. The concentration of PM_{10}, activity pattern, and body weight were used in equation 1 to obtain chronic daily intake of PM_{10} (CDI, mg/kg/day).

Equation 1:

$$\text{CDI} = \frac{C \times R \times t_E \times f_E \times D_E}{W_b \times t_{\text{avg}}}$$

The mean concentration of indoor PM_{10} (C, mg/m^3) was analyzed for each school. The inhalation rate (R, m^3/hour) of the students was based on inhalation rate of 11-16 year olds, 15.7 m^3/day[19]. Junior high schools in Depok city apply school hours 6 hours/day (tE, hour /day), 5 days/week. Based on the 2017/2018 academic calendar set by the West Java Education Office, school days were 218 days/year, including the exam days which then reduced by the mean of absence day according to the survey to obtain frequency of exposure (fE, day/year). Duration of exposure (D_E) based on the compulsory period of junior high school education, 3 years. The mean of student body weight (Wb, kg) was obtained. The average daily period of carcinogenic exposure was duration of exposure for 365 days per year (tavg, D_E x 365 days/year). The daily intake value would be used for the calculation of Hazard Quotient (HQ) using equation below.

Equation 2:

$$\text{HQ} = \frac{CDI}{RfC}$$

The RfC value of PM_{10} was not provided by Integrated Risk Information System (IRIS) so this research used a safe daily intake reference value based on an annual guideline of PM_{10}, the default of exposure factors for adult recommended by U.S. EPA 2014[18], and the *Exposure Factors Handbook* 2011[19]. The annual guideline of PM_{10} is 0.5 mg/m^3, according to the National Ambient Air Quality Standards (NAAQS) U.S. EPA in 1997. The reference value of PM_{10} safe intake obtained was 0.009 mg/kg/day. Then the risk management for the population was conducted if HQ > 1 by calculating a safe threshold value for PM_{10} based on the mean and the 10th percentile of the students body weight.

Results

PM_{10} Concentration: The selected schools are located in different sub-districts, namely Cimanggis (school A), Tapos (school B), and Beji (school C). The mean percentage of V/C in three schools was 14.39%, 14.50% and 29.65%, did not differ statistically. Regulation of Health Minister of Republic of Indonesia No. 1429/2006 on Requirements of Environmental Health in School sets the percentage of V/C in classroom at 20%. The concentration of PM_{10} in three schools was shown Table 1, the highest concentration of indoor PM_{10} was found in school C, located in the city center with busy main highway was 0.229 mg/m^3. The concentration of indoor PM_{10} between the three schools was statistically significant (p = 0.000). Measurement of indoor and outdoor PM_{10} was carried out at different hour but the same day. The highest value of I/O PM_{10} was found in school A, 3.12 and statistically significant (p = 0.000). The level of measured PM_{10} were compared with several guidelines, i.e. National Ambient Air Quality Guidelines (NAAQS) U.S. EPA, WHO air quality guidelines, Government Regulation of Republic of Indonesia No.41/1999 on Environmental Management (PP RI No. 41/1999), Regulation of Health Minister of Republic of Indonesia No. 1077/2011 on Guideline for Air Sanitation in House (Permenkes RI No. 1077/2011).

Table 1: The Concentration of PM_{10} in Three Schools

Parameter	School			Guidelines	
	A	B	C	[1)]NAAQS U.S. EPA 1997, [2)]NAAQS U.S. EPA 2012,	[3)]PP RI No. 41/1999, [4)]Permenkes RI No. 1077/2011
	Mean ± SD				
PM_{10} (mg/m^3)					
Indoor (I)	0.215 ± 0.123	0.075 ± 0.246	0.229 ± 0.583		[4)]0.70, 24 hours
Outdoor (O)	0.069 ± 0.527	0.094 ± 0.209	0.218 ± 0.152	[1)]0.15, 24 hours, [2)]0.05, 1 year	[3)]0.15, 24 hours

Conted…

I/O (p value)	3.116 (0.000)	0.798 (0.000)	1.050 (0.000)		
Temperature (^{0}C)					
Indoor (I)	30.04 ± 0.99	30.08 ± 1.03	30.07 ± 0.61		[4]18-30
Outdoor (O)	43.98 ± 2.34	33.53 ± 0.35	36.4 ± 0.85		
Humidity (% Rh)					
Indoor (I)	69.85 ± 5.19	68.99 ± 5.13	65.72 ± 4.36		[4]40-60
Outdoor (O)	27.43 ± 5.36	52.73± 1.18	44.46 ± 3.36		

Health Risk Assessment: The risk assessment was carried out on the exposure for three academic years to the population of junior high school student in Depok. The respondents consisted of 157 males (44%) and 200 females (56%) with characteristics as shown in Table 2. One school day was 6 hours long not included additional activities or lessons after school hours.

Table 2: Student Characteristic and Activity Pattern

Variabel		Min-Max	Mean ± SD
Age (years)		10.23 - 17.16	13.95 ± 0.82
Body Weight (kg)	W_b	22 - 89.5	47.90 ± 10.84
Frequency of exposure (day/ year)	f_E	188 - 218	215.41 ± 4.35
Duration of exposure (year)	D_t	1 - 3	1.60 ± 5.35
Time of exposure (hour/day)	t_E	6	
Inhalation rate (m^3/day)	R	15.7	

The non-carcinogenic health risk of PM_{10} exposure to the students was HQ > 1 in School A and C, as shown in Table 3. The exposure of PM_{10} was estimated to have health effects so risk management is needed by setting a safe threshold of 0.192 mg/m^3 (for Wb = 47.9 kg) and 0.142 mg/m^3 (for Wb = 35.5 kg).

Table 3: Chronic Daily Intake dan Health Risk of PM_{10}

PM_{10}	School		
	A	B	C
Intake (CDI, mg/day)	0.011	0.004	0.011
Health Risk (HQ)	1.118	0.390	1,191

Discussion

PM_{10} Concentration: The concentration of indoor and outdoor PM_{10} were found to be highest in school C and exceeded the standard value of 24-hour and annual referring to NAAQS U.S. EPA 1997 and 2012, PP RI No. 41/1999, and Permenkes RI No. 1077/2011. It is located in the city center and adjacent to a busy main highway. Traffic activity is one of the sources of indoor and outdoor particulate matters due to the burning of fossil materials from motorized vehicles. Another research on indoor PM_{10} reported that highway dust was a major component of indoor PM_{10} and associated with high levels of indoor PM_{10}[8]. The I/O ratio at school C indicated that indoor PM_{10} might be sourced from the classroom such as particles attached to students or resuspension of deposited particles[6,20]. In addition, the chemical component of PM_{10} might indicate the sources of pollutants and could be identified further[6,8,21].

High indoor PM_{10} yet low outdoor PM_{10} was found at School A. The level of indoor PM_{10} exceeded the guideline of 24-hour and annual referring to NAAQS U.S. EPA 1997 and 2012, PP No. 41/1999, and Permenkes No. 1077/2011. Low level of outdoor PM_{10} might be caused by the rain that occurred a day before measurement at School A. It was expected to dissolve outdoor PM yet less affect on indoor. This study did not record meteorological conditions but several studies reported that meteorological conditions such as wind and rain can reduce the concentration of PM[22]. By considering its environment characteristics, PM might be sourced from traffic, not cemented school field, or attached to students[8,23]. Similar to School C, indoor PM_{10} might be sourced from the classroom and trapped in due to deposited particles or inefficient room cleaning and inadequate ventilation leading to the accumulation of indoor PM. Resulting in, School A had the highest I/O ratio for PM_{10}. The mean percentage of V/C in School A was not in accordance with Permenkes RI No. 1429/2006.

Meanwhile, indoor PM_{10} in School B which located in the residential showed lower concentration. However, the indoor PM_{10} were found to exceed the guideline of

24-hour PM_{10} referring to Permenkes RI No. 1077/2011 and annual referring PM_{10} to NAAQS U.S. EPA 1997. In residential areas, PM_{10} sourced from vehicles, biomass burning, cooking activities, and unpaved yards. The concentration of indoor PM_{10} in School B was lower than outdoor PM_{10} and the I/O ratio was the least among three schools. This might indicate low contribution of indoor sourced PM_{10} or good room cleanliness but might not related the percentage of V/C. The mean percentage of V/C at school B was not in accordance with Permenkes RI No. 1429/2006.

Health Risk Assessment: Health risks due to $PM1_0$ exposure to students were estimated in Schools A and C. This study estimated health risk for junior high school students based on annual mean of PM_{10} (50 mg/m^3) set by NAAQS U.S. EPA 1997. The U.S. EPA has revised the guideline to 150 mg/m^3 for 24 hours because of insufficient evidence of long-term exposure on public health. However, some studies reported association of long-term exposure of PM_{10} and respiratory problems in children i.e., study in Mexico finding an increase in PM_{10} significantly correlated with decreased lung function of children and a study in Utah showed a positive correlation with PM_{10} reduction and decreasing hospital visits, asthma, and bronchitis in children[16,24]. In addition, WHO recommends annual PM_{10} 50 mg/m^3 and $PM_{2.5}$ 25 mg/m^3 expected to reduce the risk of premature death by 6%[25]. The health risk of PM_{10} might be quantified based on its chemical components. Research in China and Malaysia reported long-term exposure of Cr in PM_{10} posed a risk of cardiovascular and respiratory diseases including lung cancer in children[8,26]. Health risk arising in School A and C could be managed by controlling the level of PM_{10} at a safe threshold of 0.142 mg/m^3 during normal school hours. The level of health risks would be higher in individual with low weight so that the 10th percentile of bodyweight 35.5 kg was set to calculate a safe threshold for 90% of the student population. The modification on time, frequency, and duration of exposure were not considered because they are mandatory and associated to academic quality.

Conclusions

The concentration of indoor PM_{10} in all schools exceeds the standard value set by NAAQS U.S. EPA 1997 and 2012, Permenkes RI No. 1077/2011, and PP RI No. 40/1999. The quantitative health risk assessment of PM_{10} for 3 years of exposure in School A and C estimated the health risk to students (HQ> 1). Therefore, we recommend managing a safe threshold of PM_{10} at 0.142 m/m^3 as by conducting air quality monitoring, provision of room air purification facilities in classrooms, and planning of school location to pollutant sources.

This research can be developed by monitoring several quality parameters in the long run, simultaneously, and considering the meteorology condition to obtain comprehensive air quality data. Health risks assessment can be improved by analyzing the components of PM, using advanced analytical methods, and involving epidemiological studies.

Analysis of Typhoid Fever Clinical Pathway Implementation in the Era of National Health Insurance in Indonesia

Widia Puspa Hapsari[1], Atik Nurwahyuni[1]

[1]Department of Health Administration and Policy, Faculty of Public Health, Universitas Indonesia, Depok, Indonesia

ABSTRACT

Starting in November 2016, pricing policy for private hospital in Indonesia was specifically set in a fixed tariff called INA-CBGs (*Indonesian Case Base Groups*). PMI Hospital which was affected by INA-CBGs regulation built Clinical Pathway for Typhoid fever in order to cope with the challenge. It admitted 705 cases in less than a year in 2016 yet it was claimed that the reimbursement for each case was still lower than the hospital cost. Study aimed to explore variation of medical practices based on Clinical Pathway considering INA-CBGs 2016 pricing policy. Cases included in the study were 156 cases with homogenous severity level chosen from October 2016 to March 2017. Historical data was taken from hospital information system including medical record and billing details. Data was processed using ClinPath V.2.0 tools developed by Faculty of Public Health Universitas Indonesia resulting in distribution of variation. Variation resulted in Length of Stay was (4.27 days) and it was expected to be 4-5 days in clinical pathway while not all patients utilized the same procedure within one period of care. There were also non-value added diagnosis such as Complete Urine (0.01) and Electrolyte test (0.01) included. Consumption of antibiotic (0.28) which consisted of 25 different trade names from different structures resulted in various tariff of services. Variation drives medical cost resulted in tariff increment. Typhidot test can be taken into consideration and the use of later generation of antibiotics are recommended considering affordability and availability.

Keywords: *Clinical Pathway, Medical Practice, Compliance, Typhoid Fever, Variation*

Introduction

Shifting system from fee for services to Case Base Groups had given new insight for hospitals to be more efficient in spending their resources without putting aside their service quality[1]. Started in 2016, tariff for private hospital for each case group was set in fixed amount and was prospectively reimbursed by BPJS (Independent pooling organization for national health insurance)[2]. PMI (Indonesian Red Cross) Hospital is a type B private hospital with 264 beds as a referral hospital for inpatient care in local area[3]. During the enactment of INA-CBGs 2016 pricing policy, hospital claimed that reimbursement offered by BPJS (third party payer) was quite lower than the cost made by the hospital.

Typhoid fever frequently happened in Bogor area (where PMI hospital is located). In 2016, there were 18.797 cases of Typhoid fever in Bogor and it was distributed among various age groups[4]. It was recorded that Typhoid fever cases in PMI hospital alone was 705 admissions in less than a year[3]. Those numbers showed that PMI hospital had both the opportunity as well as the challenge to manage its resources in a more efficient way. In order to answer the challenge, PMI hospital has established their own Clinical Pathway for Typhoid fever. Length of Stay for homogenous cases of Typhoid fever were found to be 1 up to 6 days. Studies in several countries showed that prospective payment system (e.g. INA-CBGs) would affect Length of Stay, type of services and consequently the medical cost[5–8]. Implementation of INA-CBGs pricing policy supported with clinical pathway was expected to reduce non-value added activities yet variation still existed. Thus, a more in depth analysis needed to be conducted to elaborate which medical practices induced more variation to the service.

Method

This study took place at PMI Hospital located in Bogor, West Java. This study used quantitative approach to identify variation in medical practices and was elaborated using descriptive statistics. Distribution of patients' characteristics included age, sex, payment methods (JKN/National Health Insurance, Private Insurance, Out of Pocket), and inpatient accommodation (class I, II, III, VIP, VVIP). Data for identifying Length of Stay were also taken from the duration between admissions to the discharge date. Data taken from medical record was then recapitulated and digitized by medical record unit. Another set of data were taken from billing unit, for example billing details. Medical and medical supporting services details were then classified as Laboratory, Consultation, Doctor Visits, and Procedure. Drugs were also classified using ISO (*Informasi Spesialite Obat*) for its therapeutic functions. Fragmented data were connected using registration number. Data selection resulted in 156 homogenous cases with the same severity level (without any complication and comorbidity). Data was processed using a public domain software ClinPath V.2.0 built by Universitas Indonesia. Variation showed in LOS, Average utilization of medical and medical supporting services, and various medical consumption of drugs, and average tariff for services then be compared to hospital clinical pathway.

Results

Since its initial implementation, Typhoid fever clinical pathway has not been evaluated. According to the hospital internal consensus, Length of Stay (LOS) for Typhoid fever was 4-5 days and patients were planned to be discharged with doctors' approval. Several medical activities e.g. anamnesis, physical assessment, diagnostic examinations, procedures, monitoring up to discharge planning were supposed to be conducted within LOS.

Average Length of Stay for homogenous cases was 4.27 days with maximum stays up to 6 days and the least stays were 3 days. Vast majority of patients paid services using Indonesian National Health Insurance/ JKN (74 patients), 37 patients paid out of pocket, and 19 patients paid via Private Health Insurance, they were mostly workers and were insured by the companies' third party payers e.g Admedika, Inhealth, Antam, Sinar Mas, Sampoerna. Five patients were discharged against advice and the rest of 151 patients were discharged with doctor's approvals. Hospitals provided patients with their accommodation of choice. Fifty three patients chose to utilize class I, 27 patients chose class II, 34 patients chose VIP class, and lastly 19 patients preferred VVIP class (See Table 1). Various medical services were used in treating patients with Typhoid fever. Doctor visits were given 4 times (once per day) in clinical pathway while only 0.39 of the services was practically performed by the Internists during the stays. Average tariff of doctor visits was IDR 94.739. The data shows that average utilization of consultation was 0.02 and average tariff for each consultation was IDR 79,839. Complete blood test was utilized 0.06 times (IDR 78,537).

Table 1: Characteristics of Patients with Typhoid Fever

Items	Cases
Number of Cases (N)	156
LOS (Days)	
ALOS	4.27
Minimum	3
Maximum	6
Age (Years of Age)	
Average	24
Minimum	1
Maximum	82
Sex (%)	
Male	45.51
Female	54.49
Payment Methods (N)	
JKN	74
Private Insurance	19
Out of Pocket	37
Hospital Staff	1
Other	25
Discharge Status (N)	
With Approval	151
Against Advice	5
Type of Accommodation	
I	53
II	27
III	34
VIP	23
VVIP	19

Complete urine test (0.01) and Electrolyte (0.01) tests were also conducted and average tariff for both services were each IDR 45,969 and IDR 319,000. Medical Procedures e.g. Crystalloid IVFD average utilization was 0.04 while it must be done every day (4 times during stays), each service was worth IDR 161,333. Nursing care was given with average utilization of 0.39 (4 times in clinical pathway). Nursing care included monitoring body temperature, nutrition intake, and personal hygiene. The service average tariff was IDR 56,669. Tariff for Injection was IDR 49,493 and was given 0.37 times during 1 period of care (See Table 2).

Table 2: Average Utilization in Medical and Medical Supporting Services

Items	Clinical Pathway	Clinical Practice	Hospital Tariff (IDR)
Visits by Specialist	4	0.39	94,739
Consultation	-	0.02	79,839
Diagnostic Examination			
Complete Blood Test	1	0.06	78,573
Widal/tubex	1	-	-
IgM Salmonella	-	0.02	251,304
SGOT	-	0.02	48,000

Complete Urine Test	-	0.01	45,969
Electrolyte (Na, K, Cl)	-	0.01	319,000
Medical Procedure			
Crystalloid IVFD	4	0.04	161,333
Oxygen	*4	-	-
Electrocardiogram	-	0.01	57,955
Nursing Care	4	0.39	56,669
Injection	-	0.37	49,493

Note: (*) Not necessarily mandatory. Tariff was counted using 2016 value of money (1 USD=IDR 13,519)

Recommended antibiotics in hospital clinical pathway were mostly broad spectrum (Quinolone and Cephalosporin) (see Table 3) although, these were not used in medical practices. Hospital also suggested using Proton Pump Inhibitor (PPI) and practically used was Omeprazole with different types of brands (0.30).

Table 3: Average Consumption of Drugs Based on Clinical pathway

Drugs	Clinical Pathway	Clinical Practice
During stays		
Quinolone	+	-
Cephalosporin	+	-
PPI	+	+
Discharge Planning		
Chloramphenicol Oral	+	-
Cephalosporin Oral	+	-
PPI	+	+

Note: + Drugs recommended by hospital CP or utilized in clinical practice, - not utilized in clinical practice

Drugs used for discharge planning were consumed starting on the last day of stays up to consecutive days after discharge (See Table 3). Variation included antibiotics classified not only in quinolone (with 4 variation in trade names) and cephalosporin (25 different trade names), but also from other lines and generations.

Table 4: Average Consumption of Drugs

Drugs Therapeutic Classification	Clinical Pathway	Medical Practice
Adsorbents	-	0.33
Analgesic	-	1.11
Analgesic Opioid	-	0.03
Anti-Dysrhythmia	-	0.01
Anti-Histamine	-	0.74
Anti-Hypertensive	-	0.05
Anti-Inflammatory	-	0.30

Conted…

Anti-Depressant	-	0.13
Vasoconstrictor	-	0.05
Adenoreceptor	-	0.08
Relaxant	-	0.03
Diuretic	-	0.02
Vasodilator	-	0.03
Decongestant	-	0.01
Anti-Diabetic	-	0.01
Compounding Medicine	-	<0.01

Several drugs were also given to the patients with typhoid fever e.g. Adsorbent classified drugs (0.33 tablet). There were also two kinds of painkiller used in practice, Analgesic (1.11) and Opioid Compound (0.03). Anti-Hypertensive e.g. Amlodipine (0.05), Anti-Inflammatory such as Triamcolone and Dexamethasone (0,3 tablet), Anti-Platelet in the form of Clopidogrel (0.01), Anti-Spasmodic as in Otilonium Bromide and Hyoscine Butylbromide (0.07). Other therapeutic drugs were also consumed as shown (See Table 4).

Discussion

Typhoid fever can be detected by using microbiological procedure, serological procedure and other examination e.g. PCR test[9]. PMI Hospital suggested widal test for diagnosing Typhoid fever on the first day of patient's admission. This test only results on moderate sensitivity and specificity and can only be done on day 6-12 for specific antibody O or H and might show negative result up to 30.0% of proven culture[10]. Typhidot IgM however has 75.0% of sensitivity and 60.7% of specificity which made it more accurate in diagnosing Typhoid fever than widal test did[11]. Average tariff for Typhidot IgM in PMI Hospital was IDR 251.304, higher than the tariff for Widal test in hospitals in the nearby area, which were IDR 55.000 for private hospital and IDR 52.000 for public regional hospital[12,13]. Despite the higher tariff for Typhidot IgM test, hospital took the test accuracy into consideration.

Diagnosis tests out of hospital clinical pathway e.g. SGOT/ SGPT became ineffective because patients with Typhoid fever subsequently experienced clinical sign in which their level of enzymes increased due to endotoxicity, immune mechanism, and the consumption of drugs[9]. Complete urine test is commonly used to detect excessive substances in blood excreted in the urine and infection related to urinary tract infections[14–16] *Salmonella typhi* can be detected through urine culture for its Vi antigen and be best detected using PCR method without any bacteriological changes interference[17,18]. Nonetheless, high tariff for PCR test was still one of the considerations.

Mostly used quinolone was Levofloxacin 500 mg (IDR 1,500) because it was more affordable than other quinolone such as Levofloxacin IV Fluids (IDR 105,600) or Lexa IV fluids 750 mg (IDR 422,400). Ciprofloxacin used by hospital had the lowest tariff (IDR 867) known for more severe adverse effect including nausea, nerve damage, and further myasthenia gravis[19]. Clinical Pathway recommended patients with Typhoid fever to be given antibiotic per day of stay. However, average consumption of 25 different Cephalosporin (antibiotics) varied. Average tariff also varied from IDR 1,573 up to IDR 369,930. Frequently consumed antibiotics was 1 gm of Ceftriaxone given via injection (IDR 18,700). Each gram of Ceftriaxone injection can be used for both adult or pediatric patients[9]. As study resulted that the youngest patient suffered from Typhoid fever was a 1-year-old and the oldest was a 82-year-old. Ceftriaxone is also more active against gram negative bacteria and less active against positive bacteria[20]. Thus, ceftriaxone was mostly used (average utilization 4.61) to treat patients with Typhoid rather than other Cephalosporin drugs. However, Ciprofloxacin (belongs to Fluoroquinolone) had higher rate of Salmonella infection eradication than Chloramphenicol (90% compared to 89%)[21].

Consumption of PPI drugs was not necessarily needed unless there were adverse effect e.g. intestinal injury of a non-steroidal anti-inflammatory drugs (NSAIDs)[20]. On that account, average consumption of PPI drugs was only 0.30. Other therapeutic drugs namely Adsorbent containing Loperamide HCL (0.33) was used to control acute non-specific diarrhea associated with inflammatory bowel disease which often happens to patient with Typhoid. There were 3 types of laxatives used which worked differently. Dulcolax containing bisacodyl (average utilization 0.02) works in stimulating mucosal sensory nerves, consequently increasing peristaltic contraction of colon[20]. Mycrolax cointaining Sucrose (average utilization 0.02) works in creating bulk and increasing amount of water in the system, and Lactulax, a non-absorbable sugar/disaccharide (0.01)

used to treat constipation by pulling water out into colon also to reduce ammonia in blood to treat liver disease[20]. Lactulax was the most expensive laxative (IDR 125,400) among the other two Mycrolax (IDR 24,063) and Dulcolax (1,580).

Commonly used analgesic was paracetamol (7,42) with average tariff (IDR 205) per tablet. It was used to reduce temperature which followed Salmonella infection. Anti-inflammatory was also used in 17 different trade names. The most consumed Anti-inflammatory was Triamcolone (0.78) which worked by suppressing inflammation due to enteric infection. Antiemetic was also consumed by patients with Typhoid fever. There were 14 trade names consisted of mostly Ondansentron worked by blocking serotonin receptor resulting in suppression of nausea and vomiting[22]. Other drugs which has no direct effect to Typhoid fever treatment were also given to patient.

Conclusion

Variation persistently happened despite the enactment of INA-CBGs 2016 Pricing Policy. Variation happened in medical supporting service (laboratory). Typhidot was the most proper test used to support Typhoid fever diagnosis in patients considering affordable tariff and availability of resources. Consumption of both various kind of therapeutic drugs and trade names including various antibiotics and other unnecessary drugs such as anti-depressant, Bronchodilator, Vasodilator, etc. was considered a non-value added activity. These induced additional costs which resulted in tariff increment. Hospital might suffer financial loss due to disproportionate fixed reimbursement set in INA-CBGS 2016 Pricing Policy. This can be averted by regularly evaluating clinical pathway based on medical practice and increase professionals' concordance in delivering services for typhoid fever.

Analysis of Primary Health-Care Resource Preparedness for Implementation of Maternal HIV Screening in Indonesia's Urban Areas

MM.Puspitasari[1], Purnawan Junadi[2]

[1]Postgraduate of Public Health, 2Department of Health Policy and Administration, Faculty of Public Health, University of Indonesia, Depok, Indonesia

ABSTRACT

The Indonesian goverment's minimum service standard (MSS) indicator stipulates that 100% of pregnant women in the country must undergo HIV checks. in 2017, however only 7% of pregnant women underwent such checks. The same condition applies to Depok City, where in 2016 only 3.6% of pregnant women were screened. Because 86.6% antenatal examinations are done within primary-care facilities, this study has to analyzed the preparedness of primary health-care resources in the implementation of HIV screening for pregnant women.The research used qualitative method with in-depth interview, FGD and document review. The Study found that human resource workers trained in HIV programs were not available at every Public Health Center (PHC) and private primary health-care (PPHC) had no such workers were trained on HIV. Roughly half (17 of 35) of PHCs Primary health care capable of HIV screening for maternal. No PPHC facilities especially inpendent midwife practice had such capabilities The number of reagents was found to be inadequate at the PHCs, and no reagents at all were found at prprivate care facilities. Counselling media was found to be lacking at both types of primary care facilities. Conclusion the implementation of HIV screening in primary health care facilities is not yet ready according to the MSS. Regulations that require PPHC facilities to be capable of HIV screening and government support for the availability of resources (especially training and reagents) are require for the achievement of the MSS.

Keywords: *HIV screening, minimum service standards, urban areas, Indonesia*

Introduction

HIV screening for pregnant women is an important strategy for the prevention of mother-to-child transmission of HIV and is mandatory in areas with widespread and concentrated HIV epidemic status[1.] Pregnant women in particular should be screened because more than 90% of pediatric HIV cases are occur through vertical infection[2,3,4]. Globally, the numbers of HIV-infected women continue to increase.The same situation applies to Indonesia, where 2,573 women had HIV in 2015 and by 2016 that numbered had increased to 15,151 women (36% of total HIV cases)[5,6]. The Indonesian goverment has thus established a minimum service standard (MSS) that recognize pregnant women as a high risk population for contracting HIV. Under the MSS, 100% of pregnant women should under go standardized HIV testing including screening[7,8].

In terms of coverage of pregnant women screened for HIV in Indonesia only 570,424 (7%) of pregnant women were screened during from antenatal visits which were conducted on a total 5,355,710 pregnant women[9]. The same condition applies to Depok City, an urban area, where the coverage of HIV testing for pregnant women in 2016 was only 1,839 pregnant women(3.98%) from coverage of K1(first visit) antenatal visit of 46,201 and K4 (4th visit) of 43,924[10,11]. These figures indicates a missed opportunity, since HIV-positive pregnant women are likely unaware of their status, despite having visited health services. Because of the large numbers of pregnant women in Indonesia, the need for HIV screening is considerable.

A 2016 data survey of the national health indicator states that 86.6% antenatal examination performed at primary care consisting of Public Health Centers (PHCs) and their related networks, private clinics and independent practice midwives. Specifically, 40.2% of these exams were carried out by independent practice midwives and 82.4% of the antenatal health workforce consisted by midwives[12]. This condition shows that primary health care facilities are still the main service in the provision of antenatal examinations.

The inclusion of HIV screening for pregnant women in MSS indicator of HIV health care service and antenatal care providers mostly done in primary health care as well as thedemand for such facilities is higher than the supply which add to the Indonesian government's obligation to allocate necessary resources to support the implementation of screening programs. Researchers thus should analyze the preparedness of primary health-care resources in the implementation of maternal HIV screening in Indonesia.

Method

The study used a qualitative method, with in-depth interviews, focus group discussion with semi structured interviews and document review. A total of 43 informants participated in the study including policy-makers, activity implementers and beneficiaries. The research was conducted from November 2017 to January 2018.

Results

Human Resources: The human resources required for the implementation of HIV screening are include health-care workers who have competencies in accordance with their profession and have been trained in HIV/AIDS programs[7].

PHCs, the primary-care of the government, have a fewer number of trained HIV/AIDS workers than the total number of health personnel available, as shown in table 1 as follows:

Table 1: Trained health-care personnel on HIV in PHCs in Depok City 2017

Personnel Type	Total	Trained	%
Doctors	134	26	19.4
Nurses	146	12	8.21
Midwives	182	28	15.3
Laboratory analysts	36	10	27.8
Recording and Reporting staff (RR)		9	

Source: P3M section, 2017, processed data

Trained personnel is not yet available in all PHC Among 35 PHCs, only 30 PHC have counselors (includings doctors, nurses and midwives), ten have trained laboratory analysts and nine PHCs have specialized recording and reporting (RR) personnel. Because of the low number of workers executing (RR) personnel, the RR process is mostly done by counselors who obtain on- the -job training from the Health Office. The low numbers of trained health personnel, the heavy workloads of these personnel and the process of transferring trained personnel who does not match the needs of the program have affected the poor coverage of pregnant women to be screened for HIV and have also become an obstacle to the availability of human resources in the PHCs. As one informant noted,

> *-----only a few human resources are trained, and they also have other duties, so if these workers aren't available then, the HIV screening for pregnant women gets postponed---* (KPKM-1)

In addition, human resources workers who are trained in private primary health-care (PPHC) facilities esspecially independet midwife practice, are not yet available. This condition has occured because of to the lack of specific training for private service workers even through 82.4% of antenatal examination conducted by midwives and 40,2% are done in independent practice midwives, only about 27.1% of such examinations are done in PHCs[12].

Facilities: Facilities for the implementation of HIV screening include health-care facilities, reagents and media counseling.

Only 17 PHCs were found to be capable of providing comprehensive HIV screening to pregnant women in 2017. Even though trained human resources workers were distributed in 30 PHCs, this situation may have arisen because reagents and human resources who are capable of performing laboratory sample examination were only available at 17 PHCs.

These 17 PHCs thar were able to perform HIV screening faced several obstacles only 13 PHCs that had trained analysts, HIV screening services were only offerd on limited days and waiting times were too long. The limited service hours and long waiting times made pregnant women reluctant to be referred to PHCs for HIV screening. As one informant noted,

---- Pregnant women whoare checked for HIV here are often lazy about being referred to PHC for VCT (voluntary counseling abd testing) because it's far away, waiting times are long,they might be too lazy tostand in line and they.re only available in the morning while they're working--- "(BPM-1)

PPHC facilities capable of HIV screening for pregnant women do not yet exist for various reasons: the goverment's socialization of service is mot yet, trained personnel are not yet available and the government is still focused on the availability of services at the PHCs.

The supply of reagents is essential for the implementation of HIV screening for pregnant women. for PHC is obtained from The central and regional governments determine the need for reagents for PHCs based on the planning needs proposed by PHCs through The Health Office. But the goverment's provision of reagents remains focused on the needs of PHCs, so the number of reagents the government provides has not matched the estimates of total pregnant women because only 27.1% of pregnant women have had their antenatal visits at the PHCs [12]. One constraint among several is that the reagents PHC receive are often approaching their expiration datebecause of delays in the delivery of reagents from the central government as well as technical constraints in the process of procuring of reagents at the central and regional levels.

Another important factor in the process of disseminating information about HIV screening for pregnant women is the availability of counseling media at both PHCs and PPHC facilities is still lack where special counseling media on the prevention of mother-to-child HIV transmission is generally unavailable.

Discussion

Both human resources and facilities, are important in the implementation of the goverment's policy, the limitations of both will hamper will hamper the successfull implementation[13,14].

The low numbers of trained health personnel in PHCs and in the private sector, especially the midwives, have affected the implementation of the program. The aim of Education and training for health personnel is to improve compliance in implementation and supplement the skills of health workers in providing counseling about HIV infection and give workers the ability to handle medical care effectively[15]. The lack of trained health personnel and health worker's heavy workloads, both affect the utilization of VCT services[16]. Thus, increasing the numbers of health workers who are engaged in this field will also increase the number of pregnant women who undergo HIV screening. Research indicates that the existence of trained health workers,esspecially doctors, who are able to provide counseling,influences affect pregnant women's willingness to undergo HIV screening [171819].

The National Health Indicator's 2016 data survey found that 84% of personnel who provided antenatal care were midwives and 40.2% of these independent practice midwives only 27.1% of such examinations were performed in PHCs[12]. This finding indicates that increased coverage of pregnant women who undergo HIV screening will require the involvement of health personnel in both public and private sectors and midwives should be the priority target for such training. Cooperation with professional organizations in socializing programs and training will be required in order to increase the active participation of private healthcare personnels.

In terms of facilities, the main factors to affect the implementation are the lack of PPHC facilities that can conduct comprehensive HIV screening and the limited capacity of PHCs. research suggests that the unavailability of both human resources and facilities and long waiting times at service sites are obstacles to HIV screening during pregnancy [202122].

The absence of PPHC facilities that are capable of screening pregnant women for HIV strongly affects the coverage of screening because it is difficult to reach all pregnant women. For example PHCs are provide only 27.1% of services, while private health care provide the remainder. 40.5% of antenatal visits are done by independent practice midwives. PPHC facilities must be involved, including in the provision of reagents for private services. The integration of HIV services with health-care services in general, both in the public and private sectors, is needed to achieve the objectives of the implementation, such integration is is a necessary for more effective and efficient service [2324].

Counseling media on HIV screening for pregnant women is still lacking both in government and PPHC

facilities. The media that can be used for information, education, and communication include *Mother and Child Health* (MCH) book and social media because every pregnant woman is required to have an MCH book. The use of social media as a bridge to disseminate information about HIV screening for pregnant women can increase public knowledge of the importance of this program which will ultimately reduces stigmas and increase the scope of screening itself [25].

Conclucions

Primary health-care resources that can conduct HIV screening of pregnant women according to MSS are not yet available. Insufficient numbers of human resources workers have been trained for such screenings in public primary health-care facilities, (in this case is the PHCs), and no trained human resources workers yet exists in PPHC facilities esspecially midwives. Only 17 PHCs are able to conduct HIV screening for pregnant women and no PPHC facilities currently have this ability. The numbers of reagents for HIV screening have not yet been adjusted tomatch the estimated needs of pregnant women because the avaibility of reagnets is still tied to the needs of the PHCs. Different counseling media in both public and private primary health-care facilities are still lacking.

HIV screening for pregnant women is part of the MSS which assesses the performance of local governments, so that the central government can provide resources to both private and public primary health-care fascilities. For the MSS to be properli implemented HIV services must be integrated into other health systems, regulations that must require primary health-care workers to be able to perform HIV screening for pregnant women and the government must commit to providing the necessary resources including training and reagents.

Getting Married to a Suspected Bisexual Man: A Silent Mode of HIV transmission among Married Women in Indonesia

Najmah[1,2], Sharyn Graham Davies[1], Sari Andajani[1]

[1]Auckland University of Technology, Auckland, New Zealand; [2]Sriwijaya University, South Sumatra Indonesia

ABSTRACT

A married woman is susceptible to contract HIV from her husband if he practices unsafe sex, especially with other men. Unsafe sexual practice (heterosexual and homosexual sex) are the major factors of significant increase of HIV in Indonesia for the last decade. The aim of this study is to reveal one woman's story about living with HIV. She contracted from her husband after he was unsafe sex with men.

Feminist Participatory Action Research was conducted in 2017 with HIV positive women, health workers from public and private organisations. Qualitative research methods were used in line with purposive sampling method and thematic analysis.

Men who have sex with men (MSM) may contract HIV through unsafe homosexual practices. Women need to be informed about the risk factors of contracting HIV and Prevention of Mother to Child Transmission-PMTCT of HIV services. In addition, compulsory antenatal HIV testing is urgently needed to early diagnosis of HIV among pregnant women and a non-discriminatory practice of comprehensive Prevention of Mother-to-Child Transmission of HIV (PMTCT) services is urgently required to prevent HIV transmission for infants.

Keywords: *MSM, bisexual man, a married woman, mother to child transmission, PMTCT service, Indonesia*

Introduction

In the past decade, four out of every 10 people diagnosed with HIV in Indonesia were women and the highest number of late stage of HIV (AIDS) suffers are married women or housewife [(1)]. Married women are considered a neglected group in HIV prevention in Indonesia [(2, 3)]. As a consequence of the lack of focus on married women, they have become a 'silent majority' of new HIV-positive cases [(1)]. In Indonesia, the majority women living with HIV find out their HIV status after their husband or children die, or after they themselves become ill [(4-6)]. Unsafe sexual practices are now the main cause of increases in HIV rates in Indonesia [(1, 7).] There is a little knowledge about lived stories of a married woman who is more likely to contract HIV from their husband who experiences to have unsafe sex practice with other men in Indonesia context.

Method

Research Paradigm and Methodology: Feminism is chosen as our epistemological stance and Feminist Participatory Action Research (FPAR) as the research methodology. Feminism includes a philosophical belief system that addresses who can be the real knower of women's problem and solution and care for the relationships between the female researcher and the research participants [(8, 9)]. Feminist research also seeks to contribute to women's empowerment [(10)], as women have the potential means to contribute to the development of collective consciousness, through their active participation, shared knowledge, and collaboration in the research itself [(9, 11)]. Within FPAR, three main dimensions of social transformation allow the necessary place and space to reposition gender, race and class, "to excavate indigenous cultural knowledge and generate voices"; and "to deploy intersectionality as an analytic tool for transformation" [(12)], pp 331. In addition, focusing gender and diversity of women's experience and voices are an integral part of this FPAR in challenging a patriarchal culture [(13)].

Participants: This study is a part of the whole study of FPAR that was conducted in 2017 with a group of 18 HIV-positive women, a group of 26 health workers, and a group of nine NGO workers. The voices of these groups were travelled visually to the final group of 12 stakeholders related to HIV in Palembang. Purposive sampling was undertaken to recruit participants in Palembang (capital city of South Sumatra) Indonesia.

Data Collection and Analysis

The methods used included informal or "go-along" or informal interviews [14], focus group discussions and participant observations over four months in Palembang. In addition, participatory visual methods were used during the Focus Group Discussions and interviews. These methods allowed for HIV-positive women and other groups to express their thoughts through visual representations, such as drawing, collages and mind-mapping [15-18]. The data collection was conducted by the first author, who was born and raised in Indonesia and was fluent in the local dialect of Palembang. Thematic analysis and reflective analysis were then conducted.[13, 19-22].

Result

Preventing Mother-to-child Transmission: Mira recalled the time when she started to feel that the labour was coming. Her pain was excruciating, and the contraction came closer to each other. Psychologically, she felt very worried that her baby would be infected with HIV during delivery. Mira, accompanied by Kuyung then rushed to the emergency unit at a public hospital. At the admission, she reported her HIV status: "I am positive HIV, I needed a Caesarean Operation*"*. The admission nurse at that time, however, did not believe her and Mira insisted for the nurse to contact the Voluntary, Counselling and Testing (VCT) centre where she and her husband had been treated for HIV. The nurse contacted the VCT centre and got confirmation of Mira' status. She was scheduled to have the caesarean.

During the waiting time, or at about 6 pm, Mira felt her contractions intensified. Yet the nurses kept telling her that she would be fine. Two hours later, at about 8 pm, Mira had delivered her baby naturally. She felt very tired and shaken and after her delivery Mira realised she did not have any meals or drinks since 2 pm as a requirement for the surgery. Following the delivery of Toleh, Mira's second child, both the mother and baby were transferred to the maternity ward and shared her in-patient room with other female patients.

Vulnerability and discriminatory practice: During her recovery process, Mira recalled some incidents when she received blame, discriminatory treatments from the nurses. For example, one of the nurses had asked her "*you knew that you were HIV-positive, why did you decide to be pregnant and deliver your baby?".* Other nurses would give signs to her peers of her HIV status, mocking on Mira, while Mira was present in the room. At the same time, Mira felt hopeless. She was angry and disappointed with the treatment she received, but there was not much she could do then hoping for some 'empathy' from the nurses, midwives or doctors at the hospital. After a few months of her recovery, she asked about a family planning of Intra Uterine Devices in the same hospital, however, she got rejection after she disclosed her HIV status. Fortunately, after 18 months of being treated with a preventative HIV medication, her son, was declared HIV free.

HIV vulnerability: deception in marriage: During her second pregnancy in 2015, Mira recalled going to the community health centre to have a check on her vaginal rashes and itchiness. The test results confirmed she had syphilis and HIV. Her CD4 count of 350 cells/$mm^{3.}$ Feeling shocked, Mira told Kuyung and demanded for Kuyung to take a blood test. Kuyung was diagnosed HIV with a CD4 count of 450 cells/mm^3. Mira or Kuyung was likely to be infected with HIV about four years ago year [23]. Both Mira and Kuyung were referred to the VCT clinic for Antiretroviral treatment and accessed PMTCT services to prevent HIV to Toleh.

Mira was not sure who whether she or her husband acquired the HIV or syphilis first by saying "I did not know, who got it first, he [Kuyung] is a man". At some point, Mira was also suspicious she might have acquired HIV from an unsterile syringe used by one of the staff at a family planning clinic. A year prior to her problem, Kuyung had told her about having genital itch and there were reddish-brown sores around his genital area.

HIV vulnerability: norms on heterosexual marriage: To gain further understandings on MSM in Palembang, the first author decided to seek further information and meeting peer support workers and outreach HIV workers who had been working with bisexual and gay communities

and health workers in VCT centres. Learning from lived stories of the insiders, the authors became aware of life of MSM in Palembang that may differ from MSM from other countries, like New Zealand. MSM, either bisexual or gay man, may contract to HIV through unsafe sex practice, have relationship with a female partner and not all of MSM may disclose their sexual orientation and HIV status to their male and female partners.

Discussion

In Mira and Kuyung's marriage, there was a complex interplay of deception, stigma around homosexuality, heterosexual morality and HIV stigma in health setting. Kuyung might have engaged in homosexual sex prior to him marrying Mira, yet there was no knowledge whether Kuyung continued his sexual practice with men after his marriage with Mira. Kuyung also had never disclosed his sexual orientation to Mira nor had he ever seek to do an HIV test although he was infected Syphilis one year prior to Mira.

This spouse was eager to seek Caesarian Section and disclose their HIV status, however they were failed to get one. The risk of Mother To Child Transmission can be reduced from up to 50 % without accessing any treatments to less than 5% by women accessing effective treatment during pregnancy, safe labour practice, and formula milk-feeding (or breastfeeding with certain rules) through PMTCT services [24, 25]. Caesarian section is seen main alternative for safe delivery for pregnant women living with HIV in limitted CD4 and viral load test [25]. We suggest in Mira and Kuyung's life were embedded to their 'perception of susceptibility' [26]. Mira, and most Muslim women, are taught that being a mother is prestigious and a high status job in Islam as per the famous hadith: "Paradise lies at the feet of the mother" [27].

HIV among MSM may bridge HIV transmission to married women as this present study also highlights being a bisexual and gay men was a considered as a lifestyle choice by participants. Being bisexual and gay man is perceived as 'abnormal' and 'sinful' within the discourse of heterosexual morality [28, 29], hence, bisexual and gay men in Indonesia may give up and decided to getting married to adhere to heterosexual normality in Indonesia [29]. To reduce social risk on their gayness, MSM generally did not open about their sexual orientation in public space, including to their female partners [29]. Unfortunately, unsafe homosexual practices may contribute the significant increase of HIV among MSM in Indonesia [1, 7, 30]. The risk of HIV transmission through anal sex is 18 times higher than vaginal sex without use of condom [31], however, the rate of condom use, which is effective for preventing HIV and other STIs, is very low amongst married couples [7, 32].

Preventing HIV among men having sex with men is still complex as their sexual practices are perceived as immoral and sinful. Consequently, this may actively prevent them from seeking HIV tests or disclosing their sexual orientation to their wives or other sexual partners [28, 29, 33]. As a result, unsafe heterosexual and homosexual relationship, a long period of asymptomatic HIV and deception within marriage may result in 'silent' HIV epidemic among Indonesian women. Another threat of this complexity of HIV transmission is a new mutation of HIV virus or recombinant strain of HIV is more likely to be occurred in Indonesia, like a recent study case among MSM in China [34].

Conclusion

This paper indicates that sexual transmission of HIV occurs among married women and men in a number of ways, including unsafe sexual practice between a married woman with a husband who has sex with men. Consequently, heterosexual married women have become a 'silent majority' of new HIV-positive cases. The notion of the shame, sinful, a hidden life-style about being a bisexual or gay man means that people do not talk about HIV and homosexual sex within a marriage. Unfortunately, there is limited HIV screening of pregnant women meaning women unknowingly pass HIV to their babies. Consequently, women need to be informed about the web of risk factors of contracting HIV within a deception and unsafe sex practice of men having sex with men with their heterosexual partners. Women should be empowered to make responsible decisions in their own right to reduce contracting HIV from their partner and transmitting HIV to their babies. In order to reduce of the risk of mothers transmitting HIV to their children and to enhance their early access to PMTCT services, these services need to be aware and address these gender discriminatory factors in their training and policies.

mHealth Development for Village Midwives to Improve the Performance of the Maternal Health Program in the Babakan Madang Sub-District, Bogor, Indonesia

Rico Kurniawan[1], Kemal N. Siregar[1], Nimas S. Martiana[1], Indriana K. Wardhani[1]

[1]Department of Biostatistics and Population Study, Faculty of Public Health, Universitas Indonesia

ABSTRACT

Maternal mortality rate is still high in Indonesia, supported by a decrease in K1 coverage. This incident often involves pregnant women who have not received services from the village midwife. An electronic application has been developed to improve the midwives' performance; however, since their workload is extremely high, many field activities, outreach, and mapping of pregnant women have not been well carried out. Village midwives will be equipped with an electronic application (mHealth) that will also be used by health cadres so that all pregnant women in the village can be mapped. With a better data collection mechanism for pregnant women, a map could be produced in all villages and the data could produce more accurate program objectives, such as identifying pregnant women in high-risk condition and preparing a better work plan. Moreover, maternal health performance can also be known immediately in real time by stakeholders, especially by the head of the sub-district and the public health center.

Keywords: *maternal health, midwife, mobile health*

Introduction

Maternal mortality rate (MMR) is an important indicator for improving maternal health status. The number of mothers who died due to complications from pregnancy and childbirth decreased from 532,000 in 1990 to 303,000 in 2015. More than 800 women die every day due to pregnancy and childbirth complications[1]. Efforts to reduce maternal mortality are still a priority in Indonesian health development. The causes of maternal deaths in several countries were 72.5% direct and 23.5% indirect[2]. In 2015, Bogor had a maternal mortality rate of 69, consisting of 2 pregnant women's deaths, 17 childbirth deaths, and 31 postnatal death; three deaths in the Babakan Madang sub-district contributed to the city's number. Maternal mortality in Bogor had several direct (such as bleeding) and indirect causes (such as maternal nutritional status, poor maternal knowledge, and the mothers' ages, either too old or too young). Late decision making, referring, and case handling are often factors that are found in obstetric complications cases[3]. Information regarding the targeted number of pregnant women in a work area is still lacking. Some pregnant women were not recorded because they were not accessed by health services.

As the spearhead of services in the work area, midwives have heavy workloads, which means that individual outreach is often not carried out optimally. Health information technology (HIT) has the potential to improve individual health, quality, costs, and greater care. Research conducted in assessments that provide health information found that 92% of the latest health HIT articles reached positive conclusions. It also found smaller benefits and services, and many more were initial users[4].

Data quality and documentation are needed to provide safe and appropriate services for the mother. For a long time, paper was used to record and report patient health and epidemiological data. However, with

the advent of technology, paper is slowly being replaced by electronic media[5]. mHealth is a part of eHealth that extensively covers electronic and digital health processes through telephones, computers, and the internet. In Kenya, mHealth was using to send text messages about malaria case management to rural clinicians. In Tanzania, information was exchanged via SMS between pregnant women and health facilities, which increased skilled birth attendance to 60% compared to 47% in a control group[6]. Ethiopia has used mHealth in the MCH field, especially in referral cases. Health workers are receptive to mHealth because it eases their work, which has made many health workers outside of MCH request mHealth development in their fields, such as immunization, family planning, and other disease services[7].mHealth has attracted attention as a means of supporting material, newborn, and child health in developing countries, and research to assess the impacts of health interventions is increasing[8].

To improve the maternal health program in Babakan Madang, mHealth was developed to assist the recording and reporting of maternal health activities. This tool is used by midwives and the community (cadres) in data collection for pregnant women; recording and reporting maternal health services is carried out to improve the midwives' performance. Midwives and workers in health centers can monitor maternal health and anticipate risks that will arise through the application. In addition, maternal health performance can also be known immediately in real time by stakeholders, especially by the head of sub district and the head of the health center.

Method

System Development: The methodology used in the development of this application is rapid application development (RAD), which combines various structured techniques with prototyping and joint application development techniques to accelerate the system development process. There are three stages in RAD: requirement planning, design workshop, and implementation. Requirement planning involves a needs analysis that explores problems and determines solutions. The design workshop explains how the business process flows in the use of the mobile health system. Implementation refers to the introduction of the socialization system that has been formed. This mHealth model uses the Open Data Kit platform.

Implementation: The system is implemented using a research operational approach. Implementation is carried out by identifying problems related to lack of system management control, which is caused by training resource issues, as well as an incomplete data and information from midwives. Work with partners to introduce this new implementation strategy into the health system and facilitate implementation, as well as an evaluation, as needed.

In Babakan Madang's community service program, target users, such as midwives, cadres, health centers, and village officials, are trained to use an mHealth application. Each user is given a form relating to health data that needs to be recorded. The form consists of the Mother Data Collection Forms and reporting forms for cadres at integrated health pots (Posyandu) level, the Maternal Care Form for midwives, and the Reporting Form for Vital Registration for village officials. Recorded data is then reported by sending data via mHealth application to the server. Reports can be monitored by midwives, community health centers, and village officials via the mHealth website.

Results

The maternal health program is currently still documented and reported manually by midwives. Midwives work independently from the data collection process for pregnant women, history, examination, recording of examination results, early detection of risk factors, and reporting data. The number of duties that a midwife has means that she cannot guarantee that all her work will be done optimally, so it is normal if the maternal health program's coverage is still low.

Input Requirements Analysis: The identified input components include health service facilities, health resources, funding, and stakeholders and organizations' support. In this case, health service facilities are health centers where data are reported (database), and health resources are midwives in five villages and health cadres that assist midwives during the data collection process with the inclusion criteria of having a smartphone (Android). Funding is the incurred cost during mobile health use, namely the loss of data and hosting packages. Stakeholders and organizations' support come from health centers and related health offices that encourage system development, and facilities and infrastructure that assists midwives and cadres in increasing maternal health programs' coverage.

Process Requirement Analysis: In the process of filling the mother's card in as primary data on maternal health services, the midwife must initial data collection of pregnant women to get first visit (K1) coverage according to the target. After the initial data collection, the midwife checks the mothers who come to health care facilities on a regular basis. From the results of routine examinations, the midwife can detect any risk factors that could endanger the mother and fetus's health so that they can be prevented or anticipated early. The process series was carried out independently by the midwife until the data was reported to the public health center regularly every month.

Mobile health development will empower health cadres to assist midwives in carrying out data collection. The cadre will record pregnant women by visiting pregnant women's homes thoroughly and using mobile phone-based applications. Therefore, when the mother is registered, she can go to the health care facility to conduct an examination, which be the midwife's responsibility. The examination results will be documented using web-based applications or a mobile phone; this will ease the work, so the midwife's performance is expected to be more optimal and maternal health services' coverage can increase.

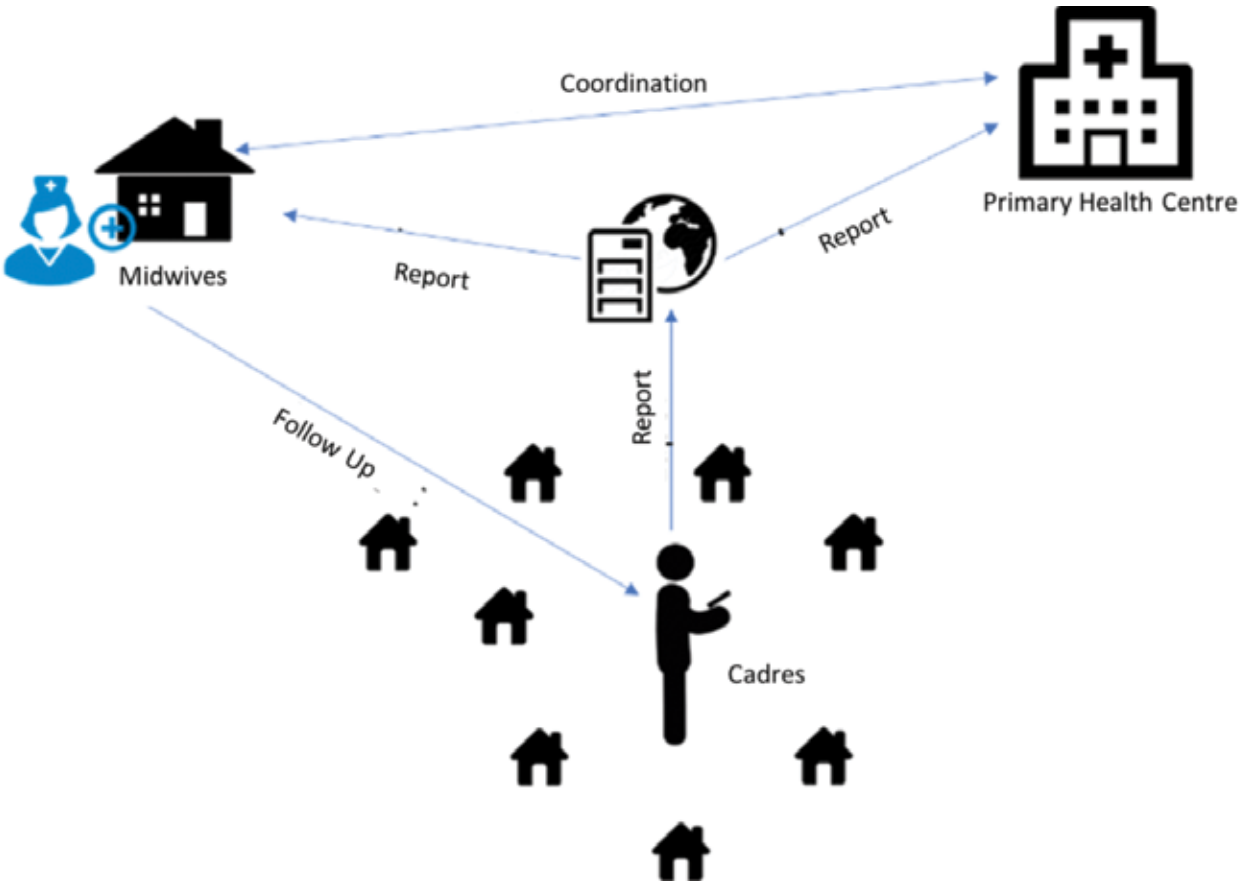

Figure 1: Workflow design of mHealth

Output Requirement Analysis: As previously explained, the recorded inspection results are reported every month as local monitoring for the maternal program report. Midwives must recapitulate manually, which some have called a burden that takes a lot of time and feels less efficient. For this reason, the development of mobile health applications aims to facilitate the maternal data recording and reporting process by making it web-based or done on a mobile phone. In addition, the application can facilitate reading data by displaying a dashboard that can be adjusted according to the level of the reader (Head of Public Health Center, Coordinator Midwife and Health Office). Based on needs from users, we developed several forms to facilitate both midwives and cadres regarding recording and reporting activities. For midwife, we created the form for recording and reporting on maternal health. As for cadre users, we developed seven forms to facilitate the recording and reporting activities at integrated health post (Posyandu).

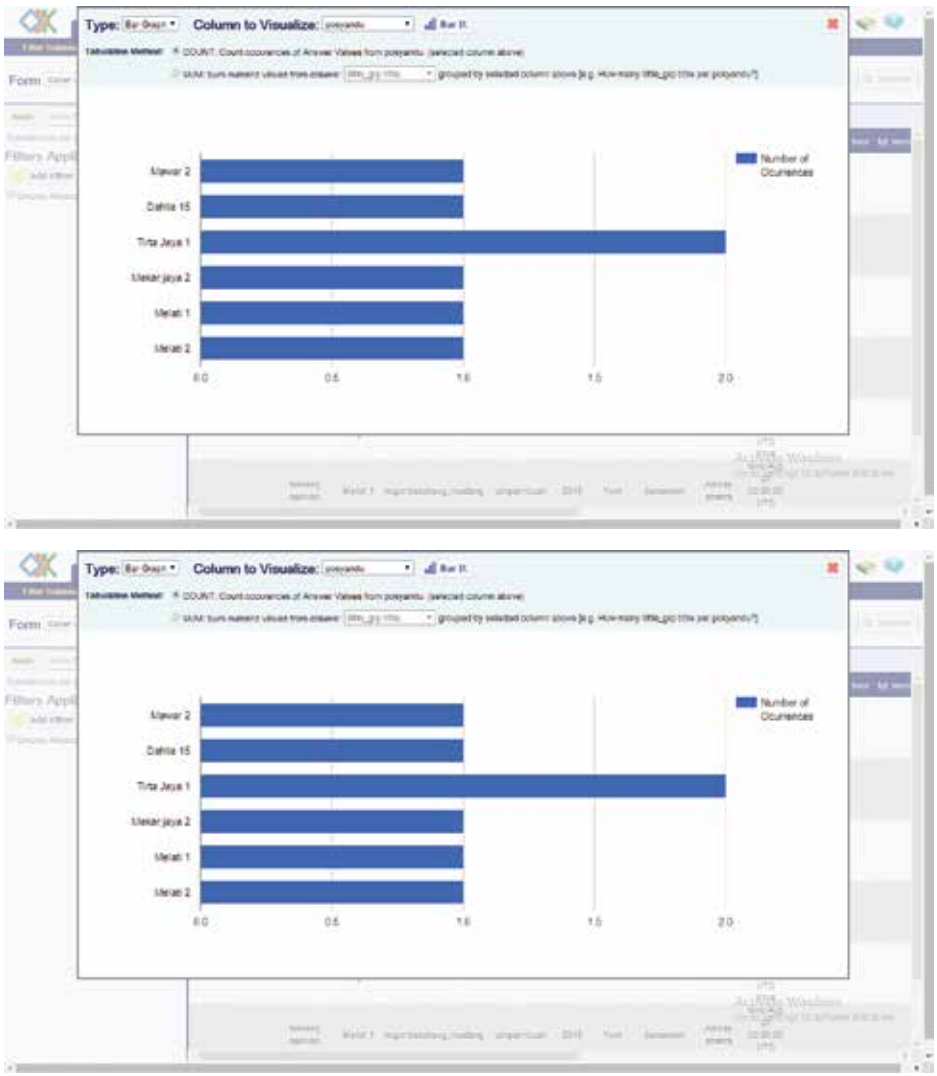

Figure 3: Direct data visualization

Discussion

Research conducted on eight choices made online in Indonesia shows that mobile phone use in health services bring positivity. The perceived benefits reported are: (i) ease of contact between patients, midwives, and supervisors; (ii) increased time efficiency due to the ability to coordinate visits; and (iii) if complications occur, assistance is only one call away[9]. At present, almost all communities, both rural and urban, use smartphones. Moreover, health workers and midwives have used hand phones in patient referral systems. As an example of using mHealth in the field of maternal health, India uses a Mother and Child Tracking System that registers pregnant women and children using cell phones so that they get scheduled services. Uganda uses the UNICEF Birth Registration System with rapid SMS to maintain an electronic database center so that data are less confusing and more efficient[10]. According to the study about mHealth intervention's role in maternal and child health service delivery, findings from a randomized controlled field trial in rural Ethiopia showed that short message service-based mobile telephone intervention could indeed improve the effectiveness of frontline health worker, primarily in improving access to antenatal care, delivery services, and postnatal care. The number of ANC visits and percentage of deliveries attended by health workers improved, and also facilitated the work process of frontline health workers[11].

This research is in accordance with previous studies relating to the use of electronic devices to help improve the performance and quality of workers, especially in the health sector, such as the Indian health service system and the Mosoriot Record System in Kenya, which states that enabling electronic devices can increase employee productivity and satisfaction, save time, and provide better quality data[12].Activities carried out in several developing countries gave the same results. The level of poverty and a decrease in the quality of life of the community[13]. mHealth has also been developed as a surveillance tool for research conducted in Sub-Saharan Africa[14].

There is some positive evidence for the effect on mHealth interventions on outcomes, such as ANC attendance, skilled attendance at birth, and oral contraception utilization[15]. It is evident that mHealth use can increase effectiveness and security for village officials and equipment. Since cadres can immediately send collected data to the server, the midwife and officials can immediately recapitulate the results and take the next step, resulting in more time.

Conclusion

mHealth was implemented in Babakan Madang to improve the performance of midwives in the public health center. The work process was carried out using an electronic-based mHealth application (web and android). Initial data collection was assisted by cadres to reach all pregnant women in the Puskesmas work area. This makes midwife work more effective because master data is available as a reference in providing services, so the midwives can immediately conduct anamnesis and examination. Thus, the performance of midwives can increase because the process of digitizing the maternal health program can ease their work.

With the mHealth application, the system of recording maternal health programs becomes more efficient and effective because it implements a paperless system in real-time, so that the resulting data becomes more accurate. In addition, coverage of pregnant women who are recorded is expected to increase because the data collection process is assisted by cadres. Mobile phone solutions may save the lives of women and their newborns, and may contribute to the achievement of Millennium Development Goals 4 and 5; therefore, they should be considered by maternal and child health policy makers in developing countries[16]. mHealth interventions targeted at pregnant women can be an effective solution to increase service utilization to improve maternal and neonatal outcomes. Integration of mHealth into the healthcare system can pave the way to improved decision making on how best to implement mHealth interventions[17].

The Influence of Dental Health Education on the Gingival Health of Students at STIKES Muhammadiyah Palembang

Dientyah Nur Anggina[1], Resy Asmalia[1]

[1]Department of Publich Health, Medical Faculty, University of Muhammadiyah Palembang, South Sumatera, Indonesia

ABSTRACT

Students often suffer from gingivitis due to stress and lack of awareness of the need to maintain good oral hygiene. One strategy for improving the behaviors to maintain good oral hygiene is Dental Health Education (DHE). This study aimed to analyze the influence of DHE on the gingival health of students in STIKES Muhammadiyah Palembang. This study was quasi-experimental with a pre-test and post-test design. Sampling was accomplished with the total sampling method, which resulted in the inclusion of 36 students in the first level of midwifery at STIKES Muhammadiyah Palembang. This study used a simulation method of tooth brushing and the study instruments consisted of a gingival examination and knowledge questionnaire. The measurements from pre-test to post-test showed that the students' knowledge of oral hygiene improved and their severity of gingivitis decreased, according to their gingival index scores. The results of the Wilcoxon test analysis showed $p<0.05$, meaning that there were significant differences in students' knowledge and gingival health before and after participating in DHE. Thus, the study results revealed that DHE had a significant influence on gingival health.

Keywords: *Dental Health Education; gingival health; students.*

Introduction

People who are classified as "students" range in age from late adolescence (18-21 years) to early adulthood (22-24 years) and are currently registered and studying at a College. As students transition from their late teens to early adulthood, they are at an age at which they should be able to adapt to various demands and new environments[1]. In terms of their growth and development, students often have oral hygiene problems, especially of the gingiva. Oral hygiene is a very important means of preventing these problems, particularly because some problems develop specifically due to poor oral hygiene. If oral hygiene is not properly maintained, it can affect the health of the entire body because the teeth and mouth are an integral part of the body's system[2].

Data from the Indonesian Dentists Association show that the prevalence of gingivitis worldwide is 75%-90%. In Indonesia, gingivitis is the second most frequently occuring oral disease, affecting 95.8% of the population[3]. Gingivitis is an inflammation of the gingiva that does not result in the attachment loss of clinical gingiva, the main cause of which is the accumulation of plaque in the cervical area of teeth and their surroundings. Gingivitis can be prevented by controlling plaque mechanically, such as by brushing the teeth, and chemically, by using toothpaste as well as mouthwash that contains antimicrobial agents[4]. According to Dumitreschu *et al.* (2010)[5], the gingiva-related problem often experienced by students is gingivitis which can be caused by psychological factors, such as stress, which commonly occurs as part of college life. Stress can induce an increased accumulation of plaque, which can, in turn, increase the risk of gingivitis in college students. In addition, gingivitis in students can also be caused by a lack of awareness of the need to maintain good oral hygiene.

Strategies are being developed to improve the behaviors that lead to good oral hygiene, particularly as it relates to the gingiva, including the simulation-based approach known as Dental Health Education (DHE). DHE is a learning process aimed at individuals and community groups to help people achieve the highest possible level of oral hygiene. To succesfully change behaviors, the aim of DHE can best be realized by choosing the right teaching method[6]. The advantage of the simulation method used in this study is that it can provide experience, encourage decision-making, and share the value of good oral hygiene. It can be used to individuals, groups and entired communities. The simulation activities can be easily understood by learners so that their application of the skill taught yields positive[7].

STIKES Muhammadiyah Palembang was chosen as a research location because it currently offers no research on gingival health and the lack of counseling about oral hygiene has resulted in students having insufficient knowledge of how to maintain good oral hygiene, especially as it relates to gingival health. The preliminary survey data of this study showed that 70% of 90 college students in the first level midwifery have a low level of oral hygiene. This study aimed to analyze the influence of Dental Health Education (DHE) on the gingival health of students at STIKES Muhammadiyah Palembang.

Method

This study was quasi-experimental study and used a pre-test and post-test design. Pre-test and post-test were accomplished through an examination of gingival health and an assessment of student's knowledge before and after participating in DHE. The assessment consisted of students filling out the questionnaire that was score according to whether answers were correct (score = 1) or incorrect (score = 0). DHE was performed by counseling using a tooth brushing simulation by modified Stillman method.

This study was conducted at STIKES Muhammadiyah Palembang, and total sampling was used to select subjects who met the inclusion criteria; students in the first level of midwifery studies at STIKES Muhammadiyah Palembang, students who had their own teeth (the element of teeth were 16, 21, 24, 31, 34 and 46), students with gingivitis, and students with willingness to participate in this study. Excluded from this study were students who were smokers, menstruating or pregnant, wearing an orthodontic appliance, or had a systemic disease and had used an antibiotic during the month before this study. After inclusion and exclusion criteria were met, a total of 36 students comprised the sample that participant in this study.

The instruments used in this study took the form of a gingival examination and a knowledge questionnaire. The examination of gingival health used the using gingival index (GI) assessment according to Loe and Sillness ; the first upper right molar (16), the first upper left incisor (21), the first upper left premolar (24), the first lower left molar (46), the first lower right incisor (31), and the first lower right premolar (34). Probing was done at the gingival sulcus of each tooth, with each tooth calculated on four sides (i.e., mesial, distal, facial and lingual) and divided by 24. The examination results were categorized as 0 (healthy), 0.1-1.0 (mild gingivitis), 1.1-2.0 (moderate gingivitis), or 2.1-3.0 (severe gingivitis).

The questionnaire was used to determine the student's level of knowledge with 10 sentences regarding oral hygiene and was scored according to three categories; "high" if the score was between 76% and 100%, "adequate" if the score was 56% and 75%, and "low" if the score was lower than 56%[8]. Other tools and materials used in this study were a periodontal probe, mouth mirror, *nierbekken*, mask, *hand scoen*, alcohol 70%, and a dental model.

Data were collected in several stages; 1) the recording of each respondent's identity, 2) before the intervention (DHE) took place, respondents gave their informed consent, 3) during the pre-test, when the gingival health was examined using the gingival index and when the respondents filled out the questionnaire, 4) when the intervention (DHE) was given to the respondents, including the toothbrush simulation with the modified Stillman method, and 5) one week after DHE, the respondents returned for the post-test which included another gingival health examination and questionnaire. Data were analyzed using the Wilcoxon test to determine the influence of dental health education (DHE) on student's gingival health

Results

Table 1: The oral hygiene knowledge levels of the respondents

Categories	Before DHE		After DHE	
	n	%	n	%
High	16	44.4	34	94.4
Adequate	18	50	2	5.56
Low	2	5.56	0	0
Total	36	100	36	100

Notes: n = number of sample, % = percentage

Based on Table 1, before DHE, only 44.4% of the students had a high level of knowledge about oral hygiene. This indicated that 55.56% students with only an adequate or low level of knowledge did not know about the importance of maintaining oral hygiene, especially their gingival health, which increased their risk of gingivitis[2]. After DHE, 94.4% of students showed a high level of knowledge.

Table 2: Result of the gingival health examination of respondents

Categories	Before DHE		After DHE	
	N	%	N	%
Healthy	0	0	0	0
Mild Gingivitis	26	72.2	36	100
Moderate Gingivitis	10	27.8	0	0
Severe Gingivitis	0	0	0	0
TOTAL	36	100	36	100

Notes: n = number of sample, % = percentage

The results of the gingival health examination using the Loe and Sillness Gingival Index (GI) can be seen in Table 2, which shows that, 27.8% of the students had moderate gingivitis before DHE. As was seen in this study, after DHE, the severity of gingivitis had already decrease. All of the students had only mild gingivitis after the study and not a single student had even moderate gingivitis.

Table 3: The influence of DHE on gingival health

Variable	Result	Probability (p value)
Level of knowledge	Pre-test	0.000
	Post-test	
Gingival Index	Pre-test Post-test	0.002

The Wilcoxon test was used to determine whether DHE with the toothbrush simulation had the effect of improving student's knowledge of oral hygiene and the result obtained was p value = 0.000 (p value < 0.05). This result indicates that there was a significant difference in the levels of knowledge before and after DHE. A similar result was obtained as it relates to the gingival health examination. Based on the Wilcoxon test, the result obtained was p value = 0.002 (p value < 0.05), which means that there was a significant difference in the Gingival Index before and after DHE. Thus, it can be concluded that DHE using the toothbrush simulation significantly influenced gingival health by improving the student's level of knowledge and decreasing their severity of gingivitis (Table 3).

Discussion

Knowledge can be improved with information, which can, in turn effect changes in behavior. Knowledgeable people typically have greater awareness and behave according to what they know[9]. Oral hygiene information can be provided by Dental Health Education (DHE), which aims to achieves high levels of oral hygiene[6].

According to Notoatmodjo[10], this increase in knowledge likely took place because the learning process provided new information that substituted for previous knowledge or represented an improvement over existing knowledge. If someone has a specific sense on object or stimulus after information is given, either through the sense of hearing, sight, smell, taste or touch, the possibility of improving knowledge grows stronger. The knowledge provided about gingival health in this study included the impact of not maintaining good oral hygiene along with a recommendation of an effective method and frequency of toothbrush.

According to Loe and Sillness (1963)[11], the symptoms of moderate gingivitis include gingiva enlargement, erythema, and bleeding when probing. Students are vulnerable to gingivitis because of college-related stress and a lack of awareness of the need to maintain gingival health[5]. Actually, most of the students in this study were already familiar with an appropriate frequency of toothbrush, but their severity of gingivitis was probably because they did not fully understand how to brush their teeth correctly.

In this study, students simply practiced better oral hygiene during this study which can be known after the

activities had been done continuously. Therefore, DHE with simulation can improve awareness and knowledge that can change behaviors and, in turn, improve oral hygiene, especially as it relates to the gingiva. Stillman method was used as a simulation method in this study because it was a highly recommended, simple and efficient toothbrush method that can applied in all parts of the mouth. This method also can give gingival massage and expected to clean debris in interproximal area and gingival sulcus[11].

The decrease in the Gingival Index scores after one week post DHE indicated a decrease in the severity of student's gingivitis and an improvement in their gingival health, perhaps because the students were motivated to follow the toothbrush instructions and maintain good oral hygiene. This result contrasts with the study conducted by Herliana *et al.*, in which there were no changes in Gingival Index scores after study respondents received counseling through video. These different results suggest that if an individual has the necessary knowledge but does not apply it every day to maintain good oral hygiene, it can have poor implications for oral hygiene particularly gingival health[12]. Motivation is the force that can encourage a person to act. Motivation is also important stimulus in the health education process because it is needed to change existing behaviors and maintain new and improved behaviors[13]. Motivation was demonstrated by the students in this study in their maintenance of gingival health and their positive response to the knowledge they gained during DHE.

The use of the simulation method in DHE is one of the strategies that supports the success of the learning process by helping the respondents better understand the learning materials. The simulation method took the form of two-way interaction between the instructor and the students, allowing the students to focus on observing, practicing and discussing the instructor's stimulation of correct toothbrush so that they could better comprehend the problems caused by poor oral hygiene. If the simulation is done correctly, it can positively affect the learning process and impart knowledge that can change attitudes and behaviors[7].

Effectiveness of health education is largely based on the use of a presentation method stimulates the sense, especially sight and hearing. If we can adequately stimulate the senses to receive a message, information can be presented more clearly and the respondents can more easily absorb and remember the information[14]. The students who participated in this study, as a young people aged 17-22 years have already begun to make independent decisions about their health, adapt to the new information about their environment, and form and adopt behaviors that affect their health[1]. As such, this study was in line with a study conducted by Haryani *et al.*, which sought to demonstrate that dental health promotion can improve student's oral hygiene. After the students in that study were given dental health information using an interactive lecture method, the results showed increased oral hygiene index scores[15].

Conclusion

The results of this study showed that Dental Health Education (DHE) significantly influenced improvement in the gingival health. The simulation method used in this study could increased student's knowledge and decreased the severity of their gingivitis, so the students could easily understand and remember how to correctly brush their teeth.

A Smart Nutrition Management System and Nutrition Related Diseases in Humans

Kardokh H. Kaka Bra[1], Eko Supriyanto[1,2,3]

[1]School of Biomedical Engineering and Health Sciences, Faculty of Engineering, [2]Advanced Diagnostics and Progressive Human Care Research Group, [3]IJN-UTM Cardiovascular Engineering Centre, Universiti Teknologi Malaysia, Johor, Malaysia

ABSTRACT

The rapid rate of urbanization and world population increase has given rise to new challenges. Increasingly more nutrition- and metabolic-related conditions are appearing as a result of poor nutritional management and lifestyle choices. Clearly, without food management, a person could suffer enormous drawbacks in his or her private and social life. The objective of this project is to help people eat smarter and more mindfully, manage their body conditions, and further improve their relationship with food, in order to facilitate the early diagnosis of certain diseases (e.g., cardiovascular diseases) and to improve the recovery as well as prognosis of these diseases. A system, method, and computer program for integrated, personalized nutrition management is proposed in this study. The nutrition management system features a user data calculation processing unit that calculates the required nutrient quantity for a person based on the person's data. It also calculates the excess or deficiency of nutrients of the person based on the required nutrient amount and nutrient evaluation outcome data of the person, including a meal information search engine user interface that searches for the food data based on input from the user. The system was used by a small group of 20 university students and staffs who, overall, found the experience to be useful and functional with comments to improve the search engine user interface. The results of analysis were fetched fast and accurately. Therefore, the system can be used not only by the general population, but also by dietitians and nutritionists to accurately manage and personalize the nutritional wellness of the society.

Keywords: *Nutrion, Management System, Computer-based, Smart System, Disease Management, Early Diagnoosis*

Introduction

Nutrients supply energy and are the building blocks of numerous materials, which are important for the growth and livelihood of each human being. Macronutrients contribute the entire required energy. However, in the end, the energy that macronutrients yield will be used to ensure muscular tissues and organs of the body function properly. The release of energy for production, motion, and different capabilities is dependent on the micronutrients, which operate as coenzymes, co-catalyst, and buffers within the remarkable, fluid environment of metabolism. States of dietary deficiency or excess could take place when a person's food consumption does not match his or her necessity for optimum wellbeing. Therefore, a balance between nutrient consumption and nutrient necessities must be maintained [1,2,3].

Resolution making involves selecting various courses of motion out of a given number of courses to achieve a purpose or objective[4]. Resolution making is a prestigious scientific, social, and financial endeavor. Hence, a choice-making scenario entails partial, incomplete, or inexact data. A decision support system (DSS) is a responsive computer-based system, which assists resolution makers to make the most of information and models to unravel unstructured issues[5,6,7]. In some resolution conditions, assistance supplied in the form of information and model administration alone is probably not enough[8]. An expert system (ES) presents further

assistance that could substitute human experience via supplying the required data; nevertheless, a number of different smart services can also be utilized to assist decision-making that requires experience[9,10,11]. ES is an influential technique that helps decision-making and can be applied for a wide range of issues[12,13,14].

Therefore, in this project, we establish a nutrition management system to deal with inexact, and overall unhealthy eating habits.

Method

A system, method, and computer program for integrated, personalized nutrition management is proposed in this study, starting with the crafting of a graphical user interface for the system using Filemaker® Pro 16 Advanced, which is an SQL-based, cross-platform relational database management system that facilitates the implementation of a database engine along with a graphical user interface utilizing the same software. The nutrition management system in this study features a user data calculation processing unit that calculates the required nutrient quantity for a person (the user) based on the user data and calculates whether the person has an excess or deficiency of nutrients based on the required nutrient amount and nutrient evaluation outcome of the user data. The system also provides a meal information search engine user interface that searches for food data based on input from the user, and a meal information calculation processing unit that calculates the nutrient quantity obtained from a meal based on the meal analyzer data. Furthermore, it also provides food information based on the nutrient quantity and shows whether the person has an excess or deficiency of nutrients. The system is designed in such a way that allows the user to input information such as age, gender, weight, height, level of activity, and whether or not the user smokes, into different fields, each with a drop-down menu whenever convenient, to assist in the filling up of data. The user could also choose weight goals such as "lose weight", "maintain weight", or "gain weight", which are implemented in a separate field. After filling out these fields, the "recommended daily energy requirement" and the "energy to achieve goal" is also calculated at the back-end of the system and presented to the user, along with the recommended daily intake for other macro- and micronutrients, each personalized according to the data obtained from the user. It is the quantity of these calculated nutrients that the meal analyzer will output as the end report against the nutrients obtained from daily foods through algorithms to find out whether there is an excess or deficiency in the nutrients. When a user inputs personal data, the data is sent to the back-end of the system and management unit, where it will be processed and then recorded. In the case of calculating daily calorie requirements or macronutrients/micronutrients, the input data is processed using mathematical formulas to output individualized results for each user. This program manipulates the food, menu, and meal and search database. The user can then choose a recommended general and therapeutic menu using this system based on his or her preference and lifestyle (Figs.1 and 2).

In the case of the meal analyzer, the management unit searches for special codes in the database to find a corresponding food nutrition component table. It then sends the corresponding food nutrition component table to the front-end user interface and compares these results to the recommended dietary requirements of calories and essential nutrients in the form of a report (Fig. 5).

The user can also take advantage of the cardiovascular risk assessment portals to determine the potential possibility of developing coronary heart diseases in the next 10 years of his or her life as well as receive customized lifestyle and dietary recommendations based on the results of the analysis. The minimal design of the database's graphical user interface displays the daily ingestion amounts for a variety of nutritions, sends a report that states whether the nutrition of the user is insufficient or in excess, and provides possible diseases and conditions corresponding to the nutrition insufficiency or excess.

Several predictive equations can be used to calculate the basal metabolic rate of the user such as the Harris-Benedict, Mifflin-St Joer and WHO/FAU/UNU equations. In our database, for the estimation of daily calorie requirement, the predictive equation for resting energy expenditure (REE) based on the Mifflin-St Jeor study was utilized because it is the most reliable and accurate according to the literature[14,15,16]. This equation is provided below:

REE (males) = 10 × Weight (kg) + 6.25 × Height (cm) – 5 × Age (y) + 5

REE (females) = 10 × Weight (kg) + 6.25 × Height (cm) - 5× Age (y) – 161

In a study in 2014, to evaluate the efficiency of the BMR formulas, the BMR of overweight and normal-weight people was measured using indirect calorimetry (IC), and then the outcomes observed from the predictive formulas were assessed to evaluate the variations presented between estimated values and those calculated by IC. In both cases, the Mifflin-St. Jeor formulas were the most accurate, with a variation of -9.1% when compared to IC in obese individuals and 0.9% variation compared to normal-weight individuals. The research reported the Mifflin-St. Jeor equations as the most accurate equation for estimating BMR since it is the only equation that allows the valid prediction of BMR in obese individuals. The study did not advise using the equations of FAO/WHO/UNU, Harris and Benedict, Schofield, and Henry and Rees for predicting BMR in these populations, because these formulas tend to exaggerate energy demands. However, these formulas could still produce satisfactory results in predicting the BMR of normal-weight individuals. Nonetheless, they advised that the BMR of overweight patients be measured more carefully and cautiously so as the most convenient course of action pertaining to the foundation of physical activity level and eating pattern of this group is accurately represented[16].

To calculate the recommended daily calorie intake, after taking into account physical activity level (PAL) (Fig. 3), the guidelines below are referred to:

- 1.200 = sedentary (little or no exercise)
- 1.375 = light activity (light exercise/sports, 1–3 days/week)
- 1.550 = moderate activity (moderate exercise/ sports, 3–5 days/week)
- 1.725 = very active (hard exercise/sports, 6–7 days a week)
- 1.900 = extra active (very hard exercise/sports and physical job)

Daily Calorie Requirement = REE×PAL

The user is able to choose from a selection of different eating styles including the Popular style, Vegetarian style, Mediterranean style, and Malaysian style. Each style encompasses a variety of food components such as vegetables, grains and cereals, meat and poultry, fruits, oils, and legumes. The food components of each style are quantified precisely and personalized according to the daily calorie needs and the presence of special conditions of the user (e.g., cardiovascular disease) (Fig. 4).

Figure 2: Welcome screen layout for the graphical user interface database

Figure 3: The screen for calculating user daily calorie requirements

Figure 4: The screen for the recommended eating styles of the user based on the nutrition management system

Figure 5: The meal analyzer search engine user interface

Results

In this study, a nutrition management system was developed, which utilizes a user information calculation processing unit that calculates the required nutrient amount of the user based on user information and calculates the nutrient excess or deficiency information of the user based on the required nutrient amount. It then outputs the nutrient analysis result information for the user. The system was used by a small group of 20 university students and staffs, who overall found the experience to be useful and functional with comments to improve the search engine user interface.

Therefore, the system can be used by not only the general population, but also by dietitians and nutritionists, who have the responsibility of creating menus for clients, as well as specialists in the field of food and nutrition. It can also be a useful tool for nutrition education and nutrition counseling, as it can help establish a really comprehensive connection between food and body.

Discussion

After using the system, the users were asked about their overall experience in using the different parts of the system and to provide feedback about the idea of integrating cardiovascular risk estimation into the developed system. Their reactions were mostly positive. Several were impressed with the implementation of the food composition database and daily meal analyzer. However, they suggested improvements to the search engine graphical user interface so that it would have a more practical feel. One strong point to improve the features of this service was to supply a diet management system and a diet management application that could enable nutrition management and acknowledgement of food-associated conditions. Within the diet management system, in line with the application example described above, the consumer information could embody private data, where the private data could include attribute information relating to at the very least one of gender, weight, age, or physical activity of the individual. Then, the user data calculation processing unit could calculate the required nutrient quantity of the person primarily based on at the very least one of gender, weight, age, or physical activity of the person. Therefore, the system can be used by not only the general population, but also by dietitians and nutritionists who have the responsibility of creating menus for clients, and specialists in the field of food and nutrition. It can also be a useful tool for nutrition education and nutrition counseling, as it can help establish a really comprehensive connection between food and body.

Conclusion

Daily energy needs is the most important nutritional determinant because energy should be provided regularly to meet the requirements of the human body to survive. Every individual has to be aware of his or her energy status so that he or she could strike a balance between energy intake and consumption and make an educated decision regarding his or her eating habits. The purpose of a sufficient and well-organized diet is to prevent calorie and nutrient excess or deficiencies. Nowadays, there is increased understanding of the vital roles that diet has in the initiation or prevention of certain diseases, such as cardiovascular diseases, stroke, cancer, and diabetes mellitus. Insufficient energy intake will restrict the potential of populations in many developing and third-world countries, while excess energy and food intakes are increasingly giving way to very high occurrences of obesity and its accompanying complications across all socio-economic groups in both developing and developed countries. This study is an attempt to provide a practical and easy-to-use tool for comprehensively understanding healthcare and decision-making concepts.

Dominant Hypertension Factors of Adolescents in West Java, Indonesia

Mujahidil Aslam[1], Trini Sudiarti[1], Ratu Ayu Dewi Sartika[1], Engkus Kusdinar Achmad[1]

[1]Department of Community Nutrition, Faculty of Public Health, Universitas Indonesia, Depok, Indonesia

ABSTRACT

Adolescents are susceptible to degenerative diseases such as hypertension. The hypertension prevalence of the adolescents in West Java, Indonesia is 10.5%, which exceeds the national prevalence of 8.7%. This cross-sectional study was conducted in 2018 in West Java, Indonesia, and involved 152 students selected using a simple random sampling technique. The data was analyzed using chi-squared and logistic regression tests, and the results revealed that 11.8% of the students exhibited hypertension. Moreover, the significantly related factors included the sex, body mass index/age, and sleeping duration, while the sex of the students most dominantly influenced the hypertension rate (p=0.021, odds ratio=8.9). Based on these results, adolescents in Indonesia should undergo regular blood pressure checks, and they should be encouraged to eat more balanced diets, while reducing fatty foods, in order to reduce their risks of high blood pressure and obesity.

Keywords: *age, body mass index, blood pressure, sleeping duration, sex*

Introduction

According to the Centers for Disease Control and Prevention, adolescents are in the development stage of the transition from childhood to adulthood at 10–19 years of age. As described by the United Nations International Children's Emergency Fund's definitions of prehypertension and hypertension, teenagers fall into two categories: early adolescence (10 –14 years old) and late teens (15–19 years old)[1]. In adolescents, hypertension is defined as repeated systolic and diastolic blood pressures above the 95thpercentile[2].

Hypertension is a blood vessel disorder from 1999 to 2010; however, there were no permanent that interferes with the oxygen supply and nutrients carried by the blood to the tissues that require them. This disease often arises without any symptoms, so it is considered to be a "silent killer"[3]. The prevalence of hypertension in adolescents is 4%, and an increase in a single blood pressure measurement indicates a 4% to 17% susceptibility[4]. Based on the National Health and Nutrition Examination Survey (NHANES) data, the 2016–2017 hypertension prevalence among adults was 29% (30.2% of men and 27.7% of women). The prevalence rate increased changes until 2016. Additionally, the 2016 NHANES data showed that there was a blood pressure increase in children and adolescents (8–17 years old) in the US[5]. According to the Basic Health Research data from 2013, the hypertension prevalence in Indonesia (≥ 18 years old) was 25.8%; it was 29.4% in the West Java Province and 27.6% in the Bogor Regency[6]. The Basic Health Research data from 2007 reported hypertension prevalence of Indonesian adolescents 15–24 years old was 8.7%, while the prevalence in West Java was 10.5%. These rates show the hypertension prevalence of individuals ≥18 years old and 15–24 years old in the West Java Province were higher than the national level[7]. Some of the factors contributing to the high hypertension prevalence of adolescents cannot be changed, such as genetics, sex, race, and age. However, some risk factors can be changed, including obesity, lack of exercise or physical activity, stress, smoking, alcohol consumption, potassium, calcium, and a diet high in fat and sodium[8].

Method

This cross-sectional study was conducted at Health Vocational School located in Bogor, West Java, Indonesia. The research began in April–May 2018, with a total

152 students which chosen by simple random sampling technique as respondents based on the Lemeshow difference in proportions hypothesis test. The data collected included direct interview using a questionnaire, subject characteristics, physical activity level, sleep duration, and stress. The subject characteristics (the sex and family history of hypertension) were obtained directly using a questionnaire. The anthropometric data (height and body weight) were used to measure the nutritional status by dividing the BMI (kg/m^2) by the age (years). The weight was obtained by having the subjects step on to a scale (increments of 0.1 kg), and the height was measured using a Microtoise (increments of 0.1 cm). The nutritional intake data (amounts of sodium, potassium, calcium, fat, fruits, vegetables, and water consumed) was obtained from direct interviews using a 2 x 24-hour dietary recall method (weekday and weekend). The questionnaire and interview formats were based directly on the Physical Activity Questionnaire for Adolescents (PAQ-A) and the Perceived Stress Scale. Each subject's blood pressure was obtained using mercury sphygmomanometer. The physical activity levels were obtained using questionnaires and interviews based on the PAQ-A.

Results

Table 1 shows 11.8% of the students exhibited hypertension 95.4% were females; 28.9% had genetic (family) histories of hypertension, and 19.7% of the students were overweight. The nutrient intakes were as follows: 50% had high sodium intakes, 50% had low potassium and calcium intakes. Another results 50% had high fat intakes,75% had low fruit intakes, 65.1% had low vegetable intakes, and 49.35% had low water intakes. Furthermore, 37.5% of the students exhibited low physical activity levels, 3.9% smoked, 31.6% had low sleep durations, and 88.2% exhibited stress.

The bivariate statistical test results are shown in Table 2. The results of the odds ratio testing (OR=6.50, 95%[CI] 1.32-32.85) showed that the male students had a 6.50 times higher risk of hypertension compared to the female students. This corresponds with the research conducted in Brazil which showed the gender exhibited a significant relationship with hypertension; the percentage of males (22%) with hypertension was greater than the percentage of females (9.7%)[9]. A study also reported the males had higher risk of hypertension than females[10]. It was because women have higher prevalence of healthy living behaviors than men, such as healthy eating habits and avoiding smoking and alcohol consumption. Additionally, male adolescents have higher hypertension risk because they accumulate more visceral and intra-abdominal fat.

Table 1: Univariate Analysis

Variable		Total	Percentage (%)
Hypertension	Yes	18	11.8
	No	134	88.2
Sex	Male	7	4.6
	Female	145	95.4
Genetic	Yes	44	28.9
	No	108	71.1
BMI/A	Overweight	30	19.7
	Normal	122	80.3
Natrium intake	Over	76	50
	Adequate	76	50
Pottasium intake	Defisit	76	50
	Adequate	76	50
Calsium intake	Defisit	76	50
	Adequate	76	50
Fat intake	Over	76	50
	Adequate	76	50
Fruit consumption	Defisit	114	75
	Adequate	38	25
Vegetable consumption	Defisit	99	65.1
	Adequate	53	34.9
Water consumption	Defisit	75	49.3
	Adequate	77	50.7
Physical activity	Sufficient	95	62.5
	Less	57	37.5
Smoking	Yes	6	3.9
	No	146	96.1
Sleep duration	Less	48	31.6
	Sifficient	104	68.4
Stress	Stress	134	88.2
	No Stress	18	11.8

The results also showed a higher BMI/A proportion in the hypertension cases (OR=5.38, 95% [CI] 1.91-15.14). These results correspond to study which described a significant relationship between the BMI/A and hypertension[11]. A study showed the adolescents with

higher BMI/A ratio had 12.3 times chance of developing hypertension[12]. A study in India also showed a significant relationship between the BMI and hypertension[13]. However, a study in Brazil showed there was no significant relationship between BMI/A and hypertension[14].

Obesity is one of factors associated with hypertension in adolescents, and related the activation of sympathetic nervous system, insulin resistance, and vascular dysfunction. Teenagers with overweight experience an increase in sympathetic nervous system activity, which causes increases the heart rate and blood pressure. The insulin resistance occurs due to obesity inhibits glucose absorption and affects the sodium resistance, causes the heart rate and blood pressure. The insulin resistance which occurs due to obesity inhibits glucose absorption and affects the sodium resistance, which causes increase in the blood pressure[15].

This study showed a difference in the proportion of smoking between those individuals with and without hypertension (OR=8.73, 95% [CI] 1.61-47.79). It means the students who smoked exhibited hypertension 8.73 times more often. These results are similar to a study which showed that the adolescents who smoked had a one-time risk of developing high blood pressure, and this was a significant relationship[16]. Contrarily, a study showed no significant relationship between smoking and the hypertension incidence[17]. Smoking is one of the causes of hypertension. This is because the chemicals contained in tobacco can damage the inner walls of

the arteries, making them more susceptible to plaque build-up (atherosclerosis). Additionally, the nicotine in cigarettes can stimulate the sympathetic nervous system, which increases the heart rate and constricts the blood vessels. Moreover, the carbon dioxide released by cigarettes can replace the oxygen in the blood, forcing the heart to work harder to meet the oxygen demands of the body[18]. The results of this study also showed that differences in the sleep duration were related to hypertension (OR=4.12, 95% [CI] 1.48-11.43). This means that those students with a lower sleep duration had 4.12 times the risk of experiencing hypertension than those with a sufficient amount of sleep. This is similar to the research which showed a significant relationship between the sleep duration and blood pressure in adolescents[19]. The biological mechanisms of a poor quality of sleep causing hypertension are not known with certainty, but they may be related to a cortisol secretion disturbance. The stimulation of the renin-angiotensin system and the sympathetic nervous system due to an increase in catecholamine secretion can cause hypertension; therefore, adolescents with a poor sleep quality may exhibit a homeostasis system disruption. This disruption can result in increased brain activity, thus, results in the secretion of various hormones. These hormones (epinephrine and norepinephrine) can affect the peripheral resistance, and factors combined can increase the blood pressure. One study showed there were no significant differences between the genetic factors with regard to hypertension[20]. Additionally, a study reported there was no significant relationship between genetic hypertension and hypertension it self[1]. However, Angesti showed a significant relationship between a family history hypertension and hypertension. The students with family hypertension histories had a 3.19 times greater risk of developing hypertension[21]. Similarly, the results of a study showed a significant relationship between a family hypertension history and the development of hypertension[13]. The statistical test results showed no significant relationship between the sodium intake level and hypertension. This corresponds to a study which showed no significant relationship between the sodium intake and hypertension[21]. However, two studies showed a significant relationship between them[12,22]. Moreover, the results showed no significant relationship between the potassium intake level and hypertension. This also corresponds with research conducted by Angesti, which showed no significant relationship between the potassium intake and hypertension[21]. Contrarily, the results of a study showed low potassium intake had a significant relationship with hypertension[20]. Finally, the present study showed no significant relationship between the calcium intake level and hypertension. This corresponds to the results of study conducted among high school students in Semarang, which also showed significant results between the calcium intake level and hypertension[22]. However, a study conducted among adolescents in Semarang showed the calcium intake level did have a significant relationship with blood pressure[23]. The present study also showed no significant relationship between the fat intake level and hypertension. This corresponds with studies which stated there was no significant relationship between the fat intake level and hypertension[11,22]. Moreover, the present study showed no significant relationships between the fruit and vegetable consumption levels and hypertension. Angesti also showed that there were no significant relationships between the fruit and vegetable consumption levels and hypertension[21]. Contrarily, a study showed the adolescents who consumed less vegetables had a systolic blood pressure 1.0 times and a diastolic blood pressure 0.8 times higher. Additionally, those who consumed less fruit can had a systolic blood pressure 1.3 times higher and a diastolic blood pressure 1.9 times higher[24].

This study showed no significant relationship between water consumption level and hypertension. These results oppose the studies conducted in Bandung which showed drinking more water contributed to prevent hypertension. Drinking more water results in greater water absorption in every cell of the body, which is a catalyst for metabolic processes. Improving the transportation system accelerates the screening process, increases reabsorption in the glomerulus, and accelerates the excretion of metabolic wastes and toxic substances[25]. Thus, water can help maintain the body organ functions and prevent hypertension. There was no significant relationship between the physical activity level and hypertension in the present study. These results correspond the study by Roberta, which showed no significant relationship between the physical activity level and hypertension[14]. Contrarily, a study conducted on high school students in Banjarmasin, and a study conducted in Europe, showed the physical activity level did exhibit a significant relationship with the risk of high blood pressure[26,10]. The results of statistical tests showed no significant association between the stress

level and hypertension. This opposes the results study in Banjarmasin who showed a significant relationship between stress and the high blood pressure risk in adolescents; the stressed adolescents had a 9.3 times higher risk of hypertension[26].These results are similar to a study which showed there was a significant relationship between stress level and the risk of high blood pressure[17]. The results of the logistic regression analysis showed the sex, BMI/A, and sleep duration exhibited p values of<0.05 (Table 3). However, the sex variable had the greatest OR value and chosen as the dominant factor associated with hypertension (OR=8.9, 95% [1.39-57.08]). It means the male adolescents exhibited hypertension at a rate of 8.9 times higher than the females, after controlling for the family hypertension history, BMI/A, fruit consumption level, vegetable consumption level, physical activity level, and sleep duration.

Table 3: Multivariate Analysis

Variable	p value	OR	95% CI	
			Lower	Upper
Sex	0.021*	8.89	1,385	57,083
Genetic	0.275	0.47	0.119	1,831
BMI/A	0.005*	5.62	1,662	19,028
Fruit Consumption	0.141	3.51	0.659	18,721
Vegetable Consumption	0.098	0.37	0.116	1,202
Physical Activity	0.138	2.53	0.742	8,609
Sleeping Duration	0.012*	5.25	1,449	19,021

Note: *statistically significant

Conclussion

Based on the results of this study, it can be concluded that 11.8% of the students who participated in this study exhibited hypertension, with blood pressure values of ≥ the 95thpercentile. Sex was the most dominant factor with regard to the hypertension incidence. Moreover, the male students exhibited a risk of developing hypertension that was 8.9 times higher than that of the female students, after controlling for the genetic factors, BMI/A, fruit consumption level, vegetable consumption level, physical activity level, and sleeping duration. Therefore, adolescents should pay more attention to consuming a balanced diet, especially if they are overweight or obese. Students should be provided with educational counseling programs describing the factors influencing hypertension and how to avoid it. Future research should incorporate a stronger research study design including causal relationships, such as a cohort study.

Acknowledgment

The authors are grateful to all participants who trusted the research team, and the student volunteers who provided support during the data collection process, ensuring that this study was performed smoothly.

Conflict of Interest: The authors declare that there is no conflict of interest.

Source of Funding: This study was self –funded.

Ethical Clearence: Ethical approval was obtained from the Institutional Review Board of the Faculty of Public Health at the Universitas Indonesia (No. 320/UN2.F10/PPM.00.02/2018, April 25 2018). Written consent was obtained from all of the participants.

ABSTRACT

Background: Diagnosis of discogenic low back pain is challenging process as a most common cause of low back pain. It is a matter of debate and concern for all health professionals involved, particularly spine surgeons. the aim of this study to establish a specific criteria for diagnosing discogenic LBP.

Patients and Method: This our study was carried on 88 patients suffering low back pain suspected to be discogenic in nature which were diagnosed clinically and radiological investigations, clinically We asked patients whether they experienced LBP after sitting too long, while standing after sitting too long, squirming in a chair after sitting too long, and in the standing position with flexion. Also, we examined patient if they have midline tenderness (centralization phenomenon) or not. Rather than classic picture of degenerated disc radiologically as back and bulging discs we analyze mri for high intensity zone in lumbosacral spine MRI. We exclude patient with lumbar spinal stenosis, spondylolisthesis and patient with post-operative lumbar surgery back pain.

We analyzed specific criteria clinically and radiologically for diagnosing discogenic LBP.

Results: We can obtain the precise diagnosis of discogenic low back pain standing on our clinical and radiological criteria.

Clinically: Medical history and Physical examination: Mainly four criteria

LBP after sitting too long: All patients experienced LBP after too sitting, it is significant indicator for discogenic LBP.

Squirming in a chair after sitting too long: There is significant relationship between Squirming during sitting and discogenic back pain, P value is highly significant as it is 0.000

LBP in the standing position with flexion: There is significant relationship between LBP in standing with flexion and DLBP, P value is significant as it is 0.014.

Centralization phenomenon (CP): All cases have midline tenderness on examination as specific signs or discogenic back pain. We suggested that the CP is a diagnostic indicator of DLBP.

Radiologicaliy: Magnetic resonance imaging (MRI) is by far the most useful and the most commonly used method for diagnosing DLBP. an MRI of DLBP shows low signal intensity of the disc on T2W, a high-intensity zone (HIZ) at the rear of the disc, and end plate changes. Low signal intensity of the disc on sagittal T2W. However, P-value is not significant, 60% of patients have high intensity zone in MRI L.S.S which considered to be useful in determining symptomatic level.

Conclusion: All three questions, centralization phenomenon and high intensity zone in MRI Lumbosacral spine were useful and specific for diagnosing discogenic LBP.

Keywords: *Dicogenic low back pain – degenerated disc disease – centralization phenomenon.*

Introduction

Low back pain (LBP) became one of the leading problems in public health systems in the western world during the second half of the 20th century [1]. Most people will experience back pain at some point in their lives. It is estimated that an individual has an 80% probability of having low back pain at some period during his lifetime.[2]

It has been difficult to identify the cause of LBP. A specific source of pain can be identified in some cases of LBP; however, the source cannot be identified in other cases of LBP (i.e., non- specific LBPMagnetic resonance imaging (MRI) can identify underlying pathologies of LBP. However, the importance of MRI findings is unclear and controversial. Some reports have shown that disc degeneration was a source of LBP [3]whereas other reports have shown that there was no relationship between disc degeneration and LBP [4]. Reports have also shown that discogenic LBP associated with degenerative disc disease (DDD) is confirmed by the MRI findings and response to the injection of contrast media or local anaesthesia into the disc [5]. Schwarzer et al. reported that 39% of cases of chronic LBP are discogenic, and the diagnosis is made by computed tomography after discography [6]. The technique of injecting local anaesthesia into a disc is analgesic discography (discoblock). However, these procedures do not necessarily indicate high specificity findings of discogenic LBP [7], and they are invasive and harmful to the disc [8].

We hypothesized that discogenic LBP is one of the causes of LBP, and we sought to determine easier and less invasive means of diagnosing discogenic LBP. Few reports have specified that LBP in the sitting position can indicate discogenic LBP [9]. The purpose of the current study was to evaluate the usefulness of our original questions in a medical interview about LBP and radiologically criteria also, which was intended to determine the characteristics of discogenic LBP and establish a support tool for diagnosing discogenic LBP.

Discogenic Low Back Pain (DLBP): Because of the variety of anatomic and pathophysiologic causes of chronic low back pain, it is a difficult diagnosis for clinicians to make. Only a small proportion (approximately 20%) of LBP cases can be attributed with reasonable certainty to a pathologic or anatomical entity. Thus, diagnosing the cause of LBP represents the biggest challenge for doctors in this field. Persistent LBP treatments are often unsatisfactory due to the lack of a precise diagnosis. Good history taking, clinical examination and investigation.

Patient Assessment

The assessment of a patient who has low back pain begins with history taking, followed by a physical examination. There are certain red flags on history and physical examination that warrant immediate evaluation and diagnostic testing. If a red flag has shown, appropriate action must be taken including urgent surgical intervention at the same day.

Red flags on history and physical examination that should lead to immediate investigation and treatment:

- Cauda equina syndrome (the most important).
- Age less than 20 years or greater than 55 years.
- Trauma.
- Malignant disease (multiple myeloma, lymphoma, primary epidural or intra dural tumor) or metastatic disease.
- Treatment with glucocorticoids.
- IV drug abuse, alcohol abuse.
- HIV infection.
- Unexplained weight loss.
- Unexplained fever.
- Constant pain that is worsening over time.
- Progressive neurologic deficit.

Diagnosis of discogenic low back pain: We can obtain the precise diagnosis of discogenic low back pain by the following:

A. Clinically: Medical history and Physical examination: Mainly five criteria

1. LBP after sitting too long
2. squirming in a chair after sitting too long.
3. LBP in the standing position with flexion.
4. Location: Centralization phenomenon (CP):

We examined patient if they have midline tenderness (centralization phenomenon) or not. Mckenzie in 1981 first described the centralization phenomenon, which consists of pain in the

central line of the spine upon lateral movement. The mechanism of the CP showed that Spinal movements may return the displaced or removed nucleus to its normal position along the crack of the disc, resulting in pain along the central line of the spine.

B. Radiological studies: Magnetic resonance imaging (MRI) is by far the most useful and The most commonly used method for diagnosing DLBP. an MRI of DLBP shows low signal intensity of the disc on T2W, a high-intensity zone (HIZ) at the rear of the disc, and end plate changes. Low signal intensity of the disc on sagittal T2W. Age-related disc degeneration is associated with nucleus dehydration and matrix degradation, causing the T2W MRI signal intensity to decrease and resulting in a "black disc", Sagittal T2-weighted images are best for evaluating disk water content (Fig. 1)

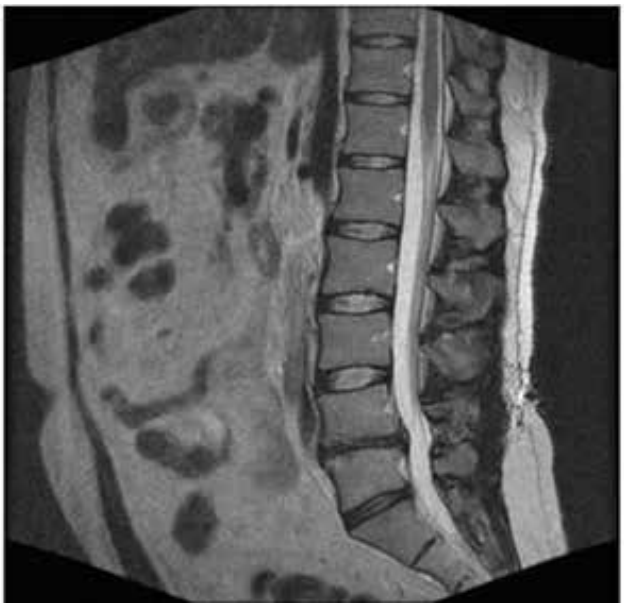

Figure 1: Sagittal T2-weighted magnetic resonance image demonstrating disk height collapse and loss of T2 signal within theL4-5 and L5-S1 disks. Note also the reactive end plate changes and overall loss of lumbar lordosis.

Rather than classic picture of degenerated disc in MRI as black and bulging disc we analyze MRI L.S.S for high intensity zone in the degenerated discs.

High-intensity zone (HIZ): In 1992, Aprill and Bogduk first described what is now known as the High- intensity zone (HIZ) seen on MRI of the lumbar spine. HIZ was a 'high-intensity signal' (bright white) located in the posterior annulus fibrosus. It is clearly dissociated from the signal of the nucleus pulposus in that it is surrounded superiorly, inferiorly, posteriorly and anteriorly by the low-intensity (black) signal of the annulus fibrosus and is appreciably brighter than the signal of the nucleus (Figure 2).

A close association between HIZ and disc pain was observed in some studies. It is suggested that inflammation of the annular fibrosus fissure causes the HIZ to appear, and this inflammation also causes irritation of pain fibers. The presence of the HIZ has a sensitivity of 82%, a specificity of 89%, and a positive predictive value of 90% for DLBP. Peng et al.found that the HIZ had a 100% sensitivity and specificity for discs classified as having a grade 3 tear according to the Dallas discogram description. Overall, most clinicians consider the presence of the HIZ is a good indicator for DLBP.

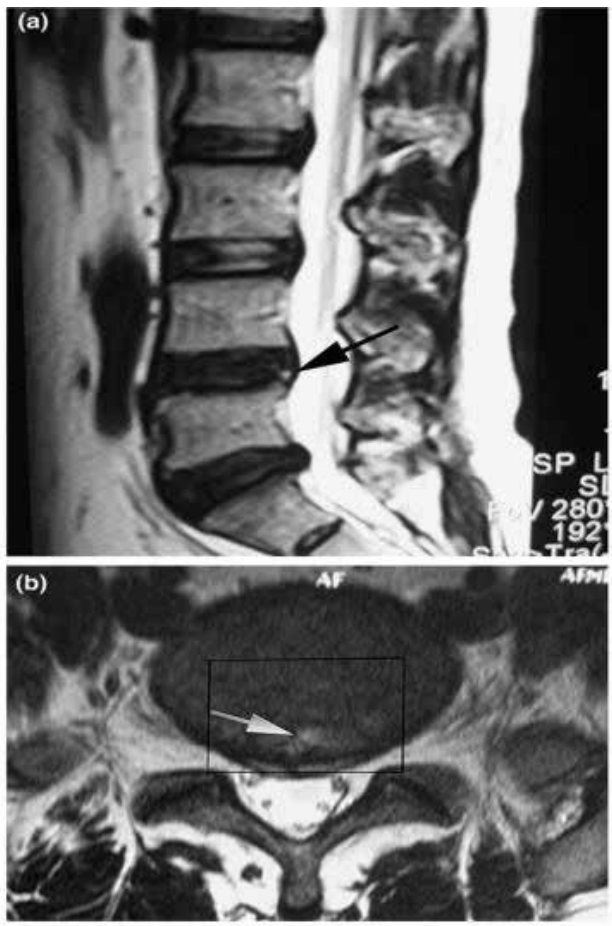

Figure 2: Sagittal T2-weighted magnetic resonance image (MRI) shows a high-intensity zone (arrow) within the posterior annulus at L4-L5 Axial T2-weighted MRI shows a high-intensity zone (arrow) within the posterior annulus at L4-L5

Results

1. **LBP after sitting too long:** All patients experienced LBP after too sitting, it is significant indicator for discogenic LBP.
2. **Squirming in a chair after sitting too long:** There is significant relationship between Squirming during sitting and discogenic back pain, P value is highly significant as it is 0.000
3. **LBP-standing with flexion:** There is significant relationship between LBP in standing with flexion and DLBP, P value is significant as it is 0.014.
4. **Local Midline tenderness:** All cases have midline tenderness on examination as specific signs or discogenic back pain. We suggested that the CP is a diagnostic indicator of DLBP.

Discussion

Because of the variety of anatomic and pathophysiologic causes of chronic low back pain, it is a diffcult diagnosis for clinicians to make, We can obtain the precise diagnosis of discogenic low back pain standing on our clinical and radiological criteria.

A. **Clinically: Medical history and Physical examination:** Mainly four criteria

LBP after sitting too long: All patients experienced LBP after too sitting, it is significant indicator for discogenic LBP.

Squirming in a chair after sitting too long: There is significant relationship between Squirming during sitting and discogenic back pain, P value is highly significant as it is 0.000

LBP in the standing position with flexion: There is significant relationship between LBP in standing with flexion and DLBP, P value is significant as it is 0.014.

Centralization phenomenon (CP): All cases have midline tenderness on examination as specific signs or discogenic back pain. We suggested that the CP is a diagnostic indicator of DLBP.

B. **Radiologicaliy:** Magnetic resonance imaging (MRI) is by far the most useful and The most commonly used method for diagnosing DLBP. an MRI of DLBP shows low signal intensity of the disc on T2W, a high-intensity zone (HIZ) at the rear of the disc, and end plate changes. Low signal intensity of the disc on sagittal T2W. **However, P-value is not significant, 60% of patients have high intensity zone in MRI L.S.S which considered to be useful in determining symptomatic level.**

Conclusion

To conclude we hypothesized 5 criteria specific for discogenic low back pain:

- LBP after sitting too long,
- squirming in a chair after sitting too long,
- LBP in the standing position with flexion.
- midline tenderness (centralization phenomenon)
- high intensity zone in lumbosacral spine MRI.

ABSTRACT

Enhanced recovery after surgery (ERAS) protocols were created to improve patient recovery and to reduce the postoperative hospital stay and comorbidities. Temporary postoperative gastrointestinal dysfunction, as nausea, vomiting, or abdominal distension, is a common morbidity after abdominal surgery that largely determines clinical recovery and hospital stay.Currently, the diagnoses of temporary postoperative GI.dysfunction and paralytic ileus are based on subjective reporting of clinical symptoms. In our study an objective assessment tool to identify temporary postoperative GI. dysfunction and paralytic ileus, as well as their resolution was used and the results showed that ERAS combined with abdominal ultrasound used for the care of patients undergoing colorectal surgery is improving standards of care by reducing postoperative hospital stay, attempting to improve the overall quality of recovery, decrease the percentage of postoperative vomiting, cost saving, and patient satisfaction.

Keywords: *Ultrasound, ERAS, Colorectal, Cancer, PONV, Recovery.*

Introduction

Enhanced recovery after surgery (ERAS) protocols were created to improve patient recovery by the early restoration of normal physiological function, and by decreasing the surgical stress response. The result was reducing the postoperative hospital stay and comorbidities. Data regarding the effect of ERAS on complications are conflicting; Some randomized trials have reported no differences in the complication rate[1–6]. however, other studies showed a reduction in minor complications only with ERAS protocols but not in major complications [7-12]. Temporary postoperative gastrointestinal dysfunction, as nausea, vomiting, or abdominal distension, is a common morbidity after abdominal surgery that largely determines clinical recovery and hospital stay[13].

Dysfunction may be prolonged (≥4 days), resulting in prolonged paralytic ileus [14,] that may reported to affect about 14% of patients after major colorectal surgery[15], Currently, the diagnoses of temporary postoperative GI. dysfunction and paralytic ileus are based on subjective reporting of clinical symptoms. Therefore, a more objective assessment tool to identify temporary postoperative GI.dysfunction and paralytic ileus, as well as their resolution, is desirable to assist with the safe postoperative introduction progression of oral intake. [16]

Patient and Method

This is a randomized control study which was registered with Pan African Clinical Trial Registry (PACTR20180600337298). The study included sixty patients, aged 18 or above who were treated with elective laparoscopic colorectal surgery for malignant or benign disease, with or without stoma, at Cairo university hospitals, (KasrAlainy), Cairo, in the period between March 2017 to February 2018.

After the agreement of the scientific and ethical committee of the general surgery department, the procedure and the study were explained for all individuals

participating in the study and all of them consented for agreement. Patients below 18 years old, patients with previous history of major abdominal surgery, patients with electrolyte imbalance as hypokalemia, haemodynamically unstable, peritonitis, and emergency operations were excluded from the study.

The 60 patients randomized into two groups (A and B) using closed envelop technique. Neither patients nor physicians were blinded to the group assignment because of the nature of the study. Group A included 30 patients who were allowed to have oral fluid intake on the first day postoperative and built up to an oral diet over the next 24 hours postoperatively. Group B included 30 patients who had abdomino-pelvic ultrasound 24 hours after surgery using abdominal probe 3.5 M.H.Z. at least for 10 minutes to assess gastrointestinal motility. Once the intestinal motility recognized the patient allowed to initiate the oral fluid and then allowed to start soft diet as tolerated. If there is no intestinal motility the ultrasound was repeated every 12 hours until the presence of good gastrointestinal motility.

All patients were counseled and trained Pre-operatively for the concept of ERAS, and curtailed fasting. The patients should be fasted for 6 hours to solids but they were allowed to have small amounts of clear free fluids for up to 2 hours before induction of general anesthesia. In addition, a clear carbohydrate rich drink should be administered orally (100 g.) the night before surgery and (50 g.) 3 hours prior to induction of anesthesia. A single dose of prophylactic antibiotics (ceftriaxone 1 gm. and metronidazole 500 mg) was given 15 min. prior to skin incision, and the second dose was administrated if the procedure prolonged more than 4 hours, or major blood loss more than 1500 ml.

Intraoperative infusion of crystalloids was tailored to avoid excess fluid administration and volume overload using goal-directed fluid therapy. intra-abdominal drains were used only when indicated.

Early postoperative mobilization was encouraged with early removal of urinary catheters and NG tubes and administration of a restricted amounts of intravenous fluid. A daily regime of 1.5 to 2.5 L. of balanced intravenous solutions should be prescribed to avoid excessive fluid administration, sodium overload, or hyperchloremic acidosis and delayed return of gut function.. A multimodal, opioid-sparing, pain management plan was adopted in all patients.

Data were coded and entered using the statistical package SPSS (Statistical Package for the Social Sciences) version 25. Data was summarized using mean, standard deviation, median, minimum and maximum in quantitative data and using frequency (count) and relative frequency (percentage) for categorical data. Comparisons between quantitative variables were done using the non-parametric Mann-Whitney test. For comparing categorical data, Chi square ($\chi 2$) test was performed. Exact test was used instead when the expected frequency is less than 5. P-values less than 0.05 were considered as statistically significant.

Results

Both groups were matched regarding the age and gender. The mean age for group A was 51.80 ± 12.95 while group B was 49.57 ± 11.65 ($p > 0.05$).

All patients in group A (100%) started oral fluid in day 1 while only (80%) of group B started oral fluid in the first postoperative day after assessment of good G.I.T motility by U/S. the rest of the patients of group B (20%) started oral fluid after reassessment of G.I.T motility by U/S in day 2. with significant statistical difference between the two groups ($p > 0.05$). Regarding the start of soft diet, 80% of patients in group A started soft diet at day two, 10% of patient at day three, and 10% at day four after toleration of oral fluid. On the other hand, 70% of patients in group B started soft diet at day two, 26.7% at day three, and 3.3% at day four after toleration of oral fluid. ($p > 0.05$)

There is significant statistical difference between the two groups regarding the postoperative vomiting ($p < 0.05$)

The mean post-operative hospital stay of group A was 3.97 ± 0.64 while group B was 3.36 ± 0.65. with significant statistical difference between the two groups ($p < 0.05$).

The readmission rate to the hospital was the same (3.3%) in both groups with no significant statistical difference between the two groups (p value 1).

Both groups were matching regarding the perioperative comorbidities as shown in table (1)

33.3% of patients in group A Pass flatus or stool or functioning stoma while 53.3% in group B at day one, 43.3% of patients in group A while 36.7%in group B at day two, and 10% of patients in group A while 23.3% in group B at day 3 after toleration of oral fluid in both groups with no significant statistical difference between the two groups ($p > 0.05$).

Table 1: Showing the summary of the collected data in both groups

		Group A		Group B		P value
		Count	%	Count	%

Discussion

This was a randomized control study, which included sixty patients who presented to the outpatient clinic of the colorectal unit in KasrAlainy hospital in the period between March 2017 to February 2018 for colorectal surgery.

The purpose of this study was to evaluate the role of abdominal and pelvic ultrasound in ERAS to assess the gastro-intestinal motility after colorectal surgery, and its effect on the postoperative hospital stay, PONV and readmission rate.

In this study, all patients were in group A (100%) started oral fluid in day 1 (under right scenario of ERAS. technique), while only (80%) of group B patients were started oral fluid after assessment of good G.I.T motility by US and the rest of the patients of group B (20%) were started oral fluid after reassessment of good G.I.T. motility by US. in day 2. There was a significant statistical difference between the two groups (p>0.05).

This study matched with what was reported by ***Andersen and his colleagues***[17]that, patients should be allowed oral fluids as tolerated on the day of the surgery and built up to an oral diet over the next 24 hours. Patients who are not meeting their nutritional requirements by 72 hours after surgery should be assessed by a dietician.

The result in this study showed that the oral intake is more tolerated when using an objective method (ultrasound) to assess the gastrointestinal motility, this was suggested by significant statistical difference between the two groups regarding to the postoperative vomiting (p <0.05). The undesirable postoperative GIT dysfunction, manifesting as nausea, vomiting, or abdominal distension, is a common morbidity after ERAS in abdominal surgery that largely determines clinical recovery and hospital stay[13]. However the cause of vomiting is multifactorial and can be classified into three factors: patient, anesthetic and surgical [18,19]

This study showed that 80% of patients in group A were started soft diet while 70% in group B at day two. While 10% of patients in group A while 26.7% in group B at day three, and 10% of patients in group A while 3.3% in group B at day four after toleration of oral fluid

in both groups with no significant statistical difference between the two groups (p >0.05).

These results were matched with what were reported that, early introduction of diet and fluids within 24 hours post-operatively has been shown to be safe [20]. Also compatible with Ljungqvist and his colleaguethat patient progressing normally on an ERAS pathway should be drinking, eating and mobilizing on the day after operation to minimize stress, improve the response to stress and maintaining homeostasis. The early feeding encourage the patient to avoid catabolism with consequent loss of protein, muscle strength, cellular dysfunction and avoiding several traditional care elements.[21,22]

The results in this study showed that 33.3% of patients in group A (patients under ERAS. technique) passed flatus or stool or functioning stoma while 53.3% in group B (patients under ERAS. technique combined with US.) at day one. While 43.3% of patients in group A, and 36.7% in group B at day two, and 10% of patients in group A while 23.3% in group B at day 3 after toleration of oral fluid in both groups with no significant statistical difference between the two groups (p >0.05). Although there were no significant statistical difference between the two groups, but the chance postoperative passage of flatus or stool or functioning stoma in group B where higher than group A. It may need a larger patient sample to be significant.

These results were matched with what were reported that, The tolerance to early feeding provides a more objective evaluation of gut function than assessment on the basis of bowel sounds of passage of flatus [20].

The result of this study showed that the two studied groups had similar readmission rate to the hospital (6.7%), with no significant statistical difference between the two groups of patients under ERAS technique, and patients under ERAS technique combined with US. (P value 1).

The results in this study showedthat, the mean post-operative hospital stay of group A was (3.97 ± 0.64) while group B was (3.36 ± 0.65). There was a significant statistical difference between patients under ERAS. technique, and patients under ERAS. technique combined with US. (p <0.05). These results were matched with what were reported by Carmichael and his colleague [23] and Thanh and his colleagues [24] that have been reported, colorectal surgery under ERAS technique had better outcomes as quicker return of bowel function, shorter hospital lengths of stay, and return of investments of at least 240%.

ERAS combined with abdominal ultrasound used for the care of patients undergoing colorectal surgery provides improved standards of care by reducing postoperative hospital stay, attempting to improve the overall quality of recovery, decrease the percentage of postoperative vomiting, cost saving, and patient satisfaction.

The Use of Intra-articular Steroid Injection to improve functional outcomes in Tibial Plateau Fractures

Sherif Hamdy Mohamed Zawam[1], Ahmad Salah Muhammad Abu Taleb[1]

[1]Department of Orthopedics, Faculty of medicine, Cairo University, Cairo, Egypt

ABSTRACT

Tibial plateau fractures should be properly managed, otherwise, they may end up in serious complications. These complications include limitation of movements, osteoarthritis and may finally result in joint stiffness. From February 2017 to August 2017, a study was conducted including 30 patients with united tibial plateau fractures to evaluate the role of intra-articular corticosteroid injection in improving the clinical outcomes after open reduction and internal fixation. Ten patients had Schatzker type I tibial plateau fractures, 13 patients had Schatzker type II and seven patients had Schatzker type III fractures. Average follow-up was 13.5 months. The average total clinical Rasmussen score was 28.3. It was excellent in 19 cases, and 11 cases had good results.

Keywords: *Tibial plateau fractures, corticosteroids injection, functional outcomes.*

Introduction

Tibial plateau fractures represent an important entity in orthopedic surgery. Nowadays, most tibial plateau fractures are managed by open reduction and internal fixation. However, in some cases with non-displaced fractures, conservative treatment may be adopted. The most common complications of tibial plateau fractures, regardless the way of management, are knee pain, limitation of movements, osteoarthritis and joint stiffness.[1,2]

The main cause of pain and limitation of movement is the immobilization that follows the fracture, either treated operatively or conservatively. Also, the disruption of the articular cartilage plays an important role, together with the intra-articular inflammatory process following the trauma or the operation.[3]

Corticosteroids were used for intra- articular injection many years ago. Their role in controlling the inflammatory process and improving the range of motion in patients with osteoarthritis is well known and established. [4]

The aim of our study was to evaluate the role of intra-articular corticosteroid injection in improving the outcomes of patients with united tibial plateau fractures treated by open reduction and internal fixation.

Materials and Method

From February 2017 to August 2017, 30 patients with tibial plateau fractures were enrolled in this study. Regarding the mechanism of the injury, 12 patients (40%) fell to the ground, 11 patients (36.7%) had road traffic accidents injury, and 7 patients (23.3%) fell from height. The study included 12 male patients (40%) and 18 female patients (60%). The mean age was 48.5 years, ranging from 41-58 years. Ten patients had Schatzker type I tibial plateau fractures (33.3%), 13 patients (43.3%) had Schatzker type II and seven patients (23.3%) had Schatzker type III fractures. The patients were fully assessed by proper history taking and full physical examination. The patients were admitted in the hospital after completing the primary, secondary and tertiary surveys.[5]

The following table shows the patients demographics. (Table 1)

Table 1: Patient Demographics

Variable	No.
Total no. of Patients	30
Average age, (range) years	48.5 years, (41-58) years
Gender :Male Female	12(40%) 18(60%)

Conted…

Side: -Right -Left	16(53.3%) 14(46.6%)
Mode of trauma: Fall to the ground Road traffic accidents injury Fall from height	12 patients (40%) 11 patients (36.7%) 7 patients (23.3%)

Above knee slabs were used until the time of the operation which was performed after an average of 4 days. The patients were treated by open reduction and internal fixation using either plates and screws or screws only. The patients were put in above knee slabs for another 2 weeks. Then, the slabs were removed and the patients were instructed to start range of motion. The patients were followed up until clinical and radiological union, which occurred at an average of 8.9 weeks. Clinically, there was minimal to no tenderness at the fracture site. Radiologically, union was determined by the disappearance of the fracture gap and continuity of the fracture lines. (Fig. 1) After that, intra-articular injection of corticosteroids was done.

The procedure was done under complete aseptic conditions. It was done in the room specialized for minor procedures in the operating theater. Sterilization and surgical draping was done using betadine solution. Standard anterolateral (soft spot) entry point was used for injection. (Fig. 2)

A **B**

Fig. 1: (a) Pre-operative x-ray anteroposterior view showing Schatzker type III tibial plateau fracture, (b) X-ray after union.

Then, using a spinal cannula, 4mg of dexamethasone was injected intra-articularly. Gentle physiotherapy was done for one week, followed by active and passive physiotherapy with anti-inflammatory modalities. The patients were followed up every 3 months, until the final assessment was done one year post-operatively.

The patients were assessed according to modified Rasmussen scoring system.[6] (Table 2)

Results

The patients were followed up for an average of 13.5 months postoperatively (range from 12 months to 15 months). Regarding the pain, twenty patients were pain free, two patients had occasional pain, and eight patients had stabbing pain in certain positions. (Fig. 3)

Twenty five patients had normal walking capacity for age. Three patients could walk outdoors for more than one hour, and two patients could walk outdoors from (fifteen minutes to one hour).

Twenty five patients had normal knee extension. Four patients had lack of extension less than ten degrees, and another one had lack of extension more than ten degrees.

Regarding the total range of motion, twenty three patients had full range of motion, five patients had at least 120 degrees, and two patients had at least ninety degrees. (Fig. 4)

Fig. 2: The marker sign shows the site of intra-articular injection (soft spot).

Table 2: Modified Rasmussen scoring system.[6]

Parameter	Score
Maximum score	30
Excellent	28-30
Good	24-27
Fair	20-23
Poor	<20

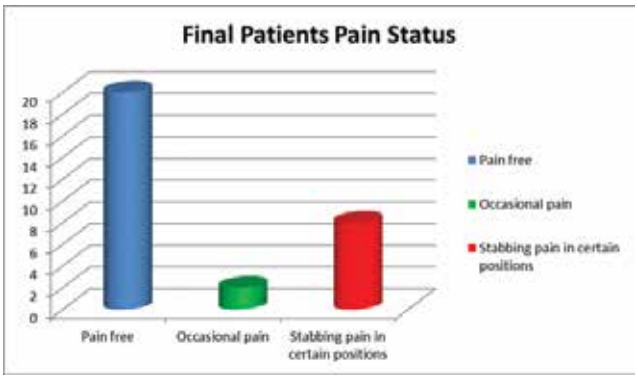

Fig. 3: Final Patients Pain Status

Twenty-eight patients had normal stability in extension and in 20º flexion, and two patients had abnormal stability in 20 ºflexion. The power of quadriceps in twenty five patients had grade V power. Five patients had grade III-IV quadriceps power.

The average total clinical Rasmussen score was 28.3. It was excellent in 19 cases, and 11 cases had good results. (Fig. 5)

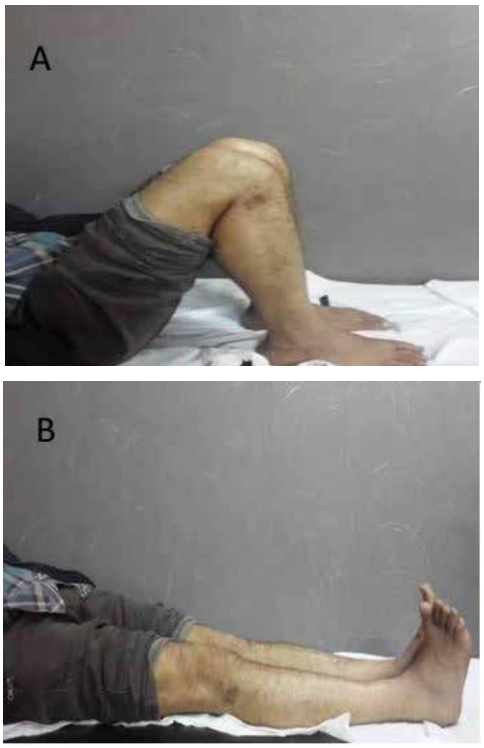

Fig. 4: Final Range of motion showing (a) full flexion and (b) full extension

DISCUSSION

Historically, a patient with comminuted tibial plateau fractures was thought to permanently lose some functions of the injured knee. With the development of new techniques of reduction and fixation, this concept started to diminish. However, nowadays, patients with tibial plateau fractures even if properly managed may suffer from some complications.[7]

These complications include persistent pain, limited range of motion, either flexion or extension. This may even end up in stiffness. This is attributed mainly to the inflammatory process and the cartilaginous disruption that occurs with the traumatic episode.[7]

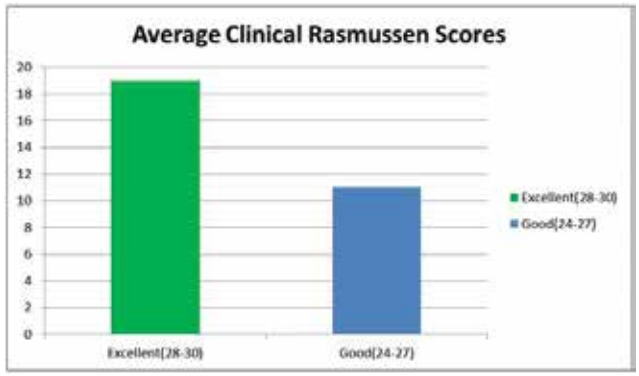

Fig. 5: Average Clinical Rasmussen Scores

Corticosteroids have been long used in the treatment of osteoarthritis. Dexamethasone is one of the most potent members of the steroids family. It is about 25 times more potent than hydro-cortisone. They are used systemically to treat a wide range of auto-immune diseases. However, their use was limited with their adverse effects, such as impairing blood glucose level, and impairing the vascularity of certain bones such as the head of the femur or the distal end of the femur. Also, the adverse effects include increasing the body weight, cardiovascular diseases, and increasing the susceptibility of infection. The use of intra-articular injection avoids these risk factors, especially, if not repeated frequently. Dexamethasone performs its anti-inflammatory effects through inhibition of metalloproteases, prostaglandins, and oxygen free radicals. [4, 8]

Lu et al., described the role of dexamethasone in protection of injured cartilage. It acts by normalization of the glycosaminoglycans release from the injured cartilage as a response to tumor necrosis factor alpha. [9]

Sofi et al., assessed the efficacy of Injection of steroids intra-articularly in patients with osteoarthritis. They concluded that corticosteroids provide good pain

relief and improved the functional outcomes in patients with osteoarthritis. They didn't find any osteopenia in radiographs as an adverse effect. [10]

Our study included 30 patients with tibial plateau fractures, 12 males and 18 females with mean age of 48.5 years. The aim of our study was to evaluate the role of intra-articular corticosteroid injection in improving the outcomes of patients with united tibial plateau fractures treated by open reduction and internal fixation.

The patients were followed up for an average of 13.5 months postoperatively (range from 12 months to 15 months). The average total clinical Rasmussen score was 28.3. It was excellent in 19 cases (63%), and 11 cases (37%) had good results.

When comparing our results to other studies on tibial plateau fractures that didn't utilize intra-articular injection, we found that our study yielded relatively better scores. Chiu CH et al. operated on 25 patients with tibial plateau fractures. The average clinical Rasmussen score was 25.9. Eleven patients (44%) had excellent results, 12 patients (48%) had good results, and two patients (8%) had fair results.[11] Siegler et al., operated on 27 patients, the average clinical Rasmussen score was 25.5. [12]

Conclusion

Intra-articular corticosteroids injection is thought to improve the pain, function, and final outcomes in patients with tibial plateau fractures.

They also act to prevent the inflammatory process that occurs in post-traumatic knee injury. It is recommended that they should be used more often, but other comparative studies with longer follow up periods are recommended.

Relationship between Hygiene and Sanitation with Coliform Bacteria Contamination in Refill Drinking Water

Indah Ananda Jamaluddin[1], Agus Bintara Birawida[1], Ruslan[1]

[1]Faculty of Public Health, Hasanuddin University, Makassar

ABSTRACT

Drinking water is the main source of consumption for the family so it needs to be maintained its quality in order to avoid Coliform bacteria. Coliform bacteria are suspected to originate from feces, therefore their presence in various places ranging from drinking water, food ingredients or other materials for human needs, is not expected. This study aims to get a description of bacterial contamination, depot environmental sanitation, equipment sanitation, worker hygiene, quality of raw water and refill drinking water in drinking water depots in BarrangLompo Island, Sangkarang District, Makassar City, 2017. This type of research is observational with a descriptive approach. The sampling technique uses Grab samples by taking directly from the tap of the drinking water depot. Water samples were examined using the Most Probable Number (MPN) method. Data analysis in this study was carried out descriptively and shows that 3 out of 6 depots have quality refill drinking water that meets the requirements. Raw water samples from all depots show no one meets the requirements. The samples examined contained gram negative bacteria. The types of bacteria that grow in the sample are Klebsiella pneumonia and Pseudomonas aerogenosa. On depot environmental sanitation and worker hygiene no one fulfils the requirements. Equipment sanitation all meets the requirements and there are depots that use the reserve osmosis method and use a combined method of reserve osmosis and ultraviolet light. The conclusion of this study is that bacteria are found in almost all drinking water samples. The bacteria found were Klebsiella pneumonia and Pseudomonas aerogenosa. Owners and depot workers are advised to improve and implement better hygiene and sanitation.

Keywords: *Hygiene; Sanitation; Coliform Bacteria; Contamination; Refill Drinking Water*

Introduction

Water is an important material in life and all living things need water. For humans, about 70% of the substances that make up the human body consist of water. Water needs for daily needs are different for each place and every level of life. Usually the higher the standard of living, the higher the number of water needs.[1] More than 100 million Indonesians lack access to clean water and 150 million contaminated water sources.[2] One effort to meet water needs in Indonesia, the government issued a policy to establish a Regional Water Supply Company (PDAM) which is engaged in the distribution and provision of clean water facilities for the general public.[3] Determination of water quality in microbiology is done by the Most Probable Number Test (MPN). If in 100 ml of water samples, Coliform bacterial cells are found to cause diarrhea and other digestive disorders.[4]

Higherlevel of Coliform bacterial contamination means presence the risk of other pathogenic bacteria. One example of a pathogenic bacterium that is likely to be contained in water contaminated with human excrement or warm-blooded animals is the Escherichia coli bacteria, namely microbes that cause symptoms of diarrhea, fever, abdominal cramps, and vomiting.[5] In addition, the rate of diarrhea is higher by 66% in children from families who defecate in rivers or sewers than those in households with private toilet facilities and septic tanks.[6]

Research conducted by Indirawati (2009) shows that there is a significant relationship between sanitation hygiene and microbiological quality of refill drinking water.[7] The Novita (2004) study in Palembang City also showed the same results for sanitation hygiene showed that depot sanitation hygiene had a significant relationship with the quality of drinking water.[8] This is due to the poor environmental conditions that make people worry about consuming ground water.

Based on data at the BarrangLompo Island Health Center, Sangkarang Sub-District, Makassar City (2015), diarrheal disease is one of the main public health problems and is classified as the highest ten diseases. The number of diarrhea patients in 2013 was 192 people, in 2014 there were 187 people and in 2015 there were 199 people. BarrangLompo Island is one of the islands within the administrative area of BarrangLompo Sub-District. So far, the needs of clean water and drinking water for residents of BarrangLompo Island have been met through dug wells, drilled wells and clean water supply businesses.[9]

The number of refill drinking water depots in BarrangLompo Island in 2016 was 6 depots of drinking water by using raw water sources from bore wells, which are likely to be contaminated with coliform bacteria. Unlike the raw water source in refill drinking water depots located in Makassar City which uses raw water sources from the PDAM. The large number of DAMIUs that are scattered on BarrangLompo Island does not guarantee the quality of drinking water produced because the method of management and filling of depots cannot always be monitored. As a result, many health problems can be caused. Research on hygiene of refill drinking water depot workers conducted by Nurmawati et al (2009) showed that there was a relationship between hygiene of drinking water depot workers and the number of coliform bacteria.[10] Hygiene and sanitation are related to bacterial contamination. Therefore, this study aims to identify the sanitation hygiene and bacterial coliform contamination in refill drinking water in BarrangLompo Island, Sangkarang Sub-District, Makassar City, 2017.

Methodology

This study uses observational methods with a descriptive approach.

Location and Time of Research: The location of the study was carried out at the drinking water refill depot in BarrangLompo Island, SangkarangSubdistrict, Makassar City, and a Microbiology Laboratory, Faculty of Medicine, Hasanuddin University. This study was conducted on February - March, 2017.

Population and Samples: The sample in this study was a refill drinking water depot of 6 depots. The type of sampling is done by Non Probability Sampling, because the population is relatively small.

Data Collection: Primary data on sanitation is obtained directly from the results of interviews using questionnaires and observations by researchers to employers or employees who work in Refill Drinking Water Depots. Data regarding the quality of refill drinking water was obtained through laboratory examination of bacteriological parameters. The secondary data was obtained from BarrangLompo Island Health Center regarding the number of AMIU depots operating and registered since 2011 - 2017.

Measurement Method: Hygiene equipment, personal hygiene of workers, environmental sanitation is measured using an observation sheet. Each of the raw water and water produced by the depot will be examined based on bacteriological parameters and the number of samples as many as 12 samples taken 150 ml per sample at each depot.

Data Analysis: Analysis of the data used is descriptive analysis, namely by making a description of the data obtained from the laboratory and then compared with the standard RI PERMENKES No. 492/Menkes/Per/VI/2010 concerning Quality Requirements for Drinking Water to find out whether refill drinking water meets the requirements so that it is suitable for consumption or not. And the data obtained from observations and interviews are compared with the Decree of the Minister of Industry and Trade of Republic of Indonesia Number 651/MPP/Kep/10/2004 concerning the Technical Requirements of Drinking Water and Trade Depots to find out whether sanitation depots are eligible or not.

Processing and Presentation of Data: Data obtained from the results of examinations in the laboratory and the results of observations are then processed manually and presented in the form of tables accompanied by explanations.

Result and Discussion

Coliform Bacteria Contamination in Refill Drinking Water and Raw Water: The number of coliform bacteria in refill drinking water was obtained from the results of laboratory tests with the MPN test with the standard of the Indonesian Ministry of Health No. 492/MENKES/PER/IV/2010. Microbiological parameters the maximum level allowed in drinking water are 0 per 100 ml of drinking water. Table 1 shows 3 refill drinking water depots that did not meet the requirements of both

raw water and refill drinking water and 3 depots that did not meet the requirements of raw water but had fulfilled the requirements for refill drinking water.

Table 1also shows no Escherichia Coli bacteria were found but 2 other bacteria were found, namely the bacteria Klebsiella pneumonia and Pseudomonas aerogenosa. These germs can cause infections in the lower respiratory tract, urinary tract, eyes and others.[11] Therefore monitoring of the quality of refill drinking water, especially monitoring of bacterial contamination must be carried out continuously by owners of refill drinking water depot facilities themselves and by the local Health Service to provide guarantees for the community in obtaining drinking water that meets the stipulated requirements.[12]

Table 1: Coliform Bacterial Contamination in Refill Drinking Water and Raw Water

Sample Code	Index (MPN/100 ml)	Qualified	Number of Colonies	Identification of Bacteria
D1 Raw water	4	Not	12	*Pseudomonas aerogenosa*
D1 Drinking water	0	Yes	0	Not cultured and identified
D2 Raw water	15	Not	52	*Klebsiella pneumonia*
D2 Drinking water	0	Yes	0	Not cultured and identified
D3 Raw water	460	Not	88	*Pseudomonas aerogenosa*
D3 Drinking water	28	Not	80	*Pseudomonas aerogenosa*
D4 Raw water	93	Not	130	*Klebsiella pneumonia*
D4 Drinking water	4	Not	6	*Klebsiella pneumonia*
D5 Raw water	8	Not	59	*Klebsiella pneumonia*
D5 Drinking water	7	Not	32	*Klebsiella pneumonia*
D6 Raw water	4	Not	15	*Klebsiella pneumonia*
D6 Drinking water	0	Yes	0	Not cultured and identified

DAMIU Sanitation Environmental: Table 2 shows the environmental sanitation in the aspect of location at 6 drinking water depots shows that there are 2 depots that meet the requirements and 4 depots do not meet the requirements namely D2, D3, D4, and D5. Also in the aspect of the building in 6 drinking water depots, all of them did not meet the 100% requirement according to the Decree of the Minister of Industry and Trade of Republic of Indonesia Number 651/MPP/Kep/10/2004.

Table 2: Environmental Sanitation of Refill Drinking Water Depots

Environment sanitation	Qualified	Frequency (n)	Percentage (%)
Location	Yes	2	33
	Not	4	67
Building	Yes	0	0
	Not	6	100

Sanitation Equipment of DAMIU: Table 3 shows the sanitation equipment at 6 water depots have all fulfilled the requirements according to the Decree of the Minister of Industry and Trade of Republic of Indonesia Number 651/MPP/Kep/10/2004.The treatment of drinking water in refill drinking water depots is not entirely done automatically so that it can affect the quality of the water produced, thus the quality still needs to be studied in order to safeguard its water quality.[13]

Table 3: Sanitation Equipment in Refill Drinking Water Depots

Equipment for Sanitation	Qualified	Frequency (n)	Percentage (%)
Made from food ingredients, corrosion resistant, does not react with chemicals	Yes	6	100
	Not	0	0
The tool used is still in use	Yes	6	100
	Not	0	0
Material is not made of heavy metal that is soluble in water	Yes	6	100
	Not	0	0

DAMIU Worker Hygiene Overview: Based on Table 4, the criteria that are not met by all depots is using masks, no workers use masks.

Table 4: Hygiene of Workers in Refill Water Depots

Worker Hygiene	Qualified	Frequency (n)	Percentage (%)
Must be free from infectious diseases	Yes	6	100
	Not	0	0
Free from wounds, ulcers, skin diseases, and other injuries	Yes	6	100
	Not	0	0
Wash hands before and after serving consumers	Yes	5	83.3
	Not	1	16.7
At the time serving consumers do not eat, long nails, scratching and scratching ears/nose/teeth	Yes	6	100
	Not	0	0
Wear clean clothes	Yes	6	100
	Not	0	0
Using a medical mask	Yes	0	0
	Not	6	100

The use of masks during the production process will minimize contamination of processed water from workers. Hygienic and sanitary behaviour needs to be done every time to serve consumers, including always washing hands with soap and running water, each serving consumers to prevent pollution.[14] Hands that are not clean can be a source of contamination of pathogenic bacteria that can increase the risk of pollution. The use of personal protective equipment such as gloves in work is also needed as a prevention of contamination.[15] Workers who do not have hygiene and healthy lifestyle such as not washing their hands and smoking while serving consumers can cause contamination of drinking water.[16] Therefore, it is better for refill drinking water depots to maintain sanitary hygiene to avoid bacterial contamination. Places that are guaranteed sanitary hygiene clean and healthy workers, recommended equipment is safe and raw water from clean water sources will ensure the quality of healthy and safe water.[17]

Description of the DAMIU Processing Method: Table 5 shows there are 4 depots that use one method of drinking water treatment that is using Reserve Osmosis (RO) and 2 depots using a combined processing method that is using Ultraviolet (UV) and Reserve Osmosis (RO).

Table 5: Processing methods in Refill Drinking Water Depots

DAMIU Processing Method	Frequency (n)	Percentage (%)
Using Reserve Osmosis (RO)	4	66.7
Using UV + RO	2	33.3

The process of purifying water with Reserve Osmosis (RO) will produce water that is truly pure free from the content of minerals and other toxic substances. In this process Reserve Osmosis (RO) there are stages that must be considered, among others, the water source of raw materials, the water treatment process, and the type of Reserve Osmosis (RO).[18] The processing of refill drinking water using ultraviolet light is known to be able to kill microorganisms because it has a lethal effect on microorganisms.[19]

Conclusion

The obtained results show that all raw water in the depot did not meet the requirements and in refill drinking water there were 3 depots that met the requirements. The types of bacteria in raw water and refill drinking water in drinking water depots are Klebsiellapneumoniae and Pseudomonas aerogenosa bacteria. Environmental sanitation for drinking water depots based on location aspects has fulfilled the requirements, but in the building

aspects all depots do not meet the requirements. Sanitation of drinking water depot equipment indicates that all drinking water depots have fulfilled the requirements. Hygiene of drinking water depot workers shows that there are 5 depots with fulfilment of criteria 84% and 1 depot with fulfilment of criteria 67%. There are 2 drinking water depots use a combined method with UV and RO and 4 drinking water depots that use RO method only.

Relationship between Work Posture and Musculoskeletal Disorders (Msds) at Processing Workers in PtToarco Jaya, Rantepao City year 2017

Januarty Triani Rimba[1], Furqaan Naiem[1], Muhammad Rum Rahim[1]

[1]Department of Work Safety and Health, Faculty of Public Health, Hasanuddin University

ABSTRACT

Musculoskeletal Disorders (MSDs) are one of the problems that are often experienced by workers in both the informal sector and the formal sector. PT Toarco Jaya Processing worker is an industry that engaged in Arabica coffee production where there are activities that are quite high, monotonous and repetitive. This can cause workers to experience skeletal muscle disorders that can reduce work productivity. This study aims to determine the relationship of work posture with Musculoskeletal Disorders (MSDs) disorders in PT Toarco Jaya processing workers in the city of Rantepao in 2017. This type of research was observational analytic with a cross sectional study approach. Data collection is conducted against 57 workers by exhaustive sampling in March 2017. Primary data collection was obtained from interviews using questionnaires, Nordic Body Map Questionnaire, Rapid Entire Body Assessment, microtoise, scales and cameras. Data analysis was performed using univariate analysis, namely frequency distribution and percentage of each variable and bivariate analysis was performed on two variables to identify relationships using the chi-square test. The results of this study indicate that there is a relationship between work posture and MSDs complaints with a p value (0.002), there is a relationship between age, nutritional status, and work period with complaints of MSDs with a value of p (0.005), p (0.030), p (0.031) < α (0.05). It is best for the company management to provide training on work posture at work. Others factors such as workload and environmental factors are recommended in future study.

Keywords: *Work Posture; Musculoskeletal Disorders; Processing Workers*

Introduction

As a developing country, Indonesia needs healthy, efficient and productive human resources to support national development. Besides that labor is an element that is directly confronted with various consequences of technological advances in industry, so it is only natural for them to be given health care protection and development towards welfare or national guarantees.[1] Based on data from the International Labor Organization (ILO) in 2013, every 15 seconds one worker dies from a work accident and 160 workers experience work-related illness.[2]

The factors that cause musculoskeletal complaints are excessive muscle stretching, languishing activity, unnatural work attitude, secondary causes and combination causes.[3] Studies of musculoskeletal in various types of industries have been carried out and studies have shown that muscle parts that are often complained about are skeletal muscle which includes the muscles of the neck, shoulders, arms, hands, fingers, back, waist, and lower muscles.[3] From various types of research, it can be seen that the complaints of diseases that are often suffered by workers are work related musculoskeletal disorders, one of which is influenced by the existence of a work position. The work method will directly or indirectly affect the muscles involved and can cause muscoleskeletas disorders with complaints of pain in the neck, back, lower back and other complaints.[4]

In a study conducted on paving workers in CV SumberGalian, Makassar, showed that of 85 respondents there were 52 respondents who experienced severe disorder Muscoleskeletas disorder and 32 other respondents had mild disorder muscoleskeletas disorder, this indicates that there are still many workers who suffer from muscoleskeletas disorder specifically in the city of Makassar.[5] Based on research conducted on Fumiture workers in Benda Kota Tangerang District, showed that there were 27 workers (81.8%) aged ≥ 30

years who had musculoskeletal disorder and as many as 22 workers (45.8%) aged <30 years also experienced musculoskeletal disorder. The results of bivariate statistical tests showed that there was a significant relationship between age and musculoskeletal disorder. According to Suma'mur (2009) in a week people can only work well for 40-50 hours. More than that negative tendencies arise.[6]

Body mass index (BMI) can also be used as an indicator of the condition of worker nutrition according to Zulfiqor (2010) who conducted research on fabrication workers at PT.[7] Caterpillar Indonesia, someone who is overweight will try to support the weight from the front by contracting the lower back muscles. And if this continues, it will cause pressure on the spinal cord pads which results in fatigue and muscle pain. Based on the results, it was obtained workers who had an index of body obesity period of 13 workers (17.3%) and workers with a normal body mass index of 32 workers (42.7%). The test results showed that most workers had a normal BMI and experienced complaints of mild MSDs, namely 26 workers. This is not in line with the research of Karuniasih (2009) which examined 52 bus travel drivers, which amounted to 90.4% of MSDs complaints experienced by bus drivers who had excessive body mass index (overweight) or obesity.[8]

Work posture and work position that are not ergonomic have an impact on decreasing work productivity and work performance which can lead to work accidents, besides that it can also affect workers' health levels, one of which is muscle and joint complaints or musculoskeletal complaints. Based on the description of the background above, the authors are interested in conducting research on the relationship of work posture with disorders of Musculoskeletal Disorders (MSDs) in PT workers,Toarco Jaya, Rantepao City.

Methodology

This study used observational analytic method. A cross sectional approach was used to identify the relationship of work posture variables with musculoskeletal disorder (MSDs). The location of the research was carried out at PT. Toarco Jaya, the city of Rantepao.The population used as samples in the study were 57 processing workers at PT Toarco Jaya, Rantepao City.

Method of Collecting Data: The data on complaints of Musculoskeletal Disorders (MSDs) were obtained using the Nordic Body Map questionnaire. The data on work posture is obtained by calculating the risk of skeletal muscle pain in certain body parts (neck, spine, upper & lower arms, wrists) using the REPR (Rapid Entire Body Assessment) sheet. The data on the Body Mass Index obtained through direct measurement of body weight and height of workers using a weight scale and microtoice role and then calculated using the BMI formula.

Data Processing: Processing and data analysis techniques were carried out by Chi Square statistical tests and using the SPSS program.

Data Analysis: Univariate analysis was performed on each variable from the results of this study to see the frequency and percentage distribution, which included work attitudes, age, length of work, length of service, nutritional status, musculoskeletal disorder (MSDs).
Bivariate analysis is done to prove the hypothesis with the chi-square test where the variable work attitudes, age, work status of nutritional status (BMI) and years of service with MSDs complaints in this study.

Result and Discussion

Retrieval of respondents' research data was conducted in March 2017 with 57 Processing workers. This study gains the permission of the Manager of PT Toarco Jaya and the head of Processing. Interviews were conducted using questionnaires and the Nordic Body Map Questionnaire. Then, measurements of workers' height were carried out using microtoise and for measuring body weight using weight scales. The data obtained is then processed using the SPSS computer program.

The characteristics of the respondents show majority of the respondents are from age group of 35-44 and 45-54 contribute by 35% and 33% respondents respectively. Next, most of the respondents about 63.2% have working period between 3 to 10 years. For nutrition status, majority about 40.4% of the respondents are under fat categories where thin and normal categories contribute by equal percentage which is 28.1% each.

Distribution of Respondents based on Musculoskeletal Disorders Complaints (MSDs): In this study, complaints of Musculoskeletal Disorders (MSDs) in processing part workers were grouped into two, namely workers who experienced MSDs complaints (80.7%)

and workers who did not experience MSDs complaints (19.3%). The highest reported body parts for MSDs are neck, waist, left ankle, right ankle, right shoulder, left shoulder and back contribute by 45.6%, 42.1%, 38.5%, 38.5%, 36.8%, 33.3% and 26.3% respectively.

Distribution of Respondents based on Work Posture, Age, Nutritional status and Working period: High-risk workers are who have 8-15 Rapid Entire Body Assessment (REBA) scores or action levels 3 and 4. For low-risk work postures, they have a REBA score of 1-7 or level 0, 1, and 2. Table 1 shows that the work posture on processing workers who have a high risk are 73.7%. The number of workers with a low risk work posture is 26.3%. The age of respondents into two categories, namely high risk (aged ≥ 30 years) and low risk (aged <30 years). High risk category has 77.2% of the respondents and a low risk category has 22.8% of the respondents.

The nutritional status has two categories where the abnormal nutritional status is BMI> 25 or <18.5 and for the category of normal nutritional status is BMI ranged from 18.5-25. Table 1 shows that 71.9% of the respondents are under abnormal nutritional status and the respondents under normal nutritional status are 28.1%. Working period is grouped into two categories where the respondents who have worked for ≥ 5 years and working period of <5 years. The working period of respondents with the category ≥ 5 years is 47.4% and category which is <5 years is 52.6%.

Table 1: Distribution of Respondents based on Work Posture, Age, Nutritional status and Working period

Items	Categories	Frequency (n)	Percentage (%)
Work posture	High Risk (8-15 REBA)	42	73.7
	Low Risk (1-7 REBA)	15	26.3
Age	High Risk (More than 30 years old)	44	77.2
	Low Risk (Less than 30 years old)	13	22.8
Nutritional status	Normal	16	28.1
	Not Normal	41	71.9
Working period	Old (More than 5 years)	27	47.4
	New (Less than 5 years)	30	52.6

Relationship between Complaints on Musculoskeletal Disorders (MSDs) with Work Posture, Working Period, Age and Nutritional Status: Table 2 shows there are 90.5% of the respondent experienced musculoskeletal disorders with high risk work posture and 53.3% of the respondent experienced musculoskeletal disorders with low risk work posture. Besides that, there are 46.7% and 9.5% of the respondent did not experienced low risk and high risk respectively. The chi-square test obtained p = 0.002 (p = <0.05), so that H0 is accepted and Ha is rejected so that it can be interpreted that there is a relationship between work posture and complaints of musculoskeletal disorders (MSDs) in processing workers PT Toarco Jaya In 2017.

Table 2 shows there are 92.6% of the respondents are from long service life which is more than 5 years and about 7.0.0% are from new work a period which is less than 5 years. Furthermore, respondents who did not experience MSDs complaints with a long working period about 7.4% and 30.0% with new years of service that did not experience MSDs complaints. The chi-square test obtained the value of p = 0.031 (p <0.05) means that H0 is rejected and Ha is accepted, so that it can be interpreted that there is a relationship between work period and MSDs complaint on processing workers PT Toarco Jaya Kota RantepaoTahun 2017.

Table 2 shows the high risk age that experienced MSDs complaints are about 88.9% and high risk age that experienced MSDs complaints are about 53.8%. Then, respondents who did not experience MSDs with a high risk age category is about 11.4% and a low risk age category is about 46.2%. The chi-square test obtained the value of p = 0.005 (p <0.05) means that H0 is rejected and Ha is accepted, so that it can be interpreted that there is a relationship between age and MSDs complaints in 2017 PT Toraco Jaya processing workers.

Table 2 shows the respondents who experienced complaints of MSDs with abnormal nutritional status were 36 respondents are 87.8% and respondents who experienced complaints of MSDs with normal nutritional status are 62.5%. Respondents who did not experience

complaints of MSDs with abnormal nutritional status are 12.2%, while respondents with normal nutritional status are 37.5%. The chi-square test obtained the value of p = 0.030 (p <0.05) means that H0 is rejected and Ha is accepted, so it can be interpreted that there is a relationship between nutritional status and MSDs complaints to processing workers PT Toarco Jaya, Rantepao, Tahun 2017.

Table 2: Relationship between Complaints on Musculoskeletal Disorders (MSDs) with Work Posture, Working Period, Age and Nutritional Status

Relationship between Complaints on Musculoskeletal Disorders (MSDs)		Complaints of MSDs		Statistical test results (P value)
		No (%)	Yes (%)	
Work Posture	Low Risk (1-7 REBA)	46.7	53.3	0.002
	High Risk (8-15 REBA)	9.5	90.5	
Working Period	New (More than 5 years)	30.0	70.0	0.031
	Old (Less than 5 years)	7.4	92.6	
Age	Low Risk (Less than 30 years old)	46.2	53.8	0.005
	High Risk (More than 30 years old)	11.4	88.9	
Nutritional Status	Normal	37.5	62.5	0.030
	Not Normal	12.2	87.8	

The results of this study are consistent with the research conducted by Suwanto, J (2016) that the results of statistical tests using the Spearman Rho test with a significant level (α≤0.05) obtained a significance value (p = 0.001) with a moderate relationship (r = 0.551) hence there is a significant relationship between the risk of work posture and the risk of musculoskeletal complaints.[9] Meanwhile, according to Nurhayati (2013), the results of statistical tests on the relationship between work posture and musculoskeletal complaints with a significance value of 0,000 p-value <0.05, a correlation strength value of 0.657 (strong) and a positive correlation means that there is a strong and very significant relationship between postures work with musculoskeletal complaints.[10]

Boshuizen et al in Margarini (2014), states that someone who works more than 5 years increases the risk of back pain compared to less than 5 years of exposure.[11] This can occur because the loading of the spine for a long time can cause the disc cavity to constrict permanently and also result in spinal degeneration which can cause chronic lower back pain. The same is true of Aisyah (2014), in lifting workers about the relationship between individual characteristics and work position with musculoskeletal complaints in lift-up workers at PT.[12] AJG Gresik is one of them concerning working period which shows that there is a relationship between years of service and musculoskeletal complaints.

Age is identical to the level of work ability by changes in body tools, cardiovascular and hormonal systems.[1] This study is in line with Tarwaka (2010) which states that workers who than 35 years old have a small risk of experiencing musculoskeletal complaints.[3] These complaints occur because in general, skeletal muscle complaints begin to be felt in working age, which is 25-65 years. Nusa, et al (2013) showed that there was a significant relationship between age with musculoskeletal complaints with a value of p = 0.003 (p <0.05) and the closeness value of the relationship was positive, namely the higher the age the higher the risk of musculoskeletal complaints.[13]

This is consistent with Puput's 2015 study which showed that body mass index (BMI) had a significant relationship with musculoskeletal complaints.[14] According to Supariasa (2002), the Body Mass Index (BMI) or Body Mass Index (BMI) is a simple tool or way to monitor the nutritional status of adults, especially those associated with underweight and overweight.[15] The association of BMI with MSDs is the more fat a person is, the greater the risk of experiencing MSDs.

Conclusion

Based on the results of research on the relationship of work posture with complaints of musculoskeletal disorders in PT Toarco Jaya Processing workers in the city of Rantepao in 2017, the musculoskeletal Disorders (MSDs) complaints on processing workers are more than workers who do not experience MSDs complaints. Work posture, Working period, Age and Nutritional status

are related to complaints of Musculoskeletal Disorders (MSDs) in PT Toarco Jaya processing workers in the city of Rantepao in 2017.

A Study on Frequency of 12-23 Months of Children Visits to Integrated Service Post (Posyandu) 3 Months in a Row against Developments in the Work Areas, Makassar City

Khalis Muliamar[1], Djunaedi M. Dachlan[1], Burhanuddin Bahar[1]

[1]Nutrition Study Program, Faculty of Public Health, Hasanuddin University, Makassar

ABSTRACT

Based on data from the National Central Statistics Agency currently there are an estimated 351,000 children with special needs under the age of five. This study aims to describe the frequency of visits between 12-23 months to Posyandu (Integrated Service Post) for 3 consecutive months on the development of baduta (children under two) in the Working Area of the Puskesmas, Makassar City. The type of study method used is descriptive survey research. The sampling method in this study was purposive sampling with predetermined criteria. The sample in this study is the age of 12-23 months with 35 badutas taken from 9 posyandu. Data was taken using the family characteristic questionnaire and the Pre Development Screening Questionnaire (KPSP) to measure the development of baduta. The collected data is processed using the SPSS program and presented in table form along with narration. The results showed that out of a total of 35 people who visited the posyandu 3 months in a row there were 34 baduta (97.1%) with normal development and the rest with deviant development (2.9%). When tested for development using a 15-month KPSP, the person could not carry out 5 tests out of a total of 10 tests in the 15-month KPSP. These 5 tests are rough movements. Based on the results of the study, it is suggested that the puskesmas conduct development checks at all posyandu so that children's development can be monitored.

Keywords: *Posyandu (Integrated Service Post); Developments; Work Areas*

Introduction

The national development goals listed in the concept of the 2015-2019 National Long Term Development Plan (RPJMN) are one of which is to improve the quality of human resources (HR). Efforts to improve the quality of human resources begin with the process of developing children from conception to young adulthood. Posyandu is a form of community participation in the health sector that is managed by cadres targeting the entire community. Posyandu is one of the health services in the village to make it easier for people to know or check health, especially for pregnant women and toddler.[1] One of the posyandu's objectives is to monitor improvement in nutritional status toddlers and pregnant women. However, public awareness of health care, especially toddlers, is still lacking, so there are still toddlers with impaired growth development.[2]

The active visit of mothers to bring their children to the posyandu is influenced by several factors such as age, education, employment, access to health services, and social economy.[3] The results of the 2007 Basic Health Research (Riskesdas) showed that Posyandu was the most visited place for underfive weighing, which was 78.3%; toddlers weighed regularly (4 times or more), weighed 1-3 times and which were never weighed consecutively were 45.4%, 29.1% and 25.5%.[4]

The results of Riskesdas in 2010 showed that the higher the age of the child, the lower the scope of the weighing was carried out at the posyandu (≥ 4 times over the past six months). The percentage of weighing children under the age of sex is not different, but according to the place of residence in urban areas the tendency is to weigh their children in the posyandu rather than in rural areas.[5]

Riskesdas 2013 shows that monitoring the growth of toddlers carried out every month shows that the percentage of infants aged 6–59 months who have never been weighed in the past six months tends to increase from 25.5% (2007), 23.8 percent (2010), to 34, 3% (2013).[6] What are the impacts on toddlers, if mothers of

children under five are not active in Posyandu activities, among others, do not get health counselling about the growth of normal toddlers, do not get vitamin A for eye health, mothers of children under five do not know the growth of body weight for months.[4]

In Indonesia, data on deviations in pre-school child development have not been recorded accurately and specifically, but UNESCO can estimate children who have a deviant tendency to reach at least 10% and this can be a strong reference. Meanwhile, based on data from the National Central Statistics Agency currently there are an estimated 351,000 children with special needs under the age of five.[7] Several studies on the relationship between language development and family socio-economic status show that children from poor families experience delays in the development of their language compared to children from better families.[8]

In Indonesia, it is famous for the term children under three years old. Even though physical development (especially feet) at this age is not the main thing, children in toddlers at stage 1 like to walk, climb or climb something. At this stage, it is very important for parents to be the main safeguards.[9] Therefore, this study is identifying the Frequency of Visits from 12-23 Months to 3-Month Consecutive Posyandu on Developments in the Work Areas of Puskesmas, Makassar City.

Methodology

The type of study method used is descriptive survey method which is to find out the description of the frequency of posyandu visits in 3 consecutive months to the growth of toddlers aged 12-23 months in the working area of the Puskesmas, Makassar City. This study was conducted in the Community Health Center Working Area between March-April 2017.

Population and Sample: The population in this study were all children aged 12-23 months. The sampling technique in this study was purposive sampling. The samples in the study were mothers of the children aged 12-23 months who were enrolled at the posyandu who visited the Posyandu for 3 consecutive months. Samples will be included in the study if they meet the criteria such as mother, who have KMS toddlers, have babies aged 12-23 months, children visited Posyandu in the last 3 months, children no hospitalized for the past 3 months and never sick for more than 7 days.

Data Collection: The data obtained directly from respondents through a questionnaire, which is the Pre Development Screening Questionnaire (KPSP) to see the development according to the age of the baby which included subtle motion, rough motion, speech and language, socialization and independence. The latest secondary data is obtained by referring at the results of the toddler weighing record and the posyandu register book.

Data Processing and Analysis: The collected data are processed using the SPSS program through Univariate Analysis.

Result and Discussion

The environmental condition of the Antara Health Center is an urban development area, a dense residential environment, some areas are still slums, mainly on the outskirts and some areas are lowlands, allowing floods to occur. Community behaviour still does not have clean culture; the personal hygiene of children is still low, consumption of fast food, and smoking. The work program of the Antara Health Center for improving community nutrition includes the provision of vitamin A capsules, Fe tablets for pregnant women, supplementary feeding to infants and toddlers. Health promotion includes alert villages, PHBS coaching/counselling, development of health posts (Poskestren and Posyandu), public health counselling, occupational health efforts (UKK).

Table 1 shows there are a total of 133 physical targets in 9 PosyandupuskesmasAntara. The population is 58 baduta who had visited in April. While baduta who visited 3 months in a row about 36 baduta and the sample considered in this study were 35 baduta, which meet the sample criteria.

Table 1: Target Data and Posyandu Visits 3 consecutive months in the working area of the health center between 2017

Posyandu	Baduta	Visited				Sample
		Feb	Mar	Apr	3 Con. months	
Kantisang	17	14	13	2	1	1
Antara	12	11	8	8	6	5
Hamzy RW 3	12	11	9	7	4	4

Conted…

Hamzy RW 2	19	16	10	7	4	4
AsalMula	12	11	10	8	5	5
Bontosugi	33	25	22	9	4	4
KeraRamsis	8	7	7	5	3	3
Hartaco Jaya	12	7	7	6	4	4
Immim	8	8	8	6	5	5
Total	133	110	94	58	36	35

Table 2 shows there are 34 baduta with normal development and 1 baduta with development deviate. Baduta with this deviant development is 16 months old and female. When tested for development using a 15-month KPSP, the person could not carry out 5 tests out of a total of 10 tests in the 15-month KPSP. These 5 tests are rough movements. The cause of the baduta was not able to do any rough motion tests because the growth of baduta legs was hampered, making it difficult to stand. Based on the KIA 2016 book, the stimulation parents can do to overcome this is by slowly training children to stand up and walk by holding on, and teach children to walk on the steps/stairs.[10] In addition, to monitor the progress of the health center the health center should do examination of developments in the posyandu so that the possibility of developmental irregularities can be prevented.

Table 2: Distribution of Baduta KPSP Score Categories

KPSP Score Category	Baduta Age Category				Total
	12-14 months	15-17 months	18-20 months	21-23 months	
Normal (%)	22.9	34.3	14.3	25.7	97.1
Deviate (%)	0.0	2.9	0.0	0.0	2.9

Table 3 shows there is 1 baduta with a percentage of fine motion KPSP score of 67% which is in the age of 12-14 months. Baduta is 14 months old. Of the 3 subtle motion test questions at the 12-month KPSP, there was 1 test question that could not be implemented by the person. The baduta fail to grab the pencil tightly and can be easily taken away. This can be caused by a lack of developmental stimulation by parents. Based on the 2016 KIA book, the stimulation that parents can give is to teach children to scribble pencils on paper, hold their own cups, and hold small objects.[10]

Table 3: Distribution of Percentage of Subtle Motion KPSP Score

Percentage of Subtle Motion KPSP Score	Baduta Age Category				Total
	12-14 months	15-17 months	18-20 months	21-23 months	
67 %	1	0	0	0	1
100 %	7	13	5	9	34

Table 4 shows Bbaduta with the percentage of KPSP score of 80% of rough motion could not carry out 1 KPSP test of gross motion from a total of 5 gross motion test questions in the 15-month KPSP. Baduta is 17 months, 15 months and 16 months old. The 17-month-old and 16 months old baduta fail to bend to pick up the toys without holding or touching the floor. When he wants to take the toy he immediately sits down and does not want to stand up again. The 15-month-old baduta cannot walk along the room without falling or staggering. The stimulation that can be given by parents based on the 2016 KIA book to optimize the development of the rough movements is such as teaching children to walk along a room or staircase and teaching children to move freely in supervision.[10]

Table 4: Distribution of Percentage of Gross Motion KPSP Scores

Percentage of Gross Motion KPSP Score	Baduta Age Category (Months)				Total
	12-14	15-17	18-20	21-23	
0 %	0	1	0	0	1
80 %	0	3	0	0	3
100 %	8	9	5	9	31

Table 5 shows there is 1 baduta with the percentage of KPSP scores speaking and language 0% that is at the age of 15-17 months. Baduta is 15 months old. The Baduta is 15 months old and cannot carry out a speech and language test from a total of 1 question. At the time of the test the baduta was not able to say the words. In other words the baduta has a delay in speaking. Possible causes are lack of speech and language stimulation by parents. The stimulation that can be given by parents based on the 2016 KIA book, among others, invites simple words such as "ma-ma" and teaches to mention parts of his body.[10]

Table 5: Distribution of Percentage of Talk and Language KPSP Scores

Percentage of Talk and Language KPSP Scores	Baduta Age Category (Months)				Total
	12-14	15-17	18-20	21-23	
0 %	0	1	0	0	1
100 %	8	12	5	9	34

Table 6 shows the distribution of Percentage of KPSP Scores on Socialization and Independence. Based on the percentage of KPSP scores on socialization and independence there are 5 baduta with the percentage of KPSP score on socialization and independence of 50%, which is in the age of 12-14 months. The Baduta was unable to carry out 1 test out of a total of 2 tests of socialization and independence in the 12-month KPSP. Baduta is aged 13 months (4 baduta) and 14 months. When tested 3 children baduta did not look for and expect researchers to reappear, but felt afraid and some were shy and some were crying out of fear. The other 2 baduta did not show a shy attitude at all, even feeling afraid. Baduta at that age should meet fear and shame when meeting new people. The stimulation that parents can provide to overcome these problems is based on the 2016 KIA book, namely by introducing to family members, invite to play with friends.[10]

Table 6: Distribution of Percentage of KPSP Scores on Socialization and Independence

Percentage of KPSP Scores on Socialization and Independence	Baduta Age Category (Months)				Total
	12-14	15-17	18-20	21-23	
50 %	5	0	0	0	5
100 %	3	13	5	9	30

Bebgei (2000) states that stimulation is less likely to experience delays in development and where children are fostered with good stimulation by providing various aspects of stimulation needed by children, namely rough motion, subtle movements, language and speech, socialization and independence. [11, 12] According to Hurlock (1994) argues that a stimulating environment is one of the factors driving children's development.[13] A stimulating environment encourages good physical and mental development, while a non-stimulating environment causes the development of children below their abilities.[7] Stimulation activities include various activities to stimulate child development such as exercise, speech, thinking, independence and getting along.[7] Also, parents are the main cause of problems arising from poor child stimulation.[12]

Jafri and IsnaOvari's study (2015) showed that the development of socialization before and after giving stimulation of socialization to the age group with poor categories increases from 52.2% to 87.0% for 36–47 months of age, 48.1% to 55.6% for 48–59 months of age and 46.7% to 86.7% age 60–71 months of age.

Social personal development is strongly influenced by the environment and interactions between children and parents/other adults.[12] Child development will be optimal if social interactions are sought according to the needs of children at various stages of development. According to Bebgei (2000) states that of 49 children 4.08% of children experience delays in development of poor stimulation, namely children who received less attention from his parents while 32.65%, children with developmental interpretations doubted, among others, with sufficient stimulation.[11, 12]

Conclusion

Based on the results of this study, the conclusion is most of the baduta are born with normal body weight. Most of the baduta who were sampled were given exclusive breastfeeding by their mothers. The type of MP-ASI given to all baduta is MP-ASI mixed (factory and local). All nurses give birth at health services and are assisted by health workers. There are 1 baduta that has a deviant development. There is 1 baduta with a percentage of subtle motion KPSP score 67% There is 1 baduta with the percentage of KPSP score of roughly 0% and 3 baduta movements with the percentage of KPSP score moving roughly 80%. There is 1 baduta with the percentage of KPSP score speaking and language 0%. There are 5 baduta with a percentage of KPSP score of 50% socialization and independence.It is recommended that the Puskesmas conduct development checks at all posyandu each month so that child development can be monitored and the possibility of developmental irregularities can be prevented. Parents must be diligent in providing stimulation to the clown so that developmental irregularities can be prevented.

Analysis of Ability to Pay National Health Insurance Contributions to Communities on Lakkang Island, Makassar City in 2017

Andi Sahriana[1], Dian Saputra Marzuki[1], Muhammad Yusri Abadi[1]

[1]Department of Administration & Health Policy, Faculty of Community Health, University of Hasanuddin, Makassar, Indonesia

ABSTRACT

This study aimed to analyse the ability to pay National Health Insurance (NHI) contributions by the community in the Lakkang Island of Makassar City. The type of research used is quantitative research with a descriptive survey approach. The population in the study was 121 families who had not participated in the NHI program on Lakkang Island. Saturated sampling method is used to obtain a sample of 95 families. Data collection was carried out by direct interviews with the people of Lakkang Island based on the questionnaire and the data analyzed using univariate analysis. The results showed that the ability to pay ATP 1 of the respondents was in the capable category, which was 61.1% with an average of IDR 90,440 per month, for non-food ATP 2 category, it was 62.1% with an average amounting to IDR23,544 per month. Non-essential is in the capable category, which is 51.6% with an average of IDR26,536 per month.

Keywords: *Lakkang Island, NHI, ability to pay and ATP.*

Introduction

The development of health insurance in Indonesia runs very slowly compared to the development of health insurance in several neighboring countries in ASEAN. Careful research on factors that influence the development of health insurance in Indonesia is not sufficiently available. Theoretically, several important factors can be stated as the cause of the slow growth of health insurance in Indonesia, including low population demand and income, lack of government will, insurance culture that has not been good and bad quality of health services, and lack of legal certainty in Indonesia[1].

The ability to pay and willingness to pay are two factors that play a role in the utilization of medical services which in turn will also affect equity. The ability to pay can be measured by the approach of calculating family income, family assets, or household expenses. The willingness to pay can be measured by asking the respondent through two methods, namely what is the real expenditure of individuals/families for health during a certain period of time and by directly asking how many individuals are willing to issue health services[2].

Community participation in the NHI program can be seen from the ability and willingness to pay contributions. Research in KabupatenJember showed that the value of ATP is greater than that of WTP. Lack of ownership of *BadanPenyelenggaraJaminanSosial* (BPJS) Health cards among handicraft workers in Jember showed low efficacy on the NHI program even though the income of handicraft workers is relatively high[3]. Whereas in the research in the City of Bengkulu, the people who do not have a BPJS Health card are those who are not able to, but the expenditure on cigarettes (essential) is greater than for paying NHI contributions each month[4]. The amount of ATP and WTP of a person or community in paying contributions is certainly inseparable from the factors that influence it. Research in the Hulu Sungai Selatan District showed that greater income and the existence of savings for health care costs are factors that influence ATP and community WTP[5]. In addition, research in Konawe Selatan District revealed that there is a relationship between income and utilization of health services by coastal communities[6].

The number of BPJS Health participants for Lakkang Island is 571 people or 60% of 952 residents and those who do not have a BPJS Health card are 381

people or 40% with 121 family heads. It can be seen that Lakkang Island has not achieved the National Health Insurance for its population[7]. Based on the background, the authors are interested in examining the ability to pay the National Health Insurance contributions by the community on Lakkang Island, Makassar City.

Methodology

This type of research is a quantitative study with a descriptive survey approach that is used to produce an overview of the ability to pay national health insurance contributions to the community on the Lakkang Island. The duration of this research was from January 19 to February 18, 2017.

The population in this study was the people of Lakkang Island who had not been covered by NHI. The number of residents who have not participated in the NHI program is 381 people, consisting of 121 family heads. Samples are measures taken from the overall population. The sample in this study was the head of the family in Lakkang Island who have not been covered by NHI. Of the 121 family heads who were sampled, 95 families were not covered by NHI during the study due to the presence of people who had enrolled the BPJS Health during the study and those who had obtained an Indonesia Health Card. Thus, the number of samples in this study was 95 people. The sampling procedure used a saturated sampling method, which is the method of sampling that often being regarded as a total sample, where all members of the population are included as samples[8].

The primary data of this study were obtained from 95 respondents through direct interviews using a prepared questionnaire on matters relating to the research, namely data on respondent characteristics, ability to pay data and willingness to pay data. Secondary data of this study was obtained from the LakkangPustu report, Lakkang Urban Village report and other sources related to this research.

Univariate analysis is used to analyze the data in this research. This analysis produced a frequency distribution and a percentage of each variable and to describe the description of each variable in the distribution table.

ATP 1 = Total income – total expenditure/total dependents

ATP 2 = 5% of total non-food and non-essential expenditure.

Result and Discussion

Based on the Makassar City minimum wage in 2016, the number of respondents with low-income levels is 69 people. The number of respondents with sufficient income was 26 people. This is caused by several factors such as the area of rice fields or ponds and the presence of family members who had helped the head of the household to fulfil daily life. The increase in commodity prices (goods and services) and the guidance of daily living needs make families have to keep thinking of other ways to get additional income. The low-income respondents did not participate in the NHI program because the people of Lakkang Island who mostly worked as fishermen, entrepreneurs, and informal workers does not have fixed monthly income and only earned enough to meet their daily food needs. The results of this study are in line with the research conducted by Mudayana[9] which stated that family income affects the ability of patients to pay for health services. If the patient's income is still lacking, they assume that they cannot afford health services. This research is also in line with the research conducted by Sihaloho[10] whereby high income affected respondents to become NHI participants and determine their willingness to pay contributions.

Based on Table 1, it is known that the majority of respondents with food expenditure of IDR500, 000-IDR999, 999 are 76 people (80%) since the interview results revealed that the average monthly food expenditure of respondents in Lakkang Sub-district is IDR 775,105. Consumption expenditures are generally spent on basic needs to meet physical needs. Food consumption is the most important factor because food is the main type of goods to maintain survival. Some respondents also planted crops by planting rice so that people's food needs were met without buying rice.

It is also known that the majority of respondents with non-food expenditure amounted to <IDR500, 000, as many as 59 people (62.1%). This is because based on the results of calculations from interviews with all respondents, the average monthly non-food expenditure of respondents in Lakkang Sub-District is IDR 4,70,876. The type of non-food expenditure is the lowest type of expenditure compared to other expenses. This is because the lifestyle of the people on Lakkang Island is very simple. Based on the results of the study, the biggest non-food expenditure was expenditure on electricity, gas, and water payments. While the lowest non-food expenditure

is on durable goods such as kitchen utensils, cutlery and cellular phones. The results of this study are not in line with the research conducted by Karimah[3] which said that the largest household expenditure on handicrafts was non-food expenditure, because many craft workers' families bought durable goods such as cooking utensils, both cash and credit.

Non-essential expenditures are household expenditures for one month which include expenses for party, ceremonies, cigarettes, alcohol, snacks and entertainment expenses that are calculated in units of rupiah. Most of respondents with non-essential expenditures amounted to <IDR500,000 - and IDR500,000-IDR999,999, respectively as many as 46 people (48.4%). This is because based on calculations from the results of interviews with all respondents, the average monthly non-essential expenditure of respondents in Lakkang is IDR530,715.

Table 1: Distribution of respondents based on expenditure per month by Lakkang Island community in 2017

Expenditure Category	Amount	Respondent	
		Total (n)	Percentage (%)
Food expenditure (IDR)	<500.000	5	5.3
	500.000-999999	76	80
	1.000.000-1499.999	6	6.3
	≥1.500.000	8	8.4
	Total	95	100
	Mean	IDR 775.105	
Non-food expenditure	<500.000	59	62.1
	500.000-1.000.000	35	36.8
	≥1.500.000	1	1.1
	Total	95	100
	Mean	IDR 470.876	
Non-essential expenditure	<500.000	46	48.4
	500.000-999999	46	48.4
	1.000.000-1499.999	2	2.1
	≥1.500.000	1	1.1
	Total	95	100
	Mean	IDR 530.715	

The biggest amount of expenditure is spending on cigarettes and snacks. This is because the heads of households in this case are husbands, most of whom are smokers who can spend a pack of cigarettes in a day or two. Based on the results of interviews with respondents it is known that the majority of families have school-age children. Thus, the expenditure for snacks in one month is quite large even those who have not yet school, have also been snacking every day.

The amount of ATP 1, indicated that most of respondents were able to pay NHI contributions each month which was as many as 58 people (61.1%). While 37 people (38.9%) were unable to pay the contributions or the ability to pay was not included in the category of care rooms for NHI service classes. Based on Table 2, it is known that of the 58 respondents who were able to pay NHI contributions, as many as 30 people (31.6%) belonged to the class 1 category. This was because the people in these categories were people who had sufficient income. Furthermore, the results of research show that respondents with low income but are able to pay the contributions each month. This is due to the simple living behaviour of the people of Lakkang Island.

Table 2: Distribution of respondents based on ATP 1 family in the community of Lakkang Island, Makassar City in 2017

Category	Contribution (IDR)	Ability to pay	
		Total (n)	Percentage (%)
No class	<25.500	37	38.9
Class 3	25.500	19	20.0
Class 2	51.000	9	9.5
Class 1	80.000	30	31.6
Total		95	100

Based on Table 1, the average food expenditure of respondents is IDR470,876. If calculated using the 5% formula multiplied by the non-food expenditure of each respondent, the average ability to pay the community was IDR23,554. This means that the respondents with more non-food expenditures were included in the incapable category, namely 59 people (62.1%). While 36 people (37.9%) belong to the category of capable. Table 3 shows that of the 36 respondents who were able, as many as 35 people (36.8%) belonged to the class 3 category services. This is because the non-food expenditure of the Lakkang Village community is not too high. As for non-food expenditure for clothes, people buy these items when necessary, or even during festive seasons, as well as for spending on beauty and durable goods.

The results showed that the average ATP 1 calculation, respondents were able to pay NHI contributions every month. These results are in line with the theory of Adisasmito[11] which stated that if a person is able to spend on non-essential goods, then surely that person is also able to pay for essential health services. If the smoking and snacking behaviour is reduced or stopped, the ability to pay for contributions or health services will increase. Yandrizal[4]'s research indicated that the majority of people who do not have a BPJS Health card are those who are not able to, but expenditures for shopping for cigarettes are greater than for paying NHI contributions each month. This research is also in line with the research conducted by Noormalasari[12] who conducted the research in Jember, saying that on average respondents had consumptive behaviour towards non-essential expenditures such as cigarettes.

Table 3: Distribution of respondents based on ATP 1 in the community of Lakkang Island, Makassar City in 2017

Category	Contribution (IDR)	Non-food		Non-essential	
		n	%	n	%
No class	<25.500	59	62.1	46	48.4
Class 3	25.500	35	36.8	46	48.4
Class 2	51.000	1	1.1	2	2.1
Class 1	80.000	0	0	1	1.1
Total		95	100	95	100

The ability to pay using the ATP formula 2 for non-essential expenses, based on Table 4, is more in the capable categories, which are 49 people (51.6%). The use of the 5% formula multiplied by non-essential expenditure, the obtained average ability to pay the community is IDR26,536. From 49 respondents (51.6%) who were able, as many as 46 people (48.4%) were included in the category of NHI class 3 services. This was due to the non-essential expenditure of Lakkang Island communities such as cigarettes and snacks. The respondents maximum expenditure for non-essential items is IDR1,667,000, average non-essential expenditure of respondents is IDR530,715. The results of this study are consistent with the research conducted by Putra [7] that the ability to pay if seen from the average non-essential expenditure of respondents of independent paying BPJS participants in Makassar City is IDR 405,484. Such non-essential expenditures should make the head of the family able to finance his family for essential needs such as paying JKN contributions each month, at least in class 3 service which is only IDR 25,500.

Table 4: Distribution of respondents based on ATP 2 families in the community of Lakkang Island, Makassar City in 2017

Ability to pay	Non-food		Non-essential	
	Total (n)	Percentage (%)	Total (n)	Percentage (%)
Not able	59	62.1	46	48.4
Able	36	37.9	49	51.6
Total	95	100	95	100

Conclusion

Based on the results of the research and discussion that has been described, the following conclusions can be drawn:

1. The level of income of respondents is mostly in the category <IDR1,500,000, which is 38 respondents (40%). If, based on the 2016 Makassar City minimum wage, the majority of income is in the low category with 69 respondents (72.6%). The level of respondents' expenditure for food averaged Rp.775,105, for non-food Rp.470,876 and non-essential Rp.530,715. The biggest type of expenditure is spending on food.
2. The ATP value of the respondents using the ATP 1 formula was mostly in the capable category of 58 respondents (61.1%) with an average ATP per person of IDR 90,440 per month. While for the ATP 2 formula, the majority are in the category of non-food for non-food namely 59 respondents (62.1) with an average ATP of IDR 23,544 and for the most non-essential are in the category of capable of 49 respondents (51.6%) with ATP average IDR 26,536.

Acknowledgement

First and foremost, the authors would like to thank Faculty of Community Health, Hasanuddin University for their support and facilities in conducting this study. The authors would also like to thank all the respondents from the community on the Lakkang Island who were willing to participate in this study.

Factors Associated with Musculoskeletal Disorders (MSDs) Complaint on the Workers of Cargo Unit at PT. Angkasa Pura Logistics, Makassar in 2017

Firmita Dwiseli[1], Muhammad Rum Rahim[1], Awaluddin[1]

[1]Department of Work Safety & Health, Faculty of Community Health, University of Hasanuddin, Makassar, Indonesia

ABSTRACT

Musculoskeletal complaints are complains on the part of skeletal musclefelt by someone starting from mild to very severe. When the muscle receives heavy load repeatedly and for a long time, it will lead to complain on damage of joints, ligaments, and tendons. The observational analytic with cross sectional study done, aimed to determined factor associated with MSDs complaints on cargo unit workers at PT. Angkasa Pura Logistics Makassar in 2017. The number of samples as many as 31 people was taken by purposive sampling technique. Data are taken from respondents using questionnaires, Nordic Body Map, Rapid Entire Body Assessment (REBA), microtoise and scales. The results showed that there was a relationship between length of work p= 0.017, work attitude p= 0.036, and Body Mass Index (BMI) p=0.041 with MSDs complaints oncargo unit workers at PT. Angkasa Pura Logistik Makassar in 2017.

Keywords: *MSDs, Musculoskeletal, BMI and PT. Angkasa Pura Logistics.*

Introduction

Musculoskeletal hazards are a disorder or decrease in the condition of the musculoskeletal system commonly referred to as Musculoskeletal Disorders (MSDs). MSDs are a major cause of industrial injury in both developed and developing countries[1]. MSDs can be one of the factors causing a decline in production, loss of working hours, high costs treatment and material, increased absenteeism, low quality of work, injury and muscle tension, increased likelihood of workplace accidents and errors, increased labor turnover costs and reduced reserves associated with emergencies[2].

Complaints of the musculoskeletal system are complaints to parts of the skeletal muscles that are felt by a person ranging from mild complaints to very sick. If the muscle receives a static load repeatedly and for a long time, it can cause complaints in the form of damage to joints, ligaments and tendons. Work attitude that causes the position of parts the body moves away from its natural position, for example hand movements are raised, the back is too bent and the head is raised. The farther the body part of the body's gravity, the higher the risk of occurrence complaints of the musculoskeletal system[3].

MSDs are one of the increasing occupational diseases in the world. The results of research conducted by Cindyastira et al.[4] on production workers in CV. SumberGalian Makassar found the prevalence of MSDs complaints felt by 26 workers (60%). The statistical results show that the age variable, work period variables, exercise habits, and work attitude variables have a significant relationship with complaints of MSDs, whereas the vibration intensity variable and the longer working duration variable have no significant relationship with MSDs complaints. Research conducted on tofu factory workers in East Bara-Baraya Village, Makassar City showed that MSDs complaints were felt by 42 workers (66.7%). The results of statistical tests show that the variables of age, smoking habits, and years of service and work posture are related to complaints of MSDs[5].

PT. Angkasa Pura Logistik is a subsidiary of PT.Angkasa Pura I (Persero) which is engaged in logistics in Indonesia. Based on the preliminary survey that has been carried out, the work process in the cargo unit includes the receipt of goods, weighing, making/ checking transport documents, storing goods in the warehouse until the process of goods is loaded into cargo compartment, withdrawing goods from the warehouse

to the aircraft and vice versa, loading goods loading) to the aircraft and unloading of aircraft, storage and shipping. From the types of work, some processes are still done manually, for example the process of lifting and moving items. This work process is usually called manual handling. Manual handling operations are all activities of transporting or sustaining loads (including lifting, placing, pushing, pulling, carrying, or moving) by hand or body strength[6].

Manually lifting activities can cause complaints about skeletal muscles often referred to as musculoskeletal complaints. Moreover, if the activity of lifting weights manually is done with repetitive positions or working attitudes repeatedly every day the possibility of a musculoskeletal complaint is greater. The results of Jaya[7] research show that there is a relationship between the weight of goods and MSDs complaints on CV Cahaya Malang Raya Makassa employees. Masliah et al. [8] research results on manual handling workers in Makassar Port showed that there was a relationship between work posture and MSDs complaints experienced by workers. In addition to being able to carry out their duties well, workers also need good physical condition. This is necessary because every day workers are required to lift heavy items, it needs a large work capacity so as not to cause harm. Based on preliminary data obtained from the administrative division of PT. Angkasa Pura Logistics, the number of workers in the cargo unit is 111 people with working experience of generally less than 3 years. Workers work every day from Monday to Sunday. Based on the description of the background above, the authors are interested in conducting research on factors related to complaints of Musculoskeletal Disorders (MSDs) in cargo unit workers at PT. Angkasa Pura Logistik Makassar.

Methodology

The type of research used is observational analytic research with cross sectional study approach, with the intentions of perceiving the relationship between the independent variables and the dependent variable which is the relationship between weight burden, work attitude, and BMI with MSDs complaints among workers in cargo unit at PT. Angkasa Pura Logistics Makassar.The research was conducted at PT. Angkasa Pura Logistics Makassar from January 2017 to April 2017.

The population in this study was all porter workers in the unit cargo PT. Angkasa Pura Logistik Makassar, which is 111 people. From this population, the sample study was workers in the cargo unit of PT. Angkasa Pura Logistics, who works in the afternoon shift (35 people). Sampling is done using purposive sampling techniques, namely sampling based on certain characteristics considered to have a close relationship with the characteristics of the population that were previously known. The inclusion criteria used in this study are as follows:

a. Minimum 1-year work period. This is done because of MSDs complaints is a complain that can arise due to a monotonous work process and continuous load over a relatively long period of time.

b. Work in the afternoon shift during the study period.

Data on complaints of Musculoskeletal Disorders (MSDs) were obtained by using the Nordic Body Map questionnaire. Primary data regarding name and age were obtained through direct interviews with respondents using questionnaire. Data on load weight is obtained from the weight of the object shown on packed weights. Data regarding work posture is obtained through the calculation of MSDs risk on certain body parts (neck, spine, upper arms & bottom, wrist) using the Rapid Entire Body Assessment scoring sheet. Data on Body Mass Index is obtained through weight and height measurement of the worker using weight scales and microtoise, then calculated using the IMT formula. Secondary data was obtained from the company in the form of data regarding company profiles and the number of workers in the cargo unit of PT. Angkasa Pura Logistics Makassar. All the gathered data were analyzed using SPSS program which consist of univariate analysis and bivariate analysis.

Result and Discussion

Univariate Analysis: Respondents' distribution based on Musculoskeletal Disorders (MSDs) complaints is shown in Table 1 which was obtained from interviews using the Nordic Body Map questionnaire. It shows that out of 35 respondents, 21 people (60%) experienced MSDs while the number of respondents who did not experience MSDs was 14 people (40%).This study categorizes the weight variable into two categories namely heavy and light. Based on Table 1, it can be seen that, 21 people (60%) who lifts heavy loads while working whereas remaining people involves in light loads. As for work attitude category,itt can be concluded that a total of 20 people (57.1%) exhibit risky work attitude in contrast

to the remaining 15 people (42.9%).In this study, BMI was categorized into two; which are ideal category if the BMI is between 18.5 – 25.0 kg/m^2 and the non-ideal category if BMI <18.5 kg/m^2 or BMI> 25 kg/m^2. Non-ideal consists of those who are underweight, overweight, and obese. Data shows that out of 35 respondents, there were 17 people (48.6%) who had ideal BMI and 18 people (51.4%) with non-ideal BMI.

Table 1: Distribution of respondents based on MSDs complaints, weight load, work attitude and body mass index at PT. Angkasa Pura Logistics Makassar workers in 2017

Category		Frequency (n)	Percentage (%)
Complaints of MSDs	Have complains	21	60
	No complains	14	40
Weight load	Heavy	21	60
	Light	14	40
Work attitude	Risky	20	57.1
	Non-risky	15	42.9
Body mass index	Ideal	17	48.6
	Non-ideal	18	51.4

Bivariate Analysis: The bivariate analysis results of the relationships between weight burden and MSDs complaints at PT Angkasa Pura Logistics is presented in Table 2. It shows that of all respondents who involved in lifting heavy loads, there were 16 people (76.2%) who experienced MSDs while 5 people (35.7%) did not complain of MSDs. While respondents who were involved in lifting light loads, 5 respondents do have MSDs while 9 people (64.3%) did not experience any MSDs. Based on the results of data analysis using Chi-square test, the value of p = 0.017 which indicated that there is a relationship between weights and complaints of MSDs in cargo unit workers at PT Angkasa Pura Logistics Makassar. The results of this study are in line with the research conducted by Masliah et al.[8] regarding MSDs complaints of workers in manual handling at Makassar port, which showed to have a significant relationship between complaints of musculoskeletal disorders and the weight of the burden. If the weight of the load exceeds the work capacity of workers, it can cause interference to workers. The heavier the burden received by a worker, the greater the likelihood of disruption to the physical of the worker, especially at parts of the muscles and bones. This is because the heavier the objects, the greater the energy that presses on the muscles to stabilize the spine and produces greater pressure on the spine. Due to transporting loads that are too heavy or too weak, physical abilities can cause a worker to suffer a disorder or disease[9].

Table 2: Relationship between load weight and MSDs complains among workers at PT. Angkasa Pura Logistics Makassar in 2017

Weight load	MSDs complains				Total		p
	Have complain		No complain		n	%	
	n	%	n	%			
Heavy	16	76.2	5	23.8	21	60.0	0.017
Light	5	35.7	9	64.3	14	40.0	
Total	21	60	14	40	35	100	

An overview of the bivariate analysis results of the relationships between work attitudes and MSDs complains at PT Angkasa Pura Logistics is shown in Table 3. Respondents with risky work attitudes who experienced MSDs were as many as 15 people (75%) while workers who demonstrate non-risk work attitude and had MSDs disorders, namely 6 people (40%). In contrast, respondents who has complains of MSDs comprises of 5 people (25%) with risky work attitudes and 9 people (60%) with non-risky work attitudes. Based on the results of data analysis using Chi-square test, the value of p = 0.036 which indicated that there is a relationship between work attitudes and complaints of Musculoskeletal Disorders (MSDs) in cargo unit

workers at PT Angkasa Pura Logistics Makassar. This research is in line with the research conducted by Riyanto[10] regarding the effect of manual lifting work on complaints of the musculoskeletal system in workers at PT. SidoMuncul Semarang as the p value is 0.001. An unnatural work attitude causes the body part to move away from its natural position. The farther the position of the body part from the center of gravity, the higher the complaints of skeletal muscles also occur. Work attitudes are not generally due to workers 'incompatibility with workers' abilities[11]. The attitude and work position that are not ergonomic have the potential to cause some health problems, including muscle fatigue, pain, and vascularity disorders[12].

Table 3: Relationship between work attitude and MSDs complaints among workers at PT. Angkasa Pura Logistics Makassar in 2017

Work attitude	MSDs complains				Total		p
	Have complain		No complain		n	%	
	n	%	n	%			
Risky	15	75	5	25	20	57.1	0.036
Non-risky	6	40	9	60	15	42.9	
Total	21	60	14	40	35	100	

Table 4 presented the bivariate analysis results of the relationships between BMI and MSDs complains at PT Angkasa Pura Logistics. It can be observed that out of 35 respondents, the number of respondents with ideal BMI who had MSDs complains was as many as 14 people (77.8%) while 7 people (41.2%) in non-ideal BMI category raised MSDs complains. Respondents who has ideal BMI and did not have any MSDs were 4 people (22.2%) while remaining 10 people (58.8%) are in the non-ideal BMI category and did not have any MSDs. Based on the results of statistical analysis using the Fisher Exact, the value of p = 0.027 which tells there do exist relationship between Body Mass Index (BMI) with complaints of MSDs. The results of this study are in line with the research conducted by As'Adi et al.[13] workers who measured the relationship of individual characteristics and manual material handling (MMH) to workers in the TanjungJember Market. He obtained p = 0.041 which concluded that there is a relationship between BMI and MSDs complaints. BMI associated with musculoskeletal complaints are the results in the body not being able to sustain body weight that makes the body feel pain. Overweight and obesity leads to serious health consequences. Risks are increasing along with increasing BMI. Body mass index is a major risk factor for chronic diseases osteoarthritis[14]. Meanwhile, underweight workers also have the potential to experience complaints of MSDs due to the inability of their bodies to support heavy loads. The possibility of injury or sprains when lifting weights is greater than workers who have a proportional body.

Table 4: Relationship between work attitude and MSDs complaints among workers at PT. Angkasa Pura Logistics Makassar in 2017

BMI	MSDs complains				Total		p
	Have complain		No complain		n	%	
	n	%	n	%			
Ideal	14	77.8	4	22.2	18	51.4	0.041
Non-ideal	7	41.2	10	58.8	17	48.6	
Total	21	40	14	60	35	100	

Conclusion

Based on the results of research on factors related to complaints of Musculoskeletal Disorders (MSDs) in cargo service workers at PT Angkasa Pura Logistics Makassar in 2017, some conclusions were obtained as follows:

a. The heavier the burden received by workers, the more likely it is to experience MSDs complains.
b. Workers need to practice ergonomic work attitude in order to reduce MSDs occurrences.
c. Maintaining BMI in ideal category helps the workers from MSDs risks.

Relationship between Heat Pressure and Age with Work Fatigue among Workers at Department Factory I of Pt. Maruki International, Makassar in 2017

Ulfa Rahman[1], Masyitha Muis[1], FurqaanNaiem[1]

[1]Department of Work Safety &Health, Faculty of Community Health, University of Hasanuddin, Makassar, Indonesia

ABSTRACT

PT. Maruki International Indonesia is the only company in Indonesia that exports Butsudan. Production activities are divided into 6 factories. The initial process that has high activity and has high heat pressure sourced from the engine takes place in Factory 1. Hence, this can cause workers to experience fatigue easily. This study aimed to determine the relationship of heat pressure and age with work fatigue experienced by Factory 1 workers at PT. Maruki International Indonesia Makassar City. The type of research is observational analytic with a cross sectional study approach. Data collection from 48 workers took place from April 10 to April 15, 2017. The work fatigue measurement technique used the Reaction timer tool, heat pressure using Heat Stress Monitor equipment, and age through direct interview. Data analyses were done using Chi-square test. The results showed that there was a relationship between heat pressure $p = 0.014$ ($p < 0.05$) and age $p = 0.026$ ($p < 0.05$ with work fatigue at factory I workers of PT. Maruki International Indonesia.

Keywords: *PT. Maruki International, Fatigue, temperature and factory I workers.*

Introduction

Fatigue is a mechanism for protecting the body so that the body can avoid further damage resulting in recovery after rest[1].The term fatigue leads to the condition of weakening of energy to carry out an activity. Symptoms of subjective and objective fatigue include feelings of lethargy, sleepiness, dizziness, lack of concentration, lack of alertness, poor and slow perception, reduced arousal for work and decreased spiritual and physical performance. Fatigue can affect work productivity, so that if the level of productivity of a workforce is disrupted caused by physical or psychological factors, then the result will be felt by the company in the form of decreased in productivity[2].

Workers will be able to carry out activities well and work optimally under conducive working environment. The comfort of a workplace is influenced by several factors, one of which is the work climate. Work climate is a combination of air temperature, air humidity, air movement speed and radiation temperature in a work environment[3]. If these four components interact with heat, it will potentially cause heat stress. Excessive heat pressure can lead to various health problems, work accidents to death. Human ability to adapt to environmental temperature is generally seen from changes in body temperature. Humans are considered able to adapt to changes in environmental temperature if temperature changes do not occur or changes in body temperature whereby still in a safe range[4]. The local temperature and existence of life are very closely related, as are the effects of work weather on labour power. Work efficiency is greatly influenced by working weather in areas where work is not cold and not hot. The recommended temperature in the workplace is around 24-26 ° C (cold temperature) and humidity of 65% - 95%[3].

Workers in hot environments, such as around furnaces, smelters, boilers, ovens, heat sinks or working under the hot sun can experience heat stress[5]. These thermal conditions can affect the performance of workers both working outside and inside buildings. The effectiveness of the performance of workers in the two work locations is strongly influenced by the comfort of the work environment where they are located, especially for workers who are in building[6]. The United States Emergency Department reports that the number of work

accident patients due to heat stress in the workplace has increased significantly from 3,192 cases in 1997 to 7,452 in 2006[7]. Based on research conducted by Indriawati[8] about the effect of heat pressure on the fatigue level of work at the concert slab steel plant I PT. Krakatau Steel Cilegon, Banteng shows that there is a relationship between heat pressure and work pressure in the concrete section, namely the higher the heat pressure in the work environment, the higher the level of fatigue of workers. Conversely the lower the heat pressure in the workplace the lower the work fatigue of the workers.

Individual factors such as age, nutritional status and haemoglobin levels also greatly influence the occurrence of work fatigue. Research by Damopoli et al.[9] concluded that there is a relationship between age and work fatigue at the Manado-Amurang bus driver at Malayan terminal. The age of bus driver is directly proportional to the level of fatigue. The results of research conducted by Febriani et al.[10] on the relationship of heat pressure to fatigue in tofu maker workers of Tofu Factory in East Bara-Barayya Sub-District, in 2016 showed that as many as 43 respondents obtained more work fatigue in the status category. 29 respondents (82.9%) experienced abnormal nutritional compared to the normal nutritional status category as many as 14 respondents (50.0%).

PT Maruki International Indonesia is the only company in Indonesia that exports Butsudan (furniture that serves as a place to respect and communicate with deceased ancestors). Types of activities carried out at PT. Maruki International Indonesia, namely wood drying, woodcutting, refinement, gluing, colouring, assembly and packaging. Examples of complaints by workers during the research work include quickly feeling tired, fast thirst, dizziness, and excessive sweating. This is the background of researchers wanting to conduct research with the title "Relationship between Heat Pressure and Age with Fatigue among Workers in Factory I Section at PT. Maruki International Indonesia Makassar City 2017.

Methodology

The type of research used is observational analytic research with a cross sectional study approach as the independent and dependent variables will be observed at the same time. This research was conducted at the factory 1 of PT. Maruki International Indonesia Makassar City. Data collection began on 10 April until 15 April 2017 against 48 workers in the factory as samples taken with exhaustive sampling techniques. The data were collected using direct interviews (questionnaires) as to find out the age and heat pressure measurements using a Heat Stress Monitor measuring device. Furthermore, work fatigue measurements were carried out using a reaction timer on a sample of 48 workers. The data obtained is then analyzed using the SPSS computer program and the data is presented in the form of a frequency table and cross tabulation (crosstab) in accordance with the research objectives and accompanied by a narrative as a table explanation.

Result and Discussion

Univariate Analysis: Distribution of respondents according to work fatigue group can be seen in Table 1. Based on Table 1, it is shown that the highest number of respondents is in the reaction time group 198-239 milliseconds as many as 18 respondents or 37.5% while the least number of respondents is in the reaction time group 502-543 milliseconds as many as 2 respondents or 4.3%.

Table 1: Distribution of respondents by fatigue group

Fatigue group	Respondents	
	n	Percentage (%)
198 – 239	18	37.5
240 – 381	5	10.4
282– 323	3	6.2
324– 365	4	8.4
366– 407	3	6.2
408 – 459	3	6.2
460 – 501	4	8.4
502 – 543	2	4.3
544 – 585	3	6.2
586 – 627	3	6.2
Total	48	100

After grouping the fatigue level based on the reaction time of workers, work fatigue in this study is then divided into 2 categories, namely fatigue if the reaction time is ≥ 240 milliseconds and not fatigued if the reaction time is <240 milliseconds. Data in Table 2 presented that from 48 respondents, it was known that respondents who experienced fatigue were 30 people or 62.5% whereas those who did not experience fatigue is as many as 18 people or 37.5%.

Table 2: Distribution of respondents by fatigue category

Fatigue category	Respondents	
	n	Percentage (%)
Experienced fatigue	30	62.5
No fatigue experience	18	37.5
Total	48	100

Data presentation based on distribution of respondent according to heat pressure can be seen in Table 3. Heat pressure is categorized into 2 categories, namely meeting the requirements for Wet Bulb Globe Temperature Index (WBGT) of not exceeding threshold value 28℃ and not meeting the requirements if the WBGT does not pass the threshold value (> 28℃). The data in Table 3 showed that from 48 respondents, it was obtained as many as 32 people or 66.7% who worked under heat pressure did not meet the requirements and 16 people or equal to 33.3% worked on heat pressure that met the requirements.

Table 3: Distribution of respondents by heat pressure category

Heat pressure category	Respondents	
	n	Percentage (%)
Did not meet the requirement	32	66.7
Met the requirement	16	33.3
Total	48	100

Distribution of respondents based on age group is tabulated in Table 4.The age of respondents working at Factory I ranged from 20-59 years. Based on table 4, the highest number of respondents is in the age group 45-49 as many as 11 respondents or 22.9% while the least number of respondents is in the age group 55-59 years as many as 4 respondents or 8.4%.

Table 4: Distribution of respondents by age group

Age group	Respondents	
	n	Percentage (%)
20-24	6	12.5
25-29	6	12.5
30-34	5	10.4
35-39	5	10.4
40-44	6	12.5
45-49	11	22.9
50-54	5	10.4
55-59	4	8.4
Total	48	100

Bivariate Analysis: The results of cross tabulation between heat stress and fatigue can be seen in Table 5 which revealed that from 48 respondents, most of workers that experienced work fatigue working under heat pressure (did not meet the requirements), as many as 24 respondents or 75.0% compared to those working under heat pressure (met the requirements) of 6 respondents or 37.5%. The number of respondents who did not experience fatigue but worked under heat pressure (within the requirements), were as many as 10 respondents or 62.5% whereas those who worked under heat pressure (did not meet the requirements), namely as many as 8 respondents or 25.0%. Based on data analysis using the Chi square test, the value of p = 0.014. The interpretation is that there is a connection between heat stress and work fatigue.

Table 5: Relationship between heat stress and work fatigue

Heat stress	Work fatigue				Total		p-value
	Experienced fatigue		No fatigue experience		n	%	
	n	%	n	%			
Did not meet requirement (>28℃)	24	75.0	8	25.0	2	66.7	0.014
Met requirement (≤28℃)	6	37.5	10	62.5	6	33.3	
Total	30	62.5	18	37.5	8	100	

The following are the results of cross tabulation between age and work fatigue which can be seen in Table 6. Table 6 showed that of the 48 respondents those who experienced work fatigue were in the old age (35 years and above) category as many as 23 respondents or 74.2% compared to the young age category that is as many as 7 respondents or 41.2%, while the percentage who did not experience work fatigue in the young age category were as many as 10 respondents or 58.8% and in the old category 8 respondents or 25.8%. Based on data analysis using the Chi square test, the obtained p value = 0.026. Thus, there is a relationship between age and work fatigue.

Table 6: Relationship between age and work fatigue

Age	Work fatigue				Total		p-value
	Experienced fatigue		No fatigue experience		n	%	
	n	%	n	%			
Old (≥35 years)	23	74.2	8	25.8	31	64.6	0.026
Young (<35 years)	7	41.2	10	58.8	17	35.4	
Total	30	62.5	18	37.5	48	100	

Discussion

The results of the heat pressure received by workers vary depending on which production process the worker works. In addition to work processes that are exposed to heat, the condition of buildings and roofs made of zinc and not equipped with air vents (exhaust fans) increase the factor of heat stress in the workplace is higher. If workers are exposed to heat, the organs will work harder to remove excess heat from the body, causing the hypothalamus to stimulate the sweat glands so that the body will sweat. In sweat contains various sodium chloride salts, the release of sodium chloride salt with sweat will reduce levels in the body, thus inhibiting the transportation of glucose as an energy source. This will cause a decrease in muscle contraction so that the body experiences fatigue[11]. This was reinforced by complaints from workers when researchers conducted interviews, where most workers experienced dehydration, headaches, excessive sweating and complained of the existence of a hot environment. Based on the results of data analysis and observations, it can be concluded that the higher the heat pressure, the respondents will be at risk of experiencing work fatigue. This research is in line with the research conducted by Indriawati[8] which stated that there is a significant relationship between heat pressure and work fatigue among workers at the Concrete Slab Steel Plan 1 PT. Krakatau Steel Cilegon, Bantensince obtained p value = 0.002.

In this study, there is a relationship between age and work fatigue whereby the older a person is, the lower the body's strength which result in faster work fatigue. A person's age will affect the condition and capacity of the body in carrying out its activities. Workers over the age of 35 have fatigue when doing work under hot temperatures compared to younger workers[12]. The results of this study are not in line with the research conducted by Winwood et al.[13] where young workers are easily tired than old age employees.

Although most respondents who experience work fatigue are included in the old age category, but there are 8 respondents who are in the old age category whom did not experience fatigue. This can be caused by workers utilizing their rest periods well. In addition, in the young age category, 7 respondents experienced work fatigue. Based on the results of interviews, these workers had poor sleep patterns. This is due to other activities after working like additional work, experiencing sleep disorders (insomnia) and the habit of spending time late at night after returning to work.

Conclusion

Based on the results of research and analysis of the variables studied about the relationship of heat pressure and the characteristics of individuals with work fatigue on workers at the factory 1 of PT. Maruki International Indonesia Makassar City In 2017 it can be concluded that:

1. The higher the temperature of the environment in the workplace, the faster the workers experience work fatigue.
2. The older the age of a worker, the faster they experience work fatigue.

Acknowledgement

The authors would like to thank Faculty of Community Health, Hasanuddin University for their support and facilities in conducting this study. The authors would also like to thank all the respondents from Department Factory I of Pt. Maruki International who was willing to participate in this study.

Relationship of Health Service Quality with Inpatients' Loyalty at RSUD M akassar City

Sri Wahyuni[1], Nurhayani[1], H. Indar[1]

[1]Department of Administration & Health Policy, Faculty of Community Health, University of Hasanuddin, Makassar, Indonesia

ABSTRACT

The purpose of this research is to get an illustration about the relationship of quality of health service with the loyalty of inpatients in RSUD Makassar City. This research type is quantitative research with cross sectional design. A total sample of 95 respondents is determined by the accidental sampling technique. The data collection is done using questionnaire. The result of Chi-square test ($p < 0.05$) on service quality variables was correlated between responsiveness ($p = 0.007$), assurance ($p = 0.000$), and reliability ($p = 0.013$) toward loyalty of inpatients in RSUD Makassar City. Meanwhile, service quality variables have no relation between tangibility ($p = 0.901$) toward loyalty of inpatient patient in RSUD Kota Makassar. In conclusion, there is relation between quality of health service variable with patient loyalty including, dimension of responsiveness, and assurance. However, there is no correlation between the variable of health service quality and patient loyalty in tangibility dimension. Thus, it is recommended that the hospital speed up the process of renovation of the rooms, hospitalization and complement each room according to the needs of patients in RSUD City.

Keywords: *Health Service, Quality, Inpatients, Loyalty and RSUD.*

Introduction

Healthcare providers such as hospitals, health centers, medical centers and medical practices are form of provision of health resources which need to have quality services that are in line with the expectations of the community[1]. Health personnel (doctors, nurses, medical and non-medical support staff in the hospital) must understand how to serve consumers well, especially patients, since they are the primary consumers[2]. There are many things to consider in improving the health status of the community, one of which is to provide health services for instance any individual or collective effort in an organization to nurture and improve the health of individuals, families, groups or communities, and the establishment of health care facilities such as health centers and hospitals[3]. Quality as a concept is applied and practiced in the same manner and style in every circumstance. Health care must understand the health status and needs of the public health services it serves in determining the most effective way to provide a quality healthcare.

Based on Gunawan et al.[4]'s research results on the quality of patient service and loyalty, the results showed that the service quality consisted of tangibility, empathy, reliability, responsiveness and assurance had partial effect on patient's loyalty. Research conducted by Mahamad et al.[5] showed that empathy, reliability, responsiveness, assurance, and tangibility had positive and significant influence on customer's satisfaction and loyalty. The results of the study conducted by Asmita[6] revealed that patient's perception about doctor's medical skill was not good at 50.9%, perception of doctor attitude was not good at 49.1%, perception of information delivery was not good equal to 53.6 %, timekeepingservice perceptions were poor with 59.1%, perception of doctor's time consultation was not good with 52.7% and less loyal patients 56.4%. Research by Berlianty et al.[7], showed that there is a significant relationship between all variables with patients' loyalty, the related variables are responsiveness p (0.00), assurance p (0.03), tangibility p (0.03), empathy p (0.03), and reliability p (0.01). While the results of research conducted by Hidayah[8], proved that the variables associated with the loyalty of inpatient

patients were reliability (p = 0.006), empathy (p = 0.000), and brand personality (p = 0.007). Variables that were not related to loyalty of inpatients is affordability variable (p = 0.314).

Based on reports from RSUD Makassar from 2014 to 2016, there has been a decreased in the number of patients especially from year 2015 to 2016 with a reduction of number of patient visits as many as 3358 patients.This is likely to be due to the quality of health services in inpatient admission was in poor condition. Consequently, patients are not loyal to re-utilizing the service in the hospital. Therefore, this study is interested to know the quality of health service quality with patient inpatient loyalty at RSUD Makassar City for the year 2017 based on tangibility, responsiveness and assurance factors.

Methodology

This quantitative research applied an observational analytic with cross sectional approach which is meant to identify the relationship between health service quality with patient loyalty in RSUD Makassar City. The study conducted in RSUD Kota Makassar (located at Jl. Pioneer of Independence Km 14 Daya, Makassar (Provincial Poros Road), was from 10th to 30th April 2017.

The population in this study was all patients in the care unit staying in Makassar Municipal Hospital in 2016 as many as 9228 people.Sampling technique used in this research was 'accidental sampling technique' that is the simplest sampling technique, because the sample coincidently exists at the time of the research and meets the criteria for research sample. The criteria for the samples are as follow:

a. Willing to be a respondent in this study.

b. Respondents are patients who have more than two visits.

c. Respondents are able to understand the questions/ statements contained in questionnaire and answer the question itself. For respondents who have difficulty completing the questionnaire, they can be assisted by his/her family.Based on this given criteria, the total number of samples accepted from the population was 95 respondents.

In this study, the primary data is obtained through questionnaires that have been prepared and distributed to the respondents to be filled up whereas the secondary data is obtained from document collection such as annual report and profile of Makassar City Hospital, and other sources related to research. The collected data were analyzed using SPSS program for univariate analysis and bivariate analysis with responsiveness, assurance, and tangibility as independent variables while loyalty as the dependent variable.

Result and Discussion

Univariate Analysis: The distribution of respondents scoring based on responsiveness dimension statements is tabulated in Table 1. Based on the description of the statement the dimension of responsiveness in the first statement, no respondents who rated strongly agree and strongly disagree, while 87 respondents rated disagree. In statement number two, 89.5% did not agree, and similar to the first statement, 0 respondents strongly disagree and strongly disagree. In statement number three, there are 4 respondents who rated strongly agree, 36 respondents judged agree, 55 respondents who did not agree and 0 respondents who rated strongly disagree. For the fourth statement, there are 12 respondents (12.6%) who ranked strongly agree, 44 respondents (46.3%) judged agree, 39 respondents (41.1%) who rated disagree, 0 respondents (0.0%) strongly disagreed. In statement number five, there are 20 respondents (21.1%) who rated strongly agree, 37 respondents (38.9%), rated agree, 38 respondents (40.0%) who did not agree, and 0 respondents (0.0%) who strongly disagreed. For the last statement, there are 0 respondents (0.0%) who rate strongly agreed and disagreed, 40 respondents (42.1%) agreed, and 55 respondents (57.9%) who did not agree. This is due to doctors are quick and responsive in providing services, and nurses inform quickly if there is a delay in providing health services. However, on the other hand from the results of data collection in the field, there are some respondents who judge poorly on the responsiveness dimension because most respondents rated not all nurses in Makassar City Hospital are quick and responsive in providing health services to patients. Therefore, health workers should be faster and clearer in providing services to patients so that they feel comfortable with the attitudes held by health workers in Makassar City Hospital.

Table 1: Distribution of respondents scoring based on responsiveness dimension statements

Statements	Responses							
	Strongly agree		Agree		Disagree		Strongly disagree	
	n	%	n	%	n	%	n	%
Doctors are fast and responsive in providing health services to patients.	0	0	8	8.4	87	91.6	0	0
Doctors are willing to listen to the patient's complaints.	0	0	10	10.5	85	89.5	0	0
Nurses inform quickly if there is a delay in providing health services to patients.	4	4.2	36	37.9	55	57.9	0	0
Health workers always provide information on every action/ treatment that will be taken to the patient/family.	12	12.6	44	46.3	39	41.1	0	0
Nurses are fast and responsive in providing health services to patients.	20	21.1	37	38.9	38	40.0	0	0
Health workers serve andaccept patients well.	0	0	40	42.1	55	57.9	0	0

Table 2 presented the distribution of respondents scoring based on assurance dimension statements. With reference to the scoring on the description of the statement, the assurance on statement number one, there are 0% strongly agree and disagree, 21.1% agree and 78.9% assessed disagree. For statement number two, there is 1 respondent who chose strongly agreed, 25 respondentsagreed, 69 respondents assessed disagreed and none rated strongly disagreed. The third statement had 0 respondents who rated strongly agree, 20 respondents agree, 74 respondents disagree, and 1 respondent who strongly disagree. As for the fourth statement, 0% rate strongly agree and disagree, 9.5% considered agree, and 90.5% assessed disagree. Likewise with the fourth statement, there were no respondents who strongly agree or strongly disagree with the fifth statement. 30 respondents judged to agree and 65 respondents assessed disagree. For the sixth statement, 23 respondents rated strongly agree, 16 respondents agreed, 56 respondents disagreed, and none strongly disagreed.

Table 2: Distribution of respondents scoring based on assurance dimension statements

Statements	Responses							
	Strongly agree		Agree		Disagree		Strongly disagree	
	n	%	n	%	n	%	n	%
Doctor can always answer every question I asked.	0	0	20	21.1	75	78.9	0	0
Nurse is always polite and friendly towards patients.	1	1.1	25	26.3	69	72.6	0	0
Doctors did their duty well till patients feel satisfied and comfortable in receiving care.	0	0	20	21.1	74	77.9	1	1.1
Nurse maintains confidentiality/privacy ofpatient's condition during treatment.	0	0	9	9.5	86	90.5	0	0
Doctors give attention to the complaints that patients feel.	0	0	30	31.6	65	68.4	0	0
Nurse is always available 24 hours if needed by the patient.	23	24.2	16	16.8	56	58.9	0	0

The distribution of respondents scoring based on tangibility dimension statements is shown in Table 3. Based on the description of the statements, the dimensions of physical evidence (tangible) on statement number 1, there are 2 respondents who rated strongly agree, 44 respondents judged to agree, 49 respondents assessed disagree, and 0 respondents who rated strongly disagree. In statement number 2, 1.1% strongly agree, 34.7% agree, 64.2% disagree and 0% strongly disagree. For the third statement, 28.4% agreed, 71.6% disagreed, and 0% strongly disagreed and

strongly agreed. As for the fourth statement, there are 4 respondents who rated strongly agree, 40 respondents agree, 51 respondents disagree, and 0 respondents who rated strongly disagree. Respondents neither voted for strongly agree nor strongly disagree for the fifth statement. 21.1% considered agreeing while the remaining 78.9% assessed disagreeing. For statement number 6, there are 2 respondents who rated strongly agree, 41 respondents agreed, 52 respondents (54.7%) assessed disagree, and nobody rated strongly disagree.

	Strongly agree		Agree		Disagree		Strongly disagree	
	n	%	n	%	n	%	n	%
Clean and attractive appearance of inpatient room.	2	2.1	4	46.3	9	51.6	0	0
Complete medical equipment is available (blood pressure measurement device, stethoscope, infusion pole, etc.).	1	1.1	3	34.7	61	64.2	0	0
All health workers always neat and clean uniforms, as well use identification/nametag.	0	0	7	28.4	68	71.6	0	0
Available facilities are reasonable at the price paid	4	4.2	0	42.1	1	53.7	0	0
Complete medicines are available at the pharmacy.	0	0	0	21.1	5	78.9	0	0
Complete health facilities are supported by sophisticated technology.	2	2.1	1	43.2	2	54.7	0	0

Table 4 presented the relationship between the dimensions and patients' loyalty. Based on the dimension of responsiveness, there were 33 respondents who considered good and loyalty or, and 33 respondents who are considered good but not loyal. While respondents who assessed the dimensions of responsiveness were not good but loyal as many as 23 respondents and 6 respondents assessed the responsiveness dimension not good and not loyal. Furthermore, the value of p =0.007 means that there is a relationship between the dimensions of responsiveness and the loyalty of inpatients.Research conducted by Ulfa[9], and Sahara[10] stated that the responsiveness dimension has a positive relationship with patients' loyalty. This is supported by the opinion of Ulfa[9] where poor systems and processes greatly influence patients' ratings even though hospitals have skilled employees since such as long waiting time can cause hospitals to lose customers.

As for the dimensions of assurance, there are 65.9% respondents who are good and loyal, while the good but not loyal ones are 34.1%. 10 respondents valued the assurance dimension as not good and are not loyal. There are health workers, especially doctors and nurses who are able to answer every question posed by the patient, the doctor is on duty so that the patient feels satisfied in receiving treatments. However, the results of data collection in the field showed there are some respondents who judge poorly about the assurance dimension because patients assume that nurses are sometimes difficult to find if patients need services. Therefore, health workers especially nurses need to pay more attention at any time if the patient needs service. The obtained p value of 0.000 proved there is a relationship between assurance and loyalty of inpatients. This is in line with the research conducted by Wandebori[11], which stated that assurance influences patients' loyalty.

With reference to the tangibility dimension that, those who assessed this dimensions as good and loyal are as many as 41 people, while the good and non-loyal are 29 people. Respondents who assessed the tangibility dimension as not good but loyal as many as 15 people, whilethose judged poor and disloyal as many as 10 respondents. This is due to the availability of complete medicines at the pharmacy, health workers are always in neat uniforms, facilities are comparable to the payment especially in general patients. Nevertheless, most of the respondents rated badly related to less clean and unattractive inpatient rooms, incomplete facilities such as air conditioner not functioning, fan was not available, and the patient complained and felt hot in the room, the X-ray instrument was not available so the patient used X-rays outside of Makassar City General Hospital. Therefore,

the hospital is supposed to be remodeling properly and completing each room accordingly with patients' needs. Moreover, since the p value= 0.901, there is no significant relationship between the dimensions of tangible with the loyalty of inpatients. The results of this study are in accordance with the research conducted by Diniaty[12] at the RSUD TengkuRafi'anKabupatenSiakwhich stated that tangibility affect patients' loyalty.

Table 4: Relationship between responsiveness dimensions and patients' loyalty

Dimension		Patients' loyalty				Total		p
		Loyal		Not loyal		n	%	
		n	%	n	%			
Responsiveness	Good	33	50.0	33	50.0	66	69.5	0.007
	Poor	23	79.3	6	20.7	29	30.5	
	Total	56	58.9	39	41.1	95	100	
Assurance	Good	56	65.9	29	34.1	85	89.5	0.000
	Poor	0	0	10	100.0	10	10.5	
	Total	56	58.9	39	41.1	95	100	
Tangibility	Good	41	58.6	29	41.4	70	73.7	0.901
	Poor	15	60.0	10	40.0	25	26.3	
	Total	56	58.9	39	41.1	95	100	

Conclusion

From the results of research conducted at Makassar City Public Hospital about the relationship between the quality of health services and the loyalty of inpatients, it can be summarized as follows:

1. There is a relationship between the dimensions of responsiveness, and assurance with the loyalty of inpatients at Makassar City Hospital.
2. There is no relationship between the dimensions of tangibility with the loyalty of inpatients at Makassar City Hospital.

Relationship of Marketing Mix with Loyalty of Patients of Dental Poly in BatuaPuskesmas, Makassar City in Year 2016

Suciana Aprilia Angraeni[1], Nurhayani[1], H. AmranRazak[1]

[1]Department of Administration & Health Policy, Faculty of Community Health, University of Hasanuddin, Makassar, Indonesia

ABSTRACT

This study aimed to determine the relationship between marketing mix and the patients' loyalty of Poly Dental in BatuaPuskesmas Makassar City using quantitative study with a cross sectional design. The total population of this study was 190 respondents which were taken using the accidental sampling method. The results showed that the variables related to the marketing mix with the loyalty of the dental polyclinic patients at BatuaPuskesmas were products (p = 0.00), place (p = 0.039), health workers (p = 0.00), process (p = 0.00), physical facilities (p = 0.00), promotions (p = 0.006). Whereas the unrelated variable was price (p = 0.076). The dental polyclinic at BatuaPuskesmas is expected to further improve the marketing mix process, although it is good enough but must continue to pay attention to the service process in terms of the time that the patient sometimes have to wait long.

Keywords: *Marketing Mix, BatuaPuskesmas, Loyalty, dental polyclinic and patients.*

Introduction

Oral and dental health is one of the supporting aspects of a healthy paradigm and is a national development strategy to realize healthy Indonesia 2010. 56.7% health centres in Indonesia have carried out community dental health business, while 86% of health centre in Indonesia have implemented the School Dental Health Business[1].

The description of the service utilization of the health centre dental polyclinic can be seen based on the number of visits by the people who get dental treatment per day. Situmorang[2]'s study showed that out of 360 respondents, it was found that only 10% had ever undergone dental treatment for health services at health centres. This indicated that high dental and oral diseases have not been matched by the utilization of health service units[3].

Marketing mix can be used as a marketing tool that makes it easier for health centres to achieve their marketing goals. Along with the times, marketing mix has also developed. This is seen from the magnitude of the influence of the direct relationship between the components in marketing mix (products, tariffs, places, promotions, people, processes, and physical facilities). Marketing mixprogram has a very important role as part of the strategy and company policy to realize customers' satisfaction which will ultimately increase consumers' loyalty[4].

In this globalization era, the social condition of society is increasing where the public is increasingly aware of the quality, it is necessary to improve the quality of satisfaction-oriented health services so that patients will feel loyal to the provision of health services. Hawkins et al.[5] researched on dental and oral hygiene measured using the Oral Hygiene Index Simplified (OHIS) showed that the average dental and oral hygiene of elementary school students in grade IV - VI in the specific district of Jakarta area was in the moderate category of 53.8% of the students who have been examined. Maharani[6]'s research results showed that 88.3% of respondents had dental and oral hygiene status in the unclean category, only 11.7% of respondents had dental hygiene status in the clean category. This problem needs to be addressed since dental and oral hygiene is a very decisive factor in the process of maintaining oral health.

The results of the research conducted by Hayati et al.[7] revealed that there is a there is no significant relation between place mix and physical proof mix with patients' loyalty, but there is significant relation between product mix, price mix, promotion mix, and process mix with patients' loyalty. Based on research done by Semboret at.[8] about marketing mixrelationship with patients' loyalty, it was concluded that there was no relationship

between the product service marketing mix and patient loyalty, whereas there was a relationship between the marketing mix of price, place, promotion, staff (people), process, physical evidence and facility services with patients' loyalty. A similar study was conducted by Riana[9] which also proved that there was a relationship between products, promotions, processes, and physical facilities with the utilization of services in the Sanrobone Health Centre dental clinic.

From the data collection at BatuaPuskesmas, an overview of patient visits per day to the dental in average was 15/day and seen from patient's visits from 2013-2015, it was known that each year the dental poly patient visits increase[10].

Based on the description above and in improving health services and the benefits obtained by the company if it has loyal customers, it is very important for the BatuaPuskesmas to have the right marketing strategy, with marketing programs that can be done to improve service quality. Therefore, to see whether marketing programs have been carried out effectively, it is necessary to conduct research to determine the relationship between marketing mix and patients' loyalty to dental polyclinic at BatuaPuskesmas.

Methodology

This research is a quantitative research in the form of a survey with cross sectional approach where the independent variables and dependent variables are examined simultaneously in the same period. The quantitative approach is done by collecting and processing data to find accurate facts and precise as well as systematic interpretations regarding the marketing mixrelationship with the loyalty of poly dental patients in BatuaPuskesmas.This research was carried out at the Dental Clinic of BatuaPuskesmas for a month from the 27th March-27th April 2017.

The populations in this study were all patients who had dental examinations at the BatuaPuskesmas. The number of patients in 2016 was 74565 patients with an average of 15 patients per day multiplied by 25 working days in dental polyclinic. Hence, there are 375 patients per month. The samples in this study were poly dental patients who were encountered during the study. The sampling procedure used the accidental sampling method, which is randomly taken by respondents or at the time of the research. Therefore, the number of samples in this study was 100 samples.

Data sources from this study were obtained from written documents/data on visits of poly dental patients at BatuaPuskesmas. The gathered data were analyzed using the SPSS program for univariate analysis and bivariate analysis. The research variable consisted of seven independent variables, the marketing mix, namely product, price, place, promotion, people, process and physical evidence, while the dependent variable was patients' loyalty.

Result and Discussion

Univariate Analysis: The distribution of respondents rating based on the product marketing mix (type of service) in BatuaPuskesmasis shown in Table 1. Based on the statement of dental poly products, 81 respondents gave answers strongly agree that the equipment used in dental poly is feasible to use. It can be concluded that the respondents who gave the most answers strongly agreed that examinations by doctors in dental poly were in accordance with the needs of patients with a percentage of 83.0%, 19.0% disagreed that the medicines needed by patients are available, while respondents who answered strongly disagreed that medicines needed by patients are provided with a total of 19 respondents. In addition, 6.0% strongly agreed that the services provided in BatuaPuskesmas covered a wide range of services. Although 4 respondents strongly disagreed that the nurses provided services in accordance to the patients' need, a majority of 84 respondents, strongly agreed with this statement.

Table 1: Distribution of respondents based on 'product' variable statements

Statements	Strongly agree	Agree	Disagree	Strongly disagree
Services in dental polyclinic in BatuaPuskesmas are diversifying.	86	6	4	4
Examination by dentists in dental polyclinic is in accordance with the patient's needs.	83	5	8	4
Nurse services in dental polyclinic are in accordance with patient needs.	84	9	3	4
The health inspection equipment used is assorted.	88	6	2	4

Conted…

Equipment used in dental poly is suitable for use.	81	9	5	5
Medications needed by patients are available.	57	12	12	19

Table 2 presented the distribution of respondents rating based on the price in BatuaPukesmas of Makassar city. Based on the statements of dental poly prices, 93 respondents gave a very agreeable answer that the details of the services cost in of the clinic was clear. While 94 respondents who strongly agreed that the payment method was easy and uncomplicated. Statement number two till number four had the same number of responses from the respondents. Majority of the respondents strongly agreed with these statements: information on examination ratesare given by the officer, affordable examination rates, and expenditures are proportional to the services.

Table 2: Distribution of respondents based on 'price' variable statements

Statements	Strongly agree	Agree	Disagree	Strongly disagree
The payment method is easy and not complicated.	94	0	5	1
Information on examination rates are given by the officer.	90	4	6	0
Affordable examination rates.	90	4	6	0
Expenditures are proportional to the services.	90	4	6	0
Cost details are clear at dental poly services.	93	0	7	0

Table 3 presented the distribution of respondents based on the people marketing mix (health workers) in the BatuaPuskesmas. Based on poly dental statements, 92 respondents (48.4%) gave answers strongly agree that doctors and dental nursesskilfully used medical devices. Whereas respondents gave the least answers for strongly agreed, was for the statement 'the doctors and nurses in the dental clinic examined patients carefully' which was voted by only 40 respondents. Among the eight statements, statement number two was highly agreed by most of the respondent with 85.0% strongly agree and only 15.0% opposed this statement.

Table 3: Distribution of respondents based on 'people' variable statements

Statements	Strongly agree	Agree	Disagree	Strongly disagree
Doctors and dental nurses are skilled at using medical devices	72	6	21	1
Service to all patients regardless of social status	85	0	5	10
Doctors and nurses examine patients carefully	40	32	20	8
Doctors and nurses pay attention to patients' complaints during examination	47	31	17	5
Doctors and nurses provide solutions to patients after being examined	46	33	15	6
Doctors and nurses provide good answers when patients ask	48	30	16	6
Doctors and nurses provide friendly and caring services	47	26	18	9
Doctors and nurses at the Batua Health Centre Dental Polyclinic look neat at work	41	31	20	8

Bivariate Analysis: Table 4 showed that of the 100 respondents who have been interviewed, it is known that 61 respondents said that on the context of 'product' it was acceptable and loyal whereas those who agreed that the 'product' was acceptable but not loyal were 11respondents (11.0%). Respondents who said the product was unacceptable but loyal, were as many as 15 respondents and those who said the 'product' was unacceptable and were not loyal as many as 13respondents. Furthermore, the results of the Chi-square test between variables obtained that there is a relationship between product and the loyalty of dental poly patients with a value of $p = 0.000$. Based on the results of the study, it can be concluded that the better the product, the more loyal the patients would be towards the health centre. This is in accordance with the research

by Husada[11] in Massenrempulu General Hospital, Kab. Enrekang which agreed that there is a relationship between product and patient loyalty in the inpatient unit, but it is different from the research conducted by Ika[12] in the outpatient polyclinic of Kediri Baptist Hospital which stated that there is no relationship between patient perceptions of products and patient loyalty.

Table 4: Relationship between products with loyalty

Product	Patients' loyalty		Total (n)	p-value
	Loyal (n)	Not loyal (n)		
Acceptable	61	11	72	0.000
Unacceptable	15	13	28	
Total	76	24	100	

The relationship between price and loyalty is presented in Table 5. Based on Table 5, it was known that respondents who said that the price was acceptable and loyal were 53 respondentswhile 24 respondents said it was acceptable but not loyal. Respondents who said the prices were unacceptable but loyal were as many as 12 respondents and those who said the prices were unacceptable and not loyal as many as 11 respondents. The results of the Chi-square test obtained a p-value of 0.076 which signified that there is no relationship between the price and loyalty of dental poly patients. This is consistent with the research conducted by Toding[13] at Elim Makassar Hospital which also proved that there is no relationship between the tariff strategy and the interest in returning inpatients. However, it was different from the research conducted by Yuliantine et al.[14] who reported that there was a relationship between rates/prices and patients' loyalty in the inpatient hospital of Muhammadiyah. In general, the consideration of a given price is generally influenced by one's work and socio-economic status. The better the person's job, the better the socio-economic status will be.

Table 5: Relationship between prices with loyalty

Price	Patients' loyalty		Total (n)	p-value
	Loyal (n)	Not loyal (n)		
Acceptable	53	24	77	0.076
Unacceptable	12	11	23	
Total	65	35	100	

Table 6 presented the relationship between people and loyalty. Based on the table, it is known that respondents who said that health workers were acceptable and loyal, were 61 respondents whereas acceptable but not loyal were 11 respondents. 15 respondents found it unacceptable yet they were loyal. Unlike the 13 respondents who said it was unacceptable and were not loyal. Chi-square test results between variables showed that there is a relationship between the people (health workers) and the loyalty of dental poly patients with a value of p = 0.000. This study is in accordance with the research by Sembor et al.[8] at Siloam Manado hospital, who reported that there was a relationship between staffs and patients' loyalty. Moreover, their study stated that among the other factors (product, price, place, promotion, process, physical evidence and facility services), staff was the most dominant factor influencing the patients' loyalty.

Table 6: Relationship between people with loyalty

People	Patients' loyalty		Total (n)	p-value
	Loyal (n)	Not loyal (n)		
Acceptable	61	11	72	0.000
Unacceptable	15	13	28	
Total	76	24	100	

Conclusion

Based on the results of the research and discussion described regarding the marketing mix with the loyalty of the dental poly patients in BatuaPuskesmas of Makassar, the following conclusions can be drawn:

1. There is a relationship between product and people with the loyalty of poly dental patients at BatuaPuskesmas, Makassar City
2. There is no relationship between price and the loyalty of poly dental patients at Batua Health Centre, Makassar City.

Relationship of Marketing Mix with Return of Outpatients' Interest at Dr.TadjuddinChalid Specialist Hospital, Makassar in 2017

YustiamkaPermana[1], H. Indar[1], Nurhayani[1]

[1]Department of Administration &Health Policy, Faculty of Community Health, University of Hasanuddin, Makassar, Indonesia

ABSTRACT

This quantitative study with a cross sectional approach aimed to determine the mix marketing relationship with interest in returning of outpatients to Dr.TadjuddinChalid Specialist Hospital, Makassar in 2017. The population was 8756 patients, taking 95 samples with non-probability sampling techniques. Data collection was done by interviewing using questionnaire. The collected data were analyzed using the Chi-square test. The results showed that there was a relationship between product (p = 0.000), price (p = 0.002), and people (p = 0.043). However, there is no relationship between place (p = 0.229) with interest in returning of outpatients. Based on the results, this study suggested some improvements to the overall supporting facilities in accordance to the patients' needs such as ATM machines, photo copy machines as well as make brochures to promote hospital services.

Keywords: *Marketing Mix, Dr.TadjuddinChalid, Specialist Hospital and Outpatients.*

Introduction

Hospital is a health service institution that organizes individual health services in a comprehensive manner that provides inpatient, outpatient and emergency services. Hospitals not only function to provide medical services but also provide nursing services and care activities, medical support services and non-medical, public health services and education[1]. In Indonesia, public hospitals are hospitals managed by the government, regional government, or non-profit legal entities whereas private hospitals are managed by a legal entity with the aim of profit in the form of a limited liability company. In 2015, 2488 hospitals in Indonesia were divided into public hospitals and private hospitals. This showed a significant increase in the previous two years, which were 2228 and 2406 respectively. In South Sulawesi alone, the increase occurred in both public hospitals and private hospitals, which was from 76 units in 2013 to 81 units in 2014[2].

Outpatient service is part of medical services that gives first impressions to patients as consumers. Outpatient services are also a place of transition for patients who come to the hospital to be hospitalized. The image of the hospital is contested herein, so that it can be said that the reputation of the hospital depends on its first service.

Dr.TadjuddinChalid Specialist Hospital Makassar City which was established in 1980 does have the outpatient services. Along with the continuous increase in number of hospitals in the province of South Sulawesi, it is crucial for Dr.TadjuddinChalid Specialist Hospital to improve the overall quality of health services. It needs to buff up the marketing strategy in making the hospital a choice among consumers. The most universal and widely developed marketing concept is the marketingmix. It is a set of marketing tools used by companies to continuously achieve marketing objectives in the targeted market.

To introduce the product or service offered, hospital needs to carry out several promotional combination alternatives which are part of the marketingmix; personal sales, advertising, word of mouth, sales promotion, public relations, and direct marketing[3]. Hospitals must be able to adjust between the marketingmix with the needs and desires of consumers, because by giving more satisfaction to consumers compared to other competitors, then it can attract more consumers. Satisfaction and dissatisfaction of consumers will influence the interest

to return. If the patient is satisfied, he/she will show a higher probability of repurchasing the product or service. Satisfied customers also tend to tell good things about the products or services they receive to others. Unsatisfied consumers act in reverse. They may take public actions, such as filing complaints against hospitals, going to lawyers, or complaining to other groups (such as business entities, the private sector, or the government). Personal actions can be in the form of deciding not to use the product or service[4].

The results of study by Setianingsih[5] showed a significant relationship between products (services) to patient loyalty with p value = 0.025. Whereas the perceptions of other marketing mixes such as location, promotion, price, people, physical evidence, and processes do not show a significant relationship in her study.Another study on marketing mix relations with loyalty among patients at Siti Khadijah Hospital Makassar City showed that there was a relationship of promotion with patient loyalty with a value of p = 0.008, there was a relationship between physical facilities and patient loyalty with a value of p = 0.000,there was a relationship between the process and patient loyalty with a value of p = 0.000. However, there was no relationship between service providers and patient loyalty with a value of p = 0.078. Thus, it can be concluded that there is a relationship between promotion, physical facilities, and processes with patients' loyalty[6].

In order to improve health services and maintain a number of visits, a better marketing strategy is needed which will later influence the decisions of patients in using hospital services. Therefore, the researchers of this study are interested in researching "relationship of marketing mix with return of outpatients' interest at Dr.TadjuddinChalid Specialist Hospital, Makassar" for the year of 2017.

Methodology

The type of research used is quantitative research which is an observational analytic with cross sectional approach. It is meant to know the relationship between marketing mix relations with returns of outpatients' at Dr. TadjuddinChalid Specialist Hospital Makassar City. The research was conducted at Dr. TadjuddinChalid Specialist Hospital's outpatient services from February 2017 to March 2017.

The population in this study was patients from 13 polyclinics that seek outpatient treatment at Dr. TadjuddinChalid Specialist Hospital with yearly average of 8756 patients. The sampling technique used in this study was carried out by non-probability sampling, namely the technique of incidental sampling whereby the sample coincidently exists at the time of the research and meets the criteria for research sample. The respondents of this research are those who qualified as follows:

a. Respondents are patients who have more than two visits.

b. Respondents are able to understand the questions contained in the questionnaire and answer the question itself whereas for respondents who have difficulty completing the questionnaire, they can be assisted by his/her family.

Based on this given criteria, the total number of samples accepted from the population was 95 respondents.

The primary data are obtained through a list of questions (questionnaires) that have been prepared previously and distributed to respondents. Meanwhile, the secondary data are obtained from document collection such as annual report and profile of Dr. TadjuddinChalid Specialist Hospital, and other sources related to research. The data collected from questionnaires are tabulated in a master table and analyzed using SPSS program which consisted of univariate and bivariate analysis.

Result and Discussion

Univariate Analysis: Table 1 presented the distribution of respondents' evaluation based on product (type of service), price, place and people (staffs) provided to outpatients by Dr. TadjuddinChalid Specialist Hospital Makassar City.

The respondents' assessment of products(type of services) can be measured through five elements consisting of a variety of health equipment used, completeness of health equipment, services provided by health workers according to patient needs, availability of medicines and availability of supporting services such as laboratories, radiology etc. Based on Table 1, it was shown that 89 respondents (93.7%) felt that the products available are quite good whereas 6 respondents (6.3%) showed disagreement.

The respondent's assessment on price of outpatient services provided is measured based on whether the service rates are affordable or the service rates are in line with the services received by respondents. Under price category,out of 95 respondents, there were 91 respondents (95.8%) who assessed the price charged for outpatient services was quite reasonable while 4 respondents (4.2%) felt that the price is not worth comparing to the available services.

Factors such as location easily accessible through personal or public transportation distance of residence close to the hospital location and easy to find a basic amenity influences the respondent's assessment to seek for outpatient services. As shown in Table 1, 54 respondents (56.8%) agreed that Dr. TadjuddinChalid Specialist Hospital is easily reachable while total of 41 respondents (43.2%) faced difficulty to reach the hospital.

Assessment from respondents' of health workers in the outpatient facility are measured based on good communication between patient and doctor, clean and neat appearance, polite and friendly health workers, highly skilled in using medical devices and keen to hear patients complaints. 93 respondents (97.9%) rated satisfactory in outpatient services found in Dr.TadjuddinChalid Specialist Hospital Makassar City. In contrast, only 2 respondents (2.1%) felt dissatisfied.

Table 1: Distribution of respondents' evaluation based on product (type of service), price, place and people (staffs) provided to outpatients by Dr. TadjuddinChalid Specialist Hospital Makassar City

Category		Frequency (n)	Percentage (%)
Product (type of service)	Good	89	93.7
	Poor	6	6.3
Price	Reasonable	91	95.8
	Unreasonable	4	4.2
Place	Reachable	54	56.8
	Not reachable	41	43.2
Staffs	Good	93	97.9
	Poor	2	2.1

Bivariate Analysis: The results of the bivariate analysis between the relationships of product, price, place and people (staffs)with outpatients' interest to return at Dr. TadjuddinChalid Specialist Hospital Makassar City are tabulated as in Table 2.

It shows that of all respondents who rated the product (type of service) as good, there were 75 respondents (84.3%) expressed interest and as many as 14 respondents (15.7%) expressed no interest. Respondents are not interested in returning to use the service because it is influenced by other factors such as distance from the patient's home to the hospital. While respondents who stated that the product (type of service) was not good, 0 respondents expressed interest to return and as many as 6 respondents expressed no interest to return. This is because the medicines needed by patients are sometimes not available and needs to be purchased outside the hospital.If the respondent's assessment is not good for the product/type of service, the respondent will feel dissatisfied. Dissatisfaction of respondents can cause respondents to move to other hospitals. The results of statistical tests using the Chi-square test show that there is a relationship between the product and the interest in returning outpatients where the value of p = 0.000.This is in line with the research conducted by Hidayat[7], that product influenced the service utilization decisions in Hasanuddin University Hospital Makassar in 2014 where the value of p = 0.006. Whereas, Akbar et al.[8] suggested that the product is related to the patient's decision to choose health services. The better the products of the hospital, more patients will choose health services at that particular hospital.

In terms of price, it shows that from all respondents who rated the price (service tariff) as reasonable, 75 people (82.4%) expressed interest to return while 16 people (17.6%) did not want to seek treatment again at this hospital. This could be due to lack of basic amenities surrounding the hospital. There were 4 people (100.0%) who felt the price is unreasonable and has no interest to return. This is due to the overall service rates charged by the hospital is not in accordance with the obtained services. The results of the analysis of the price (service

tariff) relationship with the return interest of patients who use outpatient services at Dr. TadjuddinChalid Specialist Hospital in Makassar using Chi-squared statistical tests obtained p = 0.002 which means that there is a relationship between price (service rates) and return interest in patients. The results of this study are in agreement with the research conducted by Syafar et al.[9] who stated that there was a relationship between price and the interests of returning patients to Hospital of Hasanuddin University. Nonetheless, the results of this study are not in line with the research conducted by Setianingsih[5] which stated that there is no relationship between the price and the interest in returning of outpatients in Dr. Sitanala Tangerang Hospital.

An overview of the results of the bivariate analysis between the relationship of place and interest in returning outpatients is shown that the total respondents that agreed the location of hospital are easy to reach and interested to return are 45 respondents (83.3%) while 9 respondents (16.7%) felt the otherwise. This shows that the location of the hospital is quite strategic and easy to reach. This is in accordance with the theory by Steiber and Boscari in Hidayat[7] whereby important reason for choosing the hospital is the location. Respondents who stated that the place (service location) is not as good but expressed their interest to seek again treatment as many as 30 people (73.2%) whereas 11 respondents (26.8%) expressed no interest to return. This demonstrated that even though respondents rated the place is difficult to reach, they are still interested in using again the outpatient services due to hospital staff being friendly and good at providing patients with explanations of the disease. From the table also obtained p = 0.229. This concludes that there is no relationship between the place and the interest in returning outpatients at Dr.TadjuddinChalid Specialist Hospital in Makassar. The result is accordance to research by Akbar et al.[8] who showed that there is no significant connection between place and the decision to choose health services.

Based on Table 2, it shows that all respondents that rated people (health workers) as good, 75 respondents (80.6%) expressed interest to return again and 18 respondents (19.4%) expressed no interest. While respondents who stated people (health workers) were not good and have no interest to return as outpatients, are 2 respondents (100.0%). The results of the analysis of the people (health workers) relationship with the return interest of patients who used outpatient services at Dr.TadjuddinChalid Specialist Hospital in Makassar using Chi-squared statistical tests obtained p = 0.043. This means that there is a relationship between people (health workers) and return interest in patients. This research is in line with the research conducted by Indar et al.[10] that there is a relationship between people and the decision to choose health services at Faisal Makassar Islamic Hospital. Widajat[11] suggested that attitude of health workers when serving patients also plays vital role in influencing patient's decision to return again.

Table 2: Relationship between productprice, place, and people (staffs)with outpatient's interest to return

Category		Outpatients' interest to return				Total		p
		Interested		Not Interested		n	%	
		n	%	n	%			
Product	Good	75	84.3	14	15.7	89	93.7	0.000
	Poor	0	0	6	100	6	6.3	
	Total	75	78.9	20	21.1	95	100	
Price	Reasonable	75	82.4	16	17.6	91	95.8	0.002
	Unreasonable	0	0	4	100	4	4.2	
	Total	75	78.9	20	21.1	95	100	
Place	Reachable	45	83.3	9	16.7	54	56.8	0.229
	Not Reachable	30	73.2	11	26.8	41	43.2	
	Total	75	78.9	20	21.1	95	100	
People	Good	75	80.6	18	19.4	93	97.9	0.043
	Poor	0	0	2	100	2	2.1	
	Total	75	78.9	20	21.1	95	100	

Conclusion

From the results of research conducted at Dr. TadjuddinChalid Specialist Hospital Makassar City about the relationship between the mix marketing and outpatients' interest to return, it can be summarized as follows:

1. There is a relationship between the product (type of service), price, and people with the interest in returning outpatients.
2. There is no relationship between the place with the interest in returning outpatients.

Acknowledgement

The authors are thankful to Faculty of Community Health, Hasanuddin University for their support and facilities in conducting this study. The authors would also like to express their gratitude towards all the respondents (patients) from Dr. TadjuddinChalid Specialist Hospital who was willing to participate in this study.

The Factors Related to Work Fatigue of Block Paving Workers at CV. SumberGalian in 2017

Putri Yanti[1], Andi Wahyuni[1], Awaluddin[1]

[1]Department of Work Safety and Health, Faculty of Community Health, University of Hasanuddin, Makassar, Indonesia

ABSTRACT

Block paving workers play an important role in CV. SumberGalian with various tasks that require moderate to high work activities and they have to make as many as 600 blocks per day. This can cause workers to experience fatigue easily. Thus, this observational analytic with cross sectional approach research, aimed to determine the relationship of work stress, energy intake, work period and haemoglobin level with work fatigue in block paving workers in CV. SumberGalian, Makassar City in 2017. The total number of samples was 40 people, taken by exhaustive technique sampling. Data were taken from respondents using the Reaction Timer questionnaire to measure the work fatigue and Nutri Survey and food recall to obtain energy intake data. The data are then analysed using Chi-square test and logistic regression. The results showed that there was a relationship between work stress p = 0.002, energy intake p = 0.005, work period p= 0.028 with work fatigue among block paving workers at CV. SumberGalian. The most influential variable in this study was work stress.

Keywords: *SumberGalian, Block paving workers, CV and Work Fatigue.*

Introduction

Work exhaustion is a phenomenon that is often experienced by workers, but this cannot be ignored because it relates to the protection of labors' health. It is stated that of 80% of human errors, 50% are caused by work fatigue[1].Work exhaustion has been estimated to be a key factor as much as 41% of causes in various incidents of injuries, accidents and deaths[2].

According to research conducted by Ricci et al.[3] in America, there were 38% of workers experiencing fatigue related problems in work capacity. Fatigue problems arise due to low energy levels and insufficient sleep. 10% of workers reported unproductive time to reduce performance and disrupt their concentration. The results of study conducted by O'Neill et al.[4] on Queensland construction projects showed that when fatigue increased among workers, productivity decreased. This is confirmed through correlation analysis, which disclosed that fatigue has a relationship with the level of productivity. It was also found through productivity analysis that the average cost due to fatigue caused a decrease in the production rate of $ 50,000 per year.

From the data of research conducted by Putra et al.[5], it can be seen that work fatigue experienced by reinforcement production workers is in light work fatigue of 14 people (58.3%) and moderate work fatigue of 10 people (41.7%). According to the results of research conducted by Jacobs et al.[6], it showed that there is a significant relationship between work stress and work fatigue, where respondents who experienced work stress have a 5 times greater chance of getting work fatigue. Research by Tasmi et al.[7] obtained a relationship between energy intake and work fatigue. Based on these studies, the category of mild fatigue was found in the appropriate energy intake of 7 workers (11.5%) and in energy intake as inappropriate categories as many as 11 people (18.0%). Meanwhile, work fatigue in the tired category was found in the energy intake of the non-tired category as many as 31 people (50.8%). Meanwhile, heavy work fatigue category was found in inappropriate energy intake as many as 12 people (19.7%). In a study conducted by Pasira[8], there was a relationship between years of work and work fatigue among tofu factory workers. The results of the study showed that all 18 workers with long working years experienced fatigue. Workers with a short working period also experienced

fatigue as many as 12 workers (75.0%). Another factor associated with work fatigue is haemoglobin, Hb level. Lack of Hb can cause a lack of oxygen (O_2) channelled to cells of the body and brain, eventually causing symptoms of fatigue, lethargy and fatigue which results in employees being able to reduce work productivity[9].

Based on the description above, the authors are interested in conducting research on factors related to work fatigue in workers in the block paving production unit of CV SumberGalianBiringkanayasub-district, Makassar for the year 2017.

Methodology

The type of research used, was observational analytic research with a cross sectional study approach. The aim was to observe the relationship of the independent variables to the dependent variable, namely work period, work stress, energy intake and haemoglobin level among workers in the block paving production unit of CV. SumberGalian Makassar. This research was conducted in February 2017 at CV. SumberGalianJalanPerintisKemerdekaan km 18, Biringkanaya District, Makassar City.

The population in this study is all labour force in the block paving block production unit of CV. SumberGalian with as many as 40 people. The number of samples to be examined is taken using the exhaustive sampling method, which is based on a relatively small population of 40 people, and then the entire population is sampled in this study (total sample). Data and information are obtained by direct interviews using questionnaires distributed to respondents to find out data on work stress, energy intake, and work period. Furthermore, work fatigue measurements were carried out using a reaction timer for the 40 respondents. The collected data were analysed for univariate analysis, bivariate analysis and multivariate analysis and the findings were tabulated in table form.

Result and Discussion

Univariate Analysis: Table 1 presented the distribution of respondents according to job stress, energy intake, working period, haemoglobin level and work fatigue.

Job stress is grouped into 2 categories, namely low stress if total stress level ≤ 90 and high stress if the total score is > 90. Table 1 showed that from 40 respondents, the number of respondents with low work stress is 18 people or 45% and high stress is 22 people or 55%.

Energy intake is grouped into two categories, which are insufficient if<the total energy needed and sufficient if ≥the total energy needed. Table 1 revealed that from the 40 number of respondents, the number of respondents with not fulfilling energy intake was as many as 23 people and the number of respondents with energy intake that is sufficient was as many as 17 people.

The working period is grouped into short which is working period is <3 years and long if the years are ≥ 3 years. Table 1 showed that from the 40 respondents, it can be seen that the percentage of respondents with a short term of work as many as 47.5% and the number of respondents with long working period was 52.5%.

The work fatigue measured in this study is physical fatigue experienced by respondents using the reaction timer tool. Fatigue of work in this study is divided into 2 categories, namely experiencing fatigue if the reaction time is> 240 milliseconds and not experiencing fatigue if the reaction time is ≤ 240 milliseconds. The data in Table 1revealed that from 40 respondents, it was known that respondents who experienced fatigue were 22 people or 55% whereas the remaining 45% did not experience fatigue.

Table 1: Distribution of respondents according to job stress, energy intake, working period, and work fatigue

Category		Frequency	
		n	Percentage (%)
Job stress	Low (≤ 90)	18	45.0
	High (> 90)	22	55.0
Energy intake	Insufficient	23	57.5
	Sufficient	17	42.5
Working period	Short (< 3 years)	19	47.5
	Long (≥ 3 years)	21	52.5
Work fatigue	Experienced fatigue	22	55.0
	No fatigue experienced	18	45.0

The following in Table 2 is the measurement result of subjective feelings of fatigue after work based on the questionnaire. Based on the data in Table 2, it was found that out of 40 respondents, the feeling of fatigue that is often experienced by the workers are difficulty

in thinking with 55.0%, 16 people or 40% tired of talking, 9 people or 22.5% feeling nervous, 28 people or 70.0% having difficulty concentrating, 30 people or 75% having difficulty in focusing attention, 31 people or 77.5% often feeling forgetful, 23 people or 57.5% lack of self-conscious, 21 people or 52.5% feeling anxious, 21 people or 52.5% difficult to control attitude, 33 people or 82.5% feel lazy, 33 people or 82.5% feel headaches, 37 people or 92.5% suffering from stiff shoulders, 40 people experienced back pain, 27 people or 67.5% feel suffocated, 40 people feel dehydrated, 28 people or 70% feel hoarse and 36 people or 90% tremble.

Table 2: Distribution of respondents according to fatigue feeling

Fatigue feeling	Frequency	
	n	Percentage (%)
Thinking difficulties	22	55.0
Tired of talking	16	40.0
Nervous	9	22.5
Concentrating difficulties	28	70.0
Attention focusing difficulties	30	75.0
Often forget	31	77.5
Lack of self-conscious	23	57.5
Anxious	21	52.5
Attitude controlling difficulties	21	52.5
Laziness	33	82.5
Headaches	33	82.5
Stiff shoulders	37	92.5
Back pain	40	100.0
Suffocated	27	67.5
Dehydrated	40	100.0
Hoarse	28	70.0
Tremble	36	90.0

Bivariate Analysis: Based on the research that has been done, the data obtained regarding the relationship of work stress with work fatigue is presented in Table 3. Table 3 showed that the percentage of respondents who experienced more fatigue were workers with high work stress categories as many as 17 workers or 77.3% compared to low work stress as many as 5 workers or 27.8%. Whereas in the percentage of respondents who did not experience fatigue with low occupational stress categories as many as 13 workers or 72.2% compared to high work stress as many as 5 workers or 22.7%. Data analysis using Chi-square test obtained a value of p = 0.002 which can be interpreted that there is a relationship between work stress and the occurrence of work fatigue among block paving workers.

The following results of cross tabulation between energy intake and work fatigue showed that the percentage of respondents who experienced fatigue were workers with insufficient energy intake category as many as 17 workers or 73.9% compared to those with sufficient energy intake as many as 5 workers or 29.4%. While the percentage of respondents who did not experience fatigue were workers with sufficient energy intake category as many as 12 workers or 70.6% compared to the lack of energy intake as many as 6 workers or 26.1%. Based on data analysis using the Chi-square test, the value of p = 0.005 proved that there is a relationship between energy intake and the occurrence of fatigue in block paving workers.

With reference to Table 3, the percentage of respondents who experienced fatigue with a long working period was 15 workers compared to 7 new workers. Whereas the percentage of respondents who did not experience fatigue among workers with a short service period was 12 workers compared to the long working period of 6 workers. Based on data analysis using the Chi-square test, the value of p = 0.028 meant that there is a relationship between years of work and the occurrence of work fatigue.

Table 3: Relationship between job stress and fatigue

Category		Fatigue categories				Total		p value
		Experienced fatigue		No fatigue experienced		n	%	
		n	%	n	%			
Job stress	High	17	77.3	5	22.7	22	55.0	0.002
	Low	5	27.8	13	72.2	18	45.0	
Energy intake	Insufficient	17	73.9	6	26.1	23	57.5	0.005
	Sufficient	5	29.4	12	70.6	17	42.5	
Working period	Long	15	71.4	6	28.6	21	52.5	0.028
	Short	7	36.8	12	63.2	19	47.5	

Multivariate Analysis: The results of the Chi-square analysis of the 4 independent variables were examined in this study consisted of job stress, energy intake, and work period. From the four variables studied, the results showed that work stress variables, energy intake, and years of work were related to work fatigue among the workers. The results of logistic regression tests between independent variables and dependent variables can be seen in Table 4. Table 4 showed that the lowest p value is in the job stress variable with p = 0.025 and Wald value = 5.040, Exp (B) = 0.102. Since the value of p<0.05, it can be concluded that the most influential variable on work fatigue among block paving workers in CV. SumberGalian for the year 2017 is job stress.

Table 4: Regression of Fatigue among Block Paving Workers in CV. Galian Source for year 2017

Variable	Wald	p-value	Exp (B)
Job stress	5.040	0.025	0.102
Working period	4.502	0.034	0.070
Energy intake	3.527	0.060	9.895
Constant	3.266	0.071	20.374

Discussion

In this study, there are differences from the results of measurements using questionnaires and reaction timer measuring instruments. Based on the results of the questionnaire from 40 respondents, they stated that they experienced signs of fatigue whereas based on the reaction timer results, it was found that only 22 workers experienced physical fatigue. This is due to the measurement using the questionnaire is only subjective about what is felt by the workers while the measurement using the reaction timer is more of a measurement of physical fatigue with an approach to test the accuracy and speed of completing work.

The respondents who experienced fatigue were more compared to those who were not tired due to job stress factors, energy intake, and working period. The job stress experienced by block paving workers in this study was higher stress compared to those who with mild/low stress. Thus, these workers experienced fatigue faster. This is in line with the theory of Mehta[10] which stated that in reality stress is present in every individual and is part of life. There is no life free from stress. According to the DepKes[11],one of the clinical manifestations of job stress is work fatigue.

In this study due to insufficient energy intake status in block paving workers, there was an imbalance between the energy needed and the total energy intake which had an effect on the efficiency and productivity of these workers. Therefore, it was easier for these workers to experience fatigue. This is in line with Gavhed[12], theory whereby energy intake is needed by the workforce to maintain the body's condition to always be energetic. Lack of energy intake results in health problems and work productivity. The level of energy intake, especially for heavy workers is a determinant of the degree of work productivity. Heavy workers, if not balanced with sufficient energy intake, usually will speed up the fatigue process.

Furthermore, in this study the long working period of respondents, had created the boredom feeling due to monotonous work. Hence, this affects the level of fatigue experienced by many of the veterans block paving workers. This is justified by Sadeghniiat-Haghighi et al.[13] study that the long working period carried out monotonously and continuously can lead to feelings of fatigue and ones' work experience will affect the level of work fatigue. Syavina et al.[14] stated that the duration of work is one of the factors included in the component of occupational health science. Physical work carried out continuously for a long period will affect the mechanism in the body (circulatory, digestive, muscle, nerve, and respiratory systems). In this situation, fatigue occurred due to the accumulation of residual products in the muscles and blood circulation where the remaining products are limiting the continuity of muscle activity.

Conclusion

Based on the results of research and analysis of the variables studied about factors related to work fatigue in paving block workers in CV. SumberGalian, Biringkanaya District, Makassar City In 2017, the conclusions can be drawn are as follow:

1. There is a relationship between job stress, energy intake and working period with work fatigue in block paving workers in CV. Source of GalingBiringkanaya District, Makassar City, 2017.
2. The most influential factor on work fatigue in block paving workers in CV. SumberGalian, Biringkanaya District, Makassar City, 2017 is job stress factor.

Factors toward Diabetes Mellitus Type II Occurrence among Patients in Tenriawaru Hospital, Bone Regency 2014

Jumriani Ansar[1], Indra Dwinata[1], Hardiana[1]

[1]Faculty of Public Health, Hasanuddin University, Makassar, Indonesia

ABSTRACT

Diabetes mellitus among patients in Tenriawaru Hospital tend to increase from year 2009 until 2012. In 2009, patient numbers were 104 patients and increased to 166 patients in 2012. This study aimed to determine the risk of age, obesity, gender and hypertension on the diabetes mellitus (DM) type II among patients in Tenriawaru Hospital, Bone regency. The study had been used simple random sampling with cross sectional design. The study population were all patients had undergone treatment in inpatients ward at Tenriawaru Hospital, Bone regency. The sample sizes were 192 patients who met the inclusion criteria. The result showed that there was correlations between gender (p=0.000), age (p=0.001), hypertension (p=0.020) and obesity (p=0.000) with DM type II occurrence in patients at Tenriawaru Hospital. The recommendation that need early detection for DM diseases, prioritized non-pharmacological treatments such as diet changes, exercise regularly and healthy lifestyle habit. Meanwhile, the hospital management should provide medical nutrition consultation services for DM patients.

Keywords: *Diabetes mellitus, age, obesity, hypertension, gender*

Introduction

Diabetes mellitus (DM) is one health problem that tends to increase from year to year. DM also known as diabetic or blood sugar disease. An estimated 171 million people suffering diabetes globally in 2000 and increased to more than 366 million in 2011.[1] In 2017, approximately 425 million people aged between 20 years and 70 years were suffered DM and expected increased to 629 million by 2045.[2]

Diabetes mellitus (DM) is characterized by chronic hyperglycaemia and impaired carbohydrates, lipids and proteins metabolism due to partial or complete insufficiency of insulin secretion and/or insulin action.[2,3] DM type I was caused by absolute deficiency in insulin due to secretion failure by the pancreas, while DM type II is characterized by insulin resistance and relative insulin deficiency, either or both of which may be present at time diabetes is diagnosed.[4] DM type II is most common of DM which involved between 90% and 95% of all diabetic patients[3]. Besides, DM type II is caused by cardiovascular disease (CVD), blindness, renal failure and amputations with tremendous impact on health expenditure.[5] Furthermore, DM type II also caused by advanced age, obesity, family history of DM, smoking habit, alcohol consumption, lack of physical activity, poor nutrition during pregnancy, ethnicity and household income.[6] Meanwhile, stroke risk is increased by 150% to 400% while risk of stroke related to dementia is increased by more than 3 fold for DM type II patients.[6]

In 2007, Basic Health Research (Riskesdas) showed that DM prevalence was 5.7% while DM risk factors included disturbed glucose tolerance prevalence of 10.2%. The DM prevalence increased due to obesity, hyperglycaemia, hyper cholesterol, lack of physical activity, lack of fibre consumption, smoking habit and genetic factors.

In Indonesia, one province had experienced increment in DM type II cases was South Sulawesi province. Based on Health Service of South Sulawesi province, non-communicable diseases found DM (6.65%) in 2008. In 2009, DM was found 4.99% and increased to 14.24% with highest number of mortality was equal to 41.56%. Meanwhile, DM cases were 29.38% with mortality of 13.4% in 2011 and DM increased to 27.64% in 2012.

In Tenriawaru Hospital, DM was found increased from year 2009 to 2013. In 2009, DM patients were

104 patients and increased to 166 patients by 2012. Based on DM prevalence trends in various regions, thus understanding of future DM with its complications which caused morbidity and mortality in Indonesia. This study aimed to determine the risk of age, obesity, gender and hypertension on the diabetes mellitus (DM) type II among patients in Tenriawaru Hospital, Bone regency.

Methodology

The study was used observational with cross section approach which observed the relationship between risk factors for disease occurrence or certain health status at same times. The study was conducted at medical record room of Tenriawaru, Bone Regency which reference from public health centres (Puskesmas) or doctors visited by the community especially the Bone regency residence. The study was conducted in February 2016.

The study population were all patients who had undergone treatment in Tenriawaru Hospital, Bone regency. The sampling was selected using simple random sampling who met the inclusion criteria. The sample sizes were 192 patients. The data was collected through secondary data. The secondary data was obtained by collected and recorded from medical record or DM type II patients status books. The data was analysed with SPSS computer program. The data was represented in table form and narration.

Result and Discussion

In Table 1, 106 respondents were categorized as non-obese and 86 respondents (44.8%) were categorized as obesity.

Table 1: Respondent distribution based on body mass index (BMI) criteria in Tenriawaru Hospital, Bone regency 2014

BMI criteria	Frequency (n)	Percentage (%)
Non obesity	106	55.2
Obesity	86	44.8
Total	192	100.0

In Table 2, there were 135 respondents (70.3%) suffered hypertension and 57 respondents (29.7%) were non-hypertension patients.

Table 2: Respondent distributions based on hypertension in Tenriawaru Hospital, Bone regency 2014

Hypertension status	Frequency (n)	Percentage (%)
Hypertension	135	70.3
Non-hypertension	57	29.7
Total	192	100.0

In Table 3, there were 94 female respondents (69.1%) suffered DM type II and 42 female respondents were non- DM type II patients. In additions, 18 male respondents (32.1%) were suffered DM type II and 38 male respondents (67.9%) were non-DM type II. The result showed there was relationship between gender and DM type II occurrence in Tenriawaru Hospital.

Table 3: Relationship between gender and DM type II in Tenriawaru Hospital, Bone regency 2014

Gender	DM type II status						p-value
	Yes		No		Total		
	n	%	n	%	n	%	
Female	94	69.1	42	30.9	136	100.0	0.000
Male	18	32.1	38	67.9	56	100.0	

In Table 4, 93 respondents (65.5%) were aged below than 45 years old and 19 respondents (38%) were aged more than 45 years old with DM type II. Meanwhile, 49 respondents (34.5%) were aged more than 45 years old and 31 respondents who aged more than 45 years old did not suffered DM type II. The statistical test showed there was relationship between gender and DM type II occurrence in Tenriawaru Hospital.

Table 4: Relationship between age and DM type II in Tenriawaru Hospital, Bone regency 2014

Age (years)	DM type II status						p-value
	Yes		No		Total		
	n	%	n	%	n	%	
≤45	93	65.5	49	34.5	142	100.0	0.001
>45	19	38.0	31	62.0	50	100.0	

Meanwhile, 50 respondents were obesity and 62 respondents (55.5%) were categorized as non-obesity with suffered DM type II as shown in Table 5. Besides, 56 respondents (55.2%) were obesity and 24 respondents (44.9%) were non-obesity which did not suffered DM type II. The statistical test showed there was relationship between BMI status and DM type II occurrence in Tenriawaru Hospital.

Table 5: Relationship between BMI status and DM type II occurrence in Tenriawaru Hospital, Bone regency 2014

BMI status	DM type II status						p-value
	Yes		No		Total		
	n	%	n	%	n	%	
Obesity	50	44.8	56	55.2	142	100.0	0.001
Non-obesity	62	55.1	24	44.9	50	100.0	

In Table 6, 86 respondents (63.7%) were hypertension and 26 respondents (45.6%) were non-hypertension with suffered DM type II. Meanwhile, 49 respondents (36.3%) were hypertension and 31 respondents (54.4%) were non-hypertension with non-DM type II. The result also showed that a relationship between hypertension and DM type II in Tenriawaru Hospital.

Table 6: Relationship between hypertension status and DM type II in Tenriawaru Hospital, Bone regency 2014

Hypertension status	DM type II status						p-value
	Yes		No		Total		
	n	%	n	%	n	%	
Hypertension	86	63.7	49	36.3	135	100.0	0.001

Discussion

In this study, the result found correlation between age and DM type II occurrence in Tenriawaru Hospital. The age is one of the factors associated with DM type II. DM was found increment cases in developing countries which most DM patients were aged between 45 years and 64 years.[7] In aging period, the cell production was decline lead to changes in beta cell morphology. Besides, DM in older adults dude to decrease in tissue function as changes in tissue itself.

Obesity is defined as abnormal or excessive fat accumulation that affect health with BMI≥30 kg/m^2.[8,9] The result also indicated that obesity was one of factor correlated with DM type II in Tenriawaru Hospital. This study found that there were 86 patients (44.8%) with low risk while there were 106 patients (55.2%) with high risk. Obesity also related with excess body fat which greatly increased risk for insulin resistance.[10] The insulin resistance contributed to increase glucose production in the liver and decrease glucose uptake in muscle and adipose tissue at set insulin level.[11] In Turkey, obesity was correlated with age (highest prevalence in adult aged between 50 years and 69 years old), female gender, hypertension, hyperlipidaemia, diabetes, parity, smoking habit, alcohol consumption, marital status (married and widowed), occupation (housewife, tradesman, officers and retied), household income, family history of obesity, diabetes and hypertension and lack of physical activity in Turkish adults.[12]

In additions, the result indicated that gender also one of factor correlated with DM type II occurrence in Tenriawaru Hospital. The obesity among factor caused DM type II in women. In global, the prevalence in male and female is very similar but men had higher incidence than women based on obesity occurrence in DM type II risk factor.[13] Meanwhile, a study found European male were usually diagnosed with diabetes at an earlier age with lower BMI than women.[14]

In this study, the result found correlation between hypertension and DM type II occurrence in Tenriawaru Hospital. There were 63.7% respondents were suffered DM while 36.3% respondents found did not suffered DM. Hypertension was two to three times more frequent in diabetic patients.[15] The pre-hypertensive state is categorized once systolic blood pressure between 120 and 138 mmHg and/or diastolic blood pressure between 80 and 89 mmHg.[16] Hypertension and DM type II were two conditions that closely related. Around 30%-60% of DM patients had history of hypertension.

Conclusion

In conclusion, the study found relationship between age, gender, obesity and hypertension with DM type II in Tenriawaru Hospital. The recommendation are high risk group should maintain healthy lifestyle and food consumption. Besides, the women is suggested to maintain their body weight and perform exercise to prevent the obesity which can contributes to DM.

Mapping of Dengue Fever Incidence in Majjene Province, West Sulawesi 2016

Jufri[1], Agus Bintara Birawida[1], Fajaruddin Natsir[1]

[1]Faculty of Public Health, Hasanuddin University, Makassar, Indonesia

ABSTRACT

Majene province is an endemic area of dengue haemorrhagic fever. Several factors played a role in changes of dengue haemorrhagic fever cases were rainfall, population density and vector density of dengue haemorrhagic fever in term of larva-free numbers. This study aimed to describe the dengue haemorrhagic fever patients distribution in Majene district, West Sulawesi province. The study had been used observational with descriptive design. The study population was all positive dengue haemorrhagic fever patients recorded in Maejn Health Office report in 2016. The study samples were 199 positive patients. The data was analysed with SPSS program and ArcGis. The result indicated that spatial trend pattern in dengue haemorrhagic fever cases tend to concentrate in one area such as coastal areas especially urban areas which had high rainfall of 100-200 mm. In area with high rainfall also had very dense population that contributed transmission rapid spread. Besides, larvae free number did not meet the requirement issued by Ministry of Health which was> 95%. The dengue haemorrhagic fever program should be prioritized in areas with high rainfall and dense population. In additions, the larvae free program achievement will be further enhanced by increase budget and improved as cross program.

Keywords: *Dengue haemorrhagic fever, larvae free, dense population, rainfall*

Introduction

Dengue virus infection is worldwide health threat affecting at least 3.6 billion people living in more than 125 tropics or subtropics countries.[1,2] An approximately 50-100 million dengue fever and 200,000-500,000 dengue haemorrhagic fever (DHF) caused 24,000 mortality annually.[3,4]

World Health Organization (WHO) declared dengue and dengue haemorrhagic fever to be endemic in the Asian sub-continents.[3] Dengue virus is belonging to the genus Flavivirus (group B arbovirus, RNA virus) and includes structural and non-structural proteins.[5] There are four distinct serotypes such as DENV-1, DENV-2, DENV-3 and DENV-4 which transmitted to human through Aedes aegypti and Aedes albopictus mosquitoes.[6]

Aedes (Stegomyia) aegypti is the main vector global and found in urban environment and Aedes (Stegomyia) albopictus was considered secondary importance in transmission expect in Asian countries which present in rural or semi-urban habitats.[7] DHF is characterized by sudden onset of fever, thrombocytopenia and vascular leak syndrome and affected children under 15 years.[8] DHF can be correlated with poor outcomes depending on the facilities availabilities for patient management.[2]

DHF is one important public health problem in Indonesia. The mosquitoes transmission (vectors) of DHF are Aedes aegypti, Aedes albopictus and Aedes scutellaris. The existence of vectors (larvae of Aedes aegypti) in the area indicated presence of Aedes aegypti mosquitoes population in that area.

DHF vector density level can be observe through larvae surveillance. The larvae surveillance was carried out with calculation were obtained to find out the larvae index included larvae free number, house index, container index and breteau index. All regions in Indonesia are in risk of contracting dengue diseases. DHF is influenced by environmental conditions, population mobility, population density, presence of artificial and natural containers in landfills (TPA) and other garbage places.

High population density increases dengue infection since flying distance of mosquitoes is estimated at 50 meters. Besides, temperature and humidity are also among environmental conditions that affects development of Aedes aegypti.

In Majene district, dengue haemorrhagic fever incidence found increased annually. In 2015, there were 16 DHF patients who treated and increased to 199 DHF cases and four mortality cases were recorded. Meanwhile, Majene regency had DHF cases and outbreaks due to surge in cases and mortality. This study had represented in map form. Map can illustrate dengue haemorrhagic fever distribution that occurred in 2016 based on environmental factors such as climate change, population density and larvae free percentage. This study aimed to describe the dengue haemorrhagic fever patients distribution in Majene district, West Sulawesi province.

Methodology

The study was used observational study with descriptive research design to determine dengue haemorrhagic fever distribution by observe with population density and climate change and larval density based on Geographic Information Systems (GIS). The study location was conducted in Majene district, West Sulawesi province between February and April 2017. This district was selected due to this region was endemic to dengue haemorrhagic fever and included in outbreak area in 2016.

The population were 119 dengue haemorrhagic fever positive patients recorded in Majen health Office report. The samples were 199 positive patients in 2016. The primary data was obtained by conducted direct case survey, observed patient coordinates used GPS. The patients who moved to domicile was still taken coordinates at residence place on positive dengue haemorrhagic fever detection.

The secondary data were obtained from dengue haemorrhagic fever data from relevant agencies such as Majene District Health Office. Meanwhile, climate variation in form of monthly report at Majene Meteorology Station in 2016. The population density data was obtained from Majene Central Statistical Agency. The larvae free numbers per Public Health Centre (Puskesmas) was obtained from related office. The data was analysed with SPSS and GIS Arc computer programs. The data was represented in form of maps, tables, graphs and narrative.

Result and Discussion

In Table 1, 65 respondents (54.6%) were male and 64 respondents (45.6%) were female. Meanwhile, 55 respondents (46.2%) were aged between 0 year and 10 years old. Besides, there were 40 respondents (33.6%) aged between 11 years and 20 years old. There was only a respondent aged between 51 years and 60 years old. In additions, 67 respondents (56.3%) were students and 32 respondents (26.7%) were unemployment.

Table 1: Patient Distributions with dengue haemorrhagic fever based on characteristics in Majene district 2016

Characteristics	Total (n)	Percentage (%)
Gender		
Male	65	54.6
Female	64	45.6
Age group (years old)		
0-10	55	46.2
11-20	40	33.6
21-30	10	8.4
31-40	6	5
41-50	2	1.7
51-60	1	0.8
>60	5	4.2
Employment		
Unemployment	32	26.9
Student	67	56.3
Civil servant/ lecturers	6	5
Housewives	6	5
Entrepreneur	3	2.5
Farmers/Fisherman	5	4.2
Total	119	100

Based in Table 2, there were seven respondents with mobility history from endemic areas from Makassar city. Meanwhile, seven respondents came from Malunda subdistrict. Meanwhile, 5 respondents were from Mamuju regency.

Table 2: Patient distribution with dengue haemorrhagic fever based on mobility history in Majene district 2016

Mobility history	Total (n)	Percentage (%)
Endemic area	16	13.4
Not traveling	103	86.6
Total	119	100

Table 3 showed average rainfall occurred in Majene district in 2016. There were 4 sub district with extreme categories and another 4 sub district with high rainfall categories. Highest rainfall occurred in Ulumanda subdistrict with 240 mm and Tammeroddo had recorded rainfall with 208 mm (extreme) and lowest rainfall was in East Banggae with 142 mm (high).

Table 3: Rainfall distribution in Majene district 2016

Sub district	Rainfall	Category
Banggae	168	High
East Banggae	142	High
Pamboang	162	High
Sendana	160	High
Tammeroddo	208	Extreme
Tubo Sendana	207	Extreme
Malunda	205	Extreme
Ulumanda	240	Extreme

Table 4 showed Banggae subdistrict had highest population density of 1579 population/km2 while Ulumanda district which had population of 19 population/ km2. There were 4 subdistrict had very dense population included Banggae and East Banggae. Meanwhile, Pamboang and Sendana had dense population. Ulumanda subdistrict had normal population density.

Table 4: Population density population by category in Majene district 2016

Sub district	Population/km^2	Category
Banggae	1579	Very dense
East Banggae	1010	Very dense
Pamboang	311	Dense
Sendana	269	Dense
Tammeroddo	202	Less dense
Tubo Sendana	212	Less dense
Malunda	97	Less dense
Ulumanda	19	Normal

In Table 5, the larvae free numbers achievement in each subdistrict in Majene did not reached Ministry of Health target set which was >95%. Highest achievement in Pamboang subdistrict was 92.2% and lowest was in Banggae subdistrict, 78.8%.

Table 5: Larvae free number distribution achievement in Manene district 2016

Subdistrict	Total house	Checked house	Larvae free	Percentage
Banggae	7787	3757	2962	78.8
East Banggae	6555	3170	2742	86.5
Pamboang	4208	2730	2516	92.2
Sendana	4419	1665	1456	87.4
Tammeroddo	2371	560	514	91.8
Tubo Sendana	1721	730	658	90.1
Malunda	3775	1195	1077	90.1
Ulumanda	1688	720	657	91.3

Discussion

In this study, the maps showed distribution pattern of dengue haemorrhagic fever patients more likely to be close together due to ability flying vector ability caused of dengue haemorrhagic fever which was only between 50m and 100m.

In additions, the dengue haemorrhagic fever also strongly influenced by height of the area since the result obtained in Majene district was mostly in the coastal areas along Majene district.

In Majene district, the coastal areas were most resided areas and connected with South Sulawesi, West Sulawesi and Central Sulawesi province which meant community in Majene district were living in lowland that were very potential as breeding place for dengue.

Meanwhile, positive dengue haemorrhagic fever patients in Majene district were widely spread in urban areas which very closely related to environment sanitation such as waste management. In urban areas, waste production was more than rural areas which contributed in Aedes mosquitoes breeding area if did not treated well.

The dengue haemorrhagic fever incidence was widespread in areas with high rainfall (100-200mm) than areas had extreme rainfall (>200mm). High rainfall category was found in Southern part of Majene district while extreme rainfall category was found in Northern part of Majene district.

High dengue haemorrhagic fever incidence in high rainfall areas compared to extreme rainfall areas due to inundation created breeding ground for Aedes mosquitoes while extreme rainfall caused flood lead water flows full with Aedes mosquitoes larvae. The rain affected the mosquitoes life in two ways such as increased relative humidity and breeding ground.

Baggae subdistrict which had highest number of positive dengue haemorrhagic fever patients in Majene district which was 76.9% in adjacent to the shoreline. In general, distribution of dengue haemorrhagic fever patients in all sub district was more prevalent in adjacent areas to the coast.

Population density was resident number living per unit area (km^2). Denser the area, greater potential for disease transmission. The population density affected the vulnerability of an area to several diseases especially those that were closely related to the environment. The disease was more easily transmitted to the areas that were densely populated due to transmission range was getting closer. In additions, density and population were among the factors that influenced dengue incidence in the region.

The region had very dense population such as in urban areas had public facilities included health facilities (hospitals, public health centres and general practitioners), other public facilities such as markets, schools, tourist attraction, hotels that caused dengue haemorrhagic fever was very easily transmitted the diseases.

Besides, population mobility was also risk factors caused dengue haemorrhagic fever spread in Majene district. Most positive dengue haemorrhagic fever patients came from endemic areas such as Makassar city and Mamuju regency.

The larvae free number achievement in seven district was <95% that did not meet the Ministry of Health requirement. The presence of Aedes larvae mosquitoes in the region indicated that there was potential for dengue haemorrhagic fever to occur.

The spot check activities were not carried out in all houses or building in their respective areas due to lack of energy and costs allocated. Tubo Sendana subdistrict had 90.1% larvae free achievement but did not received by positive dengue haemorrhagic fever patients. The larvae free numbers was measure of larvae density in an area to reduce the dengue fever risk or dengue haemorrhagic fever transmission which necessary to eradicate mosquito nests.

Conclusion

In conclusion, positive dengue haemorrhagic fever patients found more in areas with high rainfall (100-200mm) compared to areas with extreme rainfall. High rainfall was caused inundation as breeding ground for Aedes mosquitoes. Meanwhile, areas with very dense population had more dengue haemorrhagic fever patients. The population density also affected dengue transmission since flying vector of disease was estimated to be only 50-100 meter. All subdistrict in Majene district had <95% larvae free number or did not fulfil the requirement of Ministry Health.

Factors Contribute to KB Contraception Equipment Service in Reproductive Age Couples in Tamalanrea Public Health Center

Karmiah[1], Muhammad Yusran Amir[1], Muh. Yusri Abadi[1]

[1]Faculty of Public Health, Hasanuddin University, Makassar, Indonesia

ABSTRACT

The contraceptive service is an effort to improve family planning quality. The study aimed to determine the relationship between age, knowledge, education, employment, information provision and spouse support in contraceptive services for reproductive age couples. The study was used quantitative research with cross sectional study approach. This study was conducted at Tamalanrea Public Health Center (Puskesmas). The study population were 3332 couples with samples of 97 reproductive age couples. The data collection was done by distributed questionnaires to the samples. The data was processed with SPSS program and the data was represented in frequency distribution table form. The result indicated there was correlation between family planning contraceptive service in reproductive age couples with age (p=0.009), education level (p=0.046), information provider (p=0.036) and spouse support (p=0.038). Meanwhile, there was no relationship between family planning conceptive service with work (p=0.291) and knowledge (p=0.448). The recommendation for health officers in provide information on contraceptive service usages for reproductive age couples.

Keywords: *Contraceptive, family planning, age, fertile, spouses*

Introduction

Family planning is defined as set activities, procedures and interventions that provide the population with counselling, health education and modern contraceptive methods (CMs) for individuals may choose their right to decide freely and responsibly whether to have children and if so, the number and appropriate timing of their children.[1] Most developing countries had higher unmet need for modern family planning compared to developed countries. Meanwhile, most sub-Saharan countries had unmet need for family planning between 13% and 34% in 2013.[2] The unmet need level is one of standard indication for measuring family planning effectiveness program in any country.[3] Family planning has potential to prevent most of maternal mortality and children and has economic and social benefits by providing correspondence between resources and population.[4]

There are around 210 million pregnancies happens global which nearly 75-80 million of these pregnancies are unintended and more than half of these unintended pregnancies undergo unsafe abortion annually. [5] 95% of unintended pregnancies happened among women who either use their method inconsistently or incorrectly or use no method at all.[6] In Egypt, 14% of pregnancies in five years prior to the survey were reported unwanted and 5% of births were identified as mistimed.[3] In 2010, American women unmet need was estimated at 5.9% and 23.2% in Africa.[7]The unmet need for contraceptive contributes to 7.4 million disability-adjusted life years.[8]

The contraceptive services is an effort to improve family quality. Over past two decades, contraceptive services in family planning development in Indonesia is considered successful. Hence, there is increasing reproductive age women prevalence who used contraceptive methods. The family planning program is helps Indonesian through improving mothers, children and families development.

The Indonesia health data showed family planning among reproductive age couples participation in Indonesia had reached 76.73% in 2013 with injection and pills. In South Sulawesi province, highest percentage of family planning methods used by active family planning participants were injections (47.39%), pills (22.90%), condoms (13.45%) and other methods (0.56%). Meanwhile, contraceptive method percentage used for new family planning participant was injections (44.61%), pills (24.78%), condoms (16.85%), implants (8.84%), IUDs (3.21%) and others (0.28%).

In Tamalanrea Public Health Centres (Puskesmas), contraceptive method had increased compared previous year. The increment in family planning participants who selected injection method compared to other contraceptive methods was influenced by several factors such as age, education level, employment status, number of children, age at first marriage, knowledge, information and contraceptive. The study aimed to determine the relationship between age, knowledge, education, employment, information provision and spouse support in contraceptive services for reproductive age couples.

Methodology

The study was used quantitative research with cross sectional study approach. The study was conducted in Tamalanrea Puskesmas, Makassar city from December 2016 until January 2017.

Meanwhile, the study population were married couples in reproductive age in Tamalanrea Puskesmas which total of 3332 people. The sample sizes were 97 people which selected using non-random sampling method.

The primary data was obtained through questionnaire and interview. The secondary data is obtained through documentation and other data. The data was analysed used SPSS program.

The univariate analysis was performed on each variable used frequency analysis. The binary analysis was performed used Chi square test to determine the relationship between independent and dependent variables. The data was represented in form of frequency distribution tables and percentages.

Result and Discussion

In Table 1, 5 respondents (62.5%) were aged below than 20 years old and 25 respondents (89.3%) aged more than 50 years old had utilized family planning contraceptive. Meanwhile, 25 respondents (41.0%) aged between 20 years old and 35 years old and 3 respondents (37.5%) aged below than 20 years old did not utilized family planning concentrative service. The statistical test showed there was relationship between age and family planning contraceptive service utilization.

Table 1: Relationship between age and family planning contraceptive in Tamalanrea Puskesmas, Makassar city

Age (years)	Family planning concentrative service						p-value
	Yes		No		Total		
	n	%	n	%	n	%	
<20	5	62.5	3	37.5	8	100	0.009
20-35	36	59.0	25	41.0	61	100	
>50	25	89.3	3	10.7	28	100	
Total	66	68.0	31	32.0	97	100	

In Table 2, there were 41 respondents (71.9%) had knowledge and 25 respondents (62.5%) had no knowledge on contraceptive with utilized family planning contraceptive services in Tamalanrea Puskesmas. In additions, 16 respondents (28.1%) had knowledge and 15 respondents (37.5%) had no knowledge on contraceptive without utilized family planning contraceptive services. There was no relationship between knowledge and family planning contraceptive services utilization in Tamalanrea Puskesmas.

Table 2: Relationship between knowledge and family planning contraceptive service utilization in Tamalanrea Puskesmas, Makassar city

Knowledge	Family planning concentrative service						p-value
	Yes		No		Total		
	n	%	n	%	n	%	
Yes	41	71.9	16	28.1	57	100.0	0.448
No	25	62.5	15	37.5	40	100.0	
Total	66	68.0	31	32.0	97	100	

In Table 3, there were 31 respondents (58.5%) had high education level and 35 respondents (79.5%) had low education level with utilized family planning contraceptive services in Tamalanrea Puskesmas, Makassar city. Besides, 22 respondents (41.5%) had high education level and 9 respondents (20.5%) had low education level without utilized family planning contraceptive services. The statistical test showed there was relationship between education level and family planning contraceptive services utilization in Tamalanrea Puskesmas, Makassar city.

Table 3: Relationship between education level and family planning contraceptive service utilization in Tamalanrea Puskesmas, Makassar city

Education level	Family planning contraceptive services utilization						p-value
	Yes		No		Total		
	n	%	n	%	n	%	
High	31	58.5	22	41.5	53	100.0	0.046
Low	35	79.5	9	20.5	44	100.0	
Total	66	68.0	31	32.0	97	100	

In Table 4, 41 respondents (73.2%) were worked and 25 respondents (61.0%) were jobless with utilized family planning contraceptive services. There were 15 respondents (26.8%) worked and 16 respondents (39.0%) were jobless without utilized family planning contraceptive services. There was no relationship between employment and family planning contraceptive services utilization.

Table 4: Relationship between employment and family planning contraceptive service utilization in Tamalanrea Puskesmas, Makassar city

Employment	Family planning contraceptive services utilization						p-value
	Yes		No		Total		
	n	%	n	%	n	%

Discussion

The pregnancy prevention is recommended for women with age less than 20 years. The contraceptive such as pills, IUDs, condoms which good in pregnancy spacing. Meanwhile, women aged between 20 years and 35 years old is recommended to use contraceptive such as IUDs, pills, injections and implants. The women aged more than 35 years old is recommended to use IUDs, implants, injections, pills and condoms. Hence, the age was determining the choices of contraceptive. The study was indicated that there was relationship between age and family planning contraceptive service utilization among reproductive age couples in Tamalnarea Puskesmas.

The study also found there was no relationship between knowledge and family planning contraceptive service utilization among reproductive age couples in Tamalanrea Puskesmas. The reproductive age couples had sufficient knowledge in long term contraceptive method selection through social media, electronics, magazines. Meanwhile, 62.5% reproductive age couples had lack of knowledge and did not utilized family planning contraceptive services. Besides, the reproductive age couples who had sufficient knowledge and did not utilized the family planning contraceptive services caused by other factors which their spouse did not support in contraceptive usage.

The reproductive age couples who had insufficient knowledge due to influences such as lack of information about contraceptives and their side effects, lack attendance in family planning counselling programs but still obtained information from family and health officers. Furthermore, reproductive age couples who had lack of knowledge and did not utilized family planning contraceptive services due to their ignorance in contraceptive usage. The women who inactive in participating in counselling in local area which expected able to consult with midwives about contraceptive method that suitable for their need.

The women education level also important in accessing to family planning information. Nowadays, the women had dual role as housewife and also role in community activities. The study had indicated there was relationship between education level and family planning contraceptive services utilization. The study also showed reproductive age couples who ha low education utilized family planning contraceptive services more which meant tendency of women with higher education will affect in contraceptive usage.

Besides, there was relationship between information and family planning contraceptive services utilization. The reproductive age couples who had received information and did not utilized contraceptive services caused by family advice on contraceptive method. The information from health officers did not affected the reproductive age couples decision in contraceptive method unless the contraceptive method had side effects and requested for contraceptive method replacement which matched age and health. Besides, there were many women who determined their contraceptive method based on information from other experiences. Some health officers also had lack of counselling in providing information caused lack of knowledge in contraceptive type selection.

Husband support such as agree, understand and know family planning and contraceptive types and monitored contraceptive side effect. The spouse role in household was in charge of leading, protecting and responsible for their family. The relationship between men and women was not based on dichotomous conflict nor functional structural but based on togetherness needs to build a harmonious partnership. The study found there was relationship between spouse support and family planning contraceptive services utilization. This result showed the respondents claimed their spouse dud not oversee the contraceptive side effects. The spouse support also influenced their wife in contraceptive usage. The lack of spouse support toward contraceptive side effect need improvement with paying attention to their wife health.

Conclusion

In conclusion, the study found there was correlation between family planning contraceptive service in reproductive age couples with age, education level, information and spouse support. Meanwhile, there was no relationship between family planning conceptive service with work and knowledge. The recommendation for health officers in provide information on contraceptive service usages for reproductive age couples.

Factors toward Dengue Haemorrhagic Fever Occurrence in Patte'ne Village, North Wara District, Palopo City

Sari Puspa Bachtiar[1], H.A. Arusnan Arsin[1], Dian Sidik Arsyad[1]

[1]Faculty of Public Health, Hasanuddin University, Makassar, Indonesia

ABSTRACT

Dengue Hemorrhagic Fever (DHF) is transmission disease through mosquitoes bites from genus Aedes especially Aedes aegypti or Aedes albopictus. This study aimed to determine the relationship between civil service efforts, hanging clothes habit, insect repellent usage, water reservoirs potential for mosquitoes breeding and abate powder usage in Patte'ne village, North Wara district, Palopo city. The study was used analytic observational with cross sectional study design. The study population were all household resided in Patte'ne village which total of 745. The study samples were head of the family. The samples were used proportional random sampling with samples of 254 households. The result showed that there was relationship between hanging clothes habit, mosquitoes repellent usage, outside water reservoirs potential for mosquitoes breeding, resting places inside the house existence and abate powder usage with DHF occurrence in Patte'ne village, North Wara district. Meanwhile, there were no relationship between civil service efforts, inside water reservoirs potential for mosquitoes breeding and resting places outside the house with DHF occurrence in Patte'ne village, North Wara district. Health agencies is recommended to provide counselling on 3M implementation to raise awareness in important of community participation in dengue prevention.

Keywords: *Dengue haemorrhagic fever, abate powder, civil service, mosquitoes*

Introduction

In 2010, International Research Consortium on Dengue Risk Assessment, Management and Surveillance (IDAMS) estimated that 390 million dengue infections global and 96 million are symptomatic cases.[1] Meanwhile, World Health Organization (WHO) approximated 2.5 billion people were at risk of dengue which living in Africa, America, Eastern Mediterranean, South East Asia and Western Pacific.[2]

According to WHO, dengue fever (DF), dengue hemorrhagic fever (DHF) and dengue shock syndrome (DSS) which classified as with or without warning signs and severe dengue.[3] Dengue infection might cause complications in nervous system and other clinical complications with mortality consequences.[4] Besides, dengue also known as arboviral disease caused by the dengue virus and have four subtypes such as DEN-1, DEN-2, DEN-3 and DEN-4 with Aedes aegypti and Aedes albopictus as principal vectors.[5,6] People who had single primary infection have higher risk of developing dengue hemorrhagic fever (DHF) and dengue shock syndrome (DSS) which contributed to antibody-dependent enhancement (ADE).[7] The dengue virus is maintained in nature through cycle transmitted by Aedes mosquitoes between humans or monkeys for the jungle cycle.[8]

In Indonesia, DHF endemic area was South Sulawesi province. Based on Prevention, Control and Environmental Health (P2PL), DHF incident rate was 35.10% per 100, 000 population with highest incident rate was Palopo city had recorded 92.18% per 100,000 population. Palopo city is an endemic area of dengue fever had 123 DHF outbreaks in February 2016.

Therefore, the study was conducted on dengue occurrence in the city. However, this study only done in one Public Health Center working area such as Patte'ne village, North Wara district. The study aimed to determine the relationship between civil service efforts, hanging clothes habit, insect repellent usage, water reservoirs potential for mosquitoes breeding and abate powder usage in Patte'ne village, North Wara district, Palopo city.

Methodology

The study was used quantitative research which was observational analytic with cross sectional study design.

The study was conducted at North Wara district Public Health Centre working area in Patte'ne village in Palopo city due to DHF outbreak area in 2016 within 21st February until 9th March 2017.The study population were 745 household living in Patte' ne village, North Wara district, Palopo city. The study samples were head of the family who willing became study respondents. The samples were 254 households. The samples were selected with proportional random sampling.

The study instrument was questionnaire sheet contained close questions related to study purpose. The questionnaire consisted of 8 parts such as respondent contribution, civil service efforts, hanging clothes habit, mosquitoes repellent usage, water reservoirs potential for mosquitoes breeding, resting places existence, abate powder usage and fogging.

The primary data was obtained through questionnaires. Meanwhile, secondary data was obtained from North Wara Puskesmas regarded the DHF occurrence description in Patte'ne village in 2016.

The univariate analysis was represented frequency distribution and percentage of each study variable. The bivariate analysis was used to determine the relationship and prove the hypothesis between independent and dependent variables. The analysis was used chi-square test analysis.

Result and Discussion

In Table 1, there were 51 respondents (21.1%) claimed did not water reservoirs became mosquitoes breeding place in their house with DHF occurrence in Patte'ne village. Meanwhile, 191 respondents (78.9%) did not had water reservoirs became mosquitoes breeding place with no DHF occurrence in Patte'ne village. There was no relationship between water reservoirs became mosquitoes breeding place and DHF occurrence in Patte'ne village.

Table 1: Relationship between water reservoirs potential became mosquitoes breeding in the house and DHF occurrence in Patte'ne village, North Wara district, Palopo city

Water reservoirs potential became mosquitoes breeding place	DHF occurrence						p-value
	Yes		No		Total		
	n	%	n	%	n	%	
Yes	51	21.1	191	78.9	242	100	0.132
No	0	0.0	12	100.0	12	100	
Total	51	20.1	203	79.9	254	100	

In Table 2, 50 respondents (23.7%) had water reservoirs became potential for mosquitoes bleeding place and only 1 respondents did not had water reservoirs which potential for mosquitoes bleeding place putside the house with DHF occurrence in Patte'ne village, North Wara district, Palopo city. There was relationship between water reservoirs potential became mosquitoes breeding place outside the house and DHF occurrence in Patte'ne village, North Wara district, Palopo city.

Table 2: Relationship between water reservoirs potential became mosquitoes breeding outside the house and DHF occurrence in Patte'ne village, North Wara district, Palopo city

Discussion

Eradication of mosquito nests was an activity to eradicate eggs, larvae and pupa of Aedes awgypti mosquitoes that transmit dengue disease in their breeding sites. The Aedes aegypti larvae existence in the environment is correlated with human behaviour. Environmental sanitation management that applied to suppress the Aedes aegypti larvae habitat through eradicated mosquito nests by 3M implementation.

The civil service efforts to implement 3M in Patte'ne village, North Wara district, Palopo city were fairly bad since 51 respondents had suffered dengue in last three years. In this study, 153 respondents who claimed poor civil service efforts and found 36 respondents (23.5%) suffered dengue in last three years.

The statistical test showed no relationship between civil service and DHF occurrence in Patte'ne village, North Wara district, Palopo city. Good civil service efforts in 3M implementation but the villagers still affected by dengue due to other factors that influenced the dengue occurrence such as environmental conditions.

The hanging clothes habit also medium favoured by mosquitoes transmission dengue and risk factors in dengue occurrence had increased. The community in Patte' ne village had hanging clothes habit had hanged clothes outside cupboard such as behind the door. Meanwhile, 51 respondents (20.1%) were affected by

dengue in last three years. There were 210 respondents who had good habit and 48 respondents were suffered DHF. In this study, there was relationship between hanging clothes habit with DHF occurrence. The community in Patte'ne village claimed hanged their clothes temporary at behind the door since the clothes were did not too dirty and smelly. Some respondents who practiced hanging clothes habit since received information on dengue prevention.

Healthy practices in DHF occurrence such as mosquitoes repellent usage. There were 189 respondents used mosquitoes repellent and only 22 respondents (11.6%) were affected by dengue. Meanwhile, the respondents who did not used mosquitoes repellent were more affected by dengue which was 44.6% from found suffered dengue in last three years. There was relationship between mosquitoes repellent usage with DHF occurrence in Patte'ne village. In additions, some respondents claimed never used mosquitoes repellent during day only used mosquitoes repellent at night.

The water reservoir potential became breeding place for Aedes aegypti mosquitoes in form of pupa such as containers. Most respondents had habit did not closed properly the water reservoirs such as bathtubs. There were 152 respondents (59.8%) did not closed their water reservoirs which only done once per week. The community in Patte'ne village who suffered dengue which had water reservoirs that potential became breeding places inside the house. Besides, water reservoirs which did not closed properly also increased potential in Aedes aegypti mosquitoes breeding. The environment around respondents house also increased potential became mosquitoes breeding place.

Furthermore, Aedes aegypti mosquitoes resting place inside the house were dark, moist and slightly clod places such as curtains, mosquito nets and clothes hanging from inside house. The result showed 210 respondents had mosquitoes resting place in their houses. Besides, 51 respondents were suffered DHF which 48 respondents had mosquitoes resting place in their houses. Hence, most respondents were affected by dengue found had mosquitoes resting place inside the house. There was relationship between mosquitoes resting places in the house and DHF occurrence in Patte'ne village, North Wara district, Palopo city. The hanging clothes habit in Patte'ne village in the house also caused resting place for Aedes aegypti mosquitoes.

The study also found relationship between abate powder and DHF occurrence in Patte' ne village, North Wara district, Palopo city. In this study, there were 183 respondents who used abate powder and 24 respondents (13.1%) who suffered from dengue. Based on the interview, there were several reasons that did not used abate powder which were abate powder was sprinkled into the water reservoir. Besides, some respondents who felt the powder was not important since no one had suffered dengue. The health workers was provided abate powder for every houses in Patte' ne village since there was an DHF outbreak in 2016.

Fogging was carried out if there are any dengue cases from Health workers. The study found the respondents claimed that fogging was carried out throughout Patte'ne village area. The result showed that 212 respondents who claimed fogging was conducted around their houses and 49 respondents were suffered dengue. The fogging implementation in Patte' ne village was carried out due to existing of DHF cases reported by Puskesmas officers. After fogging implementation, DHF cases was observed reduced, thus there was relationship between fogging implementation and DHF occurrence in Patte' ne village, North Wara district, Palopo city.

Conclusion

In conclusion, there was relationship between hanging clothes habit, mosquitoes repellent usage, outside water reservoirs potential for mosquitoes breeding, resting places inside the house existence and abate powder usage with DHF occurrence in Patte'ne village, North Wara district. Meanwhile, there were no relationship between civil service efforts, inside water reservoirs potential for mosquitoes breeding and resting places outside the house with DHF occurrence in Patte'ne village, North Wara district. Health agencies is recommended to provide counselling on 3M implementation to raise awareness in important of community participation in dengue prevention.

[1]Hospital Management Department, Faculty of Community Health, Hasanuddin University

ABSTRACT

This study aims to analyze the factors that influence patients in utilizing outpatient services at Hospital of Universitas Hasanuddin, which consists of hospital facility variables, physician services, nursing service or midwife, service fee, ease of information, and service utilization decisions. This research type is quantitative research with cross sectional design. Sampling technique with stratified random sampling. The number of samples in this study is 100 respondents. Data collection using questionnaire instrument. Data were analyzed by SPSS with Chi-Square statistic test. Chi-Square analysis showed that there were correlation between hospital facility variable (p=0,004), physician service (p=0.033), nurse service or midwife (p=0.011), ease of information (p=0.001) with service utilization decision. The advice given is to maintain and provide the best service, should the hospital continue to make improvements on the availability of facilities, type, or variety of health services more complete.

Keywords: *Hospital; outpatient; services*

Introduction

Consumer behavior is a process or activity when someone searches, selects, purchases, uses, and evaluates products and services to fulfill all aspects needed and desired[1]. Consumer behavior is an action that is directly involved in acquiring, consuming, and consuming products and services, including decisions to overtake and follow these actions[2].

Parsons et al.[3] stated that service is any action or activity that can be offered by a party to another party which is basically intangible and does not result in any ownership. David et al.[4] also defines service as a form of product consisting of activities, benefits or satisfaction offered for sale and basically intangible and does not result in ownership of something. For example, banking, hotels, airlines, taxes and home improvement services[3,4].

Purchasing health services is something that is often found by consumers. This type of purchasing service has special characteristics where most consumers feel compelled to use it[5].This ultimately affects the level of customer satisfaction and affects the willingness to use the service again.

Hospitals are unique organizations, because they blend between solid technology, labor intensive and capital intensive, so that hospital management becomes a separate scientific discipline that produces two things at once, namely technology and human behavior in organizations[6]. Thus the hospital as a form of health service facilities engaged in the service sector actually provides full attention to the quality of service, so that it is used as an indicator of assessment by consumers or in this case patients.

Tjiptono et al.[7] stated that the creation of customer satisfaction can provide several benefits including: 1) the relationship between the company and its customers become harmonious, 2) provide a basis for repurchasing and creating loyalty, and the formation of word of mouth recommendations which can be profitable for the company.

The potential of the hospital includes all the resources owned including all hospital resources as input, management as a process and health service products as an outcome are expected to be able to sell the products produced. In order to remain competitive, the products produced must be of quality and in accordance with the criteria of community needs. In determining target consumers, hospitals need to understand consumer behavior in the decision-making process[8].

The service process provided starts from the registration stage until the patient receives treatment and

healing. The form and procedure of services provided by the hospital is tailored to the type of patient who is treated. Today, the types of patients who go to each hospital are categorized as patients with health insurance or general patients[9].

Health service utilization is the process of interaction or relationship between consumers who use services and health service providers. Where the interaction process is very complex and is influenced by many factors. These factors come from consumers, the consumer environment, and providers in this case the Hospital[9,10]

Basically, the community began to be smart in accessing health services, they began to demand good service in government institutions, where at the time they only hoped for good service to private institutions[9-11]. Today government institutions are public institutions that must provide good servants to the community as a form of responsibility. Every leader of government agencies is always required to improve the quality of service of the agencies they lead, especially agencies directly related to public services such as hospitals and health centers[11].

From the marketing perspective itself, in such a competitive situation, the hospital management needs to be able to design and implement a marketing strategy that can create, maintain and increase customer satisfaction in this case, so that it can ultimately influence patient decision-making of the product offered by the hospital[9-11].

Based on Hibbard et al.[12] study, it was shown that there was a significant relationship between patient education, patient income, cost insurer, hospital facilities, and doctor's service with the decision on the place of delivery. The factors that influence the most are patient income and hospital facilities.

According Grol et al.[13] hospital competition it is necessary to develop services that are oriented towards meeting consumer needs. One of the things that must be considered in the health service system in the 21st century is patient-centered health services, which pay attention to individual desires, needs, patient values, and ensure that the values given by patients direct all treatment decisions [9,13].

Hasanuddin University Hospital is one of the government-owned hospitals under the ministries of research, technology and higher education that has a vision of becoming a trusted pioneer in integrating international standard education, research and health care. So that with this vision hospitals are challenged in facing the current era of competition with the number of hospitals in the city of Makassar.

To achieve this vision Hasanuddin University Hospital implements the mission of creating international-standard professionals in education, research and health care; creating an optimal academic environment to support education, research and health care; pioneering health care innovations through superior research and continuous improvement in service quality; provide integrated health care with education, international standard research without forgetting social functions; developing networks with other institutions both regionally and internationally.

Therefore, this work aimed at identifying the factors that influence patients in utilizing outpatient services at Hasanuddin University Hospital. This is done in order to assess the characteristics of patients in the hospital, so they can determine the description of what kind of service a patient wants to be satisfied with the service and have the willingness to use health services. In addition, these results can be used as benchmarks in the development of hospitals.

Methodology

Types of Research: The type of research used is cross-sectional. In cross-sectional studies, the number of variables is one or more. Data collection is done only once or one time. If more than one variable is examined, the data is collected relatively simultaneously. This research was conducted to explain the factors that influence patients in utilizing outpatient services at Hasanuddin University Hospital.

Location and Time of Research: This research was conducted at Hasanuddin University Hospital, in February - March 2017.

Population and Samples: The population in this study were all outpatients at Hasanuddin University Hospital. The data used to determine the population number is assumed from the total number of outpatient visits at Hasanuddin University Hospital in 2015, which amounted to 101,903 patients. The sample size is determined by Slovin formula[14] and the number of samples in this study were 100 respondents. The sampling technique used in this study is the stratified random sampling.

Data Collection: Primary data is data taken directly by researchers from the source obtained using questionnaires. The questionnaire used in this study is a modified questionnaire about the factors that influence patients in utilizing health services. Secondary data sources in this study were obtained from reports and documents from Hasanuddin University Hospital, namely data on the number of outpatient visits in 2013-2015.

Data Analysis: The collected data is processed using SPSS. The analytical method used in this study is bivariate analysis for each independent variable with the dependent variable presented in the form of tables and narrative explanations.

Result and Discussion

This research was conducted at Hasanuddin University Hospital from 11 February 2017 to 11 March 2017. Data collection was conducted through direct interviews with respondents using questionnaires. The sample size was 100 outpatients. The way that researchers do in getting respondents is when they will conduct interviews, the researchers first ask patients who visit, whether they are willing to be interviewed or not. Then if the patient does not meet the criteria as a respondent who can be interviewed, the researcher will not conduct an interview and will look for other patients who meet the predetermined criteria. The results are displayed in table form accompanied by explanations.

General Characteristics of Respondents: The research results from the characteristics of the respondents are described as follows. Age is the age of the respondent at the time of the study. Distribution of respondents based on age groups is listed in Table 1.It is seen that out of 100 respondents, the majority of respondents were in the age group of 25-34 years (28%) and at least in the age group of 65 years (5%). In additionthat most of the respondents were female, with 57 respondents (57%). While respondents male were 43 respondents (43%).

Table 1: Distribution of Respondents by Age Group at Hasanuddin University Hospital In 2017

Age Range (years)	Frequency	Percentage (%)
≤ 24	19	19.0
25-34	28	28.0
35-44	25	25.0
45-54	15	15.0
55-64	8	8.0
≥65	5	5.0
Total	100	100.0

Relationship of Hospital Facilities and Utilization of Services: The relationship between hospital facilities and service utilization is listed in Table 2. The results showed that of the 91 respondents who stated that hospital facilities were in good category, there were 80 respondents (87.9%) who stated that they would use hospital services again and 11 respondents (12.1%) stated that they would not use the same services. The chi-square test results showed ($p = 0.004$), ($p < 0.05$) so that Ho is rejected means that there is a significant relationship between facilities and utilization of services in the hospital.

Table 2: Relationship between Facilities and Utilization of Outpatient Services at Hasanuddin University Hospital In 2017

Facilities	Utilization of Services				Total		P value
	Yes		No				
	n	%	n	%	n	%	
Good	80	87.9	11	12.1	91	100	0.004
Not Good	4	44.4	5	55.6	9	100	

Relationship between Doctor Services and Utilization of Services: The relationship between physician services and service utilization is listed in Table 3. The results showed that of the 95 respondents who stated that the doctor's service in the hospital was in a good category, there were 82 respondents (86.3%) who stated that they would use hospital services again and 13 respondents (13.7%) stated that they would not use the same service. The results of the chi-square test shows value of ($p = 0.033$), ($p < 0.05$) so that Ho is rejected, meaning that there is a significant relationship between the service of doctors and the utilization of services in hospitals.

Table 3: Relationship between Doctor Services and Utilization of Outpatient Services at Hasanuddin University Hospital In 2017

Doctor services	Utilization of Services				Total		P value
	Yes		No				
	n	%	n	%	n	%	
Good	82	86.3	13	13.7	95	100	0.033
Not Good	2	40	3	60	5	100	

Relationship between Nurse Services and Midwives with Use of Services: The relationship between nurse or midwife services and service utilization is listed in Table 4. The results showed that of the 93 respondents who stated that the services of nurses or midwives in hospitals were in good category, 81 respondents (87.1%) stated that they would use hospital services again and 12 respondents (12.9%) stated that they would not use the services. The results of the chi-square test shows value of ($p = 0.011$), ($p < 0.05$) so that Ho is rejected, meaning that there is a significant relationship between service services for nurses or midwives with the use of services in hospitals.

Table 4: Relationship between Nurse Services and Midwives with Utilization of Outpatient Services at Hasanuddin University Hospital In 2017

Nurse Services and Midwives	Utilization of Services				Total		P value
	Yes		No				
	n	%	n	%	n	%	
Good	81	87.1	12	12.9	93	100	0.011
Not Good	3	42.8	4	57.2	7	100	

Relationship between Service Costs and Utilization of Services: The relationship between service costs and service utilization can be seen in the following Table 5.The results showed that of the 98 respondents who stated that the cost of service in hospitals in the affordable category, there were 82 respondents (83.6%) who stated that they would use hospital services again and 16 respondents (16.4%) stated that they would not use the same service. The chi-square test results showed ($p = 1{,}000$), ($p > 0.05$) so that Ho is rejected means that there is no relationship between service costs and utilization of services in hospitals.

Table 5: Relationship between Service Costs and Utilization of Outpatient Services at Hasanuddin University Hospital In 2017

Service Fee	Utilization of Services				Total		P value
	Yes		No				
	n	%	n	%	n	%	
Affordable	82	83.6	16	16.4	98	100	1.000
Not Affordable	2	100	0	0	2	100	

Relationship between Ease of Information and Utilization of Services: The easy relationship of information with service utilization can be seen in the following Table 6. The results showed that of the 95 respondents who stated the ease of information in the hospital in the good category, there were 83 respondents (87.4%) who stated that they would use hospital services again and 12 respondents (12.6%) stated that they would not use the same service. The results of the chi-square test showed ($p = 0.001$), ($p < 0.05$) so that Ho is rejected. Thus this means that there is a significant relationship between the ease of information and the utilization of services in the hospital.

Table 6: Relationship between Ease of Information and Utilization of Services Outpatient at Hasanuddin University Hospital In 2017

Ease of Information	Utilization of Services				Total		P value
	Yes		No				
	n	%	n	%	n	%	
Good	83	87.4	12	12.6	95	100	0.001
Not Good	1	20	4	80	5	100	

Conclusion

Based on the results of this study, namely the factors that influence patients in the use of outpatient services at Hasanuddin University Hospital. Conclusions can be taken as follows. There is a relationship between hospital facilities, doctor's service, services of nurses or midwives and ease of information with the utilization of outpatient services, at Hasanuddin University Hospital. However, there is no relationship between service costs and utilization of outpatient services at Hasanuddin University Hospital.

Acknowledgment

The author would like to thank the Faculty Of Community Health, Hasanuddin University for unconditionally support and funding. The ethical clearance was attained from Hasanuddin University Hospital. The author(s) declare that there is no conflict of interest in publishing this article.

Relationship of Marketing Mixes with the Return Interest of Patients at ArifinNu'mang Hospital

Ardiyansah H. Lammade[1], Asiah Hamzah[1], Sukri Palutturi[1]

[1]Administration Department and Health Policy, Faculty of Community Health, Hasanuddin University

ABSTRACT

Marketing mix is a combination of variables or activities which are the core of the planning system, variables that can be controlled to influence the reaction of buyers or consumers. This work aims to analyze the marketing mix relationship (product, people, physical evidence, and process) with the patient's interest in returning for treatment at ArifinNu'mang Hospital, Sidrap. Sampling is done by simple random sampling technique. The number of samples is 100 people, all of whom are inpatients of ArifinNu'mang Hospital, Sidrap. The results of this study indicate that the product strategy (p = 0.002), people (p = 0,000), process (p = 0,000), and physical facilities (p = 0.002) have a relationship of interest in returning to inpatient services at the hospital. ArifinNu'mang, Sidrap District. Based on the results of the research, ArifinNu'mang Hospital, Sidrap Regency is expected to continue to be able to improve and develop the quality of services, it is expected that all parties within the hospital understand the elements and marketing mix strategies.

Keywords: *Marketing mix; return interest; hospital*

Introduction

Marketing is a social and managerial process where individuals and groups get what they need and want by creating, offering and exchanging valuable products on the market[1]. Marketing is a planning process and implementation of the price-giving manifestation, promotion and distribution of service items and ideas to create exchanges with target groups that meet customer and organizational goals[2].

The marketing goal is to make the maximum sale or use of services. Marketing is the activity of modern organizations in order to survive and succeed. Organizations must know the market, attract resources, turn these resources into products and services, ideas that are in accordance with the effective ways of various people in need[3].

Services have many meanings, ranging from personal services to product services[4]. Every organization always tries to stay alive, develop and compete in terms of its service[5]. In this context, each organization always sets out and implements strategies and ways to implement its marketing activities[5].

The marketing mix is one of established marketing strategy[6]. Marketing mix is a combination of variables or activities that are the core of the planning system, variables that can be controlled to influence buyers or consumers ' reactions. Marketing mix aims at creating market share (access) through the uniqueness or differentiation of service products offered and ended with sales or transactions[6].

The healthcare market has moved towards becoming a customer-focused and anticipating amazing consideration at reasonable cost[7]. Additionally, the mushroomed advancement of the worldwide rivalry facilities of corporate doctors acquires gigantic changes in the structure of the industry. In this particular situation, hospital services marketing is gradually and unquestionably transforming and is being woven into the texture of hospital planning and advertising programs[8]. Throughout the last two decades, however, huge numbers of corporate doctor's facilities have created advertising society in their setting – which has empowered them to scale new statures in their endeavors[9].

Several studies has been reported on marketing mixes for hospitals. Sreenivas et al.[10] investigatedthe Marketing procedure in corporate health centers and analyzed the view of Administrative staff, Doctors and Nursing staff towards advertising process. Varkevisser et al.[11] inspected the connection between clinic quality,

as estimated by freely accessible quality appraisals, and patient doctor's facility decision and found that patients have a high penchant to pick health centers with a decent notoriety. Moscone et al.[12] studied the impact of social cooperation on patients' decision of doctor's facility and its association with the quality that is conveyed by clinics and found that past involvement in the use of wellbeing administrations by the system assumes a critical job in clarifying current patients' decisions of doctor's facility. Jung et al.[13] analyzed the impacts of differing measurements of doctor's facility quality including consumer decision in selecting future health center and found that consumers' view of notoriety and therapeutic administrations contribute considerably in selecting a health center. De Groot et al.[14] evaluated the impact of past patients' encounters in respect to other data while picking a health center for treatment and found that the decisions depends most on data in regards to doctors' mastery, holding up time, and doctors' correspondence while picking a healing facility. Zwijnenberg et al.[15] investigated patients' inclinations on doctor's facilities and found that there us a requirement for data about the medicinal pro while picking a health center

Hospitals as providers of health services are increasingly in both state-owned hospitals and private hospitals. In particular, at South Sulawesi, inpatient visits at ArifinNu'mang Hospital, Kab. Sidrap has increased for the last three years, namely in 2012 the number of inpatients reached 3,136 patients, in 2013 reached 3,838 patients, and in 2014 reached 4,439 patients. In order to improve health services and maintain the number of visits and as a regional southeastern pilot and referral hospital in South Sulawesi, there is a need for a better marketing strategy which will influence the decisions of patients in using hospital services. Thus, this work aims to analyze the marketing mix relationship (product, people, physical evidence, and process) with the patient's interest in returning for treatment at ArifinNu'mang Hospital, Sidrap.

Methodology

Research Design and Location: This research is a quantitative research survey form with the design of the Cross Sectional Study, which is a study that conducts descriptive analysis and explains causal relationships between independent variables and the dependent variable simultaneously. This research was conducted at the hospital. ArifinNu'mangKab.Sidrap.

Population and Samples: The population in this study were all patients in the hospital inpatient unit. ArifinNu'mangKab.Sidrap Year 2016. The average inpatient from 2012 - 2014 was 3,804 patients/year. Sampling is done by simple random sampling technique. The number of samples were100 respondents.

Data Source: Primary data is data obtained directly from respondents. This data is obtained by distributing questionnaires to respondents who use services at the research location. The secondary data is collected from reports or other written documents available from the hospital. The independent variables that will be analyzed in this work consist of products, physical facilities, people, processes. The dependent variable in this study is return interest.

Data Analysis: Primary data in this study was processed using computer software through the SPSS program. Based on the objectives of the study, namely to find out the relationship of the independent variable with the dependent variable, the method of analysis of multiple linear regression is used to determine which tendency of independent variables is more related to the dependent variable. Bivariate analysis is to do an analysis relationship between each independent variable and the dependent variable using Chi Square (X2). This test is used to test the freedom between two variables arranged in table rows and columns with $\alpha = 0.05$, which means the null hypothesis (Ho) is rejected if p value $<\alpha$ which means there is a relationship between the dependent variable and the independent variable.

Result and Discussion

Description of Respondents Characteristics: Respondents in this study were 100 respondents. All respondents were patients in the hospital of ArifinNu'mangKab. Sidrap. Distribution of respondents based on age at the hospital. ArifinNu'mangKab.Sidrap can be seen in the Table 1. Table 1 above shows that the percentage of the highest age group of respondents in the age group 21-30 years is 22 respondents (22.0%). Furthermore, the lowest age group of respondents in the 81-90 year group was 1 respondent (1%).Results showed that the percentage of the highest gender respondents is male as many as 61 respondents (61.0%), then the lowest gender of the respondents is female as many as 39 respondents (39.0%).

Table 1: Distribution of Respondents by Age Group

Age Group (Years)	Total	
	N	Percentage %
1-10 years	3	3.0
11-20 years	11	11.0
21-30 years	22	22.0
31-40 years	10	10.0
41-50 years	17	17.0
51-60 years	20	20.0
61-70 years	12	12.0
71 –80 years	4	4.0
81-90 years	1	1.0
Total	100	100.0

Relationship between Product with Patient Interest: Based on Table 2, result showed that of all respondents who rated good product as much as 85.5% expressed interest and as many as 57.9% stated no interest, while for respondents who stated that product was not good as much as 14.5% expressed interest and as many as 42.1% stated no interest. The results of the analysis are to see the relationship between the product and the interest in returning of patients was done using the chi-Square statistical test, and result showed the value p = 0.002 because the value of p <0.05 then Ho is rejected and Ha is accepted. This means there is a relationship between the product and the patient's interest in the hospital.

The results indicate that there is relationship of the product with the interest of returning patients. If the patient's perception of the product is good then the patient will be satisfied with the product or service in the installation, so they are interested in continuing to use the service. The outcome of this work is inline with findings reported in De Groot et al[14] where it was stated that patient tend to choose if the product is good.

Table 2: Relationship between Product with Patient's Return Interest

Product	Return Interest of Patient				Total		P value
	Yes		No				
	n	%	n	%	n	%	
Good	53	85.5	22	57.9	75	100	0.002
Not Good	9	14.5	16	42.1	25	100	
Total	62	100	38	100	100	100	

Relationship between People with Patient Interest: Based on Table 3, the results showed that of all respondents who rated good people as much as 95.2% expressed interest and as many as 65.8% stated no interest, while for respondents who said people were not good as much as 4.8% expressed interest and as many as 34.2% stated no interest. The results of the analysis are to see the relationship between people and the interest in returning of patients was done using the Chi-Square statistical test, and result showed the value p = 0.000 because the value of p <0.05, then Ho is rejected and Ha is accepted. This means that there is a relationship between people and the interest of returning among patients in hospitals. The outcome of this work is inline with the findings reported in Jung et al.[13] as the patient's perception of health personnel is good, the patient will feel satisfied with the skills and abilities of the health personnel involved in providing services at the Installation.

Table 3: Relationship between People with Patient's Return Interest

People	Return Interest of Patient				Total		P value
	Yes		No				
	n	%	n	%	n	%	
Good	59	95.2	25	65.8	84	84	0.000
Not Good	3	4.8	13	34.2	16	116	
Total	62	100	38	100	100	100	

Relationship of Process with Patient Interest: Based on Table 4, the results showed that of all respondents who rated the process well as many as 77.4% expressed interest and as many as 39.5% stated no interest, while for respondents who said the process was not good as many as 22.6% expressed interest and as many as 60.5% expressed no interest. The results of the analysis are to see the relationship between the process and the interest in returning of patients was done using the Chi-Square statistical test, and result showed the value p = 0,000 because the value of p> 0.05, then Ho is rejected and Ha is accepted. This means there is a relationship between the process and the interest in returning of patients in the hospital. The outcome of this work is inline with the results reported in De Groot et al.[14] where it was reported that process of healthcare has significant influence on patient's return interest.

Table 4: Relationship between Process with Patient's Return Interest

Process	Return Interest of Patient				Total		P value
	Yes		No				
	n	%	n	%	n	%	
Good	48	77.4	15	39.5	63	100	0.000
Not Good	14	22.6	23	60.5	37	100	
Total	62	100	38	100	100	100	

Relationship between Physical Evidence and Patient Interest: Based on Table 5, the result showed that of all respondents who assessed physical evidence as good as 90.3% expressed interest and as many as 65.8% stated no interest, while for respondents who stated physical evidence (physical facilities) were not good as many as 9.7% expressed interest and 34.2% stated no interest. The results of the analysis to see the relationship of physical evidence with the interest of returning of patients was done using the Chi-Square statistical test, and result showed the value = 0.002 because the value of p <0.05 then Ho is rejected and Ha is accepted. This means there is a relationship between physical evidence with the interest of returning patients in the hospital. The outcome of this analysis is inline with the work done by Zwijnenberg et al.[15] where physical evidence of health care information plays a key role in patient's decision.

Table 5: Relationship between Physical Evidence and Patient's Return Interest

Physical evidence	Return Interest of Patient				Total		P value
	Yes		No				
	n	%	n	%	n	%	
Good	56	90.3	25	65.8	81	100	0.002
Not Good	6	9.7	13	34.2	19	100	
Total	62	100	38	100	100	100	

Relationship between Elements of Marketing Mix with Patient Return Interest: Based on Table 6, it can be seen that the elements of the marketing mix that are most associated with the interest in returning patients are people and processes with p = 0.000 <0.05.

Table 6: Recapitulation of Chi Square Test Results Relationship between Marketing Mix Elements with Patient Return Interest

Marketing Mixes	Chi Square Test	
	P (P<0.05)	Outcome
Product	P < 0.002	Related
People	P < 0.000	Related
Process	P < 0.000	Related
Physical Evidence	P < 0.002	Related

Conclusion

The conclusions that can be generated from this study are as follows. Based on the results of the analysis and discussion, there is a relationship between product, people, process and physical evidence with an interest in returning patients to the hospital. Of all the elements of the marketing mix, the people and process elements that are most related to the patient's returning interest. Thus, it is recommended that hospitals to improve or develop the quality of service for patients because over time, service standards will continue to increase along with increasing levels of satisfaction and standards desired by service users.

Relationship Analysis between the Quality of Health Services and Patients Satisfaction in Kapasa Health Center Makassar City

Fidelia Lolo Pirade[1], AmranRazak[1], Nurhayani[1]

[1]Administration Department and Health Policy, Faculty of Community Health, Hasanuddin University

ABSTRACT

Health center is tasked with implementing health policies to achieve health development goals in its working area. By increasing the quality of service, the service function in the health center needs to be improved so that it becomes more effective and efficient and gives satisfaction to patients and the community. The purpose of this study was to determine the relationship between the quality of health services and the satisfaction of patients at the Kapasa City Health Center in Makassar. This research is a quantitative study with a cross sectional study design. The population in this study were 1,956 patients who had used services at the KapasaHealth Center. Sampling using systematic random sampling technique, obtained a sample of 92 respondents. Based on the results of the study indicate that there is a relationship between the dimensions of technical competence ($p = 0.046 < 0.05$), convenience ($p = 0.023 < 0.05$), relations between humans ($p = 0.001 < 0.05$), and timeliness ($p = 0.001 < 0.05$) with patient satisfaction at the Kapasa Health Center, and there was no relationship between the dimensions of access to services ($p = 0.316 < 0.05$) and patient satisfaction at the Kapasa Health Center. Based on the results of these studies it is recommended that Kapasa Health Center retain and/or improve the quality of services that are already good. The puskesmas has more attention to the needs of patients and the environmental conditions of the community health center.

Keywords: *Service quality; patient satisfaction; health center; indonesia*

Introduction

The world report defines the notion of health as a state of physical, mental, and social welfare which is a unity and not only free from disease or disability[1]. Therefore, every element of society, both individuals, families, has the right to obtain services for their health and the government is responsible for proclaiming, regulating the organization and supervision of health services evenly and affordable by the community[2].

Health care is a critical factor in enhancing the wellbeing and prosperity of each individual on the planet. Everybody has the directly to get wellbeing administrations and the legislature is in charge of the accessibility of all types of value, protected, proficient and reasonable wellbeing endeavors by all dimensions of society[3]. One such exertion is to expand the accessibility and value of essential social insurance offices, for example, wellbeing focuses in every locale[4].

Users of health care services demand quality services not only regarding physical illness but also satisfaction with the attitudes, knowledge and skills of officers in providing services and the availability of adequate facilities and infrastructure that can provide comfort[5]. By increasing the quality of service, the service function in the health center needs to be improved so that it becomes more effective and efficient and gives satisfaction to patients and the community. The function of the health centers in providing services to the community is faced with several challenges in terms of increasingly sophisticated human resources and health equipment, but however must continue to provide the best service[5].

Patient satisfaction is considered as a critical factor in medicinal services maintainability. Patient satisfaction identifies with each of the three of the manageability columns[6]. Understanding this factor and its connections enhances manageability contemplations. The essential goal of a healthcare framework is to accomplish a more beneficial populace[6]. Healthcare social maintainability guarantees the present patients get quality administration and tries to adjust the assets and requirements[6].

For users of health services, the quality/quality of services is more related to the responsiveness of officers to meet the needs of patients and the smooth communication

between officers and patients. Several studies has been conducted to evaluate customer's view and satisfaction on the service provided by health centers. Faezipouret al.[7] investigated imperative factors that influences human services with patient fulfillment utilizing a framework elements approach. Lee et al.[8] experimentally tested the impacts of high end frameworks on consumer loyalty, and client faithfulness in social insurance associations. Kessler et al.[9] evaluated patient fulfillment that influences patients to return for future administrations and found that there is a measurably noteworthy connection among fulfillment and return interest. Gallan et al.[10] surveyed how circumstance explicit feelings and patients satisfaction influences the experience of using health center services. Ndubisi et al.[11] inspected the impacts of administration dependability on consumer loyalty and satisfaction in health care conveyance in Malaysia. Kitapci et al.[12] analyzed the effect of administration quality measurements on patient fulfillment, repurchase expectations and verbal correspondence in general society human services industry. Murti et al.[13] work measured the nature of administrations and its results on patient's fulfillment based on the service provided by health center in India. Ramez et al.[14] assessed the dimension of administration nature of medicinal services suppliers in Bahrain with the end goal of revealing, essentially; the connection between administration quality measurements and the general patients' fulfillment and breaking down conduct aim of patient.

Patient satisfaction is related to the quality of health services. If a health institution, one of which is a health center, will make efforts to improve the quality of health services, measurement of the level of patient satisfaction must be done. Through these measurements, it can be known to what extent the quality dimensions of health services that have been held can meet patient expectations.

Thus, to the best knowledge of the authors, there has been very minimal work done in evaluating customer's satisfaction on health centers in Indonesia, in particular on the Kapasa Health Center that located is Tamalanrea District, Makassar City, Indonesia. Hence in this work, The authors were interested in conducting research at the Kapasa Health Center regarding the quality of health care services for patient satisfaction because good service would establish loyalty for patients to reuse the service or at least recommend services received to others who also needed the same service. Therefore, this work reports the relationship between the quality of health services and the satisfaction of patients at the Kapasa City Health Center in Makassar.

Methodology

Types of Research: The type of research used in this study is quantitative research with the cross sectional study approach. The variables in this study consisted of dependent variables, namely patient satisfaction and independent variables which consisted of variables of technical competence, access to services, human relations, timeliness, and comfort.

Location and Time of Research: This research was conducted at the Kapasa Community Health Center which is located in Tamalanrea District, Makassar City, South Sulawesi Province. The research was conducted on March 24 - April 24, 2017.

Population and Samples: The population in this study were all patients who came to visit the Kapasa Health Center, Makassar City, South Sulawesi Province. The computed number of samples in this study was 92 samples.The sampling technique in this study is with using the accidental sampling method.

Data Collection: Primary data is obtained by providing aids in the form of a questionnaire to respondents accompanied by interviews to collect data about patient satisfaction with health care services. Primary data is taken from the results of questionnaires for quantitative data covering five dimensions of quality, namely, technical competence, access to services, comfort, human relations, timeliness and patient satisfaction. Secondary data was investigated by visiting the relevant agencies, namely the Kapasa Health Center to obtain related data.

Data Analysis: Data obtained in the study were then obtained and analyzed using a computer software SPSS. Bivariate analysis was carried out on two variables that allegedly related or correlated. In this study analyzed the relationship of the quality of health care services to the level of satisfaction of patients at the Kapasa Health Center. Data analysis was done by tabulating data and testing hypotheses. Ho will be tested with a significance level of 0.05.

Result and Discussion

Technical Competency Variables with Patient Satisfaction: Based on Table 1, It is known that the number of respondents who said quite good was 83 respondents (90.2%) and respondents who said that good were 9 respondents (9.8%). From these results can be seen respondents feel good and satisfied are 81 respondents (88%) and respondents who feel good and feel quite satisfied are 2 respondents (2.2%).

The results of the statistical test obtained p = 0.046 or p <0.05. Thus Ho is rejected and Ha is accepted. This shows that there is a relationship between the variable technical competence and the satisfaction of patients at the Kapasa Health Center. Thus the outcome of this work which showed technical competence is significant is line with the findings reported by Faezipour[7]. Thus, the increasingly fulfilled technical competence by the health center will lead to higher patient satisfaction.

Table 1: Relationship between Technical Competence and Satisfaction of Patient

Technical Competency	Frequency				Total		P value
	Satisfied		Quite Satisfied				
	n	%	n	%	n	%	
Good	81	88	2	2.2	84	84	0.046
Quite Good	7	7.6	2	2.2	9	116	
Total	88	95.6	4	4.4	92	100	

Access Variables on Services with Patient Satisfaction: Based on Table 2, it is known that the number of respondents who felt good was 66 respondents (71.7%) and respondents who felt quite good were 26 respondents (28.3%). The results of statistical tests obtained p = 0.316 or p> 0.05. Thus Ho is accepted and Ha is rejected. This shows that there is no relationship between the access variable to service and the satisfaction of BPJS patients in Kapasa Health Center. Thus the outcome of this study is inline with the work done by Owusu-Frimpong et al.[15] means that there is no significant relationship between variable access to services with patient satisfaction.

Table 2: Relationship between Access to Services and Patient Satisfaction

Access Variables on Services	Frequency				Total		P value
	Satisfied		Quite Satisfied				
	n	%	n	%	n	%	
Good	64	69.6	2	2.2	66	71.7	0.316
Quite Good	24	26.1	2	2.2	26	28.3	
Total	88	95.7	4	4.4	92	100	

Convenience Variable with Patient Satisfaction: Based on Table 3, it is known that the number of respondents who felt good was 74 respondents (80.4%) and respondents who felt that quite good were 18 respondents (19.6%). The results of the statistical test obtained a value of p = 0.023 or p value <0.05. Thus Ho is rejected and Ha is accepted. This shows that there is a relationship between the convenience variable and the satisfaction of BPJS patients in Kapasa Health Center. Hence, the outcome of this study is inline with the work done by Kitapci et al.[12] means that there is no significant relationship between convenience and patients satisfaction

Table 3: The Relationship between Convenience and Patient Satisfaction

Convenience	Frequency				Total		P value
	Satisfied		Quite Satisfied				
	n	%	n	%	n	%	
Good	73	79.3	1	1.1	74	80.4	0.023
Quite Good	15	16.3	3	3.3	18	19.6	
Total	88	95.7	4	4.4	92	100	

Relationship Between Interpersonal Relations with Patient Satisfaction: Based on Table 4 it is known that the number of respondents who felt good was 85 respondents (92.4%) and respondents who felt was quite good were 7 respondents (7.6%). The results of statistical tests obtained p = 0.001 or p <0.05. Thus Ho is rejected and Ha is accepted. This shows that there is a relationship between variables between human relationships with satisfaction of patients in Kapasa Health Center. Hence, the outcome of this work is inline with the work done by Murti et al.[13] as it was reported that good human relations instill trust and credibility by respecting, keeping secrets, respecting, responsive and attentive between the health care personal and patient.

Table 4: The Relationship Between Interpersonal Relations with Patient Satisfaction

Interpersonal Relations	Frequency				Total		P value
	Satisfied		Quite Satisfied				
	n	%	n	%	n	%	
Good	84	91.3	1	1.1	85	92.4	0.001
Quite Good	4	4.3	3	3.3	7	7.6	
Total	88	95.7	4	4.4	92	100	

Timeliness Variable with Patient Satisfaction: Based on Table 5, it is known that the number of respondents who said good was 85 respondents (92.4%) and respondents who said that they were quite good enough were 7 respondents (7.6%). From these results it can be seen that respondents who say good and feel satisfied are 84 respondents (91.3%) and respondents who say good and feel quite satisfied are 1 respondent (1.1%). While respondents who said they were quite good and felt satisfied were 4 (4.3%) and respondents who said they were quite good and felt quite satisfied were 3 (3.3%). The results of statistical tests obtained p = 0.001 or p <0.05.Thus Ho is rejected and Ha is accepted. This shows that there is a relationship between the timeliness and satisfaction of patients in Kapasa Health Center. The results of this study are in accordance with the theory which states that timeliness is a condition where everything must be done in accordance with the time[12,13].

Table 5: The Relationship between Timeliness and Satisfaction Patient

Timeliness	Frequency				Total		P value
	Satisfied		Quite Satisfied				
	n	%	n	%	n	%	
Good	84	91.3	1	1.1	85	92.4	0.001
Quite Good	4	4.3	3	3.3	7	7.6	
Total	88	95.7	4	4.4	92	100	

Conclusion

Based on the findings of this work regarding the relationship between the quality of health services and the satisfaction patients at the Kapasa City Makassar Health Center, the following conclusion can be drawn. There is a relationship between variables of technical competence, comfort, human relations, timeliness with satisfaction of patients in Kapasa Health Center. However, there is no relationship between the variables of access to services and the satisfaction of patients at the Kapasa Health Center. Thus, it is recommended to the management of the health center to better monitor and analyze community complaints related to access to services so that the services can be improved and satisfy the customers.

Factors Related to Complaints of Low Back Pain in Workers in Pt Maruki International Indonesia Makassar City

Ridha Astuty T[1], Syamsiar S. Russeng[1], Awaluddin[1]

[1]Work Safety and Health Department, Faculty of Community Health, Hasanuddin University

ABSTRACT

Low Back Pain (LBP) is a musculoskeletal disorder that occurs in the lower back caused by various diseases and poor body activities. This study aims to determine the risk factors associated with complaints of low back pain in workers at PT Maruki International Indonesia Makassar City in 2017. This type of research is analytic observation with a cross sectional approach. The sample technique uses 72 purposive sampling. Data analysis was univariate and bivariate using computer programs and using chi square test analysis to determine the relationship between dependent and independent variables. The study found that the prevalence of LBP complaints was felt by 49 workers (68.1%). The results of the analysis of the relationship of each variable with complaints of low back pain are work attitude (p = 0,000), age (p = 0,594), work period (p = 0,010), Body Mass Index (p = 0,036) and smoking habits (p = 0,715). The conclusions of this study are work attitudes, years of service and body mass index have a relationship with complaints of low back pain. While age and smoking habits have no relationship with complaints of low back pain.

Keywords: *Low back pain; worker; risk factor*

Introduction

Much work has been done in recent times with machines, ranging from very simple machines to high-tech machines. On the other hand, it turns out that there is still a lot of work to be done manually in different industries, which requires physical contact. One result of manual work is the emergence of various kinds of health problems, such as back and waist pain, neck tension, wrist pain, arms and legs, eye fatigue and many other complaints[1].

The emergence of various kinds of occupational health issues invited the attention of company managers and many parties outside the companies concerned, such as government and trade unions. This has led to the application of rules on occupational safety and health management systems in the hope that they can overcome or at least reduce the problems of occupational diseases[2].

Occupational disease is an artificial disease because it occurs due to human work. One form of work-related interference, particularly in the industry, is low back pain with different levels of complaints, ranging from mild complaints of pain to severe complaints that cause patients unable to work or carry out activities[3].

The National Safety Council reports that work-related illnesses with the highest frequency of occurrence are back pain with 22% of 1,700,000 cases[4]. Low back pain (LBP) is a musculoskeletal disorder that occurs in the lower back area caused by various diseases and poor body activities. LBP can be either local pain or radicular pain or both[5]. This pain is felt between the corners of the lower ribs to the lower buttocks, namely in the lumbar or lumbosacral region and is often accompanied by spreading pain towards the legs and feet. Generally LBP is short, but the risk of recurrence is very high[6].

LBP is a symptom often described as blunt, deep pain, stiffness, persistent, and radiating to the bottom of the buttocks, legs, and feet. Pain often occurs suddenly in strains (back pain disorders that occur because muscles and ligaments are attracted when lifting heavy objects or sudden movements) or real injuries and sometimes also appear slowly[7].

Several studies have been reported on LBP. Yue et al.[8] explored the predominance of and hazard factors for LBP among secondary teachers. Their investigation demonstrated that LBP was all the more reliably connected with curving stance, awkward back help and delayed sitting and static stance. Durmus et al.[9] assessed

the pervasiveness of work related musculoskeletal pain among educators in Samsun, Turkey and they found that pain in low back locales are every now and again found in instructors and expressed that alterations of ergonomics in working conditions may diminish the torment. Vandergrift et al.[10] analyze the relationship between ergonomic physical and psychosocial exposures and the danger of predominant and occurrence low back torment (LBP) in a longitudinal companion of car fabricating laborers and found that unbalanced back stance, hand drive, physical exertion and entire body vibration were each related cross-sectionally with LBP. Janwantanakul et al.[11] performed a review to recognize chance components for the beginning of low back agony (LBP) in office laborers and found that LBP was caused by few factors such as previous history, work related and psychosocial risk factor. Manchikanti et al.[12] contemplated the pervasiveness of low back pain in adults and found that comorbid factors with mental disarranges and different medicinal issues, including heftiness, smoking, absence of activity, expanding age, and way of life factors, are considered as hazard factors for low back pain. Coenen et al.[13] examined the imminent relationship of combined low back burdens with LBP and found huge affiliation between lifting and working in a flexed stance with LBP. Yu et al.[14] depicts the recurrence of event work related muscle pain among assembly line laborers in Shenzhen, China and found that long work hours, high mental worry at work and past damage history were critical hazard factors for work related pain. Fujii et al.[15] evaluated low back pain (LBP) predominance in a Japanese grown-up populace and found that Smoking, bring down instructive dimension, history of impairing back agony among relatives, word related LBP, traffic damage, repaid work damage, emanating torment and low back medical procedure were related with LBP over a lifetime.Das et al.[16] evaluated the commonness of low back pain (LBP) among brick field workers and found that LBP happened among female laborers because of cumbersome stance and dreary work.

PT Maruki International Indonesia is a branch of a company in Indonesia that exports Butsudan. Butsudan is furniture that serves as a place to respect and communicate with deceased ancestors. Most of the production process still relies on human power, such as wood cutting, refining, gluing, coloring, assembly and packaging. In doing its work, workers always work in a standing position long enough or sit with their backs bent. Working conditions like this force workers to always be in an attitude and position that is not natural that lasts long and settles/static. In addition, some of the seats used do not meet the standards because they do not have a backrest. Such work positions are very risky to cause work risks in ergonomics which can lead to complaints of low back pain. Thus, this work aims to determine the risk factors associated with complaints of low back pain in workers at PT Maruki International Indonesia Makassar City in 2017.

Methodology

Type of Research: The type of research used is observational analytic with the cross sectional approach. The dependent variable in this study is complaints of low back pain and the independent variables are work attitude, age, years of service, body mass index (BMI) and smoking habits.

Time and Location of Research: The study was conducted on January 21-25, 2017. The location of this study was at PT Maruki International Indonesia, Makassar City.

Population and Sample: The population in this study were employees of PT Maruki International Indonesia who worked in a production unit of 300 people divided into six factories. Determine the minimum sample so that this research is valid, the researcher uses the formula from Stanley Lemeshow. Thus, then the sample size computed for this study is 72. This study uses purposive sampling.

Data Collection: Data collection carried out in this study is primary data collection and secondary data. Primary data is data obtained through questionnaire. Secondary data was attained in terms of company profile of PT Maruki International Indonesia Makassar City.

Data Analysis: Data processing was doneusing the SPSS program. Analysis was conducted to determine the relationship of work attitudes, age, years of service, Body Mass Index (BMI) and smoking habits with complaints of low back pain using the Chi Square test. Taking hypothesis acceptance decisions based on a significant level (α value) of 95%. If the value is> 0.05, the research hypothesis is accepted. Conversely, if P value is <0.05, the research hypothesis is rejected.

Result and Discussion

Relationship between Work Attitudes and Low Back Pain Complaints (LBP): The data in Table 1 shows that more workers who experience LBP complaints in collapsing work positions than workers who are classified as job positions are not at risk. When viewed from a working position, workers with more risky work positions experience complaints compared to those who do not experience complaints. The results of data analysis using the fisher exact test obtained a value of p = 0,000 (p <0.05), it can be concluded that Ho is rejected so that there is a relationship of work position with LBP complaints on workers at PT Maruki International Indonesia Makassar City. The outcome of this work is inline with the work done by Das[16] which stated that body posture has a significant effect on LBP.

Table 1: Relationship between Work Attitudes and Low Back Pain Complaints on Workers

Work Attitudes	LBP complaints				Total		P value
	There is a complaint		No complaints				
	n	%	n	%	n	%	
At risk	48	84.2	9	15.8	57	100	0.000
Not at risk	1	6.7	14	93.3	15	1100	
Total	49	68.1	23	31.9	72	100	

Age Relationship with Low Back Pain Complaints (LBP): Based on data in Table 2, results shows that more workers experience LBP complaints in high risk age categories (≥ 35 years) than workers with low risk categories (<35 years). The results of data analysis using the chi square test obtained a value of p = 0.594 (p> 0.05), it can be concluded that Ho is accepted so that there is no relationship of age with complaints LBP on workers at PT Maruki International Indonesia Makassar City. The outcome of this work is inline with the review done by Janwantanakul et al[11] as age had minimal significance with LPB occurrences.

Table 2: Relationships between Age with Low Back Pain Complaints for Workers

Age	LBP complaints				Total		P value
	There is a complaint		No complaints				
	n	%	n	%	n	%	
At risk	35	70	15	30	50	100	0.594
Not at risk	14	63.6	8	36.4	22	1100	
Total	49	68.1	23	31.9	72	100	

Relationship between Years of Service and Low Back Pain Complaints (LBP): Based on the data in Table 3, results shows that more workers experience LBP complaints in the old working period (≥ 5 years) than workers belonging to the new employment period (<5 years). The results of data analysis using the fisher exact test obtained a value of p = 0.010 (p <0.05), it can be concluded that Ho is rejected so that there is a relationship of work period with LBP complaints on workers at PT Maruki International Indonesia Makassar City. The outcome of this work is inline with Yu et al. [14] where it was stated that work period is significant for LBP.

Table 3: Relationship of Years of service with Low Back Pain Complaints For Workers

Years of service	LBP complaints				Total		P value
	There is a complaint		No complaints				
	n	%	n	%	n	%	
Long	46	74.2	16	25.8	62	100	0.010
New	3	30.0	7	70.0	10	1100	
Total	49	68.1	23	31.9	72	100	

Relationship between Body Mass Index (BMI) and Low Back Pain Complaints (LBP): Based on Table 4, results shows that workers who experience complaints are more in the normal BMI category (18.5 - 25) than abnormal BMI (<18.5 or> 25). The results of data analysis using the chi square test obtained a value of p = 0.036 (p <0.05), it can be concluded that Ho is rejected so that there is a relationship between BMI and LBP complaints. The outcome of this work is inline with the work done by Yu et al.[14] as it was reported that although the effect is relatively small, body weight, height and muscle mass are factors that can cause complaints of skeletal muscles pain and LBP.

Table 4: Relationship between Body Mass Index (BMI) and Low Back Pain Complaints (LBP)

BMI	LBP complaints				Total		P value
	There is a complaint		No complaints				
	n	%	n	%	n	%	
Not Normal	19	55.9	15	44.1	34	100	0.036
Normal	30	78.9	8	21.1	38	1100	
Total	49	68.1	23	31.9	72	100	

Relationship between Smoking Habits with Low Back Pain Complaints (LBP): Based on Table 5, results shows that more respondents experienced LBP complaints in the high risk category than the low risk category. The results of data analysis using the chi square test obtained a value of p = 0.715 (p> 0.05), it can be concluded that Ho was accepted so that there was no correlation between smoking habits and LBP complaints in workers at PT Maruki International Indonesia Makassar City. However the outcome of this work was not inline with work done by Fujii et al.[15] where is was said that smoking is a significant factor for LBP.

Table 5: Relationship between of Smoking Habits with Low Back Pain Complaints on Workers

Smoking	LBP complaints				Total		P value
	There is a complaint		No complaints				
	n	%	n	%	n	%	
High Risk	17	65.4	9	34.6	26	100	0.715
Low Risk	32	69.6	14	30.4	46	1100	
Total	49	68.1	23	31.9	72	100	

Conclusion

Based on the results of this work, it can be concluded that work attitudes, years of service, and body mass index (BMI) are associated with complaints of low back pain on workers at PT Maruki International Indonesia Makassar City in 2017. However, age and smoking habits not related to complaints of low back pain to workers at PT Maruki International Indonesia Makassar City in 2017. In addition, the authors recommend that the company managers provide information about ergonomic work positions, make adjustments to work desks and work benches with users and add backs for seats that do not yet have a backrest to avoid LBP.

Relationship of Marketing Mixes and Utilization of Dental Poly in KassiKassi Health Center

Sitti Arabiyah Yunus[1], Darmawansyah[1], Nurhayani[1]

[1]Administration and Health Policy, Faculty of Community Health, Hasanuddin University

ABSTRACT

The success of health services is determined by the management's ability to take advantage of opportunities that exist in the community and manage the existing marketing mix. Thus, this work reports the relationship between Marketing Mix and Utilization of Dental Poly in KassiKassi Health Center. This type of research is quantitative research with an observational analytical approach with Cros Sectional design that aims to determine the relationship of independent variables with dependent variables. As for the variables in this study, namely products, prices, places/locations, promotions, people/health workers, processes, physical facilities and utilization of poly dental services. The population in this study were patients who visited KassiKassi's poly dental services from March to April 2017 were 94 people. Chi-Square and Fisher's analysis test results showed that in this study the variables related to the utilization of dental poly in theKassiKassi Health Center were products (p = 0.00), price (p = 0.00), place/location (p = 0,00), promotion (p = 0,00), persons/health personnel (p = 0,00), and process (p = 0,00). While the variables that are not related to the utilization of dental poly in KassiKassiHealth center are physical facilities (p = 0.019).

Keywords: *Marketing mixes; dental; poly; product; patient*

Introduction

Oral and dental health is an integral part of complete human health, thus efforts in the field of dental health will ultimately play a role in improving the quality and productivity of human resources[1].

According to WHO tooth decay is still a major health problem for most industrialized countries because the problem affects 60% -90% of school-age children and most adults[2]. It has been reported that dental caries is the most common infectious disease in children around the world. Where at the time of entering elementary school: 50% of children suffer from caries[3,4].

The definition of health services is many kinds. In the opinion of health services are any efforts that are held alone or jointly in an organization to maintain and improve health, prevent and cure diseases and restore the health of individuals, families, groups and or communities[5,6]. Health centers need to design marketing programs so that products get a response from the target market. Because it needs tools, so that the program reaches the target[7]. The tool here is a program that can be controlled by the organization, the tool is commonly called the marketing mix[8]. The marketing mix defined as a set of marketing tools used by companies to achieve marketing goals within the target market. Marketing mixes are controlled variables that can be used by companies to influence consumers of certain market segments that the company is aiming for[9].

There are several studies based on marketing mixes for health centres. Purcărea et al.[10] investigated the use Servqual scale to characterize the statistic profiles of social health service users who utilized open administrations in Romania. Elg et al.[11] assessed a model for the procedure of patient co-creation and diverse instruments through which healthcare specialist can gain from the patient. Abedi et al.[12] examinedthe marketing mixes components on patients' inclination to the emergency clinics utilizing diagnostic chain of importance process and found that the principle critical variables were cost, physical resources. benefit, services, individuals and management. Abedi et al.[13] has reviewed the effect of marketing mixes in patients' propensity towards the general population and private clinics in Sari and found that medical cost and staff's administration was noteworthy factor in picking clinic. Hyder et al.[14] presented a review on medicinal services benefit showcasing between Brazil, China and Philippines and

found that treatment, benefit quality and trust was a factor that impacts quiet decisions. Keyvanara et al.[15] evaluated the role of institutions and its marketing strategies on the demand of their products by patients. Yaghoubi et al.[16] displayed a precise survey of elements in influencing medicinal services administrations showcasing in Iran and found that nature of gave administrations, bring down costs, benefit accessibility, as huge variables for health care promotion. Hosseini et al.[17] analyzed the propensity Of patients toward private Clinic and found that individuals, physical proof, effectiveness, profitability and quality are the essential variables for patient in picking a health center.

Thus health care marketing is an overall system of activities - business activities aimed at planning, pricing, promoting, and distributing goods and services that can satisfy the needs of the patients and users. KassiKassi Health Center[18] is a Nursing Health Center and based on the annual KassiKassi Health Center data report, the number of visits in dental polyclinic services in the last three years has decreased, namely in 2013, which was 4,418, in 2014 which was 3,519 and in 2015, 3,259[18].

Based on the description above and in order to improve the utilization of poly dental health services, it is necessary to have a better marketing strategy which will affect patients in utilizing health services at KassiKassi Community Health Center. Therefore, thus, this work has examined the relationship of marketing mixtures with the utilization of dental poly in the KassiKassi health center.

Methodology

Research Design: This study is a quantitative study with an observational analytical approach with a cross sectional design with the intention of identifying the variables to be studied, namely knowing the relationship of the marketing mix with the utilization of dental poly at the KassiKassi Health Center in Makassar City.

Research Location: This research was conducted at the KasiKassi Health Center in Makassar City, South Sulawesi. This research was conducted on 13 March 2017 - 13 April 2017.

Population and Sample: The population in this study was a dental poly patient at the KassiKassi Community Health Center, Makassar City. As for the number of dental poly patients in 2015, 3259 patients.The sample in this study is the patient in Makassar's KassiKassi Community Health Center utilizing dental poly services. The sample size of this work is n=94.

Data Collection: Primary data is obtained by directly visiting respondents who are in the KassiKassi Health Center. The tool used is using a questionnaire by giving a set of questions or written statements to the respondent to answer. Secondary data was obtained from documents and reports of patients visit with dental and oral diseases at KassiKassi health center.

Data Analysis: In this study, bivariate analysis was used to determine the relationship between the marketing mix and the use of dental poly using the SPSS program with Chi-Square and Fisher statistical tests.

Result and Discussion

Relationship between Product with the Usage of Dental Poly: Based on Table 1, result shows that of the 94 respondents who stated good products and used dental poly services were 70 respondents (100%) and those who stated good and not utilizing were 0 respondents (0%). The results of statistical tests using Fisher obtained a value of p = 0.00 <0.5 so Ho was rejected and Ha was accepted. This shows that there is a relationship between the product and the utilization of poly dental services at KassiKassi Health Center. The outcome of this work is inline with Hosseiniet al.[17] that showed product is a significant factor.

Table 1: Relationship between Product with the Utilization of Dental Poly

Product	Utilization of Dental Poly				Total		P value
	Yes		No				
	n	%	n	%	n	%	
Good	70	100	0	0.0	70	100	0.000
Not Good	4	16.7	20	83.3	24	1100	
Total	74	78.7	20	21.3	94	100	

Relationship between Price with Utilization of Dental Poly: Based on Table 2, result showed that shows that of the 94 respondents who stated that the price is good and utilizing dental poly services were 69 respondents (93.2%) and those who stated that they were good and did not use were 5 respondents (25.5%). The results

of statistical tests using Fisher obtained a value of p = 0.00 <0.5 so Ho was rejected and Ha was accepted. This shows that there is a relationship between price and utilization of poly dental services at KassiKassi Health Center. The outcome of this work is inline with Abedi et al.[13] that showed price is a significant factor.

Table 2: Relationship between Pricewith the Utilization of Dental Poly

Price	Utilization of Dental Poly				Total		P value
	Yes		No				
	n	%	n	%	n	%	
Good	69	93.2	5	25.5	74	100	0.000
Not Good	5	6.8	15	75.0	20	1100	
Total	74	100	20	100	94	100	

Relationship between Place with Utilization of Dental Poly: Based on Table 3, result showed that of the 94 respondents who stated that the place/location was affordable and utilizing dental poly services were 72 respondents (100%) and those who stated that they were good and did not use were 0 respondents (0.0%). The results of statistical tests using Chi Square obtained a value of p = 0.00 <0.5 so Ho was rejected and Ha was accepted. This shows that there is a relationship between place/location and utilization of poly dental services at KassiKassi Health Center. The outcome of this work is inline with Abedi et al.[12] that showed place is a significant factor.

Table 3: Relationship between Place with the Utilization of Dental Poly

Place	Utilization of Dental Poly				Total		P value
	Yes		No				
	n	%	n	%	n	%	
Affordable	72	100	0	0.0	72	100	0.000
Not Affordable	2	9.1	20	90.9	22	1100	
Total	74	100	20	100	94	100	

Relationship between Promotion with Utilization of Dental Poly: Based on Table 4, results shows that of the 94 respondents who stated that promotion and utilizing dental poly services were 69 respondents (100%) and those who stated that they were good and not utilizing were 0 respondents (0.0%). The results of statistical tests using Chi Square obtained a value of p = 0.00 <0.5 so Ho was rejected and Ha was accepted. This shows that there is a relationship between promotion and utilization of poly dental services at KassiKassi Health Center. The outcome of this work is inline with Hosseini et al.[17] that showed promotion is a significant factor.

Table 4: Relationship between Promotion with the Utilization of Dental Poly

Promotion	Utilization of Dental Poly				Total		P value
	Yes		No				
	n	%	n	%	n	%	
Good	69	100	0	0.0	69	100	0.000
Not Good	5	20.0	20	80	25	1100	
Total	74	100	20	80	94	100	

Relationship between People with Utilization of Dental Poly: Based on Table 5, result showed that out of 94 respondents who stated that people/health personnel and utilizing dental poly services were 73 respondents (92.4%) and those who stated that they were good and did not use as much as 6 respondents (7.6%). The results of statistical tests using Fisher obtained a value of p = 0.00 <0.5 so Ho was rejected and Ha was accepted. This shows that there is a relationship between people/health workers with the utilization of poly dental services at KassiKassiHealth Center. The outcome of this work is inline with Abedi et al.[13] and Hosseini et al.[17] that showed people and health personnel is a significant factor.

Table 5: Relationship between People with the Utilization of Dental Poly

People	Utilization of Dental Poly				Total		P value
	Yes		No				
	n	%	n	%	n	%	
Good	73	92.4	6	7.6	79	100	0.000
Notgood	1	6.7	14	93.3	15	1100	
Total	74	100	20	100	94	100	

Relationship between Process with Utilization of Dental Poly: Based on Table 6, results shows that of the 94 respondents who stated that the health process and utilizing dental poly services were 69 respondents (98.6%) and those who said that they were good and not utilizing were 1 respondent (1.4%). The results of statistical tests using Chi Square obtained a value of p

= 0.00 <0.5 so Ho was rejected and Ha was accepted. This shows that there is a relationship between the health process and the utilization of poly dental services at KassiKassi Health Center. The outcome of this work is inline with Abedi et al.[12] that showed process is a significant factor.

Table 6: Relationship between Process with the Utilization of Dental Poly

Process	Utilization of Dental Poly				Total		P value
	Yes		No				
	n	%	n	%	n	%	
Good	69	98.6	1	1.4	79	100	0.000
Not good	5	20.8	19	79.2	24	100	
Total	74	100	20	100	94	100	

Relationship between Physical Facilities with Utilization of Dental Poly: Result showed that of the 94 respondents who stated that the health process and utilizing dental poly services were 70 respondents (82.4%) and those who stated that they were good and did not use as many as 15 respondents (17.6%). The results of statistical tests using Fisher obtained a value of p = 0.08> 0.5 so Ho was accepted and Ha was rejected. This shows that there is no relationship between physical facilities and the utilization of poly dental services at KassiKassi Health Center.

Conclusion

Based on the results of the analysis of the study, there is a relationship between the product, price, place, promotion, people, and process with the utilization of dental poly in the KassiKassi Health Center in Makassar City. However, there is no relationship between physical facilities and the utilization of dental poly at the KassiKassi Health Center in Makassar City with a value of p = 0.019. Thus, it is recommended to KaasiKaasi Health center to further improve health services, especially in dental polyclinics and health centers, that are more likely to maintain products, prices, promotions, processes.

Factors Related to the Fatigue in Workers in the Cargo Unit of Pt. AngkasaPura Logistic Makassar

Syur Aulia Jufri[1], Andi Wahyuni[1], Muhammad Rum Rahim[1]

[1]Work Safety and Health Department, Faculty of Community Health, Hasanuddin University

ABSTRACT

Fatigue showed different condition to each individual that can lead to loss of efficiency and a reduction in work capacity and endurance. In this work, the fatigue in of workers in the cargo unit of Pt. AngkasaPura Logistic Makassarwas analyzed. This work is an observational analytic with cross sectional study aimed to determine the relationship of age, energy intake, workload, and work attitude with fatigue in workers in cargo unit. The number of samples were 51 people. Questionnaire was utilized for data collection. SPSS program was used for data analysis. The results showed that there was a relationship between age P = 0.004 (p <0.05), the workload of p = 0.004 (p <0.05), energy intake P = 0.004 (P <0.05) and workload of P = 0.000 (P <0.05) with fatigue workers. Based on the result of research that has been done can be concluded that there is relationship between age, workload, energy intake and work attitude with fatigue in cargo unit at the PT. AngkasaPura LogisticMakassar in 2017.

Keywords: *Fatigue work; cargo unit; workers; load*

Introduction

Technological advances have raised standards and quality of human life better through increased production and work productivity[1]. On the other hand, technological advances have also resulted in a variety of adverse impacts, namely in the form of an increase in environmental pollution, workplace accidents and the emergence of various kinds of occupational diseases[2]. Overcoming these problems requires a high performance of human resources[3].

Besides the increasingly sophisticated aspects of technology, the progress of industrialization in the world cannot be separated from the role of labor. Labor is an asset for companies in work activities[4]. Activities carried out in the form of physical and mental activity. Work capacity that is not in accordance with the workload carried out will speed up someone feeling tired. Labor has a role and position that is very important as an actor and development goal[5]. The involvement of humans, especially labor in the development process is increasing[6].In order for workers to be healthy and productive, the role of occupational health and safety becomes increasingly important. The purpose of occupational health is to create a healthy and productive workforce. This goal can be achieved if supported by a work environment that meets health requirements[7].

Problems that involve the workforce if not addressed immediately will cause physical fatigue as a result of short-term and psychological fatigue as a result of its long-term[8]. Physical fatigue is characterized by weak body muscles, difficult to move and sometimes accompanied by pain and dizziness. This is usually caused by the weight of the workload, the length of sitting, the length of use of certain physical parts such as hands, feet, eyes, and ears[8]. Continuing without treatment for recovery, such as exercise, can cause a decrease in stamina, easy emotions, lazy work and difficulty sleeping[9].

Fatigue is a condition that is accompanied by a decrease in efficiency and endurance at work. Fatigue shows different conditions of each individual, but all lead to loss of efficiency and decrease in work capacity and fatigue is a mechanism for protecting the body so that the body avoids further damage, resulting in recovery[10].

Studies has been reported on work fatigue analysis and its outcome. Fernandes-Junior et al.[11] evaluated the rest time, weakness and personal satisfaction of night shift workers and confirmed the connection between these factors with the presence or absence of kids in various age, and found that laborers without kids had higher rest time amid the working days. These laborers

additionally were more averse to feel exhausted amid night work than workers with kids. Pinetti et al.[12] analysed if the fatigue of the workers can be reduced with exercise and ergonomic conditions and found that workers whom performed exercise showed less fatigue compared to those who did not exercise. Yu et al.[13] analyzed the work fatigue of workers in the furniture industry using simulation software and found that improved ergonomics and work flow reduces the fatigue of the workers. Lee et al.[14] decided the burdensome manifestations and their relationship with rest quality, word related pressure and fatigue among the workers and found that workload contributed to fatigue and depression. Gell et al.[15] broke down the hazard factors for lower extremity fatigue among industry workers and found that fatigue among workers was related with a higher pervasiveness of smoking, rheumatoid joint inflammation and work dissatisfaction. Thomas et al.[16] examined the empathy fatigue among clinical social specialists and found that higher individual pain is related with higher sympathy fatigue among the clinical labourers. Hwang et al.[17] studied the impacts of rest quality, discouragement and fatigue on occupation stress of geriatric medical clinic specialists and found that the most dominant indicator of employment stress was fatigue. Wang et al.[18] inspected the mental and physiological fatigue variety in airline maintenance laborers and found that enhancing workplaces may additionally diminish the apparent exhaustion of maintenance crew. Hébert et al.[19] evaluated rest, light introduction designs, social rhythms, and business related fatigue of student workers and found that absence of rest lead to the weariness in student workers.

PT. AngkasaPuraLogistik is a company engaged in logistics in Indonesia. Work processes in cargo units include receiving goods, weighing goods, making/ checking transport documents, storing goods in warehouses until the time is put into cargo compartment aircraft, withdrawal of goods from warehouse to aircraft and vice versa, a series of work processes carried out by these workers can lead to fatigue in workers that can affect productivity. Thus in this work, the fatigue in workers in the cargo unit Pt. AngkasaPura Logistic Makassar was analyzed. The purpose of this study was to determine the factors associated with work fatigue in workers in the cargo unit.

Methodology

Types of Research: The type of research used is an observational analytic study with a cross sectional study approach, which aims to see the relationship of independent variables to the dependent variable, namely the relationship of age, energy adequacy, workload and work attitude to workers in the cargo unit of PT. AngkasaPura Logistic Makassar.

Time and Location of Research: This research was conducted in January - February 2017 located in the cargo unit of PT. AngkasaPura Logistic Makassar.

Population and Sample: The population in this study were all workers in the cargo unit of PT. AngkasaPuraLogistic Makassar. The number of samples computed was 51 people who are all workers in the cargo unit of PT. AngkasaPura Logistic. The sampling technique is using simple random sampling technique.

Data Collection: The data used in this study comprised of primary data and secondary data. Primary data was collected through questionnaire that was distributed to the samples. Secondary data obtained from the General Manager of PT. AngkasaPura Logistic in the form of data on company profiles, work processes and data on the number of workers in the cargo unit.

Data Analysis: Data analysis performed using SPSS. The data analysis model performed is Bivariate analysis was performed on two variables that were suspected to be related. Data analysis was performed using statistical tests namely Chi Square.

Result and Discussion

Age Relationships with Work Fatigue: Based on this work, the data obtained regarding the relationship of age with work fatigue and it cross tabulation can be seen in Table 1. Result in Table 1 shows that the percentage of respondents who experience more fatigue in workers with a decreased physical resistance category (> 25 years) is 21 workers (77.8%) compared to workers with good physical resistance (≤ 25 years) are 5 workers (20.8%). While the percentage of respondents who did not experience fatigue, most of the workers including the category of good physical security (≤ 25 years) were 19 workers (79.2%) while workers with decreased physical resilience (> 25 years) were only 6 workers (22.2%). Based on data analysis using the chi-square test, the

value of p = 0.000 (p <0.05) means that Ho is rejected and Ha is accepted, so it can be interpreted that there is a relationship between age and the occurrence of work fatigue in the cargo unit of PT. AngkasaPura Logistic Makassar.

Table 1: Relationship between Age and Work Fatigue for Workers

Age	Work Fatigue				Total		P value
	Yes		No				
	n	%	n	%	n	%	
Decreased Physical Resilience (> 25 years old)	21	77.8	6	22.2	27	100	0.000
Good Physical Resilience (Age ≤ 25 years)	5	20.8	19	79.2	24	100	
Total	26	51	25	49	51	100	

Relationship between Workload and Fatigue: Based on this work, the data obtained regarding the relationship of age with work fatiguecan be seen in Table 2. Results in Table 2 shows that the majority of respondents who experienced fatigue were workers with a heavy workload of 23 people (74.2%) compared to workers with a light workload of 3 people (15.0%). While the majority of the respondents who did not experience fatigue were workers with a light workload of 17 workers (85%) compared to workers with a heavy workload of 8 workers (25.8%).Based on data analysis using the Fisher Exact Test, the value of p = 0.000 (p <0.05) means that Ho is rejected and Ha is accepted, so that it can be interpreted that there is a relationship between workload and work fatigue in the cargo unit of PT. AngkasaPura Logistic Makassar.

Table 2: Relationship between Workload and Work Fatigue for Workers

Work load	Work Fatigue				Total		P value
	Yes		No				
	n	%	n	%	n	%	
Weight (≥100 beats/minute)	23	74.2	8	25.8	31	100	0.000
Mild (<100 beats/minute)	3	15	17	85	20	100	
Total	26	51	25	49	51	100	

Relationship between Energy Intake and Fatigue: Based on this work, the data obtained regarding the relationship of energy intake with work fatigue. can be seen in Table 3. Results in Table 3 shows that the percentage of respondents who experience more fatigue in workers with an energy intake that does not meet is 20 people (74.1%) compared to workers with fulfilling energy intake is 6 people (25.0%). While the percentage of respondents who did not experience more fatigue in workers with an energy intake category that fulfilled was 18 workers (75%) compared to workers with fulfilling energy intake were 7 workers (25.9%). Based on data analysis using the chi-square test, the value of p = 0.000 (p <0.05) means that Ho is rejected and Ha is accepted, so it can be interpreted that there is a relationship between energy intake and work fatigue in workers in the cargo unit of PT. AngkasaPura Logistic Makassar.

Table 3: Relationship between Energy Intake and Fatigue in Workers

Energy	Work Fatigue				Total		P value
	Yes		No				
	n	%	n	%	n	%	
Does not Meet	20	74.1	7	25.9	27	100	0.000
Meets	6	25	18	75	24	100	
Total	26	51	25	49	51	100	

Relationship between Work Attitudes and Fatigue: Result in Table 4 shows that the percentage of respondents who experience more fatigue in workers with non-ergonomic work attitudes is 24 workers (85.7%) compared to workers with ergonomic work attitudes as much as 2 workers (8.7%). While the percentage of respondents who did not experience more fatigue in workers with

ergonomic work attitudes was 21 workers (91.3%) compared to workers with non-ergonomic work attitude were 4 workers (14.3%). Based on the data analysis using Fisher's Exact Test, the value of p = 0.000 (p <0.05) means that Ho is rejected and Ha is accepted, so that it can be interpreted that there is a relationship between work attitudes and work fatigue in workers in the cargo unit PT. AngkasaPura Logistic Makassar.

Table 4: Relationship between Work Attitudes and Work Fatigue for Workers

Work Attitude	Work Fatigue				Total		P value
	Yes		No				
	n	%	n	%	n	%	
Not ergonomic	24	85.7	4	14.3	28	100	0.000
Ergonomic	2	8.7	21	91.3	23	100	
Total	26	51	25	49	51	100	

Conclusion

Based on the results of the research and analysis of the variables studied about factors related to work fatigue in workers in the cargo unit of PT. AngkasaPura Logistic Makassar, conclusions can be drawn as follow. There is a relationship between age, workload, energy intake and work attitude with work fatigue on workers in the cargo unit of PT. AngkasaPura Logistic Makassar. Thus, it is recommended that the management of the company needs to conduct training for workers regarding ergonomic work attitudes when carrying out work activities primarily on workers who lift, pull and move goods because they have a heavier workload and improve the overall work output and reduce fatigue.

Relationship of Climate Factors with Diarrhea Evaluation in City of Makassar

Tri Hastuti Handayani[1], Anwar Daud[1], Makmur Selomo[1]

[1]Faculty of Community Health, Hasanuddin University, Makassar

ABSTRACT

Diarrhea is still a public health problem in developing countries like Indonesia. Environment is one of the determinants of the occurrence of diseases due to uncertain climate change. The purpose of this study was to determine the relationship of climate factors (air temperature, humidity, and rainfall) with the incidence of diarrhea in Makassar City. This study used an ecological study design with univariate and bivariate analysis. Bivariate analysis using correlation analysis. The study sample is the number of months in five years from 2011-2015, which is 60 months. Univariate results show that the average air temperature of Makassar City in 2011-2015 has increased every year, while humidity and rainfall in general have decreased. The results of bivariate analysis showed that there was a relationship between humidity (p = 0,000; r = 0,501) and rainfall (p = 0,001; r = 0,429) with the incidence of diarrhea in Makassar City in 2011-2015 with a moderate strength relationship. While the temperature variable has no relationship with the incidence of diarrhea in Makassar City in 2011-2015 (p = 0.113).

Keywords: *Air Temperature; Humidity; Rainfall; Diarrhea*

Introduction

Humans as living beings are very dependent on the environment for their survival[1]. An easy example, living things need an environment to live in and fulfill their metabolic needs. Therefore, living things have a very close relationship with nature. Right now our nature is being hit by uncertainty about weather and climate or what is called climate change[2].

Climate change or better known as global warming is often considered the same, but has different meanings[3]. Because climate parameters are not hot, there are other parameters such as rainfall, cloud conditions, wind, and sunlight radiation. The occurrence of climate change is inseparable from natural factors and the consequences of human activities[3]. Climate change occurs due to an increase in greenhouse gases. The increase in greenhouse gases is predominantly caused by industry, especially in the fields of forestry, peat land, waste, agriculture, transportation, and energy[4]. Increased greenhouse gases have an effect that will accelerate the process of global warming and increase the frequency of extreme weather events[2-4].

The current global environmental problem is the increase in greenhouse gas (GHG) emissions, especially carbon dioxide (CO_2), methane (CH_4), and nitrous oxide (N_2O)[5]. Changes in composition of some of these gases will lead to climate change. This causes the conditions on the surface of the earth to become unstable[6]. The temperature on the earth's surface is increasing and it is estimated that in 2020 the increase in earth's temperature can be 2°C[7].

The greenhouse effect occurs because the sun's rays in the atmosphere vibrate the molecules of greenhouse gases so that the solar radiation energy is absorbed by the molecule. The energy of solar radiation that should be reflected back into space. The presence of greenhouse gases, the solar radiation energy is held in the atmosphere and causes an increase in the temperature of the earth[6,7].

Global climate change affects human health through varied and complex roads, in different scales and time frames. Some of the diseases that have increased due to climate change include mosquito-borne diseases that can cause dengue fever, malaria, chikungunya, and others[8]. Diseases due to increased environmental temperature and pollutants result in acute respiratory infections, malnutrition to malnutrition, heart disease, respiratory diseases, asthma, allergies, and other chronic pulmonary diseases[8]. Then the lack of availability of clean water results in diarrhea and skin diseases.

Water is one of the most important components in the survival of human life and other living things[9]. Water has the ability or direct influence on humans, especially human health. The health effects depend heavily on the quality of water used and water can also function as a distributor or spreader of diseases[9]. Diseases transmitted through water are called waterborne disease. The occurrence of an illness certainly requires agents and sometimes vectors[9].

The causes of diarrhea diseases vary, can be caused by a virus, where the virus attaches to the surface of the intestinal mucous cells and causes damage to the intestinal cells. Absorption of the intestine decreases and the release of water and electrolytes increases[8,9].

Several studies has been reported on association of climate change and diarrhea. Chou et al.[10] explored and evaluated the connection between climate changes and diarrhea related issue in Taiwan where it dissected the neighbourhood climatic factors and the quantity of diarrhea related contamination cases. Moors et al.[11] evaluated the effect of environmental change on diarrhea as a delegate of a waterborne irresistible ailment influencing human wellbeing in the Ganges bowl of northern India. Alexander et al.[12] assessed month to month reports of diarrheal ailment among patients showing to Botswana wellbeing offices and contrasted this with climatic factors. Kolstad et al.[13] demonstrate a strategy to evaluate a scope of conceivable wellbeing effects of environmental change on diarrhea while taking care of vulnerabilities in an unambiguous way. Phung et al.[14] assessed the diarrhea and climate change relationship in Can Tho city, Mekong Delta region in Vietnam where waterborne infection frequently takes place. Levy et al.[15] reviewed of connections between Diarrheal Diseases and Temperature, Rainfall, Flooding, and Drought brought about by environmental change. Xu et al.[16] utilized the information on satellite remote detecting temperature and dissected the impact of temperature on children diarrhea. Wu et al.[17] analyzed the logical confirmations on the effect of environmental change on human irresistible illnesses and how human culture may react to, adjust to, and plan for the related changes. Bhandari et al.[18] evaluated the connection between climatic factors, and jungle fever and discovered the scope of non-climatic variables that can frustrate the relationship of environmental change and human wellbeing.

Based on diarrheal disease data in the Makassar City Health Office in 2015, through recording and reporting on morbidity from year to year it was found that diarrhea was among the highest ten diseases in Makassar in 2011 with 37,940 cases, in 2012 it dropped to 29,265 cases, in 2013 as many as 28,908 cases, in 2014 there were 26,485 cases and increased again in 2015 by 28,257 cases according to gender. Thus in this study was done to evaluate the relationship of climate factors (air temperature, humidity, and rainfall) to the incidence of diarrhea in Makassar City in 2011 - 2015.

Methodology

Research Concept Framework: In this concept framework consists of independent variables and dependent variables. This research was carried out based on framework as shown in Figure 1. The independent variable of this work is air temperature, humidity and rainfall. The dependent variable of this work is diarrhea events.

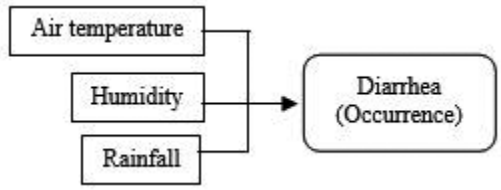

Figure 1: Conceptual framework

Type of Research: This research is a time series study of time is a study design that is used to see the relationship of the frequency of morbidity or mortality due to a disease that occurs in the community over time. While based on the level of analysis this study uses correlation analysis methods

Time and Location of Research: The research location is in the Makassar City area, with 14 sub-districts. The location was used as the location of the study taking into account that diarrhea cases were among the 10 highest diseases in Makassar City. The timing of data collection and processing is carried out during January-February 2017.

Population and Samples: The population in this study is the number of months in the period 2011-2015 from the data that will be used, namely data on air temperature, rainfall, air humidity, and the incidence of diarrhea. The sample in this study was the number of months in the five-year period namely in 2011-2015 which was namely 60 months. In this study total sampling was carried out because the population was taken all for analysis.

Data Collection: The data used in this research is secondary data. Data collection of diarrheal diseases was carried out by taking secondary data from the Makassar City Health Office. Diarrhea data contains all sub-districts in Makassar City. While data on climate factors (air temperature, humidity, and rainfall,) were obtained from the Office of the Meteorology and Geophysics Agency of Region IV Makassar in the form of monthly reports during 2011-2015.

Data Analysis: Climate data and diarrhea case data are obtained in the form of monthly data were processed using SPSS software. Statistically bivariate analysis using correlation was done to analyze the degree or closeness of the relationship between climate factors including air temperature, humidity, and rainfall with diarrhea cases in Makassar City and find out the relationship between two variables. Correlation test was done to determine the correlation coefficient (r), while the correlation requirements are interval/ratio data scale and normally distributed data. The correlation coefficient that has been produced is the first step to explain the degree of linear relationship between two variables. Then test the hypothesis to find out whether the relationship between the two variables is significant.

Result and Discussion

Normality Test: One of the correlation test requirements is that the data must be normal. Based on the table below for data on air temperature, humidity, and prevalence of diarrhea having normal data because p value> $\alpha = 0.05$. While for rainfall data has abnormal data so that the spearman correlation test is used. This can be seen in the following Table 1.

Table 1: Data Normality Test

Variable	p value
Air temperature	0.200
Humidity	0.76
Rain Fall	0.00
Diarrhea prevalence	0.61

Relationship between air temperature and diarrhea incidence rate: The correlation test results between the air temperature and the incidence of diarrhea in Makassar City in 2011 – 2015is shown in Table 2. Thus results shows that the average monthly temperature with the incidence of diarrhea cases shows a weak relationship (r = -0,196) with a negative pattern that can be interpreted as higher average In fact, fewer cases of diarrhea occur. The results of further statistical tests also explain that the insignificant relationship between temperature and incidence of diarrhea cases with (p = 0.113) is greater than $\alpha = 0.05$. This means that there is no significant relationship between air temperature and the incidence of diarrhea in Makassar City in 2011 - 2015. Thus the outcome of this work is inline with the work done by Levy et al.[15] which reported that temperature has minimal influences on the occurrence of diarrhea.

Table 2: Relationship between Average Temperature and Diarrhea Incidence Rate

Variable	r	p value
Temperature	-0.196	0.113

Relationship between humidity with the incidence of diarrhea: The correlation between humidity and diarrhea incidence in Makassar City in 2011 - 2015 is shown in Table 3. Results shows that the average monthly humidity with diarrhea cases shows a moderate relationship (r = 0.501) with a positive pattern that can mean greater humidity, the greater also the number of cases of diarrhea. The results of further statistical tests also show that the relationship between humidity has a significant relationship (p = 0,000) greater than $\alpha = 0.005$ for the incidence of diarrhea cases in Makassar City. Thus the outcome of this work is inline with the works done by Kolstad et al.[13], Phung et al.[14] and Levy et al.[15] which reported that humidity has influences on the occurrence of diarrhea. This is because, in the rainy season, humidity increases so that places that contain a lot of wet waste have sufficiently high humidity to cause diarrhea germs can develop well and quickly. This condition can also make animals as vectors for diarrhea such as mice, cockroaches or flies can multiply so that the population increases and indirectly increases transmission of diarrhea.

Table 3: Average humidity relationship with diarrhea incidence rates

Variable	r	p value
humidity	0.501	0.000

Relationship between rainfall with the incidence of diarrhea: The correlation test results between rainfall and diarrhea incidence in Makassar City in 2011 – 2015is shown in Table 4. Results shows that the average rainfall

in the case of diarrhea cases shows a moderate relationship (r = 0.429) with a positive pattern that can be interpreted as greater rainfall, then the greater the number of diarrhea cases. The results of further statistical tests also show that the relationship between rainfall and diarrhea has a significant relationship (p = 0.001) greater than α = 0.05 for the incidence of diarrhea cases in Makassar City. Thus the outcome of this work is inline with the works done by Wu et al.[17] and Bhandari et al.[18] which reported that rainfall has significant influences on the occurrence of diarrhea. This is because Scarcity of clean water and extreme rainfall that can cause flooding have shown a connection with the incidence of diarrheal diseases in several regions of the earth. In recorded cases, in some areas that are often flooded, the incidence of diarrhea cases including cholera has increased after floods.

Table 4: Relationship to Average Rainfall with Numbers Diarrhea

Variable	r	p value
Rain fall	0.429	0.001

Conclusion

Based on the results of research and statistical tests, the following can be concluded. Air temperature with the incidence of diarrhea in the city of Makassar in 2011 - 2015 has no relationship, the higher the air temperature, the lower the case of diarrhea in the city of Makassar. Climate factor in the form of air humidity has a relationship with the incidence of diarrhea in the city of Makassar in 2011 - 2015. The higher the humidity the greater the risk of transmission of diarrheal disease through vectors. Higher rainfall increases diarrhea sufferers and vice versa. So that there is a relationship between rainfall and the incidence of diarrhea in Makassar City in 2011–2015.

Analysis of Health Service Quality on Patient Satisfaction in Malimongan

Putri Lisyah Tome[1], Nurhayani[1], Darmawansyah[1]

[1]*Administration and Health Policy, Faculty of Community Health, Hasanuddin University*

ABSTRACT

The creation of quality will certainly create user satisfaction with the service. The purpose of this study to determine the relationship of the quality of health care to patient satisfaction in Malimongan health center. This type of research uses descriptive survey method. Location of the study conducted in Malimongan Health Center in February 2015. The sampling technique accidental sampling. The primary data obtained through interviews to using questionnaires to 81 National Health Insurance (NHI) patients. Secondary data were obtained from the clinic a profile of community health centers. The results showed that there was a relationship between the five variables with NHI patient satisfaction with the results obtained chi square test p=0.018 for the variable reliability, responsiveness, assurance the values were p=0.028, p=0.000, p=0.002, respectively. Furthermore for empathy, and tangibility, p value was p=0.002.

Keywords: *quality; satisfaction; patient; health center*

Introduction

Administration quality is one of the imperative components in administration associations. This is brought about by the nature of administration is one of the apparatuses used to gauge the execution of administration associations[1]. Nature of administration is a push to satisfy the necessities and wants of buyers and the precision of conveyance in adjusting purchaser desires[2]. Administration quality is the means by which far the contrast between the desires and truth of the clients for the administrations they get. Administration quality is the primary concern that is genuinely considered by the organization, which includes every one of the assets claimed by the organization[3].

In the medicinal services industry, hospitals give similar sorts of administration, however they don't give a similar nature of administration[4]. Moreover, customers today are increasingly mindful of choices on offer and rising guidelines of administration have expanded their desires. They are additionally ending up progressively disparaging of the nature of administration they encounter[5].

Service quality can in this way be utilized as a vital separation weapon to construct an unmistakable preferred standpoint which contenders would discover hard to duplicate. To accomplish benefit magnificence, hospitals must serve each client that the organization can gainfully serve[6]. This will require consistent endeavors to enhance the nature of the administration conveyance framework. Besides, quality does not enhance except if it is estimated. In any case, not at all like made products quality, medical clinic benefit quality is a slippery and unmistakable build[7].

As patient don't actually explain hospitals quality, the beneficiary of the administration can just truly evaluate it, along these lines making its estimation more abstract than correct[8].Patient satisfaction has turned into a key standard by which the nature of health service is assessed[9]. Thus, various health center routinely gather and screen patient fulfillment information for inward evaluations of their own execution.

Several studies has been reported on analyzing patients satisfaction on hospitals service. Aiken et al.[10] analyzed if medical clinics with a decent association of consideration can influence understanding consideration and attendant workforce solidness in European nations. Al-Borie et al.[11] investigation featured benefit quality impact in the plan of more extensive human services techniques for Saudi Arabian open and private clinics. It requests that administration scientists and experts must distinguish provincial administration quality textures and related inpatient statistic markers. You et al.[12] work gave an extensive assessment of medical attendant assets in Chinese emergency clinics and the connection

between medical caretaker assets and medical attendant and patient results. Sack et al.[13] analyzed the relationship between medical clinic accreditation and patient fulfillment with emergency clinic care and found that hospital accreditation may speak to a stage towards absolute quality administration, however may not be a key factor to nature of consideration estimated by the patient's readiness to prescribe. Boulding et al.[14] reported a studyon hopitals where patients stated higher fulfillment with their cooperations among the medical clinic and staff, with their involvement with the release procedure of the patients Schoenfelder et al.[15]investigation distinguished key determinants that ought to be changed first so as to enhance worldwide patient fulfillment. The outcomes additionally show that a few parts of the clinic remain are not seen as important by patients and accordingly are inconsequential to fulfillment appraisals. Ramez et al.[16] assessesed the dimension of administration nature of social insurance suppliers in Bahrain with the end goal of revealing, fundamentally; the connection between administration quality measurements and the general patients' fulfillment and examining conduct expectation of patients. Amin et al.[17] explored clinic benefit quality and its impact on patient fulfillment and conduct aim and found that that management should utilize the apparent administration quality and consumer loyalty as instruments to build the fulfillment of patients. Nabbuye-Sekandi et al.[18] recognized factors related with general fulfillment among customers going to outpatient centers in a referral emergency clinic in Uganda.

Health service is one of the rights possessed by every human being and is recognized by all nations in the world, including Indonesia. Thus, this work will investigate about the quality of health center services at MalimoganHealth Center, Makassar City, where satisfaction or dissatisfaction of patients with national health insurance (NHI) was analyzed.

Methodology

Types of Research: The type of research used is descriptive survey method, namely research that takes samples from a population and uses a questionnaire as an instrument of data collection. The independent variable of this study is tangibility reliability, responsiveness, assurance and empathy. The dependent variable is patients satisfaction

Research Location: The location of the study was carried out at the MalimonganHealth Center, Makassar City.

Population and Samples: The population in this study were all NHI patients received health services at MalimonganHealth Center in Makassar City. The number of samples in this study were 81 NHI patients.

Data Collection: Primary data was obtained through direct interviews with respondents at the time of the study using a research questionnaire. Secondary data obtained from the Malimonganhealth center is in the form of a Community Health Profile and other data related to the research.

Data Analysis: The data analysis was done using SPSS software. In bivariate analysis, a cross tabulation (Crosstab) analysis was performed on each independent variable and the dependent variable to find meaningful relationships. This analysis process can use Chi Square test to find out the correlation between the independent variable and the dependent variable.

Result and Discussion

Variable Relationship Test for NHI Patients: Table 1 shows the relationship between reliability with NHI Patient Satisfaction. Based on Table 1, it is observed that 44 NHI patients who felt reliability services were not very good, 50.0% felt they were not satisfied with the services at the health center and from 37 NHI patients who felt reliability services were very good at 24.3% who felt less satisfied with services at the health center. The value of p obtained is 0.018 where the value is smaller than the value of α which is equal to 0.05 so that Ho is rejected, which means that reliability is related to the satisfaction of NHI patients in the MalimonganHealth Center, Makassar City.

Table 1: Reliability Relationship with NHI Patient Satisfaction

Reliability	Satisfaction				Total		P value
	No		Yes				
	n	%	n	%	n	%	
Not Good	22	50.0	22	50.0	44	100	0.018
Good	9	24.3	28	75.7	37	100	
Total	31	38.3	50	61.7	81	100	

Table 2 shows the relationship between responsiveness with NHI patient satisfaction. Based on Table 2, the value of p shows a significant number of 0.028 which means responsiveness is related to patient satisfaction at Malimongan Health Center Makassar City.

Table 2: Responsiveness Relationship with NHI Patient Satisfaction

Responsiveness	Satisfaction				Total		P value
	No		Yes				
	n	%	n	%	n	%	
Not Good	14	56.0	11	44	25	100	0.028
Good	17	30.4	39	69.6	56	100	
Total	31	38.3	50	61.7	81	100	

Table 3 shows the relationship between assurance with NHI patient satisfaction. From Table 3, the value of p obtained is 0.000 where the value is smaller than the value of α which is equal to 0.05 so that Ho is rejected, which means that assurance is related to the satisfaction of NHI patients in MalimonganHealth Center, Makassar City.

Table 3: Assurance Relationship with NHI Patient Satisfaction

Assurance	Satisfaction				Total		P value
	No		Yes				
	n	%	n	%	n	%	
Not Good	21	60.0	14	40	35	100	0.000
Good	10	21.7	36	78.3	46	100	
Total	31	38.3	50	61.7	81	100	

Table 4 shows the relationship between empathy with NHI patient satisfaction. Based on Table 4, results showed that NHI patients who felt very good empathy service was 23.9%. The p value showed a significant number of 0.002 which means empathy was related to patient satisfaction at the New Malimongan Health Center Makassar city.

Table 4: Empathy Relationship with NHI Patient Satisfaction

Empathy	Satisfaction				Total		P value
	No		Yes				
	n	%	n	%	n	%	
Not Good	20	57.1	15	42.9	35	100	0.002
Good	11	23.9	35	76.1	46	100	
Total	31	38.3	50	61.7	81	100	

Table 5 shows the relationship between tangibility with NHI patient satisfaction. Based on Table 5, the p value was obtained at 0.002 where the value was smaller than the α value of 0.05 so Ho rejected, which means tangibility is related to satisfaction of NHI patients in Malimongan Health Center, Makassar City.

Table 5: Tangibility Relationship with NHI Patient Satisfaction

Tangibility	Satisfaction				Total		P value
	No		Yes				
	n	%	n	%	n	%	
Not Good	29	48.3	31	51.7	60	100	0.002
Good	2	9.5	19	90.5	21	100	
Total	31	38.3	50	61.7	81	100	

Conclusion

Based on the results of the analysis that has been done, it can be concluded as follows. Reliability relates significantly to the satisfaction of NHI patients. Responsiveness is significantly related to NHI patient satisfaction while it not related or not significant to the satisfaction of general patients at the Malimongan Health Center. Assurance is significantly associated with satisfaction of NHI patients. Empathy was significantly associated with NHI patient satisfaction. Tangibility is significantly associated with satisfaction of NHI patients at the Malimongan Health Center. Thus, although all variables in NHI patients have a relationship to patient satisfaction, the Malimongan Health Center must maintain or even improve the quality of these five variables, so that the welfare of the patients are taken care.

Work Fatigue Overview in Female Workers in PT Manakarra Unggul Lestari

Gracella[1], Awaluddin[1], Andi Wahyuni[1]

[1]Work Safety and Health Department, Faculty of Community Health, Hasanuddin University

ABSTRACT

Women's entry into Indonesia's workplace is not an unusual fact. The decision to work in the public sector required women to be responsible with work performance. However, the division of tasks inappropriately adjusted to the working capacity resulted in many women experiencing exhaustion. This research was conducted in PT ManakarraUnggul Lestari (Persero), Mamuju, West Sulawesi, with the aim to determine the relationship of the workload, estimated time work, nutritional status, and hemoglobin levels with the fatigue in female workers applying a type of *analytic survey* research with *cross sectional* method. The instruments used in this study were reaction timer, weight scales, stopwatch, digital Hb measurement, and microtoise. Samples used were all female workers for 38 people (exhaustive sampling) and tested using *Fisher's Exact Test*. The results of this study indicate that there is a relationship between workload variables ($p = 0.001$), nutritional status ($p = 0.021$) and hemoglobin levels ($p = 0.018$) with work fatigue and work duration variables ($p = 0.076$) not related to work fatigue.

Keywords: *Women Labors; Work Exhaustion; Workload*

Introduction

Current technological developments greatly assist industrial processes in producing a product of the highest quality and quality. To produce products of the highest quality and quality, of course, they are not released from the role of labor as human resources in the workplace[1]. In order for the workforce to be more maximal and more productive in working, there needs to be a balance between workload factors, additional burdens due to the environment and work capacity[2].

Human resources at work have an important role in increasing the productivity of a workplace. Talking about male labor and female labor, of course they cannot be separated from their participation in the workplace as human resources[3]. Born with privileges and distinct advantages women have an important role not only to play a role in the family but women also play a role in building the community, organization and also the country[4]. The dual role of women in social life results in an increase in the burden of women and increased fulfillment of needs including health.

Increased burden borne, coupled with the generally different physiological conditions of women that make women more at risk for various health problems. Women's physiological conditions concerning the size and strength of muscles that are affected by the hormonal system[5]. Biologically women also experience menstrual cycles, pregnancy, childbirth and menopause. This situation if it is not addressed with special treatment, it will have an impact on labor productivity in terms of fatigue[6].

Fatigue is a condition that must be given attention. All types of work both formal and informal create work fatigue. Women who work face greater psychological problem, thus making them more vulnerable to fatigue[6]. Workload is the body's ability to work when receiving work. Every workload received by a person must be in accordance with the physical abilities, mental abilities and limitations of the person who receives the burden[7]. Workloads that are not in accordance with physical and psychological abilities will have an impact on fatigue. Nutritional status is one of the causes of fatigue[8]. A worker with good nutritional status will have a better body resistance and work capacity, while a worker with a poor nutritional status will have a good body resistance and work capacity. The condition of anemia is generally more common in women. Besides being a workload, consuming less nutrients and natural conditions for

women who experience menstrual cycles each month, it is a reason why women are more likely to suffer from anemia[9]. Women workers with anemic status will experience fatigue and have a lower level of productivity than workers without anemic status.

Studies has been done previously to analyzed the factor that causes fatigue among women workers. Wong et al.[10] inspected the danger of work fatigue among shift workers in Canada and found that rotating shift and night shiftworkers have exhibited higher fatigue, especially among the women workers. Nag et al.[11] inspected the commonness of musculoskeletal agony and inconvenience (MSD) among fish preparation workers and found that cold condition and standing work act for extend periods of time caused fatigue in ladies laborers. Cobankara et al.[12] analyzed the occurrence of fatigue among material laborers in Turkey and found that fatigue caused restorative condition and it seems higher among female workers. Bültmann et al.[13] analyzed whether lack of sleep influences and exhaustion are autonomously related among ladies laborers and found that the two variables has connection that leads to fatigue.

Hanklang et al.[14] investigatedthe commonness of musculoskeletal issue side effects and its hazard factors among ladies rebar specialists and expressed that that a proper ergonomic workstation configuration will enhance the working condition. Caruso et al.[15] examined the women shift worker pattern in US and found that these work routines can likewise strain individual connections, inferable from exhaustion and poor disposition from lack of sleep and decreased quality time to go through with family and companions. Smith-Miller et al.[16] examined the fatigue among nurses and found that long working shift has contributed to work related fatigue. Sundstrup et al.[17] reported a randomized study on fatigue analysis in women workers and found that the fatigue level in woman can be improved through strength training. Palupi et al.[18] analyzed occurrence of tiredness among vagrant women worker and found that the danger of exhaustion is expanded when they display burdensome indications and their cooking method is broiling.

Therefore, this work was done to examine factors related to work fatigue in female workers at PT ManakarraUnggul Lestari (Persero) Mamuju West Sulawesi. The work fatigue is analyzed interms of workload, length of work, nutritional status and hemoglobin levels in female workers.

Methodology

Types of Research: The type of research used is analytic survey research using a cross sectional study design to determine whether there is a relationship between the dependent variables on the independent variables. The independent variables in this study include workload, length of work, nutritional status and hemoglobin level (Hb) while the dependent variable is work fatigue.

Location and Time of Research: This research was conducted at PT ManakarraUnggul Lestari (Persero) Mamuju West Sulawesi in December 2016 until January 2017.

Population and Samples: The population in this study were all female workers in the division of nurseries, harvesters and fertilizers at PT ManakarraUnggul Lestari (Persero) Mamuju West Sulawesi as many as 38 female workers. The sampling technique was carried out by Exhaustive Sampling with a total sample of 38 people.

Data Collection: Data on the characteristics of respondents, years of service, and length of work, obtained by conducting direct interviews with respondents using a questionnaire. Data on fatigue is measured using reaction time. Data on workload is measured using the work pulse method. Data on body mass index is measured using scales and microtoise. Data on hemoglobin (Hb) was measured using FamalyDr MHD-1 Test Meter.

Data Analysis: Data processing is done using a SPSS 22 software program. Bivariate analysis is an analysis carried out to see related variables. Data analysis was performed to see the relationship of workload, length of work, body mass index (BMI) and hemoglobin (Hb) levels with work fatigue in female workers at PT ManakarraUnggul Lestari (MUL) Mamuju West Sulawesi using Chi Square equation formula.

Result and Discussion

Relationship Workload between and Fatigue: Based on Table 1 shows that 25 respondents with a heavy workload category all experienced fatigue while from 13 respondents with a light workload category 7 respondents (36.8%) experienced fatigue while 6 other respondents (46.2%) did not experience fatigue. The results of the significance test between workload variables and work fatigue variables using the Fisher Exact Test obtained a value of $p = 0.001$

where the value of p <0.05 then Ho is rejected and Ha is accepted which means that there is a relationship between workload and work fatigue. The outcome of this work is line with the work reported by Nag et al.[11] as workload influences the fatigue rate of the worker.

Table 1: Relationship between Workload and Work Fatigue for Female Workers

Work load	Work Fatigue				Total		P value
	Yes		No				
	n	%	n	%	n	%	
Heavy	25	100	0	0	25	100	0.001
Light	7	53.8	6	46.2	13	100	
Total	32	84.2	6	15.8	38	100	

Relationship Length of Work with Work Fatigue: Table 2 shows that respondents who experience work fatigue are respondents whose length of work does not meet the requirements (> 8 hours/day) as many as 13 people and all experience fatigue while workers who have long working hours are eligible (≤8 hours/day) too experiencing fatigue 19 respondents (76.0%) were in the fatigued category and 6 other respondents (24.0%) did not experience fatigue. Based on the results of data analysis using the Fisher's Exact Test the value of p = 0.076 (p> 0.05) means that Ho is accepted and Ha is rejected, so that it can be interpreted that there is no relationship between the length of work and the occurrence of fatigue in female workers at PT ManakarraUnggul Lestari Mamuju West Sulawesi

Table 2: Relationship between Length of Work and Fatigue for Female Workers

Length of work	Work Fatigue				Total		P value
	Yes		No				
	n	%	n	%	n	%	
Not fulfilled	13	100	0	0	13	100	0.076
Fulfilled	19	76.0	6	24.0	25	100	
Total	32	84.2	6	15.8	38	100	

Relationship between Nutritional Status and Fatigue: Based on the data presented in Table 3, results showed that of the 20 respondents who had normal nutritional status as many as 14 respondents (70.0%) experienced fatigue and 6 other respondents (30.0%) did not experience fatigue. While 18 respondents who had abnormal nutritional status all experienced fatigue. The Fisher Exact Test results showed that the value of p = 0.021, because the value of p <0.05, Ho was rejected and Ha was accepted. The interpretation is that there is a relationship between nutritional status and work fatigue in female workers at PT ManakarraUnggul Lestari Mamuju West Sulawesi. The outcome of this work is inline with the work reported by Palupi et al. [18] as it was stated that nutrition plays a significant role bad nutrition will caused the workers to be easily fatigued.

Table 3: Relationship between Nutritional Status and Fatigue for Female Workers

Nutritional status	Work Fatigue				Total		P value
	Yes		No				
	n	%	n	%	n	%	
Not normal	18	100	0	0	18	100	0.021
Normal	14	70.0	6	30.0	20	100	
Total	32	84.2	6	15.8	38	100	

Relationship between Hemoglobin Levels and Fatigue: Based on the data presented in Table 4, results showed that of the 14 respondents who had normal hemoglobin levels, from it 9 respondents (64.3%) experienced fatigue and 5 other respondents (35.7%) did not experience fatigue while those who had abnormal/ anemia hemoglobin level, 23 respondents (95.8%) experienced fatigue and 1 respondent (4.2%) did not experience fatigue. The Fisher Exact Test results show that the value of p = 0.018, because the value of p <0.05, Ho is rejected and Ha is accepted. The interpretation is that there is a relationship between hemoglobin levels and work fatigue in female workers at PT ManakarraUnggul Lestari Mamuju West Sulawesi. The results of interviews conducted with workers, physical complaints that are more often felt by most workers are often dizzy, possibly due to low levels of Hb[19].

Table 4: Relationship between Hemoglobin Levels and Fatigue

Hemoglobin Levels	Work Fatigue				Total		P value
	Yes		No				
	n	%	n	%	n	%	
Not normal	23	95.8	1	4.2	24	100	0.018
Normal	9	70.0	5	35.7	14	100	
Total	32	84.2	6	15.8	38	100	

Conclusion

Based on the results this work which analyzed the factors related to work fatigue in women at PT ManakarraUnggul Lestari (Persero) Mamuju West Sulawesi, the following can be concluded. There is a relationship between workload, nutrition status, hemoglobin level and work fatigue in female workers at PT ManakarraUnggul Lestari (Persero) Mamuju West Sulawesi in 2016. However, there is no relationship between the length of work and work fatigue in female workers. This study found that there was a relationship between workload and work fatigue, so it was recommended that the company should improve company policies related to standard operating procedures (SOP) so that workers have standards in carrying out their work.

Factors Related to the Satisfaction of Patients in Pelamonia Hospital

Andi Nahlah[1], Sukri Palutturi[1], Muh. Yusri Abadi[1]

[1]Administration Department and Health Policy, Faculty of Community Health, Hasanuddin University

ABSTRACT

Patient satisfaction depends on the quality of service. New patients will be satisfied if the performance of health services gained equal or exceed expectations and conversely, dissatisfaction or feeling disappointed patient will appear when the performance of health services obtained it not in accordance with expectations. The purpose of this study was to determine the factors associated with patient satisfaction in hospitals Pelamonia of Makassar in 2016. The factors analyzed were human relationships, timeliness, convenience and access. This type of research is observational research with cross sectional study design. Total population in this study were 17 802 patients in the inpatient units Pelamonia Hospital in Makassar City and took a sample of 100 patients. The data collection was done by interview with using a questionnaire and the collection of documents such as reports of patient visits, hospital profiles, hospital structure, journals and books. The results showed that, there is a relationship between the variables human relationship (p = 0.040), punctuality (p = 0.020), comfort (p = 0.005), and access (p = 0.002) on service satisfaction of inpatients at Hospital Pelamonia Makassar. The conclusion of this study indicate that there is a relationship between human relationships, timeliness, convenience and access to patient satisfaction.

Keywords: *Satisfaction; relationships; punctuality; convenience; access*

Introduction

The development of the health sector is one of the important elements in people's lives which continues to increase from time to time[1]. Community needs for health services continue to develop. Along with this, health service providers continue to make improvements to win the competition and provide quality services for the community[2].

One definition states that the quality of health services usually refers to the ability of hospitals to provide services that are in accordance with health professional standards and acceptable to patients[3]. In this case, certainly need to consider the use of resources as efficiently as possible. In addition, it is also necessary to avoid the possibility of iatrogenic problems due to hospital care

Consumer assessment of the quality of hospital services is an important matter as a reference in improving services so that customer satisfaction is created[4]. Customers generally expect products in the form of goods or services consumed to be accepted and enjoyed by good or satisfying services. Customer satisfaction can shape perceptions and can further promote the company's products in the eyes of its customers[4].

The hospital was declared successful not only in the complementary facilities seeded, but also in the attitudes and services of human resources, which significantly affected the services produced and perceived by patients[5]. If these elements are ignored, in a short time, the hospital will lose many patients and be shunned by prospective patients. Patients will switch to other hospitals that meet patient expectations, because patients are a valuable asset in developing the hospital industry[5].

Patient satisfaction depends on the quality of service. New patients will feel satisfied if the performance of health services obtained is the same or exceeds their expectations and vice versa, dissatisfaction or feelings of patient disappointment will arise if the performance of health services obtained is not in line with expectations[6]. Patient satisfaction is a level of patient feelings that arises as a result of the performance of health services obtained after the patient compares it with what he expected[6].

Community complaints often occur due to unsatisfactory health services. Along with the advancement of science, medical and health technology requires quality improvement and health services to the community[7]. Quality of service and customer or patient satisfaction is one of the important strategies that cannot be ignored by policy makers in the health sector[7].

Patient dissatisfaction is interpreted the same as complaints against hospitals, along with services performed by health personnel (doctors, nurses, pharmacists, psychologists and others) and health care system structures (costs, insurance systems, capabilities and infrastructure of health centers and others)[8]. The patient expects good, polite, friendly, comfortable interaction with health workers, so that the competence, qualifications and good personality of the health care worker. The main factors in influencing patient satisfaction are complete medical equipment, buildings and adequate hospital facilities, complete supporting facilities in the service[9].

Several studies has been reported in analyzing patients satisfaction on the service provided by hospitals. Hamilton et al.[10] examined the variables which impact tolerant fulfillment with careful administrations and to investigated the connection between overall patients satisfaction. Tsai et al.[11] analyzed if clinics with high patient fulfillment have bring down dimensions of execution on acknowledged proportions of the quality and effectiveness of careful consideration. Al-Abriet al.[12] discussed about the relationship of reliant and free in uential properties towards in general patient fulfillment notwithstanding its effect on the quality enhancement procedure of medicinal services associations. Khamis et al.[13] analyzed patients' dimension of fulfillment on the nature of medicinal services conveyed at an emergency clinic at Tanzania. Lyu et al.[14] resolved if patient fulfillment is free from careful process measures and emergency clinic wellbeing by contrasting information from thirty-one US medical clinics. Bowling et al.[15] studied the capacity of the framework to live up to patients' desires in regard of the passionate consulation, and the clinical results, that matters the most to the patients. AsifRaza et al.[16] contemplated drug store benefit affect on patient fulfillment and to figure out what factors strikingly connect with pharmaceutical administration execution at Hamad General Hospital.Merkouris et al.[17] evaluated medicinal and careful patient fulfillment with nursing care in the general population emergency clinics of Cyprus and investigate its conceivable connection with foundation factors. Joon Choi et al.[18] inspected the job of recognition as a directing variable, finding that result quality impacts consumer loyalty just when patients know about administrations given by a medical clinic.

In this work, the factors associated with patient satisfaction in Pelamonia Hospital of Makassar, Indonesia were analyzed. The factors that was accessed were human relationships, timeliness, convenience and access.

Methodology

Types of Research: This research is a quantitative study with a cross sectional study approach, which aims to see the relationship of inpatient satisfaction at Pelamonia Hospital Makassar. The independent variables of this work were Human relationship, Punctuality, Convenience, and Access. The dependent variable of this work is patient satisfaction.

Location of Research: This research was conducted at the Inpatient Installation of PelamoniaHospital which is one of the hospitals located in Makassar City.

Population and Sample: The populations in this study were all patients in the inpatient unit at Pelamonia Hospital based on data on 2015 patient visits of 17802 people. The sampling technique used in this study is the Accidental Sampling Technique. The number of samples used for this work is 100.

Data Collection: Primary data in this study was conducted by conducting interviews directly with respondents using the prepared research questionnaire. Secondary data was obtained from document collection such as reports of patient visits.

Data Analysis: Data obtained from the results of interviews were processed using SPSS program. Bivariate analysis was used to find the effect and prove the two-variable hypothesis. Ho will be tested with a significance level of 0.05. The statistical test used is chi-square Test

Result and Discussion

The relationship between human relationships with patient satisfaction: Table 1 shows that patients' perceptions of human relations with the satisfaction of patients receiving health services at inpatient care at

the Pelamonia Hospital, Makassar City. Where as many as 59 (73.8%) people stated well and that 21 (26.2%) people stated that they were not good. The results of the analysis using Chi-Square obtained p = 0.040 because p <0.05, H_o is rejected and H_a is accepted, meaning that there is a relationship between human relationships with patient satisfaction at the inpatient care. Thus, the outcome of this work is inline with the work done by Khamis et al.[13] as it was stated that human relation is significant element for patients satisfaction.

Table 1: Distribution of Relationships Between Human Relationship and Patient Satisfaction

Human Relationship	Patient Satisfaction				Total		P value
	Yes		No				
	n	%	n	%	n	%	
Good	59	73.8	21	26.2	80	100	0.040
Not Good	10	50.0	10	50.0	20	100	
Total	69	69.0	31	31.0	100	100	

The relationship between punctuality and patient satisfaction: Table 2 shows that patients' perceptions of the relationship of timeliness with patient satisfaction stated that they were 34 (59.6%) people and those who stated were not good, was 23 (40.4%) people. The results of the analysis using Chi-Square obtained p = 0.020 because p <0.05, H_o was rejected and H_a was accepted, meaning there was a relationship between punctuality with patient satisfaction at the inpatient installation of Pelamonia Hospital, Makassar City. The outcome of this work is inline with the work reported by Tsai et al.[11] where it was said that punctuality is important as patient expect the service to be done at the proper and promised timing.

Table 2: Distribution of Relationships Between Punctuality and Patient Satisfaction

Punctuality	Patient Satisfaction				Total		P value
	Yes		No				
	n	%	n	%	n	%	
Good	34	59.6	23	40.4	57	100	0.020
Not Good	35	81.4	8	18.6	43	100	
Total	69	69.0	31	31.0	100	100	

The relationship between convenience and patient satisfaction: Table 3 shows that the patient's perception of the relationship of convenience with patient satisfaction states that it is 26 (55.3%) people and who states that it is less good is 21 (44.7%) people. While respondents who were not satisfied with comfort but satisfied with service were 43 (81.1%) people and those who expressed dissatisfaction with comfort and service were 10 (18.9%) people. Perceptions about the comfort of health services at Pelamonia Hospital in Makassar City tend to be satisfied with the services obtained by patients, namely 26 (55.3%) people. While patients with perceptions of dissatisfaction are 10 (18.9%) people. The results of the analysis using Chi-Square obtained p = 0.005 because p <0.05, H_o is rejected and H_a is accepted, meaning there is a relationship between convenience with patient satisfaction at the inpatient installation of Pelamonia Hospital, Makassar City. The outcome of this work is inline with the work done by Al-Abri et al.[12] as patient value the conveniences in the service provided by health care. This will determine the quality of the service provided.

Table 3: Distribution of Relationships Between Convenience and Patient Satisfaction

Convenience	Patient Satisfaction				Total		P value
	Yes		No				
	n	%	n	%	n	%	
Good	26	55.3	21	44.7	47	100	0.005
Not Good	43	81.1	10	18.9	53	100	
Total	69	69.0	31	31.0	100	100	

The relationship between access and patient satisfaction: Table 4 shows that the patient's perceptions of the access relationship with patient satisfaction stated that they were 33 (56.9%) people and those who stated that they were not good were 25 (43.1%) people. While respondents who expressed dissatisfaction with access but were satisfied with service were 36 (85.7%) people and those who expressed dissatisfaction with access and service were 6 (14.3%) people. Perceptions about access to health services at Pelamonia Hospital in Makassar City tend to be satisfied with the services obtained by patients, namely 33 (56.9%) people. While patients with perceptions of dissatisfaction are 6 (14.3%) people. The results of the analysis using Chi-Square were obtained p = 0.002 because p <0.05, H_o was rejected and H_a was accepted, meaning there was a relationship between access with patient satisfaction at the inpatient installation of Pelamonia Hospital, Makassar City. The outcome of this work is inline with the work done by Merkouris et al.[17]where access to service is significant for patients and their fulfillment.

Table 4: Distribution of Relationships Between Access and Patient Satisfaction

Access	Patient Satisfaction				Total		P value
	Yes		No				
	n	%	n	%	n	%	
Good	33	56.9	25	43.1	58	100	0.002
Not Good	36	85.7	6	14.3	42	100	
Total	69	69.0	31	31.0	100	100	

Conclusion

Based on the overall outcome of this work, the following can be concluded. There is a relationship between human relationships, punctuality, convenience and access with the satisfaction of inpatients at the Pelamonia Hospital in Makassar City. In addition, the authors recommend the Pelamonia Hospital of Makassar City (administration, nurses, doctors and drug officers) to be more friendly and considerate to patients in responding or advising and listening to complaints and requests from patients and maintaining the quality of services provided to patients.

Risk Factors of Pulmonary Tuberculosis Relapse in Working Population of Makassar City

Irmawati[1], Ridwan A[1], Jumriani Ansar[1]

[1]Faculty of Community Health, Hasanuddin University

ABSTRACT

Pulmonary tuberculosis relapse is a common complications in tuberculosis patients and causing problems around the world, especially in Indonesia. In 2016, Makassar City overall was reported to have high incidence of tuberculosis relapse case detection rate about 4,9% of 1.850 total smear-positive pulmonary tuberculosis in working population. This present study aimed to investigate risk factors of pulmonary tuberculosis relapse in working age population in public health centers of PanakkukangSubdistrict and TalloSubdistrict of Makassar City. This present observational-analytical study using case-control study design. This study using exhaustive sampling method for case group and simple random sampling for control group. Data analysis performed with Risk Estimate test (odds ratio)e. This present study shows BCG immunization history (OR=0,619; 95% CI=0,197-1,941), disease comorbidity (OR=2,143; 95%CI=0,663-6,924), smoking (OR=1,272; 95%CI=0,317-5,111), regular medication intake history (OR=6,111; 95%CI=2,010-18,584), air ventilation (OR=0,706; 95%CI=0,191-2,603) and flooring type (OR=1,909; 95%CI=0,599-6,081). This present study concluded that regular medication intake was significant risk factor in pulmonary tuberculosis relapse in working population.

Keywords: *Risk factors; TB relapse; age*

Introduction

Tuberculosis (TB) is an infectious disease caused by infection with the bacterium Mycobacterium tuberculosis basil and is a disease that is of global concern. This infection is the most common in the world, with an estimated one third of the population infected and 2.5 million deaths every year. In addition, various control measures were taken to reduce the incidence and mortality from tuberculosis, but tuberculosis is still estimated to attack 9.6 million people and cause 1.2 million deaths in 2014[1].

This disease is one of the top five causes of death in women aged 15-44 years and the deadliest in HIV positive patients[2]. For distribution based on location, India, China, and Indonesia are the countries with the most tuberculosis sufferers, namely 23%, 10% and 10% of all sufferers in the world[3].

Factors that influence the likelihood of someone becoming a tuberculosis patient are low endurance, including HIV and AIDS infections and malnutrition[4]. HIV infection causes extensive damage to the cellular immune system and is the strongest risk factor for those infected with tuberculosis to become tuberculosis[5].

Global progress depends on progress in control of prevention of tuberculosis and treatment in countries in the world. WHO states that tuberculosis control relies on disease identification and treatment for each case scheduled for 6 months[6]. One of the problems with tuberculosis control is the occurrence of recurrence and the need for a second treatment[7]. Relapse pulmonary tuberculosis or relapsing pulmonary tuberculosis were tuberculosis patients who had previously received tuberculosis treatment, and who had been declared cured or had complete treatment, were diagnosed with positive smear tuberculosis based on swab examination or culture[8].

The incidence of pulmonary tuberculosis recurrence is a fairly common occurrence in tuberculosis patients and causes various problems[9]. The occurrence of this recurrence can increase the source of tuberculosis transmission in the community, so that it can inhibit the achievement of the goals of tuberculosis treatment and control[10].

Few studies has been reported on analyzing the existence of Tuberculosis among world population. Millet et al.[11] recognized the likelihood of death and its prescient factors of effectively treated TB patients and found that the death rate among TB patients who finished treatment is related with elderly population, HIV-contaminated IDU and alcohol drinkers. Millet et al.[12]distinguished the repeat rate of TB in Barcelona, the related hazard factors and found that relapses takes place in the initial three years, with patients at higher danger of repeat TB are those with HIV. Liao et al.[13] recognized the patterns and indicators of tuberculosis in Taiwan and found that easonality, natives, sexual orientation, and age had a steady and prevailing job in developing TB rate designs in Taiwan. Choi et al.[14] distinguished the indicators of aspiratory tuberculosis treatment results in South Korea and found that it was impacted by patient variables (diabetes status, age, BMI) and illness factors. Sanchez-Padilla et al.[15] reported a high pervasiveness of MDR TB in Swaziland, which at present seems to have the most noteworthy commonness in Africa, and demonstrates a quick increment in the predominance of MDR TB in the space of marginally over 10 years. Stuckler et al.[16] assessed the connection among mining and tuberculosis (TB) among nations in sub-Saharan Africa and found that mining is a huge determinant of countrywide variety in TB. Azhar et al.[17] evaluated recurrence instances of TB in India and found that hazard factors for recurrence included medication inconsistency, initial medication obstruction, smoking and liquor abuse. Moosazadeh et al.[18] analyzed the rate of repeat of TB in Iran and found that impressive level of smear-positive aspiratory TB patients encounter repeat and that a few patients are at a higher danger of repeat. Chen et al.[19] analyzed TB frequency and relative hazard factors in country regions of China and found that diabetes mellitus, smoking and liquor, history of TB were the distinguished risk factors.

It has been reported that in Indonesia, The highest cases of pulmonary tuberculosis recurrence occurred in productive age (15-64 years) in 2015 and increased by 18.3% in 2016[20]. Based on the highest recurrence area, it occurred in the PanakkukangSubdistrict area and Tallo Sub-District working areas in Makassar City. Thus, this work has aimed to analyze analyze the risk factors for recurrence of pulmonary tuberculosis in productive age in the working area of the health center in Panakkukang District and Tallo District, Makassar City.

Methodology

Type and Design of Research: This type of research is an observational analytic study with a case-control study. The independent factors associated with TB relapse that will be analyzed is BCG immunization history, history of co-morbidities, smoking habit, history consuming medication regularly, house ventilation, and types of house floors,. The dependent variable is recurrence of pulmonary tuberculosis

Location and Time of Research: This type of research is an observational analytic study with a case-control. This research was conducted in Panakkukang and Tallo Sub-Districts, Makassar City, South Sulawesi. The research was conducted on February 19 to March 27, 2017.

Population and Sample: The population case for this work were all pulmonary tuberculosis patients. The number of samples for this study were 80.

Data Collection: Primary data was obtained through interviews with pulmonary tuberculosis patients who had relapsed and patients recovered from tuberculosis as the study sample. Secondary data can be obtained from patient reports tuberculosis in the form of data on the number of tuberculosis cases.

Data Analysis: Data processing was analyzed using the SPSS program. Bivariate analysis was carried out on two variables suspected of being risk factors using the risk estimate test.

Result and Discussion

History of BCG Immunization against Recurrence of Lung Tuberculosis: Table 1 shows the result of Risk Factors for History of BCG Immunization against Recurrence of Lung tuberculosis. Based on the analysis, it was found that for the case group and control group the highest percentage was respondents who had a low risk (75.0% cases and 65.0% controls) and the lowest high risk (25.0% cases and 35.0% controls) who experienced recurrence of pulmonary tuberculosis. With the results of the risk estimate test, OR = 0.619 (OR <1) with intervals of 0.197-1.941 are obtained.

Table 1: Risk Factors for History of BCG Immunization against Recurrence Lung tuberculosis

BCG immunization	Recurrence of pulmonary TB				Total		P value
	Cases		Control				
	n	%	n	%	n	%	
High Risk	5	25.0	21	35.0	26	32.5	0.619 (0.197-1.941)
Low Risk	15	75.0	39	65.0	54	67.5	
Total	20	100.0	80	100.0	80	100	

History of Co-morbidity against Recurrence of Lung Tuberculosis: Table 2 shows the result of Risk Factors for History co-morbidityagainst Recurrence of Lung tuberculosis. The result showed that for the case group and control group the highest percentage was respondents who had a low risk (70.0% cases and 83.3% controls) while the lowest was high risk (30.0 % of cases and 16.7% of controls) experienced recurrence of pulmonary tuberculosis. With the results of the risk estimate test the OR value is obtained = 2.143 (OR> 1) with an interval of 0.663-6.924.

Table 2: Risk Factors for History of Co-morbidity against Recurrence Lung tuberculosis

Co-morbidity	Recurrence of pulmonary TB				Total		P value
	Cases		Control				
	n	%	n	%	n	%	
High Risk	6	30.0	10	16.7	16	20	2.143 (0.663-6.924)
Low Risk	14	70.0	50	83.3	64	80	
Total	20	100.0	60	100.0	80	100	

Smoking Habit against Recurrence of Lung Tuberculosis: Table 3 shows the result of Risk Factors for Smoking Habit against Recurrence of Lung TB. Results showed that for the case group and the control group the highest percentage was respondents who had a high risk (85.0% cases and 81.7% controls), while the lowest was low risk (15.0% cases and 18.3 % of controls) who experience recurrence of pulmonary tuberculosis. With the results of the risk estimate test the OR = 1,272 (OR> 1) with an interval of 0.317-5.111is obtained.

Table 3: Risk Factors for Smoking Habit against Recurrence Lung tuberculosis

Smoking	Recurrence of pulmonary TB				Total		P value
	Cases		Control				
	n	%	n	%	n	%	
High Risk	17	85.0	49	81.7	66	82.5	1.272 (0.317-5.111)
Low Risk	3	15.0	11	18.3	14	17.5	
Total	20	100.0	60	100.0	80	100	

History of taking regular medicine against Recurrence of Lung Tuberculosis: Table 4 shows the result of Risk Factors for History of taking regular medicine against recurrence of Lung TB. Results showed that for the case group the highest percentage was respondents who had high risk (55.0%) and the lowest low risk (45.0%), while for the control group the highest percentage was low risk respondents (83, 3%) and the lowest high risk (16.7%) experienced recurrence of pulmonary tuberculosis. With the results of the risk estimate test the OR = 6.111 (OR> 1) with an interval of 2.010-18.584 is obtained.

Table 4: Risk Factors for History of taking regular medicine against Recurrence Lung tuberculosis

Medicine	Recurrence of pulmonary TB				Total		P value
	Cases		Control				
	n	%	n	%	n	%	
High Risk	11	55.0	10	16.7	21	26.25	6.111 (2010-18.584)
Low Risk	9	45.0	50	83.3	59	73.75	
Total	20	100.0	60	100.0	80	100	

House Ventilation against Recurrence of Lung Tuberculosis: Table 5 shows the result of Risk Factors for House ventilation against recurrence of Lung TB. Results showed it was found that for the case group and the control group the highest percentage was respondents who had a high risk (80.0% cases and 85.0% controls), while the lowest were respondents who had low risk (20.0% of cases and 15.0% of controls) experienced recurrence of pulmonary tuberculosis. With the results of the risk estimate analysis obtained OR = 0.706 (OR <1) with an interval of 0.191-2.603

Table 5: Risk Factors for House Ventilation against Recurrence Lung tuberculosis

Ventilation	Recurrence of pulmonary TB				Total		P value
	Cases		Control				
	n	%	n	%	n	%	
High Risk	16	80.0	51	85.0	67	83.75	0.706 (0.191-2.603)
Low Risk	4	20.0	9	15.0	13	16.25	
Total	20	100.0	60	100.0	80	100	

Types of House Floors against Recurrence of Lung Tuberculosis: Table 6 shows the result of Risk Factors for Types of House Floorsagainst recurrence of Lung TB. Result showed that for the case group and control group the highest percentage was respondents who had a low risk (70.0% cases and 81.7% controls), while the lowest were respondents who had high risk (30.0% cases and 18, 3% of controls) who experienced recurrence of pulmonary tuberculosis. With the results of the risk estimate test, OR = 1.909 (OR> 1) with an interval of 0.599-6.081 is obtained.

Table 6: Risk Factors for House Floor against Recurrence Lung tuberculosis

Floor	Recurrence of pulmonary TB				Total		P value
	Cases		Control				
	n	%	n	%	n	%	
High Risk	6	35.3	11	18.3	17	21.25	1.909 (0.599-6081)
Low Risk	14	22.2	49	81.7	63	78.75	
Total	20	100.0	60	100.0	80	100	

Conclusion

Based on the results of research on risk factors for events Recurrence of Pulmonary Tuberculosis in productive age in the working area of Panakkukang District Health Center and Tallo District of Makassar City, the following was summarized. History of BCG immunization, history of co-morbidities, smoking habits, ventilation of the house, type of floor of the house, occupancy density and home contact with patients with pulmonary tuberculosis is not risk factors for recurrence of pulmonary tuberculosis in productive age. Nevertheless, history of taking regular medication is a risk factor for recurrence of pulmonary tuberculosis in productive age in the working area of Panakkukang District Health Center and Tallo District of Makassar City. Thus, It is expected that patients with pulmonary tuberculosis will regularly take medication, seek treatment in accordance with the schedule, and find out information regarding the stages and duration of treatment for pulmonary tuberculosis so as not to discontinue treatment.

Health Belief Model and Its Association with Cervical Cancer Screening Among Malaysian Women

Fadzilah Siraj[1], Md Radzijohari[1], Nur Azzah Abu Bakar[1], Faizzudin Sahazudin[1]

[1]School of Computing, Universiti Utara Malaysia, 06010 Sintok, Kedah; [2]Faculty of Medicine, Universiti Teknologi Mara, 47000 Sungai Buloh Selangor, Malaysia

ABSTRACT

In Malaysia, the most common cancer that suffered by women is cervical cancer. The rate of death among the patients are mostly can be prevented since there are many screening test offered for early diagnosis. This study aims to explore about the association of cervical cancer among the Malaysian and Health Belief Model (HBM). The study also investigates demographic factors associated with cervical cancer screening and HBM constructs. A set of questionnaires containing the demographics of the respondents and THREE constructs of HBM including *Perceived Risk*, *Perceived Severity* and *Perceived Benefits* were distributed among the Malaysian women in the selected hospitals. The study indicates that the most likely age structure that has undertaken Pap Smear Test are those whose age is more than 60 years old, women from Indian race, they are the smallest group receiving a pap smear test and also the smallest group that do not know the importance of being screened. In addition, Malay women are the second less group to receive Pap smear test compared to Chinese women. In terms of individual income and educational background, the women under these two aspects are less likely to report screening. Although limited in terms of scope, the information from this study has provided insight into the association between demographics, *Perceived Risk, Perceived Severity* as well as *Perceived Benefits* with regard to cervical cancer screening. For those who are interested with the intervention project to enhance the participation of this cancer screening this kind of information will be very useful.

Keyword: *Health Belief Model, Cervical Cancer Screening, Malaysian Women*

Introduction

In Malaysia, the most common cancer that suffered by women is cervical cancer. The rate of death among the patients are mostly can be prevented since there are many screening test offered for early diagnosis. The mortality caused by cervical cancer is having a sharp decline since it has been introduced in 50's. There are just a few of women all over the world are having cervical cancer proper screening even though the Pap smear testing is well established for years (Community Health Assessment, 2012).

The cases of cervical cancer that have been recorded in developing countries are as high as it counts to more than 80% of the total half a million cervical cancer cases worldwide (WHO, 2010). According to the Second Report of the National Cancer Registry in 2003, Malaysia has 19.7 cases per 100,000 per populations that being reported (Lim, Chye&Yahaya, 2003). Approximately, about less than two thousands of new cases of cervical cancer are diagnosed in Malaysia and about 3,000, cases are being treated in public hospitals. The incidence is highest between the ages of 50 and 69, about 50% of the cases were diagnosed between the ages of 35 and 55, which are the most economically productive years for women. The Women Health Organization (WHO) projects more than 250,000 women die annually from cervical cancer, 99% caused by HPV and it will rise to 320,000 in 2015 and 435,000 in 2030. Similar to the other types of cancer, cervical cancer may not cause any symptoms until the cancer is spreading and is already on its advanced stage.

Health Belief Model: The Health Belief Model (HBM) was developed by Hochbaum, Leventhal, Kegeles and Rosenstock in 1950 to explain the widespread failure of people to participate in programs to prevent and detect disease. HBM is one of the oldest templates that has been extended to study peoples' responses to symptoms

and their behaviors in response to diagnose illness, in particular an adherence to medical regimens (Glanz et al., 2008). It also aims to explain preventive behaviors(Ben-Natan&Adir, 2009). The HBM has been used extensively to determine the relationship between health beliefs and health behaviors as well as to inform interventions. For a behavior change to succeed, individuals must have the incentive to change, feel threatened by their current behavior, feel that a change will be beneficial and be at acceptable cost. They must also feel competent to implement that change (Bush, 2009). In other words, HBM is a comprehensive model which is primarily related to prevention and is based on the individual's motivation for action (Karimy, Heidarnia&Ghofranipour, 2009). Research using a theory-based assessment approach to study women's behavior with regard to Pap smear testing is limited and there is an immediate need to understand the Pap smear practices that would allow healthcare professionals to develop more effective and cost-effective programs (Wong et al., 2008). Inherently, there are challenges to working with patients to change their behavior (Masoudiyekta et al., 2015) to reduce the likelihood of experiencing a condition of suffering from a disease (Sundstrom et al., 2018), and that some of the challenges are highlighted in the dimension of the HBM.

Basically, HBM comprises four constructs: *Perceived Susceptibilty or Perceived Risk*, *Perceived Severity,* Perceived *Benefits,* and Perceived *Barriers,* each of which can be used to explain health behaviors. More recently, other constructs such as *Self-efficacy* and *Cues to Action* have been added to the HBM (Wayne, 2014). However, in this paper, only three constructs will be presented which are: *Perceived Risk*, *Perceived Severity* and *Perceived Benefits. Perceived Susceptibility* refers to beliefs about the likelihood of getting a disease or condition This is one of the strongest perception in urging people to adopt healthy behaviors(Tavafian, 2012). The more a person perceived the risk, the more likely that the person engages the behavior to decrease the risk. In other words, when a woman believes that she is at risk for a disease, she will definitely do something to prevent from happening. *Perceived Severity or Risk* construct refers to the severity of a health problem as assessed by the individual (Tavafian, 2012)by specifying the consequences of the risk and the condition. *Perceived Benefits* refer to a person's opinion of the value or usefulness of a new behavior in decreasing the risk of developing a disease (Wayne, 2014). It plays an important role in the adoption of secondary prevention behaviors such as screening.

Cervical cancer mortality is largely preventable, given the availability of internationally accepted screening tests for early diagnosis. However, screening policies and practices vary by country, along with attendance rates. This study aims to explore about the association of Health Belief Model (HBM) with cervical cancer screening among Malaysian women. The study also investigates demographic factors associated with cervical cancer screening and HBM constructs.

Method

For this study, a total of 1000 pamphlets has been distributed throughout the region around the study region. However, a total of 300 who met the criteria for inclusion and agreed to participate in the study. The women were recruited in person, using information pamphlets and flyers.

Data Collection Procedure: Prior to project implementation, the research assistants are trained how to administer the research instrument as well delivering the right information to the respondents, data collection, accuracy and confidentiality. The measures were translated from English to Malay to ensure the appropriateness for the community.

Measures: The measures included in the study are (1) socio-demographics and(2) perception related to HBM constructs. Socio-demographic characteristics includes age, marital status, education and employment status. This study aims to explore about the association of HBM with cervical cancer screening among Malaysian women. As mentioned earlier, the THREE constructs of HBM include *Perceived Risk*, *Perceived Severity* and *Perceived Benefits*. The study also investigates demographic factors associated with cervical cancer screening and HBM constructs. Items for HBM constructs were adapted from Grace et al. (2013) and in this paper, only THREE constructs are presented. Other results are reported elsewhere.

Cronbach's alpha is the most common measure of internal consistency when using multiple Likert questions in a survey. The Cronbach's alpha coefficients ranging from 0.929 to 0.964. The factor loading for

factor analysis is 0.935 to 0.967 for Perceived Risk, 0.916 to 0.962 for Perceived Severity and 0.920 to 0.973 for Perceived Benefits. The alpha coefficient for the three constructs suggesting that the items in each construct has relatively high internal consistency.

A univariate logistic regression was used to examine the association between the pap smear test and the HBM constructs. In addition, the logistic regression was also used in conjunction with the demographic variables to determine the confounding effect between HBM that associated with ever having the Pap Smear Test. To assess whether these factors contribute significantly to a model, the likelihood ratio test (LRT) is reported since it is a much preferred as suggested byHilbe (2009).

Results and Discussion

A total of 171 of 300 respondents (57%) reported having undertaken a Pap Smear test. Among these respondents, the highest percentage of age structure is more than 60 years old (32% or 55 out of 171) and the least is from the group of 17-40 years old (17.5% or 30/171). On the contrary, the highest percentage of group structure that has not taken a pap smear test is from the age of 17-40 years old (31.8%), followed by 24 % of the age structure of 51-60 years old, 23.2%% of them were above 60 years, and 20.9% of the respondents whose age is in the range of 41-50 years (Table 1). Among the respondents, nearly 50% (142 out of 300) were married women, followed by widowed (20%), never married (18.7%) and divorced (14%).

Table 1: The distribution of respondents based on age, marriage status based on Pap Smear test

	Pap Smear				**Total**
Age	**No**	**%**	**Yes**	**%**	
17-40 years	41	57.7	30	42.3	71
41-50 years	27	42.2	37	52.1	64
51-60 years	31	38.8	49	69.0	80
>60 years	30	35.3	55	77.5	85
Total	**129**		171		300
Marriage Status	No	%	Yes	%	
Widowed	8	13.3	52	86.7	60
Divorced	7	16.7	35	83.3	42
Never Married	23	41.1	33	58.9	56
Married	91	64.1	51	35.9	142

Indian women are the least likely to have had a pap smear test and also the least likely to know the reasons why they have been screened. In addition, Malay women are less likely than Chinese women to have received Pap Smear Test. The analysis also indicates that 60% of Muslim women participated in the study, followed by the Buddhist (17%), Christian (13%) and Hindu (10%). The analysis also indicates that the higher the education the women have, the higher the percentage of cervical screening among women. The participation of cancer screening was higher among the employed women compared to the others (Table 2).

Table 2: The distribution of respondents based on age, marriage status based on the Pap Smear test

	Pap Smear				
Education level	**No**	**%**	**Yes**	**%**	**Total**
Below high school	67	58.8	47	41.2	114
High school	56	49.1	111	66.5	167
Higher education	6	5.3	13	68.4	19
Total	129		171		300

Employment	No	%	Yes	%	Total
Housewife	35	39.8	53	60.2	88
Retired	6	15	34	85	40
Unemployed	41	67.2	20	32.8	61
Employed	47	42.3	64	57.7	111

Perceived Risk: Fig. 1 provides a visualization of Perceived Susceptibility (*at risk) of getting cervical cancer*. Among those who have taken the Pap Smear test (171 in total), higher percentage of the respondents perceived that they are not at risk (41.5%) of getting cervical cancer, some are unsure (48.5%) and some think they are at risk (10%). Among those who have not taken the test, about 42.6% perceived that they are not at risk of getting cancer. Comparing these two cohorts, it is obvious that respondents either they had undertaken the test or not believe that they are not at risk of getting cervical cancer. This may be due to the fact that the respondents do not have an access to the information about the cervical cancer and its consequences. However, those who have taken the test show a higher percentage of perceived at risk than those who have not (9.9% versus 1.6%).

Another question on perceived risks is "Are you more likely than average women to get the cervical cancer?". The respondents who had Pap Smear Test perceived that they are not likely than average women to get cancer (52%). The figure also reveals that the same distribution of patterns for those who did not take the pap smear test. The percentage of those who perceived that they are more likely than average women to get cervical cancer for the YES group is higher than from the NO group. The logistic regression analysis of the demographic variables and the Perceived Risk with respect to screening, the Likelihood Ratio Tests indicate that age ($p<0.001$), employment ($p<0.001$) and marriage status ($p<0.023$) are significant to cervical cancer screening. However, the item "Perceived at risk of getting cancer" is only significant at 10% level ($p<0.07$).

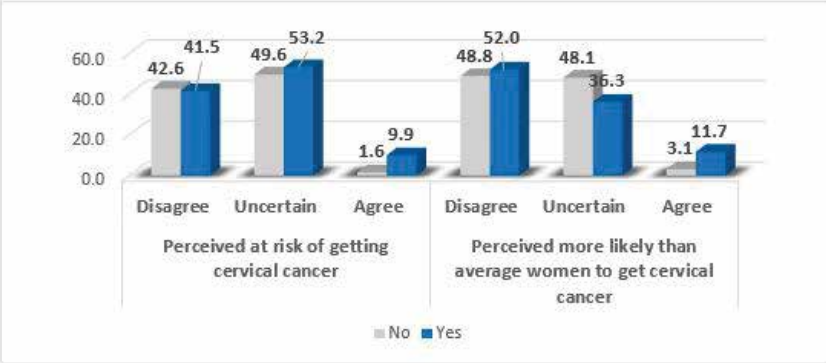

Figure 1: Perceived at risk of getting cervical cancer Based on Pap Smear Test

For completeness, the analysis within each answer scale is also presented. Among the respondent who Agree, about 83% of the respondents that have taken Pap Smear Test perceived that they are more likely than average women to get cervical cancer (Fig. 2). However, the percentage of those who have not taken the pap smear test is increasing by 14.9%.

Figure 2: Perceived more likely than average women to get cervical cancer

Perceived Severity: With respect to perceived severity, the graphical representation is shown in Fig. 3. The percentage of respondents agree with the three statements ranging from 31% to 50.9%, in particular, they perceived that "Having cervical cancer changes their life" (50,9%) and "threaten the relationship with their partner" (46.2%). Among the Perceived Severity items, the item "Women having cervical cancer will die from it" and "Having cervical cancer changes life" are significantly associated with cervical cancer screening (both $p<0.001$). The items become insignificant when demographic variables are included in the model. However, age ($p<0.12$) and Marriage Status ($p<0.001$) remain significant to the cervical cancer screening.

Perceived Benefits: Another constructs of HBM explored in this study is Perceived Benefits. In terms of Perceived Benefits of Pap Smear Test, about 54% of those who had undertaken the test believe that Pap Smear test is the best way to detect cervical cancer (Fig. 4) and also an important test for staying healthy (60.2%). They also believe that it is easier to treat cervical cancer if detected early (64.3%), the chances of dying due to cervical cancer decreases if the test is taken annually (58.5%) and having a test so as not to worry about the cancer (52.6%). In addition, those who did not take the test also agree that Pap Smear Test is the best way to detect cervical cancer (46.5%).

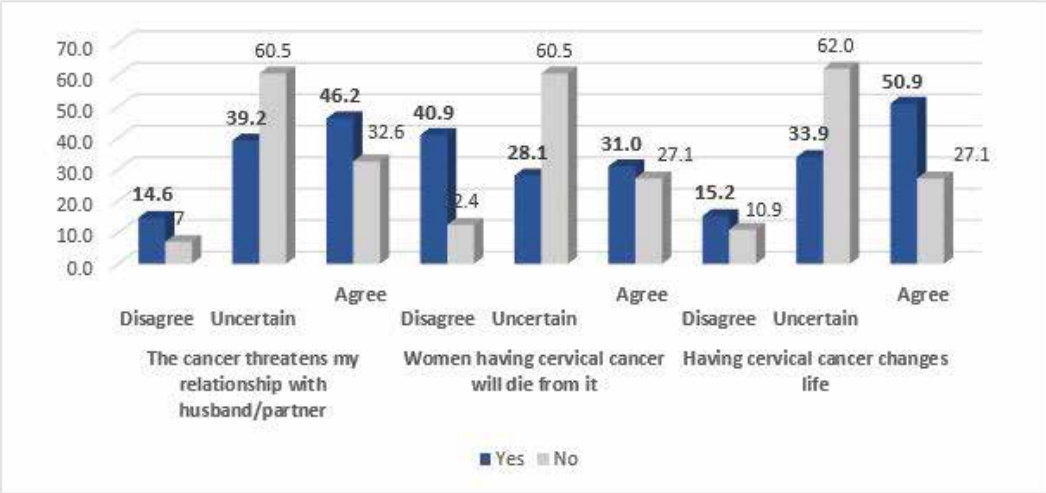

Figure 3: Perceived more likely than average women to get cervical cancer

Based on the Likelihood Ratio Test, all items for Perceived Benefits are significant at 5% level ($p \leq 0.001$). The adjusted model with demographic variables reveals that Age ($p < 0.001$), Marriage Status ($p < 0.001$), item "Easier to treat cervical cancer due to early detection ($p < 0.02$).

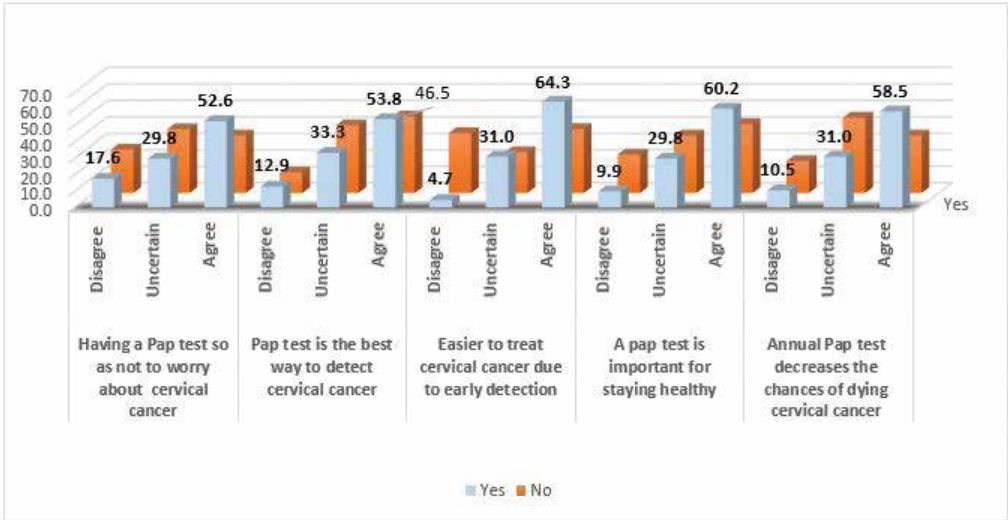

Figure 4: Perceived benefits of cervical cancer screening

Conclusion

The HBM Scale for Cervical Cancer Screening was found to be valid and reliable tool in assessing the women's health beliefs as agreed by GuvenenAkyuz and Acikel (2011). In conjunction with the Perceived Susceptibility, demographics variables such as *Age, Employment* and *Marriage Status* are significant ($p < 0.001$) to Cervical Cancer screening. However, for *Perceived Severity*, only *Age* and *Marriage Status* are significant. Similarly, for *Perceived Benefits* these two factors from demographic are significant to Cervical Cancer Screening. As a conclusion, *Age* and *Marriage Status* are significant factors for the three HBM constructs explored in this study.

Although the study is limited to selected hospitals, an insight to what extend the HBM influences the cervical cancer screening has been presented. Consequently, the information can be used as a reference towards enhancing cervical cancer uptake in the future. The study also could be directed to the aimed specific groups of women besides establishing its dependability in other selected locations. Nevertheless, understanding the beliefs of women with respect to Cervical Cancer Screening that inevitably helps healthcare professionals to develop more effective cervical cancer screening programs.

Level of Spirituality and Demographic Factors among People Living with HIV/AIDS

Rajwani Md. Zain[1], Zarina Mat Saad[1], Fatimah Zailly Ahmad Ramli[1]

[1]School of Applied Psychology, Social Work & Policy, Universiti Utara Malaysia,06010Sintok,Kedah,Malaysia

ABSTRACT

Individuals infected with the HIV/AIDSfrequentlyreceive negative conjecture from the public in all aspects of life as well as in the aspects of spirituality. However, spirituality has been identified to contribute positive impact on people who are suffering hardship including individuals infected with HIV/AIDS. Spirituality is often used as asource of strength or coping strategy to deal with the challenges in life.The HIV/AIDS virus is commonly related to social problems and promiscuous activities. This research was conducted to identify the level of spirituality among people living with HIV/AIDS (PLWHA)in the state of Kelantan.The respondents consisted a total of 34 male and female HIV/AIDS patients. The data was gathered using a set of questionnairesadapted from the Spiritual Quotient Questionnaire (SQQ). The results showed that majority of the respondents have a moderatelevel of spirituality; and there were no significant relationshipsamong the respondents' spiritual level and the selected demographic factors which are age, income, number of dependentsand duration of infection.This somehow shows that even though the respondents had involved withactivities that are against the norms of society, they still maintain a considerablelevel of spirituality. Therefore, the society should avoid casting their prejudice against people living with HIV/AIDS.

Keywords: *spiritual, HIV/AIDS, social problems, prejudice.*

Introduction

HIV continues to become one of the global health issues. In 2015, an estimated 36.7 million of the world population living with HIV including 1.8 million children. However, the percentage of adults with HIV is higher at 0.8% andmost of the HIV patients live in the low-income countries. It was also reported that 1.1 million people died due to AIDS related diseases in 2015. Since the beginning of the epidemic, 78 million people have been infected with the deadly virus, and 35 million have perished as a result of AIDS complications (Malaysia AIDS Council, 2010).

Psychosocial issues have played a major role in the life of people living with HIV/AIDS (PLWHA). According to Fabianova[11], people living with HIV/AIDS will experience emotional stress once they know their HIV/AIDS status. Based on the conducted researches, HIV victims will experience frustratation, fear, anger, anxiety, guiltand fear of losing something precious. Besides that, some victims have experienced denialsituation where they cannot accept the fact that they are infected with the terminal disease. This could lead to depression and severe emotional stress that may end in negative action such as suicide.Furthermore, normally people living with HIV/AIDS are afraid and worry to face their family members, spouses and the community. The issues of discrimination and negatives stigma are among the factors that contribute to their emotional stress. Apart from that, they are presumed to be deviated from healthy lifestyle as well as lacking the righteousness and proper religious practices.

Spirituality and religion are two interrelated terminologies but carry different meanings. Most researchers use the two terms in their studies as the concepts are complex in nature and intertwine with one another. These two concepts cover variousvariables such as cognitive, interpersonal, emotion, behavior and physiology dimensions Plante & Sherman[17].Many experts concluded that there is an apparent different between spirituality and religion. Religion is communal in nature and manifested in the context of formal religious institution. On the other hand, spirituality carries a larger concept that involve a belief system and values that an

individual holds onto, in which also covers the concept of religion. However, the nature of spiritualityis more on the personal side of an individual and inclusive of one's inner self as compared to religion Mattis & Jagers[14]; Westgate[24].

Spirituality is often defined as non-material matters that assists the quests of finding the meaning of life and relationship more than the individual's self.It can increase one's knowledge (knowledge acquired through other ways than by normal means) and make a person live a compassionate life.This knowledge can be acquired through devotion on certain religion, belief system, culture, value and custom Zarina Mat Saad, Zulkarnain Ahmad Hatta & Noriah Mohamed[25]. Therefore, this research uses and measures the concept of spirituality based on the spiritual intelligence.

Spiritual intelligence is the basis of the search and usage of information in problem solvingEmmons[6]. It contains several abilities and competencies for a person to deal with a problem or adaptation process. Thus, Emmons stated that spiritual intelligence is the most important intelligence compared to other forms of intelligence. It enables an individual to cater daily problems and achieve goals which will eventually improve the wellbeing and quality of life.

The Level of Spirituality Determining Factors Of People Living With HIV/AIDS: The research on spirituality was conducted by Bernstein, D'Angelo and Lyon[2]nvolving teenagers aged between 12 to 21 years old. The respondents, male and female, consisted of teenagers from various ethnicities; some were HIV/AIDS positive while others were not.The research found that majority of the respondents favored spiritual based activitiesespecially the ones with positive HIV/AIDS who had shown higher percentage of interest. This was due to their seriousness of mental stress, and they have high confidence that spiritual based activities will cure them of their disease.High level of spirituality/religiosity helps HIV/AIDS patients cope with the infection through bolstering and changing the attitude, reducing the anxiety and mental health problem which indirectly give a positive impact to their statusArrey, Bilson, Lacor & Descheppe[1].

The staff who are directly involve in providing humanitarian and health service should have the knowledge on how individuals who come from various ethnicities or religious backgrounds express their spirituality towards their illness Koenig & Cohen[9]. According to, there are six causes as to why spirituality aspect should be given a consideration among the patients.They are:

i. Most patients emphasize religion and spirituality, and want these matters to be considered in their treatment.

ii. Religion/spirituality influence their ability to cope with their illness.

iii. In-patients receiving care in hospitals are isolated from their religious community.

iv. The belief of a religion/spirituality influence the patients' decision making regarding the treatment that they will receive.

v. Religion/spirituality influence the mental and physical health or vice versa.

vi. Religion/spirituality influence health care in the community.

Dalmida[4]found that women infected with HIV/AIDS have turn to faith or belief in religion were able to determine their wellbeing and quality of life including excellent health status. In her article, she explained about the relationship between stress or depression and spiritual level among persons living with HIV/AIDS. Without a strong faith in the respective religions, patients have the tendency to be affected with other mental problems. This statement showed that one's spirituality enable a person to determine a better quality of life. Spirituality has also been used as an individual's resource to cope with illness or psychological and emotional related issues Sowell, Moneyham, Hennessy, Guillory, Demi & Seals[22], and to adapt to uncertain situations especially in cases where options to deal with common illnesshave ran out Simoni, Martone, & Kerwin[22]. For most women diagnosed withHIV positive, spirituality has played an important role to deal with emotional stress related to HIV infection McCormick, Holder, Wetsel, & Cawthon[15]; Powell, Shahabi, & Thoresen[18]; Sowell et al.[22].

Besides that, Rentala, Lau and Chan[19]conducted a study regarding the relationship between spirituality and emotional stress faced by people living with HIV/AIDS. The study involved 120 Hindu and Muslim patients in a hospital in Karnataka, India. The result of the study showed that patients who were having high level of

stress greatly require spiritual activities as compared to those who were less stress. The spiritual activities are hoped to assist the patients to share the meaning and purpose of life.

Spirituality Aspect That Affects the Life Of People Living With HIV/AIDS: A study by Szaflarski, Ritchey, Leonard, Mrus, Peterman, Ellison, Tsevat[23]has found that spirituality/religion positively related with emotion, and the life has increasingly become better for HIV/AIDS patients after being diagnosed.Indirectly, their health status also improved once they comprehend the aspect of spirituality.Besides that, according to Cotton, Puchalski, Sherman, Mrus, Peterson, Feinberg and Tsevat[3], the high level of spirituality also increases the satisfaction in life, health status and the quality of life.

According to Arrey, Bilsen, Lacor dan Deschepper[1], spiritualityis an important element in establishing coping strategy, survival and ensuring the wellbeing of the community in Africa.The comprehension and practice in the aspect of spirituality and religion become more important once a person has been diagnosed with chronic diseases including HIV/AIDS. A study conducted on 44 respondents has found that religious practices like prayers, meditation and performing charity work in places of worship have made the patients accept their health conditions and consider it as fated by God. Besides that, they believe that certain religious activities will enable them to receive divine assistance.

The research of Mohammad Amin Wani[16]in the district of Jammu and Kashmir, India among the people living with HIV/AIDS on the quality of life has found that 65% of the respondents have showed a low level of spirituality while only 35% of the respondents have high level of spirituality. Spiritual and religious elements has been the source of strength and has a direct connection with HIV patients especially those who are receiving palliative care.However the direct connection differs from male to female patients.The research of Hutson, Darlington, Hall, Heidel and Gaskins[8] further explained that spiritual wellbeing moderately differs between the male and female respondents. However, the researchers reported that religious wellbeing were high among the female respondents as compared to the male's moderate level.

Specifically, among the female HIV patients, engagement in spiritual activities such as praying relieve emotional stress, depression, promote optimistic attitude and be more adaptable with the psychological change that has happened.Laveena, Govindraju, & Monterio[10]. The belief in God and higher power among the HIV patients in Malaysia have become a strong foundation to face the challenges as a person living with HIV/Aids Shaw, Cornwell, Lim, Saifi, Lik, & Kamarulzaman[20]. Shaw's study also explained that believing in God gives an impact to the HIV patients' spiritual strength while facing the stigma in the community.

Systematic reviews research by Doolittle, Justice and Fiellin[5]supported the 15 researches that were conducted in the period from 1980 to 2016 for topic concerning HIV/AIDS and spirituality showed that there was a positive relationship between religious aspect and the conducted HIV clinical study.All of the researches showed that involvement in religious/spiritual activities were related to the count increase of the CD4 cell, lower the viral loads which refers to the total HIV in the blood vessels and decrease the number of death among the HIV patients.

To summarise, based on the previous literature, spirituality seems to be crucial to the people living with HIV/AIDS. It acts as the source of strength to cope with the disease, help to make better decision and parallel with the faith of the patients. It is also said to increase the physical and mental wellbeing of the people living with HIV/AIDS to live peacefully after being diagnosed with the virus.

Methodology

This research utilized the quantitative approach and the data was gathered using the survey method through a set of questionnaire. For the purpose of questionnaire distribution, several Non-Government Organisation(NGOs) providing care service to people living with HIV/AIDS in the state of Kelantan were contacted.

The respondents involved in this study were people who are infected with the HIV/AIDS virus. The main constraint of this study was to get respondents who were willing to be involved in the study. This was due to self disclosure issue. Therefore, only 37 persons had agreed to fill in the questionnaire with assistance. However, only 34questionnaires were completed and can be analysed.

The spirituality level was measured using the Spiritual Quotient Questionnaire (SQQ) that was developed by MySkills Profile.com (2006) and were translated and adapted to the Malay language by

Zarina Mat Saad, Zulkarnain Ahmad Hatta and Noriah Mohamed[25]. The instrument's internal reliability is acceptable with a Cronbach's Alpha value of 0.91. The instrument uses the 5 points likert scale from 1 = very disagree to 5= very agree. The spiritual intelligence are divided into 3 levels which are low (score of 72-168), moderate (169-264) and high (265-360).

The quantitative data was analized using Statistical Package for Social Science(SPSS-PC). Descriptive statistics analysis method which involved percentage and mean were used.

Result and Disscussion

Demography: All of the respondents involved in this research were Muslims of the Malay origin.Genderwise, 29 (85.3%) respondents were male and the remaining 5 (14.7%) were females. They aged between 17 to 57 years old with the majority of the respondents aged between 31-40 years old (52.9%). The profiles of each respondents were almost similar to the study conducted by the Malaysia AIDS Council which showed that majority of people living with HIV/AIDS are Malays aged between 30-39 years old.

Majority respondents had a moderate level of education and earned income between RM500 – RM1000. Only one respondent earned an income of RM3000 while ten respondents (29.4%) do not earn any income.Most of them are HIV positive and only one respondent were diagnosed with AIDS. The main source of infection was needle sharing due to the habits of drug abuse injection.Most of the respondents were infected in less than 5 years (Refer Table 1)

Table 1: Socio-Demographic Profile

Respondent Information		**Illness Information**	
Gender		**Infection Status**	
Male	29 (85.3%)	HIV	33 (97.1%
Female	5 (14.7%)	AIDS	1 (2.9%)
Age (years old)		**Source of Infection**	
<30	6 (17.6%)	Needle Sharing	25 (73.5%)
31–40	18 (52.9%)	Sexual Relation	7 (20.6%)
41–50	9 (26.5%)	Needle Sharing & Sex	1 (2.9%)
>51	1 (2.9%)	Infected	1 (2.9%)
Average = 37.18; Min= 17; Max = 57			
Marital Status		**Risky Activities**	
Single	21 (61.8%)	Drug Abuse	23 (67.6%)
Married	5 (14.7%)	Sexual Relation	8 (23.5%)
Widow/Widower	8 (23.5%)	Both	1(2.9%)
Level of Education		**Duration of Infection (years)**	
Primary	9 (26.5%)	< 5 years	20 (58.8%)
Lower secondary	14(41.2%)	6 – 10 years	4 (11.8%)
Upper secondary	10 (29.4%)	11 – 15 years	3 (8.8%)
High school	1 (2.9%)	16 – 20 years	4 (11.8%)
Income (RM)		>21	2 (5.9 %)
None	10 (29.4%)	not reported	1 (2.9%)
Indefinite	1 (2.9%)		
<500	4 (11.8%)		
501 – 1000	12(35.3%)		
1001-1500	3 (8.8%)		
2500-3000	1 (2.9%)		
Unreported	3 (8.8%)		
Min= 100; Max = 3000; Average = 916.50			

Level of Spirituality: The study shows that majority of respondents have a moderate level of spirituality (18; 53%) and high (15; 44%). This depicts that even though the people living with HIV/AIDS were involved in social misbehaviors they still possess a good level of spirituality (average 255.82) (refer table 2)

Table 2: Respondents' Spirituality Level

Spirituality Level	Score	N (%)
High	265 – 360	15 (44%)
Moderate	169 – 264	18 (53%)
Low	72 – 168	1 (3%)

The Relationship Between Level of Spirituality And Selected Demographic Profiles: Pearson Correlation was run to test the relationship among demographic factors and the respondents' spirituality.

Age: To determine the relationship of age and level of spirituality amongpeople living with HIV/AIDS. The result is shown in Table 3.

H_1: There is no significant relationship between age and level of spirituality.

Based on Table 3, failed to be rejected because of the probability value (significant) > 0.05 for spirituality level of people living with HIV/AIDS. At the significant level 5%, there is no significant difference in age based on the level of spirituality. This shows that age difference does not correlate with the spirituality level of HIV/AIDS patients.

Table 3: Correlation Analysis Result between Age and Level of Spirituality

		Level of Spirituality
Age	Pearson Correlation	0.252
	Significant (p-value)	0.133

Income: Conducting correlation analysis to test the relationship between income and spirituality level of people living with HIV/AIDS, the result is shown in Table 4.

H_2: There isno significant relationship between income and level of spirituality.

In table 4, H_2 failed to be rejected because the value ofprobability (significant) > 0.05 for spirituality level of HIV/AIDS patients. At significant level of 5%, there is no significant difference between income and spirituality level. It can be deduced that difference in income does not correlate with the spirituality level of the HIV/AIDS patients.

Table 4: Correlation Analysis Result between Income and Spirituality Level

		Spirituality Level
Income	Pearson Correlation	0.288
	Significant (p-value)	0.083

Number of Dependents: Analysis was conducted to test the relationship between the numbers of dependents and spirituality level of people living with HIV/AIDS using the Pearson correlation. The results is recorded in Table 5.

H_3: There is no significant relationship between the numbers of dependents and spirituality level.

Based on the result in Table 5, H_3 failed to be rejected because the value of probability (significant) > 0.05 for spirituality level of HIV/AIDS patients. At significant level of 5%, there is no significant difference between the number of dependents and spirituality level. The difference in the number of dependents does not correlate with the spirituality level of the HIV/AIDS patients.

Table 5: Correlation Analysis Result between Numbers of Dependents and Spirituality Level

		Level of spirituality
Number of Dependents	Pearson Correlation	-0.208
	Significant (p-value)	0.218

Duration of Infection: To study the relationship between factor of duration of infection and spirituality level of people living with HIV/AIDS, correlation analysis was conducted.The result is shown in Table 6

H_4: There isno significant relationship between the duration of infection and spirituality level

The result in Table 6, H_4 failed to be rejected because the value of p probability (significant) > 0.05 for spirituality level of HIV/AIDS patients. At significant level of 5%, there is no significant difference between the duration of infection and spirituality level. It can be said that the difference in the duration of infection does not correlate with the spirituality level of the HIV/AIDS patients.

Table 6: Correlation Analysis Result between Duration of Infection and Spirituality Level

		Level of Spirituality
Duration of Infection	Pearson Correlation	0.339
	Significant (p-value)	0.043

The results of this research suggested that all of the analyzed variables (age, income, number of dependents and duration of infection) do not establish any relationship with the level of spirituality of the respondents. The findings of this research do not support the previous literature's findings which shown relationship or influence between demographic factors and the faith, belief, religious practices as well as spirituality among person infected with the HIV. The probable cause may due to the respondents' way of life that still attach to the local culture as well as living with family. Family acceptance and support play vital roles in a person's spirituality including people living with HIV/AIDS.

Conclusion

In short, the findings showed that all people living with HIV/AIDS (PLWHA) as the respondents of this research have moderate and high level of spirituality. Most probable, through prayers or other forms of coping strategy offerrespondents with positive psychological impacts which then affects their physical being. Apparently, even though they are the social perpetrators, they have excellent level of spiritualityHowever, the researchers are unable to determine whether the level of their spirituality has increased or otherwise after their regular health diagnosis. The findings of this research have proven that people living with HIV/AIDS should not be discriminated, instead their family members and the community need to provide the necessary supports in their effort to further improve the quality of life.

Description on the Quality of Life among Elderly Affected by Dental and Oral Health in Jagir Health Centre Surabaya

Rima Arsyilviasari[1], Tiara Meilena[1], Ayu Setyowati[1], Retta Gabriella Pakpahan[1], Nur Latifah Zuniati[1], Alvita Wibowo[1], Darmawan Setijanto[1]

[1]Faculty of Dental Medicine, Airlangga University, Surabaya 60115 Indonesia

ABSTRACT

Macroscopically, teeth experience changes in shape and color along with increasing age. In Indonesia around 24% of elderly people aged 65 years or older experience tooth loss. This condition was a threat to quality living elderly in living everyday life. Taking this into consideration, this study is intended to investigate the factors such as education level, frequency of brushing teeth, frequency of dental visit and illnesses (hypertension, diabetes mellitus and coronary heart disease) affected the caries severity and the quality of life among the elderly of Puskesmas Jagir. The findings from this study proved that lack of awareness of maintained a healthy oral health and lack of awareness of the side-effects of medication taken to the oral health as well as low interest in visiting dental clinics are three of the major problems that deteriorate the oral health of the elderlies since the DMF-T scores (> 13) for these factors were high. Thus, the elderly need to acquire the necessary knowledge by attending counselling classes and visiting the dentist in order to apply this knowledge for a better quality of life.

Keywords: *Dental Caries, Elderly, Oral Health, Quality of Life*

Introduction

Oral hygiene among the elderly must be maintained in view of various changes that happen such as thinning of the oral mucosa, decreased in salivary production, and tooth loss[1]. The number of teeth in the elderly is also affected by dental and oral hygiene. Poor oral hygiene can result in irritation and health problems of the gums and surface of the teeth. These teeth disorders eventually decreased the appetite and weight loss, and teeth become infectious. In addition, the decreased in health and endurance of the body of the elderly will facilitate the occurrence of mucosal infections in the cavity and periodontal tissue[2].

Caries is a destruction process that causes decalcification of enamel and dentin and formation of holes in the teeth. The caries process is characterized by the occurrence that causes bacterial invasion and damage to the pulp tissue and the spread of infection to the periapical tissues and caused pain. The decayed, missing, filled tooth (DMFT) index is a number shows dental caries status and can also be used to measure degrees of caries severity. The examination includes all teeth except for third molars which rarely grow. Indonesian DMF-T index in 2013 is 4.6% which means tooth decay of the Indonesian population of 460 teeth for every 100 people. It is known that the average DMF-T index in East Java is as large as 5.5 with hole tooth details (D) of 1.6; missing teeth (M) of 3.8; and patched teeth of 0.08[3].

In May 2017, there were 170 cases of pulpitis amongst the elderly at the Puskesmas Jagir clinic. Whereas in 2016 total cases of pulpitis in the elderly amounted to 1961 with details of 498 in the first quarter, 446 in the second quarter, 446 in the third quarter, and 571 in the fourth quarter. Based on that, this research focused on investigating the effects of lifestyle on the development of dental caries of the elderly at Puskesmas Jagir.

Methodology

This study was conducted at Puskesmas Jagir in the month of June 2017. 91 elderly (aged 45 and above)

Corresponding Author:
Darmawan Setijanto
Faculty of Dental Medicine, Airlangga University,
Surabaya 60115 Indonesia
Email: r-darmawan-s@fkg,unair.ac.id

were randomly selected as the test subjects. The factors which were investigated are education level, frequency of brushing teeth, frequency of dental visits, and the level of stress experience by these elderlies.

The information needed for this research is gathered using WHO Quality of Life Questionnaire as well as dental and oral health examinations. All questions is based on a five-point Likert scale (1-5) that focused on intensity, capacity, frequency and evaluation. The intensity response scale refers to the degree to which the status or situation is experienced by the individual. Capacity response scale referred to the capacity of feeling, situation or behavior. The frequency response scale referred to the number, frequency, or speed of the situation or behavior. The evaluation scale referred to the estimated situation of the situation, capacity or behavior.

Result and Discussion

In this study, the DMF-T index was used to measure dental caries in the study subjects. Based on the results obtained, DMF-T population index had a median value of 13. If the number of teeth subject to caries is ≤13, it can be categorized as good whereas if the number of teeth subject to caries > 13, then it was categorized as bad. This information was further broken down into three other groups (D-T, M-T and F-T). The D-T population index had a median value of 3. If the number of teeth subject to caries ≤ 3, it can be categorized as good while if the number of teeth subject to caries > 3, then categorized as bad. As for the M-T population index had a median value of 7. The number of teeth is ≤7, falls under the good group. However, if the score for loss of tooth is more than 7, then it is bad. The F-T population index had an average value of 0. If the number of subject teeth has caries patch of 0, it can be categorized as good. Whereas if the number of teeth of subjects who have fillings > 0, then categorized as bad.

Table 1 showed the cross tabulation between DMF index in population with frequency of brushing teeth routine. There was no significant difference between the DMF indexes of the population with irregular brushing teeth frequency compared to the population with routine brushing teeth frequency. Nonetheless, those who brushed their teeth routinely had a lower caries severity than those who did not.

Table 1: Cross tabulation between DMF index with frequency of brushing teeth

Frequency of brushing teeth	DMF-T index		Total
	>13	≤13	
Non-routine	8 (17.39%)	9 (20%)	17 (18.68%)
Routine	38 (82.61%)	36 (80%)	74 (81.31%)
Total	46 (100%)	45 (100%)	91 (100%)

Cross tabulation between DMF Index in population with frequency routine dental visits is presented in Table 2. Those respondents who did not have a routine visit to the dental had DMF-T index > 13 by 1.39 times higher than those who went to dental frequently. This result were justified by Pratiwi et al[4] who stated that regular visits to dentist increased public awareness through counselling which can help in early diagnosis. Thus, one of the preventative actions which can be taken to improve the level of oral health is by attending dentist's counselling session conducted during the routine visit at the dental at least once every 6 months[5].

Table 2: Cross tabulation between DMF index with frequency of dental visit

Frequency of dental visit	DMF-T index		Total
	>13	≤13	
Non- routine	39 (84.78%)	36 (80%)	75 (82.42%)
Routine	7 (15.22%)	9 (20%)	16 (17.58%)
Total	46 (100%)	45 (100%)	91 (100%)

Table 3 is the results of cross tabulation between DMF Index in population and education level of the elderly respondents. The education level is divided into two distinguish category which is till junior high school and those who continued studying after junior high school. Results indicated that despite having a better education level (higher than junior high), these respondents still had a poor oral health (severe caries) compared to those who studied up to junior high only. According to Budiman A. R. [6] found level of education is related to the level of knowledge someone against disease and behavior to deal with it. The higher the level education, it is easier for someone to receive information on the importance of preserving a good and healthy oral hygiene.

Table 3: Cross tabulation between DMF index with education level

Education level	DMF-T index		Total
	>13	≤13	
Till junior high	13 (28.26%)	26 (56.53%)	39 (42.85%)
Higher than junior high	33(71.74%)	19 (43.47%)	52 (57.15%)
Total	46 (100%)	45 (100%)	91 (100%)

Cross tabulation between DMF-T index with DM is shown in Table 4. It is identified that those with DM were at 1.143 times risk to develop caries compared to those without DM. diabetes mellitus with poor oral hygiene and presence diabetic angiopathy caused a reduced in oxygen supply, thence Anaerobe bacteria to develop easily. Dental caries occurs due to bacteria certain that have acid-forming properties, so low pH can cause progressive dissolution of enamel minerals to slow down and form perforation. However, those in-controlled diabetes patients have almost insignificant dental caries compared to normal healthy people.

Table 4: Cross tabulation between DMF index with diabetes mellitus (DM)

Has Diabetes mellitus (DM)	DMF-T index		Total
	>13	≤13	
Yes	8 (53.33%)	7 (46.67%)	15 (100 %)
No	38 (50%)	38 (50%)	76 (100 %)
Total	46 (50.55%)	45 (49.45%)	91 (100%)

Table 5 presented the cross tabulation between DMF index with hypertension. Based on the table, it proven that hypertension patients were at 1.946 times more likely to suffer from severe dental caries (DMF-T > 13). The usage of antihypertensive drugs could cause several things to occur including reduced salivary production which lead to increased chewing activity till the stimulation of salivary production in some active salivary glands increases and this eventually leads to exacerbations and decreased speech ability due to reduced lubrication function. Thus, decreased salivary production has a high risk of dental caries[7]. Furthermore, Bradley P.J. et al.[8] found antihypertensive drugs can affect salivary flow directly by mimicking the action of the autonomic or nervous systems by directly acting on cellular processes needed by saliva, while indirectly affect the flow of saliva to the gland or alter the fluid and electrolytes balance. The consumption anti-hypertension drugs are also proven to rise xerostomia, hypo-salivation, and increase in the number of oral microbiota, including Angiotensin Converting Enzyme (ACE-inhibitors) and beta blockers.

Table 5: Cross tabulation between DMF index with hypertension

Has hypertension	DMF-T index		Total
	>13	≤13	
Yes	9 (64.28%)	5 (35.72%)	14 (100 %)
No	37 (48.05%)	40 (51.95%)	77 (100 %)
Total	46 (50.55%)	45 (49.45%)	91 (100%)

Table 6 is the outcome of the cross tabulation between DMF index with coronary heart disease. Those with DMF index > 13 had a 3.07 chance of having coronary heart disease compared to the respondents with DMF index ≤ 13.

Table 6: Cross tabulation between DMF index with coronary heart disease

Has coronary heart disease	DMF-T index		Total
	>13	≤13	
Yes	3 (75%)	1 (25%)	4 (100 %)
No	43 (49.42%)	44 (50.57%)	87 (100 %)
Total	46 (50.55%)	45 (49.45%)	91 (100%)

Untreated dental caries can result in periapical infection. Chronic periapical infections can cause the formation of granulomas, abscesses, or cysts. Caries in the form of residual roots that are not revoked can also cause periapical infection. This periapical infection can be focal infections that cause various diseases included coronary heart disease. Focal infection itself is the process of spreading from germs or toxins (toxic germ products) from the focus of infection to other places far away from infection and in this place can cause tissue damage or form new infections or new disorders. Dental plaque and calculus are strong risk factors for coronary heart disease. Strong indicators of death in addition to coronary heart disease are periodontal disease and poor oral hygiene[9].

Conclusion

In conclusions, several risk factors such as frequency of brushing teeth, knowledge on brushing

teeth and awareness of dental visits influenced the high level of elderly dental caries. The high level of dental caries also affected the condition of systemic diseases such as diabetes mellitus, hypertension, and coronary heart disease.

Genetic Diversity of Anopheles sp as Malaria Vectors Who Carries Plasmodium Falciparum and Plasmodiumvivax Which Can Infect Human in Jayapura Municipal, Papua Province, Indonesia

Yohana Sorontou[1], Henny Sesanti Budi Hastuty[1]

[1]Ministry of Health, Polytechnic of Health Jayapura, Jalan Padang Bulan II, Hedam, District Heram, Jayapura Municipal, Papua Province.

ABSTRACT

Background. Jayapura municipal are region which are rainfall not erratically down will affect the development larvae of *Anopheles* mosquito which are can be threat of outbreak still remains due to the high prevalence and abundance on malaria vectors. Aim. The aim of this study to analyze species of *Anopheles* mosquito and genetic diversity species of *Plasmodium* which are found into *Anopheles sp* as malaria vector which are cause malaria in Jayapura Municipal. Methods. This type of research is a descriptive study using a cross sectional design. Adult of mosquito Anopheles were collected from four study sites located in in two district using human landing catch and aspirators. Representative samples of each species which are morphologically confirmed were selected of each locality in generally was found there is higher areas and low areas. Results. A total of 38 samples from *Anopheles sp* which are found by determination key shown that *An. punctulatus* as mush as 23(60.5%), *An. koliensis* 13 (34.2%) and *An. farauti* 2(5.3%) respectively with Pv < 0.05, and analyze through DNA extracted by PCR product, we did not found DNA bands from *P. falciparum* and *P.* vivax. Conclusions. The result of this study shown which are Pv < 0.05, there were significant correlation between located with Anopheles sp. Genetic diversity of *Anopheles* sp based on PCR product, overall not found DNA bands of *P. falciparum and P.vivax* because probably *Anopheles* mosquito species which such the blood of the captured person has not been infected by the both *Plasmodium* above in Hamadi rawah areas.

Keywords: *Genetic diversity, Anopheles sp, P. falciparum, P. vivax, Malaria.*

Introduction

Malaria is still remain a major public health of morbidity and mortality with a concerning issue of increase in cases that reported in the 2017.According to thereport there were 212 million new cases of malaria worldwide in 2015. The incidence become 148-304 million clinical cases of malaria each year, and most them are caused by *P. falciparum* and *P. vivax*[1,2]. The report draws on data from 91 countries and regions with ongoing malaria transmission in 2016[3].

Malaria is an infectious disease caused by protozoan parasites from the Plasmodium family which can be transmitted by bitten of the *Anopheles* mosquito. Falciparum malaria is the most deadly type. The symptoms of malaria include cycles of chills, fever, sweats, muscle aches and headache that recur every few days. There can also be vomiting, diarrhea, coughing, and yellowing (jaundice) of the skin and eyes. Persons with severe falciparum malaria can develop bleeding problems, shock, kidney and liver failure, central nervous system problems, coma, and die[4].

Its epidemiology is determined by three components; the human host, the *Plasmodium* malaria parasite, and

Corresponding Author:
Yohanna Sorontou
Ministry of Health Polytechnic of Jayapura,
Street of Padang Bulan 2, Hedam, Districk Heram,
Jayapura City, Papua, Indonesia
Email: yohanna.sorontou@gmail.com

the environment, The latter includes both the psysical and biological environment is female mosquito Anopheles as malaria vectors[5]. The majority of mosquito in Papua Province are *An. farauti*, *An. Punctulatus* and *An bancrofti* whereas *An,koliensis* and *An. Kowari* are secondary vectors[4,6.]

In Indonesia, the populations were living in endemic areas of malaria, local transmission is still at risk of malaria. By 2014 there are 74% of the population living in malaria without risk areas and 3% living in high risk areas. In the last 4 years most of the population lives in free Malaria areas whereas the population shows an increasingly. While people in high endemic areas have the lowest pretentage and level to fall from 4.7% in 2012 to 2.2% in 2015[5].

In Papua Province of Indonesia, malaria is a major health problem because this area is one of malaria endemic areas with hyper-endemic category in Indonesia.. Regency Health office reported in Jayapura that the annual parasite incidence (API) of malaria cases in 2014 was 90 per 1000 populations and Annual Malaria Incidence (AMI) is still 122 per 1000 populations[7].

Clinical Manifestation of malaria is influenced by several factors in the human host, *Anopheles* sp, parasite and enviroment. In human, age, immunity, pregnancy and genetic factors have been shown to determine the malaria cilinical outcome whereas in the malarial parasite, drug resistance, multiplication rate, invansion pathway, cytoadherence and rosetting, antigenic variation and polymorphisms, and malaria toxin are among other factors that have been identified[8].The mosquito species as malaria vectors mainly in Indonesia, expecially in Papua are *An, punctulatus, An. farauti,*and *An koliensis, respectively* which can be cause falciparum malaria, vivax malaria, and malariae malaria however ovale malaria rarely found in Papua, Indonesia[4,6.]

Genetic diversity of *Anopheles* sp has the effect of the capacity value occurrence transmission and the vector's ability to transmit malaria[9.10]. Understanding the biology and behavior of *Anopheles* sp could be help understood how malaria is transmitted and can aid designing appropriate control strategies. Factors that effect a mosquito's ability to transmit malaria include it's innate susceptibility to *Plasmodium*, its host choice and its longevity[11], and difference in habitat conditions and community environment will be also affect the distribution of *Anopheles* in one area.

Material and Method

Description Study Site: This study was conducted in September to November 2017.Mosquito samples are obtained from different locations in Jayapura Municipal namely, Hamadi rawah, Skyline and Organda villages. In the microscopic examination, we were conducted at Laboratory of polytechnic of Health, Ministry of Health Jayapura and Eijkman Institute laboratory in Jakarta. Jayapura Municipal its wide territory covering 442,540 km^2.Jayapura Municipal is divided into mainland, swamp (146,576 ha), river areas and large heading to the Pacific Ocean. The Municipal is bordered in the North through Pacific Ocean and in the east with Papua New Guinea. The populations of Jayapura Municipality is mainly Papuan, migrants Java, Sulawesi, Moluccas and the other parts of Indonesia.

Hamadi rawah village, this place is a lot of *Mangrove* trees which are a breeding ground for larvae of *Anopheles* sp. People were living in these areas from Papuan and non-Papuans tribes with a high population density the same with skyline and Organda villages[12,13]

The climate is typically tropical with average temperature between 25-35^oC. The difference between rainy season and dry season as because of wind effect. May to November, the wind is blowing from South east with less amount of water vapor whereas in December to April the westerly wind is blowing sea and causes rainfall. The range of rainfall is between 1,500-6000 mm per year[6].

Mosquito collection and identification: There are several sites in Jayapura Municipal which we were collected sample of mosquitoes. The technic for obtain sample we use human landing catch method. The mosquitoes that select reside around the resident's house by using aspirator. After sample we collect and inserted into the paper cup and then covered with gauze, on top of which was placed cotton which had been fed mosquitoes to keep the mosquitoes alive until identified process in the laboratory. Collecting malaria vectors we start from 06.00 pm to 06.00 am with long catch for 15 minutes with an interval of 1 hour[12,13]. For identification we were using determination key in Polytechnic Health Laboratory in Jayapura and molecular laboratory of Malaria Eijkman Institute in Jakarta.

Mosquito DNA Extraction: Individual mosquitoes were crushed in 1.5 mL micro-centrifuge tubes (Eppendorf, Hamburg, Germany) containing 100 µL of

lysis buffer (0.2 M NaCl, 10 mM Tris HCl pH 8,25 mM EDTA, 0.5% sodium dodecyl sulfate) containing1.0 mg/ml of proteinase K and then incubated at 55°C for 2 hour prior to being extracted twice with 50 µL of chloroform: iso-amyl alcohol (24:1). The upper aqueous layer was transferred to a new tube and the DNA was precipitated by adding 50 µL of 7.5 M ammonium acetate and 300 µL of ice cold absolute ethanol. The tubes were then placed at -70 °C. for 15 min, microfuge at 4°C for 15 min, and then washed in 500 µl of ice cold 70% ethanol. The pellet was dried and reconstituted in 50 µl of TE buffer (10 mM Tris-HCl, 1 mM EDTA, pH 8.0) containing RNase (100 µg/ml) [14,15,16].

Primer Selection and Design: The primer designed ITS2A was designed as a 19-mer from the 5.8S rDNA of Drosophila melanogaster (5'TGTGAACT GCAGGAC A CAT) and the primer ITS2B was designed from common invertebrate sequences at the 5' end of the 28S rDNA (5' TATGCTTAA ATT CAGG GGGT). The oligonucleotide primers were constructed on an applied. Biosystems (Foster City, CA) 394 DNA/RNA Synthesizer[14,15,16].

Amplication of ITS2: All PCRs were carried out in 0.5ml microfuge tubes in a 25 µl volume using a Minicycler PTC-150 (MJ Research Inc. Watertown, MA). The final PCR mixture contained 50 mM KCl, 10 mM Tris HCl pH 9.0.1.5% Triton X-100,1.0 mM $MgCl_2$, 0.2 mM of each deoxynucleotide triphosphate, 50µM of each primer, 10% Dimethylsulfoxide (DMSO),and 2.5 units of *Taq polymerase*. The template was either purified DNA (1-10 ng), 1µl of allozyme triturate (reconstituted in 20 µl of double distilled water) or from a single leg placed in the PCR. Cycling involved an initial denaturation at 94°C for 5 min prior to the addition of *Taq enzyme* and an oil overlay and then 35 cycles at 94°C for 1 min, 51°C for 1 min, and 72°C for 2 min using minimum transition times[16,17].

Product digestion and visualization: A 5µl aliquot of the PCR mixture was added to water, 2.5µl of 10 x *msp1* buffer and 10 x bovine serum albumin (10 mg/ml) and 1µl of *msp1* restriction endonuclease (20 units: New England Bio labs, Beverly, MA) to give a total volume of 20µl, and the sample was incubate at 37°C for 2 hr. Ten microliters of the digested product was run on a 3% agarose gel (NuSieve GTG; FMCBI products, Rockland, ME) containing 0.5µg/ml of ethidium bromide and visualized at 312 nm on an ultraviolet trans-illuminator (International Biotechnologies, Inc, New Haven, CT)[14,15,16].

Result

The result of this study indicate that mosquitoes were collected from three sites in Jayapura Municipal. Total a sample 100 were collected. There were 38 materials samples which are positive *Anopheles* from three *Anopheles sp* was identified such as *An. punctulatus* (23), *An. koliensis* (13) and *An. farauti* (2) respectively. See in table 1.

Diversity and dominance of *Anopheles* sp in Jayapura Municipal was found in this study; *An.punctulatus* more higher than *An. koliencis* and *An. farauti*.

Table 1: Species of Anopheles mosquito identified from among those collected in three villages in Jayapura Municipal

Anopheles sp	Located			Frequency	P value
	Hamadi Rawah (%)	Sky Line	Organda		
An.puntulatus	23 (60.5)	0	0	23	0.000
An.koliensis	13 (32.2)	0	0	13	
An.farauti	2 (5.3)	0	0	2	
The others species and male *Anopheles*	0	37	25	62	
Total	38 (100)	37	25	100	

The result shown that the species of *A.punctulatus* as much as 23 (60.5%) were found more higher than *A. koliensis* as much as 13(34.2%) and *A.farauti* 2(5.3%) and others species and male *Anopheles* which exclude of this research as mush as 100 samples.P<0.05.

Based on PCR product shown that genetic diversity from species of *Anopheles* mosquito after giving restriction enzyme ALL1 for cutting of DNA length target band ladder (λ =432bp) for *P. falciparum* and *P. vivax* with band ladder 342bp and108 bp.See in Fig 1 and Fig 2

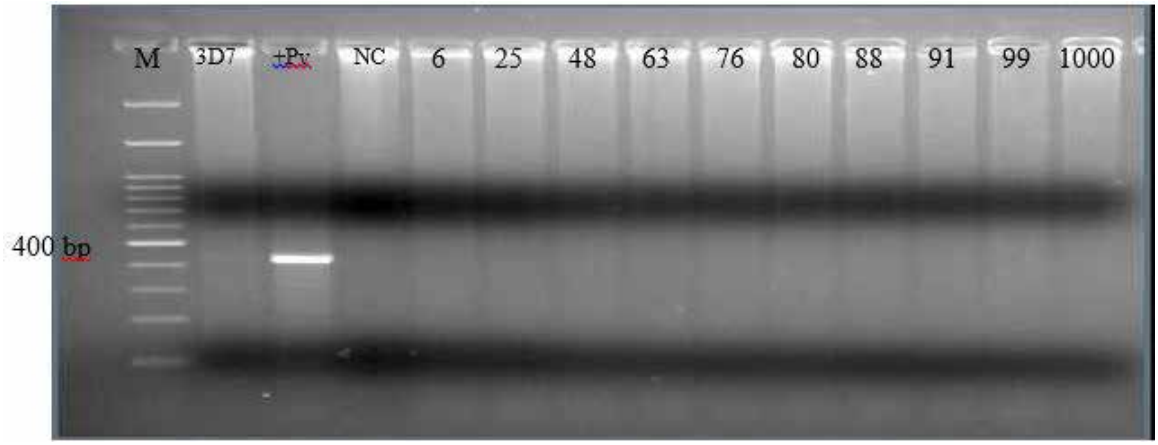

Figure 1: Electrophoregram result show which are PCR product from *Anopheles sp* there were of number 6,48 and 63 are *An.koliensis*, and then number 25,76,80,88,91 and 100 are *An.punctulatus*. M is ladder marker with 100bp, 3D7 was strain of *P. falciparum* (3D7 *strain*) as positive control and *+PV (P. vivax)*, positive control from hospital sample. NC is negative control. Based on PCR result of above was not founded there is DNA band of *P. falciparum* and *P. vivax*.

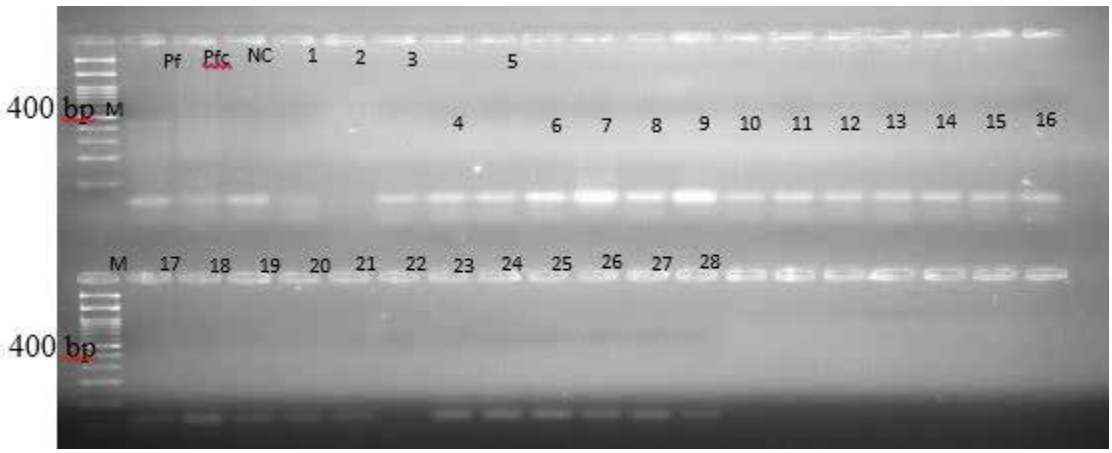

Figure 2: Electrophoregram result show which are PCR produce from species of *Anopheles* mosquitothere were of (number 1,2 are *An. farauti}*, (number 3,4,5,6, 7,8,9.10,11. 12,13,14, 15,16 and 17 are *An. punctulatus*) and (number 18,19,20, 21,22,23, 24,25,26,27, 28 are *An.koliensis*). Pf 1/10 = *P. falciparum*-1 (*Pf/Pfc* is positive control) and *Pfv* 1/10 : mixture between *P. falciparum* and *P. vivax*, negative control (NC). Legend : M: 100 bp ladder marker. Based on PCR product of above was not founded there were DNA band of *P. falciparum* and *P.vivax*

Discussion

Diversity of *Anopheles* sp was found in this study with high dominance in Jayapura Municipal is *An. punctulatus* than *An. koliensis* and *An. farauti*. The high dominance *An. punctulatus* in Hamadi rawah shown that genetic diversity of *An. punctulatus* have the effect of capacity of numbers were indicated the occurrence of transmission and nature of the ability of vector in transmitted malaria[12,13].

The result of DNA Extraction are using a PCR product with direct PCR phusion kit (thermo) and with using the Mito F370 and Mito F5904 primers and there were 38 samples that have been DNA isolated but did not found *Plasmodium* as cause of probably samples without containing *Plasmodium*. It must be fresh or stored frozen to prevent protein degradation; moreover, difficulties in storage arise when working in the field and according[14] species of *An.punctulatus* complex were readily distinguished using a PCR-RFLP analysis based on the ITS2 region of the rDNA. The mosquito samples did not require a particular storage condition because air dried samples contain ample template to generate a PCR product whether the DNA was extracted or a segment of the mosquito was used[14,15,16].

Conclusions

Dominance of *Anopheles* sp in Jayapura Municipal was found in this study; *An.punctulatus* more highly than *An. koliensis* and *An. farauti* because of *An.punctulatus* is a primary of malaria vector and habitat of *An. puntulatus* is in the open pool with clear of pool water or murky the absence of aquatic vegetation, puddles former or human[12,13].

Genetic diversity of *Anopheles* mosquito species based on PCR product of *Anopheles* overall we were not found DNA bands of *P. falciparum and P.vivax* because probably *Anopheles* which such the blood of the captured person has not been infected with *P. falciparum* and *P. vivax*[15,16,17.] The absence of DNA template bands or deletion and insertions at the primer attachment site[14]. DNA insertion can be lead to a change in the size of the DNA fragment, via simple base alterations or band to DNA fragment and the Anopheles sp are not founded more in Jayapura Municipal.

Acknowledgements

We gratefully thank the Director of Polytechnic of Health Jayapura, Chairman of Primary Health Center in Hamadi and Abepura, Jayapura Municipal. We grateful to Prof. dr. Din Syafruddin, Ph.D and Puji BSA, BSc, Ph.D also all assistant at Molecular Laboratory of Eijkman Institute (especially molecular malaria laboratory) in Jakarta.

Ethics Approval and Consent to Participate: Research approval was taken from Health Research Ethics Committee of polytechnic of health, ministry of health Jayapura. The formal permission was also obtained from Ministry of Health, Jakarta. Indonesia.

Source of Funding: The research is self funding.

The Use of Portable WSD Wound Models to Improve Student Clinical Lab Skills

Pramita Iriana[1], Ratna Sitorus[1], Agung Waluyo[1], Sutanto Priyo Hastono[1]

[1]Nursing Program of Health Polytechnic Ministry of Health Jakarta III

ABSTRACT

Innovative laboratory learning methods have been developed for students to be more independent and play an active role during the learning period. Students learn by using media such as modules and portable models. The study aimed to determine the effectiveness of portable WSD wound model to improve the wound care clinical skills. Research design: The study used quasi experiment pretest-post test with control group design, respondents were given module and WSD wound model made of synthetic rubber with the tube inserted to a bottle as if a patient were attached a WSD. Sample; A total sample of 90 using the stratified random sampling method, the respondent were divided in two groups by using 2.75 GPA as cut of point. Data analysis: Using independent and dependent t test with α= 0.05, data were gathered using two instruments with α cronbach 1 = 0.8331 and 2= 0.909 that were greater than α table = 0.632. The results: at P-value = 0,001 based on the pre-post test, the mean difference of student clinical lab skills using the portable model increased 0.31 higher than using the non portable model increased only 0.26. In conclution, using the portable model is more effective than the other one.

Keywords: *clinical skill lab, learning media, a portable wound care model*

Introduction

Nursing education generally has a goal to produce nursing graduates who are professional and have good knowledge, affective and psychomotor abilities and ready to work. To achieve the above, educational institutions develop various learning methods that can facilitate the improvement and development of nursing knowledge, affective and psychomotor abilities in students Notoatmojo[12]. Lab skill learning method is one of them. Through learning in the laboratory, students can get a learning experience similar to that in the clinic Jones & Barlett[10]. Thus, students will be better prepared to take part learning in the clinic. Baldwin, Hill & Hanson[1] believe that students who have studied in the laboratory have better preparation when studying in a clinical setting. With the implementation of the lab skill method, it is expected that psychomotor skills will improve that enable nursing graduates to work professionally and skilfully.

However some problems are often found in the practice fields related to lab skill learning, as stated by which concluded her research that nursing students do not have sufficient ability in applying nursing skills acquired during education, students have knowledge but lack of skills. In line with the above, Roni's research[8] concluded that the low motivation of students and improper lab skill learning methods and the selection of inappropriate learning media would greatly influence students' mastery of nursing psychomotor skills. According to the factors that influence the skills learning process (psychomotor) are divided into 4 major groups namely material, environment, instrumental and individual internal factors.

Instrumental factors in the learning process are emphasized on hardware and software learning Jones & Barlett[10]. Hardware learning include equipment and teaching aids (media) that are used in learning. While software in learning is the curriculum and learning methods. To obtain effective skills learning outcomes, these instrumental factors are designed in such a way

Corresponding Author:
Pramita Iriana
Nursing Program of Health Polytechnic,
Ministry of Health, Jakarta III
Email: pramitairiana70@gmail.com

that they are in accordance with the material and subject of learning. For example for learning skills (appropriate psychomotor, namely the lab skill, while the media or teaching aids used in learning are adjusted to the skills that will be learned or trained.

Psychomotor learning methods (lab skills) have been widely developed. One method that has been widely known and used is demonstration learning methods, redemption and supervision. With this learning method, educators will explain and demonstrate the expected psychomotor abilities, followed by redemption and training by students Buhat, Dorothy, & Mendoza[11]. During practicing, the teaching staff will supervise. This learning method is known as traditional learning methods Beeson & Kring[2]. Furthermore an innovative skill learning method has been developed where students are more independent and play an active role during the learning period Candy[13]. One method that has been developed is an independent learning method in which students learn with the help of modules, portable teaching aids, video recordings, and computer programs without the supervision of teaching staff. Using this method, the role of the teaching staff in one learning period is minimized. The teaching staff acts more as facilitators who prepare the material needed by students Bye[14].
