1 and 2. The effect size was large at post-test 1, (3.88) and still large (3.62) at post-test 2. Further comparison of the mean differences in the mean knowledge score (post-test1- pre-test), (post-test2- pre-test) revealed that the mean differences were significantly larger in study group than control group, (P<0.001). The difference between post-test 1 and 2 was insignificantly different between both studied groups, (P>0.05). Changes in knowledge scores regarding the knowledge about the use of partograph during labor before and after teaching program of studied groups. Changes in knowledge levels about the use of partograph during labor domain before and after teaching program of studied groups, (Table 6).

Abstract

The research’s aim is to identify the effect of the strategy of the pyramid of preference in the achievement of students at the second grade in science. To achieve the goal of the research, the researcher put the zero hypothesis which states: There is no significant difference at the level of significance (0.05) between the average grades of students of the experimental group, The strategy of the pyramid of preference and the average grades of the students of the control group who will study according to the usual method in the test of the collection of the science prepared for this purpose, and applied his experience in the second half of the academic year (2018-2019). The sample consisted of (70) intermediate school (35) students. The total number of students in the control group reached (35) students. The two groups were rewarded in the following variables (age, IQ tests, grade of science in the first grade average). In the light of the relative importance of the content and the behavioral purposes, daily teaching plans were prepared (32) for each group (16) plan and also for the construction of an achievement test consisting of (40) multiple choice types.

Key words: Effect of strategy of the pyramid of preference, achievement, second grade students, science.

Introduction

The Physics subject is one of the important science curricula and plays a major role in the change and scientific development. It has brought with it the attention of educationalists, including the hand of innovation, development and modernization in terms of content, methods of teaching and teaching aids. Physics is one of the important branches of science. The development of modern technology. If a nation wants to become rich, it must acquire a high degree of experience in physics, and physics is important in the development of scientific thinking, as its study helps us to understand more deeply. Physics, which contribute to the development of mental skills and different thinking skills. The physics of the subject matter requires skills, requires thinking, and employs the learners’ mental abilities and uses them for questions and activities. Thus, To understand the meaning of scientific terms that help him to understand and interpret phenomena, and help him to understand the relationships between the elements of the phenomenon to access the laws, and recognizes the importance of physics in the development of human life in the field of health and energy And help him in the analysis of physical phenomena to form a comprehensive view of the development of the correct results, and help him to show the impact of physics in the rest of the other science subjects such as biology and chemistry. At the global level, Science, and called to focus on the use of modern methods and strategies in the study of science. The teacher’s choice of effective teaching method is an important reason for the success of teaching and success of the educational process because of the multiplicity of teaching methods and strategies, and there is no preferred method to the other. The teacher should be familiar with the teaching methods and the modern strategies so that he is able to choose the best methods or strategies that fit and fit the material he studies to reach the maximum
goals, teachers sought to find the best methods and strategies that are more useful in teaching science in general. It has been found that one of the methods that may contribute to a broader understanding of science and achieve many of the objectives of teaching in the middle stage is the use of active learning strategies and It is a strategy of the pyramid of preference, because it is a modern strategy that may help overcome the problems that hinder the students' understanding of science and raise their level of achievement. Moreover, this strategy has not been put into the experiment in teaching science for intermediate stage. If there is a difference between the students of the experimental group, which will study according to the pyramid strategy of preference, and among the students of the control group, which will study according to the usual method.

**Physics in Medicine**

International Organization of Medical Physics (IOMP), founded in 1963, is a scientific, educational and specialized institution with membership of 75 countries and more than 16,000 members. American College of Medical Physics (ACMP) published a scientific journal (Journal of Applied Clinical Medical Physics) jointly with the International Organization of Medical Physics. The American Board of Radiology - ABR aims to serve the citizens and medical professions by certifying that the certificate holders have obtained and maintained the required level of skill and science for the practice of radiotherapy, radiotherapy and radiation physics, The fields of Therapeutic Radiological Physics, Diagnostic Physics, and Nuclear Physics. The American Board of Medical Physics (ABMP) was founded in 1987 and is accredited by the Medical Board of Radiologists. Since 2001, the Council has stopped the accreditation of medical physicists in the fields of therapeutic Radiological Physics, Nuclear Physics, and Diagnostic Physics, where it has moved to the American Board of Radiation Medicine (ABR). The accreditation is now restricted to the MRI specialist Magnetic Resonance Imaging Physics and Health Physics Medical Health Physics. UK: Institute of Physics and Engineering in Medicine – IPEM: A charitable organization founded for the advancement of the community - with the applications of physics and engineering in medicine and biology, to push the wheel of education in this field and to represent the needs and interests of engineering and physical sciences in improving health care. Europe: European Federation of Organisms in Medical Physics - EFOMP was established in 1980 and covers national organizations representing more than 5000 physicists and engineers in the field of medical physics. Its objectives include: Encourage and coordinate the activities of national organizations and their interaction with international organizations, promote the exchange of professional and scientific information, exchange of medical physicists between countries, propose guidelines for education and training and the adoption of programs in medical physics and make recommendations in general responsibilities, organizational relations and the role of medical physicists, And to encourage the formation of medical physics organizations in places where such organizations do not exist. [11]

**Methodology**

It includes a presentation of the procedures necessary to achieve the research objective, starting with the research methodology and experimental design, defining the research community and its design, the equivalence of the research groups (experimental and control), preparation of the research requirements and tools.

**Experimental design of the research:**

The independent variable includes the strategy of the pyramid of preference, the normal method, and the dependent variable. Therefore, the researcher used the experimental design of the two groups of homogeneous and equal, one experimental and the other control.

**The research community and its model:**

The research community represents all the second grade students in the secondary and intermediate schools in the Diyala governorate for the academic year (2018-2019), where the average second grade population is not less than two divisions, As for the research, the researcher (Middle Iraq) in the center of Diyala province chose randomly to conduct his research. It was found that it comprises four divisions for the second intermediate grade (A, B, C and D) To represent the experimental group and the number of students (35) students who will study their students according to (Astra (C) to represent the control group and the number of its students (35) students who will study their students according to (the normal method). The researcher conducted a statistical equivalence between the experimental and control groups in some variables that affect the results of the
experiment.

**Control of Exotic Variables**

Although the researcher investigated the equivalence of the two sets of research in some variables that are believed to affect the course of the experiment, he tried to avoid the effect of some of the extraneous variables in the course of the experiment. Some of these variables and how to adjust them are as follows: Accidents Accompanying the Experiment: The experimental experience was not subjected to any emergency or accident that impeded its progress. Experimental extinction: There was no interruption or transfer of any student throughout the experiment. Sample selection: The two groups were randomly selected and the two groups were confirmed. The experiment is unified between the two groups. The effect of the experimental procedures: The researcher worked to limit the effect of experimental procedures that could affect the dependent variable during the course of the process. Experience. Preparation of research requirements: The research requirements are fundamental to the research on which the research procedures are carried out. These requirements are as follows: (The scientific material (content): The scientific material that the researcher is teaching was determined for the students of the two research groups during the period of the experiment (2018 - 2019). The researcher prepared (16) a plan for the experimental group which is taught according to the strategy of the pyramid of preference and the same for the control group which is taught according to the normal method.

**The research’s tool**

The “Collective Test” has been prepared according to the following steps: Determining the purpose of the achievement test The objective of the achievement test is to measure the achievement of the first grade students (information, skills and experience) in science in the study of physics related to the units (first, second and third), teaching the following subjects (movement, traffic laws, Power and energy, work and machinery, waveform and sound, light).

**Determination of behavioral goals:** After the purpose of the test was determined the achievement of behavioral goals to determine the extent of achievement and the researcher formulated a number of behavioral goals. The test subjects were formulated in the initial form in light of the test map. The researcher chose the type of test (multiple choice) which is one of the best objective tests. The test consisted of (40) test paragraphs distributed at levels of cognitive knowledge, Understanding, application, analysis). Test instructions: Specific instructions and instructions are written on how to answer (choosing only one correct alternative, answering all paragraphs, answer time, typing the triple name, row and division in the assigned space).

**Correcting the test answers:** A standard was set for correcting the answers by placing one score for each correct test paragraph and zero for the wrong answer, the left paragraph that the student did not answer and the paragraph for which more than one choice was made. Thus, (40) degrees) and the lowest score (zero). The validity of the test showed that the veracity and authenticity of the content were tested for the test. The results showed that the virtual honesty obtained the percentage of agreement (80%) of the opinions of the arbitrators and specialists. As for the validity of the content, the results showed that all the clauses of the test are statistically significant. In measuring the understanding and understanding of students in the second grade intermediate in science.

**The pilot application for the test of achievement:** including the following:

The first test was carried out on a group of second-grade students from a non-research sample. The number of students was 30 students. The purpose of this test was to know the clarity of the test instructions and guidelines, the understanding of the students’ For the test, the researcher recorded the exit time for each student. In calculating the arithmetic mean of time, it was found that the time needed to answer all the test paragraphs was (41) minutes.

**The second test application:** The test was applied to a sample of (100) students in the second intermediate grade without a research sample. The purpose of the test is to analyze the statistical achievement test paragraphs, namely paragraph difficulty, paragraph discrimination, effectiveness of the wrong alternatives. The statistical analysis of the test scores: The test scores were analyzed as follows: The difficulty of the paragraph: The statistical analysis of the test test subjects found that the coefficient of difficulty of the paragraphs ranged from (0.20 - 0.80) and thus all the test scores are acceptable and their difficulty is appropriate. The distinction of the
paragraph: An important feature that must be provided in the test paragraphs is the distinguishing feature. It means that the items or paragraphs can detect the individual differences of the students. The test items are valid. The coefficient of distinguishing the items is 30.0 and above. (0.37 - 0.74). Thus, the test scores are considered to have a good and appropriate discrimination coefficient.

The effectiveness of the wrong alternatives: The researcher conducted a statistical analysis (highest 27% and lowest 27%) degree to find the effectiveness of the wrong alternatives ranging between (0,03) and (-0.44) and it turned out that the alternatives to test paragraphs are all effective and thus prepare All of them are suitable.

Test stability: The stability of the test depends on the relationship between the test paragraphs, and this is shown by the stability of the degree and organization of the paragraphs, so the stability coefficient is the statistical indicator on the accuracy of the measurement and then the stability factor was calculated using the equation (Kyodrichadson-20) because it is a measure of the internal consistency of the test, The correlation coefficient (92%) indicates that the test has a high degree of stability. Application of the research tool: A week prior to the test, the students of the two research groups were notified after completing the course, and the researcher conducted the test at the same time within the pre-defined material.

The statistical methods

The researcher used the statistical means, including the test (t.test) for the independent samples to make the parity between the experimental group and the control group and analysis of the results, and Pearson correlation coefficient.

Results and Discussion

The students of the experimental group were superior to the students in the control group. Therefore, there is a statistically significant difference at the level of (0.05) between the averages of the students of the experimental group who studied the science according to the pyramid strategy of preference. Who studied the same material according to the “normal method” of collection and for the benefit of the experimental group?

Table 1. The results show that the experimental group is superior to the control group.

Conclusions

Through the results of the research was reached some of the most important conclusions: Teaching the pyramid strategy of preference gave students the opportunity to build and develop their knowledge and organize and arrange ideas sequentially as the previous information mainly to build new experiences, enabling students to be able to master the activities well. Teaching the second grade students according to the strategy of the pyramid of preference has had a positive impact in raising the level of their academic achievement.

Abstract

This research aims at identify the reading comprehension skills needed for Arabic curriculums according to teacher’s point of view, to achieve this aim, the literature and previous studies related to the study were reviewed, based on that, a questionnaire was designed that included a preliminary list of the necessary reading comprehension skills for Arabic language curriculums, in order to ascertain its validity apparent, it ruled by (23) specialists, according to the pinions of specialists and the suggestions, the researcher reach to a list of reading comprehension skills consists (20) skills, that distributed at three levels, the list of reading comprehension skills and levels was transformed into a final questionnaire, for the purpose of determining the relative importance of each skill in the whole list from the point of view of a short sample of Arabic language teachers, the sample number was (70) Teachers, and then sort the skills of the acceptable relative importance, that should be available in Arabic books, after the adoption of their opinions by adopting a percentage (75%)

Keywords: The Reading Comprehension Skills, Arabic Books, Arabic language teachers.

Introduction

The development of the educational curriculum is one of the requirements of modern-day educational systems because of the dramatic changes in the different life magazines that result in constant changes in the personal needs of learners, social needs and many problems facing persons and communities, which require a review and develop the educational curriculum in a way that makes it able to meet the requirements of the era. The Arabic language has a prominent place among the subjects at all levels of education, because it is the instrument of thought, and a means of communication and understanding, and the transfer of heritage from one generation to another; so it has received a great care and attention in the present era, even in the early ages of Arab-Islamic civilization. the aim of teaching Arabic at all grades of education is to provide students with the four basic language skills (listening, speaking, reading, writing) and helping them to acquire them, in a logical progression through the educational stages, to reach a level of linguistic excellence that enables them to exercise their thinking and expression in working life successfully and in scientific life in all future stages of education, and depends on the Arabic language success in the collection of other subjects. The reading is one of the most widespread and most significant of the Arab language, so it’s the first of all to be the language of the century, its development and the “mental and spiritual food that achieves a balanced and harmonious human being”, it became at the present time the activity of thought in the era of great knowledge revolution, it starts from the human sense of one problem, so he/she get reading in order to solve this problem, through that he/she tries to collect information needed to solve this problem in thinking, working and active, Since acquiring skills is the key to knowledge and the learning tool, it needs a aware study, , and a good view that takes the scientific curriculum as a style, So it’s not limited to the interpretation of written symbols, but the interaction between the reader and the readable text, the link between the language and the facts, the reader examines with his/
her experience and knowledge what is contained in the
text of the connotations and signs, symbols, semantics,
words, phrases, methods, deletion, interpretation,
commentary, analysis, criticism, linking, conclusion,
and generalization 6. A rational understanding is a
complex and basic mental process that helps students to
discovering or correcting the truth of the reading, whether
it is for pleasure or scientific achievement or for solving
a problem, and helps them to understand the visible and
subtle meanings, and to understand the various linguistic
relationships, so it is the basis of the educational process
and the interaction positive students with the community
in which they live, and the understanding is associated
with the person’s previous experience, and its interaction
with the new information included in the subject of
reading, the reader interprets and modifies and links past
experience with new information 7. The textbook is an
effective means of teaching, learning and presenting
the Arabic language to the learner, as it is the basic
framework that defines the minimum capacity, skills
and knowledge, and the factual image of the curriculum,
the first reference of the teacher and the learner, is
indispensable in any educational program. As a basic
guide to the content of educational programs, teaching
methods, and the process of evaluation 8. The problem
of research shows that there is a weakness in the content
of Arabic language books, as it does not develop the
skills of understanding students in the different stages of
the school, and despite the importance of understanding
and the corresponding importance of the attention both
in terms of the Ministry of Education and making it a
major aim of teaching Arabic language, or in terms of
the interest of researchers in developing skills, studies
and research in this field have confirmed the existence
of a weakness among students of different stages in the
skills of reading comprehension. Some Arabic studies
have indicated that Arabic textbooks often focus on the
skills of minimum reading comprehension levels, The
levels of primary targets, as well as their low balance
and comprehensiveness, and the lack of some of them,
such as 9 studies.

Methodology

The researcher tracked the results of previous
studies and researches in the field of the evaluation of
Arabic books, literature and books in the field of Arabic
language, the methods of teaching them in general, and
the skills of comprehension and levels in particular,
and the objectives of teaching the Arabic language for
the first middle grade, and from the previous sources
extracted A preliminary list of reading comprehension
skills and levels of ((36)) skills distributed at three
levels, offered to a group of specialized arbitrators, to
verify their sincerity, and to express their opinions on
the suitability of these skills for the students of the first
grade intermediate, The results of the arbitration after
modification, deletion and addition showed a list of
the reading skills and levels required for the first-grade
students, and the list included in its final form (20) a skill
spread over three levels, and a table 1. The researcher
converted the list of comprehension skills and levels in
final form to a questionnaire, and applied it to a sample
of the Arabic language teachers for the first middle grade
in the day schools affiliated to the General Directorate
of Education of the Province of Baghdad al-Karkh II, who
teach the language book Arabic for the first intermediate
grade actually for the academic year (2017-2018) by 70
teachers, and then extracted the relative weight of the
importance of each skill in each level of the reading
comprehension, and the following table (2) explains this:

From the previous table (2), it follows:

The skills (twenty) are arranged according to the
sequence of their relative importance.

... all teachers responded to each skill, thereby
enhancing confidence in the results and reflecting their
importance.

The (19) skill has a relative weight higher than
(75%), demonstrating its importance to respondents on
the one hand, and the importance of including it in the
Arabic language book content on the other.

The skill (8) of the first level: the level of literal
understanding, about the level of acceptance specified
in the search, and its text “encourages the giving of a
new title to the text read. “, since I got a relative weight
(7, 67%) Its failure to accept the level of acceptance,
and this does not reflect the poor importance of this skill
as one of the most important skills of literal reading
comprehension, as it does not indicate that respondents
ignore it, perhaps because of the frequent inclusion in
the content of the Arabic language book, as found by
the researcher in the Arabic language book, and maybe
some of them saw the lack of hajj The existence of such
a skill with the title of each text of my readers, and some
of them may understand that the reading text is intended
to be the whole study of the unit, without regard to the
paragraphs and their ideas.

The relative weights at the level of the three main levels were varied, with the first level: literal understanding of arithmetic mean (41, 2), relative weight (3, 80%), and second level: implicit understanding of arithmetic mean (39, 2) and relative weight (7, 79%), and finally got the third level: understanding The critic on arithmetic mean (36, 2) and relative weight (7 and 78%), this downward gradient logically corresponds to the importance of the skills of each level, as the first level represents the base of the hierarchical levels of understanding, which means that it should be of great importance in the content of the Arabic language book, as it applies to the majority of students Its importance ranked first, the pyramid is second level, and the number of students who reach it, its importance in the second place, and the third level at the top of the pyramid, and the distinguished students who will reach it, these results confirm the sincerity of the sample responses, frequency and persistence, as It could be interpreted according to the concept or the sincerity of the building, which underscores the importance of all skills.

**Conclusion**

Reaching (20) skills of reading comprehension skills, divided by (3) levels of the President, specialists saw their suitability for the Arabic language book for the first grade. Adoption of (19) skills of reading comprehension skills, the crisis for the Arabic language book for the first grade intermediate, and exceeded (75%) From the opinion of the sample, from the point of view of the Arabic language teachers. To introduce the teaching skills of the study (19), which is necessary for the Arabic language book for the first grade, and therefore recommends that the study should be based on these skills and be taken into account by the authors of the reading methods when building and composing the Arabic language curriculum, and to work on its development and impart For students in a reading lesson.
during educational situations.

The Impact of Yowadi’s Strategy on the Acquisition of Rhetorical Concepts to Develop the Habits of Mind for Students is the most honorable science

Fatima Nouri Bahaa Al-Moussawi1, Zeina Ghani Abdul-Hussein Al-Khafaji1, Jalal Aziz Farman Al-Barqawi1

1University of Babylon / Faculty of Basic Education / Iraq

Abstract

The objective of the research was to identify the effect of Jawadi’s strategy in acquiring the rhetorical concepts of the fifth graders. The researcher adopted the empirical research method as a methodology for its research procedures, which includes a separate variable (Yawadi strategy, the usual method), and a dependent variable (acquisition of rhetorical concepts) In order to obtain accurate and objective results, the following variables were computed: (the age of time calculated in months, the academic achievement of the parents, the grades of the first semester of the Arabic language, Bar previous information, and test Ravn). After the equivalence between the two research groups, the researcher prepared the application requirements of the plans, objectives and test for the two groups of research. After the application of the experiment, the researcher applied its research tools to the two research groups. After correcting the students’ answers, the researcher obtained the data for the experimental group and the control. (t-test) for two independent samples. The results showed that the experimental group, which was studied according to the Yawadi strategy, exceeded the control group studied in the normal way in the acquisition variable.

Key words: The strategy of the Yawadi, the acquisition of rhetorical concepts, fifth grade literary students, rhetoric.

Introduction

The language is a natural gift, God’s gift to man, to be his way to know himself first and then knowledge of the universe after that, it is a live and honest translation of a people to reveal the beads material and moral together, and is originally a social tool made by society to symbolize the elements of his life and ways of behavior. It is a system of symbols and spoken sounds that are used to communicate, understand and participate in conveying the meaning and conveying the idea. It has different characteristics and characteristics. It is a means and a tool for transmitting cultures, including Arabic. It is the language of the Holy Quran. The Arabic language is divided into sections for each branch of the article. These branches are not the language in themselves, but are used to control the means of linguistic communication. The attention to these branches is not fruitful unless they are related to the Arabic language itself. Since rhetoric is one of the branches of the Arabic language, we need to take care of its study and teaching and to learn the secrets of its beauty through its science, which is the most honorable science in learning. The eloquence is a great function is to express the precise meanings reached by the owner of a summit in himself, and informs his intention to listen to him in a technical way deepen the choice, from the briefness of words and good design, and elegance in drafting, and wonderful in photography, And Ronga. Concepts are more relevant to the learner’s life, helping him to adopt the functions of science in interpreting phenomena that attract attention in the environment to help guide and predict any activity that may lead to the discovery of new things. In addition, it is a group of things, accidents, or special symbols

Methods of Teaching Arabic Language;
E-mail: Fatimaalmusawi849@gmail.com
that are grouped together on the basis of their common characteristics that distinguish them from other groups and categories. Helping students to learn concepts is an essential learning objective. School and the basis of the process of thinking, and those important concepts that must be learned and acquired are rhetorical concepts. Al-Balajah is the path leading to understanding the book of Allah and the words of the Arabs. Therefore, the ancient scholars have given great importance to this science. They have put many studies in the original and the proper approach. Without the delinquency of literary life in the late centuries to the tradition, the rhetoric has remained vibrant but the literature of wilting has become frozen. And the causes of weakness in rhetoric as many as confirmed by educational research conducted in this regard has confirmed the apparent weakness in learning and education, and this phenomenon of weakness is a complex phenomenon and many reasons may be the cause of the same rhetoric as if the subjects are many and complex and have many definitions and details. You need more explanation, clarification and analysis. There are some important terms that should be clarified as follows:

Yowadi’s strategy: procedural words because they depict sequential actions or tools to solve problems by focusing on procedural knowledge and remembering them to facilitate the acquisition of skill and sequence processes. (Qatami, 2013: 287).

Acquisition: “It is the ability of the learner to know, understand and apply the fundamental features of the concept.

Concept: “It is not the name or the term but the content of the name or term and what each means, and the content of this name or term changes and grows by acquiring new experiences and moving from one study stage to another.

Allegorism: “It is identical with the fluency of his words, which defines the laws governing the literature and its texts”.

Acquired concepts in the brain, which is the center of the nervous system in humans and animals, and controls all organs of the body through many functions, including vision, thinking and movement or doing any complex or simple activity. Information processing takes place as scientists view the individual as a complex and unique system of information processing. His interpretation of this system stems from a number of assumptions that have made him a new trend in studying processes of attention, perception, learning, and human memory. In the field of cognitive psychology, the process of information processing represents an organized and harmonious series of mental activities that began from sensation and attention through perception, memory and other mental activities. The three processes of perception, sensation and attention are interrelated and sequential processes. You cannot pay attention to something unless there is an alarm or a stimulant that stimulates the specialized neurons in the various sensory organs by detecting stimuli and stimuli through the discovery element or the receptor. Of a particular type of stimulant, which leads to the conversion of these stimuli or stimuli to the signals or impulses of electrons and chemical sent to the brain that the physiological responses to attention such as: Extend the blood vessels in the head, constriction of external blood vessels, etc., all of which help to prepare the organism for attention by contributing to: Facilitate the efficient and efficient reception of the stimuli and prepare the human to respond quickly, especially if this response is required. Is a product of a series of cognitive processes that mediate between receiving this stimulus and producing the appropriate response. The time between the reception of the stimulus and the corresponding response production depends on the nature and quality of the cognitive therapies. Where the strategy adopted by Yoadi steps on the operations and functions, including the sense and awareness and attention that lead to the subsequent processing of information, and steps as follows: The school then memorizes the concept, and then the students repeat the concept by the whole class aloud. One of the students writes the concept on the blackboard, then the school uses a familiar style for being related to the concept, then draws the analogy or uses a picture or an outline of the concept to divide the concept into The school then analyzes the texts in the course book and explains the material with questions to the students to draw their attention. After completing the explanation and clarification, the strategy procedures are done by asking the students to draw a mental outline on the subject of the lesson or concept and its sections in any way to make sure that the students understood the lesson and can remember a For a topic in a sequential way, then reaching the generalization by mentioning the definition of the concept and giving examples (Qatami, 2013: 301).
Methodology

It includes a description of the procedures that have been carried out to achieve the research objectives, starting with the research methodology and experimental design, defining the research community and its design, the equivalence of the research groups (control and experiment), preparation of the research requirements and tools, Experimental Design: The researcher used experimental design with partial control of two equal groups, one experimental and the other control. Search community and design: The current research community consists of fifth grade students in the preparatory schools affiliated with the General Directorate of Babil province for the academic year (2017-2018), which is located within the center of Babil province, after the researcher identified the school in which she is applying, The researcher and the book of the Directorate of Education of Babylon, and its grandmother includes two divisions, and in a random drawing method chose B to represent the experimental group, and a division to represent the control group. The number of female students in the two research groups was 67 students. (30) in the experimental group, and (32) in the sample The control group. My search group parity: The researcher conducted a statistical equivalence between the experimental and control groups in some variables that affect the results of the experiment. Although the researcher chose the two groups in the random drawing method, although the sample of the research from the social and economic environment is very similar and study in one school, The results of parity between the two research groups showed that the number of students in the first semester in the Arabic language for the academic year (2017-2018) and the previous information test, The two research groups are equivalent to the variables mentioned earlier. Adjust variables: Although the researcher investigated the equivalence of the two sets of research in some variables that it believes affect the course of the experiment, it tried to avoid the effect of some extraneous variables in the course of the experiment. Some of these variables and how to control them are as follows: Accidents associated with the experiment: Any emergency or accident that obstructs its progress, Experimental extinction: No interruption or transfer occurred to any student or length of the experiment. Sample selection: The two groups were randomly selected and the two groups were confirmed. The maturity factor: Since the duration of the experiment was uniform between the two groups, and the age of the students in the two groups was very similar, so the growth of the two groups would return to the same level. , Effect of Experimental Procedures: The researcher worked to limit the effect of experimental procedures that could affect the dependent variable during the course of the experiment. Preparation of research requirements: The research requirements are fundamental to the research, according to which the research procedures are carried out. These requirements are as follows: (The scientific material is the scientific material that the researcher is teaching to the students of the research groups during the period of the experiment The academic year (2017-2018), the scientific article (13) topics from the book of rhetoric, Formulation of Behavioral Goals The researcher formulated 74 behavioral objectives based on the general objectives and the content of the material covered by the experiment according to the Bloom classification in the field of knowledge distributed between the three levels (knowledge, understanding, application), preparation of the teaching plans, The number of plans (13) was a plan, and the researcher presented a sample of them to a group of experts specialized in the methods of teaching the Arabic language to express their views on the soundness of its formulation and after taking their observations, it became its final form and its application.

Search Tool: The acquisition of rhetorical concepts: It is a set of stimuli (oral, written, picture, drawing, or device questions) that have been prepared in a systematic way to measure a sample of content in a quantitative way or to predict what may happen to a phenomenon or situation and give a degree or value to the examinee, And sets a measure of the phenomenon or situation (Tal and Isa, 2007: 80-81), and there are several steps in which the preparation of the test to acquire the concepts of rhetoric is as follows: Determine the purpose of the test: The purpose of the test is to measure the extent to which the students of the literary fifth acquired the rhetorical concepts in the language of rhetoric, according to the behavioral goals that were formulated from the scientific material. Setting test objectives: After the purpose of the test was determined to acquire the rhetorical concepts, the objectives of the test are determined to determine the extent of their achievement. The researcher formulated a number of behavioral goals.

Select the test paragraphs: The researcher determined the number of paragraphs to be composed of the test of acquisition of rhetorical concepts as the number of paragraphs of the test (39) paragraph.
Test Instructions: Specific instructions and instructions were formulated on how to answer (selecting one correct alternative to the paragraph, answering all paragraphs, the time period for answering, writing the triple name, the row and the division in the assigned space).

Correct the test answers: After the objective test paragraphs were formulated from a 39-paragraph multiple choice type, a standard was developed to correct the answers. One (one grade for each correct test paragraph) and 0 for the wrong answer and the abandoned paragraph that the students did not The highest final score for the acquisition of rhetorical concepts is (39) degrees and the lowest (zero). Sincerity test: The authenticity of the test was verified and the content was validated. The results showed that the virtual honesty obtained 80% by the arbitrators and the specialists, either the validity of the content. The results showed that all the clauses of the test of acquisition of the rhetorical concepts are statistically significant. In measuring students’ acquisition of rhetorical concepts.

Statistical Methods: The researcher used the t-test equation for two independent samples to make the equivalence between the experimental and control groups in the following variables (the age of the months calculated, the academic achievement of the parents, and the first semester of the students).

Results and Discussion

The students of the experimental group who studied according to Jawadi’s strategy surpassed the students of the control group who studied according to the usual method in the test of acquisition of rhetorical concepts. Table (2) shows this.

| Table (1) The arithmetic mean and variance and the calculated value (t) obtained by the students of the two groups in the test of acquisition of rhetorical concepts |
| --- | --- | --- | --- | --- | --- |
| Statistical significance | value (t) | Degree of freedom | variance | SMA | the group |
| tabular | Calculated | | | | |
| At a significance level of (0.05) | 2 | 32,37 | 3 | 28,20 | 27,10 | Experimental |
| | | | | 27,67 | 22,91 | Control |

Conclusions

In the light of the research results, the researcher reached the following conclusions: The use of Jawadi’s strategy contributes to the organization of the process of teaching rhetorical concepts in a sequential, interrelated and integrated way and enhancing their learning abilities.

Thyroid Status in Iraqi Subfertile Women: a Case Control Study

Hyfaa Abdulhasan Raffas¹, Hussein Abdulzahra Al-janabi², Raheem Ghadhab Jawad²
¹Gynecology specialist / Al-Diwaniyah Child and Maternity Hospital / Department of Obstetrics and gynecology / Al-Diwania / Iraq, ²General Surgeon / Al-Diwaniyah Teaching Hospital / Department of Surgery / Al-Diwania / Iraq

Abstract

Aim of the study: to evaluate the thyroid hormone status in a group of subfertile Iraqi women in comparison with fertile women of comparable age. The present case control study included 50 infertile Iraqi women serving as study group and 30 fertile women of comparable age serving as control group. The study has been carried out in Al-Diwaniyah maternity and child teaching hospital in Al-Diwaniyah province in the Mid-Euphrates region of Iraq. Venous blood sample was obtained from each woman in order to assess T3, T4 and TSH hormonal levels. Hormonal assay was done using Mini-Vidas Immunofluorescence Hormonal assay machine, at the central Biochemistry lab, AL-Diwaniyah Teaching Hospital. Taking the reference range of both serum T3 and serum T4, no women, whether in the control group or in the study group, had a value neither higher nor lower than normal, that is all subjects were within normal reference ranges. On the other hand, mean serum TSH was significantly higher in infertile women in comparison with control group, 3.04 ± 1.39 versus 2.52 ± 1.08 mIU/L (P = 0.027), and that significant proportion of infertile women had higher than normal TSH serum level, 7 out of 50 (14.0 %).

Key words: Thyroid status, infertility, Iraq

Introduction

Infertility is defined “by the International Committee for Monitoring Assisted Reproductive Technology (ICMART) and WHO as the ‘failure to achieve a pregnancy after 12 months or more of regular unprotected sexual intercourse’” (1). Infertility affects approximately 48.5 million couples globally (2); in other words it affects about 8 to 12 % of couples during the reproductive age (3). The incidence of subfertility and infertility in the Iraqi community has been rising since 2000 because of a number of factors such as changes in lifestyle, the second and the third Gulf wars, increasing smoking, occupation and probably the contribution of hereditary factors (4). Causes of infertility may be categorized as male factor, female factor, combined and unexplained (5-7). Causes of infertility in women may be attributed to anatomical, functional and genetic defects and the prevalence of these causes shows significant geographic variations among nations worldwide (7). Systemic disorders such as diabetes mellitus (8), renal causes (9) and endocrine problems (10) are among the long list of causes of female infertility. Thyroid abnormalities have been studied in association with female subfertility (11-14); however, significant controversy exists in the available published articles so that clear judgment about the exact bi-directional relationship between thyroid function and fertility is still incompletely understood. Symptomatic hyperthyroid status causes changes of estradiol metabolism and the hyper-responsiveness of gonadotropin to stimulation by gonadotropin-releasing hormone. Baseline gonadotropin levels are also often higher than normal. The prevalence of irregular cycle in women suffering from hyperthyroidism was previously high; however, the early detection and prompt management resulted in less prevalent cycle irregularities in those women (15). The number of studies

highlighting the prevalence of infertility in association with hyperthyroidism is relatively low and the majority of these studies is retrospective and is of small size. Infertility prevalence, whether primary or secondary, in women with hyperthyroidism has been estimated in the range between 0.9 – 5.8 %; however, the exact association between hyperthyroid status and infertility in women remains to be disclosed (11). Disturbed ovarian function, increased rate of abortion, abnormal menstruation and subfertility have all been linked to hypothyroidism in addition to the observation that these abnormalities get improved when hypothyroid status is corrected following administration of therapeutic thyroxin hormone (11). When the level of thyroid stimulating hormone is high despite normal free thyroxin level, the condition is termed subclinical hypothyroidism (16) and it has been linked to sub-fertility with a wide range of prevalence, 0.7% up to 43 % (17). Nonetheless, the available data are inadequate to clearly label and association between subclinical hypothyroidism and infertility in women (11). The lack of clear association between thyroid status and subfertility and the rarity of Iraqi literatures dealing with this subject encouraged us to plan and conduct the current study aiming at defining the thyroid hormone status in a group of subfertile Iraqi women in comparison with fertile women of comparable age.

Methodology

The present case control study included two groups. The first group was comprised of 50 infertile Iraqi women serving as study group and the second group included 30 fertile women of comparable age serving as control group. The study started on June 2018 and ended on February 2019 and it has been carried out in Al-Diwaniyah maternity and child teaching hospital in Al-Diwaniyah province in the Mid-Eastern region of Iraq. Each women enrolled in the current study was informed about the aim and the procedures of the study and verbal consent was obtained from all women. The study was approved by the Ethical Approval Committee of The College of Medicine / University of Al-Qadisiyah. Venous blood sample was obtained from each woman in order to assess T3, T4 and TSH hormonal levels. Hormonal assay was done using Mini-Vidas Immunofluorescence Hormonal assay machine, at the central Biochemistry lab, AL-Diwaniyah Teaching hospital. Statistical analysis was carried out using version 23 of the SPSS statistical software and Microsoft Office Excel 2010. Numeric data were expressed as mean and standard deviation while nominal data were expressed as number and percentages. Independent samples t-test was used to study mean difference in hormonal levels between study and control groups. Chi-square test was used to study associations among nominal variables. The level of significance was considered at $P \leq 0.05$.

Results and Discussion

Mean age of infertile women was $29.22 \pm 7.06$ years and it ranged from 14.28 to 43.97 whereas, mean age of control group was $28.97 \pm 6.08$ years and it ranged from 20.06 to 43.06 years. There was no significant difference in mean age between study and control groups ($P = 0.840$). Mean body mass index of infertile women was $24.72 \pm 3.43$ kg/m² and it ranged from 19.25 - 33.05 kg/ m² while mean BMI of control group was $25.03 \pm 3.48$ kg/m² and the range was from 19.81 to 32.52 kg/m². There difference in mean BMI between control and study groups was insignificant ($P = 0.636$), as shown in table 1. Infertile women with primary infertility accounted for 9 out of 50 (18 %); whereas those with secondary infertility accounted for 41 out of 50 (82 %), as shown in figure 1. Regarding thyroid status, the range of serum T3 and T4 levels of infertile women was within normal range, 1.01 - 2.15 nmol/L and 67 – 115 nmol/L, respectively. The same finding was observed also in control subjects, 1.12 -2.25 nmol/L and 59 -145 nmol/L, table 2. In addition, there was no significant difference in mean serum T3 as well as serum T4 between study and control groups, $1.61 \pm 0.28$ versus $1.57 \pm 0.28$ nmol/L and 90.34 $\pm$ 11.64 versus $86.2 \pm 15.57$ nmol/L, respectively ($P > 0.05$), table 2. Taking the reference range of both serum T3 and serum T4, no women, whether in the control group or in the study group, had a value neither higher nor lower than normal, that is all subjects were within normal reference ranges, table 2. On the other hand, mean serum TSH was significantly higher in infertile women in comparison with control group, $3.04 \pm 1.39$ versus $2.52 \pm 1.08$ mIU/L ($P = 0.027$), table 2, and that significant proportion of infertile women had higher than normal TSH serum level, 7 out of 50 (14.0 %), table 2. Serum T3 showed significant negative correlation with BMI, $r = -0.317$ and $P = 0.025$. TSH showed significant positive correlation with BMI, $r = 0.323$ and $P = 0.022$, as shown in table3. The present study showed that infertile women had essentially normal serum total T3 and T4 levels; however, their mean serum TSH was significantly higher than that of control group and
that significant proportion, 14% had serum TSH level higher than reference range. These findings suggest that significant proportion of infertile women had subclinical form of hypothyroidism and that it may be at least in part participating in the pathophysiology of infertility in those women. In a Danish study, it was found that subclinical hypothyroidism was significantly associated with infertility (18). In another study (19), carried out in Argentina and included 244 infertile women the prevalence rate of subclinical hypothyroidism was seen in 13.9% and that the association between infertility and subclinical hypothyroidism was highly significant, a finding that is similar to the finding of the present study. Normal functioning thyroid gland is critical for conception to be successful and the outcome of pregnancy to be fruitful (20). Hypothyroid females with TSH levels >15 mIU/L possess a high rate of menstrual irregularities in comparison with women who are euthyroid (21). Indeed clinically overt hypothyroidism is significantly associated with risk of infertility in most published literatures; however, data linking between infertility and subclinical hypothyroidism is controversial. A prospective study including 538 women revealed that the mean TSH concentration was significantly higher in women with infertility in comparison with apparently healthy fertile women; however, the difference in the proportion of women with higher than normal TSH between the two groups was insignificant (22). Another cross-sectional study evaluated the sera of 704 infertile women undergoing found that the prevalence rate of women with a higher than normal TSH concentration was 2.3%, which is lower than that found in our study. Nonetheless, other authors have proposed that subclinical hypothyroidism, in agreement with our finding, is more prevalent in infertile women (23, 24). Indeed, there is some shortage in data evaluating the effect of subclinical hypothyroidism on fertility because of varied definitions of condition (variable TSH limits) and absence of sufficient control participants. Actually the “American Society for Reproductive Medicine” deny the association between infertility and subclinical hypothyroidism (25). The clinically mild form of hypothyroidism, subclinical hypothyroidism, is defined as a higher than normal serum TSH level in the presence of normal free thyroxine (FT4) levels (26). It is a frequent finding among women during reproductive age accounting for 4 to 8%; therefore it may affect negatively women planning pregnancy (27). Because of the nonspecific symptoms that accompany hypothyroidism (e.g., fatigue), the characterization of subclinical hypothyroidism is based principally on hormonal study (28). We suggest that the available evidence in the current study, supported by similar opinions of previous literatures that infertile women should be investigated for subclinical hypothyroidism and should receive appropriate management if proved so.

Prevalence of Back Pain and its Socio-Demographic, Postural and Behavioral Associated Factors among Primary Schoolchildren in Baghdad City

Nawar Sahib Khalil¹, Mazin Ghazi Jasim Alrubaey¹

¹Family and Community Medicine Department, Mustansiriyah University, College of Medicine, Iraq

Abstract

To identify back pain prevalence and its socio-demographic, postural and behavioral associated factors among primary schoolchildren in Baghdad city.

This study conducted at a random sample of 4667 pupils from multistage random sampling of 79 primary schools within Baghdad city, using developed, validated and piloted questionnaire form. Chi-square test was used for test the associations between back pain as outcome variable and socio-demographic, postural and behavioral factors as independent variables. Multivariate logistic regression was used to find out the predictors for back pain.

The prevalence of back pain during last month prior to study was 43.4%. Back pain was significantly associated with socio-demographic, postural and behavioral factors. Multivariate analysis showed that, positive parent history, sleeping, sitting and lifting postures, physical exercise and its frequency, time spent in sedentary activities and habit of bed’s study are significant predictors expected to increase back pain prevalence among primary schoolchildren.

The prevalence of back pain is high and suggesting the necessity for increasing the awareness of general public about risk of back pain among children.

Keywords: Pupils, back pain, prevalence.

Introduction

Back pain among schoolchildren were largely ignored until recently owing to the perception that they are less vulnerable, uncommon in clinical setting and it’s not fatal nature¹².

Recently, musculoskeletal health particularly of this age group has been a global health concern³, especially after World Health Organization (WHO) declaration of the years 2000–2010 as a bone and joint decade owing to realization the potential of musculoskeletal problems that impair the health of societies⁴.

Globally, there has been an ongoing concern of back pain among schoolchildren for education and health authorities as well as for communities at large, as a complain starts early in life could accelerate during teenage up to adulthood and its early life presence is considered as a precursor for adult’s back pain⁵⁶.

Over last decade, several studies revealed that back pain among schoolchildren were not uncommon and increasing, indeed, its prevalence sometimes similar to that reported for adults⁷ which varies from 11 to 86% depending on the regions.

Several reviews have been demonstrated that more than 85% of back pain among children is not due to a specific single condition, but to a set of factors including socio-demographic, postural and behavioral habits³⁸⁹.

As widely accepted that children are the future productive of any nation; therefore, early detection of their health problems and prevention from long-term sequels is of greatest significant¹⁰.

DOI Numbers: 10.5958/0976-5506.2019.00787.3
Worldwide alteration in lifestyle of current generations leads children to be largely stressed, overweighted, and experienced either physical inactivity or stressful ones that negatively influence back comfort. Iraqi children specifically after 2003 are not so far from these alterations particularly sedentary lifestyle as they indoor most of times for either security or recreational reasons as they have been opened to all aspects of westernization and globalization.

To best of our knowledge, no epidemiological study was conducted locally regarding this problem among this target-group, thus this study aiming to have local baseline database about back pain prevalence and identifying its associated factors among primary schoolchildren.

Materials and Method

This cross-sectional design study was conducted at random sample of 4667 pupils aged 9+ years old from multistage random sampling of 79 public primary schools within Baghdad city; from November 2017-April 2018. All sixth Kharkh and Russafa Educational Directorates and all urban sectors within such directorates were selected as first and second stage respectively. Third stages include sample of primary schools stratified by schools type were selected from chosen sectors by simple random sampling. Similarly, one class from each of 4th-6th grades within selected schools was chosen by simple random sampling as fourth stage. At fifth stage, within selected classes, pupils were chosen through systematic random sampling.

The inclusion criteria include pupils in 4th-6th grades who brought back informed consent and generally healthy. Pupils who forgot to bring consent back or those who have disabilities or diseases related back pain were excluded.

Questionnaire form was developed by authors based on published researches. However, it revised and modified by Experts and piloted on 90 pupils who were not included in the final study.

The questionnaire consists of four sections. The first section was related to socio-demographic characteristics included age, grade, gender, parent’s education and back pain history.

The second section was related to back pain and its location. The pupils were inquired that whether or not they experienced back pain during the last month prior to the study. The last month recall period was chosen to minimize recall bias. The site was indicated by body map picture exhibiting four body regions (the neck, shoulders, upper- and lower-back) that derived from Greek study.

The third section was related to postural habits that measured by modified items derived from Brazilian studies which based in present study on parents’ observations to get more reliable non-subjective responses. The postural habits included postures adopted during sleeping (supine, prone or lateral decubitus); sitting posture when writing or using computer; and during lifting objects from floor. The latter three postural habits were illustrated by alternatives pictures derived from Portuguese study for aiding parents to select their children often manner during performing such activities.

The fourth section includes the behavioral habits questions that borrowed and modified from other studies. It was assessed by author-asked the pupils whether or not they practicing physical exercise and those with yes response they further asked regarding its frequency. Sedentary activities were assessed by inquired the parents about the time in hours that their child spent daily for watching TV or using PC or other electronic devices. The student’s habit of studying on bed was also assessed based on the parent’s observation.

Regarding ethical issue, official permissions were obtained from educational directorates and schools administrations. The written consents were obtained from parents who assured about the confidentiality of information.

The pupils were informed that they have choice for participation regardless their parents’ willing. The interview was done in last-desk within classroom or in the lab accompanied by teacher for privacy.

Data collection was done by one author. Selected pupils who preliminary accepted for participation were provided with consent. Out of 5000 distributed questionnaires, 4667 pupils returned it back made 93.3% response rate, for whom, interviews were done individually during 5 minutes average.

Data were entered and analyzed by SPSS version 25. Chi-square test was used to assess associations between back pain and pupils’ socio-demographic, postural
and behavioral habits. Any significant associations by bivariate (Chi-square) analysis were further analyzed by multivariate (Binary logistic-regression) analysis to determine the predictors for back pain independently. P value <0.05 was set significant for all tests.

RESULTS

Out of 4667 studied pupils, 2024 (43.4%; 95% CI: 41.9-44.8) were experienced back pain during last month prior to study. Girls (46%) experienced back pain more than boys (41%) (10.640, P= 0.001) (Figure 1). Among sufferers, shoulder was the maximum reported site (Figure 2).

Results related to socio-demographic characteristics are shown in Table 1. Those related to postural and behavioral habits are shown in Tables 2. Bivariate analysis revealed that back pain was highly prevalent among pupils who aged 13-14 years (70%), in the sixth grade (47%), whose father and mother had intermediate and lower education, and those whose parents had positive back pain history (75.5%) (Table 1).

* Bivariate analysis. Pearson Chi-square test.
Significant at logistic-regression ($P<0.05$).

The output of logistic regression demonstrates that positive parent’s history is expected to increase back pain prevalence by 6 times independently (Table 1). Prone sleeping posture is expected to increase back pain prevalence by 2.6 times, and adoption of unsuitable postures when sitting for writing, using computer or picking objects from floor are expected to increase back pain prevalence by 4.7, 2.5 and 4.5 times independently respectively. None performing physical exercise or too frequent exercise performing (5+days/week) are expected to increase back pain prevalence by >3 and 2.7 times independently. Longer time spent in sedentary activities (6+ and 4-5 hours /day watching TV or using computer) are expected to increase the prevalence of back pain by 10 and 5.7 times respectively. Pupils’ habit of bed’s study is expected to increase back pain prevalence by >3 times independently (Table 2).

**Discussion**

This study illustrated that back pain is not uncommon among Iraqi primary schoolchildren as 43% of sample reported to have such pain which is approximately in the line of global and regional studies[6,8,14,15]. However, our-finding is higher and lower than what was reported by other studies[3-5,13,16]. This variability could be attributed to differences in age of target-group, sample size, and recall period. Our-results revealed that shoulder was the maximum pain site reported which is consistent with other studies[3,4,13].

Concerning the socio-demographic factors, prevalence was higher among eldest age-group which is supported by other studies[3,5,13,16]. This variability could be attributed to differences in age of target-group, sample size, and recall period. Our-results revealed that shoulder was the maximum pain site reported which is consistent with other studies[3,4,13].

Parent’s educations were found to be associated with back pain suggesting that back pain prevalence increased progressively with decreased level of education which supported by Egyptian study[3]. However, parents’ education isn’t found to have significant effect on back pain independently. This might attributed to that back pain might be related to general socio-economic status including family’s living condition reflected by income and providing facilities that ensure proper ergonomic and postures rather than education itself, and such variable could not be measured because of difficulties in gathering such information from our-families.

Parent’s history of back pain was significantly associated with back pain as well as it is found to be a significant predictor that expected to influence back pain prevalence like other studies[6,9,14].

Regarding postural factors, this study found significant association between sleeping posture and back pain prevalence and is found to be as predictor expected to influence back pain prevalence which is supported by Brazilian studies[8,9]. Such finding could support the recommendations regarding proper sleeping position that any sleep position other than recommended is not advisable and could result in load imbalance on the intervertebral discs and facet joints and could interference disc hydration that take-place mainly during sleep[8].

Significant associations were also found between sitting and lifting postures and back pain that are supported by other studies[3,8,9] and simultaneously found as significant predictors that expected to increase back pain prevalence independently.

Regarding behavioral factors, our-study found significant associations between physical exercise and its frequency with back pain and simultaneously are found as significant predictors expected to have effect on back pain prevalence independently which is supported by other studies[9,13] and suggesting the important effect of physical activity in back pain prevention when performed regularly on moderate-basis.

Significant associations were found between sedentary activities and back pain and such findings are in the line of else studies[3,6,8,9,16]. Such activities are found as significant predictors expected to increase back pain odds independently and could indicate an obvious trend of back pain prevalence that increased with increased
time spent in such activities.

Finally, significant association between back pain and pupils’ habit of bed’s study was identified in our-study and is found as predictor expected to influence back pain prevalence independently which is also supported by Brazilian studies\cite{8,9}.

**Conclusion**

Back pain sounds to be common among upper primary schoolchildren and quantify subjective morbidity among Iraqi children. Back pain was significantly associated with socio-demographic, postural and behavioral factors. It is necessary to increase the awareness of general public about risk of children’s back pain as precursor for adulthood back pain.

The Relationship between Dental Caries in Primary Teeth and Permanent First Molars in Schoolchildren Aged 8-9 Years in Wasit Governorate- Iraq

Hanan F. Abbas
College of Dentistry, Wasit University, Iraq

Abstract

“first molar” has an important role at individual’s dental health among the known risk factors, the experience of previous caries is of the best predictors for future caries. The aim of this study is to determine the relationship between dental caries in primary teeth and permanent first molars. The sample examined in this study consisted of 436 schoolchildren aged 8-9 years in Wasit governorate divided into control group (children with caries free in permanent first molars) and case group (children with at least caries in one permanent first molar) these case group subdivided into four groups according to the value of DMFT of the first molars. All children subjected to clinical examination to obtain information about “dental caries” of permanent 1st molars (DMFT) by assessment of decayed teeth, missing teeth due to caries and filling teeth according to WHO 1997. Also information obtained about dental caries prevalence and severity in primary teeth (dmft/dmfs) by assessment decayed teeth/ surfaces, missing teeth/ surfaces due to caries and filling teeth/ surfaces according to Gruebbl 1944. The data collection started from 1/March to 20/April 2018. Data analyzed using statistics package for social science SPSS Inc, 2016 version 24 for windows and Excel 2007. The mean value of dmft in control group was (3.42 ± 2.30) while in total case group was (5.48 ± 2.25), statistical analysis showed highly significant difference in the mean value of dmft between the two groups. The mean value of dmfs in control group was (0.09 ± 0.07) while in case group was (0.15 ± 0.10), statistical analysis showed significant differences in the mean value of dmfs between the two groups also. It was concluded that caries status in “primary teeth” can be used as a “risk indicators” for predicting caries in “permanent teeth”.

Keywords: caries in primary teeth, dental caries in permanent molars, dental caries in wasit governorate.

Introduction

“Dental caries” still a serious problem in many populations worldwide, with a marked increase of the prevalence and severity in several countries during the last decade. “Caries risk assessment” has been considered one of the principles of oral health promotion. So that by finding the causes and dilemmas of “dental caries” for each person, the correct treatment plan progression of stopping and prevention of new lesion is presented. The relationship between various factors and tooth decay has been shown in a large number of cross-sectional studies. The limitations of these studies in spite of the measurement of the relationship between the factors, they have the power to relate caries and various risk factors have not been mentioned.

Longitudinal studies on development of dental caries in child populations are relatively rare compared to the large number of cross-sectional studies, one aspect of caries development which has received some consideration in past studies is a possible relation between “dental caries” in the primary and the permanent dentition of the same individual. The existence of such a relation be of obvious importance for the planning of dental service of child populations, since it would permit early selection of child with a high probability of developing carious lesions in the permanent dentition. “dental caries” is the most prevalent of all chronic disease among US children, it affects 52% of children ages 6-8 years. High caries prevalence still endures as one of the major oral health issues in children, because “dental caries” is a disease that is both preventable and costly.
to treat, previous studies have focused on identifying caries risk predictors including developmental tooth defect, Mutans Streptococci infection, (time, source and level) Lactobacilli counts, salivary buffer capacity and flow rate, sucrose intake frequency and past caries experiences. Most of these studies, however consisted of a single or several cross-sectional surveys; information validating the correlation between caries in primary and permanent dentition of the same individuals is needed, "first molar" has an important role at individual's dental health among the known risk factors, the experience of previous caries is of the best predictors for future caries.

Materials and Method

The sample examined in this study consisted of 436 schoolchildren aged (8-9) years old in Wasit Governorate, the sample divided into control group (children with caries free in permanent 1st molars DMFT=0) and case group (children with at least one carious permanent 1st molars DMFT). Case group subdivided into four groups according to the value of DMFT of 1st molars, case 1(DMFT=1), case 2 (DMFT=2), case 3 (DMFT=3), case 4(DMFT=4). All children subjected to clinical examination to obtain information about "dental caries" of permanent 1st molars(DMFT) by assessment of decayed teeth, missing teeth due to caries and filling teeth according to WHO 1997. Also information obtained about dental caries prevalence and severity in primary teeth (dmft/dmfs) by assessment decayed teeth/ surfaces, missing teeth/ surfaces due to caries and filling teeth/ surfaces according to Gruebbel 1944. Data collection started from 1/March to 20/April 2018. Data analyzed using statistics package for social science SPSS Inc, 2016 version 24 for windows and Excel 2007. Both "descriptive" and "interferential" statistics were used.

Interferential statistics: "statistical significant of mean differences between groups was analyzed using student t-test. Comparison was done with a 5% level of significance. P < 0.05 significant.

Results

The sample examined in this study was 436 schoolchildren aged 8-9 years in Wasit governorate. The mean value of dmft in control group was (3.42 ± 2.30), while in case groups (1,2,3,4) was (4.20±2.04), (4.92 ± 2.16), (6.22 ± 1.77), (6.50 ± 2.20) respectively (Figure 1).

![Figure 1. Mean values of dmft in control group and in case groups](image)

The mean value of dmft in case groups is higher than in control group, analysis of variance showed no significant differences between the mean value of dmft in control group and in case 1 group, while analysis of variance showed significant differences between the mean value of dmft in control group and in case 2, case 3 and case 4 groups (Table 1).

Discussions

First molar has an important role at individuals dental health among the known risk factors, the experience of previous caries is of the best predictors for future caries. In present study the mean value of dmft in control group was (3.42 ± 2.30) while in total case groups was(5.48 ± 2.25), caries development in the “permanent dentition” was indicating that children who had caries in their primary teeth this is in agreement with 10-14. Also in this study the mean value of dmfs in control group was (0.09 ± 0.07) while in total case groups was (0.15 ± 0.10) that means there was “linear correlation” between dmfs in primary teeth and DMFT of 1st permanent molars this in agreement with 1 but disagreement with 5, other risk factors of dental caries such as cariogenic diet, mothers educations was controlled. In present study the mean value of dmft and dmfs increased gradually with increasing DMFT scores of 1st permanent molars this in agreement with 5.

Conclusions

This study conclude that caries status in the “primary teeth” can be used as “a risk indicator” for predicting caries in the “permanent teeth”, and Caries prevalence and severity of primary teeth affects on the caries status of the permanent molars.

Molecular Diagnosis of some Virulence Genes in *Pseudomonas aeruginosa* Clinical Isolates in Wasit Province

Rawan Hassan Abdulaali Al-Saeedi¹, Rana Hussein Raheema¹

¹Department of Medical Microbiology, Faculty of Medicine, University of Wasit, Iraq

**Abstract**

*Pseudomonas aeruginosa* is an opportunistic pathogen and is a common cause of nosocomial infection, which causes a wide range of infection. Two hundred and seventy eight samples were collected from different hospitals and private clinics in Waist province during the period from 15th September 2017 to the 15th December 2017. Seventy one isolates were identification as *Pseudomonas aeruginosa* by culture characterized, biochemical tests, API20E. Sixty seven isolates were detected as *Peudomonas aeruginosa* by molecular methods of 16SrRNA gene. The polymerase chain reaction technique was used for screening, the (9) virulence genes (*opr L, opr I, tox A, lasB,phzS,exoS,phzM, phzH* and *nan1*), the result showed that 67(100%) isolates were PCR positive for *oprL* and *oprI*. The determined of *toxA* gene that PCR positive for 56(83.6%). Another gene *lasB* were 65(97%) PCR positive. *phzS* gene were 61(91%) PCR positive. The result of PCR showed that 50(74.6%) isolates were PCR positive for *exoS* gene. The *phzM* gene in sixty seven isolates of *Pseudomonas aeruginosa* give PCR positive result in 36(53.7%). Results of *phzH* gene in *Pseudomonas aeruginosa* 32(47.8%). The *nan1* gene detected in 67 isolates of *Pseudomonas aeruginosa* and percentage of PCR positive were 48(71.6%). In conclusion, in studied the samples, still wounds are the common sites for *Pseudomonas aeruginosa* followed by ear and urine. 16SrRNA based PCR assay is highly accurate and reliable for identification of *Pseudomonas aeruginosa*.

**Keywords:** *Pseudomonas aeruginosa*, virulence genes, multiplex PCR

**Introduction**

Nosocomial infections or healthcare associated infections occur in patients under medical care. These infections occur during hospital stay, they cause prolonged stay, disability, and economic burden, during hospitalization, patient is exposed to pathogens through different sources environment, healthcare staff, and other infected patients, and also hospital waste serves as potential source of pathogens¹. *Pseudomonas aeruginosa* is a common cause of nosocomial infections². in individuals who are immune compromised, such as UTI, respiratory system infections, dermatitis, soft tissue infections, bacteremia, bone, joint infections, GI and a variety of systemic infections³. A major clinical problem caused by *Pseudomonas aeruginosa* is burn, lung infection in patients with cystic fibrosis and is the leading cause of fatality rate in these patients is around 50 percent⁴.

It possesses a various virulence factors which contribute to the bacterial invasion and toxicity⁵, such as las B elastase, encoded by the *las B* gene⁶. *nan1* gene encoding neuraminidase helps bacteria to adhere to epithelial cells⁷. Exoenzyme S encoded by the *exo* assist *Pseudomonas aeruginosa* to keep away from phagocytosis and in the end murder the host cell⁸. Exotoxin A encoded by the *toxA* gene, inhibit protein synthesis of the host cells⁹. Also, synthesizes phenazines that consider redox-active that are toxic to human cell¹⁰. There are also two outer membrane genes that help to rapidly diagnose of *Pseudomonas aeruginosa* oprL and oprI gene¹¹,¹². This study aimed to assess the 16SrRNA and nine virulence factor genes (*oprI /oprL /lasB / toxA /exoS /nan1 /phzS /phzM /phzH*) in *Pseudomonas aeruginosa* isolates.

**DOI Numbers: 10.5958/0976-5506.2019.00789.7**
Materials and Method

Sampling

A total of 278 samples were collected from different site (wound, ear, sputum, seminal fluid, CSF, stool, and urina) of patients in the hospital and private clinics in Wasit province.

Identification of *Pseudomonas aeruginosa*

The collected sample (278) was cultured on blood agar, MacConkey agar, Cetrimide agar, and incubated at 37°C for 24 hours. The isolated bacteria were identified according to colonial morphologies and biochemical tests. Then identification by API E test.

Extraction of genomic DNA

The DNA of isolates of *Pseudomonas aeruginosa* was extracted according to the instruction of Presto Mini g DNA bacteria Kits (Geneaid, Thailand).

Detection of gene and PCR protocols technique

PCR technique was used for amplifying 16SrRNA and *nan1* gene. The mixture reaction was performed in a total volume 20µl of PCR Pre Mix (Bioneer, South Korea) consisting of 1µl from each primer forward and reverse, 3µl of DNA and, the volume completed up to 20µl with free nucleases deionized water according to the instructions of the company. Detection of *(oprL, oprI, toxA, exoS, lasB, phzS, phzM, phzH)* gene were carried out by using a 20µl master mix of Gold Multiplex PCR (Bioneer, South Korea) including 1µl DNA, 1µl from each primer forward and reverse, and the volume was completed up to 20µl with free nucleases deionized water according to the instructions of the company. Table (1) shows the list of primer that using to identification *Pseudomonas aeruginosa* and detection of virulence gene.

Statistical Analysis

The statistical analysis of all the evidence was done using the system SPSS IBM version 20 software, Chi-squire test. P-value ≤ 0.001 was considered statistically significant.

Results and Discussion

Collection of sample

Total 278 clinical samples were collected in this study which include wound (n=80), ear (n=71), UTI (n=55), burn (n=23), stool (n=18), throat (n=15), sputum (n=14), seminal fluid (n=1) and C.S.F (n=1).

Identification of *pseudomonas aeruginosa*

Seventy one pure bacterial isolated were obtained from 278 clinical samples. These isolates were identified according to culture characteristics of isolate on different media (Table-3). All isolates were gram negative, rod shape, coliform under the microscope examination as described previously by Holt *et al.* then biochemical tests(Table4), API 20E system identification kits and confirmed by 16SrRNA.

All 71 isolates of Pseudomonas aeruginosa gave the same result by using API20E diagnostic kit. According to this study, 71(25.53%) of Pseudomonas aeruginosa were isolated from different clinical samples, Similar results were recorded by Hassan in Kurdistan who obtain (26%) isolates from different clinical source.

Highest percentage of Pseudomonas aeruginosa infections was observed in wound infection 24(33.8%), this bacterium can be considered the major agents of nosocomial infections in wound followed by ear infection and the frequency of Pseudomonas aeruginosa was 19(26.8%), then UTI 12(16.9%). While in throat was 5 (7%), burn 4 (5.6%), sputum 3(4.2%), stool 2(2.8%) seminal fluid and C.S.F 1(1.4%) for both. These results came in accordance to results obtained by Hassan, 2012 in Kurdistan, which showed percentage of Pseudomonas aeruginosa isolated from burn (10.9%).

Other study in Iraq by Ahmad, show similarity with this study that revealed the percentage of Pseudomonas aeruginosa isolated from wound, UTI and ear were 32%, 27% and 17% respectively except burn was(24%). In this study, the percentage of the source of infection is a reflection of the actual reality of pseudomonas aeruginosa in hospitals, but the differences in these ratios for other studies may be due to non-sampling regularly or other factors such as contamination. Further tests were conducted to confirm the identification by using 16SrRNA after diagnosis of bacteria by biochemical test and API20E. DNA of 71 isolated were extracted and conventional PCR was performed to amplify gene, and 67 isolated were identified as Pseudomonas aeruginosa. The results showed that 16SrRNA is a more accurate method for the detection of Pseudomonas aeruginosa than biochemical methods this was concurred with the result of Marhoon, Abdulammer.

DNA Extraction

The DNA extraction of 71 isolates was extracted; purity and concentration were confirmed with Nanodrop. The purity of Pseudomonas aeruginosa isolated (1.7-2),
and the concentration was between 50-360 ng/µl. The purity DNA is a good indicator of the extraction process as well as confirming the absence of impurities that could impede the process 24.

DNA samples were taken from different sources and using an electrophoresis relay device, the results were seen using transillumintor UV light as shown in (Figure 1). Gel electrophoresis is used to determine of extracted DNA fragments 25.

Figure 1. Gel electrophoresis of genomic DNA with loading dye, from Pseudomonas aeruginosa.

**Polymerase chain reaction for Identification of Pseudomonas aeruginosa**

From 71 isolate, 67(94.36%) were positive for the 16SrRNA and identified as Pseudomonas asaeruginosa, as show in figure (2).

Figure 2. Gel electrophoresis of Pseudomonas aeruginosa16SrRNA. Lane (M): DNA ladder(100-3000bp), Lanes (1,12): sample from different site.

**Detection of the Pseudomonas aeruginosa Virulence Genes**

The detection of virulence gene (opr L, opr I, tox A, lasB, phzS, exoS, phzM, phzHand nan1) by using PCRfor 67 isolated of Pseudomonas aeruginosa. The result of PCR revealed (100%) were positive for opr L gene as shown in Figure (4).These result agree with Al-Mayyahi, 26 was showed (100%) of isolated harbored of this gene. The oprI gene dissemination showed (100%) isolates were PCR positive as shown in Figure (4). These results came in according with Al-Mayyahi; 26 in Iraq.

The detection toxA gene by PCR revealed positive percentage were 56(83.6%), as shown in Figure (3). In a similar study done in Baghdad by Ahmad,21 report a rate of toxA as (80%). The percentage of lasB gene show PCR-positive were 65 (97%).As shown in Figure (3). These result came in according with thses obtained by Ra’oof,27 in Tikrit (100%). The percentage the phzS gene 61(91%) PCR-positive. As shown in Figure (4). Our result, disagrees with the finding of previous study by Fazeli et al.28 who obtain (19.6%) isolated harbored this gene.
Figure 3. Gel electrophoresis of amplified for *Pseudomonas aeruginosa* (opr L, opr I, tox A, lasB, phzS) gene. Lane (M): DNA ladder (100-3000bp), Lanes (1,12): sample from different site.

The result of PCR showed 50 (74.6%) were PCR positive for exoS gene, as shown in Figure (4). A study by Azimi, in Iran which (26.3%) contain this gene. The result of PCR of (phzM) gene show 36 (53.7%). As shown in Figure (5). Globally, the percentage of phzM in Iran Fazeli *et al.* was (36.27). The result of this study showed 32 (47.8%) had phzH gene, as shown in Figure (4). Similarly Fazeli *et al.* noted that 20.8% were positive for this gene.

Figure 4. Gel electrophoresis of amplified for *Pseudomonas aeruginosa* (exoS, phzM, phzH, ) gene. Lane (M): DNA ladder (100-3000bp), Lanes (1,12): sample from different site.

The nan1 gene detected in 67 isolates of *Pseudomonas aeruginosa* and the percentage of PCR-positive were 48 (71.6%), as shown in Figure (5). Nearly, similar results were recorded by Wolska, which showed that the (83.9%) were positive for this gene.

Figure 5. Gel electrophoresis of amplified for *Pseudomonas aeruginosa nan1* gene. Lane (M): DNA ladder (100-3000bp), Lanes (1,12): sample from different site.

Differences in the distribution of virulence genes in the world may be owing to; some strains of *Pseudomonas aeruginosa* are characterized by their ability to adapt to infection areas while taking advantage of the conditions of that sites. It may also be because isolates of patients have different clinical and physiological conditions. Conclusions, still wounds are the common sites for *Pseudomonas aeruginosa* followed by ear and urine, also using 16SrRNA-based PCR assay is highly specific, sensitive and reliable for identification of *Pseudomonas*
aeruginosa and its differentiation from other closely related Pseudomonas species.

Persistently Elevated Levels of Serum Autoimmune Inflammatory Markers after Total Thyroidectomy for Hashimoto’s Thyroiditis An Indicator of Prevailing Autoimmunity

Adil Shaker Al-Tamimi¹, Israa A Dheeb²

¹Department of Surgery, College of Medicine, University of Al-Qadisiyah, Iraq, ²Department of Medical Microbiology, College of Medicine, University of Al-Qadisiyah, Diwaniyah, Iraq

Abstract

Hashimoto’s thyroiditis characterized by glandular lymphocytic infiltration with progressive parenchyma destruction and fibrosis. The autoimmunity was suggested by the reduced immune tolerance and the production of antibodies. The description of Th17 subpopulation has undesirable role in the pathogenesis of Hashimoto’s disease. Among the cytokine secretion of Th17 is cell-type specific which carry its major effectors functions, IL17 and IL 22 are the most important.

Fifty two drug native patients with Hashimoto’s thyroiditis were enrolled in the study. Preoperative, 6 weeks and 6 months postoperative serum assay of ATPO Ab, IL6, tumor necrosis factor TNF-α, IL17 A, IL22,IL23 was adopted. Surgery in form of total thyriodectomy was carried out for patients with suspicious nodule based on cytological examination or large symptomatic multinodular goiter.

The preoperative elevated Anti TPO Ab significantly higher levels than the 6 weeks and 6 months post operative measurement. Serum levels of IL 6 and TNF-α were significantly higher in the preoperative measurement than the 6 weeks post operative measurement, and higher than 6 months serum level for IL6 but not TNF –α. The IL 17A levels were significantly higher in the preoperative patients sera than the 6 wk post operative measurement, but not the 6 months measurement. No statistical difference was observed in the preoperative and post operative levels of IL 22. The preoperative serum Level of IL-23 was apparently high, and significantly different from 6 weeks and 6 months post operative measurement.

The measured selected immune parameters exhibit partial decrease in serum level which would not reach the normal circulatory levels 6 months after thyroidectomy.

Keywords: Autoimmunity, Thyroidectomy, Inflammatory Markers.

Introduction

Hashimoto’s thyroiditis (HT) is common autoimmune thyroid disorders with glandular lymphocytic infiltration with progressive parenchyma destruction and fibrosis. HT affects 3–4% HT of the general population. The disease is 10 times more frequent in females than males. The exact etiology of the disease is still elusive however genetic and environmental factors influence the development of autoimmunity against thyroid tissue. The autoimmunity was suggested by the reduced immune tolerance and the production of antibodies. The majority of patients have raised anti-thyroid peroxidase (anti-TPO). As destruction of thyrocytes progress followed by loss of thyroid hormone synthesis and eventual hypothyroidism. Cell mediated autoimmune response is the main although not the sole pathogenic finding in HT, this response arise from a disruption of self-tolerance to thyroid antigenic structure. In HT Th1 (T helper) lymphocytes generate an intense inflammatory infiltrate (predominantly lymphocytic) of thyroid gland, which initiate further thyroiditis and loss of thyrocytes. The activated cytotoxic lymphocytes...
and macrophages, directly attack and destroy the thyroid follicular cells\textsuperscript{11}. The suggested accelerated apoptosis seen in HT is thought to be induced, when thyrocytes express molecules involved in cell cycle and apoptosis (Fas receptor and also Fas ligand), a process mediated by cytokine released from Th1 and macrophage\textsuperscript{12}. Th2 also induce B lymphocytes and plasma cells to produce thyroid targeted antibodies\textsuperscript{13}. In fact, although the cell-driven destruction of thyrocytes is the main pathological finding, antibodies to TPO and Tg are also important components. Th1 cytokines stimulate the release of immunoglobulin (Ig) G1, whereas Th2 cytokines participate in production of IgG4\textsuperscript{14,15}. TPO and Tg auto antibodies are of both IgG4 and IgG1 subclasses, indicating participation of Th2 and Th1 cytokines, including IL6 and TNF alpha\textsuperscript{16}. The Th1 mediated disease is the most widely accepted, however the concept is further modulated by the description of Th17 subpopulation\textsuperscript{17}. The Th17 cells mediate both normal and pathological immune response by its major role in immune response to the confounding extracellular pathogens and the disadvantageous role in the pathogenesis of several autoimmune diseases\textsuperscript{18}. The cytokine secretion of Th17 is cell-type specific which carry its major effectors functions, among which IL17 and IL 22 are the most important. Moreover, the Th17 cell expansion and survival is mainly mediated by IL-23\textsuperscript{19}. The clinicopathological course of the disease is very variable ranging from subclinical state to overt thyroid failure\textsuperscript{20}. Clinically HT present early with transient subclinical or overt hyperthyroidism for a variable periods followed by a stationary phase of euthyroid state eventually culminating on hypothyroidism, all stages of the disease may or not associated with goiter\textsuperscript{21}.

**Aim** : To evaluate some immune parameters in the sera of selected patients with Hashimoto’s thyroiditis before and after total thyroidectomy.

**Materials and Method**

Fifty two patients with presumptive diagnosis of Hashimoto’s thyroiditis were included in the study. The preoperative diagnosis was based upon clinical features, raised serum thyroid peroxidase Ab, cytology, TSH, thyroid hormone estimation and thyroid ultrasound. All patients were drug native euthyroid or mildly hypothyroid. Blood samples were collected in three different occasions, preoperatively as part of the assessment, 6wk and 6 months post operatively as part of the follow up, serum obtained for assay of ATPO Ab, IL6, tumor necrosis factor TNF-\textalpha, IL17 A, IL22, IL23. The indications for surgery was Hashimoto’s thyroiditis with suspicious nodule based on cytological examination or large symptomatic multinodular goiter. Surgery in form of total thyroidectomy was successful in all patients and was followed by full Levo-thyroxin replacement. All resected specimens were subjected to histopathological examination which proved the diagnosis of Hashimoto’s disease.

**Inclusion criteria**

Adults patients (18-60 years) with recent diagnosis of Hashimotos thyroiditis with euthyroid or subclinical hypothyroid state who were not subjected to any form of thyroid hormone replacement therapy.

**Exclusion criteria**

1. Patients with malignant disease including patients in whom thyroid malignancy was discovered after thyroidectomy.
2. Patients on thyroxin replacement.
3. Patients with advanced hypothyroidism.
5. Patients with chronic or autoimmune disease other than HT.
6. Patients on chronic steroid or immunosupresive drugs.

All candidates informed about the details of the research including the hazards of surgery and the planned follow up, for which they signed a written consent. Levels of antithyroid peroxidase (anti-TPO) antibodies in the sera of all candidates was determined, using the diagnostic enzyme-linked immunosorbent assay (ELISA) kit (Monobind Inc., Lake Forest, USA). Values more than 40 IU/ml were considered positive.

IL-6 ,TNF-\textalpha ,IL-17A, IL-22, and IL-23 serum measurements were detected using human ELISA kit in accordance to the manufacturer’s instructions (KOMABIOTECH- INC. Korea).

**Statistical analysis**

\textit{t}-test for Independent sample was used for comparing the means of the two groups.
**Results**

The preoperative elevated Anti TPO Ab showed higher levels than the 6 weeks and 6 months post operative measurement p value 0.001 and 0.0001 respectively. The 6 weeks serum level of anti TPO Ab was significantly higher than the 6 months measurement p value 0.0001. Serum levels of IL 6 were significantly higher in the preoperative measurement than the 6 wk and 6 months post-operative measurement p value 0.01 and 0.003 respectively. Furthermore, no statistical difference was found between the 6 wks and the 6 months post operative measurement. The serum level of TNF-α in the preoperative measurement was significantly higher than the 6 wk post operative measurement p value 0.02 but no significant difference was found between the preoperative and 6 months measurement. The IL 17A levels were significantly higher in the preoperative patients sera than the 6 wk post operative measurement P value 0.04, but not the 6 months measurement. Furthermore no significant difference found between the 6 weeks and 6 months measurements. No statistical difference was observed in the preoperative and post operative levels of IL 22. The preoperative serum Level of IL-23 was apparently high, and significantly different from 6 weeks and 6 months post operative measurement p value =0.0001. No difference was found in serum level between the 6 weeks and 6 months measurements (Table 2).

**Discussion**

In 2003 the discovery of Th17 cells, a unique CD4+ T-cells sub population have been found to have both beneficial and harmful immunological function, especially as a result of extravagant Th1 responses. These lymphocytes are the major source for production of cytokines from IL-17 family namely the IL17A and IL17 F, together with IL21 and IL22, which particularly accentuate the immune state by further release of other pro inflammatory cytokines like IL-Beta, TNF-α, and chemokines which are involved in cellular induced tissue damage. The IL-17A is the well known form in this family and has established proinflammatory effect in HT. Many cytokines have been suggested to have a potential role in the Th17 cells differentiation in humans among which the IL23, IL21, IL6 and TNF-α are the most important players. It has been found that patients suffering from HT found to have abnormally raised levels of Th17 cells and Th-17 related pro inflammatory cytokines. Our findings was supportive of the persistently high serum level of ATPO antibody following total surgical thyroid ablation.

The pro inflammatory IL6 and TNF alpha has been found to have crucial role in the pathogenesis of HT, most of the published data agreed with the finding of increases serum level in patients with HT irrespective to the clinical state. To date no available data regarding the serum level of these proinflammatory cytokines in thyroidectomised patients with HT. Yet no available research has depict the changes in the IL17 serum level in
patients with HT after thyroidectomy. IL22 has a potential role in autoimmune disorders including HT, through its ability to induce other pro inflammatory cytokines[30]. Our results are associated with only modest increased serum level of IL-22 in HT patients preoperatively, results which has been demonstrated by[31]. Moreover our results declared no difference in serum level of IL-22 results between pre and post operative measurement in our sample. IL-23 is known to have potent stimulatory effect on Th-1 to differentiate, producing the Th-17 subpopulation. Ruggeri et al has recorded a significant increase in serum level as compared with healthy control[32], While results displayed by Fatemeh et al declare a non significant difference in serum level of IL-23 between patients with HT and healthy control[31]. Our data revealed an abnormally high serum levels of IL-23 in the pre operative measurement which was statistically different from the post operative one, in which the levels approximately halved and remained static in an abnormally higher level for the following 6 months period. These parameters are indicative that the immune process is still working in spite of removal of the thyroid gland. The mechanisms, by which the auto reactive T cells escape deletion earlier and subsequent anergy, and activated thereafter remain elusive. Furthermore it has been found that patients with HT have elevated levels of Th-17 and its associated pro inflammatory cytokines both in the thyroid and peripheral blood[27]. The natural T regulatory cells regarded by many as the natural suppressor of T reactive cells and responsible for maintaining the peripheral tolerance[33], In HT they found to be dysfunctional and loss their immunosuppressive function and in the affected patients, and possibly converted to a pro inflammatory cells (Th- 1 and Th-17)[34]. On the other hand the coexistence of HT and other autoimmune diseases like diabetes and Addison disease and the existence of autoimmune polyendocrine syndrome type II, supplement the involvement of generalized autoimmune process rather than isolated thyroid targeted autoimmunity[35]. Moreover the development of Hashimotos related encephalopathy which has immunologically based pathogenesis, may uncover the prevailing autoimmunity[36].

**Conclusion**

The level of selected circulating immune parameters which was essentially elevated before thyroidectomy in patients with Hashimoto’s thyroiditis, exhibit only partial reduction after total surgical removal of the gland. Therefore, in autoimmune disease extirpation of the target organ will not ablate the autoimmunity in particular patient.

Depression among Islamic School (Madrasah) Students in Marang and Setiu District, Terengganu

Ain Syahada H.1, Siti Hajar A. R1
1Lecturer, Faculty of Applied Social Sciences, Universiti Sultan Zainal Abidin, Gong Badak Campus, 21300 Terengganu, Malaysia

Abstract

DASS stand for the Depression, Anxiety, and Stress Scale. The DASS questionnaire is a set of three self-report scales designed in order to measure the negative emotional states of depression, anxiety, and stress. The main objective of this study is to determine the depression’s level between male and female students in Madrasahs selected in Marang and Setiu district, Terengganu. The research instrument used to collect data are 448 sets of DASS questionnaire. The participants in this study consist of 448 respondents (177 male, 271 female) regardless of their status either an orphan or non-orphan. The analysis used was Analysis of Variance (ANOVA) and Chi-Square test. There are 7 questions (items) about depression in DASS. The validity of the items tested by using ANOVA and it shows a high validity and reliable to use in this study. Results from the chi-square test show that gender does affect the level of depression with the value of $p = 0.001$ which are smaller than the value of $\alpha = 0.05$. In this research, it shows that gender does affect the level of depression between male and female respondents. Hence, a precaution steps need to be taken in order to avoid any unwanted accidents.

Keywords: DASS, Depression, Mental health, Madrasah, Islamic school

Introduction

Mental health is a person’s condition with regard to their psychological and emotional well-being where all this pressure seems to be affecting individual mental health. According to the USA1, emotional, psychological, and social well-being included as a mental health. All those things do affects how we think, act, and feel. World Health Organization (WHO)2 defined mental health as a state of well-being in which every individual realizes their own potential. Depression, Anxiety, and Stress Scale (DASS) questionnaire3. The DASS questionnaire was modified and shortened and eventually it contained 21 items from its original version.

Depression is defined as a state of intense sadness or despair that has progressed to a level that is troublesome to an individual’s social functioning and the basic activities of daily living. Common feelings of depression are not limited to irritability, fatigue, apathy, and sadness but it can be included. When these feelings become stronger and more consistent, substance abuse and risky sexual behavior tend to become outlets for young adults who experience frequent low feelings4.

In daily use, the “depression” word referred to sad feelings experienced by an individual5. Based on6, depression can be regarded as a feeling, a syndrome or a clinical disease. The main objective of this study is to determine whether there are significant differences in depression level between male and female students in Islamic School (Madrasah) selected in Marang and Setiu district based on the Depression, Anxiety, and Stress Scale (DASS) questionnaire.

Methodology

Participants: Participants of this study consist of 66 respondents in the Madrasah Ad-Diniah Al-Islamiah in the Setiu district. While 151 respondents were selected in the Ma’ahad Darul Quran and 231 respondents were selected in Madrasah Mazahirul Ulum where both
Madrasahs were in Marang district. The total number of participants selected was 448 respondents (177 male, 271 female).

**Mental Test:** The DASS questionnaire containing 21 items was adapted and translated to Malay for the Malaysians’ use where the Cronbach Alpha value is 0.947. Each of the DASS questionnaires consists of 7 questions. The DASS questionnaire used a Four-Point Likert-Scale, where the scoring range is between 1 to 4. Scoring scale 1 illustrates the statements that do not reflect and describe the respondent’s self-condition (never at all). The scoring scale 2 represents a few or fewer statements that describe the respondent’s self-condition (rarely). Scoring scale 3 then illustrates many statements, always or often reflects the respondent’s self-condition (frequent). While for scoring scale 4, they represent various statements or very often statements that describe the respondent’s self-condition or situation (very often). The depression, anxiety, and stress scores are calculated by summing the scores for the relevant items.

**Analysis of Variance (ANOVA):** Analysis of Variance (ANOVA) is a collection of statistical models and their associated estimation procedures such as the variation among and between groups that are used in order to analyze the differences among group means in a sample. ANOVA was developed by statistician and evolutionary biologist. The observed variance in a particular variable is partitioned into components attributable to different sources of variation in the ANOVA setting. The items of the questionnaire divided into 7 part and all of them added as variables. All the results have shown p ≤ 0.05 alpha level of confidence. The ANOVA test was done using XLSTAT Statistical Software.

**Chi-Square Test:** A Chi-Square test found by Karl Pearson in his 1900 paper. A Chi-Square Test which also written as a χ² test is any statistical hypothesis test where the sampling distribution of the test statistic is a chi-squared distribution when the null hypothesis is true. Chi-squared test is short for Pearson’s chi-squared test. The test is used in order to determine whether there is a significant difference between the expected frequencies and the observed frequencies in one or more categories or not. To analyze the frequencies of the Islamic School (Madrasah), Chi-squared test was run in Statistical Package for Social Science (SPSS) version 20.0.

---

**Results and Analysis**

The Depression, Anxiety, and Stress Scale (DASS) items or questionnaire’s sub-scale. The test results show Pr > F values of all sub-scale or items where the result is < 0.0001 and having a high validity and valid to be used in the study. So, it is significant because the value is smaller than 0.05. The validity of questionnaire items is significant and can be used. The test results are as shown in Table 1. The reliability of the sub-scale level of depression was high and appropriate for the purpose of measuring the level of depression among male and female respondents (students) selected Madrasah in Marang and Setiu district, Terengganu. It shows that the sub-scale of depression level has a high-reliability value because it achieves Alpha Cronbach coefficient value which is 0.5 and above. The findings of the study show the Alpha Cronbach coefficient for the reliability of the scale of depression level reaches the value of α = 0.947. Table 2 shows the frequency table of distribution and percentage of respondents by gender involved in this study in Madrasah Ad-Diniah Al-Islamiah, Langkap in Setiu district. Based on the tables shown below, it shows that the total of male respondents is 64 respondents (97 percent). While, the total of female respondents is 2 respondents (3 percent). The total of male and female respondents combined are 66 respondents (100 percent). Based on the tables shown below, it shows that the total of female respondents is 231 respondents (100 percent).

Table 3 shows the frequency table of distribution and percentage of respondents by gender involved in this study in Madrasah Mazahirul Ulum in Marang district. Based on the tables shown below, it shows that the total of male respondents is 113 respondents (74.8 percent). While, the total of female respondents is 38 respondents (25.2 percent). The total of male and female respondents combined are 151 respondents (100 percent). As the Table 4 shows below, by combining both male and female respondents in all three Madrasah, 287 (64.10 percent) respondents have a normal scale of depression which is they are not having a depression. A total of 92 (20.50 percent) respondents are having a mild depression and 33 (7.40 percent) respondents are having a moderate depression. 23 (5.10 percent) respondents are suffering a severe depression. There are 13 (2.90 percent) respondents are suffering an extremely severe depression. There are 448 (100 percent) respondents in total who are going through a various scale of depression. Based on Table 5 it is found that the value of \( p = 0.01 \), which is smaller than the value of \( \alpha = 0.05 \), then the research question is answered. This means there is a significant difference between male depression and female depression. As the result of the test shows that there is a significant difference, it can be concluded that gender does affect the scale of depression among male and female respondents in Islamic School (Madrasah) selected in this study both in Marang and Setiu district.

**Discussion**

Scale of depression cross tabulation by gender below shows the count and percentage within gender in all 3 Islamic School (Madrasah) in Marang and Setiu district. The scale of depression of male respondents in all 3 Madrasah when combined shown a result of respondents who are not suffering any depression by means that they are scoring up a normal scale of depression are 134 (75.70 percent) respondents. While, there are 28 (15.80 percent) respondents who are having a mild depression. 6 (3.40 percent) respondents who are showing a moderate depression. 5 (2.80 percent) of the respondents shockingly suffered a severe depression. Up to 4 (2.30 percent) respondents suffered an extremely severe depression. The total of the male respondents who are going through a various scale of depression when counted is 177 respondents. As for female respondents, based on the scale of depression cross tabulation by gender shows that count number of female respondents who are scoring a normal scale of depression is 153 (56.50 percent) respondents. There are 64 (23.60 percent) respondents having a mild depression. 27 (10.00 percent) of them are going through moderate depression. The counts of respondents who are suffering severe depression are 18 (6.60 percent). The balance of 9 (3.30 percent) female respondents are suffering an extremely severe depression. The total of the female respondents who are going through a various scale of depression when counted is 271 respondents.

Based on the results shown in chi-square test, it means that there is a significant difference between male depression and female depression which means that gender does affect the level of depression in Islamic School (Madrasah) selected in this study both in Marang and Setiu district. It has been said that gender aspect is often disputed that it will affect the level of worker stress\(^{10}\). The results of the study were found to be consistent with the study conducted by\(^{11-12}\) that women’s staff were more depressed than male staff. Hence, it can be concluded that gender factors can influence the stress among the staff. The gender differences among adolescents begin to exist at the age of 13-14 years and significant differences will exist at the age of 17-18 years, where female adolescents will record higher rates than man adolescents. Other researchers say that girls are usually more susceptible to depression than boys\(^{13-15}\). Previous studies have found that there are significant differences between adolescent females and males who suffer from depression. According to a conducted study\(^{16}\), teenage girls are twice as likely to experience depression compared to boys. There also found that girls adolescent have higher scores of depression compared to boys\(^{17}\).

**Conclusion**

Several precaution steps can be taken into account in order to prevent depression from happens or to reduce the level of depression. Firstly, organizing more activities with groups that are not among the depressed individuals. This is because when an individual associated with other persons who are not of their own (family and close friends), they will be more open and willing to accept. Secondly, the welfare agencies in Malaysia need to focus more on students, especially for underprivileged students.

Perspective of Malaysian Youths towards Homosexuals

Mohd Syaiful Nizam Abu Hassan¹, Ahmad Zafran Azhar¹, Nasriah Kamaruddin¹, Amanina Mohamad¹
¹Lecturer, Faculty of Applied and Social Sciences, Universiti Sultan Zainal Abidin, Gong Badak Campus, 21300 Kuala Nerus, Terengganu, Malaysia

Abstract

Lesbian, gay, bisexual, and transgender are from the acronym LGBT. Gay are men who has emotions or feelings toward the men but although gay is also use for women too. They are men who are attracted towards the same sex and are unattached towards the opposite sex. Gay usually refers towards homosexual men or men who had sexual intercourse with other men. This research was conducted to identify the perspectives of teenage boys and girls towards homosexuals. The method that was used in this research was the quantitative method. XLSTAT with non-parametric tests were used in this research. A total of 1200 respondents were involved in this research. There were 664 male and 536 female respondents. A questionnaire was handed out to students of University Sultan Zainal Abidin (UniSZA), Gong Badak campus. The results showed that 6/10 from the research question were significant towards the perspective of youths toward gays. One of them is the first question which has a p-value of 0.160. This showed that there is significant difference between male and female towards gay to be allow to adopt a child.

Keywords: Lesbian, XLSTAT, University Sultan Zainal Abidin (UniSZA), p-value, Youths

Introduction

Nowadays, homosexuality has been widely discussed. It has become a phenomenon worldwide. It is spreading day after day. Efforts had been made to deter this activity but has not able to pull it off¹. Homosexuals came from a diverse background regardless of age, religion, and status. Sexuality rights have been around for the past two decades and has made a big difference. Sexual rights is one of the most controversial among other rights. This right has been the basis of many policies by many non-governmental organisations (NGO). This research shall discuss the perspectives of Malaysian youths towards gay². Homosexual is the act of sexual intercourse with the same sex. Besides that, homosexual also refers to the same sex couple who has special relationship together or in love with each other. Homosexual has existed for a long time which includes sexual activities and same sex marriage. Homo is a Greek word meaning “same” and Latin root word sex roughly means gender³-⁴.

The existence of the LGBTs in Malaysia started with the emergence of trannies during the 1980s. During that time, the government has stated that LGBT is immoral and can’t be made a lifestyle⁵. The act of changing one’s gender from male to female and vice versa will give a conundrum of an implication on Islamic laws including marriage, death, and prayer among others. This is why it is considered a sin and forbidden to change one’s gender in Islam. Men and women who aren’t clear what their gender are due to two sexual organs are asked to have surgery.

Homosexuals are men or women that has feelings or emotions toward the same sex⁶. They feel that their couple are a lot more understanding and follows their needs compared to opposite genders. They wanted more attention and love from their mate⁷. Society are quite worrying about teenagers nowadays as they are prone to be involve in immoral activities. One of the factors of homosexuality is the lack of religious education, lack of love from parents, influence of social media, and mental illness⁸.

Methodology

Participants: There are a total of 1177 respondents
consisting of various race and religion. Male consists of 663, while female has a total of 514. Respondents are UniSZA student from the Gong Badak campus. Respondents are between the ages of 18-27. They came from various states including Kuala Lumpur, Selangor, Pahang, Perak, Kelantan, Terengganu, Sarawak, Sabah, Pulau Pinang, Perlis, Negeri Sembilan, Melaka, Kedah and Johor. A majority of the respondents came from Terengganu is 269 in total. Respondents are picked randomly.

**Measures:** The research that was conducted is quantitative in form. This method was carried out by collecting information from respondents. The statistical descriptive is the study of current issues. Questionnaire are one of the method in descriptive research to get feedback from samples and make a generalisation on the population. Section A has 10 questions regarding perception towards lesbians. While, Section B consist of 10 questions on perception towards gay. Using the measurement scale respondents are required to tick one of the scale in the questionnaire. The measurement scale used in the questionnaire are: 1 = strongly disagree, 2 = disagree, 3 = not sure, 4 = agree, 5 = strongly agree.

Study sample consists of 1200 respondents from students of UniSZA, Gong Badak campus. The questionnaire was handed out randomly by the researcher. The output gained from the respondent depends on the aspects of validity and reliability. The researcher used a questionnaire that was used on past research. To get a viable validity respondents are were required to answer it individually. The method that was use is simple random sampling method. Respondents must be of the ages 12-25.

**Analysis Reliability Assessment Instrument:** This method gives equal chance for respondents to be chosen for the research. In order to gain validity and reliability, the data obtained must be analyse using XLSTAT to gain reliability value which is Cronbach alpha. Reliability is often related to stability and inner strength. Cronbach Alpha value is refer when measuring the inner strength of a construct. A Cronbach Alpha value that is above 0.60 is used as an index for reliability. While according to, the value of reliability that is below 0.60 is considered low and cannot be used, alpha value from 0.60 to 0.80 is acceptable while above 0.80 is excellent. In this research, the Cronbach Alpha is valued at 0.677. By referring to what was stated above, Cronbach Alpha value was used for the reliability of the questionnaire.

**Results and Discussion**

**Results:** Based on the non-parametric test that was conducted, the minimum reading for all variables is 1, while the maximum is 5. The average for every question is different. C1, which is gay couples should be allow to adopt, has a higher male average of 1.893% compared to female at 1.800%. C2, which is gays are disgusting has a higher average of males at 3.454% compared to females at 3.315%. C3, which is gay should not be allow to teach at school has a lower average for males at 3.030% compared to females 3.130%. C4, which is homosexuality is something that deviates from the norm shows a lower average for male at 3.229% and female at 3.352%. C5 which is homosexuality is a natural phenomenon also experienced by animals shows a lower average for male at 2.943% and female at 2.992%. C6 which is if a person is gay he should ignore and try to control his desire and seek help showed a lower average for male at 4.404% and female is at 4.685%. C7 is I won’t be disappointed if my child turns out gay showed a higher a male average at 1.816% than female at 1.414%. Homosexual is immoral is C8 with a lower average for male at 3.409% and female at 3.572%. C9 is I do not support gay marriage has a higher male average at 3.882% while female is at 3.759%. Lastly, C10 which is homosexuality is just a lifestyle nothing to make a fuss about has a higher male average at 2.012% compared to female at 1.562%.

Table 2 shows all the variables that is represented for every question shows the significant score on the perspective of male and female youths towards gay. For the question C1, gay couple should be allow to adopt a child, the p-value is 0.160% which is more significant than 0.05. So, there is a significant difference between male and female youths in stating that gay couples should be allow to adopt a child.

C2 shows there is a significant difference between male and female in gays are disgusting. The p-value is larger than the significant level of 0.05 which is 0.237%. So, the researcher can reject Ho and accept Ha as there is a significant difference between male and female. C3 shows there is a difference in perspective between male and female on gays should not be allow to teach at school. The p-value is larger than the significant level of 0.05 which is 0.237%. So, the researcher can reject Ho and accept Ha as there is a significant difference between male and female. C4 shows no difference in perspective between male and female on homosexuality is a deviation from the norm. The p-value is less than the significant level of 0.05 which is 0.049%. The researcher can reject Ho and accept Ha in which there are no significant difference in perspective between male and female. C5 displays a difference in perspective between male and female on homosexuality is a natural phenomenon that is also experienced by animals. The p-value is above the significant level of 0.05 which is 0.649%. Ho can be rejected and accept Ha in which...
there is a significant difference in perspective between male and female.

C6 shows no difference in perspective between male and female on gays should control their desire and seek help. The p-value is less than the significant level of 0.05 at < 0.01. The null hypothesis is rejected and alternative hypothesis is used which means there are no significant difference between male and female. C7 shows no significant difference between male and female on not being disappointed if their child turns out gay. The p-value is less than the significant level of 0.05 at < 0.01. The Ho is rejected and Ha accepted as there is no significant difference between male and female. C8 shows a difference between male and female on homosexual is immoral. The p-value is greater than the significant level of 0.05 at 0.059%. The null hypothesis is rejected and Ha accepted as there is a significant difference between male and female. C9 shows a difference between male and female on not supporting same sex marriage. The p-value is higher than the significant level of 0.05 at 0.138%. The null hypothesis is rejected and Ha is accepted as there is no significant difference between male and female. C10 shows no difference between male and female on homosexuality is just a lifestyle nothing to make a fuss on. The p-value is less than the significant value of 0.05 at < 0.01. The null hypothesis is rejected and the Ha is accepted as there is no significant difference between male and female.

### Discussion

Beforehand the word gay refers to the word happy or at ease. But, it usually means those who are homosexual. Nowadays, it exclusively means homosexuals compared to happy. Gay is the noun use to refer to an individual who is involve in a relationship with the same sex and gender, and make it a daily lifestyle openly. Those who have feelings towards the opposite sex but doesn’t accept the feeling and lifestyle, usually are not refer as gays. You are refer as one if you live its lifestyle. The term homosexual has been used as a sexual identity together with heterosexual and bisexual.

Besides that, when a person is attracted to someone of the same gender but does not have any relationship of any kind with that someone, that person is not refer as gay. However, a gay almost always have some kind of relationship with the same gender. The word gay is use for both men and women who are attracted toward the same sex. But, lesbian is specifically use for women who are attracted toward the same sex. There are cases when an individual develops feeling or attracted towards the same sex rejected those feelings and tried to overcome it, so they are not refer as gay. Once he accept it and live his life living the homosexual lifestyle, only then would he be called as a gay.

LGBTs should be monitored, kept at bay, and prevented through the syariah criminal law in Malaysia. A strict action must be taken so that they won’t continue to mock the institution of Islamic law in Malaysia. The existence of the Federal Constitution is to uphold and respect Islam as the religion of the federation and its law should not be meddle with and make a mockery off.

Besides that, LGBTs exist worldwide. They are a minority who not only has a misguided lifestyle, they also fight for it to be accepted by people around the world. But according to Islam, their fight for the perceived rights is totally misguided in the context of religious principles. Even though that is the case, this movement has been reeling for support and the do it openly and, discretely even though in majority Muslim Malaysia. So, preaching activities has to be active and widespread so that none will fall victim to this lifestyle and other vice activities. Besides that, preachers should use effective approach and varied in teaching Islamic values to the LGBT. Without us realising, the LGBT problem is getting severe and harming the harmonious life of society today. Although, LGBTs in Malaysia is still not accepted s it violates social ethics. Malaysia still make it illegal. The existence of new media has made LGBT lifestyle to carry out much easier and their numbers are increasing.
This research shows the perspective, feelings, and attitude of Malaysian youths toward homosexuals. The result matches with Malaysia’s stand on this issue which is, the homosexual culture is not accepted in this country. However, there are a small minority that accepts them. We can see that even though Malaysia is a majority Muslim country and Islam is the religion of the federation, there exist those who accept this lifestyle and culture. This can be seen with the formation of NGOs and organization who supports the homosexual communities. This parallel with the result of this research, the majority disapprove of homosexual and there are minorities who accept them.

Factors Associated With Post-stroke Nutritional Status in Stroke Survivors under Rehabilitation

Chin Yi Ying¹, Sakinah Harith², Aryati Ahmad², Hassan Basri Mukhali³

¹Student, School of Nutrition and Diëtetics, Faculty of Health Sciences, Universiti Sultan Zainal Abidin, Terengganu, Malaysia; ²Lecturer, School of Nutrition and Diëtetics, Faculty of Health Sciences, Universiti Sultan Zainal Abidin, Terengganu, Malaysia; ³Lecturer, Faculty of Medicine, Universiti Sultan Zainal Abidin, Terengganu, Malaysia

Abstract

Malnutrition is a common phenomenon in stroke survivors. However, the extent of malnutrition and their associated factors in stroke survivors are yet to be discovered. This study aims to determine the prevalence of malnutrition and the factors associated with it. A cross-sectional study was conducted on 169 stroke survivors in Terengganu, Malaysia. Sociodemographic and clinical data were recorded using a structured questionnaire. Nutritional status was assessed using body mass index (BMI). Malnutrition was defined either BMI <18.5 kg/m² for subjects <60 years or BMI <20.0 kg/m² for subjects ≥60 years. Multivariable logistic regression was performed. The prevalence of malnutrition was 8.9% (men 55.0%, 51.5% were 60 years or older, with a median age of 60.0 ± 14.0 years. Median BMI was 25.4 ± 7.2 kg/m². Age was significantly associated with good nutritional status (adjusted OR, 1.10; 95% CI, 1.03 to 1.17; p=0.004). However, it is not associated with gender, educational level, household income, smoking history, previous stroke, and post-stroke physical condition. Age is the most important determinant in nutritional status of stroke survivors.

Keywords: Stroke, Nutritional status, Malnutrition, Rehabilitation

Introduction

Stroke is a significant global health burden and plays a role as the world’s second largest killer and has remained as the leading cause of death globally for the last 15 years¹. In Malaysia, stroke is the third leading cause of death (6.9%)² and is also one of the top three causes of disability-adjusted life years (DALYs) (6.0% of total DALY’s from all causes) in 2017³.

With the growing of aging population in the nation⁴ and increasing of stroke risk factors such as hypertension among Malaysian adults and elderly⁵, the incidence of stroke would increase, which in turn would increase expenditure and post threat to stroke-related healthcare system, patients and caregivers due to the post-stroke complications⁶. The estimated lifetime treatment costs for ischemic and hemorrhagic stroke patients in Malaysia were USD$ 8,607 and USD$ 8,928 respectively⁷. The impact of stroke burden can be significant when the outcomes, especially malnutrition, continue to be the serious issues in stroke patients.

To date, few studies have been carried out on assessing the nutritional status of stroke survivors during chronic phase, causing the nutritional status of this population beyond the acute phase of stroke to be neglected⁸. Malnutrition interferes with the recovery thereby affecting the stroke survivors to have a poorer response to rehabilitation⁹.

Stroke causes long-term disability and morbidity in an individual such as functional declines¹⁰, behavioral changes such as depression and dementia¹¹, declining in quality of life¹², eating and dysphagia¹³, as well as malnutrition¹⁴. These unfavorable conditions increase the catabolism of the body, and thereby the nutritional status of stroke survivors getting worse¹⁵.
Malnutrition is evident among stroke patients. Prevalence of malnutrition in stroke survivors during the chronic phase of stroke varies from 8.2% to 33.0%\textsuperscript{13,16-17}. Several studies have demonstrated that malnourished patients have serious complications such as infection, falls, dysphagia\textsuperscript{18} and are associated with increased mortality, increased morbidity, and a poorer functional recovery\textsuperscript{19,20}. Numerous factors that affect the nutritional status of stroke survivors were elderly, women, previous stroke\textsuperscript{21}, previous history of smoking\textsuperscript{17}, and subtype of stroke\textsuperscript{22}.

Realizing the prevalence of malnutrition provides an insight into the importance of early recognition of malnutrition and timely nutritional intervention for stroke survivors. Despite the proven negative outcomes of malnutrition, the monitoring of nutritional status is still lack of attention. Thus, the study conducted nutritional assessment and looks into the prevalence of malnutrition and the factors associated with malnutrition to ensure the greatest recovery in stroke survivors.

**Methodology**

This study was carried out among 169 stroke survivors who were followed-up to either rehabilitation medicine specialist clinic in Hospital Sultanah Nur Zahirah (HSNZ) or Rehabilitation Health Organization in Terengganu. We collected demographic and clinical information from stroke survivors or their caregivers using a standardized questionnaire. Nutritional status was assessed in terms of body mass index (BMI), which is calculated by weight (kg) divided by the square of height (m\textsuperscript{2}). Anthropometric parameter of body weight was measured on an electronic weighing scale, whereas standing height was measured using portable stadiometer.

Alternative anthropometric measurements were performed to stroke survivors who were unable to ambulate and wheelchair bound. The measurements required for the calculation of the predictive equation for body weight were mid-upper arm circumference (MUAC), knee height (KH), calf circumference (CC), and subscapular skinfold (SS). The equation used for the estimation of body weight are as follows; weight (men) = (0.98 x CC) + (1.16 x KH) + (1.73 x MUAC) + (0.37 x SS) - 81.69; while weight (women) = (1.27 x CC) + (0.87 x KH) + (0.98 x MUAC) + (0.4 x SS) - 62.35\textsuperscript{23}. Estimated height was obtained by demi-span measurement. The demi-span equations used to calculate the height are as follows; height (men) = 67.51 + (1.29 x demi-span) – (0.12 x age) + 4.13; while height (women) = 67.51 + (1.29 x demi-span) – (0.12 x age)\textsuperscript{24}. Measurements were performed by inelastic measuring tape on the non-paretic side of the body.

The BMI were categorized using Asian-specific BMI cut-offs\textsuperscript{25}: underweight (<18.5 kg/m\textsuperscript{2}), normal (18.5-22.9 kg/m\textsuperscript{2}), overweight (23.0-27.4 kg/m\textsuperscript{2}), and obese (≥27.5 kg/m\textsuperscript{2}). Malnutrition was defined either BMI <18.5 kg/m\textsuperscript{2} for subjects <60 years or BMI <20.0 kg/m\textsuperscript{2} for subjects ≥60 years\textsuperscript{13}.

The data was analyzed using IBM SPSS Statistics for Windows version 22.0 software. Descriptive statistics were performed for the characteristics of the respondents in this study. Multiple logistic regression was conducted to determine the predictors of malnutrition. P-values less than 0.05 were considered significant.

**Results and Discussion**

Stroke survivors consisted of 55.0% men and 45.0% women; with a median age of 60.0 ± 14.0 (range 26-82) years. As shown in Table 1, most of the survivors were Malay (96.4%), had secondary education (48.5%), not working (76.9%), without income (52.1%), and only 10.7% were smoker. Almost one-third of stroke survivors were ischemic stroke (71.0%) and 85.8% had their first-ever stroke. The median of post-stroke duration was 12 months. The most commonly reported comorbidity was a combination of hypertension, hyperlipidemia, and diabetes mellitus (33.7%).

</table>
The median of BMI of stroke survivors was 25.4 ± 7.2 kg/m². According to the Asian-specific BMI cut-off points, most of the stroke survivors were classified as obese (36.7%), whereas 4.7%, 29.6%, and 29.0% were categorized as underweight, normal, and overweight respectively. The prevalence of malnutrition was 8.9% (Table 2). There was a significant association between age and nutritional status. Older age stroke survivors were 10% higher risk of becoming malnourished compared to younger stroke survivors (95% confidence interval (CI) 1.03,1.17, p=0.004). However, malnutrition was not associated with gender, educational level, household income, smoking history, previous stroke, and post-stroke physical condition (Table 3).

Odds ratio (OR); 95% confidence interval (CI)

\(^a\) Binary logistic regression

\(^b\) Backward LR multiple logistic regression model was applied
Hosmer-Lemeshow test, \((p=0.733)\), classification table (overall classified percentage=91.1%) and area under the ROC curve (73.1%) were applied to check the model fit.

The average age of stroke survivors found in our study was younger than the age reported in our nationwide hospital-based registry which was accounted for 62.7 years\(^26\). Stroke is no longer interpreted as commonly prevalent in the elderly\(^27\). The current study reveals that stroke is emerging in almost half of these stroke survivors in adulthood. The changing of stroke incidence across the age spectrum may be due to the increasing prevalence of stroke risk factors such as hypertension in adults\(^28\). This study also found that the prevalence of malnutrition among stroke survivors was slightly higher than study in Hong Kong (8.2%)\(^17\), but lower compared to other studies including among stroke survivors in Denmark (22.0%)\(^16\) and Swedish (33.0%)\(^13\).

These broad discrepancies in prevalence rates are due to the nutritional assessment methods and the timing of measurement\(^29\).

The results for previous history of smoking as a significant risk factor for malnutrition in stroke patients are inconsistent. A previous study \(^17\) reported that previous history of smoking was associated with malnutrition. Nonetheless, our study found no significant association which is in agreement with that of the review\(^30\). Previous stroke was not significantly related to malnutrition in our study. On the contrary, previous stroke was identified as an important risk factor for malnutrition in other studies\(^21,30\). Gender, post-stroke hemiparesis, socioeconomic status, and education level were not considered as the risk factors for malnutrition, supported by the previous study\(^31\).

In concordance with previous findings\(^20-21\), the present study has shown that malnutrition in stroke survivors is influenced by age. Hemiparesis presented in all stroke survivors may result in the changes of body composition such as decrease in fat-free mass in the paretic side\(^9\). Additionally, the elderly have been found to be at high risk of undernutrition\(^32\). Therefore, the nutritional status of stroke survivors worsens with the accompanying ageing process.

This study recommends that the nutritional assessment in stroke survivors is necessary for malnutrition checking to enhance optimal recovery and rehabilitation. Nutritional intervention strategy, such as dietary intake and anthropometric assessment, is targeted to these at-risk stroke survivors to limit the impact of undernutrition on stroke outcomes. Further investigation is needed to determine the exact mechanism and risk factors of malnutrition in stroke survivors due to the inconclusive previous studies.

**Conclusion**

Stroke has become a global health problem. Early recognition of malnutrition significantly affects the outcomes. The optimization of nutritional status is essential to reduce the risk of developing further complications including physical, metabolic dysfunction, to recover from stroke rehabilitation, and lastly to improve health and quality of life of stroke survivors.

Effect of Phytochemicals in *Phoenix Dactylifera* L. on Human Body Using LC-QTOF-MS

Sabri Nurul Elma¹, Dzulfadli Rosli², Khalilah Badarusham¹, Shamala Salvamani¹³, Mohd Sukri Hassan¹

¹Lecturer, Faculty of Science and Technology, Universiti Sains Islam Malaysia, 71800 Bandar Baru Nilai, Negeri Sembilan, Malaysia; ²Lecturer, Institute of Halal Research and Management (IHRAM), Universiti Sains Islam Malaysia, 71800 Bandar Baru Nilai, Negeri Sembilan, Malaysia; ³Lecturer, Division of Applied Biomedical Science and Biotechnology, School of Health Sciences, International Medical University, 57000 Bukit Jalil, Kuala Lumpur, Malaysia

Abstract

The presence of nutrients and phytochemicals including alkaloids, sterols, phenols and flavonoid in *Phoenix dactylifera* L. has been related to the health-benefits of date fruits consumption. Metabolomics study has been conducted to explore the human urine metabolome modifications after date fruits intake. After overnight fasting, urine samples were collected before the ingestion at 0h and every 4 hours after the consumption of date fruits at 4-24-h. Samples were analysed using LC-QTOF-MS, followed by Principal Component Analysis (PCA). Results revealed the changes of urinary metabolome during the 24 h after date fruits intake. Some phytochemicals, including alkaloids, sterols, phenols and flavonoids were appeared and disappeared after date fruits intake. These findings confirm that metabolomics is an effective tool that can be practiced in order to further discover the metabolism of phytochemicals and its relation with human health.

Keywords: Ajwa dates, Human urine, Liquid chromatography mass spectrometry (LCMS), Metabolomics, Principal component analysis (PCA)

Introduction

Metabolomics investigations attempt to detect and profile the changes in metabolites, which reflect changes in metabolic pathways and may provide information concerning a disease state or the biological stress of an organism¹ or for discovery of biomarker². There are two metabolomics based analyses; nuclear magnetic resonance (NMR-based) and mass spectrometry (MS-based). 1H-NMR-based is widely used in metabolomics study as it can simultaneously display resonance peaks resulting from hundreds of metabolites³⁴, requires little or no sample preparation⁴⁵ and highly reproducible and non-destructive⁶. Meanwhile, many researches using MS-based analysis due to the high sensitivity and selectivity. For instance, Liquid Chromatography Mass Spectrometry (LCMS) could be benefited from lower detection limits and improved MS data quality due to reduced background noise⁷⁸ stated that Gas Chromatography Mass Spectrometry (GCMS) gives high resolution chromatographic separation and wide applicability through derivatization.

In our previous study using 1H-NMR-based metabolomics indicated that a complete recovery of 24 hours after the Ajwa dates intake as a result of the urinary metabolome 24 hours after consuming Ajwa dates back to blank (0 hour). In other words, the effect of ajwa dates remained in body within 24 hours (unpublished data). Thus, in order to study the beneficial effect of Ajwa dates in human health, metabolomic study on the consumption of Ajwa dates flesh has to be performed. The aim of this study is to investigate the changes of metabolites in urine after the consumption of Ajwa dates using LC-QTOF-MS.

Methodology

Ten healthy volunteers (5 females and 5 males) between 20 and 25 years old with body mass index of
20-25 were enrolled with informed written consent. This study was approved by the Human Ethics Committee (HEC) of Universiti Sains Islam Malaysia (USIM/JKEP/2016-14). Subjects were required to fasting overnight and follow the control diet, which exclude fruits and vegetables, supplements and beverages such as tea, coffee, fruit juice or any bicarbonate drinks. Equal meals were given to subjects during the experiment after considering their food allergy.

The urine samples were obtained before consumption of Ajwa dates as blank (0h). Immediately, all subjects consumed 7 Ajwa dates that were given. Urine were collected at 4, 8, 12 and 24 hours after the consumption of Ajwa dates, which were at 11 am, 3 pm, 7 pm and 7 am (the next day), respectively. All the collected urine were stored in -20 °C. This design was followed Lopez et al (2014) with some modifications. Organic solvent used in this study is methanol (Merck, Darmstadt, Germany).

This method was followed by previous research with some modifications. Briefly, the urine samples were thawed before the analysis and vortexed using vortex mixer to homogenize the sample. An aliquot of urine (2.0 mL) was filtered using syringe filter (0.25 μm) and then centrifuged at 13 000 rpm for 5 min to remove the precipitate. The supernatant (1.0 mL) was transferred into a vial (2.0 mL) and diluted with an organic solvent; methanol (0.5 mL) and then well mixed. The prepared sample directly injected to LC-QTOF-MS.

Urine analysis was performed on ACQUITY UPLC I-Class system (WATERS Corporation, MA, USA) instrument. Compounds were chromatographically separated using a column ACQUITY UPLC HSS T3 (100 mm x 2.1 mm x 1.8 μm), maintained at 40 °C. A linear binary gradient of water (0.1 % formic acid) and acetonitrile was used as mobile phase A and B, respectively. The mobile phase composition was changed during the run as follows: 0 min, 1% B; 0.5 min, 1% B; 16.00 min, 35% B; 18.00 min, 100% B; 20.00 min, 1% B. The flow rate was set to 0.6 mL/min and the injection volume was 1.0 μL. The UHPLC system was coupled to a Vion IMS QTOF hybrid mass spectrometer, equipped with a Lock Spray ion source. Data were acquired in high-definition MS (HDMS®) mode in the range m/z 50 - 1500 at 0.1 s/scan. Thus, two independent scans with different collision energies (CE) were alternatively acquired during the run: a low-energy (LE) scan at a fixed CE of 4 eV, and a high-energy (HE) scan where the CE was ramped from 10 to 40 eV. Argon (99.999%) was used as collision-induced-dissociation (CID) gas.

The multivariate analysis has been done using Unscrambler 10.3 (CAMO Software, Norway) which is a complete multivariate data analysis software solution, equipped with powerful methods including Principal Component Analysis (PCA), Partial Least Square (PLS), clustering and classification. The Unscrambler 10.3 is an ideal tool to analyze any sort of multivariate data quickly, easily, and accurately.

**Results and Discussion**

From our previous GCMS results, Ajwa dates flesh was found to have possible pharmacological functions such as antioxidants, antimicrobial, anticancer, antifungal, antidiabetic, anti-inflammatory, anticonvulsant and anti-asthmatic. According to previous study, phytochemicals that rich in dates pulp are like phenolics, sterols, carotenoids, anthocyanins, procyanidins and flavonoids. The ratio and concentrations of these constituents depend on the type of the fruit, stage of fruitpicking, location and soil conditions. A research who studied Algerian dates stated that the results obtained for phenolic content were much higher than Omanian dates. Another study indicated that mono and di-glycosides identified in dates fruits were mostly flavonol derivatives (quercetin) and flavone derivatives (luteolin and apigenin).

In this study, compounds that had been identified in Ajwa date flesh using LC-QTOF-MS are quercetin, apigenin, caffeic acid, rhoifolin, crocetin, procyanidin, cyanidin, ferulic acid, glucoside, glucopyranoside, trimethylgallic acid, quercimetrin, proanthocyanidin, pyrogallic acid, coumatic acid, luteolin, β-sitosterol, decaffeolaceoside, elaecyanidin and glucosyringic acid.

Metabolomics originally refers to the sum of the pool of cell metabolites. This brief review of result focuses on untargeted metabolomics using LC-QTOF-MS. Investigation on the urinary metabolome could further confirm the beneficial effect of Ajwa dates in human health. There are a number of metabolites identified in 0h (blank) only such as flavonoids; Cnidimol F, Kushenol I, Kushenol M, Kushenol T, Liquiritin, Pachypodol and Sanggenon J, alkaloids; Ephedradine B, Isomaistemonine, Melicopidine, Piperyline and Pellitorin, phenolics; Feruperine and
Glabrol. Other known compounds that identified in blank urine are Isoanhyoicaritin and Riboflavin.

Urinary metabolome that appeared after 4h consuming Ajwa dates flesh are flavonoids; 2-Methoxykurarinone, Bavachin (Corylifolin), Kaempferol-3-O-α-L-arabinoside, Leachianone G and Licoflavone, alkaloids; Codonopsine and Nigeglanine. Other compounds that identified after 4h Ajwa dates intake are Ophiopogonanone B and Retusine. Meanwhile, 2 alkaloids; Loganin and Polycanthine, 1 phenolic compound; Eugenyl glucoside and 1 sesquiterpene; Pseudosantonin were identified in 8h after consumption of Ajwa dates flesh. Geniposidic acid and Paeonilactone A is another compound that found in the same urine time collection (8h). And there is only 1 known compound that appeared after 12h consuming Ajwa dates flesh which is Methyl lucidenate Q.

Most urinary metabolome appeared after 24h Ajwa dates flesh consumption. There are 32 urinary metabolome including alkaloids, phenol, amino acid, flavonoids, terpene glycoside and terpenoid. Other known compounds found to be appeared in 24h after Ajwa dates intake are Ajugasterone C-2,3,20,22-diacetonide, Andropanolide, Bruceine H, Citric acid, Cyclo(Ala-Ile), Dehydroabietic acid, Desmodimine, Glucosyringic acid, Glutamine, Heterodendrin, Kusulaactone, Linustatin, Methyl-α-D-fructofuranoside, Methyl-β-D-fructofuranoside, Morusimic acid F, Mudanpioside F, Paeonisuffrone, Paenolide, Pterodontriol D, Ranunculin, Schizonepotoside E, Scutellone E, Sibiricaphenone and Vitamin B5. Alkaloids that identified are Coniferol, Gentianine and Picrasidine P. Meanwhile other compounds are phenol; Ginkgolic acid, flavonoid; Lutonarin, amino acid; Tyrosine, terpene glycoside; trans-Carveol-6-β-glucopyranoside and terpenoid; Xanthatin.

Some peaks were spotted appeared and disappeared in the chromatogram. There also peaks that belong to certain compounds remain in almost all the time collection (0h to 24h). The compounds named 6-Hydroxykynurenic acid, Adenosine, Coixol, Cuscohygrine, Dictysine, Evoxanthine, Isoxanthohumol, Lindelofine, Magnocurarine, Neokurarinol, Oxymaistenonine, Uridine and Xanthosine (black color in Figure 1).

![Figure 1: Scores and Loadings Plot of Urinary Metabolomes 24h after Consuming Ajwa Dates Flesh in Positive Ionization](image-url)
All healthy respondents are required to follow the given diet schedule in which, they are allowed to drink plain water only during one week experiment, the same dietary intake (breakfast, lunch and dinner). No fruits, vegetables or beverages are allowed during experiment. They also required to fasting overnight. It is because we have to lessen the consequence of the metabolites change from other sources. Compared to urinary metabolome identified in 0h, more urinary metabolome are appeared after the consumption of Ajwa dates flesh. The metabolism pathway of the urinary metabolome before and after Ajwa dates intake should be investigated to study the beneficial effects of Ajwa dates to human body.

One of the techniques in chemometric had been used in this study is Principal Component Analysis (PCA). This technique is a powerful tool to help us to comprehend the multivariate data. The scores plot elucidating the urinary metabolome and the loadings plot is the urine time collection. The urinary metabolome that identified only in respective time collection has been highlighted. As illustrated, the scores and loadings plot pattern is similar. Urinary metabolome that had been circled in scores plot are belongs to each time collection in loadings plot, accordingly. The metabolome that scattered in between time collection are showing that metabolome had been identified in both or more time collection.

Conclusion

Phytochemicals that rich in Ajwa dates flesh are phenolics, sterols, carotenoids, anthocyanins, procyanidins and flavonoids. Results revealed the changes of urinary metabolome during the 24 h after date fruits intake. Some phytochemicals, including alkaloids, sterols, phenols and flavonoids were appeared and disappeared after date fruits intake. Investigation on the urinary metabolome could further confirm the beneficial effect of Ajwa dates in human health. These findings confirm that metabolomics is an effective tool that can be adept in order to further discover the metabolism of phytochemicals and its relation with human health.

Recommendations: In future, there should be a study that focuses on discovery of the effects of dates flesh which differ in quantity of date fruits.

Phytochemistry and Antibacterial Activity of Cynometra Cauliflora

Noor Zarina Abd Wahab¹, Norhidayah Badya², Nazlina Ibrahim³, Mohd Khairul Amri Kamarudin⁴

¹Lecturer, Faculty of Health Sciences, Universiti Sultan Zainal Abidin, Malaysia; ²Lecturer, Faculty of Medicine, Universiti Sultan Zainal Abidin, Malaysia; ³Associate Professor, Faculty of Science and Technology, Universiti Kebangsaan Malaysia, Malaysia; ⁴Lecturer, East Coast Environmental Research Institute (ESERI), Universiti Sultan Zainal Abidin, Malaysia

Abstract

Here we report the potential of Cynometra cauliflora methanolic leaves extract as potential antibacterial agent against clinical isolated microorganisms. Phytochemical analyses reveal the presence of tannin, flavonoid, saponins, cardiac glycosides and terpenoids. In spot test, antibacterial activity can be observed through the formation of zone inhibition of three types of bacteria only which are at concentration of extract used were 75 mg/mL and 100 mg/mL. The MIC was determined ranging from 6.25 mg/mL to 100 mg/mL. The highest value of MIC showed by MRSA which is 6.25 mg/mL. For MBC test, no antibacterial activity have been observed showed that the extract was bacteriostatic which can inhibit the growth of bacteria at concentration less than 100 mg/mL but not kill the bacteria. The results provide evidence that leaves of C. cauliflora extract might indeed be used as a potential source of effective natural antimicrobial agents in pharmaceutical industries. Our findings suggest that C. cauliflora methanolic leaves extract contains antibacterial active compounds and could be potential antibacterial agent.

Keywords: Cynometra cauliflora, phytochemistry, cytotoxicity, antibacterial

Introduction

Emerging of antibiotic resistance cases and the insufficiency of effective new antimicrobials agent has long been noticed. The biggest problem in global health care is the requirement for novel, effectual and inexpensive medicines to treat microbial infections without unnecessary side effects¹. Thus, exploration for a new antimicrobial compound or drugs with different antimicrobial targets is necessary. Plant origin medicines are comparatively cheaper than synthetic substitutes, offering great therapeutic benefits and more affordable treatment².

The medicinal value of plants depends on their phytochemical constituents that provide a vital physiological or pathological effects in the human body³. These bioactive constituents are tannin, flavonoid, alkaloids, phenol compounds, saponin, glycoside and anthraquinones⁴. The knowledge of phytochemical composition of plant is important for the development of novel natural products with therapeutic potential. Many plant extracts are known to have antimicrobial properties. In recent years, several studies have evaluated antimicrobial activity of crude plant extracts⁵⁻⁸. About 20% of medicinal plants have been used in pharmaceutical studies especially in cancer and dangerous diseases prevention and treatment⁹. Plants are able to produce the variety of bioactive substances. High contents of phytochemicals in fruits and vegetables may protect human body destruction against free radical¹⁰.

Cynometra cauliflora L. or commonly known as ‘Nam-Nam’ among native Malaysian is a tropical plant under the Fabaceae family. It is a homegrown fruit-bearing tree that is found primarily in rural areas of Peninsular Malaysia¹¹. This plant is a neglected and underutilized traditional fruit tree that has the

Corresponding author:
Noor Zarina Abd Wahab
E-mail: zarinawahab@unisza.edu.my
medicinal properties in traditional medicine and planted as decorative plant in the village\textsuperscript{13}. The fruit which are kidney-shape pod, greenish yellow to brown, with a sandy and wrinkled surface can be consumed as fruit salad\textsuperscript{13}. Previous studies have shown antioxidant, anti-inflammatory, antitumor, antidiarrheal and antidiabetic activity of \textit{C. cauliflora}\textsuperscript{14-15}.

Phytochemical screening of \textit{C. cauliflora} aqueous extract from different plant parts showed the presence of tannins, saponins, flavonoid, terpenoid and cardiac glycosides are present in all parts of the plant\textsuperscript{16}. Thus, this study was carried out to evaluate phytochemical constituent and antibacterial activity of \textit{C. cauliflora} methanol leaves extract in search for active antimicrobial activity.

**Methodology**

**Plant Material:** The plant materials were cleaned with distilled water then dried in shade at room temperature (27±2°C) and pulverized using electric blender (Kenwood Ltd., Harvant, United Kingdom). The resulting powder was kept in air tight container until required.

**Phytochemical Analysis:** For the phytochemical analysis and evaluation of the medicinal potential of \textit{C. cauliflora}, methanolic extract was prepared from leaves\textsuperscript{17}. Dried leaves powder of \textit{C. cauliflora} was extracted with methanol. \textit{C. cauliflora} leaves (100 g) was macerated with methanol (300 ml) to produce crude methanol extract. The extract was filtered and evaporated to dryness.

**Test for Tannin:** 1 mL of 0.1% ferric chloride was added to the extract. The formation of dark green or blue green coloration indicates the presence of tannins\textsuperscript{18}.

**Determination of Saponin:** 2 mL extract solution was diluted with distilled water and was shaken for 15 minutes. The formation of soap-like foam layer indicates the presence of saponins\textsuperscript{19}.

**Detection of Steroid:** 10 mg of extract was dissolved in 2 ml of chloroform and 2ml of concentrated sulphuric acid. The tube was shaken well. Chloroform layer appeared red after few minutes. These confirm the presence of sterols steroid\textsuperscript{20}.

**Test for Anthraquinones:** 50 mg of the extract was boiled with 1 ml of sulphuric acid and filtered. Filtrate was added with 500 µL and shaken. Chloroform layer was transferred to another tube and mixed with 400 µL of 25% of dilute ammonia. The presence of pink, red or violet colour indicates the presence of anthraquinones\textsuperscript{21}.

**Test for Alkaloids:** 2 mL of 25% ammonia was added to 10 mg/mL of extract. After that, 5 ml of chloroform was added to the mixture. Test tube was shaken for few minutes. A few drops of Mayer’s reagent were added. The formation of a cream colored precipitate indicating the presence of alkaloids.

**Test for Cardiac Glycosides:** 50 mg of extract was diluted in 2 ml of chloroform. Then, 1 ml of concentrated sulphuric acid was added. The presence of a brown ring indicates the presence of deoxysugar.

**Test for Flavonoids:** About 10 mg of extract was added to 2 mL of 25% dilute ammonia. Followed by concentrated sulphuric acid (500 µL) was added. Appearance of yellow colouration indicates the presence of flavonoids.

**Test for Terpenoids:** 10 mg of extract was dissolved in 2 ml of chloroform and 3 ml of concentrated sulphuric acid was added to form a layer. The formation of a reddish brown colouration of the interface indicates the presence of terpenoids\textsuperscript{22}.

**Test Pathogens:** Four pathogenic Gram positive bacteria, \textit{Staphylococcus aureus} (ATCC 11632), Methicillin-resistant \textit{Staphylococcus aureus} (MRSA) (ATCC 43300), \textit{Streptococcus mutans} (ATCC 25175), \textit{Streptococcus pyogenes} (ATCC 12344) and four pathogenic Gram negative bacteria, \textit{Shigella sonnei} (ATCC 25931), \textit{Klebsiella pneumoniae} (ATCC 10031), \textit{Vibrio cholera} and \textit{Escherichia coli} (ATCC 10536) were used. Bacterial strains were grown and maintained on Mueller-Hinton agar (MHA).

**Antibacterial Test:** Overnight cultures (10\textsuperscript{7}-10\textsuperscript{9} CFU mL\textsuperscript{-1}) of bacteria strains were inoculated as a 5 µL spot on MHA plates and incubated at 37 °C for 24 h. Subsequently, colonies were exposed to 5 µL extract with concentrations of 100, 50, 25, 10 or 5 mg/ml of extract. Positive control was performed using chloramphenicol and 10% methanol was used as negative control. The plates were incubated aerobically at 37 °C. The diameter of the zone of inhibition surrounding the disks were examined and scored\textsuperscript{23}.
Minimum Inhibitory Concentration (MIC) and Minimum Bactericidal Concentration (MBC): MIC was performed to determine the lowest concentration of the plant extract that inhibits the growth of a microorganism\(^{24}\). Two sets of standardized microdilution plates with shallow wells that contain increasing dilutions (decreasing concentration) of plant extract was inoculated with bacterial suspensions. The plates were incubated at 37°C for 24 h.

The lowest concentration of the extract in the well of the microtiter plate that showed no turbidity after incubation are MIC. Bacterial suspensions were used as negative control, while broth containing standard drug was used as positive control. MBC was determined when the lowest concentration of the plant extract that yields no growth was subculturing or second inoculation and then incubating 37 °C for 24 hr. Positive and negative cultures were also prepared.

Results and Discussion

Phytochemical analysis shown in Table 1 indicates the crude extract does not contain alkaloids, steroid and anthraquinones. Methanol is a less polar solvent compared to water thus lesser ability for the phytochemical to be extracted\(^{25}\).

Therefore methanol is commonly used for extraction of bioactive compounds. Flavonoids, saponins, tannin, steroids and alkaloids were obtained in the test samples is secondary metabolites that played the important role in cell growth, replacement and body building\(^{26}\). Plant origin antimicrobials have great therapeutic values as they can provide lesser side effects than synthetic antimicrobials\(^{27}\).

In the present research work, in vitro spot assay was performed against eight bacterial species to evaluated antibacterial activity of the extract. The data in Table 2 show the antibacterial activities of the tested extracts on a panel of four Gram positive and four Gram negative bacteria.

Most microorganisms tested were found not susceptible to the extract except *S. aureus* and MRSA. At 75 and 100 mg/mL, extract showed a slightly higher antibacterial activity with mean zones of inhibition 6 and 7 mm against *S. aureus* meanwhile, 8 and 10 mm against MRSA, respectively. Only Gram positive bacteria, *S. aureus* and MRSA were susceptible to the extract, while neither of the Gram negative bacteria showed any inhibition.

Gram positive bacterial strains were less resistance to the extracts when compared to Gram negative bacteria. The Gram negative bacteria are resistance to the extracts because of its thin cell wall and partly because of the relatively large quantities of lipoproteins and lipopolysaccharide in the wall, which could inhibit the attachment of the active compound from the plant extract\(^{28}\). Our founding is complement with the previous result gained from the earlier report which has proven that Gram positive bacteria are less resistant to the antimicrobial agent origin from plant compared to Gram negative bacteria\(^{29}\).

The results in Table 3 showed that the minimum inhibitory concentration (MIC) of the extract ranged between 6.25 and 12.5 mg/ml against both \textit{S. aureus} and MRSA. It is worthy of note that MBC values obtained for the extract against \textit{S. aureus} and MRSA are higher than MIC, indicating that the extract is bacteriostatic at lower concentration and bactericidal at higher concentration.

This suggests that the extract, when used traditionally as antimicrobials will be effective to inhibit bacteria growth but not necessarily kill the bacteria.

\textbf{Conclusion}

The findings indicated that the methanolic extract prepared from \textit{C. cauliflora} leaves has good potential for prospective nature-based antimicrobial drug. Further studies are needed to investigate the exact mechanism of their antimicrobial action, purification and characterization of their bioactive contents.

Spatial Model of Non-Ionizing Radiation Exposure around Gong Badak

Nurul Syafiqah Hassim¹, Roslan Umar¹, Nor Hazmin Sabri², Khairul Anwar Rosley², Hajar Jaafar³, Roha Tukimin⁴, Shamesh Raj A/L Parthasarathy⁴

¹Lecturer, East Coast Environmental Research Institute (ESERI), Universiti Sultan Zainal Abidin Gong Badak Campus, 21300, Kuala Nerus, Terengganu Malaysia; ²Lecturer, School of Fundamental Science Universiti Malaysia Terengganu, 21030 Kuala Terengganu, Terengganu, Malaysia; ³Lecturer, Faculty of Electrical Engineering, Universiti Teknologi MARA, 23000 Dungun, Terengganu, Malaysia; ⁴Lecturer, Radiation Safety and Health Division, Malaysia Nuclear Agency, Bangi, 43000 Kajang, Selangor, Malaysia

Abstract

This study describes an evaluation of Electric Field (EF) strength around Gong Badak located at Kuala Nerus, Terengganu. This area was selected because it is categorized as residential area and the population density is high due to its location nearby learning institute (Institute of Industrial Training Gong Badak). Spectrum analyzer connected to an omni-directional antenna was used to measure the EF strength. The measurement was obtained for 10 minutes for each 26 selected points. The data was then analyzed to determine the highest EF exposure level detected at each site. The spatial model of EF exposure using GIS software was then developed to get the map of exposure. The value of highest exposure was compared with the permitted limit recommended by ICNIRP and previous study. From the analysis, it can be concluded that the exposure level at selected area were still below the ICNIRP limit. However, the value is quiet high which is approximately 25.05 V/m peaked at 2137.5 MHz. The results of this study will complement existing studies that have been done at around Kuala Nerus area. This exposure map can be used to propose the government to revise the policy and guidelines for non-ionizing radiation safety. The Ministry of Health Malaysia may utilize the map to monitor the EF exposure in this country for public health purpose.

Keywords: Electric field strength, Spatial model, Highest exposure, ICNIRP limit, Exposure map

Introduction

In recent years it has increased public concern due to health risks from radiation emissions from wireless communication systems. All wireless electronic devices generate electromagnetic fields (EMFs). EMF propagates through space and interferes with other electromagnetic changes around them. Users will be exposed to electromagnetic radiation (EM) in the field near the EM source¹. The wireless system is part of our daily life today which has become a necessity and operate at a frequency below 300GHz which is in a non-ionizing spectrum which does not have enough energy to remove electrons from the atom².

EMF may be classified as non-ionizing radiation (NIR) and known to be hazardous because of it has the ability to promote health effects if the amount of radiation received is excessive⁴. However, the potential EMR health effects radiated by them are still the subject of public debate. Due to the issue, there are several organizations investigating the potential of non-ionizing radiation effects and offering international standards at exposure limits, such as the International Commission on Non-Reflective Radiation Protection (ICNIRP) and the Institute of Electrical and Electronic Engineering⁴. Electromagnetic waves are generated from many sources which is both natural and man-made, that produce background levels of electromagnetic radiation. The numbers of sources that emit electromagnetic waves such as radio and TV transmitters, base stations, power line transmission, transformers, and all electrical and medical devices have also increased correspondingly.

Corresponding author:
Roslan Umar
E-mail: roslan@unisza.edu.my
with growing number of users. Exposure to various NIR sources as shown in Table 1 including residential exposure to high voltage power lines, transformers, and domestic electrical installations, varies by duration and by distance from source. Exposure is usually to low frequency radiation (LF-EMR) or very low frequency (ELF-EMR) and continuous increasing among the population in the industrial world. Apart from LF-EMR and ELF-EMR radiation, individuals are increasingly vulnerable to radio frequency (RF) from television towers (TVs), radio stations, Wi-Fi phones or Wi-Fi systems, and personal computers with increasingly sophisticated technology.

Non-ionizing radiation also affects the children. Based on previous research, they have studied the childhood incidence leukemia as a function of the distance from the TV transmitter, there are increased risk of leukemia in children, living in radius less than 4 km compared to those living in radius 4 to 12 km. A study reported that absorbed microwave radiation (MWR) penetrated significantly to the brains of children aged 5 and 10 compared to the adult brain, in addition, children’s brain tissue absorbed two more MWR adult brain tissue. The children’s hippocampus and the hypothalamus absorbed 1.6-3.1 times higher and cerebellum absorbed MWR 2.5 times higher than adults, the children’s eye absorbed MWR higher than adults.

EF radiation also has negative effects on animals. One study has been done on a bee. Bees are endowed with magnetite clusters in the abdominal area, bee hives are exposed to 900MHz for 10 minutes. Immediately losing the hive natives, leaving only the queen bee, the eggs and some immature workers behind. With the navigation skills affected, the worker bees stopped coming to the hives for 10 days, which affected the production of eggs.

Because there is a growing issue, measuring, evaluating, EM field levels and controlling their compliance with standards or limit values has become more crucial. In this study, the main purposes are to measure the EF exposure around ILP to determine the highest level of exposure. Then the measured values will be compared with the limit set by ICNIRP and will be compared with the previous study.

**Methodology**

**Site Selection:** In this study, measurement of EF strength took place at nearby Institute of Industrial Training (ILP) Gong Badak Kuala Nerus Terengganu. 26 points were selected and marked using Google Earth software. The location for measurement is chosen based on highly populated area where the public used to spend their activity and time.

**Data Collection:** The main equipment for this measurement is spectrum analyzer (Key Sight N99915A, USA). This equipment is capable to identify the level of ambient exposure at a wide range of frequency up to 9000 MHz and relevant instruments for high mobility and robustness. The omni-directional circular patch antennas were used in order to detect signal radiated from the ambient. The omni-directional antennas were connected to the low noise amplifier and the connected to the spectrum analyzer to reduce the background noise. The antennas were positioned in open area in order to receive the maximum radiation from the surrounding. Before the measurement carried out, the coordinate of
the points are recorded by using the Global Positioning System (GPS). The measurement of EF strength was performed for 10 minutes at selected point. The data of radiation in form of power level (dBmV) against frequencies (f) were recorded.

Data Analysis: After the measurement done, the data were extracted from the spectrum analyzer to computer. The data were saved in one file for each second, so there are plenty of files were created during the measurement. The files were then merged into one file using Anaconda software. The conversion stage took place where the raw data of dBmV were converted to V/m using the formula as shown in equation below:

$$V/m = (dBmV/20) \times 0.021f \times 1000$$  

where (dBmV/20) is the voltage amplitude received from the measurement, f is the frequency received during measurement in MHz. 0.021 is multiplication factor on leakage measurement with included the antenna factor of a resonant half-wave dipole.

The data obtained were analyzed to determine the highest data of EF strength. The spatial model of EF exposure using GIS software was then developed to get the map of exposure. The value of highest exposure was compared with the permitted limit recommended by ICNIRP and previous study for several locations around Malaysia.

Results and Discussion

From the obtained data, the EF strength against frequencies were plotted as shown in Figure 1. We can see that the peak detected at frequencies 2137.5 MHz, 1845MHz, 495MHz, 2835MHz and the highest peak is 25.05V/m at 2137.5 MHz as shown in Table 2. Based on Figure 1, there are four main highest value of EF strength which are at frequency of 2137.5 MHz which is 25.05 V/m, followed by frequency 1845MHz which is 22.89 V/m, at frequency 495MHz which is 13.74V/m and the lowest is at frequency 2835MHz which is 9.78V/m.

</tbody>
</table>

Figure 1: The Highest Electric Field Strength at ILP Area

From Figure 1, it can be seen that the EF strength value are varies at the different peaks. Each peak represents the different sources. It can be referred to the allocation spectrum plan guided by International Telecommunication Union (ITU) as shown in Table 3. The VHF and UHF frequency allocation for Malaysia are provided by Malaysian Communication and Multimedia Commission (MCMC), which contains radio frequency allocation for various wireless services in Malaysia as a pilot notes on limitation when using the frequency between 9 kHz to 420 THz. It is divided into frequency bands and specifies the general purposes for which the bands may be used. Based on ITU, it is found that the highest values of EF strength were contributed from the Cellular Mobile Services and Mobile broadcasting. GSM1800 and 3G base station tower were found as the main influencers to NIR exposure levels.

In addition, the 1800 bands are more used in densely populated areas.

Figure 2 shows the comparison of EF strength against international limit ICNIR. The highest limit of ICNIR limit is 61 V/m. Meanwhile, the highest peak is 25.05V/m. We can see that the values of exposure almost 50% of the limit but the values are still below the limit.

Figure 2: The Comparison of Electric Field Strength at ILP Area with ICNIRP Limit
Figure 3 shows the comparison between EF strength with previous study. This study, ILP was compared between the UniSZA Gong Badak, IIUM and UMT.

This comparison recorded the different values of EF strength between campuses around Malaysia. However, the trends show that the exposure is quite high where the exposure are around 50% off the limit. This might be due to the instruments used, the population density, and the location criteria\textsuperscript{12}. The IIUM recorded the highest reading of exposure which is 38.44 V/m, followed by UMT which is 37.82 V/m. According to previous study, the population density might influence the value of exposure. ILP shows quite high exposure which is 25.06 V/m possibly also due to the population density, where there are student’s hostels and residential area nearby. The ILP is located nearby in industrial area, where we already known that they may operate heavy machinery or electrical appliances with high voltage usage. In addition, there are also other surroundings factors that can affect the NIR exposure level of an area such as mobile phone users, construction or moving vehicles\textsuperscript{11}. Mobile telecommunication were existed in all environments together with radio broadcasting\textsuperscript{13-15}. The installation of base station nearby also one of the factor that suspected causing stronger exposure due to the layering of the antenna radius patterns\textsuperscript{12}. As in the other telecommunication antennas, the energy from a cellular phone antenna is directed toward the horizons that are parallel to the ground, with some downward scatter. Base station antennas use higher power levels compare to the other types of land-mobile antenna\textsuperscript{16}.

**Conclusion**

Non-ionizing radiation may affect human life in the long term. Measuring and evaluating EM field levels has become an important agenda to make sure their compliance with the standards limit set by ICNIRP and thus contribute to the health monitoring action for public NIR exposure. After thorough analysis and evaluation of the radio frequency radiation, it can be said that the exposure levels at Gong Badak, especially nearby ILP are well below the limits set by ICNIRP. The high exposure pattern among campuses (even though the value is not exceed the limit) is somewhat worrying. Future measurement should be conducted to make sure the exposure would not increase further.

Mental Health Mediate Social Support to Predict Quality of Life among Drug-Abuse Inmates

Fazida Karim¹, Mahadzirah Mohamad¹, Norhilmi Muhammad¹
¹Lecturer, Faculty of Economics and Management Sciences, Universiti Sultan Zainal Abidin, Gong Badak Campus, 21300 Kuala Nerus, Terengganu, Malaysia

Abstract

This study examined mental health as a mediator between social support and Quality of Life (QoL). Survey data from 451 drug-abuse inmates were analyzed using structural equation modeling. Results indicated that mental health partially mediate social support to predict QoL. These findings suggest not only that it is important to consider social support in understanding QoL, but also that mental health plays an important role in these relationships. Implications for these more complex relations are discussed for further research.

Keywords: Inmate, Support, Health, Quality of life

Introduction

Drug abuse has become the leading malignancy in worldwide¹. In United States, 66% of prison inmates were related to drug crimes roughly², and about 60% of drug-abuse inmates were charged in Malaysian prisons³. Studies have indicated that drug-abuse inmates facing with low QoL in comparison with other populations⁴. Previous finding shows that lacking in personal success such as social support and mental health can significantly impair QoL outcomes⁵,⁶.

Social support refers to the various types of free assistance from family, friends and significant others⁷. The literature indicates that social support systems are very important protective factors for individuals experiencing stressful events⁸ and that protective factors are necessary for better life⁹. Social support plays a critical role in mental health and QoL⁹. It has been reported that social support can improve the negative mental health on an individual’s well-being⁹.

Mental health is an ability of individuals to cope successfully with significant change that create a balance between life activities⁹. Several researchers report that drug-abuse inmates have significantly different levels of QoL, which may be due to varying levels of mental health¹⁰ Mental health affects many aspects of QoL, and positive mental health have significantly better QoL¹⁰. However, little is known about how mental health affects QoL, especially for drug-abuse inmates in Malaysian prisons.

Specifically for drug-abuse inmates, positive mental health has been considered to be a defense mechanism to deal with treatment-related difficulties, for example, emotional and social stressors¹¹. Stronger mental health has been associated with psychological well-being in inmates. Additionally, mental health has also been examined as a potential mediator related to an individual’s QoL outcome¹¹.

Despite, mental health and social support became crucial and important factors to predict the different aspects of QoL based on drug-abuse inmates’ perceptions. Thus, this study hypothesized that mental health play an important mediator in the relationship between social support and QoL. A framework diagram is shown in Figure 1.

Corresponding author:
Mahadzirah Mohamad
E-mail: mahadzirahmd@unisza.edu.my
Therefore, this study aimed to determine the role of mental health as mediator to predict social support on QoL.

**Methodology**

**Participants:** The sample of current research was the drug-abuse inmates of nine Peninsular Malaysia Prisons. 551 questionnaires were distributed among inmates using a simple random-sampling. The 451 of the inmates returned the questionnaires. In this regard, response rate was 81.85%.

**Instruments:** This study adapted instrument of Multidimensional Scale of Perceived Social Support (MSPSS) consisting 12 items. While, Short-Form 12 (SF-12) was applied to measure mental health with 12 items. Maqasid Shariah Quality of Life instrument was adopted for QoL. This study used scale 1 = strongly disagree to 10 = strongly.

**Statistical Analysis:** This study applied descriptive analysis and Exploratory Factor Analysis (EFA) using SPSS 21.0. While, AMOS 21.0 was for Confirmatory Factor Analysis.

**Results and Analysis**

**Demographic Profile:** Majority of respondents were male drug-abuse inmates (58.3%) and were single (50.3%). The respondents averagely in age of 26 - 40 years old. 66.2% of them were contract worker and self-employed. Most of them had received monthly income of RM1000 to RM2000 (45%). The finding shows that 75% of them got involved in drug-abuse incidents since ages of 13 to 25 years.

**Measurement Model:** All constructs shown in measurement model were measured for validity and reliability using confirmatory factor analysis (CFA). The validated measurement model of the constructs and the value of factor loading illustrated in Figure 2 and Table 1. The constructs with factor loadings greater than 0.6 have achieved the unidimensionality requirement. Finding also indicated the model have achieved the requirement of construct validity. Composite reliability with greater than 0.6 is required. While, convergent validity with value greater than 0.5 was measured using AVE. The results in Table 1 (QoL), Table 2 (mental health) and Table 3 (social support) recommend the reliability and validity requirement were achieved. Finally, the discriminant validity was measured using discriminant validity index.

**Mediation:** The mediation was performed to support H4. Statistically found mental health is a partially mediated social support on QoL (lower bound= 0.0344, upper bound = 0.1231). This study applied bootstrapping to check mediations effects. Thus, it demonstrates when upper and lower bound did not include zero, there is mediation occurred. H4 shows partial mediation happened as the direct effect and indirect effect were significant (β=0.620, p-value = 0.002, β=0.06, p-value = 0.001).

**Discussion**

The objectives of this study was to model a relationship among social support, mental health and QoL. Furthermore, the research was performed to find the role of mental health as mediator on to social support on QoL. The result showed that social support had positive effect on mental health and QoL. The result of social support in a form of friend have more influence as compared to significant others and family. In contrast, family have fewer impact in clarifying the respondents’ mental health and QoL.

In addition, the result show that mental health effect QoL positively. Mental health mediate support group to help individuals to accomplish to live successfully. Moreover, when a state of peace appeared in drug abuser’s mind they begin to recover their life by focusing on five aspects in QoL.

**Conclusion**

The research shows that most of drug-abuse inmates facing a poor QoL. The aim of this study was to assist drug-abuse inmates to reback into the society successfully. Thus, it is important to model a relationship of social support, mental health, and QoL.

Moreover, the most important aspect in QoL to be improved is property. In other words, inmates are very concern on employment matters upon release from prison. The aspect of friends, significant others, and family in social support would provide sources of support such as emotional, informational and appraisal support. The study suggested having good mental health reflect to better QoL.

This study has contributed to body of knowledge in terms of development of new model of social support, mental health, and QoL. In addition, mental health act as mediator in the context of drug-abuse inmates add a new knowledge in mental health literature. At managerial implication, this study helps prisons department to understand background of inmate through aspect of QoL to be improved. The information also assists the management to improve programme or policy.

Abstract

This study investigates the nature of governance system around Limboto Lake and its impact on the conservation of the freshwater resources. It also seeks to understand the structural process and contribution of local knowledge in freshwater conservation, which is a gap identified in freshwater governance. Data was based on residents’ impact and institutions involved in collation, formulation and implementation of freshwater policy. Based on the findings there is a unanimous indication that, locals are not part of freshwater governance at Limboto Lake and this finding has nothing to do with their educational background. This renders the system of governance as a top-bottom approach. Indications are that this system does not support the conservation of the Lake considering the apathy in adhering to rules and regulation by the locals. The locals believe that their contributions and participation would help strengthen capacities of knowledge and practices in freshwater governance to reduce degradation.

Keywords: Freshwater governance, Local knowledge, Conservation, Perception

Introduction

Water scarcity is a severe global problem; billions of people experience water scarcity at least parts of the year¹. Water shortage is common at remote rural areas, for example on islands². Industries and energy production may depend on a vast amount of clean water. Access to clean water is at the heart of sustainable development - inducing social, economic and environmental growth³. The United Nation’s goal for access to freshwater, described in the 2030 Agenda for Sustainable Development, is to “ensure availability and sustainable management of water and sanitation for all”²⁴-⁵.

There is increasing global need to improve the crisis in freshwater governance (FWG)⁶-⁷, which is the major threat to freshwater degradation⁸-⁹. Freshwater governance is describes
are likely to be affected by or can affect the resources.

Even though considerable efforts have been made towards the conservation of freshwater resources, the trade-offs between man and the freshwater resource needs are increasing all over the world. This is because unregulated human activities around freshwater resources are increasing and leading to their degradation.

The study examined the institutions and structures that govern the use of Limboto Lake, as a common resource. In addition, the research investigated relevance of government rules guarding the lake, aimed at the perception of the differences in the educational level of local communities from the two districts around Limboto Lake. The rationale for the study was based on the fact that understanding local concerns within a resource-context would provide the dearth of information for policy formulation and implementation towards freshwater conservation.

The analysis was on how relevant current state of governance in terms of data collected, formulation, implementation and enforcement of water laws and practices are towards networking and relationship amongst freshwater stakeholders. The results were consistent and do imply that majority of the respondents believe that government’s rules are ineffective in protecting the lake based on its top-down approach.

**Study Area:** Limboto Lake is a natural resource located in Gorontalo province. Its presence plays a vital part in supporting the lives of the society as well as the organisms living in the lake. This leads to an aligned and balanced environment for the ecosystem native to Gorontalo province. However, due to the siltation of the lake, the Limboto Lake loses its function to maintain the balance of the environment within the area. A number of recent studies report that the lake is in its critical status. Since 1934, sedimentation and the trend to open farming sites or to build houses decreased the area and the depth of the lake; from ±7000 ha with 14 meters depth to ±3000 ha with the depth of 2.5 - 4m.

The community nearby the Limboto lake riverbank, i.e. farmers, traditional fishermen or small-scale fisheries, and other citizen are prone to the issues of economic, social, and resources related to the poor lake environment. This circumstance forces the people to be able to manage their income from resources around Limboto Lake.

**Methodology**

With a population of 17,783, a targeted population of 9,702 was determined using available figures provided by the Indonesia Statistical Service based on the communities immediately surrounding the Limboto Lake in the Gorontalo town and Gorontalo Districts. A sampling size of 354 respondents was determined, using the Krejice and Morgan sampling size methodology.

A multi-staged sampling was used for the selection of respondents. The data was collected through a questionnaire which was administered verbally by six research students and the researcher. Semi-structured questionnaires and well-structured interview schedule were administered mainly to the local leaders during an in-depth interview. Educational Attributes of the respondents interacted with are shown in Table 1. Age distribution of the respondents is also shown in the Figure 1.

**Table 1: Educational Background of Respondents**

| No formal education | 67 | 18.9 | 18.9 | 18.9 |
| SD (Elementary) | 58 | 16.4 | 16.4 | 35.3 |
| SMP/Junior High School (JHS) | 107 | 30.2 | 30.2 | 65.5 |
| SMP + Technical Course (MSLC) | 86 | 24.3 | 24.3 | 89.8 |
| SMA/Senior High School (SHS) | 18 | 5.1 | 5.1 | 94.9 |
| Tertiary | 16 | 4.5 | 4.5 | 99.4 |
| N/A | 2 | 0.6 | 0.6 | 100.0 |
| Total | 354 | 100.0 | 100.0 |
Results and Discussion

Relevance of Current Freshwater Governance:
Responses to the perception of respondent are presented in Figure 2 based on local community level of education. Responses by those with SHS level of education with reference to “Yes”, government rules are working and “No” it is not working, does not show any significant differences. Yet, there is a unanimous affirmation that government rules and regulations are not helping to reduce the degradation of the Limboto Lake. The majority of respondent 74 percent with the “No” decision were JHS level graduates, followed by MSLC level graduate with 71 percent. The least respondents who were not sure were 7 percent with MSLC level of education.

Using the Pearson Chi-square as an indicator with a Cramér’s V of 0.2 and a Pr of 0.025. Indications are that the differences in the responses have weak relationship, therefore the responses are not dependent on their level of education. This result is confirmed through observation of human activities around the lake that impacts on the lake. Evidence from Plates, 1, 2 and 3, show unregulated human activities around freshwater resources. This gives indications of weak institutional governance where locals do not adhere to rules and regulations.

There is a nexus between the aspirations of the local communities and the aim of protecting and conserving the lake as a sustainable resource. According to a male respondent, enforcement of rules and regulations are in the hands of the government, yet within the communities there is no one to ensure that the right practice is adhered to. Another female respondent indicated that the chiefs, who can help to enforce these laws are not respected by the government officials.

This is because their authority to enforce certain laws has been taken away by the district assembly officials who do not live in the communities around the lake and therefore do not even understand their plight.

Perception of Policy Formulation and Implementations: On the issue of stakeholders’ perception of governance with respect to government’s policy formulation, one of the facilitators for policy formulation said:

“Sometimes the key stakeholders or local communities, are not involved in policy formulation. It is better to involve them so that they would own it. Broad stakeholder’s consultation is the best option”

Ownership and Control of Limboto Lake:
Perception of respondents on who has ownership and therefore has the authority to make rules and control practices around the lake is shown in Table 2. A cross tabulation of the ownership of the lake and control of the lake shows that majority (n=183, 51.7%) of the respondents believed that Local wisdom who is the king of rule owned the lake and therefore has the right to make rules and control issues around the Lake. Another significant number of respondents indicated that God controlled the lake (n=83, 23.4%). There was significant dependence on the control and ownership of the lake as shown in Table 2 and based on Table 3 of the Chi-square analysis.

There is association between Ownership and the person who controls the Limboto Lake (Table 4). This was evident from the Pearson chi-square results of \( \chi^2 = 4.3252a, \ df=25, \ p=0.000 \). Government’s authority to enforce rules and regulations is not strong since the respondents do not recognise the control of government and its officials around Limboto Lake.

In addition, there is a clear lack of distinction or collaboration between local traditional governance and formal institutional governance. This makes it uncertain as to “who” has the right to formulate and implement rules, as well as whose rules and regulations should be enforced and by whom.

Another dilemma observed was if the traditional authorities (TAs) who are in the locality own the Lake, then it would not be in wrong for government to impose its rules. To ensure enforcement of rules, there should be a collaboration in the area on data gathering for the formulation and implementation of rules and regulations.

The respondents explained that the chiefs and priests have better ways of presenting stringent rules that
attract strict measures for not adhering to rules, yet all these systems have broken down due to the inception of the western system of governance which puts authority in the hands of the government. Analysis of the data presented in Table 2 confirms this assertion. Indications are that they are not involved in making rules or in the management of the lake.

The situation around the Lake also depicts how current government institutions have shaped the behavior of individual members and produced the chain of apathy around Limboto Lake. This is because the people perceive that, the ancestors (local wisdom) is supposed to own and control the lake with his own set of customary rules, well understood by the people in the community.

Conclusion

Indications are that locals do not have a good grasp of some of the rules and their implications on the lake and their livelihood. Here, their participation in the rules, principles, values, policies and laws which provide the bases for strengths and weaknesses of governance is not properly in place signifying a weak institutional system23,19. The opportunity to participate and contribute their knowledge to policy is thus lost. There is a signal that there are inadequacies in the dearth of information for policy formulation and implementation towards freshwater governance, confirming17-18,24-25. There was no mention of any institution or the collection of information on social, anthropogenic and cultural issues pertaining to the catchment area that could impact on the freshwater resources. This is a clear indication of top-down, stewardship style of governance and not the stakeholder approach as the current integrated system of governance on paper26. There is a gap identified in freshwater governance. This would inform freshwater stakeholder’s knowledge in freshwater governance at Limboto Lake. The data will contribute to knowledge on the use of local ideas and practical solutions to control the degradation of freshwater resources. Furthermore, it would help strengthen capacities of local knowledge and practices to be effectively used in freshwater policy formulation, enforcement and management.

Non-Ionizing Radiation Measurement around Four Different Selected Areas

Khairul Anwar Rosley¹, Nor Hazmin Sabri¹, Roslan Umar², Nurul Syafiqah Hasshim², Roha Tukimin³, Shamesh Raj A/L Parthasarathy³

¹Lecturer, School of Fundamental Science Universiti Malaysia Terengganu, 21030 Kuala Terengganu, Terengganu, Malaysia; ²Lecturer, East Coast Environmental Research Institute (ESERI), Universiti Sultan Zainal Abidin Gong Badak Campus, 21300 Kuala Nerus, Terengganu Malaysia; ³Lecturer, Radiation Safety and Health Division, Malaysia Nuclear Agency, Bangi, 43000 Kajang, Selangor, Malaysia

Abstract

Telecommunication is the most demanding services nowadays. The increasing demands toward technologies especially in cellular phones, computers, electronic gadgets and other electrical appliances lead to the increase of non-ionizing radiation (NIR) exposure. This kind of exposure may harmful to living things based on previous research findings. This study aims to measure the electric field (EF) strength around several selected areas and compared the obtained value with the international standard recommended by ICNIRP. The measurement was conducted using Spectrum Analyzer which connects to two circular patch antenna which can detect frequencies up to 3 GHz. The coordinates of the selected sites were recorded by Global Positioning System (GPS) and the measurement were conducted for 10 minutes for each point. The obtained values of each area show that each area values still under the limit recommended by ICNIRP. However, some area shows high exposure especially at denser populated area. All these data can be used as a reference for further study and as a guide for the Ministry of Health Malaysia to proposed guidelines of the usage of technology in our daily life for public concern.

Keywords: non-ionizing radiation, EM exposure, Electric field strength, Radiation protection

Introduction

Human daily life always exposed to the same type of non-ionizing radiation source. Electrical and electronic hardware for examples cordless phones, microwaves, computers, televisions and others can produce non-ionizing radiation¹. Electromagnetic field (EMF) energy is energy that created from the electric and magnetic field. Electric and magnetic fields are an unobservable area of energy that referred to as radiation either non-ionizing or ionizing radiation which indicated by wavelength and frequency². This EMF created by any wiring or hardware that conveying electric current³. The increasing demands toward technologies especially in cellular phones, computers, electronic gadgets and other electrical appliances lead to the increase of non-ionizing radiation (NIR) exposure. The exposure to electromagnetic fields could lead to changes in body tissues, which can promote harm to the body. Exposure can cause harm depending upon an assumption from an increment of temperature above a certain range, which causes a thermal effect happens¹. Thermal effect specifically happened from tissue heating due to the infusion of EMF in dissipative medium and non-thermal effect not accompanying with the increase of temperature. Temperature distribution patterns within the tissue depend on tissue permeability⁴. Previous study reported that the radiation exposure level around the selected based station in Kuala Nerus is far below the ICBIRP standard limit². The observation had been done based on the distance between the based station with a selected point where distances were set up at 15 m, 50 m, 100 m, 150 m, 200 m, 250 m, 300 m, 350 m, 400 m and 450 m from the BST. They found that the exposure level

Corresponding author:
Nor Hazmin Sabri
E-mail: norhazmin@umt.edu.my
values are somewhat worrying where in some locations the value is more than 50% off the limit is far below the ICNIRP standard limit. The main scope of this study is to measure the ambient public NIR exposure around several selected areas with different population interest by using Spectrum Analyzer that connects to two circular patch antenna, which enables to capture frequencies up to 3 GHz. The observed values are then compared with the international standard recommended by ICNIRP to ensure the limit is not exceeded. By leading this study, the data can be used to monitor the exposure value of Malaysia for public health concern. The guidelines on the usage of technology should be developed for safety and the awareness program should be conducted to educate people in the non-ionizing radiation.

Methodology

In this study, four different areas were measured by using Spectrum Analyzer (keysight N9915A) connected to two circular patch antenna (Figure 1). These antennas were raised about 1.5 meters from the ground by using plastic fibre tripod stand to prevent any reflection from the ground\(^5\) (Figure 2).

The spectrum analyzer is ready to discover the extent of measurable strength at wide selection of frequency up to 9000 MHz and acceptable instrument for prime quality and lustiness. The antenna that used to notice and capture signals that radiates in ambient was an omnidirectional circular patch antenna that had been invented specifically for this study. The observation areas are selected randomly around Kuala Nerus and Bachok. The points were marked using Google Earth where the selection based on it accessibility to conduct the measurement, anthropogenic factor such as residential, commercial or plantation area, nearby base station and public places. The coordinates of each points were recorded by using Global Positioning System (GPS) (Figure 3) when the measurement was taken.

The measurement was conducted for 10 minutes for each points and the data were taken in the time interval of one second. All collected data was then managed and analyzed by using Microsoft Excel. The obtained data was then converted from power level in the unit of dBmV to EF strength in the unit of V/m. the detected exposure value was compared with ICNIRP standard limit provided\(^6\). The Electric Field strength (V/m) versus Frequencies (\(f\)) graph has been plotted to see the NIR source contributing to the exposure reading and to determine how high the value off the limit.

Results and Discussion

The NIR exposure exist everywhere, even though one did not have mobile phone or electronic gadget. Most of the people assume that the radiation come from this popular technology nowadays, but in fact the radiation comes from anything related to electricity,
electronics devices, electric appliances and wireless telecommunication technology around us which we cannot avoid it.

From the data obtained, the EF strength was plotted against frequency to determine the EF peak of each area. The measurements were taken during the day and pleasant weather around 9 am to 5 pm. The strength of EF around these locations are as shown in Figure 1 and their maximum and average values of each area are shown in Table 1 and 2. There are three different analyses will be discussed in this study. First, to observe the trend of exposure level around each area. Second, to determine the highest EF strength value of each area and its frequency sourced from the surrounding. Lastly to compare the obtained values with the International Commission on Non-Ionizing Radiation Protection (ICNIRP) guidelines.

From Figure 5-6, each graph shows that the peak of EF strength were exist starting from 675 MHz, 945 MHz, 1845 MHz and 2860 MHz. From Figure 1, the highest EF value recorded at Teluk Ketapang is 0.073 V/m at frequency of 1848 MHz while the average value recorded around 0.0023 V/m. At Bachok, the highest EF value is 37.251 V/m at frequency 1845 MHz while the average value for this area is around 1.909 V/m. From Figure 6, Sultan Mahmud Airport recorded the value of 0.583 V/m at frequency 2140 MHz while the average value around 0.034 V/m. The highest value recorded at Bukit Tunggal is 0.499 V/m at frequency 2140 MHz, the same source of frequency as in Figure 5 while the average value of this area around 0.020 V/m.

From this findings, it shows that the highest EF strength between these four area belong to Bachok area where the value is 37.251 V/m. this possibly due to the stranded land area. The EF emitted from nearby base station directly captured by antenna. The number of scatters may be small and the magnitudes of the individual scattered components can vary with line-of-sight paths being common. The effect of these conditions is to cause the fast fading signal. Therefore, the transmitter power would be unnecessarily high due to the possibly leading to interference problems.

The expected data around Sultan Mahmud Airport is supposed to be higher than other places due to its communication between control tower and the plane. However, the obtained data shows the opposite. This may be because it just a small airport and there was no flight standby for take off or landing at the time the measurement was taken.

Data obtained from Figure 4 and 7 which both classified as residential area show a drastic difference. The EF value and average EF value from Figure 7 which in Bukit Tunggal area is higher compared to data from Figure 4 which in Teluk Ketapang Village area. This happen due to the presence of base station telecommunication tower at Bukit Tunggal area. Location of base station in Teluk Ketapang Village quite far from the measurement site if compared with in Bukit Tunggal area. Thus, one of the factors why the obtained data shows a drastic difference.

The VHF and UHF frequency allocation for Malaysia spectrum plan is developed by the Malaysian Communication and Multimedia Commission (MCMC).
The plan is a report that contains radio frequency distribution for various wireless service in Malaysia as a pilot notes on impediment when utilizing the frequency. The Spectrum Plan designates the range in Malaysia between 9 kHz to 420 THz and is divided into frequency bands and indicates the general purposes for which the bands might be utilized. This range plan is utilized as a guide for the researcher. Based on the spectrum plan table, the highest EF strength around these four areas is contributed by the cellular mobile services, which is 3G and GSM1800. GSM1800 and 3G base station tower were found as the fundamental influencers to NIR exposure levels. Figure 8 shows the comparison between the obtained value of each area with the permitted limit recommended by the ICNIRP. The values obtained from the observation for each area still under the limit recommended.

**Figure 8: Comparison of Electric Field Strength of All Areas with ICNIRP Limit**

**Conclusion**

The measurement of Electromagnetic Field strength has been conducted in four different selected areas in East Coast Malaysia. The highest EF strength recorded among these four areas is in Bachok, Kelantan. All measured values are compared with International Commission on Non-Ionizing Radiation Protection (ICNIRP) recommended for safety guidelines. The compared values show that the exposure level around all selected areas are still under the ICNIRP recommended limit. The measured values can be influenced by a few factors such as the present of base station in observe area, the population density in residential area lead to the high EF strength value. Moreover, stranded land also lead to high EF strength due to the line-of-sight phenomena happens causes the antenna to directly capture the signal. Therefore, it is highly recommended to measure the radiation exposure level especially around a residential area in Malaysia. This will help the government especially the Ministry of Health Malaysia to monitor and investigate the radiation trend and plan any precaution or prevention to overcome this problem.

In Facing the Challenges of Islamic-Based Social Development through Mental Health Wellbeing

Siti Nur Aafifah Hashim¹, Wan Norhaniza Wan Hasan²

¹PhD Candidate, Centre for Islamic Development Management Study (ISDEV), Universiti Sains Malaysia, 11800 Pulau Pinang, Malaysia; ²Lecturer, Centre for Islamic Development Management Study (ISDEV), Universiti Sains Malaysia, 11800 Pulau Pinang, Malaysia

Abstract

The globalised era causes a great impact to human and become the core for development. However, the demands of economic development and progress led to humans being burdened hence results in mental health issues. Consequently, the emergence of moral issues caused by this neglect of mental wellbeing. This phenomenon has negative effect on the implementation of Islamic-based social development. Based on these matters, few questions are raised. First, what is the concept of mental health prompt to Islamic-based social development? Second, how mental health able to affect the process in realisation of Islamic-based social development? Grounded on these issues, this paper intends to analyse the concept of mental health wellbeing from the Islamic perspectives and propose strategies in facing social development challenges of today with special regard to Islamic-based social development accordingly. Study conducted on literatures related to mental health shows differences between the concept of mental health according to the conventionally mainstream perspectives and Islamic perspectives. Therefore, different strategies are needed if the objective that wants to be achieved is the goal of Islamic-based social development: the pleasure of Allah (God).

Keywords: Mental health, Social development, Islamic-based social development, Social development strategy

Introduction

Economic growth is accepted commonly as a prerequisite to develop a nation. However, a sturdy economy alone does not ensure a holistic wellbeing of a community or society. Therefore, a comprehensive framework for development is needed. To achieve this, economic growth must be balanced with social development and progress. At par with the increasingly expanding economic development, it is undeniable that mental health issues become the interest of many parties due to alarming statistics related to it.

World Health Organization (WHO) recorded suicide rate close to reach a million people every year. They found that the global rate for suicidal has increased to 60% compared to 45% in 2017¹. Some countries recorded the highest suicide rate among people aged 15 – 44 years old and while some other countries has it within the age of 10 – 24 years. However, these figures only recorded loss of lives with no suicide attempts included. WHO indicates that for every adult who died by suicide there may have been more than 20 others attempting suicide¹. The study carried out by this international organisation finds that the root cause for suicide is due to weak mental health condition results by extreme mental issues such as depression, stress, personality disorders, schizophrenia and alcoholism (substance abuse).

The global trend of mental issues has also taken place in Malaysia. The National Health and Morbidity Survey in 2015 estimated that 1 for every 3 adults aged 16 years and above faced issues related to mental health with the prevalent value of 29.2%. This value is a double increase compared to the prevalence for the past ten years with 10.6% in 1996 and 11.2% in 2006. The survey also finds that there has been the highest prevalence of mental health amongst adolescents aged 16 to 19 and

Corresponding author:
Siti Nur Aafifah Hashim
E-mail: aafifahhashim16@gmail.com
These findings show the society has become pressured to sustain their economic stability. This is especially befallen amongst adolescents who need to work hard to achieve success in academic, career and personal life. Based on the Depression, Anxiety and Stress Scales (DASS-21) conducted in National Health and Morbidity Survey 2017, anxiety is the most relatable issue among Malaysia young generation as shown in Figure 1.

Figure 1: State of Adolescents' Mental Health in Malaysia Based on DASS-21 Scoring

As the effect, a lot of individuals experience stress, worry, low self-appreciation, role conflict, and value also emotional and interpersonal problems. A human cannot escape from stress, depression and anxiety especially when dealing with hardships of life interactions with other people or how one leads his or her life. However, the increasing rate of mental health might influence negatively to the success of development. This is because one’s mental health effects one’s work productivity and their capability to contribute to the society.

Additionally, mental health also influences national economic and social developments. Failure in safeguarding mental wellbeing can lead to many social issues, among which are crime and substance abuse that also leave a negative impact to the overall process of national development. Following these issues, this paper intends to look more closely into mental healthcare method as the implementation in Islamic-based social development.

Challenges of Social Development

Development is a process of improvement from one state to a better state encompassing all aspects, be it humanity, materialism, knowledge and technology. In other words, development contains the idea to increase capability and potential in forward movement begin from a lower position to a greater position in terms of achievement, opportunity and benefit. Other than that, definition is also a process of structuring a proactive society or nation towards a better quality of life.

Social development is one of the most important aspects to develop a nation. It is a method to improve the status of a society. According to previous research, the purpose of social development is to build the strength of the society from every aspect. In other study claimed that social development is a development process that focus on human and their social system. It involves various strategies, programs and activities that emphasize on values to increase life quality and wellbeing. Social development is defined from the perspective of Islam as a focal value in Islam that urges man to act in politics, religion, social and economy.

In other words, social development in Islam can be defined as a balanced development between religious, social, political and economic aspects. Unfortunately, current situation does not illustrate this definition as the moral values of culture and religion in the society are eroded by the global culture. Efforts to achieve Islamic-based social development have become tougher as the understanding towards cultural and religious values has weakened. Furthermore, various negative elements now become the sources of social problems that lead to mental disease.

Mental Health

Mental health is a state in which an individual reacts positively or negatively to his or her surroundings. WHO defines mental health as psychological wellbeing. For this international organisation, a healthy mental means healthy mental state and capability to function at a satisfactory level of emotional and behavioural adaptation. WHO stated that mental health encompasses an individual’s capability to enjoy life and create a balance between life activities and the efforts to achieve psychological resistance. Based on this definition, mental health involves mental and emotional health that serve to be as important aspects in human psychology.

Other than the aspect of psychology, mental health according to Islam is also a state of health that influences human behaviour. However, discourse about mental health in Islam tends to be focused more on spiritual aspect. Mental health in Islam is associated with having
a healthy heart. It means believing in God, friendship, and cooperation with other people. In previous study points out that mental health in Islam is a reaction of human psychology, emotions and physicality with their life experiences. In other study adds that one’s mental state and condition can react to the social obstacles and values that might oppose the mainstream society, values, culture and Islam.

In previous research states that mental health for Muslims depends on one’s characteristics comprising of two mutually-connected components namely physical and soul. The latter will react to control every action done physically. Thus, he stated that if one’s soul is good, then the physical conduct will be good too. Meanwhile, if the soul is not good, one might break the Islamic rules and limits. It is belief that the ease of mind able to encourage human towards life wellbeing, depends on how one’s understanding and committing to soul-cleansing process or better known as tazkiyah al-nafs. Tazkiyah al-nafs is a process of soul enlighten in the form of inner cleansing and outer formation so that any ill intention or poor characteristics that can lead to mental and behavioural disorders can be controlled.

There are four stages of tazkiyah al-nafs. The first stage is the anatomical control of human physical state with the control of seven part of human’s body parts as the first element that should be taken care of. They are the eyes, ears, tongue, stomach, the genitals, a pair of feet and hands. This stage stressed on the enjoyment of the body by preserving body parts from the bad deeds and channel them towards good deeds. The second stage is elimination of negative elements. At this second stage, one must diagnose himself or herself by evaluating any negative elements that they have. In previous study outlined ten negative elements which are the most detrimental such as, greed towards food, talking about pointless things, anger, jealousy, stingy and materialistic, love towards worldly assets, proud, arrogance, vanity and ostentation.

The third stage is the stage of inculcation and strengthening of positive attributes. It requires the efforts to empower, reinforce and systemise good noble behaviours following Islamic law so that human’s life can be more directed and stay in a religious scope. The final stage encompasses the stability and surrendering of a person to Allah SWT. The final process is the peak of tazkiyah al-nafs which is perfected through four attributes of praised characteristics namely love for Allah SWT, accepting the fate of Allah SWT, remembering the death and thankful for every blessing.

THE RELATIONSHIP BETWEEN MENTAL HEALTH AND ISLAMIC SOCIAL DEVELOPMENT

Progress, urbanisation and globalisation have given a striking implication to the society and nation which are striving to balance between social development and economic growth. Behind an exponential development, there are emergence of trend related to mental health issues. This might be an indication for desperate needs of safety and protection, serenity and in result of mental and physical wellbeing.

Religion has a significant influence in mental health. According to previous study, religion can increase the level of mental health in a positive way. However, it is also capable to ruin mental health. Both condition depends on the interpretation towards religious values, spiritual aspiration, communication ability and belief. When all these aspects have been carried out positively, religion benefits mental health by giving a sense of wellbeing, better life quality and contributing to low rates of depression, anxiety and suicide. However, if religion is implemented negatively, individuals will be exposed to spiritual struggle when coping with mental issues which is called as religious coping. Based on previous study opinion, religious influence towards mental health relates with the acceptance and the process of individual evaluation on the religious values.

According to previous research, humans are always searching for divinity power that can ensure their wellbeing before or after death. This humanistic nature leads humans to live a religious life that involves rituals of soul cleansing and worshipping aiming to attain the state of wellbeing. This is consistent with the decree of Allah in Al-Quran:

“Thus, do remember Me, so I could reward you with goodness; and be grateful to me and do not be deviant. To most pious men, ask for help with patience and perform your prayer because Allah will be with those who are patient.”

(al-Baqarah, 2:152)

Based on this decree, the soul-cleansing process through tazkiyah al-nafs that opens the room for one to
remember The Almighty Allah and to improve oneself hence become the opportunity for them to become closer to Him. Due to this, tazkiyah al-nafs of humans is expected to ensure individuals’ mental health and wellbeing to be in line with Islamic demands thus realising the aims of the Islamic-based social development. The mental wellbeing obtained by humans must always be in pursuit of Allah’s pleasure, regulation of physical behaviour, rectification of negative traits and implementation of good and noble practices and characteristics.

**Conclusion**

Mental disease is a disturbance that involves the change in thinking, emotion and behaviour that can cause difficulties in undergoing daily life. Diseases related to the soul is a worrying issue and can give a negative implication to the Islamic social development. Mental health has even become the government’s cause for concern as its impact towards the national development is more extensive. Humans are the most important element in Islam. Thus, a holistic mental health is very important to the life of individuals and the society especially for the purpose of the Islamic social development. Thus, various strategies have to be carried out to eradicate mental diseases and next, to render success to the process of Islamic social development to achieve the blessings of Allah

An Analysis of Mercury (Hg) Content in Drinking Water with Renal Dysfunction in the Traditional Gold Miners in TahiIte village, District of Rarowatu, Bombana Regency

Lucia Yogyana Suramas¹, Anwar Daud¹, Agus Bintara Birawida¹

¹Faculty of Public Health, Hasanuddin University, Jl. Perintis Kemerdekaan Km. 10, Tamalanrea Indah, Tamalanrea, Tamalanrea Indah, Tamalanrea, Kota Makassar, Sulawesi Selatan 90245, Indonesia

Abstract

The aim of this study to analyze mercury (Hg) content in the water toward renal dysfunction among gold miners in TahiIte village, Rarowatu district, Bombana regency, Southeast Sulawesi Province. This study was conducted in TahiIte village, Rarowatu district, Bombana regency. This study was used a quantitative observational research with cross sectional approach. The samples were taken from well water samples and respondent’s urine and conducted with purposive sampling. There were 32 respondents in this study. The data were analyzed used correlation test. The mercury content (Hg) in the drinking water source among gold miners in TahiIte village was below than limitation by Regulation of Health Minister (Permenkes) 492/2010 (<0.001 mg/L). The mercury content in gold miner’s urine was ranged from 3.8788 µg/L to 155.4950 µg/L. There were 31 respondents (96.7%) had mercury content in urine that higher than 4 µg/L. There were 4 respondents had experienced albuminuria as early symptom on kidney disease in traditional gold miners. There was no significant relationship between working period and water consumption duration had increased albumin content in urine. Besides, there was no significant relationship between ages with mercury content in the urine. The higher in working period, water consumption duration and nutritional status had increased mercury content in urine. There also no significant relationship between mercury content on urine and drinking water with kidney failure.

Keywords: Mercury; Renal dysfunction; Traditional gold miners; Urine

Introduction

The purpose of mercury in the gold mining was separated gold from sand through amalgamation process. The mercury in the water disposed into soil and groundwater and potentially made water became acidic and contained heavy metals. The waste with no treatment had higher chemical concentration entered the groundwater aquifer. There were factors that related to metal exposure such as mercury in the mine area. The risk factors related to mercury exposure such as resident period, gender, occupation, health status and distance from pollutant source.

The mercury poisoning had commonly found in the gold miners through skin contact, inhalation and food contaminated consumption. The mercury contamination caused some health problems in brain, lungs, nervous system and kidney. The mercury (Hg) content in urine was indicator that used to examine the mercury (Hg) contamination in gold miners since the urine accumulated mercury for long period. There were 40 people had mercury contamination in the urine among gold miners in Jenda village, Selogiri sub-district, Wonogiri regency.

The mercury contamination had increased in environment and food chain. In Indonesia, mercury was used in various industries especially small scaled gold mining in gold amalgamation process. The initial symptom of mercury exposure was examined by urine testing. There were increased protein molecules in the urine among gold miners for 5-10 mg/g of creatinine.

TahiIte village was gold mining location in Rarowatu Bombana district. The villagers had worked in gold mining near hill area and lump was separated in amalgamation process which is using mercury. The
tailing waste was released to the environment which contaminated soils and groundwater in TahiIte village. Most of villagers used the water from well for their drinking water source. The mercury usage in the gold mining was predicted contaminate in water and caused renal dysfunction in gold miners that consumed the water. Based on these background, a study was conducted to analyze mercury (Hg) content in the water toward renal dysfunction in gold miners in TahiIte village, Rarowatu district, Bombana regency, Southeast Sulawesi Province.

**Methodology**

**Study Type**

This study was quantitative observational research with cross sectional approach.

**Location and Time**

This study was conducted in TahiIte village, Rarowatu district, Bombana regency, Southeast Sulawesi province. The study was conducted from April to May 2016. In this study, the variables were included working period, working hours per day, water consumption period and nutritional status in traditional gold miners in TahiIte village.

**Population and Sample**

The gold miner group that have risk in mercury poisoning in the gold mining area in TahiIte village. The population for drinking water was from water resources. The samples for this study were gold miners that still active working in gold mining with purposive sampling based on the criteria as follows:

i) The gold miners willing to be respondents and give urine samples

ii) Still working as an active miner

iii) The gold miners that have working period more than 1 year

iv) The gold miner aged between 15 years and 64 years

The gold miners urine was taken in morning and stored in the container and check the albuminuria content by dipstick method. The mercury level analysis was used atomic absorption spectroscopy (AAS) at Central Health Laboratory of South Sulawesi province. The drinking water samples were taken from water resource that daily consumption by gold miners in TahiIte village.

**Data Collection**

The primary data was obtained included mercury level in water and urine, working hours per day, working period, water consumption period and nutritional status through questionnaire. Meanwhile, secondary data was collected from relevant government or private agencies. This study was conducted in TahiIte village, Rarowatu district, Bombana regency. This study was used a quantitative observational research with cross sectional approach. The samples were taken from well water samples and respondent’s urine and conducted with purposive sampling. There were 32 respondents in this study. The data were analyzed used correlation test.

**Data Analysis**

The data was analyzed used SPSS program version 21. The univariate analysis was described in frequency distribution table. The bivariate analysis was conducted to determine relationship between independent variable (mercury) on water, nutritional status, water consumption, working period and working hours per day with dependent variable such as mercury content in urine and renal dysfunction.

**Result and Discussion**

**Univariate Analysis**

Based on Table 1, the higher mercury content was observed at point 8 which was 0.4730 µg/L and was drank by 13 respondents (40.6%). The lowest mercury content was at point 3 (0.2524µg/L) and only 2 respondents (6.3%) used point 3 as their drinking water source. Next, Table 2 showed albuminuria content in 32 respondents. There were 28 respondents (87.5%) that had negative proteinuria and only 1 respondent (3.1%) had ++ (75 mg/dl) proteinuria. Based on Table 2, there were 31 respondents (96.9%) had mercury content in their urine more than 4µg/L. Meanwhile, only 1 respondent (3.1%) had mercury content less than 4µg/L.

From Table 3, there were 10 respondents (31.3%) had worked for 10 years in the mine. Meanwhile, there was 1 respondent (3.1%) worker for 2 years and 3 years. A shown in Table 3, there were 8 respondents (25%) that had water consumption period for 5 years.
Besides, there was only 1 respondent (3.1%) that had consumed contaminated water for 1 year.

Based on Table 4, there were 26 respondents who worked 8 hours per day and only 2 respondents that worked for 14 hours per day. In Table 5, there were 21 respondents that had normal body mass index (BMI) compared to 3 respondents that were obesity (BMI > 27.0).

Bivariate Analysis
Based on Table 6, there was a significant relationship between working period and water consumption duration with renal dysfunction in traditional gold miners in Tahilte village. The longer the working period and water consumption period, the higher the albumin contents in the urine \((p<0.05)\). Besides, no significant relationship between working hours per day, nutritional status, age, mercury \((Hg)\) content on water and urine with renal dysfunction in traditional gold miners in Tahilte village.

In Table 6, there was no significant relationship between age with mercury \((Hg)\) content in urine \((p=0.908>0.05)\). In addition, the working period, working hours per day, water consumption period, nutritional status and mercury \((Hg)\) content on water had significant relationship with the mercury \((Hg)\) content in the urine.

### Overall Discussion

In this study, working period among traditional gold miners was 2-8 years. There was a significant relationship between working period and renal dysfunction \((p=0.048<0.05\) and \(r=0.353\)). The result shows no significant relationship between the working hours per day and renal dysfunction with \(p=0.245>0.05\) and \(r=0.212\). The positive \(r\) value indicated longer working period caused higher potential in renal dysfunction. The mercury continuously entered in human body in term of methyl or alkyl form caused permanent damaged to the brain, liver and kidney\(^6\). The inorganic mercury compound had absorbed by lung and transferred through blood to the kidneys\(^7\). The inorganic mercury compound had accumulated in the kidney and removed with urine. In a study found long term work exposure caused renal dysfunction among miners in Slovenia\(^8\). The mercury poisoning symptom included anemia, albuminuria, renal dysfunction and affected gastrointestinal system\(^9\).

The statistical test result showed \(p=0.019<0.05\) with \(r=0.412\) which meant there was relationship between water consumption period and renal dysfunction. The statistical test result showed no significant relationship between nutritional status with renal dysfunction \((p=0.416>0.05\) and \(r=-0.149\)). Even though, 3 respondents had exposed to albuminuria 25
mg/dL, which respondents were in normal, overweight and obesity. The respondents with renal dysfunction with albuminuria of 75 mg/dL had body mass index (BMI) of 17.58 (underweight). This study showed renal dysfunction happened on anyone within any BMI category. In contrasts, theory had showed nutritional status had influenced the disease.  

The albumin in urine is indicated renal dysfunction. The result showed no significant relationship between age and renal dysfunction (p=0.421>0.05 and r=−0.147). The age did not related on renal dysfunction since respondent aged 17 years old had positive albumin in the urine.

This study indicated a significant relationship between working period and mercury (Hg) content in the urine (p=0.005<0.05 and r=0.481). There was a significant relationship between working hours per day and mercury (Hg) content in the urine (p=0.007<0.05 with r=0.470). There was a significant relationship between water consumption period with mercury (Hg) content in the urine (p=0.033<0.05 and r=0.378). The positive r value showed longer working period in the mine had increased mercury (Hg) content in the urine. In RengasTujuh village, a study showed working duration, working period and personal protective equipment implementation had influenced urine mercury level among gold miners. In additions, there was a significant relationship between nutritional status and mercury (Hg) content in the urine (p=0.011<0.05 and r=0.444). There was no relationship between age with mercury (Hg) content in the urine (p=0.908>0.05 and r= 0.021).

The water samples were contained mercury (Hg) between 0.2524 to 0.4730 μg/L. However, mercury (Hg) content in drinking water was still below the Permenkes standard 492/2010 (<0.001 mg/L). Even though, the mercury had contaminated on the water source in the mine, but it did not polluted water source in the community. The factors that influenced concentration of mercury in the human body were exposure duration, mercury compound type, mercury dose entered in body, body metabolism and age. The maximum level was allowed only 0.001 ppm. There was significant relationship between mercury (Hg) content in drinking water with mercury (Hg) in the urine (p=0.048>0.05). Based on this study, 31 respondents (96.7%) had exceeded mercury content in urine accorded to World Health Organization, WHO (<4μg/L). The mercury (Hg) content had influenced by exposure through inhalation and skin contact that resulted high mercury (Hg) content in the gold miners in Tahilte village.

The statistical result showed a significant relationship between mercury (Hg) content in the urine with renal dysfunction in traditional gold miner (p=0.814>0.05 and r=0.043). The albumin level more than 500μg/L was considered as dangerous lead to mercury intoxication. Furthermore, no significant relationship on mercury (Hg) content with renal dysfunction because mercury (Hg) content in urine was still below than 500 μg/L so some respondents still not showed the disease symptom.

There was no significant relationship between mercury (Hg) content in the drinking water with renal dysfunction (p=0.073>0.05). The mercury reached in the digestive system through food and contaminated water. The mercury entered the bloodstream and absorbed by the organ and accumulated in the kidney. Besides that, the mercury exposure through respiratory system also resulted in renal dysfunction due to proteinuria or nephrotic syndrome and acute tubular necrosis.

**Conclusion**

In conclusions, mercury content (Hg) in the drinking water source among gold miners in Tahilte village was below than limitation by Permenkes village was below than limitation by Permenkes 492/2010 (<0.001 mg/L). The mercury content in gold miner’s urine is ranged from 3.8788 μg/Lto 155.4950 μg/L. There were 31 respondents (96.7%) had mercury content in urine that higher than 4 μg/L. There were 4 respondents were experienced albuminuria as early symptom on kidney disease in traditional gold miners. There was no significant relationship between working period and water consumption duration had increased albumin content in urine. Besides, there was no significant relationship between age with mercury content in the urine. The higher in working period, water consumption duration and nutritional status had increased mercury content in urine. Besides, no significant relationship between mercury content on urine and drinking water with kidney failure. The environment friendly program and counseling for traditional gold miners about dangerous of direct contact with mercury. The routine mining area and medical checkup has suggested on gold miners in Tahilte village so that precautionary measurement taken as early as possible.

The Determinant Quality of Antenatal Care in the Rural Area of Jeneponto Regency

M. Wahidin¹, Ansariadi¹, Nurhaedar¹

¹Faculty of Public Health, Hasanuddin University, Jl. Perintis Kemerdekaan Km. 10, Tamalanrea Indah, Tamalanrea, Kota Makassar, Sulawesi Selatan 90245, Indonesia

Abstract

The aim of this study to determine the factors related to the quality of antenatal care in the rural area of Jeneponto Regency. The study was an observational analytic study with cross sectional study. The populations were all women who giving birth from January to May 2016 in rural area of Jeneponto Regency in 2016. The samples were mothers lived in the villages in working areas of Bontomate’s Health Centre which consisted of 277 respondents. They were selected by cluster technique taken from each of four villages. The data were analyzed by computerization with SPSS application with chi square test and logistic regression test and multivariate test. The maternal reproductive status had no significant relationship with quality of antenatal care with p value =0.373> 0.05. The higher family welfare level had increased opportunity to obtain in the quality of antenatal care. The family support was related in maternal efforts on quality of antenatal care (p=0.009<0.05). Besides, the health center distance also affected in the quality of antenatal care with p=0.001<0.05. The closer health center with respondent house had increased the quality antenatal care. The mother’s decision making was not affected efforts to meet quality of antenatal care. Most influential factor on the quality antenatal care was family welfare level.

Keywords: Antenatal care; Determinant; Quality

Introduction

There were 535 900 maternal mortality worldwide between 1990 and 2005 with sub-Saharan Africa and Asia are recorded highest maternal mortality rate for 50% and 45% respectively¹. In global, maternal mortality rate had decreased by 45% in between 1990 to 2013. An estimated 15% to 20% of pregnant women in both developed and developing countries had experienced high risk complications due to lack of maternal health care quality², ³. The main cause of maternal mortality included hypertension in the pregnancy and postpartum hemorrhage had minimized if the quality of antenatal care was well implemented⁴. The pregnant women regularly had their antenatal care visit more alert on preparation for emergency time⁵. There were 20% of pregnant women had experienced pregnancy complication⁶. The high quality of antenatal care had reduced maternal mortality⁷. In India, many factors affected quality of antenatal care such as maternal education, lack of knowledge in pregnancy diet and pregnancy complications⁸. The quality of antenatal care also affected by the access to health facilities, number of health worker, attitudes, awareness on antenatal care and decision making for seek health care⁹. In Indonesia, no research on quality of antenatal care based on service components but only depend on labor data and health care visit⁹. There was many antenatal care services had implemented in public health center (Puskesmas), auxiliary public health centre(Pustu), village health post (Poskesdes), integrated service posts (Posyandu) even home visit from health worker. However, there was no antenatal care component coverage report based on facility type. Based on this observation, this study had been on determine quality of antenatal care in the rural area of Jeneponto regency.

Methodology

Study Type

The type of study was an observational based analytic population with cross sectional research design. This study was analyzed quality of antenatal care service in Jeneponto district rural area based on antenatal care
component and antenatal care service location.

Location and Time

This study was conducted in rural area of Jeneponto regency. The selected area for this study was Bontomate’nePuskesmas and BontorambaPuskesmas. Bontomate’nePuskesmas clustering area included Bululoe village, Bungungloe village, Parasangangberu village. Meanwhile, BontorambaPuskesmas included Kareloe village, Tanammawang village, Lenu village and Maero village. The study was began with data collection and study population in first week of June, clustering of study area and primary data collection in study area between third week of June until first week of July 2016. The data processing was done in the second and thirds week of July.

Population and Sample

The sample in this study was pregnant women that delivered infants in January to June 2016 in rural area of Jeneponto regency 2016 with 8 cluster of village in BontorambaPuskesmas and Bontomate’nePuskesmas. This study is consisted of 277 respondents that met criteria as follow:

i) Domicile started since last pregnancy.
ii) Willing to be respondents.
iii) Being in place during the study.

Data Analysis

The data had been collected and analyzed by computerized using SPSS program. The bivariate analysis was conducted to determine relationship between independent and dependent variables by used logistic regression test. Meanwhile, multivariate analysis was done to determine relationship between welfare level and dependent variable that controlled with other factors.

Result and Discussion

Bivariate Analysis

Based on Table 1, 78 respondents (52.7%) had received more in antenatal care quality in reproductive status parity 2-3. Meanwhile, 13 respondents from parity >3 had received more quality in antenatal care. There was no significant relationship between maternal reproductive statuses with antenatal care quality in rural area of Jeneponto regency. The respondents with poor of family welfare likely received unqualified antenatal care of 105 respondents. There was a significant relationship between family welfare levels with quality of antenatal care in rural areas of Jeneponto regency. In additions, 133 respondents (48.0%) had obtained higher quality of antenatal care with their family supports. Besides, there was a significant relationship between family welfare levels with quality of antenatal care in rural areas of Jeneponto regency. In additions, 133 respondents (48.0%) had obtained higher quality of antenatal care with their family supports. Besides, there was a significant relationship between family welfare levels with quality of antenatal care in rural areas of Jeneponto regency. **Multivariate Analysis**

Based on bivariate analysis result, reproductive status was not correlated with antenatal care status with p=0.373 and maternal involvement in decision making with p value=0.197. The respondent characteristic on age, education level, health facilities visit frequency and delivery sites, which are assumed to be related to antenatal care quality was included into multivariate analysis.

Based on result of multivariate analysis in Table 3, family welfare showed highest value was 15.187 so statistically is dominant factor or variable that most influenced to antenatal care status. Based on OR value=0.347 (95% CI 0.204-0.591) meant respondents with poor welfare 0.347 times had chance to get poor antenatal care quality compared to respondent that with rich status in rural area of Jeneponto regency 2016.

Source: Primary data
Overall Discussion

There was no significant relationship between parity with quality of antenatal care. The mother in parity 1 tended to visit health care because mother had some concern during their first trimester. However, there is no significant disparity to show difference in the proportion to the parity between quality and non-quality. In additions, parity was related to pregnancy complications especially in high parity (>5) and lower parity (≤1) were more dominant in pregnancy complications10. The potential pregnancy complications in women had increased maternal mortality rate in rural area of Jeneponto regency.

The family welfare level had related with quality of antenatal care. The women came from rich background were three times likely to receive quality of antenatal care than women from poor background11, 12. In this study, most of respondent’s husband worker as farmer or fisherman with uncertain family income level. The family welfare in the rural area was very small, but rich families had more access to the health center13. The government had provided free access on health center for poor families and home visit program for pregnant women who did not completed their antenatal care check. Unfulfilled quality of antenatal care among poor families in Jeneponto regency also influence by low education among women. Women had obtained completed education more likely had antenatal care than uneducated women12. Health problem on poor families was due to their reluctant to seek health service since there were a gap among health worker with patient, limited in health facilities and low knowledge in deal with the health problem14. The women from poor background had non quality health service included antenatal care15.

The respondents had family support were more likely had quality of antenatal care than respondents with no family support. There was important women had their family support to meet their quality of antenatal care16. The family support had occupied important position for positive, emotional, information and appreciation17. In this study, family support was related to antenatal care coverage and affected antenatal care utilization quality. The lack of awareness in antenatal care quality that resulted in less family support on utilizes the antenatal care service which increased the risk in maternal mortality. There was a significant relationship between health facilities access with quality of antenatal care. The lack of antenatal care quality was due to the health facilities distance from house8. The pregnant women more likely meet quality of antenatal care if the health facilities were closer with their house17. The health facilities had related with quality of antenatal care in rural area of Jeneponto district in this study. The government had implemented to build more health center in most of villages for provided health service.

Besides that, there is no significant relationship in maternal involvement for decision making with the quality of antenatal care. In contrast, the decision making among women was important to obtain quality of antenatal care8. The women involved in decision making had higher chance to receive completed antenatal care than women that never involved in any decision-making11. The women needed to have their own decision on her antenatal care visit and not relied on her family for the decision.

Conclusion

In conclusion, maternal reproductive status had no significant relationship with quality of antenatal care. Higher family welfare level had increased opportunity to obtain in the quality of antenatal care. The family support was related in maternal efforts on quality of antenatal care. Besides, health center distance also affected in the quality of antenatal care. The closer health center with respondent’s house had increased quality antenatal care. The mother’s decision making was not affected efforts to meet quality of antenatal care. Most influential factor on the quality antenatal care was family welfare level.

Relationship of Management Functions Implementation with Health Workers’ Performance in Batua Public Health Centre at Makassar City

Machsur Tunggal¹, Yusri Abadi¹, Darmawansyah¹
¹Faculty of Public Health, Hasanuddin University, Jl. Perintis Kemerdekaan Km. 10, Tamalanrea Indah, Tamalanrea, Kota Makassar, Sulawesi Selatan 90245, Indonesia

Abstract

The productivity of an organization strongly depends on the management itself. A good management will create a productive and efficient work atmosphere. This is crucial especially at hospitals and health care centre since it deals with lives. Therefore, the management is responsible in ensuring the staffs are at their highest performance level. With that in mind, the aim of this study is to determine the relationship between management function implementation and health workers performance in public health centre (Puskesmas) Batua at Makassar city. The study type was quantitative research with cross sectional approach. 43 respondents have participated in this study. The primary data was obtained by questionnaire and secondary data had been obtained from Puskesmas administration section such as Puskesmas profile and number of staffs. The results found there was a correlation between planning function (p= 0.008), organizing function (p=0.011), actuating function (p =0.014) and controlling function (p= 0.0.011) with health workers’ performance.

Keywords: correlation study; health worker performance; management functions; public health centre

Introduction

The management is described as process involved in technical and social functions and activities which happens within an organizations in achieving the goal through humans and other resources¹. The health care and patient safety are common principle in all primary and secondary health care providers². There are six management functions implementation which included planning, organizing, staffing, controlling, directing and decision making³. Besides, the competencies also influenced management effectiveness such as technical, conceptual and interpersonal skills.

Indonesia have public health centre (Puskesmas) which consisted of 9759 units 3401 inpatient units and 6358 outpatient units. In South Sulawesi, there were 227 inpatient units and 221 outpatient units⁴. Puskesmas Batua has 43 health workers consisting of 3 general doctors, 1 administrative worker, 2 dentists, 2 specialist doctors, 2 pharmacists, 16 general nurses, 1 pharmacist assistant, 2 sanitarians, 3 nutritionists, 1 dental nurse, 2 laboratory workers, 7 midwives and 1 health promotion worker⁵. Puskesmas performance assessment had been done by internal organization including resource management such as medical tools, medicine, financial and workers and supported by Puskesmas Management Information System (SIMPUS). The performance is influenced by individual characteristics (abilities and skills, personality, perception, attitude, experience, gender, age, race, personal characters and learning capacity) and working environment (organization structure, job design, policy, rules, rewards, sanctions and resources). The performance assessment through self-assessment is among common approach in individual measurement and understanding⁶.

Puskesmas Batua is a health centre that had health quality standard using ISO 9001-2000, application of international health service⁷. The aim of this study is to determine relationship between management function implementation and health workers’ performance in

public health centre (Puskesmas) Batua at Makassar city.

Methodology

Study Type

This study used quantitative research with cross sectional approach.

Location and Time

This study was conducted from February 2017 to March 2017 in Puskesmas Batua at Makassar city.

Population and sample

The population in this study were all health workers in Puskesmas Batua. The sample sizes were 43 respondents who are working in Puskesmas Batua.

Data Collection

The primary data was obtained by questionnaire and secondary data had been obtained from Puskesmas administration section such as Puskesmas profile and number of staffs.

Data Analysis

The data was analysed using SPSS program. The bivariate analysis was obtained to determine relationship between dependent and independent variables in the form of cross tabulation with Chi-square test.

Result and Discussion

Bivariate Analysis

Based on Table 1, 36 respondents (94.7%) had good planning with good performance and only 2 respondents (5.3%) had good planning but poor performance. Meanwhile, 2 respondents (40.0%) had good performance but poor in planning, while 3 respondents (60%) had poor performance with poor planning. Based on Fisher’s Exact test, there was a significant relationship (p = 0.008) between planning functions and health workers’ performance in Puskesmas Batua.

Overall Discussion

The result found that 38 respondents had good planning functions. These results had pointed out that planning functions had influenced on health workers’ performance in Puskesmas Batua. The first step in planning is grouping the work before task division\(^9\). A study found relationship between planning with nurse’s performances in the inpatient ward of Fatmawati Hospital\(^9\). Good planning contributed to several benefits such as the organization know objectives to be achieved and how to achieve them\(^10\). Nonetheless, nurses’ work quality is not influenced by the planning functions at Puskesmas\(^11\).

In this study, organizing functions was health workers’ main duty to be carried out and this function is based on skills and knowledge in supporting resources in Puskesmas Batua. The study showed a relationship between organizing functions and health workers’ performance in Puskesmas Batua at Makassar city. Good staff arrangement helps in objective arrangement by allocating its function and responsibilities\(^12\). There was a significant relationship between actuating and controlling functions with health workers in Puskesmas Batua. Some respondents had implemented actuating functions in performing their tasks and certain procedures had led to limitation in their responsibilities. In this study, controlling functions is related on review activity of health services that had been implemented and act to improve the performances. Some respondents who implemented controlling functions felt there were no
any orders in their work. The assignment and schedule monitoring affected health workers’ performance in performing their duties and responsibilities provided in health services.

**Conclusion**

In conclusions, there existed a correlation between planning function, organizing function, actuating function and controlling function with health workers’ performance in Puskesmas Batua at Makassar city.

Integrated Health Post Visit Frequency for 3 Months Consecutively Towards Children Development in Puskesmas Working Area at Makassar City

Muh Iffah Nurhikmah¹, Burhanuddin Bahar¹, Djunaidi M. Dachlan¹
¹Faculty of Public Health, Hasanuddin University, Jl. Perintis Kemerdekaan Km. 10, Tamalanrea Indah, Tamalanrea, Kota Makassar, Sulawesi Selatan 90245, Indonesia

Abstract

The aim of this study is to analyse integrated health post (Posyandu) visit frequency for 3 months consecutively towards children development in public health centre (Puskesmas) working area at Makassar city. This study used descriptive survey research and was conducted from March to April 2017 in Puskesmas working area at Makassar city. The sample sizes were 29 children aged between 24 months and 36 months. The primary data was obtained through questionnaires whereas the secondary data was obtained through Posyandu register books and children weight. The data was analysed using SPSS program. The univariate analysis was represented in form of frequency distribution for each variable. The result found 28 children (96.5%) had normal score for pre-screening developmental questionnaires and only a child (3.45%) had abnormal score for pre-screening developmental questionnaires based on children’s age. The child with abnormal development is born with low birth weight, exclusive breastfeed and incomplete vaccination. In additions, the child’s mother also had low education level background that contributed in poor children development.

Keywords: Children development; Posyandu visit frequency; pre-screening developmental questionnaires

Introduction

Early child period is a vital development phase in human lifespan¹. Approximately 200 million children worldwide fail in achieving cognitive development due to several factors such as poverty, insufficient care and poor health². Based on initial estimation from UNICEF’s Early Childhood Development Index (ECDI), 36.8% of children aged 3 and 4 years in low-income and middle-income countries, failed in basic cognitive and socioemotional skills based on reports from nearly 100 000³.

The first two years in children development is important phase which involved rapid development, adaption and consolidation in the brain structure and function which included peak growth in sensory, speech/language and higher cognitive functions⁴. The developmental delay is related with poor psycho-social, intellectual development and learning ability⁵. Besides, the children development is also affected by culture and biological factors. A study found language development in children was influenced by perinatal/postnatal and environment factors such as antenatal care (ANC), Apgar scores, birth weight, premature delivery, birth order, parental education, infants gender and family background related to language impairment⁶. Based on Basic Health Research (Riskesdas) in 2007 showed 74.5% children under 5 years old were weighed at least once during last 6 months, while 60.9% among children were weighed more than 4 times⁷. Meanwhile, 12 million children have children growth chart card. The pre-screening developmental questionnaires purpose is to monitor children development⁸. The aim of this study to analysed Posyandu visit frequency for 3 months consecutively towards children development in Puskesmas working area at Makassar city.

Methodology

Study Type

This study used descriptive survey research to
describe antenatal care visit frequency to Posyandu for 3 months consecutively towards children development in Puskesmas working area at Makassar city.

Location and Time

This study was conducted from March to April 2017 in Puskesmas working area at Makassar city.

Population and sample

The population in this study were all children aged between 24 months and 36 months who are in Puskesmas working area at Makassar city. The samples were obtained by using purposive sampling method. The samples were children aged between 24 months and 36 months who had ANC visit for 3 months consecutively which met the following criteria:

a) Mothers who have children aged between 24 months to 36 months.

b) Mothers who had ANC visit for 3 months consecutively.

c) Mothers whose children never been hospitalized in last 3 months.

d) Mothers whose children never been sick for more than 7 days.

e) Mothers who had children development growth chart card.

f) Willing to be respondents for this study.

Data collection

The primary data was obtained through questionnaires while secondary data was obtained through Posyandu register books and children’s weight.

Data Analysis

The data was analysed using SPSS program. The univariate analysis was represented in the form of frequency distribution from each variable.

Result and Discussion

Univariate Analysis

Based on Table 1, there were 29 respondents who had been involved in this study. More than half of respondents’ father aged between 21 years and 30 years and only 1 respondent’s father aged less than 21 years old. Meanwhile, 15 respondents’ mothers aged between 21 years and 30 years old and only 1 respondent’s mother aged between 41 years and 50 years. For education levels, 14 respondents’ fathers had completed their senior high school and 13 respondents’ mothers had completed junior high school. All mothers were housewives and 12 respondents’ fathers worked as entrepreneur.

As shown in Table 2, there were 28 respondents (96.55%) had normal score and 1 respondent (3.45%) had abnormal score. Children with normal scores for pre-screening developmental questionnaires aged between 24 months and 29 months were 17 respondents (60.7%) and aged between 30 months and 36 months were 11 respondents (39.3%). Meanwhile, 1 respondent (100.0%) aged between 30 months and 36 months had abnormal score for pre-screening developmental questionnaires.

Based on Table 3, only 1 respondent (100.0%) had scored 66.67 for fine motor skill. There were 18 respondents (64.3%) aged between 24 months and 29 months who scored 100.0 and 10 respondents (35.7%) aged between 30 months and 36 months had scored 100.0. Besides, 1 respondent (100.0%) aged between 24 months and 29 months had scored 0 and 66.67 in gross motor skill on pre-screening developmental questionnaires. Meanwhile, 16 respondents (59.3%) aged between 24 months and 29 months had scored 100.0 and 11 respondents aged between 30 months and 36 months (40.7%) had scored 100.0 in gross motor skill for pre-screening developmental questionnaires as shown in Table 4. In additions, 5 respondents (100.0%) aged between 30 months and 36 months had scored 75.00 in speech and language development. There were 18 respondents (75.0%) aged between 24 months and 29 months had scored 100.00 and 6 respondents (25.0%) aged between 30 months and 36 months had scored 100.0 in speech and language development for pre-screening developmental questionnaires based on Table 5. As shown in Table 6, 3 respondents (100.0%) aged between 24 months and 29 months had scored 66.67 on social and independence development. There were 15 respondents (57.7%) aged between 24 months and 29 months had scored 100.00 and 11 respondents (42.3%) aged between 30 months and 36 months had scored 100.00 on social and independence development for pre-screening developmental questionnaires.

**Overall Discussion**

The pre-screening developmental questionnaire is an early detection instrument for children’s development aged 0 until 6 years old. The results found that most children had normal development and only a child had abnormal development based on pre-screening developmental questionnaires. A child with abnormal development had incomplete vaccination, exclusive breastfeeding and low birth weight. Family support also contributed in children development which included personal social, language and motor skills.

The fine motor skills involved small muscles in the fingers, hand and arm able to manipulate, control and use material and tools. The results found 28 children had scored 100.00 for fine motor skills. Fine motor skills lead children to be creative like cutting paper with straight cut, sewing, drawing and coloring. In China, a study found children in rural areas had better fine motor skills in term of drawing, cutting and folding than children in urban areas. Meanwhile, gross motor skill require large muscles in the arm, legs and torso in walking, running and jumping. In this study, 27 children had scored 100.0 and a child had scored 0.00 for gross motor skills. Based on this study, the child was not able to stand without help. The main factor contributed in children motor development is physical activities involvement. The games and activities lead motor skills to develop more rapidly.

There were 24 children who had scored 100.00 for speech and language development. The speech and language development involved listening, recording words, understanding and speaking by using appropriate word in certain situation. Meanwhile, 26 children had scored 100.00 for social and self-dependent development. This development included eating, wearing clothes and bathing without parents’ help. The cognitive development is also important in social learning for children to express their feeling and behaviour. Besides, family bonding also influenced the social and emotional development among children. The family bonding is reduced if the child had experienced abused.
**Conclusion**

In conclusions, most children had normal score for pre-screening developmental questionnaires and only a child had abnormal score for pre-screening developmental questionnaires based on children’s age. The child with abnormal development is born with low birth weight, exclusive breastfeed and incomplete vaccination. In addition, this child’s mother has low education level background which also contributed to poor children development.

Effect of Musculoskeletal Ergonomics Chair on Silver Smith in Borong Villages, District Maggala, Makassar City

Muhammad Azrul Syamsul¹, Syamsiar S. Russeng¹, Fridawaty Rivai¹

¹Faculty of Public Health, Hasanuddin University, Jl. Perintis Kemerdekaan Km. 10, Tamalanrea Indah, Tamalanrea, Kota Makassar, Sulawesi Selatan 90245, Indonesia

Abstract

This research aimed to determine the effect of ergonomic chair on silversmith craftsmen who have musculoskeletal complaint when they are working. This study was a quasi-type experiment, with the design of preventive intervention based on 16 respondents from Borong Village. The results indicated that the ergonomic chair have an effect on musculoskeletal complaint on the silver craftsmen while working. The group who have complaint on intervened musculoskeletal; neck (p=0.023), lower neck (p=0.016), right shoulder (p=0.01), back side (p=0.01), upper arm (p=0.011), waist (p=0.009) lower waist (p=0.009), buttock (p=0.008), right forearm (p=0.011), right wrist hand (p=0.009), right thigh (p=0.008), right knee (p=0.015), right calf (p=0.009). While in the group who do not have complaint on the intervened musculoskeletal, the ergonomic chairs do not give negative effect on the intervened muscle; neck (p=0.655), lower neck (p=0.257), back side (p=0.564), right upper arm (p=1.00), waist (p=0.157), right forearm (p=1.00), right wrist hand (p=0.655), and right calf (p=0.317). On working posture, ergonomic chair gives effect on the working group who has on musculoskeletal complaints with the value of (p=0.011), and to the group who do not have musculoskeletal complaint with the value of (p=0.024).

Keywords: Ergonomic chair; Musculoskeletal; silversmith craftsmen; working posture.

Introduction

Musculoskeletal disorders are common phenomena experienced by workers who do manual work¹. Musculoskeletal complaints are complaint on the skeletal muscle sections felt by a person ranging from very mild to very painful complaints. Study by Niu et al², suggested for the improvement of work productivity, the work must be done by meeting the requirements of safety and health to avoid work discomfort, health problems, illness and accidents. The problem is also caused by the imbalance between the workload with the capacity or workability of the workers. Arfiasari³ found that there is a relationship between work posture and workers’ productivity. The value of work posture in high-risk categories requires immediate action because the higher the risk level of work posture, it can increase musculoskeletal complaints that greatly affect productivity. Similarly, Frizka et al⁴, showed there is a strong relationship between musculoskeletal complaints with age, work period, work attitude sitting and work posture⁴. Therefore, an ergonomic condition and facility is needed for the workers to be more productive.

Research conducted by Kristanto et al⁵, related to the design of tables and chairs on cutting stations in a more ergonomic manner for small industry that can increase work productivity. Based on the implementation, a comparison of initial and final conditions is obtained; conditions before design, standard time and standard output were 9.068 seconds / unit and 396 units / hour. After design, standard time and standard output are 7.377sec / unit and 468 units / hour. That is an increase in output of 72 units / hour, productivity of 18.8%. Faulty seating due to seats that are incompatible with the anthropometry of the body, or due to positioning errors, can add pressure to the lower back and is a major cause of back problems⁶.

In South Sulawesi precisely in the city of Makassar there are many gold and silver craftsmen one of which is located in Kelurahan Borong. In the preliminary field study most of the work attitude of the silver and gold craftsmen is the static working attitude of sitting on a
chair facing the table and the back bending, the right foot is used to press the stove pump for brazing jewellery products. This work is done for an average of 8-9 hours/day and stands once to take something that is needed.

This research requires a good health handling. From the initial discussion that the researcher had with one of the gold craftsmen in Borong Manggala sub-district, Makassar, the researcher concluded that the craftsmen often experience back pain due to the work position that requires bending, and this condition is worsened by a work chair that does not have a backrest and does not fit the work table. Hence the bending condition is inevitable in this line of work. Therefore, the researcher intended to examine the influence of the work chair design on musculoskeletal complaints on gold and silver craftsmen in Manggala sub-district of Makassar city.

Methodology

Research Type

The type of research to be used is Quasi Experiment. The approach taken in this study is preventive intervention, whereby it attempted to study the relationship of risk factors to the incidence of a disease, by giving treatment or manipulation of exposure to these risk factors on the subject. In this case, the improvements of chair design work. The design of this study used the design of retreatment (One group pre-test and post-test design). Although in this research, there are two groups:

1. Working groups with musculoskeletal complaints at work, where this group will see a positive effect of ergonomic chair on musculoskeletal complaints and work attitudes at work.

2. Working group with no musculoskeletal complaints, where this group will see whether there is a negative effect of giving the work chair against musculoskeletal complaints and work attitude at work.

Location and Time

This research was conducted in home industry which engaged with silver artisans in Manggala sub district. Manggala sub-district was chosen to be the location of research because this location is the center of silver artisans in Makassar City. The research and intervention data collection plan was conducted in September -October 2016.

Research Subjects

In accordance with our sampling technique the number of samples examined is 16 people consisting of two groups of 8 persons each, in which one group is a group with specified muscle and skeletal complaints aimed at measuring the effect of giving the chair to the musculoskeletal complaints of workers. While group 2 is a group that is categorized as having no complaints on skeletal muscle that will be intervened while working, which aimed to measure and see the effect of seats on non-complaining workers so that this group can determine whether this chair can be used for all silver craftsmen or can only be used on silver craftsmen who encounter musculoskeletal complaints.

Research Instrument

Musculoskeletal complaints is determined using the Nordic Body Map method (NBM) to estimate the type and level of skeletal muscle complaints felt by workers. Researchers also use the RULA method because the work done by silver craftsmen is a work done by sitting. The equipment used in this measurement consists of a stopwatch, a camera, a bow and a scale.

Data Collection

The work flow included pre-test data collection, provision of designed chairs to both groups, taking post-test data for each group. This is followed by comparing the pre-test and post-test data of NMB and RULA per group.

Data Analysis

Data processing was done using SPSS program. The statistical test that was used to analyse the data from each measurement is based on the research design, simple allocation and measurement scale. The data of research results is analysed using inferential statistics.7

Results

Table 1 presented the distribution of data of skeletal muscle complaints that were intervened in the complaining group. All together there were 13 parts of the body have been examined. Based on the results shown in the table, H<sub>0</sub> is rejected for the entire 13 hypothesis which indicated that the ergonomic chair did make a difference in the users who complained of musculoskeletal pain.

The distribution of data of skeletal muscle intervention in the non-complaining craftsmen is tabulated in Table 2. The same body parts were compared and it was found that $H_0$ were rejected for five different body parts which were right shoulder, below the waist, buttocks, right thigh and right knee. The rejected $H_0$ proved that the usage of ergonomic had prevented or reduced pain in those five muscles of the craftsmen’s body.

</table>

The average value of the work posture before the ergonomic chair is 4.88 with the standard deviation of 0.641 and after the use ergonomic chair, it was 3.75 with the standard deviation 0.463 while the p value = 0.024 which is smaller than 0.05, then H₀ is rejected. It can be concluded that there is a difference in posture before the ergonomic chair and after the ergonomic chair. It can also be concluded that there is an effect of giving ergonomic chair to the work posture of silver craftsmen.

Overall Discussion

From the results of the research conducted, the ergonomic chair made the craftsmen feel comfortable compared with the previous seat. This is in line with research conducted by Murrell⁸ where the respondent was an employee and the findings proved that a chair in accordance with the body shape of a sitting person can provide comfort and not strain the person who occupies it. Providing ergonomic chairs can reduce skeletal muscle complaints on silver craftsmen, in agreement with research conducted by Purnomo, et al⁹, where this experimental result of intervention with ergonomics approach can reduce musculoskeletal complaints by 87.8%, reduce fatigue by 77.5%, reduce workload by 21.55%, reduce the risk of injury at work by 10.65% and increase work productivity by 59.49%. The research conducted by Wulandari¹⁰, with a sample of 25 female workers in the batik industry, where the results of that study found there were differences in average musculoskeletal complaints before and after ergonomic chair.

Conclusion

1. Giving an ergonomic chair can reduce musculoskeletal complaints while working for silver craftsmen who have musculoskeletal complaints.

2. Provision of ergonomic chairs do not negatively impact workers who do not experience complaints, as this seat can also be used by craftsmen who do not experience musculoskeletal complaints.

3. The use of ergonomic chairs can reduce the angle of the craftsman posture (work posture value) formed at work, so that it can reduce musculoskeletal risk.

4. All craftsmen can use the ergonomic chair by taking into account the size of the user’s body.

Effect of Skill, Compensation and Job Satisfaction on the Nurses Performance at Emergency Unit in Anutapura General Hospital Palu 2016

Munawarah¹, Alimin Maidin¹, Indahwaty Sidin¹
¹Faculty of Public Health, Hasanuddin University, Jl. Perintis Kemerdekaan Km. 10, Tamalanrea Indah, Tamalanrea, Kota Makassar, Sulawesi Selatan 90245, Indonesia

Abstract

The emergency department (ED) is considered as one of the most stressful and hectic department of a hospital because trauma comes in unexpectedly and in all kinds of scenarios. Therefore, usually the nurses and doctors working in this department need to be highly skilled and quick-witted. Taking into account these factors, this research aimed to investigate the effect of skills, compensation and work satisfaction on nurses’ performance in Emergency Unit of Anutapura General Hospital of Palu in 2016 is studied. The research was an analytical survey using quantitative study. The samples were the civil servant of Anutapura General Hospital of Palu consisting of 45 people. They were selected using census technique. The data were processed using SPSS program with multiple linear regression analysis. The results of the research indicated that skill, compensation and work satisfaction simultaneously affect the nurses’ performances in Anutapura General Hospital of Palu. The most dominant variable on nurses’ performances is compensation.

Keywords: Compensation; performance; skill; work satisfaction.

Introduction

Human resources are a basic element of every company, because human resources are the makers of goals, innovation, communication and strategy for the company¹. Thus, the success of an organization is strongly influenced by the level of employees’ performances. Because of the importance of employees’ performances in the achievement of corporate goals, it is necessary efforts by the company to improve employee’s performances, such as work skills, compensation and job satisfaction².

One of the factors that affect employee performance in nursing department is job skill. A nurse’s skills can be seen when the nurse performs a nursing action in accordance with the applicable Standard Operating Procedures (SOP). In addition, the nurse’s work skills can be seen from the nurse’s competence test³. Some of the literature emphasized the importance of individual skills, which include communication skills and team work skills as factors that play a role in organizational productivity and are an organizational form expected by the worker⁴.

Work skills are a person’s ability to accomplish tasks assigned to them. Skills here include technical skills, human skills, conceptual skills, such as the ability to take advantage of opportunities and accuracy⁵. Compensation is the overall remuneration received by employees as a result of the execution of employment in the organization in the form of money or other, which may include salaries, wages, bonuses, incentives and health benefits, holiday allowances, meal allowances, leave money and others. Compensation can be provided in various forms, such as in the form of giving money, the provision of materials and facilities, and in the form of giving career opportunities. The above payments are directly related to performance such as wages or salaries, bonuses and commissions which are not directly linked to performance in an effort to improve employees’ comfort and satisfaction such as benefits⁶.
The impact of a fair, decent and understandable compensation system by all employees, and controllable will build employee’s perceptions of the organization as a place to work and develop. The compensation given should be fair and reasonable in accordance with the performance of each employee is very influential on the level of employees’ satisfaction, control of the implementation of this compensation system through performance appraisal, so as to maintain the stability of employee motivation in achieving optimal performance. One of the important means of human resource management in an organization is the creation of employee job satisfaction. Job satisfaction is basically one of the psychological aspects that reflects one’s feelings toward his/her work, he/she will feel satisfied with the suitability of his ability, skills and expectations with the work he/she is facing.

Shahab et al. stated that effective leadership and job satisfaction are two factors that are considered the basis of a successful organization. Employees with high job powers tend to exert more effort in their tasks and pursue the interests of the organization. Based on the study problems and the results of previous researches, this study is interested to conduct a research on “The Influence of work skills, compensation and job satisfaction on the performance of nurses in emergency department of Anutapura General Hospital in Palu City”.

Methodology

Research Type

The type of research used in this study is quantitative method. Data collected in the form of statements or numbers will be analyzed by statistical methods to facilitate in interpreting each research variable. The data has been collected and then analyzed quantitatively by using descriptive or inferential statistics so that it can be concluded that the hypothesis formulated is proven or not. Survey method is used to have a better understanding about phenomenon that happened in an organization and by using research of survey method the researcher want to know the factors that influence the work skills and compensation and job satisfaction of nurses’ performance at emergency department of Anutapura General Hospital in Palu City.

Location and Time

The location of this study is at the emergency department of Anutapura Hospital of Palu City and this study was conducted from Jan 2016 to July 2016.

Population and sample

The population in this study were nurses at the emergency department of Anutapura Hospital, which is about 45 people. In this research no sampling technique is used because the whole of the population is analyzed by using the census method. It is with the consideration of the population of only 45 nurses, it is feasible to be taken overall to be sampled without having to take samples by random sampling technique in a certain amount.

Data Collection

The data used in this research were primary data and secondary data obtained from several source that is, results of interview and result of questionnaire given to nurse at emergency room department of Anutapura General Hospital.

Data Analysis

In this research, the researcher managed data with data analysis method using SPSS software. The collected data was analysed through bivariate analysis to see the relationship and the influence of independent variable to dependent variable by using Chi square test and see p-value and followed by logistic regression analysis.

Result And Discussion

Bivariate Analysis

Influence of work skills

The effect of work skills on nurse’s performance, in this study is listed in Table 1. According to the respondents’ response that if the nurse has good working skills then performance will tend to be good and this is evidenced by the high nurse work skills to good performance as many as 22 people (78.57%). Conversely, if the work skills are low, nurses tend to have poor performances. This is indicated by the high number of respondents who have low job skills and less good performances as many as 10 people (58.82%). The probability value (ρ value) = 0.011, <α = 5%, which means that there is influence between nurses’ work skills and their performance.

Effect of compensation

The effect of compensation on the performance of nurses in this study is listed in Table 2. Responses from some nurses stated that although the compensation received is low, it does not affect the performance of nurses. This is reflected on the high number of nurses having good performance as many as 21 people (75%). On the contrary, the opinion of some nurses stated that if the compensation received is low, then the performance will tend to be less good, which is proven by the high number of nurses who have bad performance as many as 10 people (58.82%). The probability value (ρ value) = 0.023 <α 5%, whereby it signified that there is influence between compensation and nurses’ performance.

Effect of Job Satisfaction

The effect of job satisfaction on nurses’ performance is presented in Table 3. According to the responses of some nurses, the higher the job satisfaction they feel or accept, the better their performances are. This statement is confirmed by 23 nurses (82.14%). On the contrary, the opinion of some nurses stated that if job satisfaction is low, it does not guarantee good performance. This can be proven by 10 nurses who have low job satisfaction and poor performance. The probability value (ρ value) = 0.005 <α = 5%, which means that there is influence between job satisfaction and nurses’ performances.

Overall Discussion

This result is consistent with the statement of Ologunde et al\textsuperscript{11}, that the implementation of a fair and reasonable compensation system will prevent employee intent to turnover. The results of this study are in line with what has been done by Cordeiro et al\textsuperscript{12}, that compensation is one of the determinants of performance. In particular, Lovelace et al\textsuperscript{13}' study also explained that in addition to compensation, leadership and physical work environment also contributed significantly to improved performance.
Job satisfaction is also important for actualization. Employees who do not get job satisfaction will never achieve psychological maturity. In turn it will be frustrating. Job satisfaction and staff motivation can be improved by doing job enrichment, job enlargement, job rotation, participation, and quality of work life.

**Conclusion**

Based on the results of this work, the following conclusion has been made. First, the job skills have positive and significant impact on nurses’ performance at the emergency department of Anutapura Palu General Hospital. Second, the compensation received positively and significantly influenced the performance of nurses. Third, job satisfaction has a positive and significant effect on the performance of nurses.

The Effect of Soybean Milk and Probiotic Drink on Total Cholesterol in Hypercholesterolemia Women in Makassar City

Nina Pratiwi N.D¹, Ida Leida Maria¹, Saifuddin Sirajuddin¹
¹Faculty of Public Health, Hasanuddin University, Jl. Perintis Kemerdekaan Km. 10, Tamalanrea Indah, Tamalanrea, Kota Makassar, Sulawesi Selatan 90245, Indonesia

Abstract

The aim of the research was to determine the effect of soybean milk and probiotic drink and their combination on the decrease of total cholesterol content in hypercholesterolemia women. The subjects of the research were women ranging from 30 to 60 years old with a total cholesterol content of 201-346 mg/di. The research subjects were divided into three groups, i.e. group I was given soybean milk (19 people); group II was given probiotic drink (19 people), and group III was given the combination of soybean milk and probiotic drink. The samples were supplied for four weeks. The results of statistical analysis indicate that there is a decrease of cholesterol content on the subjects having been given soybean milk, probiotic drink, and the combination of soybean milk and probiotic drink. The combination given for four weeks can decrease cholesterol total content. However, there is no difference among soybean milk, probiotic drink, and the combination of soybean milk and probiotic drink.

Keywords: Probiotic drink; Soybean milk; Total cholesterol; Women.

Introduction

The development of world civilization is marked by the increasing status of human welfare and advanced science, especially in the medical world where health problems today are not only caused by infectious diseases but health problems began to be taken over by non-communicable diseases such as cancer, diabetes, hypertension and disease cardiovascular events such as coronary heart disease and stroke. Anwar¹ showed that the risk of atherosclerosis or CHD will increase if blood cholesterol levels rise. It has also been shown that lowering blood cholesterol levels can reduce the risk. Hypercholesterolaemia is one of the risk factors of Coronary Heart Disease and also the risk factors for death at younger ages according to World Health Organization (WHO) report in 2002, as many as 4.4 million deaths due to CHD due to hypercholesterolaemia or 7.9% total death at a young age².

In Indonesia, the proportion of abnormal cholesterol in 2013 at age ≥ 15 years is 35.9%, and the proportion of abnormal cholesterol by gender at age ≥ 15 years by 30% male and 39.6% female¹. Women in pre-menopausal period will experience a decrease in estrogen hormones where the hormone estrogen works to lower blood serum cholesterol so that the risk of high cholesterol. As for residence, the proportion of abnormal cholesterol at age ≥15 years was higher in urban areas (39.6%) than in rural areas (32.1%)³.

Most people prefer to overcome the problem of hypercholesterolemia with synthetic drugs that are lowering cholesterol levels of the body⁴. However, these drugs are expensive because their raw materials are still imported. In the early stages, non-pharmacological treatments such as diet and exercise are preferred, but if these non pharmacologic therapies fail, pharmacologic therapy is performed, using both traditional and modern medicine. However, the prevention of drugs has low success rates because of the high discipline required. Almost 70% of hypercholesterolemia patients in Indonesia fail to achieve the target of cholesterol levels according to the treatment guidelines⁴.

Soy is one of the most abundant vegetable sources in Indonesia and it is potential to be developed as a health food beverage for people with hypercholesterolaemia. Soybeans contain isoflavone bioactive components that are beneficial to health. Isoflavones have non-
steroidal and antioxidant phytoestrogens that have the potential to protect hormone-dependent diseases such as breast cancer, prostate cancer, menopausal syndrome, hypercholesterolaemia and osteoporosis. Jenkins found that postmenopausal women given soy isoflavone diet significantly lowered total blood cholesterol.

Lin showed that chemical components in soybeans can also lower blood cholesterol levels, thereby reducing the risk of coronary heart disease. Soybeans (Glycine max L.) contain chemical components, including: protein, isoflavones, niacin, and dietary fiber that are reported to lower blood cholesterol levels. In addition the nutritional value of soy essence is almost the same as cow’s milk.

In addition to soy milk, probiotics also benefit on the decrease in cholesterol levels. Probiotics are microbes that provide health benefits to the host through its effects in the intestinal tract. Probiotics play a role in lowering cholesterol through bile acid deconjugation and through binding of cholesterol by bacteria. The results from Ataie-Jafari stated that giving 300 grams of probiotics daily for 6 weeks can lower total cholesterol and LDL and increase HDL.

The result of Chiu research found that fermented soy milk gives cholesterol reduction effect, higher than soybean milk in hamster animal. Isoflavones in fermented soy milk in the form of its smaller (molecule) aglclone (genestein), resulting in faster absorption. The isoflavon absorption of fermented soy milk is faster than that of controversal soy milk.

Aggarwal noted that there is no difference in the reduction of cholesterol from soygurt with a combination of soy milk and probiotics. Based on this background, in this work, the authors have examined the effects of soy milk, probiotic drinks on the decrease in total blood cholesterol levels in housewives at some puskesmas in Makassar City 2014.

**Methodology**

**Research Type**

The type of this research is Quasi Experimental research with nonrandomized Pre-Post Test Control Group Design model. This design is also known as nonequivalent control group design.

**Location and Time of Study**

This research was conducted at Mamajang Community Health Center and MacciniSawah Community Health Center. The reason for choosing the research site is because the clinic has cholesterol examination so it can identify housewife who has high cholesterol level. The time of study was 2 months, ie from May-July 2014.

**Population and Sample**

The populations in this study were housewives in several puskesmas in Makassar City. The sample of this research is part of housewife in several health centers of Makassar City that meet the following criteria of aged between 30-60 years with cholesterol levels more than normal cholesterol levels (> 200 mg / dl). The sample set for this work is 54 samples with estimated dropout of 10 %. The sample of research is divided into 3 groups, that is group I is housewife who get soy milk. Group II is a housewife who gets a probiotic drink. Group III is a housewife who gets soy milk and probiotic drinks.

**Treatment Method**

Panelists are divided into three groups: Group I is given 1 cup of soy milk (175 mL) twice daily (morning and night). Group II is given 1 bottle of probiotic drink containing probiotic bacteria 108 colonies (65 mL) 2 times a day (morning and night). Group III is given 1 cup glass of soy milk (175 ml) and 1 bottle of probiotic (65 ml) drink twice daily (morning and night). The researcher came to each sample house and gave treatment twice a day (morning and night) for 1 month. In the second week, the total measurement of blood cholesterol by nurses. All measurements of nutritional status of research subjects were carried out in each Puskesmas by weighing BB using the scales of “Camry Digital” brand body and TB using height measuring instrument “MicrotoiseStaturmeter” before intervention and after intervention to calculate BMI, so the quality of measurement remains the same. Measurement of Food Frequency and Food Recall 24 hours was done at the time before the intervention and after intervention to obtain data about the frequency of consumption of a number of foodstuffs from the study subjects.

**Data Analysis**

Data processing is done by using computer program SPSS version 18. Bivariate analysis was conducted to
find out the correlation of independent variable and dependent variable by using statistical test. The results obtained were compared between before and after intervention with T paired sample test or Wilcoxon Signed Rank Test. Meanwhile, to compare the results between patients who received intervention of soymilk, probiotic drink intervention and intervention of soymilk and probiotic drink was done T unpaired sample test and Mann Whitney U Test. As for the conversion and regularity of treatment was done in the form of percentage comparison.

Result And Discussion

To test the difference of mean total blood cholesterol level before and after intervention of soymilk, probiotic drink and combination of both, paired T test. To perform paired T test then the data distribution should be normal. Normality test results can be seen in Table 1. Since P>0.05 it can be concluded that the distribution of treatment type data for each group has normal distribution so that ANOVA test can be done.

Table 2 shows that in the soybean intervention group at the first measurement the mean value of cholesterol 229.37, the second measurement 180.95, and at the third measurement of 193.00. From ANOVA repeated test results obtained p value (0.000) <0.05 which means that there is difference in each measurement. Table 3 shows in the intervention group using probiotic drinks, for the first measurement of cholesterol mean values of 235.74, second measurement 167.74, and third measurement 196.63. From ANOVA repeated test results obtained each p value (0.000) <0.05 which means that there is a difference in each measurement. Table 5 shows that for the first measurement there is no average difference in the three intervention groups with p = 0.174 (p>0.05). For the second measurement there was no average difference in the intervention group with p = 0.464 (p>0.05). For the second measurement there was no average difference in the three intervention groups with p = value 0.276 (p>0.05).

The housewives taken as research samples had initial cholesterol levels, the lowest 201 mg / dL (1 respondent) and the highest 346 mg / dL (1 respondent). The average initial cholesterol level for the 300 ml soybean-fed (K1) group was 229.37 ± 18.67 mg / dL, the group given 2 bottles of probiotics “Y” containing probiotics Lactobacillus casei strain Shirota 108 colonies / mL (K2) is 249.11 ± 43.62 mg / dL, while the combination group of soy milk and probiotics (K3) is 235.74 ± 30.86 mg / dL. This shows that generally the respondents used still include mild to moderate hypercholesterolemia. High grade hypercholesterolaemia if total blood cholesterol levels more than 240 mg / dL.

According to Gardner, a daily dose of 25 g protein from soy milk can lower LDL-cholesterol levels in adults who are high in LDL-cholesterol. Chen suggests that soy protein significantly lowers total cholesterol (17.2%). Taku suggests that soy protein significantly lowers total cholesterol. The results of Taku found that isoflavones total cholesterol serum blood and LDL-cholesterol. The main components in soy milk that play a major role in lowering cholesterol according to some researchers include: soy protein and isoflavones. The 1 g protein in soy milk contains 56 mg of total isoflavones. Ishimwe stated that probiotics are able to lower cholesterol through the mechanism of binding of cholesterol in the intestines by probiotic bacterial cell membranes and by deconstruction of bile salts into bile acids by enzymes produced by probiotic bacteria.

Consumption of combination of soy milk with probiotic drink (L.casei strain shirota) in this study showed no statistically significant differences with soy milk or probiotics in reducing total blood cholesterol levels, while Larkin found that combination of soybean and probiotics in respondents aged above 45 years of moderate hypercholesterolaemia decreased cholesterol 4.7 ± 2.0%. There are differences in the results are caused among others: the type of probiotics used, the dose of probiotics and soybeans, and the duration of administration.

Conclusion

This research aim to estimate the prevalence of under nutrition and Based on the results of research and discussion on the provision of soy milk, probiotic drinks and a combination of soy milk and probiotics in lowering total blood cholesterol levels, it can be concluded:

1. Provision of soy milk, probiotics, and its combination for 2 weeks can reduce total blood cholesterol levels.

2. Statistically, there is no difference in the provision of soy milk, probiotics, or a combination of total blood cholesterol levels.

The Correlation between Birth Weight and the Essential Fatty Acid Levels in the Milk of Breastfeeding Infants Aged 1 to 4 Months in Makassar

Nur Nikmah Siradjuddin1, Veni Hadju1, Ida Leida Maria1
1Faculty of Public Health, Hasanuddin University, Jl. Perintis Kemerdekaan Km. 10, Tamalanrea Indah, Tamalanrea, Kota Makassar, Sulawesi Selatan 90245, Indonesia

Abstract

This research aimed to examine the correlation between the birth weight and the higher level of essential fatty acids (AA and DHA) in the milk of the mother who breastfeed the 1 to 4 month infants in Makassar City. The research was conducted in the health Centers of Tamaumaung, Layang and Tamangapa. The research type was analytical observational using the cross sectional design. The 30 samples were chosen using the purposive sampling technique. The samples were divided into two groups: the first group constituted of 15 mothers who breastfeed the infants with the normal birth weights and the second group con essential fatty acid (AA and DHA) were examined using the High Performance Liquid Chromotography (HPLC) method. SPSS was utilized to analyze the data based on independent t-test in order to see the correlation between the birth weight of the infants and the levels of the essential fatty acid in the mother’s milk of the two groups. The research results indicated that the mean level of the AA milk in the infants with the normal birth weight was lower compared to that in the LBW infants (0.098 ± 0.006 mg/ml against 0.085 ± 0.024 mg/ml); the mean level of milk DHA in the infants with the normal birth weight was also lower compared to that in LBW infants (0.076 ± 0.005 mg/ml compared to 0.072 ± 0.007 mg/ml), but their correlation was not significant (p>0.05).

Keywords: Breastfeeding mothers; Breast milk; Essential fatty acid; LBW

Introduction

Breast milk is the most perfect food for babies. Naturally, every human being is prepared to have a pair of mammary glands that serve to produce milk or breast milk for the baby at the time after childbirth. Breast milk is a source of nutritional choices for infants, according to the World Health Organization (WHO), the American Academy of Pediatrics (AAP) and Canada Pediatric Society (CPS), ideally breastfeeding is the only source of nutrition for six months at the beginning of life. The composition of breast milk may change according to the baby’s nutritional needs at all times. Only breast milk is uniquely adapted to the needs of human infants. For example, for premature infants, breast milk has a high nitrogen content of milk produced by a mother of a term infant. The content of enzymes in breast milk that helps digestion, the immune substance that can prevent infants infected by the seeds of certain diseases, it cannot be replaced by formula milk. In addition, breastfeeding has psychological benefits for both infants and mothers.

Breastfeeding in infants in addition to improving health and intelligence optimally, also able to make potential children have a stable emotion, spiritual mature and have good social development. The advantages and benefits of breastfeeding can be seen from several aspects: nutrition, immunology, psychological, neurological, intellectual, economic, and postponed pregnancy. Breastfeeding will ensure the baby will be healthy to start life.

Infant growth and development is largely determined by the amount of breast milk obtained including energy and other nutrients contained in the milk. Breast milk...
without other food can meet the needs of baby’s growth at the beginning of life. After that, breast milk only serves as a source of protein, vitamins and minerals for babies who get additional food.

Breast milk composition is intended as baby nutrition. Breast milk also contains hundreds to thousands of different bioactive molecules in each mother to protect infants against infections, inflammation and contribute to immune maturation, organ development, and healthy microbial colonization. The composition of breast milk including the minerals contained therein may be affected by various factors such as maternal health and nutritional status, lactation phase and food intake.

Breastfeeding a mother specifically tailored to the needs of her own baby. The results showed that the fat and lactose content of breast milk in mothers who gave birth less than a month lower than breast milk in mothers who gave birth monthly, while the protein content significantly higher in infants less than months of mature enough. Besides breast milk also contains many essential fatty acids. Essential fatty acids are a component of all body tissues and are necessary for the synthesis of cell membranes. Some studies have shown that infants who get formula milk despite containing LA and ALA in the same composition in breast milk, DHA levels in the body tissue was lower than breastfed babies because the ability of babies to change LA and ALA to AA and DHA is still very limited. The results showed that there were differences in growth between breastfeeding infants and infant formula without DHA. However, the minimum amount of DHA contained in ASI is sufficient for optimum growth and development.

The presence of appropriate protective and nutrient factors in breast milk can ensure good baby’s nutritional status and morbidity and mortality rates may decrease. In order to reduce morbidity and mortality, UNICEF and WHO recommend that infants should be breastfed for at least 6 months. Based on Indonesia Demographic and Health Survey (SKDI) Survey 2007, the coverage of exclusive breastfeeding from 0-6 months showed an increase from 32% to 42% in 2012. Data from the Ministry of Health indicate coverage of exclusive breastfeeding in 2013 in infants 0-6 month in South Sulawesi was 66.5% higher than the national figure of 54.3%. The total amount of breast milk production and infant intake varies for each feeding time in the amount of between 450-1200 ml and the average between 750-850 ml per day. The amount of breast milk that comes from mothers who have malnutrition status can decrease to the number only100-200 ml per day. Breast of pregnant hormonal women and women who has breastfed, will be able to produce a lot of breast milk when the woman is relaxing.

Based on the above background plus the lack of research related to that in the city of Makassar, researchers interested in conducting research related to the birth weight relationship to the levels of essential fatty acids (AA and DHA) in breast milk from mothers breastfeeding infants aged 1-4 months in the city of Makassar.

Methodology

Research Design

The type of research used in this study is observational analytic that is, research is directed to explain the linkage of a situation or situation. In this study was directed to explain the relationship between birth weights with the levels of essential fatty acids in breast milk by comparing the levels of essential fatty acids in breastfeeding mothers with LBW infants who breastfeed babies with normal birth weight. The research design used is cross sectional where the research object is measured or collected simultaneously at the same time. In other words, data collection for this type of research, both independent variables and dependent variables were done together or at once.

Location and Time of Study

The research was conducted in three health centers in Makassar city, namely PatingalloangPuskesmas, PuskesmasLayang and Tamangapa Health Center. The study period starts in October 2015 until December 2015.

Population and Sample

The populations in this study were breastfeeding mothers whose babies were enrolled in PatingalloangPuskesmas, PuskesmasLayang and Tamangapa Health Center. The study sample was breastfeeding mothers who fulfilled the inclusion criteria. The way of subject selection is by purposive sampling method that is sample determination technique based on certain criterion. Total sample minimum is 30 people.
**Data Analysis**

In this work, questionnaire for characteristic and demographic data of the sample was used. All primary data from the results of the study were analyzed and calculated using SPSS. Bivariate analysis, using Independent t-Test to was done to analyze there a significant relationship between the 2 free groups of normal birth weight group and group with the average of essential fatty acid (AA and DHA) in breast milk.

**Ethical Considerations:** This study was conducted with the permission of the Ethical Committee of Faculty of Medicine Unhas No. Register UH 15110962.

**Result and Discussion**

The association of AA and DHA levels in breast milk based on the baby’s birth weight.

Results showed that infants of normal birth weight had a mean birth weight of 3086.67 grams and mean baby BBLR was 2186.33 grams. Furthermore, the comparison of AA and DHA levels in breast milk based on birth weight category showed different mean values, where the mean AA of ASI in the LBW group was higher at 0.098 ± 0.006 mg / ml than the normal group of 0.085 ± 0.024 mg / ml, but unrelated statistically with p value = 0.052 (p> 0.05). While DHA levels showed higher mean in LBW group with group mean of u 0.072 ± 0.007 mg / ml, but not related by p value 0.170 (P> 0.05).

Breast AA and DHA levels based on breastfeeding experience.

In Table 1, AA levels in breast milk were compared based on breastfeeding experience in breastfeeding mothers in the City showed no significant association between mothers who had breastfeeding experience and who did not have breastfeeding experience with AA levels in breast milk, this was also confirmed by p = 0.589 (> 0.05).

The level of DHA in breast milk in Table 2 compared with breastfeeding experience in breastfeeding mothers in Makassar City showed no significant relationship between mothers with breastfeeding experience and who did not have breastfeeding experience with breastfed DHA levels, this was also proved by the value of p = 0.052 (> 0.05).

Table 2. Average breastfeeding DHA levels based on breastfeeding experience

AA and DHA levels of breast milk based on nutritional status of breastfeeding mothers

Mean AA levels in breast milk Table 3 compared with maternal body mass index (IMT) at the time before pregnancy and at the time of breastfeeding showed no significant relationship with ASA AA levels, where p> 0.05. Furthermore, AA levels in breast milk that were related to the size of the upper arm circumference of the mother at the time of breastfeeding showed no significant relationship (p = 0.423).Mean levels of DHA in breast milk (Table 4), which were linked by maternal body mass index (IMT) at the time before pregnancy and BMI at breastfeeding showed no significant association with ASH DHA levels, where p> 0.05. Furthermore, levels of DHA in breast milk linked by maternal upper arm size (LLA) at breastfeeding showed no significant association (p = 0.165).

Overall Discussion

The levels of essential fatty acids (AA and DHA) of breastfeeding mothers differ in each mother in a population in different parts of the world. This is influenced by the mother’s diet during breastfeeding or other factors. The mean value of AA levels in breast milk was 0.092 mg / ml and DHA levels were 0.072 mg / ml of breast milk. This is in contrast to breast milk protein levels in many countries, one of which was research in Iran with an average AA level of 0.16 mg / ml of breast milk and DHA levels of 0.08 mg / ml of breast milk.

The levels of the essential fatty acids of breast milk (AA and DHA) in breast milk in this study associated with body mass index (IMT) at breastfeeding showed no significant association in both conditions. This result is different from the results of research conducted by Chang and Yang have found a positive relationship between the composition of breast milk and breastfeeding mother’s BMI. These results are in line with the results of studies conducted by Quinn and other studies.
supporting this result suggest that maternal weight gain results in increased volume but not with breast milk composition ie fat, protein and energy\textsuperscript{22}.

**Conclusion**

Based on the results of research conducted, it can be concluded that:

1. Mean of essential fatty acid (AA) level in breast milk from breast feeding mother of LBW tends to be higher compared to normal birth weight baby with p = 0.052 (p> 0.05). Statistically, however, there was no relationship between infant birth weight and essential fatty acid (AA) levels in breast milk from nursing mothers aged 1-4 months in Makassar.

2. Mean levels of essential fatty acid (DHA) in breast milk from breast-feeding mothers of LBW tends to be higher compared with normal birth weight infants with p = 0.170 (p> 0.05). Statistically, however, there was no relationship between infant birth weight and essential fatty acid level (DHA) in breast milk from nursing mothers aged 1-4 months in Makassar.

Relationship between Early Breastfeeding Initiation and Involution Uteri of Childbirth Mothers in Nenemallomo Regional Public Hospital and Arifin Nu’mang Public Regional Hospital of SidenrengRappang Regency in 2014

Nurjanna¹, Suryani As’ad¹, Irfan Idris¹
¹Faculty of Medicine, Hasanuddin University, Jl. Perintis Kemerdekaan Km.10, Makassar, 90245, Sulawesi Selatan, Indonesia

Abstract

Early Initiation of Breastfeeding (EIBF) and exclusive breastfeeding are two of the factors to accelerate involution uteri. The aim of the research was to find out the relationship between early breastfeeding initiation and involution uteri of postpartum mothers. Independent variables were early breastfeeding initiation and independent sub-variables were age, education, and continuous breastfeeding (exclusive breastfeeding) until day 7, while dependent variables were involution uteri. The research was conducted in Nenemallomo Regional Public Hospital and Arifin Nu’mang Public Regional Hospital of Sidenreng Rappang Regency from October to December 2014. The subjects were primiparous mothers (giving birth first time normally). The data were analyzed statistically with Mann Whitney U, while independent sub-variables were analyzed using Chi square. The results of the research indicated that the variable of mother’s age and education have a relationship with involution uteri, while continuous breastfeeding variable (exclusive breastfeeding) until day 7 has a relationship with involution uteri. There is also a relationship between early breastfeeding initiations with the size of uterus in woman postpartum in day 7. Moreover, there exists a correlation between early breastfeeding initiation and lochia discharge of postpartum mothers in day 7. There is a significant correlation between early breastfeeding initiation and involution uteri of postpartum mothers.

Keywords: Childbirth; early breastfeeding initiation; involution uteri; postpartum.

Introduction

One of the causes of high maternal mortality rate (MMR) in Indonesia is due to postpartum hemorrhage caused by the occurrence of sub-involution of the uterus. EIBF and exclusive breastfeeding are two of the factors that can accelerate uterine involution. Breastfeeding is when the baby sucks the smooth muscles of the nipple, then the nerve is passed to the brain, then the brain instructs the hypophysis gland to release oxytocin so that the breast muscles emit breast milk. Besides, the hormone oxytocin also stimulates the smooth muscles of the uterus to contract better. Thus, the involution of the uterus is faster and lochia expenditure is smoother¹.

Research conducted by Palupi², showed that out of 20 respondents who had EIBF, 17 (85%) respondents experienced changes in uterine involution as seen from the normal majority fundal height and lochia and also found that respondents who carried out EIBF had a decreased in the fundal height and evenly distributed lochia abnormality is encountered at over 30 years of age and had given birth more than once.

With reference to Agusvina³ research, indicated that mothers who provided exclusive breastfeeding for up to 7 days have the opportunity to get normal process of fundal height is 29.8 times higher than those who do not exclusively breastfeed. Research on EIBF was also carried out by Handayani et al⁴. suggested that there was a significant difference in mean height of fundus uteri of 2 hours, 12 hours and 7 days after EIBF is done.

The Indonesian Government supports the WHO and UNICEF policies that recommended early breastfeeding initiation as an act of “Rescue of Life” because EIBF
can save (22%) of babies who die before the age of one month.

Touch, skin / emotion and baby lick on the mother’s nipple will stimulate the release of the hormone oxytocin, causing the uterus to contract and help remove the placenta and reduce the occurrence of postpartum hemorrhage. EIBF is an important starting point for the process of breastfeeding and to help speed up the return of the uterus to its original shape and reduce bleeding after birth. This is due to baby suction on the breast stimulating the pituitary gland in the brain to release oxytocin. The speed of uterine involution is influenced by several factors including maternal age, number of children born (parity), early mobilization and early breastfeeding. Oxytocin in addition to working to contract the milk channel in the milk glands also stimulates the uterus to contract so as to accelerate the process of involuntary uterus, on this basis, EIBF is carried out in order to speed up the course of involuntary uterus which ultimately reduces maternal mortality due to postpartum bleeding.

The exclusive coverage of breast milk in SidenrengRappang Regency in 2013 showed that out of 1056 babies, 897 babies (84%) received exclusive breastmilk. The purpose of this study was to determine the relationship of early breastfeeding initiation with uteri involution among postpartum mothers in Nenemallomo Regional Hospital and ArifinNu’ mang District Hospital in SidenrengRappang District.

Methodology

Research design

The research design used in this study was a longitudinal study with a prospective cohort. This study compared changes in research subjects after a certain period of time, prospective research to monitor the characteristics for a certain period of time, where the event was recorded when it happened.

Population and sample

The population in this study was all postpartum mothers who gave birth for the first time and had vaginal birth at RSUD Nene Mallomo and RSUD ArifinNu’ mang SidenrengRappang District between October to December of 2014. Samples were part of the number and characteristics possessed by the population. The sample selection of a study is adjusted to the type of research and research objectives. The sampling technique used in this study was non-probability sampling with a total of 30 samples.

Data collection

The research instrument is a tool used to measure research variables specifically so that the data needed in the research is produced. In quantitative research, instruments that can be used are interview guidelines and observation guidelines. In this study, data collection instruments used was questionnaires, observation sheets and checklists.

Data analysis

The test used in this data analysis is the Mann Whitney U Test and Chi square test, followed by univariate and bivariate statistical analysis.

Results

Univariate analysis

In Table 1, most of the distribution of maternal age was low risk (age 20 - 35 years) as many as 17 people (56.7%) and high risk distribution (age <20 or > 35 years) as many as 13 people (43.3%). The educational characteristics of the mothers revealed that 22 (73.3%) of them were highly educated while those with low education were 8 respondents (26.7%). In terms of feeding breastmilk to their newborn, 16 respondents (53.3%) fed their baby breastmilk (without other intakes) until the 7th day. Nonetheless, as many as 14 respondents (46.7%) did not give only breast milk (there was other intake) to the baby until day 7. In the administration of colostrum, majority of them gave colostrum to their babies, namely 25 respondents (83.33%) and only 5 respondents (16.66%) who did not give colostrum to their babies. For the EIBF category, there were 15 respondents (50%) who started EIBF fast (≥1 hours) while 15 respondents (50%) started EIBF slow (≥2 hours).

### Bivariate analysis

Based on Table 2, it can be seen that the value of $\rho = 0.083 (< 0.05)$, thence $H_a$ is rejected and $H_o$ is accepted indicating there is a relationship between age factors and uterine involution. The relationship of education variables which are sub-variables with uteri involution showed that the value of $\rho = 0.421(> 0.05)$ which on the other hand signified that $H_o$ is accepted and it can be concluded that there is no relationship between variables of education with involution of the uterus.

Table 3 presented the results of the analysis of the relationship between variables of breastfeeding (sub-variable) with uteri involution which showed that the value of $\rho = 0.00 (<0.05)$. Therefore, $H_o$ was rejected and $H_a$ was accepted, implying that there was a relationship between breastfeeding and involution of uteri.

With reference to the results of the analysis of the relationship between EIBF and uterine size as tabulated in Table 4, it was found that the value of $\rho = 0.00 (<0.05)$. Thus with that, $H_o$ was accepted and this signified there was a relationship between EIBF and Fundus Uteri Height among mothers on the 7th day of postpartum.

Based on Table 5, it can be explained that the results of the analysis of the relationship of EIBF with lochia discharge showed there was a significant relationship between early initiation of breastfeeding and lochia discharge since the value of $\rho = 0.00 (<0.05)$. $H_o$ was rejected whereas $H_a$ was accepted.

Discussion

Among mothers who are older, many are affected by the aging process, where the aging process increased the amount of fat, decreased muscle elasticity and decreased absorption of fat, protein, and carbohydrates. If this process is associated with a decrease in protein in the aging process, then this will consequently inhibit uterine involution. Among relatively young age mothers, whereby the individual reaches a state of prime vitality so that muscle contraction and uterine involution are also faster due to the regeneration of the cells because

The results of research conducted by Agusvina showed that there was no difference in the proportion of uterine fundus height between mothers aged 20-30 years with mothers aged 31-35 years meanwhile the study carried out by Palupi, stated that respondents who were EIBF found there were changes in fundal height and abnormal discharge of lochia, which were found on average over women age 30 years and had given birth more than once. Heriati also agreed that age is very closely related to a decrease in uterine fundal height. The older a person is, the less reproductive function is found on average over 35 years of age and has given birth more than once.

The results of research obtained from the Chi square test showed that the value of $\rho = 0.421 (> 0.05)$, thus $H_0$ is accepted meaning there is no relationship between mothers’ education level with uteri involution. This statement was supported by Agusvina, who found out that education has no direct effect on uterine involution because there are many other variables that influence it. Education is often related to socioeconomic status. A person with low education usually has a low socioeconomic status and will affect the income and purchasing power of daily needs such as staple foods which will impact the nutritional status. The more education a person gets, her maturity increases and eventually they will easily accept and understand positive information related to health problems. In other words, women who have higher education tend to pay more attention to their health.

Chi square analysis of the relationship of continuous breastfeeding alone for 7 days showed that the value of $\rho = 0.00$, thence there is a relationship between continuous breastfeeding alone during 7 days with uterine involution. Suctioning of the nipple by the baby during the EIBF process stimulates the sensory nerve endings on the nipple which will cause an action potential which then spreads to the spinal cord and then to the hypothalamus. One way to maintain good contractions d until the end of childbirth is by performing exclusive breastfeeding. Because by breastfeeding, the muscles in the uterine area will experience contractions and retractions which in the presence of this contraction will cause the blood vessels in the uterus to stretch so that bleeding can be avoided.

The process of involution is accelerated in mothers who breastfeed their babies because oxytocin is released in response to baby suction, early breastfeeding will cause touch, emulation and licking of the baby in the mother’s nipples during the suckling process will stimulate oxytocin release which causes the uterus to contract so as to help reduce bleeding. Oxytocin is a powerful simultaneous for uterine muscles.

According to Nissenet al. It was found that oxytocin levels in the maternal peripheral circulation were much lower during labor than during breastfeeding. In women who fully breastfed their babies, oxytocin levels turned out to increase from 4.6 µU / ml at the second and fourth weeks of postpartum to 8.6 µU / ml at 15 and 24 weeks.

Agusvina showed that postpartum mothers who had breastfeeding frequency were more than13 times per day as many as 10 people (33.3%) with an average fundal height decrement of 3.08 cm. 8 mothers (26.7%) that were breastfeeding between 10-12 times per day had an average of 4.03 cm decreased in fundal height. Those mothers with frequency of breastfeeding less than 10 times per day as many as 12 people (40%) had an average fundal height decreased by 5.22 cm only. This results proved that there is a significant effect between the frequency of breastfeeding and a decrease in fundal height ($p$-value = 0.000).The conclusion of the study emphasized that mothers who exclusively breastfed had the opportunity to obtain normal fundal height 3.973 times faster compared to mothers who do not breastfeed exclusively.

The results of the analysis of the relationship between EIBF and uterine involution seen from fundal height showed that the value of $\rho = 0.000$, thus it is proven that there is a relationship between early breastfeeding initiation and fundal uteri height among mothers of postpartum day 7.Fundal uteri height in postpartum
mothers on day 7 was based on palpation by determining the location and height of the uterus, namely mid-center and upper edge of pubic symphysis with uterine weight of 500g with a diameter of 7.5 cm.

In the research conducted by Agusvina\(^3\), the results of the study stated that there was a difference in the proportion of uterine fundal size between mothers who were EIBF and mothers who did not do EIBF (there was a significant relationship) between EIBF and size of fundal uteri height. This was supported by Handayaniet al\(^4\) research which found that there were significant differences in fundal height averaging from 2 hours, 12 hours and 7 days after EIBF was performed with those who did not EIBF. Hence, it was known that EIBF had an influence on uterine involution.

The results of the analysis of the relationship of early breastfeeding initiation with lochia discharge showed that the value of \(\rho = 0.00\), which concluded that there is a significant relationship between early breastfeeding initiation and lochia discharge. The relationship between EIBF and uterine involution is measured from two indicators, namely uterine size (USG) and lochia discharge (observation). The results of the analysis of the relationship between EIBF and uterine involution seen from the size of the uterus showed that the value of \(\rho = 0.00\) which deduced that there is a relationship between EIBF and uterine size, while the results of breastfeeding initiation relationship analysis with lochia discharge shows that the value of \(\rho = 0.000\). Early breastfeeding initiation and lochia discharge had a significant relationship.

Ambarwati et al\(^1\) studied the relationship of early breastfeeding initiation to the high decrease in fundus of postpartum maternal uterus at Sidorejo Health Center, Lotaota Salatiga. Out of 20 respondents, the number of respondents given EIBF with primiparous parity and changes in involution seen from fundal height and lochia, majority of the normal were 17 people (85%). Based on the results of the study, respondents who had EIBF with primiparous parity were found to have changes in fundal height and normal lochia discharge with a \(p\) value of 0.003. According to Hasinuddin\(^1\), the results of statistical tests with t-test of 2 free samples showed that the significance level was smaller than \(\alpha\) (0.000 <0.05), thus it could be concluded that there was an effect of early breastfeeding initiation on uterine involution in primiparous postpartum mothers.

### Conclusion and Recommendation

Conclusions from the results of the study showed that there was a significant relationship between early breastfeeding initiation (EIBF) and uterine involution among postpartum mothers. It is hoped that this research can be a reference for further researchers and measurement of uterine involution can be done using a more sophisticated ultrasound device (3D or 4D).

The Pay Ability and Willingness to Pay for Treatment at Pangkajene Hospitals

Nurul Fajriah Istiqamah¹, Darmawansyah¹, Amran Razak¹
¹Faculty of Public Health, Hasanuddin University, Jl. Perintis Kemerdekaan Km. 10, Tamalanrea Indah, Tamalanrea, Kota Makassar, Sulawesi Selatan 90245, Indonesia

Abstract

Determination of tariffs in health services is very instrumental in influencing demand from low and high income groups. The aim of the study was to find out the level of ability and willingness to pay general patients hospitalization in the Pangkep District Hospital. This research is a quantitative research with descriptive method with a sample of 87 people taken by means of quota sampling technique and analyzed using univariate analysis. The results showed that 38 respondents (43.7%) agreed that the highest ability to pay based on willingness to pay ATP 1 was <Rp. 15,000,000 while 2 respondents (2.3%) settled for the minimum rate of ≥ Rp. 60,000,000. While ATP 2 showed that the ability to pay based on expenditure for the largest non-food was Rp.100,000-Rp.500,000 as supported by 68 respondents (78.2%) are in class III and the smallest Rp.1,000,001-Rp.1,500,000 were 4 respondents (4.6%) were in the VIP class, the largest non-essential expenditure <Rp.150,000 as many as 36 respondents (41.4%) were in class III while the lowest was Rp.3,500,000-Rp.4,500,000 as much as 2 respondents (2.3%) were in the VIP class. 57 respondents (65.5%) said that the hospital rate is non-reasonable whereas and as many as 30 respondents (34.5%) said it were affordable rates. The conclusion of this study showed that the ability and willingness to pay the community was in accordance with their respective classes.

Keywords: Ability and willingness; bills; health care; hospitals; inpatient

Introduction

Based on the concept of national development, the Ministry of Health is responsible for implementing the ‘Indonesia Sehat’ program which aims to increase knowledge, willingness and ability to live healthily for everyone in a healthy living environment. The implementation of the ‘Indonesia Sehat’ program requires a comprehensive regulatory framework and health development financing policy between government and health development sector¹.

Limited health financing coupled with the production costs of health services in hospitals continued to increase, which will affect the tariff of government hospitals. Current tariffs do not allow government hospitals to develop, while the need to develop is higher because of the competition between hospitals is growing³. Thabrany ³ stated that even though the tariff rates which are calculated on the basis of Ability to Pay (ATP) and Willingness to Pay (WTP) have been introduced previously, the problem of affordable tariffs is still not completed because of the nature of uncertain needs. Despite the number of patients who do not pay in government hospitals is relatively small, but that does not mean that the community is able to automatically reach the services provided. For instance, someone who has an income of Rp.2,000,000 per month if being hospitalized for 60 days, and maintenance costs per day is Rp.35,000, so 60x35,000 = Rp.2,100,000 not to mention the cost of medicine, doctor services, supporting examinations and others. If he does pay the total cost of the hospital, then the nature of the payment is considered as a forced payment.

Based on the results of previous studies, conducted by Juliasih et al²., it was found that the ability to pay by the inpatients in the VIP class for 3 days of hospitalization was categorized as high in the range of Rp. 700,000 to Rp. 1,200,000 because this service user usually has relatively

DOI Number: 10.5958/0976-5506.2019.00810.6
high income. Study done by Mudayana, found that the patient’s ability to pay for hospital services was an average of Rp. 100,033 per three-day hospitalization whereas the lowest cost was Rp. 9,333. This was due to the amount of income of respondents less than Rp.1,000,000 per month. Those with low incomes are usually educated up to high school only. Thus, they are not able to secure themselves a high paying income jobs.

Determination of tariffs in Kabupaten Pangkep District Hospital is not determined based on ability and willingness to pay by the patients, but because of the high operational costs in 2013. In 2014 until now, the tariff increase was caused by an increase in operating costs in the year.

Therefore, it is necessary to analyse the ability and willingness of patients or community users of health services to pay so that later they can find out the appropriate costs and finally as one of the references to policy makers regarding the determination of rates and guideline for budget planning in hospitals, especially in inpatient units.

Methodology

The type of research used is quantitative research with a descriptive survey to obtain an overview of the ATP and WTP of general patients hospitalized in the District General Hospital. The population in this study were all 1646 general patients who underwent inpatient care at Pangkep District Hospital. Samples in this study were general patients who were inpatient care. The number of samples obtained using quota sampling technique was 87 people. Data collection was obtained through interviews using questionnaires or data processing questionnaires performed computerized using SPSS. Data is presented in narrative form, frequency distribution tables accompanied by interpretations.

Results

The calculation of respondents’ ATP in this study was based on the ability of general patients to pay tariffs of inpatient installations at Pangkep District Hospital using ATP 1 formula and ATP 2 formula and these results are tabulated in Table 1. The results showed that VIP care classes had the largest ATP 1, ranging from Rp. -Rp.30,000,000 per year as many as 9 respondents (52.9%) while the lowest ATP 1 is around Rp. 30,000,001-Rp. 45,000,000 with only 1 respondent (5.9%). treatment for class 1 had the biggest ATP 1, which ranged from Rp. 15,000,000 to Rp. 30,000,000 per year as many as 7 respondents (36.8%) while the lowest ATP 1 ranged from Rp. 45,000,001 to Rp. 60,000,000 supported by 2 respondents (10.5%). Class II care had the largest ATP 1, which ranged from <Rp. 15,000,000 for 9 respondents (42.9%) while ATP 1 is the lowest, which was Rp. 45,000,001-Rp. 60,000,000, 1 respondent (4.8%). In class III treatment, it had the largest ATP 1, which was <Rp. 15,000,000 as many as 22 respondents (73.3%) while the lowest ATP 1 was Rp. 45,000,001-Rp. 60,000,000 with 1 respondent (3.3%).

Based on non-food expenditure results (refer to Table 2) which is calculated using ATP 2 formula, showed that VIP care class had the biggest ATP 2, which ranged from Rp. 100,000 to Rp. 500,000 per year, which was 13 respondents (76.5%) while the lowest ATP 2 was around Rp.1,000,001-Rp.1,500,000 as many as 4 respondents (23.5%). The class I treatment had the biggest ATP 2, which ranged from Rp.100,000-
Rp.500,000 per year as many as 17 respondents (89.5%) while the lowest ATP 2 ranged from Rp.100,000 to 2 respondents (10.5%). In the class II care, it has the largest ATP 2, which ranged from Rp.1,000,001-Rp.1,500,000, as many as 18 respondents (85.5%), while ATP 2 is the lowest, which is <Rp.100,000, 3 respondents (14.3%). For class III treatment had the biggest ATP 2, which ranged from Rp.1,000.001-Rp.1,500,000 as many as 20 respondents (66.7%) while ATP 2 was the lowest, which was <Rp.100,000 as many as 10 respondents (33.3%).

The highest ATP by the responders are calculated using the ATP formula 2 based on non-essential expenditure which was <Rp.150,000 while the smallest is in the range of Rp.350.001-Rp.450,000. As shown in

Table 3, the average ATP by the respondents were Rp. 211,724. The VIP care class had the largest ATP 2, which ranged from Rp. 2,500,001 to Rp. 3,500,000 per year as many as 12 respondents (70.5%) while the lowest ATP 2 was ranged from Rp.350.001 to Rp.450,000 as many as 2 respondents (11.8%). Based on Table 4, it is found that class I care had the largest ATP 2, which ranged from Rp.2,500,001-Rp.3,500,000 per year as many as 14 respondents (73.7%) while the lowest ATP 2 ranged from <Rp.150,000 for 5 respondents (26.3%). Class II treatment, had the largest ATP 2, which ranged between Rp.2,500,001 to Rp.3,500,000 per year as many as 16 respondents (76.2%) while the lowest ATP 2 ranged from <Rp.150,000 with 5 respondents (23.8%) In class III treatment, ATP 2 ranged from <150,000 as many as 26 respondents (86.7%) while the lowest ATP 2 was Rp.2,500,001-Rp.3,500,000 as many as 4 respondents (13.3%). In Table 5, the results of the study showed that out of 87 respondents there were 30 respondents (34.5%) who said the rates of care in the District Hospital. Pangkep has been affordable, while as many as 57 respondents (65.5%) said the rates of care in the District Hospital. Pangkep is not affordable.

Discussion

ATP and WTP are two factors that play a role in the utilization of medical services, which in turn will affect equity. The calculation of household expenditure is considered to be a quite sensitive method for Indonesia’s economic conditions\(^6\). ATP for health is the actual funds that can be allocated by someone to pay for health\(^7\). In this study, ATP was calculated using 2 approaches, ATP I is calculated based on Equation 1 whereas ATP is calculated using Equation 2.

\[
\text{ATP1} = \frac{\text{Total income} - \text{Total expenditure}}{\text{number of dependents}}
\]

Eq. 1

\[
\text{ATP2} = 5\% \times \text{Total non - food expenditure} \times 5\% \times \text{Total non - food expenditure}
\]

Eq. 2

High income is directly proportional to the higher expectations of getting services that are in line with the costs incurred to obtain this services\(^8\). The results of this study are in line with research conducted by Mudayana\(^4\) which stated that family income affected the patients’ ATP for health services that have been provided. Furthermore if the patient’s income is still lacking, then they assumed that they cannot afford health services.

Besides income factors, the number of families also affects the ability of respondents. Alam et al\(^9\) justified that the number of family members or the number of family dependents, have a positive and significant effect on the amount of household consumption that affects the ability to pay patients. Educational factor indirectly contribute to influence the socio-economic conditions of the family. Thus, this will also affect families in the utilization of health services. Someone who has a higher education will have a better thought in processing information so that it can influence his knowledge in a matter, including in the utilization of health services\(^10\). However, this is not proven
in the research done by Sutrusmi because of the results indicated that there was no correlation between knowledge and willingness to pay for general patients in class III of Pekalongan City Hospital.

The expenditure for meals in this study consisted of respondents’ expenditure in one year in the form groceries and other consumption which were calculated in units of rupiah. The income level of most respondents is high and also the majority of respondents have as many as 5-7 family members which results in a high amount of food expenditure. This study also showed that the type of food expenditure is the highest type of expenditure compared to other expenses. This is very reasonable because the expenditure on food is a basic need that must be fulfilled for human survival.

Non-food expenditure in this study consisted of respondents’ expenditure for one year in the form of expenditure for utilities, clothing, durable materials, taxes, and education. The majority of respondents spend high food costs so that the costs incurred for non-eating purposes are quite low when compared to the costs for food and non-food expenses such as land and building tax payments paid jointly.

In this study the most non-food expenditure issued by respondents is expenditure for utilities. Household needs are daily necessities, while the least non-food expenditure issued by respondents is expenditure to buy durable goods such as kitchenware, jewellery and vehicles because the purchase of durable goods can be done in long term. This is in line with the research conducted by Wuryandari who concluded that the higher the proportion of money spent on food, the lower the household’s purchasing power for other needs. In this study non-essential expenditures consist of expenses for necessities parties and ceremonies, expenditures on cigarettes, alcohol and snacks, expenses for entertainment, recreation and others. On the other hand, the least non-essential expenditure of respondents is for parties and ceremonies, because these occasions are rarely done or/and usually done only once a year. The results of this study is analogous with Situmeang et al’s theory which stated that if a person is able to spend on non-essential goods, then of course the person also would be able to incur costs for essential health services. Handayani et al concluded that the amount of food expenditure is inversely proportional to expenditure for other needs or higher.

WTP of the respondents is high in this variable because the majority of respondents rated the services they received during treatment in the District Hospital. Pangkep is good.

WTP for high health services is usually driven by one’s perception in choosing a class of care based on good quality service. Hence, the hospital needs to pay attention to their wishes and complaints. Moreover, to increase the willingness to pay for the patients, the hospital needs to increase public perception that services in inpatient installations, especially in the VIP class and class I are the best treatment rooms and they will get satisfying services so that the sacrifice of patients in the form of paying tariffs will suit what they receive.

**Conclusion & Recommendations**

Based on the results of the study, it is known that the ability to pay of the inpatients in Pangkep District Hospital is in accordance with the class of care they want. While the willingness to pay for inpatient of Pangkep District General Hospital is high because of the good quality of service. Thus, the hospitals need to provide complete information about the rates before admitting the patients.

Analysis of KarebaBaji Community Role as Peer Educators in Healing Effect of Multi Drug Resistance Tuberculosis at RSUD LabuangBaji Makassar City

Rachmawati1, Muh. Syafar1, Ida Leida1

1Faculty of Public Health, Hasanuddin University, Jl. PerintisKemerdekaan Km. 10, Tamalanrea Indah, Tamalanrea, Kota Makassar, Sulawesi Selatan 90245, Indonesia

Abstract

The aim of this study to analyze role of KarebaBaji community as peer educator in healing effort of tuberculosis (TB) multi drug resistance (MDR) in LabuangBaji Hospital at Makassar City. This study had used qualitative research design with case study approach. This design was used to analyze KarebaBaji community role as peer educator in effort in healing of MDR TB patients. This study was used 3 data collection techniques that were in-depth interview, focus group discussion (FGD) and observation. The informant determination method used in this study was purposive sampling method. The informants were 10 peer educators, 3 MDR tuberculosis (TB) patients, 2 health workers, and 1 expert informant. The study was planned in early March until mid-April 2016. Peer educator understood meaning, transmission, diagnosis, temporary/previous treatment, transmission prevention and MDR TB side effects based on experiences, information from health workers, and training. The motivation in peer educators as sharing experiences, support people for complete the treatment, became friends and help the patient and reduce and transmission prevention. The peer educator skills in mentoring MDR TB patients used persuasive methods. The communication was done through verbally and non-verbally such as support in term of information, treatment discipline and side effect, and emotional support by listens their complaint and self-esteem support in form of motivation, spirit and confidence.

Keywords: KarebaBaji; MDR TB; Peer educator

Introduction

Tuberculosis (TB) is still one of health problem faced on most of countries although control directly observed treatment (DOTs) strategy had been implemented in many countries since 1995. World Health Organization (WHO) had reported estimation 450,000 people suffered Multi Drug Resistance (MDR) TB and 170, 000 people were died. There were 6800 new MDR TB cases had recorded in Indonesia each year and 2% from new cases with 12% from TB treatment were MDR TB cases. Besides, estimated more than 55% of patients with MDR TB had not been diagnosed or not received proper and correct treatment. Meanwhile, 300 000 MDR TB cases were resistance in the drug and half of case from India, China and Russia. There were 1.6 million MDR TB patients worldwide from year 2006 until 2015 where 60% of these patients were from countries with high TB MDR cases.

The resistance of mycobacterial tuberculosis to anti tuberculosis drug is a condition where bacteria were not killed by drug such as Isonicotinic Acid Hydrazide (INH) and Rifamfizin or together with other first-line anti-TB drugs such as ethambutol, streptomycin and pyrazinamide. The resistance drug is “human made phenomenon resulted from insufficient treatment of TB patients or trasmission from TB drug resistance patients”. There were 100% of MDR TB patients experienced side effects, 20% of patients had family members suffered TB diseases, and 60% of patients faced difficulty in treatment. The delay in diagnosis due to lack of knowledge in community about TB had increased transmission risk. The TB patients with previous treatment had experienced greater anti tuberculosis drug resistance (96.2%) than those who recovered tuberculosis (23.1%) and about 40 times anti tuberculosis drug resistance more than those with sufficient treatment. The MDR TB monitoring treatment was not optimal.
due to in cooperative among patients in treatment, health program and health service facilities. The main obstacles in handled MDR TB cases in RSUD LabuangBaji were influenced by medication compliance and accessibility aspects, treatment side effects, economic problems; especially transportation costs.

The peer educator concept is provided motivation and education by patient to patient. The support and information from peers more effective in provided psycho social support to patients in order to be healthier. The peer educator selection method versus other methods such lecture or counseling methods was based on the peer educator concept that accepted by the target.

The MDR TB treatment is more complicated than first-line TB treatment. The main support and information were needed by the patient especially support from former patients in share their experience. Besides, the stigma and discrimination from environment and community had affected the MDR TB recovery. Based on this background, the authors were interested to conduct the study on the role of KarebaBaji community as peer educator in healing effort of MDR TB in LabuangBaji Hospital at Makassar City.

**Methodology**

This study had used qualitative research design with case study approach. This design was used to analyze KarebaBaji community role as peer educator in effort in healing of tuberculosis (TB) multi drug resistance (MDR) patients. This study was conducted in Poly MDR TB RSU LabuangBajiin Makassar city. The study implementation was planned in early March until mid April 2016. The informants were 10 peer educators, 3 tuberculosis (TB) MDR patients, 2 health workers, and 1 expert informant. The informant determination method used in this study was purposive sampling method. This study was used 3 data collection techniques that were in-depth interview, focus group discussion (FGD) and observation.

The questions included in first part are Peer educator knowledge on MDR TB, MDR TB symptoms, MDR TB transmission, MDR TB diagnosis, MDR TB temporary/previous treatment, MDR TB disease transmission prevention and the MDR TB side effects. The second part are about the motivation to be peer educator, Peer educator benefit, Reward received after became peer educators, Risk of transmission again (relaps), Methods in peer educator activities and Training as peer educator. The last part are about the way on Given information, education and motivation, The relationships with health workers and related agencies in government and non-government, The experience as peer educator, The communication way with MDR TB patient, Peer educator effort made communication more effective, Communication barriers, Support toward TB MDR patient and Peer educator support from the environment.

**Result and Discussion**

From in-depth interview with KarebaBaji informants, most of informant understanding about MDR TB was good but still not explained accurately about MDR TB. The peer educators generally understood about MDR TB from experiences as patient and during peer educator training. There were three things in healthy lifestyle such as right knowledge, motivation, and skill. The knowledge also important affected person’s behavior. The former patients or current TB patients provided more knowledge than person that never experienced this disease. The patient had undergone treatment was did good prevention efforts, especially cough prevention and treatment ethic. The knowledge in treatment was important in the treatment successful since patient had experienced long term treatment. Besides, patients that did not knew TB treatment process was among factor in drop out in TB treatment. The lack in socioeconomic condition was factor that the patient did not continuous treatment. The health worker informants were important since their role in given support, motivation and increased patient’s self-esteem.

The study showed KarebaBaji peer educator motivation had reduced MDR TB incidence, prevent transmission, given information, motivated patient for treatment, shared experiences, and supported the patients. The motivation was psychological concept in form of behavior, feeling and word for achieved goal. The peer educators shared their experiences with TB MDR patients. The competence factor influenced persuasive communication successful were motivation, knowledge and skill. The impact has occurred was patient experienced drop out treatment and led to occurrence MDR TB cases. In additions, environment factors were important motivation to support individuals that led behavioral changes. Besides, same language in communication had more intimate relationship and interaction that helped in behavior changed.
In this study, benefits became as peer educator were social activities, made new friends, increased experiences, more confidence, increased knowledge and information sources. The unhygienic environment led to mycobacterium tuberculosis bacteria transmission. The effort in transmission prevention included natural ventilation, mechanical ventilation and ultraviolet light\textsuperscript{21}.

The peer educator method used in this study were good listener without judging, talk from heart to heart, counseling, shared experienced, given motivation and showed pictures. Besides, peer educator also provided their assistance related to knowledge and skill about MDR TB disease. The training is needed for peer educator that never experienced in MDR TB disease\textsuperscript{11}. Based on assumption, peer educator efforts on provided health care to individuals, families and communities. The informant provided motivation based on knowledge gained during training and experience when MDR TB treatment. The peer educator had understood basic skills in helping values. The understanding in self and others need and learned lesson occur in social environment\textsuperscript{22}. The peer groups had influenced each member in behavior for mutual respect, help and responsible\textsuperscript{23}. The role in healing of TB patient was important in treatment effectiveness\textsuperscript{24}.

The communication process is delivery of messages (encode) from communicator through certain channel to beneficiary party caused certain effects. The communication was important in peer educator role in persuaded MDR TB patients to complete treatment. MDR TB patients were often sensitive to their feeling during treatment due drug side effects or discrimination from community. The patients are given chance for spoke out and complaint about problem encountered during MDR TB treatment. The two-way communication with patients needed skill in deal with patient’s complaint\textsuperscript{24}. The ability in communication provided productive input, mutual trust, accepted and appreciated\textsuperscript{25}. The purpose in communication effective was produced desired changes from message recipient. Besides, good environment was required so that patients received all information from health workers\textsuperscript{27}. In additions, communicator had credibility, and good experience and knowledge factor was associated with trust\textsuperscript{28}. The communication barrier was social status that led MDR TB patients embarrassed and hides status in their environment\textsuperscript{29}.

The social support was aid individual received from group around patients by led recipient felt comfortable, love and appreciated. The information and motivation were important to support MDR TB patients in undergone treatment so that not transmitted toward family and environment. The study is obtained peer educator’s support to MDR TB patients were motivational support for recovery, enthusiasm and confidence in treatment, be listener for patient’s complaint and information support in treatment. The motivation support for recovery, spirit and confidence in treatment included self-esteem support. The peer educator support had transformed patient in a positive way\textsuperscript{30}. Besides, patient complained lost job because of long term treatment. There was significant relationship between social support and life quality for tuberculosis patient in Manado\textsuperscript{31}. The self-esteem support such as motivation and spirit from family and health workers was important for MDR TB patients in completed treatment. The support was increased to peer support groups from patient itself, families, partners and public for information\textsuperscript{32}.

**Conclusion**

In conclusions, peer educator understood meaning, transmission, diagnosis, temporary/previous treatment, transmission prevention and MDR TB side effects based on experiences, information from health workers, and training. The motivation in peer educators as sharing experiences, support people for complete the treatment, became friends and help the patient and reduce and transmission prevention. The peer educator skills in mentoring MDR TB patients used persuasive methods. The communication was done through verbally and non-verbally such as support in term of information, treatment discipline and side effect, and emotional support by listened their complaint and self-esteem support in form of motivation, spirit and confidence.

Yellow Passion Fruit Peels (Passiflora edulis F. Flavicarpa Deg.)
Juice effect on the Defecation Pattern of the Patients with Diabetic Mellitus Type 2 in Pinrang Regency

Rahma1, Citrakesumasari1, Stang1
1Faculty of Public Health, Hasanuddin University, Jl. Perintis Kemerdekaan Km. 10, Tamalanrea Indah, Tamalanrea, Kota Makassar, Sulawesi Selatan 90245, Indonesia

Abstract

This research aimed to analyze and assess the acceptability of the juice of yellow passion fruit peels defecation pattern of the patients with DM type 2 in the work areas of Teppo and Salo Health Centers, Pinrang Regency. The research type was a quasi-experiment with the design of non-randomized pre test and post test with control group. The samples were then divided into two groups: the treatment group was given the juice of the yellow passion fruit peels of 250 ml/day and education for 7 days, and the control group was given education only. The defecation patterns were measured before and analyzed using Wilcoxon paired t-test in order to compare the result of the Mann Whitney independent t-test was used to compare the defecation patterns between the treatment group and the control group. The research results revealed that the treatment with the juice of the yellow passion fruit peels in the intervention showed a mean increase of defecation frequency in the treatment group was from 3.7 to 6.3 times, while in the control the difference between the groups was significant (p<0.05). The feces consistency also showed a significant difference within the intervention group before and after the intervention (p<0.05), whereas there was no significant difference within the control group (p>0.05). As for the straining strength, the two groups showed no significant difference before the intervention, but the two groups showed a significant difference after the intervention (p<0.05).

Introduction

Economic progress as a result of development in developing countries as in Indonesia leads to improved lively hood sand patterns of human life especially in big cities1,2. Improving the welfare of the population in developing countries has led to changes in living standards, service to society, and lifestyle changes, from traditional life style to sedentary life style1. This lifestyle is characterized by a lack of physical activity as well as dietary deviations ie intake tends to high energy and low fiber that triggers obesity and implies the onset of degenerative diseases1. Modern lifestyles and high activity levels require individuals to do practical things including food consumption2. According Muchtadi1, changes in lifestyle impact on changes in consumption patterns of society.

Based on data from RISKESDAS4, consumption behavior of vegetables and fruits which is a source of fiber is still relatively low in Indonesia is still less than amount required by Nutritional Sufficiency (AKG), which is at least 25 grams of fiber per day. The results of the study by Nutrition Center of ministry of health showed that the average consumption of Indonesian fiber per day was only 10.5 g or just one third of the recommended fiber intake 25-35 g per day5. The data from RISKESDAS4,show that the proportion of population is predominant≥10 years less eating vegetables and fruits of 93.5% did not show a large difference from the year 2007 amounted to 93.6%. For South Sulawesi Province, the proportion of consuming less fruits and vegetables has increased in 2013 with 96.7% prevalence from the year 2007 amounted to 93.1%4.

One of the degenerative and metabolic diseases that are often associated with low fiber consumption is diabetes mellitus disease. According to World Health Organization (WHO), Indonesia is the second largest country after India that has the most DM patients i.e. 8,426,000 people in Southeast Asia, and is expected to increase to 21,257,000 by 2030.

High-fiber diet has gained great attention in recent years due to its association with an increased incidence of some metabolic disorders such as hypertension, diabetes, obesity, dyslipidemia, heart disease and colon cancer. Fiber serves to slow digestion, filling the stomach and slowing hunger. The fiber diet can be used in the treatment and prevention of many diseases such as obesity, heart disease, type 2 DM, colonic diverticulosis, and constipation.

Passion fruit waste processing in Indonesia is generally processed as animal feed. Meanwhile, in some other countries have utilized yellow passion fruit bark waste (Passiflorae dululis f. Flavicarpa deg.) as a form of intervention to enhance the body metabolism. Research conducted by de Souza showed 30 gr / day of passion fruit shoots for two months in type 2 diabetics to help lower insulin resistance and showed significant differences in fasting blood glucose during the treatment period.

Yellow passion fruit has a fiber content of 17.4 grams in 30 grams for total fiber, 6.3 grams of water soluble fiber, and 11.1 grams of water insoluble fiber. The content of yellow passion fruit leather fiber is higher than other vegetables and fruits per 100 grams for total fiber, such as melinjo contains 21 grams, pare contains 8.4 grams, wine contains 6 grams, red apples contain 1.49 grams, star fruit contains 9.31 grams, guava contains 22.50 grams, passion fruit contains 19.95 grams, mangosteen contains 20.40 grams, pear 11.05 grams, papaya contains 4.75 grams, and avocado contains 24.8 grams. Juice is one form of processed food that is easy to consume and is spent because it is in liquid form. Consistency of juice in the form of liquid causes cellulose cell walls of the fruit to be destroyed and dissolved so easily digested by the stomach and gastrointestinal tract.

Currently there is no home industry or company in Indonesia that produces juice by using passion fruit skin. For that passion fruit juice will produce drinks rich in fiber. This juice will be one of the beverages that are rich in health benefits that can increase daily fiber intake and are favored by the community. Based on the above description, the researchers are interested to examine the relationship of yellow passion fruit juice (Passiflorae dululis f. Flavicarpa deg.) on the pattern of defecation in DM patients in Puskesmas in Pinrang District.

**Methodology**

**Research Type**

The type of research used in this study is an experimental study with a quasi-experimental research design (Quasy Experiment). The research design model is a non-randomized group pre-post test with control group design.

**Location and Time of Study**

The preliminary study was conducted during May to July 2015. Intervention of Kunisakunisa skin juice product was conducted in August 2015. The research site for proximate test, yellow passion fruit skin test is done at Integrated Laboratory of Hasanuddin University Public Health Faculty and Health Laboratory of South Sulawesi. For the manufacture of yellow passion fruit juice and organoleptic done in the Laboratory of Nutrition Culinary Faculty of Public Health Hasanuddin University. Intervention of yellow passion fruit juice was performed on DM patients in Pinrang District.

**Population and Sample Research**

As population in this research is all patient of DM which treatment in PKM one last year. The sample of this research is the respondents who were treated consisting of adults with a defect pattern of less than 7x a week. So, the minimum sample size is 36 people.

**Materials and Implementation**

The material in this research is the mesocarp (white / albedo) part of yellow passion planted in MalakajiGowa regency of South Sulawesi. The material used in this research is yellow passion fruit taken directly from passion fruit factory in Makassar City and still fresh, not dry and decaying. The chemicals used are 95% ethanol, N2 gas, refined filter paper, ethanol pro analysis, 1.25% H2SO4, 3.25% NaOH, aquadest, 1% HCl, concentrated HCl, 95% alcohol. Each respondent who entered the intervention group was given yellow passion fruit juice
as much as 250 ml for 7 days, and given education about DM conducted in counseling / individual. Education is done at the time of taking blood and at recall 24 hours.

Respondents were given a juice drink control card to be filled each time the respondent drank a yellow passion fruit juice containing the day and date of drinking juice and the amount of juice taken. Researchers distributed juice between 14:00 to 16:00 and watching / waiting for the respondent to drink juice until it runs out. Each respondent who entered the control group was given education about DM done at the time of taking blood and at recall 24 hours. Education is done individually / counseling. In addition 24-hour recall was conducted for 3 days determined on certain days i.e. 2 days during the intervention (holidays, working days) and 1 day after intervention to know the description of food intake, both the treatment group and the control group.

Change of Average Intake before and After Intervention

The results of the study in Table 2 showed that the mean intake of nutrients consisting of energy, carbohydrate, fat, protein decreased after intervention, but statistically showed an insignificant decrease in mean p> 0.05 in fat and protein. While on energy and carbohydrate have a significant decrease that is with value of p <0.05. For fiber increased intake after intervention, statistic showed significant improvement with indigo p <0.05.

White water intake in the intervention group experienced an average change in intake before and interventions but statistically did not show significant improvement with p> 0.317. In the control group, the average change in energy intake, carbohydrate and fiber decreased before and after intervention, but statistically did not show a significant decrease with p> 0.05. While the intake of fat, protein and water show the average change in the increase before and after intervention. Statistically, however, it did not show a significant increase due to the value of p> 0.05.

Ethical Considerations: The study was conducted with the permission of the Ethical Committee of Faculty of Medicine UNHAS No. Register UH 15060473.

Result and Discussion

Differences of Respondents Intervention between Groups before Intervention

The results In Table 1 showed that the nutritional intake and water of the respondents between the intervention group and the control group did not show significant differences with p> 0.05.

Picture of Elimination / Frequency of Defecation Patterns, Straining and Consistency of Feces

The results of the study in Table 3 showed that the frequency distribution of respondent defecation before intervention in the intervention group has defect frequency 2-5 times in seven days i.e. 5% (2 times), 40% (3 times), 35% (4 times) and 20% (5 times). In the control group the frequency distribution of defecation before the intervention had defect frequency 3-5 times in seven days i.e. 35% (3 times), 40% (4 times) and 20% (5 times). In the control group the frequency distribution of defecation before the intervention had defect frequency 3-5 times in seven days i.e. 35% (3 times), 40% (4 times) and 20% (5 times). The frequency distribution of defecation after the intervention shows the most frequent change of frequency of defects is the change in frequency to be 7 times a week that is 60% (7 times). While in the control group the most frequent defect frequency picture is 4 times a week 40%. The results showed that the strength of respondents before intervention in the control and intervention groups showed the same percentage of 20% strong straining and 80% who did not push. While the percentage of straining strength after intervention showed in the intervention group experiencing an improvement change that is 100% of respondents experiencing no push. While in the control group showed no change in strength pushing before and after intervention done. Result shows the consistency of the feces before intervention in the intervention group by 40% hard and 60% soft. After intervention, the consistency of feses presentation in the intervention group was changed by 0% hard, 85% soft and 15% liquid. While in the control group consistency of feses before and after intervention did not show percentage change that is 20% hard and 80% soft.

Results of Analysis of Difference in Frequency of Respondents Intervention and Control Before and After Intervention

The results of this study showed that statistically the frequency of defecation in the intervention group before and after the intervention showed a significant difference with the value of \( p < 0.05 \). The average frequency of defecation of respondents in the intervention group increased from 3.7 times to 6.4 times in seven days. While in the control group statistically also showed a significant difference in frequency of defecation before and after intervention with \( p < 0.05 \). However, the increase in the frequency of defecation in the control group for seven days was lower than that of the intervention group, which increased 3.90 times to 4.35 times a week. The frequency of defecation before intervention between the control group and the statistical intervention showed no difference \( p > 0.05 \) whereas after intervention the frequency of defecation between the control group and the intervention showed a significant difference with the value of \( p < 0.05 \). This suggests that the education of the control group influences the frequency of defecation of the control group.

Result of Strength Analysis between Respondents Intervention and Control Group

The results of the study showed that the strength of respondents before and after intervention and control did not show significant changes with the value of \( p > 0.05 \). The strength of push between the intervention group and the control group before the statistical intervention also did not show significant difference with the value of \( p > 0.05 \), while the strength of push between the control group and intervention after the intervention was done statistically showed a significant difference with the value of \( p < 0.05 \).

Result of Strength Analysis between Respondents Intervention and Control Group

The results of the study showed that the consistency of hard feces in the intervention group as much as 8 respondents and the flabby as much as 12 respondents but after the intervention of respondents who have hard feces consistency (decreased) and the softening increased to 17 respondents as well as the consistency of the liquid feces 3 respondents. Based on statistical test of change of consistency of feces in intervention group showed significant change before and after intervention with \( p < 0.05 \). While the control group consistency of feces of respondents did not show significant changes before and after intervention with \( p > 0.05 \).

Overall Discussion

The juice in this study uses a yellow Passion Fruit Passifloraeedulis Flavicarpa Degener taken from MalakajiGowa. Based on the Decree of Minister of Agriculture No.583 / Kpts / Tp.240 / 7/1994 this yellow leather passion fruit is one of the leading varieties plant in Malino, Gowa Sulawesi Selatan.\(^{14}\) According to Simmakyand Jaanaki\(^{15}\), passiflora passion fruit is an exotic fruit with a distinctive flavor and grows in the tropics and sub tropics.

Characteristics of respondents in this study were women with type 2 diabetes with the distribution of age 36-65 years. Based on a study conducted by Maleki\(^{16}\), the prevalence of constipation was higher in diabetic patients than those who did not have diabetes. Result of this analysis has indicated that yellow passion fruit juice can increase the frequency of defecation of DM patients. According to Gropper and Smith\(^{17}\), the consumption of soluble and insoluble fiber can retain water in the intestine thus increasing the volume of the stool and reducing the transit time of food waste in the intestine which can increase the frequency of defecation.

Conclusion

The discovery of yellow passion fruit juice can be one alternative drink that can increase daily fiber intake of patients with type 2 diabetes. Yellow passion fruit juice with 250 ml serving sizes can improve the pattern of defecation of patients with type 2 diabetes, which increases the average frequency of defecation of 3.7 times to 6.3 times a week and improves the consistency of the feces from hard to soft and fluid. The yellow passion fruit juice did not show any effect on the straining force of people with type 2 diabetes.

Acknowledgment: The author would like to extend the appreciation to all the participants from Puskesmas in Pinrang District as well as Faculty of Public Health, Hasanuddin University for unconditionally support.

The Giving of Exclusive Breastfeeding to Moronene Etnics of Bombana Southeast Sulawesi

Ratnawati1, Indar1, Burhanuddin Bahar1

1Faculty of Public Health, Hasanuddin University, Jl. Perintis Kemerdekaan Km. 10, Tamalanrea Indah, Tamalanrea, Kota Makassar, Sulawesi Selatan 90245, Indonesia

Abstract

Breast milk is the best food for babies up to 6 months old. The aim of this work is to examine various factors affecting the giving of exclusive breastfeeding to Moronene Etnics of Bombana, Southeast Sulawesi. The research was a quantitative study with survey analytic design and cross sectional approach design. The sample consisted of 144 samples of mother having infants above 6 months old. They were selected using proportional random sampling technique and they represent all villages in the work area of Rumbia Health Center. The primary data were collected through interview and secondary data were obtained through library study. The results of the research indicate that exclusive breastfeeding is very low (16.0%). There is a correlation between knowledge, social support and exclusive breastfeeding (p=0.000). Socio-cultural factor has the most dominant effect on exclusive breastfeeding (p=0.000, B=3.841), while socio-demographical factor of mothers (mother’s age and parity) does not have a significant correlation with exclusive breastfeeding.

Keywords: Bombana; breastfeeding; moronere ethnics; socio-cultural

Introduction

Babies are one of the groups that are susceptible to health problems and disease attacks. Infants and toddlers’ health should be monitored to ensure their health is always at optimal levels. Infant health care is one of several indicators that can be a measure of the success of efforts to improve the health of infants and toddlers. Infant care is aimed at infants aged 29 days to 11 months by providing health services in accordance with standards by health personnel with health clinical competence (doctors, midwives, and nurses), counseling of infant health care and exclusive breastfeeding, complementary feeding and others. The infant formula category begins to receive breast milk according to Riskesdas 2013 is less than 1 hour (Initiation of Early Breastfeeding / IMD), between 1 to 6 hours, 7 to 23 hours, 24 to 47 hours and equal to or more than 47 hours1.

The results of research Karen M. Edmond2 said early initiation of breastfed infants can reduce neonatal mortality. All causes of neonatal mortality can be reduced by 16.3% if all infants breastfeed on the first day of birth and by 22.3% if initiation takes place within the first hour2. The first time to get breastmilk soon after birth significantly improves the baby’s chances of survival. If the baby starts breastfeeding within 1 hour of birth, 22% of babies who die within the first 28 days (equivalent to about one million newborns each year in the world) can be prevented. If the breastfeeding process begins within the first day, only 16% of babies can be saved2. Although the proportion of infants who had received high milk was 95.7%, but the proportion of exclusive breastfeeding in infants 0-6 months was still low at 32.4%, as well as the proportion of breast-fed infants around 1 hours after birth is 43.9%3. Not giving colostrum is one of the most commonly detrimental habits. Breastfeeding may reduce neonatal mortality by 55-87%4.

The Government of Indonesia supports the WHO and UNICEF policies that recommend early breastfeeding initiation as “life-saving” measures, since early breastfeeding initiation can save 22% of babies who die before the age of one month. So it is expected all health workers in all levels of health services can socialize the program. The result of Riskesdas states that the percentage of the process begins to get milk less than an hour (early breastfeeding initiation) in children aged
0-23 months in Indonesia in 2013 amounted to 34.5%. The percentage of process started to get ASI between 1-6 hours by 35.2%, the percentage of process started getting breast milk between 7-23 hours by 3.7%, while the percentage of process started getting milk between 24-47 hours by 13.0% and percentage the process began to get milk more than 47 hours by 13.7%. The percentage of the process of getting breastfed less than an hour (early initiation of breast feeding) was highest in West Nusa Tenggara (52.9%) followed by South Sulawesi (44.9%) and West Sumatera (44.2%). Meanwhile, the lowest percentage of early initiation of breastfeeding in West Papua province was 21.7%, Southeast Sulawesi province 33.2% below the national rate (34.5%)^5.

Breastfeeding Global World Health Organization report (WHO) in 2012 (De Onis et al.; Cai et al.) stated that the target of achieving global Exclusive Breastfeeding coverage is at least 50% by 2025, factors contributing to the low achievement of exclusive breast milk coverage of socio-cultural, health systems and political policies. These factors include public confidence that babies need food / drinks other than breastmilk, the practice of health services that do not support Exclusive breastfeeding programs, knowledge of health workers and the community about exclusive breastfeeding, lack of policy support governing maternal support efforts in exclusive breastfeeding^7.

Several other studies on factors affecting the success of exclusive breastfeeding in infants, among others, research conducted by Afifah^8 found that the mother’s knowledge about Exclusive Breast Milk can be obtained from various sources of information. The low knowledge of mothers on Exclusive breast milk, at the same time they have local cultural knowledge of food ideology for babies. This local cultural knowledge can hinder the practice of exclusive breastfeeding. Satino’s^9 research results show that age, education, occupational, knowledge, behavioral and environmental factors influence exclusive breastfeeding Another study conducted by Suratno^10, in Padang that husband support has an influence on Exclusive breastfeeding.

Hector^11 work has demonstrates greater significance of social, cultural and environmental factors in influencing the mother’s decision to breastfeed, how long breastfeeding and exclusive breast feeding. Socio-cultural and environmental factors contribute greatly to health problems in identifying factors that affect exclusive breastfeeding. Thus, The general objective of this study was to examine the various factors affecting the exclusive breastfeeding of Moronene Bombana Southeast Sulawesi.

**Methodology**

**Research Type**

The research method used is quantitative research method with analytical survey research design aims to describe the phenomenon found in the form of risk factors, effects or results and then search the relationship between variables^12. The approach used in this study is cross sectional analytic study to identify whether or not there is relationship between independent variables, influencing factors that are social culture, social support, social characteristics of mother’s demography (mother age and parity), knowledge with dependent variable of giving Exclusive Breast Milk^13.

**Location and Time**

The selection of case study sites was conducted in the working area of Rumbia Health Center, Bombana Regency, Southeast Sulawesi Province. This research was done from in January until May 2016.

**Population and sample**

The populations in this study were all mothers who had babies over 6 months in Bombana District Southeast Sulawesi Province. Target population is the number of mothers who have babies over 6 months in Rumbia Health Center working area of 231 mothers. Sample in this research is part of mother who have baby over 6 month in working area of Rumbia Health Center of Bombana Regency Southeast Sulawesi Province at the time of research. So the number of samples required in this study is as many as 144 people.

**Data Collection**

Primary data were collected using a research questionnaire containing information on respondents’ identities (name, age, gender, education, occupation), socio-cultural, social support, social characteristics of maternal and maternal demographics and mother’s knowledge of Exclusive breastfeeding. Qualitative data was obtained through in-depth interviews to obtain additional information supporting questions in the questionnaire. Secondary data were obtained from health
profiles of Rumbia Puskesmas, Exclusive Breastfeeding coverage report of Rumbia Puskesmas and Exclusive Breastmilk coverage report of Bombana district, general data of BPS Bombana district.

Data Analysis

The data obtained was processed using SPSS version 20.0. Bivariate analysis was done by using chi-square analysis to see the relationship between dependent and independent variables. Hypothesis test on each analysis result using 95% confidence level ($\alpha = 0.05$), hypothesis accepted if $p < 0.05$. Multivariate analysis was done to know together independent variable related to dependent variable or see effect of independent variable to dependent variable and know the most significant variable to Exclusive breastfeeding. The analysis model used is the analysis of Multiple Logistic Regression (logistic regression), where the dependent variable is a dichotomous / binary category.

Result and Discussion

Bivariate Analysis

Socio-cultural relationship with Exclusive breastfeeding

Table 1 shows that respondents who did not give exclusive breastfeeding stated that there were socio-cultural factors that impedes exclusive breastfeeding, ie 90 respondents (96.8%) than those who stated that there are socio-cultural factors that inhibit exclusive breastfeeding of 31 respondents (60.8 %). The respondents who gave exclusive breastfeeding stated that there were no socio-cultural factors that prevented the exclusive breast feeding of 20 respondents (39.2%) compared to the stated social-cultural factor which inhibited Exclusive Breastfeeding 3 respondents (3.2%). Chi square test results obtained $p$ value = 0.00 ($p < 0.05$) which means Ho rejected. This shows that there is a social-cultural relationship with the status of Exclusive breastfeeding.

b) Age group relationship with Exclusive breastfeeding

The age group relationship with Exclusive breastfeeding can be seen in the Table 2 whereby results shows that respondents who did not give Exclusive Breast Milk had more age group less than 25 years old ie 19 respondents (86.4%) than age group more than or equal to 25 years that is 102 respondents (83.6%). The respondents who gave exclusive breastfeeding had more age group more than or equal to 25 years ie 20 respondents (16.4%) than the age group less than 25 years ie 3 respondents (13.6%). Fisher’s exact test results obtained $p$ value = 1.000 ($p > 0.05$) which means Ho accepted. This indicates that there is no relationship between maternal age and exclusive breastfeeding status. This means that there is no difference between ages less than 25 years and more or equal to 25 years on Exclusive breastfeeding.

Parity relationship with Exclusive breastfeeding

Parity relationship with Exclusive breastfeeding can be seen in Table 3 whereby results shows that respondents who do not give Exclusive Breast Milk have multiparent parity that is 78 respondent (84.8%) compared to primipara parity that is 43 respondent (82.7%). The respondents who gave exclusive breastfeeding had more primipara parity with 9 respondents (17.3%) than the multiparous parity of 14 respondents (15.2%). Chi square test results obtained p value = 0.742 (p> 0.05) which means Ho accepted. This shows that there is no parity relationship with the status of exclusive breastfeeding.

Social support relationship with Exclusive breastfeeding

The relationship of social support with exclusive breastfeeding can be seen in Table 4 whereby the decision shows that respondents who do not give Exclusive Breast Feed say less social support in exclusive breastfeeding is 70 respondents (94.6%) than those who stated enough social support in exclusive breastfeeding is 51 respondents (72.9%). Respondents who exclusively breastfed, were more likely to express sufficient social support in the exclusive breastfeeding of 19 respondents (27.1%) than those who expressed less social support in exclusive breastfeeding, ie 4 respondents (5.4%). Chi square test results obtained p value = 0.00 (p <0.05) which means Ho rejected. This suggests that there is a social support relationship with the status of exclusive breastfeeding. Chi square test results obtained p value = 0.00 (p <0.05) which means Ho rejected. This suggests that there is a social support relationship with the status of exclusive breastfeeding.

e) Knowledge relationship with Exclusive breastfeeding

Knowledge relation with exclusive breastfeeding can be seen in table 5. The result shows that respondents who do not give exclusive breastfeeding have less knowledge that is 85 respondents (95.5%) than those having enough knowledge that is 36 respondent (65.5%). The respondents who gave exclusive breastfeeding had better knowledge of 19 respondents (34.5%) than those with less knowledge of 4 respondents (4.5%). Chi square test results obtained p value = 0.00 (p <0.05) which means Ho rejected. This suggests that there is a relationship of knowledge to the status of exclusive breastfeeding.

Multivariate Analysis

Multivariate analysis is an analysis involving more than two independent variables with the dependent variable. Multivariate analysis aims to determine the most dominant variables associated with exclusive breastfeeding status. The requirement to participate in multivariate analysis is the variable having p value at bivariate test (chi square test) <0.250. The result of chi square analysis shows that socio-cultural variables, social support and knowledge have p value <0.250. Table 6 shows the results of statistical tests with multiple logistic regression on the status of exclusive breastfeeding. Of the three variables tested by multiple logistic regression, only two variables remained in contact with exclusive breastfeeding status ie socio-cultural and social support. Of these two variables most closely related to exclusive breastfeeding status are socio-cultural values B = 3.84 and Wald = 20.15.

Overall Discussion

This study is in line with research conducted Afifah\(^8\) found that although mothers have knowledge about the importance of breastfeeding, they also have local cultural knowledge of food ideology for infants. This local cultural knowledge may be called an obstacle to the practice of exclusive breastfeeding. Research by Kehler et al\(^{14}\). found that maternal age had an effect on exclusive breastfeeding. Mothers aged ≥25 years tend to breastfeed to their babies, because they have better emotional and mental health maturity than younger mothers <25. Research by Kuan et al\(^{15}\). shows an aged mother <25 years has a 2.3 times greater chance of breastfeed failure exclusive compared to mothers aged>25 years.

The same study by Fahriani et al\(^{16}\). found that the absence of a relationship between parity and exclusive breastfeeding is due to the number of primiparous mothers comparable to multiparous mothers in terms of exclusive breastfeeding. Research by Al- Sahab et al\(^{17}\). found the multiparous mother group was 2.6 times more likely to exclusively breastfeed than primiparas. Study by Rosane et al\(^{18}\). found successful practices of exclusive breastfeeding 1.5 times greater when supported by husbands. Similar findings of research at Sukarama District Health Center Tasmalakya District, exclusive breastfeeding 2.9 outcomes in maternal groups supported by husband\(^{19}\). This study is similar to the results of research Wulandari et al\(^{20}\). which states that there is a significant relationship between knowledge variables with exclusive breastfeeding variable.

Conclusion

Based on the result of research, it can be concluded that exclusive breastfeeding by mothers on Morone tribe in the work area of Rumbia Health Center is still very low. In addition, there is influence of a socio-cultural, social support and knowledge on exclusive breastfeeding on Exclusive Breastfeeding of Moronene in the work area of Rumbia Health Center. However, there is no maternal social influence (mother’s age and parity) on Exclusive Breastfeeding of Moronene in the work area of Rumbia Health Center. Also, Socio-cultural factors are the most influential variable on Exclusive Breastfeeding on Moronene Tribe in the work area of Rumbia Puskesmas.

The Effects of Soybean Chocolate Drink Treatment on the Calcium Levels in Patients with Pulmonary Tuberculosis

Rezky Amelia¹, Nurpudji A. Taslim¹, Citrakesumasari¹

¹Faculty of Public Health, Hasanuddin University, Jl. Perintis Kemerdekaan Km. 10, Tamalanrea Indah, Tamalanrea, Kota Makassar, Sulawesi Selatan 90245, Indonesia

Abstract

The aim of study is to analyze effect of soybean chocolate drinks on calcium level in blood of patients with pulmonary tuberculosis in Makassar. The study was used quasi-experiment with pre-post test (a Quasi-Experimental Design with pre-posttest), which was conducted on 34 patients with pulmonary tuberculosis. The patients were divided into two groups and each group consisted of 17 patients. The intervention group received soybean chocolate drinks of 100 grams/day with nutrient education, and control group only received nutrient education for 30 days. The data of the food intakes and the food recalls of 24 hours were collected during the intervention. There occurred an increase in the calcium intakes by both intervention and control group of the patients with pulmonary tuberculosis. Meanwhile, calcium level in the intervention group had experienced an increase. The statistical analysis of the comparison in calcium levels before and after intervention in both groups was insignificant (p=0.169). The comparison between calcium intakes before and after intervention in both groups was significant (p=0.000). Thus, the treatment with soybean chocolate drinks had no effect on the calcium levels in the patients of pulmonary tuberculosis.

Keywords: Calcium level; Pulmonary tuberculosis; Soybean chocolate drinks.

Introduction

The pulmonary tuberculosis (TB) was an acute or chronic disease that affected the respiratory system. The disease was recorded increased every year¹. There were 9.4 million cases and 1.7 million deaths globally in 2009. The most deaths were recorded in developing countries with limited resources. Besides, Africa continent was recorded double pulmonary TB cases compared to Southeast Asia, 35 per 100,000 populations. In 2011, prevalence in TB with positive bladder tumor antigen (BTA) was 289 per 100,000 population. The pulmonary TB cases rate was 189 per 100,000 population and mortality rate were 27 per 100,000 population². In some studies, pulmonary TB disease was correlated with hypocalcemia. The pulmonary TB patients showed low level than reference in Japan³. Furthermore, the calcium level in blood in pulmonary tuberculosis patient was lower than control group³. The pulmonary TB patients had low calcium level had high risk in death⁴. In addition, Rohini⁴ found that low in calcium level in the pulmonary TB patient’s blood affected calcium availability for phagolysosome maturation. The calcium signaling was required to increased T cell proliferation and immunologic synapse stability⁵.

The calcium plays an important role in phagocytosis process.⁶ The calcium signaling also affected regulation of T cell activation, tolerance and homeostasis⁷. The high protein food such as soy improved nutritional status in pulmonary TB patients⁸. Besides, soy had functioned to repair cells, tissues, immune system and acted as antioxidants⁹. The soybean is very suitable processed into beverages because soy protein had an amino acid structure. The soy and chocolate combination had increased calcium intake in pulmonary tuberculosis patients. The author had conducted study to analyze the effect of soybean chocolate drinks on the calcium level in blood of the patients with pulmonary tuberculosis in Makassar.

Methodology

Study Type

This study was a clinical trial study or interventional study to determine effect of soy chocolate drink in
calcium level in patients with pulmonary tuberculosis. The anthropometric status was taken on pre and post study. The study subject were divided into two groups included intervention and control groups. The intervention group had received soy chocolate drink and education, while control group only received education.

**Location and Time**

This study was conducted from February to June 2014 at Community Center for Lung Health Makassar city.

**Population and Sample**

The population in this study was pulmonary tuberculosis patients in Community Centre for lung Health Makassar city. The samples sizes were 34 pulmonary tuberculosis patients. The samples were selected by purposive sampling method. The inclusion criteria for this study as below:

i) Male and female aged between 18 year and 60 years;

ii) The patients with pulmonary tuberculosis;

iii) Willing to participate in this study.

**Data Analysis**

The data was analyzed by using SPSS program, while food consumption data is processed with Nutrisurvey computer program. The statistical test is using to observe changes in calcium levels pre and post intervention by paired T-test. The difference of calcium level between intervention and control group that analyzed by independent T test.

**Result and Discussion**

**Bivariate Analysis**

Table 1 and Table 2 showed mean of energy intake, carbohydrate, protein, fat and calcium before and after intervention in both groups. Both groups had experienced increment in energy, protein, fat, carbohydrate and calcium. The energy was observed increased from 1,308.0 kcal to 2,119.50 kcal in the intervention group, while energy in control group increased from 1,238.0 kcal to 2,014.62 kcal. In intervention group, protein had increased from 42.72 gram to 97.20 gram and control ground had observed increment in protein from 42.70 gram to 68.72 gram. Meanwhile, fat intake had increased from 24.30 gram to 56.20 gram in intervention group, while fat intake increased from 20.80 gram to 45.37 gram in control group. The carbohydrate intake increased from 224.02 gram to 280.02 gram in intervention group in intervention group while, carbohydrate intake increased from 216.60 gram to 328.50 gram in control group. The increment had observed in calcium intake among intervention group from 239.5 mg to 696.16 mg and calcium intake increased from 137.5 mg to 288.85 mg in control group. The consumption of nutrients was increased after intervention and showed significant (p=0.000). The carbohydrate, protein and calcium intake showed significant value.

Overall Discussion

The calcium is controlled several processes in body’s immune cells, included chemotaxis, adhesion, and secretion of pro and anti-inflammatory cytokines. The calcium level in the blood had affect in phagocytosis process\(^7\). Besides that, the calcium was functioned in bone and tooth formation, catalyzed biological reactions and muscle contraction. The combination of soy and chocolate in form of drinks contained 440 mg/100 grams per day for 30 days had increased calcium intake in pulmonary tuberculosis patients. Based on this study, calcium was increased obviously due to calcium rich food consumption in the intervention group. Meanwhile, the control group also observed increment in calcium level due to treatment and nutritional education.

There was no significant change in calcium levels in both intervention and control group (p=0.169). The soy chocolate drinks were not affected calcium level in blood of pulmonary tuberculosis patients. The study was conducted by Wejse\(^11\) showed there were no increment in vitamin D and calcium level in blood of pulmonary tuberculosis patients. The lower calcium levels increased osteoporosis occurrence risk\(^12\). The pulmonary TB patient experienced low vitamin D caused bone demineralization and resulted in decrement in bone mineral density (BMD). The study conducted by Riancho\(^13\) showed 27% lower in 25-hydroxyvitamin D in pulmonary tuberculosis patients. In addition, antituberculous treatment and vitamin D supplementation had improved clinical result in TB patients\(^14\).

Conclusion

In conclusions, an increase in calcium intakes by both intervention and control group of patients with pulmonary tuberculosis. Meanwhile, calcium level in the intervention group had experienced an increment too. The statistical analysis of comparison in calcium levels before and after intervention in both groups was insignificant (p=0.169). The comparison between calcium intakes before and after intervention in both groups was significant (p=0.000). Thus, treatment with soybean chocolate drinks had no effect on the calcium levels in the patients of pulmonary tuberculosis.

Personal Hygiene among University Students in Hasanuddin University Hostel

Rinda Limbong1, Indra Fajarwati Ibnu1, Muh Arsyad Rahman1
1Faculty of Public Health, Hasanuddin University, Jl. Perintis Kemerdekaan Km. 10, Tamalanrea Indah, Tamalanrea, Kota Makassar, Sulawesi Selatan 90245, Indonesia

Abstract

The aim of this study is to obtain information on personal hygiene among university students in hostel of Hasanuddin University. The study type was qualitative research with phenomenology approach. The informants were selected by using purposive sampling of students living in university hostel. The number of informants was 16 students and a head of hostel. The data was collected through in-depth interview, observation and documentation. The data was analysed by using content analysis and represented in narrative form. The results found all informants understood the purpose of personal hygiene and have own self-care to maintain health for disease prevention despite some actions deviate from informant’s knowledge level. The lead factors in personal hygiene included availability of facilities and infrastructure and individual factors. The students should maintain personal hygiene and environment for their good health. The coordination between university management and hostel is necessary in improving hostel facilities and infrastructure for students to maintain their personal hygiene.

Keywords: hostel; personal hygiene; qualitative research; university students;

Introduction

The personal hygiene is one of most important way in infection control activities1. An estimation 2.5 billion people had lack of sanitation facilities and living with poor personal hygiene in worldwide2. In global, 5.3% of mortalities and 6.8% of disability due to poor hygiene, sanitation and unhygienic water3. Personal hygiene is practice in body cleanliness maintenance4. The personal hygiene helped in maintain good health. Personal hygiene involved several good habits such as body shower, brushing teeth and washing hand to keep away the bacteria and virus from bodies5. The poor hygiene caused skin disease, diarrhea, dental diseases, worm infestations4,6,7,8.

Poor knowledge, attitude and practice had contributed in lack of personal hygiene. Based on initial in-depth interview, several students found lack of availability of clean water in the hostel. Besides, students also experienced in skin problem and ulcers. Lack of personal hygiene behavior among students due to insufficient of facilities and infrastructure in the university hostel. The aim of this study is to obtain information on personal hygiene among university students in hostel of Hasanuddin University.

Methodology

Study Type: This study was used qualitative research with phenomenology approach. The techniques used were observation and in-depth interviews.

Location and Time: This study was conducted from March 2016 to April, 2016 in Hasanuddin University student’s hostel.

Study Informant: The informants are 16 students and head of hostel by using purposive sampling method.

Data Analysis: The primary data was obtained by in-depth interviews and observation. Meanwhile, secondary data was obtained from university hostel management about number of hostel residents and availability of facilities and infrastructure in Hasanuddin University student hostel.
Result and Discussion

Based on in-depth interviews, the informants understanding about personal hygiene such as body shower, brushing teeth, hand washing, hair washing, foot washing and changing clothes. The purpose of personal hygiene is to maintain health and disease prevention. Besides, personal hygiene purpose is part of religious obligations, comfortable and body care. The informants suggested bath twice and three times per day and take bath to prevent germs and bacteria that caused illness, increase the comfortable and cleanliness. Besides, knowledge of informants about oral and dental hygiene is to avoid toothache, bad breath, feel comfortable and avoid microorganism such as bacteria and germs lead in teeth damage.

The informants suggested washing hand with soap has been done before and after meals and touching dirty objects. Meanwhile, informants mentioned drying clothes under sun exposure so that dry quickly, odorless and protected from germs and bacteria. Based on in-depth interview, some informants claimed bedsheets replaced two to four times per month or changing when felt uncomfortable. Most informants revealed changing clothes after bath. Meanwhile, some informants would change clothes when felt uncomfortable and did not wear repeated clothes. In additions, all informants found lending bath tools to others lead to skin diseases and diarrhea. An informant claimed bath tools are privacy thing and not encouraged to lend to other persons. Based on knowledge on nail hygiene, most informants suggested regular nail cutting had maintained nail hygiene and prevent diseases such as diarrhea and abdominal pain. Besides, informants understood about importance of maintain genital hygiene to prevent infection such as vaginal discharge, itching and odor which affected comfortable. The informants understood water reservoir container need regularly cleaning to prevent skin disease and mosquito larvae lead to dengue fever. Most informants suggested throw daily garbage in the trash. In additions, some informants revealed never lend their bath tools to others. Based on Table 3, there were many facilities and infrastructure need to be improved and needed addition of cleaners for maintaining cleanliness of hostel.

The result found all informants understood personal hygiene purpose is to maintain body health in disease prevention. In additions, personal hygiene is religion obligation. Based on in-depth interview, most informants revealed had bath for two to three times per day and depend on their daily activity. The clothes are drying under sun exposure so that odourless and protected from various germs and bacteria. Meanwhile, informants changed clothes and not wear repeatedly. In University of Sumatera Utara, most of students had good knowledge in changing clothes with twice a day or after bath. Borrowing and lending bath tools also impacted skin diseases such as pruritus, itching and tinea nigra. The bedsheets had changed by two to four times per month. Some informants also suggested bedsheets replaced when bedsheet was dirty. Based on this study, informants had maintained hair and scalp hygiene which lead to uncomfortable.

A study found hair hygiene is an effort to keep hair and scalp hygiene by washing hair at least twice a
week in University of Sumatera Utara\textsuperscript{10}. Nail hygiene was cutting and cleaned caused diseases such as diarrhoea and abdominal pain. The hygiene practices are most influences by individual’s awareness, attitude and knowledge\textsuperscript{11}. The water reservoir containers had cleaned when the containers were dirty and empty. The informants had good actions toward bath habits. The sharing bath tools also lead to skin disease such as itching. In additions, the clothes had changed regularly so that to prevent skin disease. Most informants are hanging clothes in the room without sun exposure. The humid clothes lead to skin disease and odor. Meanwhile, the informants washed hair once to three times per week and regularly washing hand by using soap. The hand is one channel in germs transmission\textsuperscript{12}. In Indonesia, most people using hand to eat, prepare food and work. Therefore, hand and nail need to be clean before and after activities such as meal or after toilet by using soap. The genital hygiene is often overlooked by women. The bad genital hygiene increased humidity caused itching and infection. The female informants suggested sanitary napkins are changed three times per day or every four hours. The oral and dental hygiene is among personal hygiene type. The toothbrush regularly twice per day also improved personal hygiene. Most informants suggested throw their daily garbage in the trash and had rubbish bin in their hostel room. The trash is potentially disease resource transmission through flies, rats, dogs and other animals. Based on observation, bathroom condition is unclean and dirty in university hostel. The water reservoir also experienced damaged or leak. This indicated that the facilities and infrastructure in the hostel is insufficient. Besides, no any staff to handle student room cleanliness.

**Conclusion**

In conclusions, all informants understand of personal hygiene purpose and have own self-care to maintain health for disease prevention. Although, some real actions deviate from informant’s knowledge level, the factor leads in personal hygiene included availability of facilities and infrastructure and individual factors. The students should maintain personal hygiene and environment for their good health. The coordination between university management and hostel in improving hostel facilities and infrastructure for students in maintained their personal hygiene.

Influence of Microskill Learning Model Toward Student’s Psychomotor Learning Outcomes in Birth Delivery care Competence Scale II in Panrita Husada Health Science School, Bulukukuma Regency

Rosnawati1, Budu1, Irfan Idris1
1Faculty of Medicine, Hasanuddin University, Jl. Perintis Kemerdekaan Km.10, Makassar, 90245. Sulawesi Selatan, Indonesia

Abstract
Midwife had the roles as main supporter in primary care during pregnancy, birth, and postpartum period and normal newborn during first 28 days of life. The study aims to determine influence of microskill learning model implementation toward students’ psychomotor learning outcomes in second stage of labor care in Panrita Husada Health Science School (STIkes), Bulukukuma regency. The study was used a quantitative approach with quasi experimental designs included non-equivalent control group design. The study was conducted in November to December 2014 in STIkes Panrita Husada, Bulukukuma regency. The study population were all midwifery study in Midwifery Diploma III study program in third semester. The sample sizes were 85 respondents which obtained by systematic random sampling technique. The data was collected using the checklist. The data had analysed by using Friedman test, Wilcoxon test and Mann Whitney test. The statistical test in the influence of microskill learning model toward student’s psychomotor learning outcomes in birth delivery care competence scale II had obtained p=0.000.

Keywords: Conventional learning model; Midwives; Microskill learning model; Psychomotor learning outcome.

Introduction
Midwife had the roles as main supporter in primary care during pregnancy, birth, and postpartum period and normal newborn during first 28 days of life1-3. According to United Nations Population Fund, midwifery involves more than mother care during childbirth, their roles also promotes women-centred care and general well-being through supportive and preventive model of care4. The midwifery is a profession had regulated scope of practice who graduated from an approved program meet necessary of essential competencies of International Confederation of Midwives and practiced in home, community, hospital, clinic or health unit5.

The care during second stage of labor is among main competencies that must have by midwifery students. This competency is targeted to provide high degree of health for mother and infants through integrate effort so that service quality can be maintain at desired or optimal level. The qualified midwives are not only received education in the classroom but also with clinical learning including practical. The learning is generally defined as self-directed, work-based process which increased adaptive capacity6. Meanwhile, Barrett et al. had defined learning is a sensory process which involved combination seeing, hearing and doing7. (Barret et al., 2008). The method used by teachers also influenced the success in teaching and learning process.

Five-step microskills model is learning model which applied in optimization of clinical guidance for laboratory and clinic. The five-step microskills model are get a commitment, probe for supporting evidence, teach general rules, reinforce what was done right and correct mistake8. The study aims to determine the influence of microskill learning model implementation toward students ‘psychomotor learning outcomes in second stage of labor care in STIkes Panrita Husada, Bulukukuma regency.
Methodology

Study design

The study was used a quantitative approach with quasi experimental designs included non-equivalent control group design.

Study location and time

The study was conducted in November to December 2014 in STIkes Panrita Husada, Bulukumba regency.

Study population and sample

The study population were all midwifery study in Midwifery Diploma III study program in third semester. The sample sizes were 85 respondents which obtained by systematic random sampling technique.

Data analysis

The data was collected using the checklist. The data had analysed using Friedman test, Wilcoxon test and Mann Whitney test.

Results and Discussion

Bivariate Analysis

Based on Table 1, 40 respondents had attended class with conventional learning model application. The median on pre-test was 3.6 and increased to 33.3 on post-test I. In post-test II, median was 64.9 and increased to 86.0 in post-test III. Based on Friedman test, there are differences on median during pre-test and post-test based on conventional learning model among midwifery students in STIkes Panrita Husada.

Table 1. The median difference during pre-test and post-test based on conventional learning model among midwifery students in STIkes Panrita Husada, Bulukumba regency

Based on Figure 1, there was rapid increment of median in microskill learning model than conventional learning model. The median was 3.6 in the pre-test for both models and microskill learning model was observed an increment to 38.1 and 33.3 for conventional learning model on post-test I. In post-test II, median for microskill learning was increased to 78.6 while 64.9 for conventional learning model. The median for microskill learning model was increased to 95.2 and conventional learning model was increased to 86.

![Figure 1. Median difference between pre-test and post-test III for students ‘psychomotor learning outcomes](image)

**Overall Discussion**

The result found median differences of students ‘psychomotor learning outcomes with conventional learning model and microskill learning model for pre-test and post-test. The median differences on each measurement indicated conventional learning model had increased students ‘psychomotor learning outcomes. The midwifery students learned or gained new information based on the learning material, hence improve students ‘psychomotor learning outcomes. Meanwhile, statistical test showed there was significant median differences between microskill learning model and conventional learning model toward students ‘psychomotor learning outcomes on post-test II and post-test III. The microskill learning method was introduced in clinical learning either in classroom nor practical. The microskill learning model is easy to learn and apply to guide midwifery in their practical so that their competencies are achieved. The five-step microskill steps helped to improve effectiveness for teacher and midwifery students’ communication. Ahern et al. mentioned interaction between teacher, colleagues and students helped in development of students’ professional value systems. The effectiveness in the microskill learning model implementation also strongly influenced by teacher’s
capabilities in their learning fundamental, build good communication with students, recognized student’s characteristic to create good relationship and provide solutions for students in order to improve their study performance. Besides, Thompson et al. had suggested effective midwifery education also needed teachers who had caring, competent and compassionate values. Midwifery teachers should be preparing systematic and organised steps based on the guideline to evaluate students ‘psychomotor behaviour. Thus, any learning method or model lead in poor student achievement, teachers are encouraging to change or combine methods to create more effective learning method or model.

Acknowledgement: The author would like to thank to STIKes Panrita Husada, Bulukumba regency for resources and data input and Faculty of Medicine, Hasanuddin University for unconditionally support.

Conclusion

In conclusions, there was significant difference in students’ psychomotor learning outcomes based on conventional learning model and microskill learning outcomes during pre-test and post-test (p=0.000). There were significant differences on students’ psychomotor learning outcomes on microskill learning model with conventional learning model on post-test II (p=0.001) and post-test III (p=0.000).

Abstract

Breastfeedings will always remain as the common way of providing babies with all the required nutrients in order to have healthy development and growth. In general, all mothers are able to breastfeed provided they get the full support from the family and society in addition to accurate information. The aim of this study is to determine the overall influence of knowledge, attitude, education level, and maternal parity in practicing of early initiation of breastfeeding at Sentani community health centre (Puskesmas), Jayapura district. The study was used observational research used cross sectional design. The study employed 36 respondents as sample selected used completely by random sampling. The data were obtained through observational checklist and questionnaire. The data were analyzed by means of univariate as well as bivariate used chi-quadrant test. The result found significant relationship between maternal knowledge and early initiation of breastfeeding implementation at Sentani Puskesmas, Jayapura district. Besides, study also found no significant relationship between attitude, education level and maternal parity in implementation of early initiation of breastfeeding.

Keywords: Attitudes; early initiation of breastfeeding; level education; parity.

Introduction

The breastfeeding is among ideal food process for infants in development and health grow1. The breastfeeding has many benefits such as reduced morbidity and mortality in childhood2,3. Based on United Nations Children’s Fund (UNICEF) and World Health Organization (WHO), mother had suggested given exclusive breastfeeding to baby up to 6 months until 24 months or beyond4. The inappropriate food feed practices led obesity and health problem in children5. The initial breastfeeding within first hour of infant life helped reduce death risk in first month for 20%6.

The initial breastfeeding help infant to get first breast milk that contain high antibodies and nutritious that protected infant from diseases7. In additions, initial breastfeeding also help mother in reduced postpartum hemorrhage8,9. The early initiation of breastfeeding improved emotional bonding between mother and infant. The prelacteal feeding had bad impact toward breastfeeding and initiation breastfeeding had reduced the foundation of optimal breastfeeding9. The exclusive breastfeeding had high potential in decreased under-five mortality about 11.6%10. Although, only 40% infants aged 6 months or less that were in exclusive breastfeeding11. Meanwhile, low percentage is observed in South Asia for early initiation of breastfeeding ranged from 45% to 72.7% in Nepal, 36.4% in India and 83.3% in Sri Lanka8. In Thailand, the prevalence of exclusive breastfeeding about 2.4% in 200611. Meanwhile, some population groups less likely to initiate breastfeeding compared to Australian mothers in South Western Sydney, Australia13. The percentage of early breastfeeding in Indonesia was still low. The early initiation of breastfeeding in Indonesia was 49.3% and lower in some provinces between 2007 and 201214.

The socioeconomic factors had influenced in early initiation of breastfeeding were maternal age, education level, birth health facility, parity, and family income15,16. In Northeastern Ethiopia, mothers who lived in urban
places, experienced caesarean section, education level, and birth order of index child are involved in early initiation of breastfeeding. In India, education level, economic status, place of birth, prenatal visits to health care facilities, mother’s tribe, assistance during childbirth and partner’s violent behavior had influenced early initiation of breastfeeding. A study in South Sulawesi found education level, lack in knowledge, and support from family and midwife were most influenced factors in early initiation breastfeeding implementation. A few studies had reported factors associated with early initiation of breastfeeding in Indonesia. The aim for this study was determined influence of knowledge, attitude, education level, and maternal parity in the practice of early initiation of breastfeeding at Sentani Puskesmas Jayaputra district.

Methodology

Study Type

The study was used analytic observational research with cross sectional study approach. The data collecting done simultaneously with correlated with education, knowledge and attitude of midwife in breastfeeding initiative management at Sentani Puskesmas of Jayapura district.

Location and Time

The study was conducted in Puskesmas Sentani, Jayapura regency for one-month period.

Population and sample

The population were all mothers who gave birth in Puskesmas Sentani, Jayaputra regency within study period. The study employed 36 respondents as the sample selected used completely random sampling.

Data Collection

The primary data was obtained through questionnaire and observational checklist. The secondary data was obtained from Puskesmas Jayaputra regency related to midwife’s behavior in early breastfeeding initiation.

Data Analysis

The univariate analysis was presented in form of frequency distribution such as characteristic respondent. The bivariate analysis was presented in form of cross-tabulation analysis to observe relationship between independent variables with dependent variable using chi-square test.

Result and Discussion

Univariate Analysis

Table 1 showed frequency distribution by majority respondents was aged from 20 years old until 24 years old with number of 14 respondents (38.9%) and only 1 respondent (2.8%) that aged below 20 years old. There were 2 respondents (5.56%) had Bachelor degree and 6 respondents (16.67%) completed junior high school. Besides, 34 respondents had only child or two children and only 1 respondent (5.56%) had 3 children until 5 children.

Bivariate Analysis

Based on Table 2, there were 26 respondents (81.2%) had good knowledge compared 1 respondent (25.0%) had less knowledge. There was significant relationship between maternal knowledge and early
initiation of breastfeeding implementation. Based on Table 3, 22 respondents (78.6%) had good attitude compared mother with poor attitude (62.5%). Besides, no significant relationship between maternal attitude and early initiation of breastfeeding implementation (p=0.310>0.05). There were 22 respondents (73.3%) had high education level and 5 respondents (83.3%) with low education level with good early initiation of breastfeeding implementation. Based on statistical test indicated no significant relationship between education level with early initiation of breastfeeding implementation as shown in Table 4.

### Overall Discussion

Most of respondents were aged 20 years old until 24 years old in Jayapura inpatient health center. Meanwhile, highest maternal education level among respondents was senior high school level. Based on respondent age of first childbirth, these young mothers were not in high-risk age. Based on respondent’s age and education level, the respondents received new knowledge and easily accessed information. The accessibility of technology and program were accepted and implemented as in early initiation of breastfeeding implementation.

The knowledge is important in early initiation of breastfeeding implementation. The sufficient knowledge helped newly mother had confidence in provided breastfeeding to the baby. In this study, mother with good knowledge had implemented good early initiation of breastfeeding. The easily accessed information and high education level had supported mother in implemented early initiation of breastfeeding. Besides, respondents had experienced previous pregnant also helped in early initiation of breastfeeding implementation. Early initiation of breastfeeding implementation failure was due to lack of maternal knowledge, attitude, family and labor support, health facilities and government policies. In this study, the maternal knowledge was important factor influenced involvement in early initiation of breastfeeding implementation.

There was no significant between maternal attitude and early initiation of breastfeeding implementation. The respondents had good attitude toward early initiation of breastfeeding implementation. The maternal knowledge and attitude influenced mother’s action in early initiation of breastfeeding implementation. The good maternal knowledge and attitude increased awareness in early initiation of breastfeeding implementation and vice versa.

The maternal education level had been sufficient to understand early initiation of breastfeeding implementation. The study suggested maternal education level had influenced early initiation of breastfeeding. However, no significant relationship between maternal education level and early initiation of breastfeeding implementation. Besides, health worker role also influenced in early initiation of breastfeeding. The health worker had provided information to pregnant women so that ease early initiation of breastfeeding implementation.

In additions, the study showed no significant relationship between maternal parity and early initiation of breastfeeding implementation. The respondents had primigravida experience and implemented early initiation of breastfeeding. Besides, respondents had experienced previous pregnant also helped in early initiation of breastfeeding implementation. Early initiation of breastfeeding implementation failure was due to lack of maternal knowledge, attitude, family and labor support, health facilities and government policies. In this study, the maternal knowledge was important factor influenced involvement in early initiation of breastfeeding implementation.

In conclusion, there was a significant relationship between maternal knowledge and early initiation of breastfeeding implementation at Sentani Puskesmas, Jayapura District. Meanwhile, no significant relationship between attitude, education level and maternal parity in
the implementation of early initiation of breastfeeding.

Implementation of First Level Outpatient Reference of BPJS Health Insurance Participants at Community Health Centres in Maros Regency

Septianus Bunga1, Indar1, Ariffin Seweng1

1Faculty of Public Health, Hasanuddin University, Jl. Perintis Kemerdekaan Km. 10, Tamalanrea Indah, Tamalanrea, Kota Makassar, Sulawesi Selatan 90245, Indonesia

Abstract

This study aims to analyze implementation of first-level outpatients reference of social insurance administration organization (BPJS) health insurance participant at community health centers (Puskesmas) in Maros regency. This study was conducted in descriptive research type at two Puskesmas included Puskesmas Mandai and Puskesmas Turikale. The data was collected by interviews, observations and document study. The data were analyzed qualitatively and supported by quantitative data. The result showed implementation was good in term of human resources. Besides, there was good understanding among doctors about capitation system and medical indication as well as non-medical needs. However, there were lacking medical equipment facilities included medical equipment for single use (BMHP) and availability of drugs. Most of references from Puskesmas Mandai are for hypertension and diabetes mellitus while hypertension, rheumatism and diabetes mellitus for Puskesmas Turikale. The patients usually initiated for outpatient references without any medical indication due to patients already admitted in hospital. Other reasons included requested from doctor in the hospital, preference to have treatment from medical specialist and limitation of drugs, BMHP and medical equipment.

Keywords: analysis; BPJS health insurance; community health; first-level outpatient references.

Introduction

The health equity and population health is among main target of World Health Organization1. Based on WHO, every human has right to the highest attainable standard of health without discrimination2. The health development is organized on humanity basis, empowerment and independence, justice and equity, included priority and benefits with special attention to vulnerable populations including mothers, infants, children, elder and poor families3. Health development aim to raise awareness, willingness and ability to a healthy live for every human so that highest degree of improvement can be realistic.

Indonesia is fourth most population in world after People’s Republic of China, India and United States of America4. In 2010, an estimation of Indonesia population was 237, 641, 326. Indonesia had established BPJS for health and manpower. The participant for this program included all Indonesian citizen and foreigners who worked in Indonesia at least 6 months and paid health insurance fees. Before BPJS implementation in 2011, Indonesia population who joined in health insurance by 76.4 million (63%) and targeted 86 million people are covered insurance in early 2014.

Maros district has a BJPJS health office included 14 Puskesmas with total of 203,529 health BPJS participants. In Acheh, 30%-75% of first level outpatients references were obtained based on own or families request in three Puskesmas in Acheh5. The main reason was patients disappointed on Puskesmas management and preferred treatment in hospital.

Meanwhile, many references based on non-medical indications and poor hospital management affected reference numbers6. A study found poor of understanding on references system, hospital management and availability of health facilities lead to system weakness...
This study aims to analyze implementation of first-level outpatient reference of BPJS health insurance participants at community health centers in Maros regency.

Methodology

Study Type

The study type was descriptive research using qualitative methods. The information was obtained through snowball sampling, collecting techniques with triangulation, qualitative/inductive data analysis and qualitative research.

Location and Time

This study was conducted in February to May 2016 at Puskesmas of Maros regency included Puskesmas Mandai(represented Puskesmas inpatients) and Puskesmas Turikele (represented non-hospitalized health centers).

Study Informants

The informants in this study were selected by snowball sampling technique. The key informants were head of BPJS health in Maros regency and other informants were two main head of Puskesmas, 4 health workers in Puskesmas (2 health workers were represented for each Puskesmas) and 6 reference participants of BPJS Health (3 reference participants per Puskesmas).

Data Collection

The primary data was obtained through in-depth interview on informants, while secondary data was obtained through document review in study location.

Data Analysis

The in-depth interviews were analyzed using content analysis method and triangulation of informants for data validity. The data processing and analysis included collecting data which obtained from in-depth interview and sources, categorized data followed same characteristics or patterns according to data collection method, comparing variables with theory or other study results and presented data in matrix qualitative form.

Result and Discussion

The number of human resources available at Puskesmas in Maros regency is shown in Table 1. In 2016, Mandai Puskesmas have 24,327 participants and Turikele Puskesmas have 22,865 participants of BPJS Health. Based on document review, both Puskesmas had met standard of health workers. The health workers in Puskesmas are sufficient so no interruption in providing service to the patients. The sufficient of health worker headcounts were fulfilled public health in a comprehensive and quality way. Based on interview result, doctors in first level public healthcare facility understood about capitation system used by BPJS Health, even though only in outline. Based on Regulation of Ministry of Health No. 69 in year 2013, health service tariff rates at first level and advanced healthcare facilities in health insurance program implementation setting capitation for Puskesmas ranged between Rp. 3,000 and Rp. 6,000. The capitation funds provided by BPJS Health and paid based on number of registered participants and doctors. Puskesmas Mandai and Turikale gained Rp. 6000 per registered participants.

Based on this study, most of doctors in first level public healthcare facility of Puskesmas Mandai and Turikale understood there are 155 diagnosis diseases and given some understanding to patients on references to the hospital. Besides, doctors also need competition standard according Regulations of the Health Minister (Permenkes) year 2014 about clinical practice guidelines in primary health care facilities. The lack of medical equipment facilities in first level healthcare facility caused service interruption to the patients and increased reference numbers to the hospital. The lack in drug supplies in Puskesmas may interfere health service to the patients thus increasing number of first level outpatients to the hospital.

The informants stated that most referred diseases among first level outpatients were diabetes mellitus, rheumatism, hypertension, gastrointestinal diseases and upper respiratory tract infections. The reference diseases from first level public healthcare facility to hospital should refer to 155 diagnosis diseases issued by BPJS Health. The reasons from first level outpatients to be references included patients already admitted in hospital, requested from doctor at the hospital, lack of medicines, BMHP, medical equipment facilities and preference to have treatment from specialist doctor. The patients have right to be outpatient references on getting health service at the hospital if Puskesmas have limitation of health facilities and drug.

**Overall Discussion**

Based on this study, availability of human resources at Puskesmas Mandai and Turikale is sufficient for health services. The human resource is very important in health service quality formation. The health insurance development for community is very necessary. Therefore, human resource in health service implementation should be sufficient and distributed throughout community. Furthermore, sufficient of human resources also help in maximize health service capability. Hence, human resource quantity and quality need to be standard requirement in providing health services quality to reduce reference number not met BPJS Health requirement.

Besides, informants understood about capitation system applied by BPJS Health and service fund was allocated had increased from 60% to at least 75%. Nevertheless, the informants still satisfied with this system since no influence on their work. A study conducted in Puskesmas Ambon found health worker performance is depend on incentives or special compensation. This incentive had increased health worker motivation and productivity on providing good health service to the patients. The capitation rate for Puskesmas was in range between Rp. 3,000 and Rp. 6,000 per registered participant. Besides, both Puskesmas received varied fund due to several factors such as uncertainty in participant numbers per month. This fund payment variation affected on Puskesmas annual budget plan.

In additions, medical and non-medical indication based on health worker’s knowledge level on clinical condition. The patients with severe disease conditions would referred to hospital due to lack of health facilities. However, patients had referred to hospital even though not in medical indications. The limitation of medical equipment facilities was found on both of Puskesmas and health workers need to spend their own money on purchasing some of BMHP. Therefore, government need to give attention on improve healthcare facilities and standardized tools in Puskesmas. The availability of medical equipment facility affected on references system implementation. Besides, sufficient medical equipment in Puskesmas also increased health worker performance and productivity. Furthermore, limitation of drug also occurred in both Puskesmas. This problem leads to patients had referred to the hospital. The informants had suggested improvement in drug availability in reducing reference numbers and provided good health service quality among patients.

Based on in-depth interview, Puskesmas have own guideline on the reference diseases included 155 diagnosis diseases. Puskesmas Mandai and Turikale have references system implementation but limitation of drug and medical equipment facilities need patients refer to hospital for further treatment. The result had found most of diseases were referred included upper respiratory infections, hypertension, diabetes mellitus, rheumatism. The first level outpatients requested references at Puskesmas Mandai and Turikale due to several factors such as limitation of drug and medical equipment facilities, preference to have treatment with specialist doctor, no and advised by doctor for referring to hospital. The patients had lack of confidence in Puskesmas health services and medicines ineffectiveness lead to have treatment in advance health centers such as
the hospital.

**Conclusion**

In conclusions, human resources in both Puskesmas was in sufficient and doctors had good understanding on capitation system and medical and non-medical indications. Besides, there are still lacking in health equipment facilities and medicine supplies. Most type of reference diseases in both of Puskesmas such as hypertension and diabetes mellitus which are chronic diseases required long and continually treatment. The patient reasons on requesting references included limitation of medical equipment facilities and drug, advised from doctors at the hospital and preference to have treatment with specialist doctor. The Maros Health Office need to improve health facilities and infrastructure as well as drug availability at Puskesmas in order to reduce reference numbers to advance health centers.

Influence of Oxytocin Massage toward Oxytocin Concentration Changes among Mothers in Siti Khadijah I Maternity Hospital, Makassar

St. Subriani¹, Nasrudin A. M¹, Irfan Idris¹
¹Faculty of Medicine, Hasanuddin University, Jl. Perintis Kemerdekaan Km.10, Makassar, 90245. Sulawesi Selatan, Indonesia

Abstract

The study aimed to determine influence of oxytocin massage toward oxytocin concentration changes among mothers in Maternity Hospital of Siti Khadijah I, Makassar. The study used a quasi-experimental research design to determine influence of oxytocin massage (independence variable) toward oxytocin concentration changes (dependence variable) among mothers. The study was conducted from March 2016 to May 2016 at Maternity Hospital of Siti Khadijah I, Makassar. The study population were primipara mothers at Maternity Hospital of Siti Khadijah I, Makassar. The sample sizes were 60 respondents (30 respondents were in control group and 30 respondents were in intervention group). The samples were obtained by using purposive sampling techniques. The univariate analysis is represented in the frequency distribution for respondent characteristics. The bivariate analysis had used Mann Whitney U test to compare the oxytocin concentration changes among mothers who had received oxytocin massage and without oxytocin massage. The statistical test in the oxytocin concentration among others with oxytocin massage and mothers without oxytocin massage was p=0.175 in the latent phase and active phase (p=0.602).

Keywords: Active phase; Latent phase; Oxytocin hormone; Postpartum mothers

Introduction

The postpartum period also known as puerperium is completed six weeks after childbirth where mother, baby and family need to adapt to the new situations. The postpartum period had divided into three periods: immediate (1st to 10th day), late (11th to 45th days) and remote (from 45th days onward). Romano et al. stated postpartum period had three distinct but continuous phases included initial or acute period which involves first 6-12 hours of postpartum, second phase known as subacute postpartum period lasts between 2 weeks and 6 weeks and third phase is delayed postpartum period which last up to 6 months. The postpartum period also known as period that susceptibility to emotional disorders especially postpartum depression. Postpartum depression (PPD) is common which developed in women within 1st year after childbirth. Lower oxytocin levels in pregnancy is among factor lead in impaired emotional adaptation in mothers which caused PPD development and affected maternal behaviour quality. The oxytocin levels are higher in pregnant and postpartum women than non-pregnant women. Oxytocin is released into circulating blood and brain structure during breastfeeding and skin-to-skin contact in mother and infant. The oxytocin massage is spinal massage from fifth or sixth costa until scalpula which stimulated parasympathetic nerves so that prolactin and oxytocin hormone are released. The study aimed to determine influence of oxytocin massage toward oxytocin concentration changes among mothers in Maternity Hospital of Siti Khadijah I, Makassar.

Methodology

Study design

The study was used a quasi-experimental research design to determine influence of oxytocin massage (independence variable) toward oxytocin concentration changes (dependence variable) among mothers.
**Study location and time**

The study was conducted from March 2016 to May 2016 at Maternity Hospital of Siti Khadijah I, Makassar.

**Study population and sample**

The study population were postpartum primipara at Maternity Hospital of Siti Khadijah I, Makassar. The sample sizes were 60 respondents (30 respondents were in control group and 30 respondents were in intervention group) which met the study criteria included postpartum primipara mothers, willing to be respondents, mothers who had oxytocin massage and never had oxytocin massage and good in mental health. The samples were obtained by using purposive sampling techniques.

**Data analysis**

The univariate analysis is represented in the frequency distribution for respondent characteristics. The bivariate analysis had used Mann Whitney U test to compare the oxytocin concentration changes among mothers who had received oxytocin massage and without oxytocin Massage.

**Results And Discussion**

**Univariate analysis**

Most of respondents were aged between 26 years and 30 years. The least of respondents were aged more than 35 years which were only 3 respondents (9.4%). Meanwhile, 26 respondents (81.3%) had low education and 6 respondents (18.8%) had high education. Majority of respondents (87.5%) were housewife and only 4 respondents (12.5%) were civil servant. Besides, 22 respondents (68.3%) had uterine contractions between 20 seconds and 40 seconds and only 2 respondents (6.3%) had uterine contractions below 20 seconds. Meanwhile, half of respondents (50%) were latent phase and half respondents (50%) were in active phase.

Bivariate analysis

The mean of oxytocin hormone on latent phase for postpartum mother with oxytocin massage were 362.1440 and without oxytocin massage were 350.3560. Meanwhile, the standard deviation of oxytocin hormone for postpartum mother with oxytocin massage was 18.8961 and without oxytocin massage was 7.9194. The minimum and maximum value of oxytocin hormone for postpartum mother with oxytocin massage were 343.2479 and 342.4366, while postpartum mother without oxytocin massage had minimum and maximum value of 342.4366 and 358.2754. Based on Mann Whitney test, there was no significant relationship between oxytocin concentration changes in mothers with oxytocin massage and mothers without oxytocin massage on latent phase.

Overall Discussion

The results showed most respondents aged between 26 years to 30 years which are primigravida mothers had no experience and knowledge in the pregnancy and childbirth. Besides, 26 respondents (81.3%) had low education levels and only 6 respondents (18.8%) had high education level. The education is important for better understanding on health information from difference sources and helped in their decision-making in reproductive issue and medical care utilization due to their awareness in health conditions. Based on Mann Whitney test found no significant relationship between oxytocin concentration changes in mothers with oxytocin massage and mothers without oxytocin massage on latent phase and active phase. The latent phase of labour is time in body changes occurring in preparation for actual labour with cervix contraction between 3 and 5 cm dilated. The higher oxytocin levels on latent phase on mothers who received oxytocin massage. Meanwhile, mean of oxytocin levels had observed higher among mothers without oxytocin massage on active phase. Hence, oxytocin levels in mothers were not influenced by oxytocin massage since mothers without oxytocin massage also had high oxytocin level. Many studies on oxytocin levels during labour and postpartum period. A study found oxytocin levels slowly increase until childbirth and decreased up to 8 weeks postpartum period. Fuchs et al. mentioned oxytocin levels receptors increased in myometrium of pregnant women and maximum in early labour. The oxytocin had affected on the uterine muscles and triggered by cervical stimulation (Prevost et al., 2014). In Semarang Hospital, oxytocin massage had increased prolactin hormone levels and breastmilk production among post caesarean section. The oxytocin levels in increase uterine contraction and helped in prevent PPD among mothers.

Acknowledgement: The author would like to thank to all respondents Maternity Hospital of Siti Khadijah I, Makassar for resources and data input as well as Faculty of Medicine, Hasanuddin University for unconditionally support.

Conclusion

In conclusions, oxytocin massage increased oxytocin concentration although not significant influence in latent phase for mothers who received oxytocin massage and without oxytocin massage, while no significant influence between mothers who received oxytocin massage and without oxytocin massage in the active phase.

Factors Associated with Medical Treatment Compliance among Leprosy Patients in Gowa District 2015-2016

Sucitra Erviana Hajid¹, Rismayanti Akhbar¹, Jumriani Ansar¹
¹Faculty of Public Health, Hasanuddin University, Jl. Perintis Kemerdekaan Km. 10, Tamalanrea Indah, Tamalanrea, Kota Makassar, Sulawesi Selatan 90245, Indonesia

Abstract

Leprosy disease is a controllable if early diagnosis and treatments are undertaken by the patients. Nonetheless, a significant number of patients become irregular and default the treatments due to a number of personal, psychosocial, economic, medical and health service factors. Up to date, there has no one time cure for this disease without undergoing a continuous treatment. Hence, this study aimed to determine factors associated with medical treatment compliance among leprosy patients in Gowa district 2015-2016. The study type was observational analytic with cross sectional design. The population in this study is all leprosy patients who still undergoing treatment. The sample sizes are 100 respondents which selected by exhaustive sampling method. The result found variables associated toward medical treatment compliance among leprosy patients were accessibility to health centres (p=0.000), knowledge (p=0.037) and family support (p=0.017). However, the drug side effect is not factor associate with medical treatment compliance (p= 0.200).

Keywords: Bivariate analysis; compliance; leprosy; medical treatment.

Introduction

Leprosy also known as Hansen’s disease, chronic infectious disease due to Mycobacterium leprae¹ ². Every year, estimated 250,000 new leprosy cases had recorded worldwide and most of leprosy cases in undeveloped countries³. Most of leprosy patients are recorded in 13 countries included Brazil, Bangladesh, India, Indonesia, Myanmar, Republic of Congo, Ethiopia, Nigeria, Nepal, United Republic of Tanzania, Sri Lanka and the Philippines⁴.

According to World Health Organization (WHO), multi drug treatment had been introduced and effective in decrease both prevalence and leprosy incidence worldwide⁵. The leprosy patients had received combination treatment with three antibiotic such as rifampicin, clofazimine and dapsone⁶. WHO had recommended two multidrug treatment routines for leprosy patients: one for tuberculoid (TT) and leivetuberculoid (BT) leprosy cases and another for borderline (BB), borderline lepromatous (BL) and lepromatous (LL) leprosy cases⁷.

In Indonesia, an estimated 17,025 new leprosy cases lead to top three highest leprosy cases in world for 2014. The prevalence for leprosy cases was 1 per 10,000 population. Based on South Sulawesi Provincial Health Office, there were increasing trend for new leprosy cases. In 2014, 1,142 new leprosy cases had been recorded with Bone district had highest cases (199 cases). Meanwhile, 21 cases on disability level 2 in Gowa district. In Gowa district, case detection rate (CDR) was 17 per 100,000 population and prevalence rate is 1.7 per 10,000 population meant new cases has increased from year to year. The aim of this study is to determine factors associated with medical treatment compliance among leprosy patients in Gowa district 2015-2016.

Methodology

Study Type

This study was used observational analytic with cross sectional design.

Location and Time

The study was conducted from February 2016 to March 2016 in Gowa district.

Population and sample

Population in this study is all leprosy patients in Gowa district who undergone multidrug treatment.
The sample sizes were 100 respondents by selected using exhaustive sampling method.

Data Collection

Primary data was obtained through questionnaires and secondary data was determined from every public health center (Puskesmas) in Gowa district.

Data Analysis

The data was analyzed using SPSS version 13.0. The bivariate analysis was obtained to determine relationship between dependent and independent variables in form of cross tabulation with chi-square test.

Result and Discussion

Bivariate Analysis

Based on Table 1, 19 respondents (19.0%) had medical treatment compliance and there were 15 respondents (60.0%) had less than 30 minutes to health centers and 4 respondents (5.3%) had more than 30 minutes to health centers. Meanwhile, 81 respondents (81.0%) had no medical treatment compliance, while 10 respondents (40.0%) had less than 30 minutes to health centers and 71 respondents (94.7%) had more than 30 minutes to health centers. There was significant relationship between accessibility to health centers with medical treatment compliance.

There were 9 respondents (32.1%) had high knowledge and 10 respondents (13.9%) had low knowledge with medical treatment compliance. Besides, 19 respondents (67.9%) had high knowledge and 62 respondents (86.1%) had low knowledge with no medical treatment compliance. Based on chi-square test, there was significant relationship between knowledge and medical treatment compliance in Gowa district (p= 0.037< 0.05) as shown in Table 2. Furthermore, 19 respondents (63.3%) had family support and 1 respondent (1.4%) had no family support with medical treatment compliance. Besides, 11 respondents (36.7%) had family support and 69 respondents (98.6%) had no family support without medical treatment compliance. There was significant relationship between family support and medical treatment compliance in Gowa district as shown in Table 3.

Overall Discussion

The accessibility to health centers is play important role for enhance health quality and equity of life. The result found accessibility to health centres is correlated medical treatment compliance in Gowa district. The accessibility to health center is a factor that affected health center visits. The geographic condition and availability of transportation also contributed on accessibility to health centres. In the United States, a study found 55% of respondents are missed appointment or late arrival due to transportation. In Mozambique, lack of accessibility to health centres due to walking scenario since 66.7% of Mozambican area is in underserved area.

The knowledge is gained through both formal and informal education. Based on chi-square test, knowledge is related to medical treatment compliance among leprosy patients in Gowa district. Most of Puskesmas did not provided detail about leprosy lead patients had lack of knowledge on leprosy transmission. Several studies had been done to determine the knowledge toward diseases among the population. The study found low knowledge among general population toward tuberculosis in North East Libya. The person had high education had better information about disease.

In this study, the family support had been associated with medical treatment compliance among leprosy patients in Gowa district. In general, families had provided support in term of time, spirit, checking medication and others for leprosy patients. Besides, the family also play important roles in reunited patients in the society. The study found most families are less supporting due to limitation of time to take care leprosy patients. In additions, limitation of knowledge in leprosy among families lead to lack of support in term of information toward leprosy patients. This study found no significant
relationship treatment side effect and medical treatment compliance among leprosy patients in Gowa district. Some respondents continued in medical treatment even though treatment had side effects. The health workers had explained to leprosy patients to handle treatment side effects. A study found 10% of non-compliance psychiatric patients because of medication side effect in India\textsuperscript{12}.

**Conclusion**

In conclusions, there was significant relationship between accessibility to health centres, knowledge and family support with medical treatment compliance among leprosy patients in Gowa year 2015-2016. Meanwhile, medical treatment side effects is not associated with medical treatment compliance among leprosy patients in Gowa district.

Effect of Platelet and Haematocrit Contents towards Dengue Haemorrhagic Fever and Impact on Economic Loss in Daya Regional General Hospital 2016

Sudirham¹, Arsunan Arsin¹, Alimin Maidin¹

¹Faculty of Public Health, Hasanuddin University, Jl. Perintis Kemerdekaan Km. 10, Tamalanrea Indah, Tamalanrea, Tamalanrea Indah, Tamalanrea, Kota Makassar, Sulawesi Selatan 90245, Indonesia

Abstract

This work is aimed to find out the effect of the platelet and hematocrit content on the Dengue Hemorrhagic Fever degree and its impact on the economic loss. This was an analytic observation research with the cross sectional approach. The research was conducted in Daya Regional General Hospital. Data were collected using the purposive sampling technique. The data collected through the questionnaire and interview with the patients and their families. This work used the pathway analysis. The research result indicated that there is effect of the platelet amount on the dengue fever degree (p=0.000) with the variable coefficiency of the negative value (0.424). Also, there is no effect of the hematocrit amount on the dengue fever degree (p=0.649) with the variable coefficiency of the negative value (0.045). In addition, the result showed that there is effect of the dengue fever on the direct cost (p=0.000) with the variable coefficiency of the positive value (0.374). Finally, there was also effect of the dengue fever degree on the indirect cost (p=0.118) with the variable coefficiency of the positive value (0.280).

Keywords: dengue fever; hematocrit; economic loss; platelet.

Introduction

Dengue Hemorrhagic Fever, DHF is found in tropical and subtropical areas. The number of DHF cases in Indonesia ranks first each year with the highest case in Southeast Asia¹. DHF disease was first discovered in Surabaya in 1968 with 58 people experiencing pain and 24 people died and the number of disseminations increasingly widespread all provinces in Indonesia². WHO (World Health Organization) states about 2.5 billion people in the world at risk of dengue virus infection. WHO describes cases of dengue fever around the world every year there are 50-100 million, of which there are 250,000-500,000 cases of dengue fever with a death rate of about 24,000 people per year³. Asia ranks first in the number of DHF patients each year, according to WHO, one of which is Indonesia with the highest dengue fever case in Southeast Asia⁴.

DHF is an infectious disease caused by dengue virus. DHF disease is not transmitted directly from person to person, but is transmitted to humans through Aedes Aegypti mosquito bites that cause some symptoms, one of them is high fever symptoms. Generally, DHF patients experience symptoms of sudden high fever for 2-7 days, followed by critical phase. In the critical phase, the patient has no fever, but this is the first sign of shock when delayed in handling⁵. The guidelines used in establishing the diagnosis of DHF to date are the criteria set by the WHO in 1999. The diagnosis of DHF can be established when two clinical criteria are found and two laboratory criteria. By relying on WHO laboratory criteria, low platelet count (thrombocytopenia) and plasma leakage marked with hemoconcentration are indicators of the severity of dengue diseases³.

Thrombocyte and hematocrit levels cannot always be used as a reference to assess the state of the patient because platelet and hematocrit levels do not always indicate the factual condition of the severity of the illness. According Widyanti et al⁶. stated that this value shows the relationship between the severity of DHF and hematocrit is a positive relationship.

Several studies have been conducted to determine whether there is a relationship between hematocrit and...
platelet values with the severity of DHF. Syumarta et al. found that platelets had a non-significant association with clinical DHF. In a study conducted by Putri et al., found a significant relationship between thrombocyte and hematocrit with the degree of DHF.

The immediate economic impact felt by DHF patients is the cost of treatment. Indirect impacts are the loss of work time, school time and other family costs such as transportation and accommodation during patient care. Research conducted by Gu et al. stated that dengue is an endemic disease in Guangzhou that has been the main disease in decades and caused economic losses to the sufferer. The total cost of a dengue fever economy far outweighs the cost that is as simple as being expended on vector control. Patients, overnight, direct mortality and morbidity, together with the potential costs of time loss and productivity due to illness also need to be considered. Extensive research has been done to analyze the economic burden of dengue fever. In America, the annual economic burden of dengue is estimated at around US $ 2.1 billion. Research conducted by Huy et al. in Cambodia showed the total cost related to dengue was no different from other febrile illnesses (31.5 vs. 27.2 US $, p = 0.44). Hospitalization nearly tripled the cost of dengue (14.3-40.1 US $) and doubled the cost of other febrile illnesses (17.0-36.2 US $).

Brief description on the background of the above problem, this work is done to determine the effect of thrombocyte and hematocrit levels on the degree of DHF and its impact on economic loss in Daya Regional General Hospital 2016.

Methodology

Research Type

The type of the research was observational analytic study with cross sectional study design with observation and measurement on the effect of thrombocyte and hematocrit values on the degree of DHF and its impact on the economic losses borne by dengue hemorrhagic patients in Daya Regional General Hospital 2016.

Location and Time

This research was conducted at General Hospital of Daya Area at the inpatient. The reason the research was conducted at that location was the General Hospital of Daya Area is one of the hospital that treated the most dengue fever patients in Makassar. The time of study was conducted from November to December 2016.

Population and Sample

The population of this study were all dengue fever patients recorded in the General Hospital of Daya District from January to November 2016 amounted to 257 people. Determination of the number of samples is done by counting the number of samples using the formula Lemeshow et al. and the sample of this study amounted to 57 respondents.

Data Collection

Primary data were obtained through research questionnaires and interviews with selected patient or patient families being sampled. Secondary data were obtained through medical records, district health profiles, hospital health profiles and a number of literature related to the research object.

Data Analysis

Data analysis was done by bivariate, and multivariate analysis using SPSS program. Bivariate analysis is used to test the relationship of each variable by using Person Correlation Product moment. Multivariate analysis in this study was done using pathway analysis with the help of computer program application of Analysis of Moment Structure (AMOS).

Result and Discussion

Direct and Indirect cost

Based on data analysis result obtained total patient expenditure for direct cost is Rp 188,281,984, and total of patient expenditure for indirect cost is Rp 84,500,101.

a) Years of Life Loss (YLL)

Years of life loss is the number of years lost because the population died before reaching the average life expectancy (LE). \( YLL = \frac{\text{number of deaths of a disease}}{\text{UHH} - \text{age at death} \times \text{total annual income}} \). Thus, \( YLL = 0 \times 72.5 - 0 \times 27,000,000 = 0 \). Based on the calculation of Years of life (YLL) Dengue Hemorrhagic Disease at Daya Regional General Hospital is 0 because during the study period there were no patients or patients who died.

b) Years Lived With Disability (YLD)

Years of lived with disability loss is the number of years lost because someone fell ill and unable to
perform daily activities. The minimum wage of South Sulawesi province for 2016 is Rp 2,250,000, (Provincial Government, 2016). To calculate YLD can be used the following formula: YLD = Total sick days x Total patient x Province minimum wage per year. Total sick days = 386/247 = 1.56. Total patients = 83 people. Provincial Minimum Wage = Rp. 2.250.000 x 12 = Rp. 27,000,000. Therefore, YLD = 1.56 x 83 x 27,000,000 = Rp 3.502.129.555.

c) Disability Adjusted of Life Years (DALY)

Disability Adjusted of Life Years the number of productive years lost due to illness plus the number of years lost due to premature death. So to calculate DALY (Disability Adjusted Life Years) used the following formula, DALY = YLD + YLL. Therefore DALY = = 3.502.129.555 + 0 = Rp 3.502. 129.555. From the calculation of Disability Adjusted of Life Years (DALY) shows the number of productive years lost due to illness plus the number of years lost due to premature death (DALY) due to Dengue Hemorrhagic disease is Rp 3.502.129.555.

d) Total economic Losses

To calculate total economic losses in the following formula,

\[
\text{Total Economic Losses} = \text{Total Direct Cost} + \text{Total Indirect Cost} + \text{DALY}.
\]

Thus, based on the calculation results obtained total economic losses due to dengue hemorrhagic disease in Daya Regional General Hospital in 2016 amounting to Rp 3,774,911,640.

Bivariate Analysis

Bivariate analysis in this section using Pearson correlation test, the results of the analysis can be seen in table 1. Results from Table 1 shows that the Mean hematocrit value 38.47 and severity 1.28. Statistical test results obtained p value (0.907)> 0.05 which means that there is no relationship between the hematocrit with the degree of severity. Also, the mean platelets value is 109.86. Statistical test results obtained p value (0.000)< 0.05 hat there is a relationship between platelets and degree of severity. In addition, the Mean value of degree of severity 1.28 and direct cost of 2268458. Statistical test results obtained p value (0.001)<0.05 which means that there is a relationship between the degree of severity and direct costs. On the other hand, the mean value of degree of severity 1.28 and indirect cost of 1018074. Statistical test results obtained p value (0.117)> 0.05 which means that there is no relationship between degree of severity and indirect cost.

Multivariate Analysis

The tested hypothesis that explains the causal relationship between thrombocyte, hematocrit, degree of severity, direct costs, and indirect costs in patients with DBD in RSUD Daya Kota Makassar is shown in Table 2. Thus the results are presented as follow. The research hypothesis for the influence of platelets to the degree of severity was, H1: There is an influence between the platelets variable and the degree of severity. From the allegations after tested it turns out the platelets -0.425. The influence of platelets is statistically significant because it is known that the significance of hematocrit variable of 0.000 is <0.05, then H0 is rejected which means there is significant effect of the platelets variable on the variable of severity.

</tr>
<tr>
<td>Degree of Severity</td>
<td>Indirect cost</td>
<td>0.118</td>
</tr>
</tbody>
</table>
The research hypothesis for the influence of hematocrit to the degree of severity was, H1: There is an influence between the hematocrit variable and the degree of severity. From the allegations after tested it turns out the hematocrit variable coefficient is negative of 0.045. The influence of hematocrit is not statistically significant because it is known that the significance of hematocrit variable of 0.649 is greater than 0.05, then H0 is accepted which means there is no significant effect of the hematocrit variable on the variable of severity.

The research hypothesis to influence the degree of severity to direct costs was, H1: There is an influence between variable severity and direct cost. From the allegations after tested it turns out the coefficient of variable severity is positive at 0.374. The influence of degree of severity is statistically significant because it is known that the significance of the severity variable is <0.000 less than 0.05, then H0 is rejected which means there is a significant influence of the variable of severity to the total direct cost variable.

The research hypothesis to influence the degree of severity against indirect costs was, H1: There is an influence between variable severity and indirect costs. Of the allegations after tested it turns out the coefficient of variable severity is positive at 0.118. The influence of degree of severity is not statistically significant because it is known that the significance of the variable severity of 0.280 is greater than 0.05, then H0 is accepted which means there is no significant influence of the variable of severity to the indirect total cost variable.

**Overall Discussion**

The results of the research indicate the total direct costs incurred by the patient is Rp 188,281,984 with the average amount of direct cost is Rp 2,268,457. This is in line with research conducted by As'ad where found the average direct cost incurred by DHF patients is Rp 688,060.

The result of the research indicates the total non-direct costs incurred by the patient is Rp 84,500,101, with the indirect cost is Rp 1,018,074. This is in line with the research conducted by As'ad where found the average direct cost incurred by DHF patients is Rp 823,333. Research conducted by Shepard et al shows indirect costs for dengue fever per person in Bhutan $34.5 US Dollar, Brunei Darussalam $733.6 US Dollar, in Indonesia $52.3 US Dollar. This study shows the varied indirect costs in each country depending on economic conditions and health services in the country. The total economic loss is the overall cost incurred during the treatment ie direct cost of indirect costs + DALY. The results showed the total economic losses due to dengue hemorrhagic disease in RSUD Daya 2016 is Rp 3,774,911.640. Other research conducted by Shepard et al shows the total economic loss due to dengue hemorrhagic disease (2001-2010) in Cambodia $16.5 Million US Dollar, Myanmar $14.5 Million US Dollar, Singapore $67.1 Million US Dollar.

From the results of the research, there is an effect of the degree of severity to the direct cost (p <0.005) with the variable coefficient 0.374. These results show that the effect of severity is statistically significant, the variable coefficient 0.374 shows the positive direction means the higher the degree of severity the greater the direct costs to be incurred. Research conducted by Kallaru et al in chronic obstructive pulmonary disease in India showed significant results between stage of lung disease and direct cost (p = 0.000). From result of research obtained no effect of degree of severity to indirect cost (p = 0.280) with variable coefficient 0.118. This result shows that the effect of degree of severity is not statistically significant, the variable coefficient of 0.118 indicates the positive direction means the higher the severity the greater the no direct cost that must be issued.

Research conducted by Kallaru et al in chronic obstructive pulmonary disease in India showed significant results between stage of lung disease and direct cost (p = 0.000). The average cost spent by patients with stage II Chronic Obstructive Pulmonary (COPD) was Rs.3179.62 per hospital visit, stage III was Rs.16414.79 and stage IV was Rs.44077.16 per visit. From result of research obtained no effect of degree of severity to indirect cost (p = 0.280) with variable coefficient 0.114. This result shows that the influence of degree of severity is not statistically significant, the variable coefficient of 0.114 indicates the positive direction means the higher the severity the greater the no direct cost that must be issued.

Another study conducted by Bavbek et al, also showed significant results between disease severity and direct cost (p <0.01) where direct costs for severe attacks were 308 Euro and mild attacks 128.6 Euro.
Conclusion

Thus, from the work done, the following conclusions are made. First, the total economic loss due to dengue hemorrhagic disease in Daya Regional General Hospital in 2016 is Rp 2.619.580.649. Secondly, there is effect of the platelet amount on the dengue fever degree with the variable coefficient of negative value. Thirdly, there is no influence of the amount of hematocrit on Dengue Hemorrhagic degree with variable coefficient of negative value. In addition, there is influence of degree of dengue hemorrhagic fever to direct cost with variable coefficient of positive value. Finally, there is no effect of degree of Dengue Hemorrhagic Fever on indirect cost with variable coefficient of positive value.

Abstract

The aim of this study is to describe determinants in maternal mortality in Tojo Una Una. This study was used qualitative research and phenomenological approach. This study was conducted from January to February 2016 in Tojo Una Una district of central Sulawesi. The informants were selected based on purposive sampling method and consisted of family of cases, midwives and coordinator midwives. The data collection is obtained through observation and in-depth interviews. The result found maternal nutritional status is among risk factors with suffered anaemia, diabetes mellitus, stroke, hypertension, and hepatitis. Besides, late maternal age also increased risk in maternal mortality. The medical treatment delay included delay in identified pregnancy risk and dangerous sign, delay in accessibility to health facilities and taking good health services. The obstacles in access to health centres is caused by long distance to hospital, high transportation fees, limitation of public transportation availability and administrative requirement that burden the patient’s family members.

Keywords: Delay causes; health service utilization; nutritional status; reproductive status

Introduction

Every year, estimated more than 350,000 women died from pregnancy or delivery complication and sub-Saharan Africa and Asia had recorded highest maternal mortality for 50% and 45%¹². Based on hospital record, approximately 25% of maternal mortality are caused by hemorrhage, 15% of infections, 12% by hypertension and 8% by labor dystocia³. The estimation between 15% to 20% of pregnant women in both developed and developing countries had faced high risk in pregnancy complications due to limitation of health care quality⁴.

Maternal mortality is classified as women death occurring during pregnancy period or within 42 days of termination of pregnancy⁵⁶. Several factors influenced maternal mortality such as pregnancy complications, labor and obstetric complications. The most influenced determinants included maternal nutritional status, reproductive status, accessibility to health facilities, health care behavior and other unknown or unexpected factors. Besides, socio-cultural and economic factors also affected in maternal mortality. In additions, the delay in decision making also resulted on maternal mortality. The decision making in family had influenced by several factors such as education, family knowledge, women status in family, socioeconomic status, health insurance and culture. A study found there is relationship between age, education, paternal employment status, family income, distance to health centers, maternal knowledge and attitude with decision making on health services utilization⁷. In central of Sulawesi, Tojo Una Una district had highest number of maternal mortality which is 35 cases in 2013 (maternal mortality rate is 352 per 100,000 population)⁸. The aim of this study to describe determinants in maternal mortality in Tojo Una Una.

Methodology

Study Type

This study was used qualitative research and phenomenological approach.
Location and Time

This study was conducted from January to February 2016 in Tojo Una Una district of central Sulawesi. The study focuses on maternal mortality cases according to preliminary observation result. The site selection is determined based on maternal mortality data.

Population and Sample

The informants were selected based on purposive sampling method. The informant’s criteria in this study as bellows:

a) Family of cases who willing to be interviewed and priority to close family such husband, parents, in-laws and sibling;

b) Midwife who serving in village;

c) Midwife coordinator of working area of the cases.

Data Collection

The data collection is obtained through observation and in-depth interviews.

Result and Discussion

In this study, there are 6 cases for maternal mortality had recorded in 2015 and 2016. Meanwhile, 2 maternal mortality occurred in mother aged 40 years and 43 years old. Four cases found in hospital, each one case occurred in community health centre (Puskesmas) and house. The maternal mortality causes included retained placenta, bleeding, depression and molar pregnancy. All mothers had received ANC in village birth delivery post (Polindes), integrated health post (Posyandu) and Puskesmas.

This study found anaemia symptom is detected during their ANC as shown in Table 1. The midwife who detects anaemia based on symptom suffered by pregnant women. The anaemia symptoms included fatigue, pale, short breathing and irregular heart beat rate. The midwife has suggested pregnant women for further examination in the hospital due to limitation on healthcare facilities. In addition, death causes also due to depression, hepatitis, hypertension and diabetes mellitus (DM) and stroke.

Based on body mass index (BMI), only one case was in obesity category with BMI 31.217 but there is no specific record in body height and weight. The obesity and overweight lead to cardiovascular disease including hypertension, DM and other diseases.

Table 1. Nutritional status variables toward maternal mortality

<table>
<thead>
<tr>
<th>Nutritional status variables</th>
<th>Informant’s answer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Anaemia</td>
<td>The anaemia is detected in mothers during their ANC and further medical examination in hospital due to limitation in healthcare facilities. Besides, informants also detected other diseases such as chronic hypertension, DM and stroke in pregnant women.</td>
</tr>
<tr>
<td>BMI</td>
<td>No specific on maternal body height and weight but only one case was in obesity category.</td>
</tr>
</tbody>
</table>

As described in Table 2, the ideal age for pregnancy is between 20 years and 35 years. The high risk in maternal mortality occurs in late age. The study found no maternal mortality cases with close pregnancy gap. The large pregnancy gap was due to difficulties in babysitting. The study found gravidity and parity more than 2 had high risk for pregnant women. Besides, maternal age and parity number influenced maternal mortality. The delay identified of pregnancy risk and dangerous signs occur in midwives, pregnant women and families. The midwives identified pregnancy risk and dangerous sign by diagnosis in pregnancy women with anemia and molar pregnancy. Besides, families preferred self-medication on pregnancy women with abdominal pain.
Table 2. Maternal status variables toward maternal mortality

<table>
<thead>
<tr>
<th>Maternal status variables</th>
<th>Informant’s answer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maternal Age</td>
<td>The maternal age is between 20 years and 35 years. The late pregnancy caused hypertension, DM and stroke.</td>
</tr>
<tr>
<td>Pregnancy gap</td>
<td>The informants did not sure about pregnancy gap. Besides, informants suggested pregnancy gap were 7 years.</td>
</tr>
<tr>
<td>Gravidity</td>
<td>The gravidity number in this study is 4 times. Besides, there are neonatal mortality occurred.</td>
</tr>
</tbody>
</table>

Besides, delay in accessibility on health facilities also among cause in maternal mortality. The delay in accessibility in health facilities in this study were due to families’ decision, delay in references system in Puskesmas for further treatment at the hospital and preference in treatment with village midwives. This study found limitation in medical equipment in Puskesmas and late to the hospital caused maternal mortality. The delay on accessibility in health facilities due to distance, emergency period and geographic. Summary of delay causes variables towards maternal mortality is shown in Table 3.

Table 3. Delay causes variables toward maternal mortality

<table>
<thead>
<tr>
<th>Delay variables</th>
<th>Informant’s answer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Delay in identify on pregnancy risk and dangerous signs</td>
<td>The delay was due to families preferred self-medication on victim and late to seek treatment in hospital.</td>
</tr>
<tr>
<td>Delay on accessibility in health facilities</td>
<td>The victim preferred contacted midwife before going to hospital.</td>
</tr>
<tr>
<td>Delay in taking good health services</td>
<td>The health workers were not on duty in Puskesmas and had decided to seek treatment in the hospital.</td>
</tr>
</tbody>
</table>

This study found distance from health facilities is among cause lead to maternal mortality as summarized in table 4. Although, there is Puskesmas in the area, but no any health worker and limitation of medical equipment causes patient need to go hospital. There are many health insurances such as delivery assurance (Jampersal), public health insurance (Jamkesmas) and social insurance administration organization (BPJS). Besides, the families need spend on transportation fees for seek treatment in the hospital. The expensive medical cost lead families preferred traditional healers for birth delivery.

Table 4. Health service utilization variables toward maternal mortality

<table>
<thead>
<tr>
<th>Health service utilization variables</th>
<th>Informant’s answer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Distance from health facilities</td>
<td>The distance from house to health service such as Puskesmas and Poskesdes are closer than hospital.</td>
</tr>
<tr>
<td>Health services cost</td>
<td>The patients are not covered with health insurance would be charged for medical cost. The community still lack understanding on free health program.</td>
</tr>
<tr>
<td>Geographical conditions</td>
<td>The poor in geographic and road conditions caused delay in accessibility to health facilities.</td>
</tr>
<tr>
<td>Transportation facilities</td>
<td>The limitation in transportation facilities to seek treatment in health services. The public transportation only operated once per day in Tojo Una Una district.</td>
</tr>
</tbody>
</table>
The poor in geographical and road conditions also lead in difficulty on accessibility to health facilities. The limitation in transportation facilities is that the public transportations only available in the morning. The study found difficulty in administration requirements when the community seek treatment in Puskesmas and hospital. In addition, there is lack of family support in accessibility to health facilities due to their beliefs and lack of knowledge. Besides, the family preferred birth delivery in house and need assistance of midwife or traditional healers during birth delivery. The families would only bring pregnant women to hospital if emergency occurs.

The study also found that accessibility on health facilities was not determined by ethnic and no specific ethnic pattern in accessing health services. The health service utilization is more influenced by family decision making based on consideration of cost, distance geographical conditions and transportation facilities.

**Overall Discussion**

Based on this study, maternal nutritional status increased risk in maternal mortality. Several factors such as maternal nutritional status, anaemia, diseases and complication history on previous pregnancy and delivery had influenced maternal mortality. Besides, nutritional status before pregnancy also related to pregnancy risks. The result also found anaemia symptom in pregnant women is detected by midwife before further examination in the hospital. Furthermore, maternal mortality was due to comorbid diseases such as hypertension, diabetes mellitus and stroke.

Meanwhile, overweight and obesity also contributed in maternal mortality. The result found pregnant women weight is still in normal category from early pregnancy until birth delivery. The pregnant women who experienced under/overweight would lack in folic acid, iron and calcium and increased risk of fetus abnormalities, anaemia, small fetus weights and premature labor. Besides, obesity risk in pregnant women is hypertension, preeclampsia, DM which are indirect cause of maternal mortality.

The late pregnancy among women increased complication risk especially preeclampsia. The pregnancy among women aged more than 35 years old have higher risk of preeclampsia than younger women. Most suitable age for pregnancy is between 20 years and 30 years. In additions, pregnancy gap in this study is still in normal level. The ideal pregnancy gap is at least 2 years. A study found mother with less than 2 years pregnancy gap had higher risk in maternal mortality. Besides, pregnancy gap less than 24 months lead in high risk for suffering severe anaemia compared to pregnant women had 36 months of pregnancy gap.

The result showed gravidity among women is still normal category. The number of children leads to tendency in shaping desired family size. In Yogyakarta, ideal numbers of children are 4 and 5 children. There are compositional factors consisting of maternal age, education, employment, father’s employment, religion, number of children and house location. The maternal mortality is affected by delay in decision making to seek treatment in health facility. The delay in seek treatment were due to distance of health facilities and health service cost.

The delay in accessibility on health facilities also caused in maternal mortality. This delay in decision making was due to several factors such as strong traditional medicine practices in pregnancy care and lack of maternal knowledge. In additions, families also claimed limitation of public transportation; high transportation fees, high medicine cost and no health insurance caused delay in seek treatment in health centres. The lack of resources, health facilities and health service quality at health centre are contributed in delay in taking good health services among pregnant women. In rural areas, pregnant women more preferred birth delivery with help of traditional healer or midwife and no immediate action on birth complication lead to maternal mortality.

The distance of health facilities is among factor in birth delivery for pregnant women since house location is far away with health care facilities (Puskesmas and hospital). Most of patients preferred seek treatment at nearest health facilities. The birth cost also influenced in decision making for birth delivery place unless this cost is covered by health insurance. Besides, transportation fees and medical cost affected on family’s decision making for seek treatment in health centres. Other factor such as poor geographical and road conditions caused delay in accessibility to health facilities. The geographic condition has negative influences to health services utilization in Bajo community.
The limitation in transportation also delayed in accessibility to health facilities among pregnant women. Based on this study, the public transportation only available on morning session and far distance from hospital increased transportation fees. The lack for health services quality lead women do not receive proper treatment in health centres. The healthcare facilities utilization was likely due to several factors such as distance, cost, geographical condition and transportation facilities which influenced mother or families in decision making for access health services.

**Conclusion**

In conclusions, several factors such as maternal nutritional status, age, gravidity, delay in seek treatment in health facilities, far distance, geographical conditions, high transportation and medical costs and limitation in transportation facilities affected decision making for modern health service which is increased risk in maternal mortality.

14. Muchtar R, Purnomo E. Proximate Determinant
Comparative of Sexual Satisfaction between Women with and without Tubectomy in Makassar 2015

Trisna Pangestuning Tyas¹, Nasrudin A. M¹, Irfan Idris¹

¹Faculty of Medicine, Hasanuddin University, Jl. Perintis Kemerdekaan Km.10, Makassar, 90245.
Sulawesi Selatan, Indonesia

Abstract

The study aims to determine the sexual satisfaction levels between women with and without tubectomy in Makassar city. The study was used cross sectional research. The study was conducted within one month in working area of Makassar city Health Office. The study population were all women who are in family planning program in working area of Makassar city. The sample sizes were 100 respondents which divided into control and intervention groups which met study criteria. The samples were obtained by using purposive sampling methods. In this study, primary data was using questionnaire Female Sexual Function Index (FSFI) in obtained data. The data was analysed using SPSS program. The bivariate analysis was used chi square test to compare the sexual satisfaction between women with and without tubectomy. The chi square test also found sexual function between women with and without tubectomy in sexual desire (p=0.774), arousal (p=0.679), lubrication (p=0.275), orgasm (p=1.000), satisfaction (p=0.408) and pain (p=0.424).

Keywords: Arousal; Female sexual function index satisfaction; Lubrication; Pain; Satisfaction; Tubectomy

Introduction

The contraception is referred as intentional prevention of conception through devices, chemical, drug, surgical procedures and sexual practices. Approximately, 222 million of women had improper need for contraception and 80 million unwanted pregnancies occurs in global annually caused by non-use or inconsistent use of contraceptive methods. The contraceptive target to avoid sperms are released into female reproductive organs (ejaculation), egg released from ovary (ovulation), intercourse of egg and sperm (fertilisation), embryo attachment in the uterus wall (implantation) or termination of developing embryo from the uterus (abortion).

Female sterilization is among contraceptive methods. Female sterilization had performed in many ways included minilaparotomy, laparoscopic sterilization and hysteroscopic methods. Female sterilization such as tubectomy or tubal ligation is permanent contraception method without affected sexual and endocrine function. In other hands, contraception especially tubectomy procedure might influenced female sexual functions in positive and negative way. Several studies had been done to determine the effect of contraception toward female sexual functions. Some studies concluded contraception method had no significant influenced in female sexual functions and some studies found contraception method had affected female sexual functions. The study aimed to determine the sexual satisfaction levels between women with tubectomy and women without tubectomy in Makassar city.

Methodology

Study design and location

The study was used cross sectional research. The study was conducted within one month in working area of Makassar city Health Office.

Study population and sample

The study population were all women who are in family planning program in working area of Makassar city. The sample sizes were 100 respondents which divided into control and intervention groups which met study criteria included women with tubectomy and husbands are willing to be respondents, aged between 35 years and 40 years, living together with husband in...
last 3 months and had tubectomy at least 3 months. The control group is used contraceptive pills included five types of contraceptive method and intervention group contained women who had tubectomy included women had tubectomy in caesarean section and interval tubal ligation. The samples were obtained by using purposive sampling methods.

Data analysis

In this study, primary data was using questionnaire Female Sexual Function Index (FSFI) in obtained data. The data was analysed using SPSS program. The bivariate analysis is used chi square test to compare the sexual satisfaction between women with tubectomy and without tubectomy.

Results and Discussion

Based on Figure 1, women in young age with low parity had higher sexual desire, arousal, lubrication, orgasm, satisfaction and pain than women in old age with high parity among women with tubectomy. For women without tubectomy, women in young age with low parity had inconsistent value for each sexual function domain.

Based on Table 1, 11 respondents (57.9%) were aged between 35 years and 37 years and 19 respondents (61.3%) were aged 38 years and 40 years had sexual dysfunction. The Fisher test found no significant relationship between age and sexual function among women with tubectomy. For education level, 8 respondents (40%) had low education level and 12 respondents (40%) had high education level had normal sexual function. The statistical test found no significant relationship between education level and sexual function among women with tubectomy. Meanwhile, 27 respondents (62.8%) were housewives and 3 respondents (42.9%) were civil servant had sexual dysfunction. The Fisher test showed no significant relationship between employment status and sexual satisfaction among women with tubectomy. There were 16 respondents (37.2%) had parity between 1 and 3 and 4 respondents (44.4%) had parity between 4 and 9 had normal sexual function. The statistical test showed no significant between parity and sexual function among women with tubectomy.

Based on Table 2, there were 16 respondents (64%) were aged 35 years and 37 years and 15 respondents (60%) were aged 38 years and 40 years had sexual dysfunction for women without tubectomy. The Fisher test found no significant relationship between age and sexual function among women without tubectomy. Meanwhile, 4 respondents (23.5%) had low education levels and 15 respondents (45.4%) had high education level which had normal sexual function. There was no significant relationship between education level and sexual function among women without tubectomy. In additions, 30 respondents (61.2%) were housewives and 1 respondent (100%) were civil servant had sexual dysfunction. The Fisher test found no significant relationship between employment status and sexual function among women without tubectomy.

**Overall Discussion**

Most women preferred family planning to prevent further pregnancy and confident with contraception method as effective way in their family planning. The tubectomy had been done at the time of childbirth, immediate postpartum or after six weeks postpartum (Allagoa et al., 2014). According to international resources, tubectomy is considered as permanent fertility control method which had low pregnancy chances about 1 in 200 (Date et al., 2014). The results found no differences in sexual satisfaction between women with tubectomy and women without tubectomy.

Based on Table 1 and 2, approximately 40% of respondents in intervention group and 38% of respondents in control group had normal sexual function. The lack of sexual desire is often related with aging, menopause, surgery, certain medical condition and drug side effect. FSFI had been developed as a brief and multidimensional self-report instrument to determine women sexual function. The results on comparison of sexual satisfaction among women with tubectomy and women without tubectomy based on FSFI included sexual arousal, desire, pain, lubrication, orgasm and satisfaction. The statistical test found no significant difference on sexual function domain between women with tubectomy and women without tubectomy. Regan et al. mentioned sexual desire is defined as attraction in sexual objects (other people) or activities or longing to find sexual objects or to engage in sexual activities and not like sexual activity (masturbation, kissing and intercourse) or sexual arousal (erection and vaginal lubrication).

The study showed sexual desire is higher in women with young age and low parity. Most of respondents were older women who aged between 35 years to 40 years which are in perimenopause period. Sexual disorders were associated to age which related to reduce in sex drive, vaginal dryness due to menopause and sexual intercourse. Meanwhile, this study showed both groups had equal number respondents for sexual orgasm. Kunkeri et al. demonstrated 71.1% of women had sexual dysfunction and most common disorders was orgasm, arousal and desire after tubectomy.

The perception among women with tubectomy that no longer become pregnancy, attention to their children lead to lack of sexual problems. Besides, the stress and depression also contributed to the sexual dysfunction. The women who suffered sexual dysfunction had relationship conflict, stress, anxiety or depression, age and poor in health. The women with tubectomy had high levels of sexual satisfaction, sexual pleasure and relationship satisfaction same as women without tubectomy due to their less concern toward unwanted pregnancies. Furthermore, high prevalence of female sexual dysfunction had observed in El Fayoum governate and several factors contributed were age gap, marriage duration and number of children. Indrayani et al. mentioned women with tubectomy had better sexual function than women without tubectomy since there were increased in sexual desire, arousal, lubrication, orgasm and satisfaction. Most women preferred family planning to prevent further pregnancy and confident with contraception method as effective way in their family planning.

**Acknowledgement:** The author would like to thank to all respondents in Makassar city for data input and Faculty of Medicine, Hasanuddin University for unconditionally support.

**Conclusion**

In conclusions, no difference in sexual satisfaction among women with tubectomy and women without tubectomy in Makassar city. The contraceptive devises installation in selected candidates and husbands by trained counsellors helps in psychology among patients toward sexual function after tubectomy.

Effect of Calcium and Vitamin D Supplements Consumption Toward Pregnancy Outcomes among Hypertension Pregnant Women in Poasia and Lepo-Lepo Public Health Centres, Kendari City

Wa Ode Sri Kamba Wuna¹, Irfan Idris¹, Werna Nontji¹

¹Faculty of Medicine, Hasanuddin University, Jl. Perintis Kemerdekaan Km.10, Makassar, 90245. Sulawesi Selatan, Indonesia

Abstract

The study aims to determine the effect of calcium and vitamin D supplement consumption among hypertension pregnant women toward pregnancy outcomes in Poasia and Lepo-Lepo Public Health Centres, Kendari city. The study was used a quasi-experimental design with pre-test and post-test design with intervention and control groups. The study was conducted from 24th March to 21st June 2016 at Poasi and Lepo-Lepo Public Health Centres (Puskesmas), Kendari city. The study population were all pregnant women who suffered hypertension with total of 38 pregnant women. The sample sizes were 32 respondents (16 respondents in intervention group and 16 respondents in control group). The samples were obtained with purposive sampling techniques. The data was analysed using SPSS program. The bivariate analysis is determined effect of calcium and vitamin D consumption among hypertension pregnant women toward their pregnancy outcome by using Wilcoxon test and Mann Whitney statistic test. The statistical test showed systolic and diastolic blood pressure changes during pre-test and post-test in intervention group were p=0.001 and p=0.003. Meanwhile, chi square test for effect of calcium and vitamin D supplement consumption toward infant body weight (p=0.000), infant body length (p=0.000), infant head circumference (p= 0.000).

Keywords: Birth body weight; Body length; Diastolic blood pressure; Head circumference; Hypertension; Systolic blood pressure

Introduction

Based on World Health Organization (WHO) factsheet, an estimation of 830 women died from avoidable causes related to pregnancy and childbirth and 99% of maternal mortality happened in developing countries¹. Maternal death is defined as death of women during their pregnancy or within 42 days of their termination of pregnancy due to pregnancy causes related but not from accidental or incidental causes¹. The study had been carried out by Hill et al. found approximately 535 000 maternal mortality in the world between 1990 and 2005 and Sub-Saharan had recorded as much as 50% of cases and Asia had been recorded 45% of cases respectively². Several causes contributed to maternal mortality such as haemorrhage, infection, pregnant-induced hypertension, obstructed labour, malaria, anaemia, preeclampsia, eclampsia³-⁶. Hypertension had affected 20% to 30% of adult population and more than 5% to 8% of all pregnancies in global⁷. The hypertension is considered when systolic blood pressure is ≥160mmHg and/or diastolic blood pressure is ≥110 mmHg on two consecutive blood pressure measurement at least four hours apart⁸.

The calcium and vitamin D deficiency is very common among pregnant women and infants⁹. Vitamin D deficiency in pregnancy had related with high risk of preeclampsia, gestational diabetes mellitus, preterm birth, low birth body weight, impaired fetal skeletal and reduced bone mass. The women who had high risk in vitamin D deficiency included those who had less sunlight exposure, use sunscreen on regular basis, dark-skinned women, mother who had infants with rickets and women with body mass index (BMI) more than 30. The recommendation of vitamin D is 400 IU daily, while
calcium is 1000 mg daily to reduced hypertension and preterm labour. The study aims to determine the effect of calcium and vitamin D supplement consumption among hypertension pregnant women toward pregnancy outcomes in Poasi and Lepo-Lepo (Puskesmas), Kendari city.

Methodology

Study design and location

The study was used a quasi-experimental design with pre-test and post-test design with intervention and control groups. The study was conducted from 24th March to 21st June 2016 at Poasi and Lepo-Lepo Puskesmas in Kendari city.

Study population and sample

The study population were all pregnant women who suffered hypertension with total of 38 pregnant women. The sample sizes were 32 respondents (16 respondents in intervention group and 16 respondents in control group) which met the study criteria i) pregnant women with hypertension and willing to be respondents; ii) maternal age less than 40 years old; iii) pregnant in third trimester between 28 weeks and 32 weeks. The samples were obtained with purposive sampling techniques.

Data collection

The pregnant women were tested the blood for the calcium levels and had given 10 tablets of 500mg calcium lactate supplement and 5 soft gel of vitamin D3 400 IU. The pregnant women in the control group only given with 10 tablets of 500mg calcium lactate supplement. The pregnant women blood levels had been monitored in every week until their labour day and birth weight, length and head circumferences had been measured.

Data analysis

The data was analysed using SPSS program. The bivariate analysis is determined effect of calcium and vitamin D consumption among hypertension pregnant women toward their pregnancy outcome by using Wilcoxon test and Mann Whitney statistic test.

Results and Discussion

Bivariate analysis

Table 1 showed significant changes in systolic blood pressure in the control and intervention groups. The systolic blood pressure changes in the intervention group was more significant than control group. Similarly, diastolic blood pressure in both groups were decreased. However, diastolic blood pressure changes in the control group were considered statistically no significant, p =0.296 > 0.05. Meanwhile, significant change to diastolic blood pressure in the interventional group.

Table 2 illustrates decrease in systolic blood pressure in the control group and intervention groups were prenatally and hypertensive at the beginning of examination. The Wilcoxon test showed significant decrease in systolic blood pressure in the control group who had prehypertension and hypertension (p=0.039<0.05 and p=0.027<0.05) respectively. Meanwhile, statistically significant decrease only occurred in the respondents who experienced prehypertension (p=0.001<0.05). The systolic blood pressure level was reduced among experienced hypertension was considered not statistically significant with p=0.157>0.05. However, systolic blood pressure decreased in the intervention group was significant than in the control group.

Table 4 illustrates reduced in diastolic blood pressure in the control and intervention group which were prenatally and hypertensive at the beginning of examination. Wilcoxon test found significant decreased in diastolic blood pressure in the intervention group with hypertension (p=0.007<0.05). The respondents in the control group with normal diastolic blood pressure at the beginning were observed increase at the end of examination but no statistically, p=0.157>0.05. Meanwhile, respondents in the control group with prehypertension and hypertension at beginning examination and reduced diastole blood pressure at end of examination but not statistically significant respectively, p=0.092>0.05 and p=0.157>0.05. Similarly, respondents in the intervention group who had prehypertension at pre-test and decrement in diastolic blood pressure at the end of examination but not statistically significant, p=0.180>0.05.

Table 6 illustrates mean value of pregnancy outcomes in control and intervention groups. The infants were born in the intervention group had higher birth body weight than infants were born in the control group. The statistical test found statistically significant differences in calcium and vitamin D supplement consumption and birth body weight, p= 0.00< 0.05. Similarly, there was significant differences between mean of birth body length and birth head circumference between control and intervention groups.

Overall Discussion

The results showed significant difference in systolic blood pressure in both groups. The systolic blood pressure in the intervention group decreased more significantly than control group. Similarly, diastolic blood pressure in both groups was observed decreased after post-test. However, statistically significant decreased only occurred in the intervention group. Furthermore, calcium and vitamin D supplement had significant effect on the respondents who had prehypertension in systolic blood pressure and diastolic blood pressure. The respondents had high systolic blood pressure in pre-test and had observed significantly decreased in systolic blood pressure after post-test. However, lactate calcium and vitamin D supplement did not provide significant differences in systolic blood pressure among respondents had hypertension. In contrast, these supplements had significant effect on reduce diastolic blood pressure among respondent with hypertension. Meanwhile, two studies shown no correlation between vitamin D and hypertension and blood pressure measurement. The calcium had provided in both groups since calcium supplement as one of the health programs in prevent preeclampsia occurrence among pregnant women. The supplement consumption compliances also affected the changes in the blood pressure. The lack of monitoring in the supplement consumption among respondents in the control group lead inconsistency calcium consumption so less perceived for calcium benefits.

Besides, mean of blood calcium levels were increased in both groups. However, increment in blood calcium level was statistically significant only occurred in the intervention group. Many factors affected calcium concentration in the blood such as kidney diseases, hyperparathyroidism, lack of albumin in the blood as well as presence of calcium absorption disorders which affected blood calcium levels. This study had proved sufficient in calcium and vitamin D supplement increased in blood calcium levels. The result also found infants were born in the intervention group had better pregnancy outcomes (birth body weight, birth body length and birth head circumference) than the control group. The LBBW was divided into two group into two groups included prematurity and dysmaturity. De-Regil et al. found women had consumed vitamin D supplement during pregnancy less frequent had infants with less than 2500 grams than women did not consumed vitamin D supplement. Furthermore, infants were born in the intervention group had better birth length than control groups. The mean of birth length among infants were born in the control group still within normal standard birth length about 46.5 cm, while average mean of birth length in the intervention group was 49.4 cm. Meanwhile, better birth head circumference among infants were born in the intervention group than in the control group. The presence of caput succedaneum affected birth head circumference. This result is opposite with the study by Charandabi et al. found vitamin D and calcium-vitamin D supplement consumption during pregnancy did not changes pregnancy outcomes result (birth body weight, birth length and birth head circumference). The fetal organs and skeleton formation in form of collagen matrix started to develop during initial to mid-trimesters and foetus skeleton began to be harden in the last trimester lead high demand of calcium among pregnant women.

The dangers of hypertension in pregnancy was great concern among pregnant women, health workers and government. The calcium supplement provision was under Ministry of Health program through WHO recommendation to prevent hypertension in pregnancy occurrence that lead to preeclampsia which harm to the mother and foetus. Meanwhile, many studies demonstrated women with low vitamin D supplementation had higher risk in preeclampsia occurrence. Currently, there is still lacking in counselling in the importance of nutrient intake (especially calcium) in the pregnancy. Main factor is lack of knowledge about importance in calcium benefits lead pregnant women did not care in calcium consumption provided by the midwives. In fact, the calcium is needed by pregnant women especially in second and third pregnant trimester. The calcium can be obtained from food sources such as green vegetables, grains and nuts, meat, eggs and milk.

Indonesia is a tropical country and sunny all year round. The vitamin D deficiency among Indonesian due to current lifestyle which tend to avoid sunlight, sunscreen protector usage and lack of food consumption which containing vitamin D. In this study, average of respondents were housewives, thus less exposure in the sunlight. In general, the result showed pregnancy outcome for intervention group is better than in control group. Based on these results, there is significant effect of calcium and vitamin D supplement consumption in pregnant women with hypertension toward pregnancy outcomes (birth body weight, birth length and birth head
circumference).

Acknowledgement

The author would like to thank to all respondentsin Poasi and Lepo-Lepo Puskesmas in Kendari city for data input and Faculty of Medicine, Hasanuddin University for unconditionally support.

Conclusion

In conclusions, there was significant decrease in systolic and diastolic blood pressure in the intervention group after calcium and vitamin D supplement consumption. Meanwhile, significant effect of calcium and vitamin D supplement consumption toward pregnancy outcomes in Poasia and Lepo-Lepo Puskesmas, Kendari city. The health worker should provide the counselling to the pregnant women about importance of calcium and vitamin D for hypertension prevention and improve pregnancy outcomes.

Relationship between Night Sleep Quality with Changes in the Infants Body Length of age between one Month and Six Months

Yola Arimbi¹, Sri Saadiyah¹, Mita Noviana¹

¹Faculty of Medicine, Hasanuddin University, Jl. Perintis Kemerdekaan Km.10, Makassar, 90245. Sulawesi Selatan, Indonesia

Abstract

The changes in infant body length can be influenced by several factors such as daily behaviour, sleep quality, nutrition intake, environmental conditions and health status. The study aim to determine the relationship between night sleep quality and changes in infant body length of one month until six months. This study was used correlational study with cross sectional approach. The study population was infants who have health examination in Tamalanrea Health Centre with total population of 160 infants. The study samples were 62 infants who met the inclusion criteria. The data was collected included sleep quality by using BISQ questionnaire (A Brief Screening Quisionare For Infant Sleep Problem). The result showed 38 respondents (61.3%) had normal body length with good sleep quality which dominated infant aged one month and 3 months. Meanwhile, 5 respondents (8.1%) had normal body length with poor sleep quality. The statistical test showed significant value p=0.002, r=0.394 and r²= 0.155.

Keywords: Exclusive breastfeeding; Infant; Maternal age; Maternal education level

Introduction

Anthropometric measurement in the neonatal period is important which height, weight and head circumference are usually used measures of growth in neonatal. The anthropometric measurement at birth are measurement used in assessment of peri- and postnatal growth and health. The neonatal is duration that infant adaption in new environment from intrauterine to extrauterine. The infant development is divided into 2 categories included neonates from first day born until 28 days and infants from 29 days until 12 months.

One aspect of infant growth that be concern is infant body length. The changes in infant body length can be indicator for assessing physical growth and comparator for other growth. The changes in body length is affected by several factors such as daily behaviour, nutrition intake, environmental conditions and health status.

The sleep also an adaption toward the environment. In general, the infant spend one-third or half of their life with sleep. As the infant grows up, the sleep duration is decreasing. Meanwhile, number of sleeps also reduced and total sleep duration is ranges between 13 hours and 15 hours for three months until six months old. The infant required long sleep duration than adults because most hormones would release during their sleep period. These hormones has stimulated the tissues and bones for infant growth. In additions, metabolism, nerves development, synapse formation and other development will occur.

The inadequate sleep is correlated with behavioural and learning problems, maternal depression, poor parental functioning and obesity. In western countries, approximately 15% to 35% of infant had sleep disorder for first year including often night waking and unwilling to sleep. Infants with sleep disorders will have experience same disruptions in the future. The preliminary study conducted at Tamalanrea Public Health Centre showed six infants often wake up at night for more than one hour and frequent crying. The study aim to determine the relationship between night sleep quality and changes in infant body length of one month until six months. This study was used correlational study with cross sectional approach.
Methodology

Study design and location

The study was used correlation research design with cross sectional approach. The study was conducted at Tamalanrea Health Centre.

Study population and sample

The study population was infant aged one month until six months who have health examination at Tamalanrea Health Centre with total population of 160 infants. The study samples were 62 infants who met the inclusion criteria.

Data collection

The data was collected by measuring infant sleep quality using A Brief Screening Quisionare for Infant Sleep Problem (BISQ) and infant body length using metered board which interpreted based on objective criteria.

Data analysis

The data was analysed by bivariate analysis technique. Besides, the study also used Spearman to determine the relationship between night sleep quality with changes in infant body length aged of one month until six months.

Results and Discussion

Univariate Analysis

In Table 1, 14 respondents (22.6%) were aged one month and 3 respondents (4.8%) were aged 5 months. Besides, 14 respondents (22.6%) were aged 3 months and 12 respondents (19.4%) were aged 4 months. Meanwhile, 32 respondents (51.6%) were male infants and 30 respondents (48.4%) were female infants. In additions, 46 respondents (74.2%) were in exclusive breastfeeding and 16 respondents (25.8%) were non-exclusive breastfeeding. Meanwhile, there were 25 respondents (40.3%) had completed high school and 21 respondents (33.9%) were completed degree. Besides, 4 respondents (6.5%) were completed associate degrees and 5 respondents (8.1%) were completed elementary school. For maternal age, there were 21 respondents (33.9%) aged between 21 years old and 25 years old and 3 respondents (4.8%) aged between 16 years old and 20 years old. Meanwhile, 18 respondents (29.0%) were aged 26 years old and 30 years old and 12 respondents (19.3%) were aged 31 years old and 35 years old.

In additions, Table 2 shows 48 respondents (77.4%) were good and 14 respondents (22.6%) were poor in night sleep quality. Meanwhile, 43 respondents (69.4%) had normal body length changes and 19 respondents (30.6%) had abnormal in infant body length changes.

**Bivariate analysis**

In Table 3, 38 respondents had good night sleep quality with normal infant body length changes and 5 respondents (8.1%) had poor night sleep quality with normal infant body length changes. Furthermore, 10 respondents (16.1%) had good night sleep quality with abnormal changes in body length and 9 respondents (14.5%) had poor night sleep quality with abnormal changes in body length. The spearman test showed p value= 0.002<0.05, r value was 0.394 and r square value was 0.155 or 15.5%. The statistical test showed significant relationship between night sleep quality and changes in infant body length which sufficient correlation and positive relationship direction. The influence of night sleep quality with changes in infant body length aged one month until six months was 1.55%, while 84.5% is influenced by other factors.

</table>

**Overall Discussion**

In this study, 48 respondents (77.4%) had good sleep quality and 14 respondents (22.6%) had poor sleep quality. The high respondent distribution was dominated by infant aged between one month and 3 months with good sleep quality is influenced by several factors included environment condition, bed condition, exclusive breastfeeding, infant sleep duration either day or night, number infant awake during sleep duration, awake duration on night and duration for initiate infant to sleep.

Most infants had sleep duration between 11 hours and 14 hours in their sleeping life with bedtime distribution of 3 hours to 5 hours from morning until evening and in evening between 9 hours and 10 hours. In additions, most sleep frequencies were between 12 hours and 14 hours per day for infant aged between one month and six months. The study also found infant was awake more than 5 times in their sleeping life and more frequent in the night time because infant need to be breastfeed. The infant would awake for 15 minutes to 30 minutes after sleep and in good mood.

In additions, sleep also helps the infant brain maturation process. High growth hormone level produced during sleep in non REM are closely related physical health number while the blood flow also
increased to the brain during sleep and REM also plays role in mental health as well as brain activity so the brain can grow optimally.

High REM sleep component in the infant is the way of the brain stimulates itself. This stimulation plays an important role in central nervous system growth. During sleep, anabolic state occurred in which energy conservation, repaired body cells and growth. The nutrition or exclusive breastfeeding, genetic and also neuroendocrine factors influenced the infant sleep quality.

Most infants who had good sleep quality and normal changes in the body length with exclusive breastfeeding. Besides, breast milk also plays important role in the infant body length changes because breast milk contains different nutrients from formula milk and other complementary foods.

Furthermore, genetic factors also contributed in the infant body length. The infant with high parent height had greater chance for infants have high body length. The mother with small body size had high chance in giving birth to small infants. In this study, 9 infants (14.5%) had poor sleep quality and abnormal body length changes and influenced by environmental factors are not conductive resulted poor sleep quality. The infants who did not had exclusive breastfeeding have irregular sleep pattern and received insufficient nutrient intake.

Acknowledgement: The author would like to thank to Tamalanrea Health Centre for resources and data input and Faculty of Medicine, Hasanuddin University for unconditionally support.

Conclusion

In conclusion, there was significant relationship between night sleep quality with the changes in infant body length of aged between one month and six months with sufficient correlation and positive relationship. The effect of night sleep quality with changes in infant body length was 15.5%, while 84.5% were influenced by other factors. Further study will be done with other study methods and factors to determine the relationship between night sleep quality with changes in infant body length of aged one month until six months.

Relationship between Knowledge, Attitude and Motivation among Midwives in the Normal Labour Care Implementation

Yuli Setiawati¹, Andi Wardihan Sinrang¹, Irfan Idris¹

¹Faculty of Medicine, Hasanuddin University, Jl. Perintis Kemerdekaan Km.10, Makassar, 90245. Sulawesi Selatan, Indonesia.

Abstract

Approximately, 350,000 women died from pregnancy-related causes every year and majority of maternal mortality occurred in developing countries. The main causes of maternal mortality included eclampsia, postpartum haemorrhage, pregnancy-induced hypertension, obstructed labour, amniotic fluid embolism, obstetric haemorrhage, thromboembolism, anaemia, unsafe abortion, infection, ectopic pregnancy, embolism and anaesthesia complication. The study aimed to determine the relationship between knowledge, attitudes and motivation among midwives in the normal labour care implementation. The study was used an observational research with cross sectional approach. The data collection was conducted from January to February 2016. The study had been done in Sawerigading Palopo Hospital. The study population were all midwives who working in maternity room of Sawerigading Palopo Hospital on October 2015. The sample in this study was entire population of midwives in the maternity room of Sawerigading Palopo Hospital. The sample sizes were 25 respondents which obtained by sampling technique. The data was collected by using questionnaire. The statistical test in knowledge and normal labour care implementation was p=0.98, attitude (p=0.98) and motivation (p=0.174).

Keywords: Attitude; Competence; Knowledge; Midwives; Motivation;

Introduction

Estimation 350,000 women died from pregnancy-related causes every year and majority of maternal mortality occurred in developing countries¹. World Health Organization (WHO) had defined maternal mortality as women death during pregnancy or within 42 days after pregnancy termination, regardless of pregnancy duration and site, from any cause related to or aggravated by the pregnancy or its management but not from accidental or incidental causes². According to WHO fact sheet, one third occurred in South Asia and more than half of maternal mortality occurred in sub-Saharan Africa². High risk of maternal mortality among girl adolescent under 15 years old. The maternal mortality rate (MMR) in developed countries (such as Norway, United Kingdom, Sweden) ranged from 5.4 to 12 per 100,000 live births and middle-income countries such Mexico and Honduras had 106 or 280 maternal mortality per 100,000 live births³. The main causes of maternal mortality included eclampsia, postpartum haemorrhage, pregnancy-induced hypertension, obstructed labour, amniotic fluid embolism, obstetric haemorrhage, thromboembolism, anaemia, unsafe abortion, infection, ectopic pregnancy, embolism and anaesthesia complication⁴-⁶.

Midwives was primary care providers included gynecologic, family planning, preconception care, care during pregnancy, childbirth, postpartum period, normal new born during first 28 days of life and sexually transmitted infections treatment in male partners. In New Zealand, midwives are provided midwifery care through pregnancy, childbirth, birth and postpartum period up to six weeks for women who had booked midwifery services⁷. Sawerigading Palopo hospital was referral hospital in Palopo city was practical hospital for midwives who participated in reproductive health training which organized by Health Office of South Sulawesi province in collaboration with Palopo city Health office. In Sawerigading Palopo Hospital, 25 midwives were on duty and 2 midwives had positions as Head of Midwifery and Vice Head of Midwifery in...
the maternity room of Sawerigading Palopo Hospital. The study aimed to determine relationship between knowledge, attitudes and motivation among midwives in the normal labour care implementation.

Methodology

Study design

The study was used an observational research with cross sectional approach to analyse the relationship between knowledge, attitude and motivation among midwives on normal labour care.

Study location and time

The data collection was conducted from January to February 2016. The study had been done in Sawerigading Palopo Hospital.

Study population and sample

The study population were all midwives who working in maternity room of Sawerigading Palopo Hospital on October 2015. The sample in this study was entire population of midwives in the maternity room of Sawerigading Palopo Hospital. The sample sizes were 25 respondents which obtained by sampling technique.

Data analysis

The data was collected by using questionnaire. The univariate analysis aims to determine frequency distribution of each study variable. The bivariate analysis is represented to determine influence between knowledge, attitudes and motivation among midwives in normal labour care implementation by using chi square test. The data were tabulated and analysed using computerized technique.

Results and Discussion

Univariate Analysis

Based on Table 1, 23 respondents (92%) were in reproductive age between 20 years and 35 years and 2 respondents (8%) were non-reproductive age which aged more than 35 years. Meanwhile, 15 respondents (60.00%) had diploma III and 10 respondents (40%) had diploma IV. There were 22 respondents (88%) were worked less than 10 years and 3 respondents (12%) had worked more than 10 years.

In Table 2, there were 14 respondents (56%) had poor knowledge in the normal labour care and 11 respondents (44%) had good knowledge in normal labour care. Meanwhile, Table 3 shows 11 respondents (44%) had positive attitudes in normal labour care and 14 respondents (56%) were negative attitudes in normal labour care implementation.

</table>
Meanwhile, 6 respondents (54.5%) were non-competence in normal labour care implementation had positive attitude and 3 respondents had negative attitudes in normal labour care implementation. There were 10 respondents (55.6%) were competence in normal labour care implementation which had good motivation and 6 respondents (85.7%) had poor motivation. There was no significant relationship between attitudes and motivation toward normal labour care implementation.

**Overall Discussion**

The knowledge is very important domain for worker performance. Based on this study, 11 respondents (44%) had good knowledge and 5 respondents (45.5%) were competence in normal labour care implementation and 6 respondents (54.5%) were non-competence in normal labour care implementation. The statistical test found no significant relationship between knowledge and normal labour care implementation. The midwives had good knowledge since midwife had been trained in normal labour care. The midwives claim their long service period in the maternity ward, so midwives had less in apply their knowledge optimally because their experience in childbirth process. Meanwhile, midwives who did not applied their knowledge in their normal labour care since midwives did not aware the training had provided knowledge in the normal labour care implementation.

Attitudes is defined as attitude as neural state or mental of readiness, organized through experience, exerting a directive or dynamic influence on the individual’s response to all objects and situations to which it is related. The statistical test found no significant relationship between attitudes toward normal labour care implementation. The junior midwives had adapted attitudes which practice by senior midwives in ignoring normal labour care implementation. Hettiarachchi et al. mentioned positive job attitudes contributed in constructive behaviour; negative jobs had contributed in figure out undesirable behaviours.

Besides, no significant relationship between motivation and normal labour care implementation. The lack of support from hospital management also contributed in midwives motivation in implemented normal labour care implementation. The continually training in normal labour care also improve motivation and performance among midwives. The training helped midwives to gain their effectiveness in their work performance through development of their habit, mind, actions, skills, knowledge and attitude. In additions, incentives also influenced performance of midwives. The incentives had increased midwives motivation and productivity on providing health service to the patients. The incentives in term of financial and non-financial are among extrinsic factors motivation which improved midwives performance to provided good of health service quality. In Cameroon, Iwoi et al. found midwifery students had moderate level of knowledge in HIV/AIDS and positive attitudes but some of respondents still have misconceptions and unwillingness about HIV/AIDS patient. The sufficient training, adequate equipment and higher wages also contributed in motivation among midwives in implemented normal labour care.

**Acknowledgement:** The author would like to thank to all midwives who working in maternity room of Sawerigading Palopo Hospital for resources and data input together with Faculty of Medicine, Hasanuddin University for unconditionally support.

**Conclusion**

In conclusions, no significant relationship between knowledge, attitudes and motivation among midwives toward normal labour care implementation in maternity room of Sawerigading Palopo Hospital.

Four Pillars Control of Blood Glucose Levels on the Patients with Diabetes Mellitus Type 2 in Ponre Village Bulukumba District

Yuyun Ariska¹, H. Ridwan A¹, Indra Dwinata¹
¹Faculty of Public Health, Hasanuddin University, Jl. Perintis Kemerdekaan Km. 10, Tamalanrea Indah, Tamalanrea, Tamalanrea Indah, Tamalanrea, Kota Makassar, Sulawesi Selatan 90245, Indonesia

Abstract

Type 2 diabetes mellitus (DM) can be regarded as one of chronic metabolic disorder in which number of patients has been increasing steadily all over the world for the past few years. The aim of this study is to determine the relationship between four pillars control toward blood glucose levels on patients with diabetes mellitus (DM) type II. The study type was analytic survey with cross sectional study approach. This study was conducted in January until February 2016 in Ponre public health centre (Puskesmas) working area in Bulukumba district. The population in this study were all patients with DM type II. The sample sizes were 82 respondents by using simple random sampling method. It can be concluded that there was significant relationship between knowledge (p=0.000), dietary habits (sugary, fatty and fibre food consumption) (p=0.000) and physical activity (p= 0.000). Meanwhile, no significant relationship between oral hypoglycemic drug consumption compliance to blood glucose levels (p= 0.000).

Keywords: blood glucose level; diabetes mellitus; four pillars; Puskesmas

Introduction

Diabetes mellitus (DM) type II is defined as metabolic disorder which caused by evolution of insulin resistance and abnormal of pancreatic beta cell function¹. An estimation of 366 million people aged between 20 years and 79 years had DM type II in worldwide². There are 85% to 95% of all diabetes had recorded in high income countries and DM type II is more dominated in developing countries³. Several causes contributed in DM type II such as gender, age, dietary habit, obesity, lack of sleep and nutritional supplement during maternal pregnancy⁴.

DM prevalence in Indonesia is estimated increased from 8.4 million to 21.3 million between 2000 and 2030. Indonesia is among highest of DM prevalence worldwide after India, China, United States and Pakistan⁵. The DM prevalence in South Sulawesi had reached 4.6%⁶. In 2008, DM was in fourth ranked of noncommunicable diseases (NCDs), 6.65% and contributed in fifth ranked caused death, 6.28%). Meanwhile, DM was main cause of mortality in South Sulawesi which is equivalence to 41.56%⁷. In Makassar city, there were 14,604 patients for DM disease in 2013. The objective for this study is to determine relationship between four pillars control toward blood glucose levels on patients with diabetes mellitus (DM) type II.

Methodology

Study Type: This study was used observational analytic observational with cross sectional study design.

Location and Time : This study was conducted from December 2015 to March 2016 at Puskesmas Ponre working area in Bulukumb district.

Population and sample: The population in this study were all patients with DM type II. The sample sizes were 82 respondents by using simple random sampling method.

Data Collection: The primary data was obtained through questionnaires and secondary data was determined from Puskesmas Ponre working area in form of DM data.
Data Analysis

The data was analyzed using SPSS program. The bivariate analysis was obtained to determine relationship between dependent and independent variables in form of cross tabulation with chi-square test.

Result and Discussion

Bivariate Analysis

Based on Table 1, 35 respondents (42.7%) had uncontrolled on blood glucose levels among DM type II patients, 28 respondents (66.7%) had lack of knowledge and 7 respondents (17.5%) had high knowledge. There were 14 respondents (33.3%) had lack of knowledge and 33 respondents (82.5%) had high knowledge for respondents with control in blood glucose levels. Based on chi square test analysis, there was a significant relationship between knowledge with blood glucose levels on DM type II patients at Puskesmas Ponre in Bulukumba district.

There were 33 respondents (71.7%) had consumed frequent sweet food and 2 respondents (5.6%) had rarely consumed sweet food with uncontrolled blood glucose levels. Meanwhile, 13 respondents (28.3%) had frequent sweet food consumption and 34 respondents (94.4%) had rarely sweet food consumption for respondents with controlled blood glucose levels. There was a significant relationship between sweet food consumption with blood glucose levels as shown in Table 2.

Based on Table 3, 35 respondents (154.7%) had frequent fatty food consumption with uncontrolled blood glucose levels. There were 29 respondents (45.3%) had frequent fatty food consumption and 18 respondents (100.0%) had rarely fatty food consumption without controlled blood glucose levels. Based on chi-
square test, there was significant relationship between fatty food consumption and blood glucose levels. As for sweet and fatty food category, 33 respondents (73.3%) had frequent consumptions while 2 respondents (5.4%) had rarely sweet and fatty food consumptions with uncontrolled blood glucose levels. In additions, 12 respondents (26.7%) had frequent sweet and fatty food consumptions and 35 respondents (94.6%) had rarely sweet and fatty consumptions with controlled blood glucose levels. There was a significant relationship between sweet and fatty food consumptions with blood glucose levels.

As shown in Table 4 in terms of vegetables consumption, 12 respondents (85.7%) had rarely fibre consumption and 23 respondents (33.8%) had frequent fibre in vegetable consumption with uncontrolled blood glucose levels. There were 2 respondents (14.3%) had rarely fibre in vegetables consumption and 45 respondents (66.2%) had frequent in fibre in vegetables consumption with controlled blood glucose levels. Based on chi-square test, there was significant relationship between fibre in vegetables consumption and blood glucose levels on DM type II patients at Puskesmas Ponre.

As for fruit consumption, 22 respondents (78.7%) had rarely with fibre in fruit consumption and 13 respondents (24.1%) had frequent with fibre in fruit consumption with uncontrolled blood glucose levels. Meanwhile, 6 respondents (21.4%) had frequent fibre in fruit consumption and 41 respondents (75.9%) had rarely fibre in fruit consumption with controlled blood glucose levels.

Based on Table 5, 25 respondents (96.2%) had lack of physical activities and 10 respondents (30.3%) had medium physical activities for respondents with uncontrolled blood glucose levels. Meanwhile, 23 respondents (69.7%) had medium physical activities and only 1 respondent (3.8%) had low physical activities for respondents with controlled blood glucose levels. There was a significant relationship between physical activities and blood glucose levels on DM type II patients at Puskesmas Ponre. Based on Table 6, 35 respondents (54.7%) were noncompliance patients with uncontrolled blood glucose levels. Besides, 29 respondents (45.3%) were noncompliance and 18 respondents (100.0%) were compliance without controlled blood glucose levels. Based on chi-square test, there was non-significant relationship between oral hypoglycaemic drug consumption compliance and blood glucose levels.

Overall Discussion

The result found significant relationship between knowledge and blood glucose level on DM type II patients. A study found significant relationship between dietary habits (sweet, fatty and fibre food consumptions) also showed significant related on blood glucose levels in DM type II patients in H. Adam Malik Medan Hospital. The knowledge was related to literary rates, household income, and self-care. Besides, dietary habits (sweet, fatty and fibre food consumptions) also showed significant related on blood glucose levels.
glucose levels among DM type II patients in Puskesmas Ponre. The glucose tolerance and sensitivity of insulin had influenced by quantity and quality of fat dietary\(^\text{10}\).

Furthermore, a study found high carbohydrate and low in fatty food with limitation of physical activities lead to overweight, obesity and other diabetes complications among Sri Lankan diabetes patients\(^\text{11}\). The fruit and vegetables are important in healthy diet and sufficient daily intake helped in prevent non-communicable diseases such as cardiovascular diseases, cancers and DM itself\(^\text{12}\). In additions, this study found some DM patients had frequently consumed vegetable but the blood glucose level still uncontrolled due to decreased in vegetable quality. The physical activities are all form of body movement activities such as cardiorespiratory fitness, exercise and physical fitness. The study found the physical activities is associated with blood glucose levels. A few studies had found benefit effect on regular physical activities on carbohydrate and insulation effect\(^\text{12}\). An estimation of 20%-30% of diabetes patients suggested light-intensity daily physical activity had reduced mortality in diabetic patients\(^\text{13}\).

There was no significant relationship between oral hypoglycaemic drug consumption compliance and blood glucose levels. Most respondents are compliance to consume oral hypoglycaemic drug had uncontrolled blood glucose levels and vice versa. Several factors had influenced in drug consumption compliance included age, social, education, knowledge on long-term treatment, psychological factors, medical treatment complexity, medical cost and treatment side effects. A study showed noncompliance DM type II patients had high 8.6 times of blood glucose levels than compliance DM type II patients for oral hypoglycaemic drug consumption\(^\text{14}\).

**Conclusion**

In conclusions, there was significant relationship between knowledge, dietary habits (sugary, fatty and fibre food consumption) and physical activity. Besides, there was no significant relationship between oral hypoglycaemic drug consumption compliance to blood glucose levels.

Social Determinants of Incidence of Maternal Deaths in Kabupaten Jeneponto in Year 2016

Abdul Rahman Akmal¹, Ridwan M. Thaha¹, Amran Razak¹

¹Faculty of Public Health, Hasanuddin University, Jl. Perintis Kemerdekaan Km. 10, Tamalanrea Indah, Tamalanrea, Sulawesi Selatan 90245, Indonesia

Abstract

Maternal death is one of the major challenges to global health system and is common in developing countries, especially in some backward villages which have inadequate health facilities. The aims of the research were to describe the social health determinants of the incidence of maternal deaths in Kabupaten Jeneponto 2016. This research was a qualitative research with an in-depth interview method with case studies approach. The research informants were 3 close relatives who accompanied the patients and were willing to be interviewed. Informants of this study were identified with snowball technique. Data were analysed with the content analysis method. The results of the study indicated that the incidence of maternal death in Tamalatea clinic was mostly caused by the disease complication, although the patients were always checked for her pregnancy and childbirth at health facilities and by existing midwife in their regions. Presence of other diseases was also the companion case to the risks of maternal death.

Keywords: Complications; Maternal mortality; Nutritional intake.

Introduction

Social determinants of health and behaviour influence the mortality and morbidity in a community. The relationship between the social determinants of health and health behaviour of mortality is an interesting topic to be analysed as mortality is one of three demographic components other than fertility and migration, which affects the number, structure and composition of a population. Social determinants and behaviours developed in the community by the government they provide public services, and health care facilities¹.

Maternal death is one of the global health problems and is common in developing countries. Maternal mortality, child mortality including infant mortality and life expectancy at birth has been established as indicators of health status in healthy Indonesia 2010. Maternal death is a complex issue that not only affects women only, but also affects families and even the surrounding community².

Maternal death continues to be a major challenge to the global health system. The greatest proportion of deaths is caused by obstetric haemorrhage, during or after childbirth, followed by eclampsia, sepsis, unsafe and indirect abortion complications, violence against women, malaria and HIV. Maternal health status affecting maternal mortality includes nutritional status, anaemia, maternal illness, and history of complications in pregnancy and delivery³.

Research conducted in the United States shows that maternal mortality will increase 4-fold in pregnant women at age 35-39 years when compared to women who are pregnant at the age of 20-24 years. The most secure pregnancy age for childbirth is age 20-30 years⁴. The Fifth Annual State of the World’s Mothers Report, published by The International Charity Save The Children, reports that annually, 13 million babies are born by women <20 years of age, and 90% of births occur in developing countries. These women have a risk of maternal deaths due to pregnancy and birth two to five times higher than women aged 20-34 years⁵.
times higher when compared to older women.

However, maternal mortality rate in Jeneponto is reported to be high is due to the low midwives’ competence in the villages, inadequate health facilities, geographical location causing delays in delivery assistance, socio-cultural factors and lack of cross-sectoral cooperation. Based on the profile of Jeneponto district health office, the number of maternal deaths in Jeneponto Regency in the last 5 years has increased from 6 people in the 2010 to 11 people in the year of 2015.

Thus, in this work, the authors have examined the determinant of social health to the incidence of maternal mortality in Jeneponto Regency for the Year 2016. This study was conducted qualitatively with in-depth interview method used in to investigate the cause of maternal death in the region.

Methodology

Research Type

The research design used is qualitative with a case study approach. Research strategy here will include observation, in-depth interview, or in-depth interview and documentation in obtaining research results on the social determinant of maternal mortality in Jeneponto District.

Location and Time of Study

This research was conducted for 2 months starting from March 2016 through April 2016. This research was conducted in Tamalatea Health Center area of Tamalatea Subdistrict of Jeneponto Regency, considering the number of pregnant women as much as 674 people in December 2015 and the incidence of maternal death as many as 3 people in most health centers in Jeneponto Regency 2015. Site selection is done based on data obtained through preliminary observations. The implementation of this research was conducted in Bontotangnga, Bontojai and Borongtala villages.

Population and Sample

Purposive Sampling method was used for selecting the informant for this study. Informants in this study were the closest relatives in which 1 sister case, 1 case husband, and 2 persons consisted of 1 case mother and 1 cousin case.

Data Collection

The primary data for this work was collected through in-depth interview and observation. The data collection was done through a retrospective time approach based on the incident case that already occurred. Secondary data was collected from obtained from Puskesmas research location related to mother’s death identity, residence address and the patient’s family. The source triangulation technique was used to ensure the degree of confidence of the data.

Data Processing and Data Analysis

Data obtained from in-depth interviews were analysed using the content analysis method. Data processing research conducted with the following stages.

1. Collecting data through in-depth interview using documentation tools such as recorder, pen and interview guide.

2. Data obtained through in-depth interviews then made in the form of narrative, then classified according to the dimensions of research.

3. Data obtained from informants without intervention researchers presented in the form of narrative text.

Research Ethics

This study was conducted after obtaining permission from University Hasanuddin and Jeneponto Regency Government. In addition consent of the informants was attained before proceeding to the interview session for data collection. All research informants were treated equally.

Result and Discussion

Data collection was conducted from 01 March until March 31, 2016, and the information about maternal deaths that exist in the work area Puskesmas Tamalatea district Jeneponto 2015 was obtained. Table 1 shows the information of the maternal death cases that were investigated.

**Death Case: CR**

For the case of CR, during in her pregnancy condition, CR has always visited health facility, taken the medication given by midwife, consumed milk and had enough rest. However, at the time of delivery she experienced eclampsia as her husband was not around during delivery. Thus this has caused high stress situation to CR which increased her blood pressure and caused seizures. Thus, the medical assistant responded to eclampsia by inserting MgSO4 injection into case fluid but the patient’s condition became more severe and finally the officer recommends the patient to be transferred to be referred to the hospital Lanto dg Pasewang immediately. However, the patient passed away while on the way to the hospital.

Reports from the WHO on maternal deaths find that the main causes of maternal mortality include bleeding, eclampsia and infection. Maternal death is a complex event caused by various causes that can be distinguished upon the determinants of near, intermediate, and distant. Close determinants that are directly related to maternal death are obstetric disorders such as bleeding, preeclampsy, and infections or illnesses suffered by women before or during pregnancy which can worsen pregnancy conditions such as heart, malaria, tuberculosis, and kidney. Close determinants are directly influenced by the determinants between health-related factors, such as maternal health status, reproductive status, access to health care, and health facility usage behaviour.

Determinants are much related to demographic and sociocultural factors. Low public awareness about maternal health, poor women’s empowerment, educational background, family socioeconomic, community and political environment, and indirect policy allegedly contributed to increased maternal mortality.

Ansariadi’s research stated that the direct cause pattern of maternal death in South Sulawesi has changed during 2008-2013. In 2008 the majority of maternal deaths were due to bleeding (62%) and hypertension during pregnancy (16%), whereas in 2013 mortality due to hypertension became the main cause of maternal mortality is 38%, while bleeding was second at 30%. In addition, there are variations in the cause of maternal deaths district level, such as changes in patterns of maternal death from bleeding to hypertension (preeclampsia).

Several factors that potentially increase the prevalence of preeclampsia / eclampsia are first pregnancy (primigravida), prior pregnancy history (kidney disease and high blood pressure), and pregnancy with increasing uterine strain (pregnant with most amniotic fluid, multiple pregnancy, and fetal pregnancy big). Observation of the prevalence of preeclampsia / eclampsia in the case group found the majority of pregnant samples at age> 35 at risk.

In the case of preeclampsia occurrence, spasm of blood vessels accompanied by salt and water retention takes place, causing growth disorders. In severe preeclampsia and eclampsia conditions there is a pathological deterioration in the function of some organs and systems in the body, due to vasospasm and ischemia. High protein affects the mother’s ability to repair the damage in her blood vessels, as the vascular build-up increases, the blood pressure rises. The fetus produced high protein due to the difficulty of attaining food.

Preeclampsia / eclampsia is more common at younger ages and nulliparas are thought to be due to an immunologic mechanism in addition to endocrine and genetic; and in the first hundreds of blocking antibodies to placenta antigen have not been perfect, which is more perfect in subsequent pregnancies. Research by Radjamuda and Montolalu states there is a relationship of age and parity with the occurrence of hypertension in
pregnancy (preeclampsia).

**Death Case: Na**

For the case of NA, she has passed away due to bleeding and delayed referral into the hospital by her family members. The most dominant type of bleeding occurs is uterine atony which is theoretically associated with anaemia during pregnancy. However, the prevalence of anaemia is unknown because not all samples tested haemoglobin during pregnancy. Atonea uteri can also be caused by handling of the third stage of labor is wrong, by massaging and pushing the uterus downward to give birth to the placenta. Therefore, competent labor is absolutely necessary to ensure safe delivery.

Postpartum haemorrhage is caused by anaemia during pregnancy. Every pregnant woman with anaemia has a risk for postpartum haemorrhage. One of the causes of postpartum haemorrhage is uterine atony, is the inability of the uterus to contract properly. In anaemia the effective amount of red blood cells is reduced. This affects the amount of haemoglobin in the blood. Lack of haemoglobin levels causes the amount of oxygen tied in the blood is also small, thus reducing the amount of oxygen delivery to vital organs.

One of the causes of death of pregnant women in Tamalatea Health Center is caused by malnutrition and lack of caloric energy (KEK). The pregnant women have anaemia because they do not consume the Fe tablets according to the prescription. Lack of adherence by pregnant women in taking iron tablets is related to their behaviour. Human behaviour is a reflection of some psychiatric symptoms influenced by experience factors, beliefs, means, physical, socio-cultural society. In addition, Socio-economic and cultural problems may be the cause of inadequate iron fulfilment, and gender equality issues also have an effect on the fulfilment of nutrients. Thus, pregnant woman whom have anaemia have the health risk and are prone to medical conditions during childbirth such as heavy bleeding which may cause mortality. The presence of labor complications, especially postpartum haemorrhage, contributes 25% to the occurrence of maternal death. This bleeding will cause the mother to lose a lot of blood, and will result in maternal death in a short time.

**Death Case: IR**

For the case of IR, her death was due to birth complication and was delayed to a health facility. Maternal health status affecting maternal mortality includes nutritional status, anaemia, maternal illness, and history of complications in pregnancy and delivery. The cause of maternal mortality can also be caused by the delay in referral to a health care facility. This condition is seen in cases of NR, where NR was treated at home for a week, and only was referred as the health conditions worsen.

The results of the Aeni’s study, in Pati regency of Central Java stated that the three most common causes of maternal mortality were pregnancy complication, birth complication and disease history. One of the causes of maternal mortality in the area Puskesmas Tamalatea is due to unavailability of health facilities in the form of completeness as doctors are not available during the time of patient’s referral.

Associated with the availability of facilities for early detection of comorbid diseases, generally Poskesdes which became a place of pregnancy check has not had complete facilities such as Puskesmas. The absence of pelvic floor tools, doppler and laboratory testing tools are Hemometer, urine protein and urine reduction in PKD facilities. Laboratory tests such as those conducted at the main health center. The condition of the facility has an impact on the quality of antenatal services provided. With limited facilities, the village midwife in the village health center needs a more complete examination to the primary health center. The availability of facilities will support the successful implementation of antenatal care according to the standard of midwifery services. If the mother needs laboratory examination then the mother will be referred to the Puskesmas.

The results of this study are in accordance with the research of Azizah and Nugrahen in the holy district which states that some midwives do not have complete pregnancy examination facilities such as hammer reflex, hemometer, pelvic length, urine protein and urine reduction because these facilities are mostly located at the primary health center, while they work a lot at village health posts.

**Overall Discussion**

Based on the interview results, the three cases of pregnant mothers who have died have always visited health facilities to check the condition of pregnancy accompanied by the close family or their husband.
Maternal deaths occurred only more due to a history of disease, bleeding factors and eclampsia. Reports from the WHO on maternal deaths found that the main causes of maternal deaths include bleeding, eclampsia and infection. Maternal death is a complex event caused by various distinguishable causes of the near, intermediate, and distant determinants. Close determinants that are directly related to maternal death are obstetric disorders such as bleeding, preeclampsia / eclampsia, and infections or illnesses suffered by women before or during pregnancy which can worsen pregnancy conditions such as heart, malaria, tuberculosis, and kidney. Close determinants are directly influenced by the determinants between health-related factors, such as maternal health status, reproductive status, access to health care, and the use of health facilities.

In addition, there are determinants which are related to demographic and sociocultural factors. Low public awareness about maternal health, poor women’s empowerment, educational background, family socioeconomic, community and political environment, and indirect policy allegedly played a role in increasing maternal mortality.

Although Say reported that the direct cause of maternal deaths globally is still caused by haemorrhage, hypertension and infection, Khan reported that there are differences in patterns of cause of death in various regions. For example Asia and Africa have the same pattern of primary bleeding and eclampsia, but in Latin America, hypertension is the leading cause of maternal mortality whereas in developed countries, maternal mortality is caused by abortion. This information demonstrates the need for cause-based death analysis, as there are likely causes in each region to differ. This study was supported by the results of Ansariadi’s study, the pattern of the direct cause of maternal mortality changes over the past five years. In 2008, more than half of maternal deaths were caused by bleeding, followed by infection and only a small percentage died of eclampsia. The proportion of maternal deaths due to eclampsia has increased from 2009 to 2013. In contrast, the proportion of maternal deaths due to bleeding has decreased. In 2013, only 30% of maternal deaths are caused by eclampsia.

In accordance with research conducted by Alkema, it is reported that mothers to die due to unavailability of personnel and adequate health facilities when there are complications of childbirth. The causes of such problems are not solely derived from the community, but are also affected by the health resources themselves.

Thus, in this work, the three cases of mothers who died always visit health facilities to check the condition of pregnancy accompanied by the close family or her husband as well as no relationship between antenatal care visits and maternal mortality. Maternal deaths are more due to a history of disease, bleeding factors and eclampsia.

Conclusion

Based on the discussion of the social determinant of maternal mortality in Jeneponto District, the authors can draw the conclusion that, CR died of eclampsia and late referenced. NA passed away due to bleeding and late referral as the family refused for an early referral and assumed the bleeding is in normal (cultural) labor. IR died due birth complications and late delivery to health facilities.

Acknowledgment: The author extends the appreciation to Jeneponto Regency Government for the permission and the Faculty of Public Health, University Hasanuddin for unconditionally support.

Abstract

Breast milk provides antibody and contains all the nutrients the newborn baby needs for the first six months. Although breastfeeding is a matter of personal preference, family support is a factor that is important in the practice of early initiation of breastfeeding (EIBF), in addition to internal factors, knowledge, attitudes, experiences and perceptions of mothers and external factors, health facilities and personnel birth attendant. This study aims to determine the relationship of successful factors in early initiation of breastfeeding at Puskesmas Jumpandang Baru. This study was quantitative research with a cross-sectional design. There were 80 sample cases of mothers who did early initiation breastfeeding. Data were analyzed using chi square. The research result indicate that there is no significant relation between birth weight, maternal age, parity, education, mother’s knowledge as well as mother’s ANC frequency and the successfulness of EIB. Whereas, there is a significant relationship between midwife’s knowledge (p=0.01) and the midwife’s attitude (p=0.00) with the success of early breastfeeding initiation.

Keywords: Birth weight; breastfeeding initiation; knowledge; midwives; parity.

Introduction

Implementation of EIBF can save 22% of babies who die before a month old. To achieve this goal, one of the things the government is doing is promoting EIBF. This effort was carried out to support the success of the exclusive breastfeeding program.

Nakao et al⁴ stated that the success of exclusive breastfeeding for up to 6 months was associated with EIBF within the first 2 hours of baby’s life and UNICEF in the WHO article wrote that 30,000 babies who usually died during the first month of birth could be saved by EIBF after the first hour of birth. The results of the study by Bakker et al⁵, in Bolivia and Madagascar, a quarter to half of infant’s deaths in developing countries occurs in the first week of life. According to research by Dashtidia et al⁶, in Middle Eastern countries only 6% of mothers breastfeed in the first 5 hours of birth, 71.6% after 36 hours after birth and 90% of them, two days after birth. The high level of delayed EIBF is strongly influenced by knowledge and culture. The results of subsequent statistics indicated that EIBF can reduce neonatal mortality by 22%. In developing countries, EIBF can reduce as much as 1.45 million deaths each year.

In normal childbirth care, EIBF is also an important step that must be carried out by health workers in assisting the delivery process, as well as the enactment of Government Regulation (GR) No.33/2012 concerning the exclusive feeding of breastmilk. The government’s efforts to succeed in the EIBF program not only in GR but also with the ‘Jampersal’ (birth guarantee) which began in 2011 with the aim to improve the quality of delivery services assisted by health workers who have understood the principles of EIBF implementation.

Various factors that cause low EIBF practices in Indonesia included lack of education, attitudes and motivation of breastfeeding mothers, and are influenced by the behavior and actions of midwives who do not conduct counseling on EIBF during pregnancy and do not support the management of EIBF in normal childbirth care and family support⁷. According to the 2010 IDHS data, the determinant of EIBF implementation consists of 1) infant factors; sex and birth weight, 2) maternal factors; health status, age, parity, education, knowledge and employment, 3) health service factors; antenatal care and birth attendant. Of the 3 factors that influence the implementation of EIBF in the 2010 IDHS data, there
is no data on the role of the family (husband / parents and relatives) in this case. Supported by research done by Sirajuddin\textsuperscript{6}, mentioned that success in implementing EIBF was not only from health workers but also from husband and family support. Family support is a very important factor in the practice of EIBF apart from internal factors; knowledge, attitudes, experiences and perceptions of mothers and external factors; health facilities and childbirth attendants\textsuperscript{7}. The purpose of this study was to determine and analyze the success factors of EIBF in the New Jumpandang Health Center.

**Methodology**

**Research Design**

This type of research is an analytic observational survey using a cross sectional study design approach to determine the success factors analysis of Early Breastfeeding Initiation (EIBF) at the New Jumpandang Health Center in Makassar, South Sulawesi.

**Population, Samples and Sample Techniques**

The population in this study was mothers giving birth with normal deliveries in the area of New Jumpandang Health Center in Makassar, South Sulawesi. The total sample in this study was 80 new mothers that had normal delivery. The sampling technique was purposive sampling.

**Data Collection and Analysis**

Data collection was carried out by direct observation using questionnaire instruments. The obtained data was processed using SPSS version 21 software and two statistical analyses (univariate and bivariate) were done.

**Results and Discussion**

**Univariate Analysis**

From Table 1 it is known that the distribution of successful EIBF from 80 samples was 44 deliveries with a percentage of 55% and those who did not succeed in EIBF were 36 deliveries with a percentage of 45%. Distribution based on baby weight born from 80 samples, babies born with 2500 - 3000 g are 54 babies with a percentage of 67.5%, 21 (26.3%) babies within 3100 - 3500 g, and 5 babies (6.3%) were 3600 - 4000 g.

From Table 2 it can be seen that the age distribution of mothers giving birth to the age group too young, which is <20 years is 57 people with a percentage of 71.3%, normal age is 21 - 35 years as many as 14 people with a percentage of 17.5% and age group too old that is > 35 years as many as 9 people with a percentage of 11.3%. Based on the characteristics of maternal education out of the 80 samples, 24 people studied up to higher education and those with low education were 56 mothers. Characteristics of maternal parity with no risk are parity 1-3 known to be 60 people with a percentage of 75.5% and those that are with high parity risk( > 3) are 20 people with a percentage of 25%. The characteristics of maternal knowledge with a good category are 49 people with a percentage of 61.3% and a category of poor knowledge were 31 people with a percentage of 38.8%. Characteristics of antenatal care (ANC) frequency among mothers during pregnancy under the high category were 55 people with a percentage of 68.8% and 25(31.3%) had low ANC frequency.

Bivariate Analysis

Based on Table 3, it can be seen that the proportion of infants in category A (2500 - 3000 g) who managed to get EIBF was 32 (59.26%) and those who did not succeed in EIBF were 22 (47.74%), in category B (3100 – 3500g) who succeeded in EIBF was 9 (42.86%) and did not succeed in EIBF were 12 (57.14%), and category C (3600 - 4000 g) had 3(60%) success EIBF and 2(40%) failed EIBF. The results of statistical analysis showed that there was no significant relationship between birth weight and the success of EIBF with a value of p = 0.43 means > 0.05, which can be concluded that there is no significant relationship between BBL and the success of EIBF in the Jumpandang Baru Makassar health center.

Data presented in Table 4 shown that the proportion of mothers aged <21 years who managed to do EIBF were 5 (55.55%) and those who did not succeed in EIBF were 4 (44.44%), 32 (56.14%) mothers aged 21 - 35 managed to EIBF while mothers aged more than 35, only 25 of them had a successful EIBF. However, the results of statistical analysis showed that there was no significant relationship between maternal age and EIBF success with p = 0.92. The proportion of tertiary education who managed to do EIBF were 29 (51.78%) and did not succeed in EIBF were 27 (48.21%), and 15 low education mothers succeeded in EIBF while the remaining 9 had a failed EIBF. The statistical analysis indicated that there was no significant relationship
between maternal education and the success of EIBF since the value of p = 0.38. The proportion of parity 1-3 who succeeded in EIBF were 30 (50%) and did not succeed in EIBF 30 (50%), and parity> 3 who succeeded in EIBF were 14 (70%) and 6(30%) did not succeed in EIBF. The results of statistical analysis showed that there was no significant relationship between parity and the success of EIBF with a value of p = 0.11. Prawirohardjo stated that based on the amount of parity, mothers with parity> 3 times tend not to succeed in EIBF because they usually face difficulties in pregnancy and labor, especially excessive fatigue, which affects emotional stability to carry out EIBF. Conversely, mothers with parity 1-3, usually have a greater motivation to do and know what is beneficial for their babies. In addition, the ideal birth span from the psychological aspect provides an opportunity for parents to devote more time to their children at the beginning of their age.

</table>

With reference to Table 5, it is found that the proportion of knowledge of both mothers who managed to EIBF was 28 (57.14%) and did not succeed in EIBF by 21 (42.87%), and poor knowledge that managed to EIBF were 16 (51.61%) and did not succeed in EIBF were 15 (48.38%). The results of statistical analysis showed that there was no significant relationship between maternal knowledge with the success of EIBF with a p value = 0.63. This is not in accordance with the theory of Helsing et al" and Amalia, who stated that the frequency of breastfeeding is higher among educated women. Learned mothers are more aware of the physiological and psychological benefits of breastfeeding early. In addition, educated mothers are more motivated and have more opportunities to get information since they have facilities. Nelvi also agreed that there is a meaningful relationship between educations with early breastfeeding where high-educated respondents carry out a successful EIBF of 74.7% unlike less-educated mothers. Based on this concept, implicitly explains that the failure of EIBF in mothers with low education will be more than those who successfully carry out EIBF. The mother category with good knowledge in accordance with the research conducted by Sutriyani, that is knowledgeable mothers have a great opportunity to want to do a job, so there is a relationship between mother’s knowledge with the success of EIBF, but in the category of lack knowledge, the number of respondents who managed to do more EIBF than those who did not. But increasing knowledge does not always reflect behavior change. Some of the factors that influence a person’s behavior are knowledge and attitudes, but the formation of behavior itself is not solely based on it but is still influenced by many very complex factors.

The proportion of good ANC frequencies that managed to EIBF was 28 (50.90%) and did not succeed
in EIBF by 27 (49.09%), and mothers with poor knowledge that managed to EIBF were 16 (64%) and did not succeed in EIBF were 9 (36%). Statistical analysis implied that there was no significant relationship between the frequency of ANC with the success of EIBF with a value of $p = 0.27$. The proportion of mothers that had midwives with good knowledge that managed to EIBF were 40 (61.53%) and did not succeed in EIBF were 25 (38.46%), and those mothers that had midwives with poor knowledge whom managed to EIBF were 4 (26.67%) and did not succeed in EIBF were 11 (73.33%). The results of statistical analysis showed that there was a significant relationship between the knowledge of midwives with the success of EIBF with a value of $p = 0.01$ means <0.05, thus it is concluded that there is a significant relationship between the knowledge of the medical officers/midwives and the success of EIBF.

The proportions of mothers whom had midwives with good behavior, managed to EIBF were 34 (72.34%) and did not succeed in EIBF were 13 (27.66%). Only 10 (30.30%) of the mothers whom had the midwives with poor behavior managed to EIBF while the remaining 23 (69.69%) failed in EIBF. The results of statistical analysis showed that there was a significant relationship between the attitudes of midwives with the success of EIBF with a $P$ value = 0.00 which is > 0.05, thus it can be concluded that there is a significant relationship between the attitudes of midwives and the success of EIBF in the Jumpandang Baru Makassar health center.

### Conclusion and Recommendations

Based on the results and discussion, it was concluded that there was no significant relationship between the weight of the baby born with the success of EIBF in the Jumpandang Baru Health Center ($p = 0.43$), the birth weight did not affect the success of EIBF. ($p = 0.92$), maternal age is not a barrier to the success of EIBF. ($p = 0.38$), meaning that maternal parity is not a barrier to the success of EIBF. ($p = 0.11$), maternal education is not an obstacle to the success of EIBF. ($p = 0.63$), maternal knowledge is not a factor that inhibits the success of EIBF. ($p = 0.27$), the frequency of ANC also does not become a major factor inhibiting the success of EIBF.
There is a significant relationship between the knowledge of midwives and the success of EIBF (P 0.01), meaning that knowledge of midwives is a factor that supports the success of EIBF. The better the knowledge of birth attendants (midwives) about EIBF, the better the success of EIBF and there is a significant relationship between the attitude of midwives and the success of EIBF (p value= 0.00), implying that the more active the midwife is, the higher the success rate of EIBF.

Relationship between Childbirth Duration and Postpartum Blues

Amalia Rizki Meilina¹, Nasrudin A. M¹, Budu¹
¹Faculty of Medicine, Hasanuddin University, Jl. Perintis Kemerdekaan Km.10, Makassar, 90245.
Sulawesi Selatan, Indonesia

Abstract

The study aimed to determine relationship between childbirth duration and postpartum blues. The study was using cohort research design to determine relationship between childbirth duration and postpartum blues. The study was conducted in maternity ward of Pangkep district Hospital for two months duration. The study population were all mothers who came to give birth at Pangkep district Hospital during intervention period. The sample sizes were 60 respondents which met the criteria for this study. The data was analysed using SPSS program. The result found 80% of respondents experienced postpartum blues. Most respondents (83.3%) aged between 20 years and 35 years (low risk), while highest parity percentage was in multiparous mothers (70%). There were 63.3% of respondents had low education level and 78.3% had pregnancy planning. The statistical test had obtained of phase I (p=1.000), phase II (p=1.000) and phase III (p= 0.340).

Keywords: Education level; Parity; Postpartum period; Pregnancy planning.

Introduction

Approximately 85% of women experienced mood disturbance during their postpartum period¹. Postpartum period is critical period which biological, social, physical and emotional changes². There are three diverse but continuous phases; third phases known as delayed postpartum period which end up to 6 months³. The postpartum period lead women highly susceptible to many psychiatric disorders. The psychiatric disorder during postpartum period included postpartum blues (maternity or baby blues), postpartum depression and puerperal psychosis³.

The postpartum blues were conditions classified by anxiety, irritability, lack of concentration, frequent crying and mood swing⁴,⁵. This postpartum blues is commonly occurred in western countries due to lack of family bonding and support⁶. The symptom was usually happened on day 3 or day 4, which continues for hours up to several days⁷. The real cause of postpartum blues is still unknown. However, many factors are contributed to postpartum blues included hormonal factors associated with changes in estrogen, progesterone, prolactin and estradiol levels. The low estrogen level after childbirth is very influential in postpartum emotional disorder since estrogen had affected monoamine oxidase enzyme activity. Besides, demographic factors also contributed in postpartum emotional disorder such as age and parity, pregnancy and childbirth experience, mother’s psychosocial background, fearful of losing or disappointment toward their infant. The postpartum blues could develop into postpartum depression or severe symptom of postpartum psychosis. The study aims to determine relationship between childbirth duration and postpartum blues.

Methodology

Study design

The study was using cohort research design to determine relationship between childbirth duration and postpartum blues.

Study location and time

The study was conducted in maternity ward of Pangkep district Hospital for two months duration.

Study population and sample

The study population were all mothers who given birth delivery at Pangkep district Hospital...
during intervention period. The sample sizes were 60 respondents which met the criteria for this study.

**Data collection**

The primary data was obtained from the partograph and questionnaire, while secondary data was obtained from patient’s medical records. The data collection process was assisted by midwives who worked in maternity ward to observe childbirth duration by using partograph.

**Data analysis**

The data was analysed using SPSS program. Univariate analysis was represented in form of frequency distribution table. Meanwhile, bivariate analysis was performed to determine relationship between dependent variable and independent variable by using chi square test.

**Results and Discussion**

**Univariate Analysis**

Based on Table 1, most of respondents, 50 respondents (83.3%) were low risk categories aged between 20 years and 35 years. Meanwhile, 42 respondents (70%) were multi parous and only 18 respondents (30%) were primipara. This study also found 38 respondents (63.3%) had low education level (primary school and junior high school) and 22 respondents (36.7%) had high education level (high secondary school, academy and university). There were 47 respondents (78.3%) had pregnancy planning and 13 respondents (21.7%) had no pregnancy planning.

Bivariate Analysis

There were 39 respondents (78%) who aged in low risk and 9 respondents (90%) were high risk who experienced postpartum blues. Meanwhile, 11 respondents (22%) who were in low risk and only one respondent (10%) were in high risk with no experience in postpartum blues. The statistical test found no relationship between age and postpartum blues occurrence. In additions, 42 respondents had multiparous and 18 respondents had primipara. There were 34 respondents (81%) had multiparous with postpartum blues occurrence and only 4 respondents (22.2%) had primipara without postpartum blues occurrence. The chi square test showed no significant relationship between parity and postpartum blues. In education level category, 33 respondents (86.8%) had low education level who experienced postpartum blues and 7 respondents (31.8%) had high education level with no experience in postpartum blues occurrence. There was no significant relationship between education level and postpartum blues occurrence. Furthermore, 10 respondents (21.3%) had pregnancy planning with no experience in postpartum blues and 11 respondents (84.6%) had no pregnancy planning with experienced postpartum blues occurrence.

**Overall Discussion**

The study found high postpartum blues incidence because most respondents were experienced in postpartum blues, 80%. In additions, a study found high postpartum blues prevalence in Semarang city, 67.5% and low postpartum blues incidence had recorded in Taiwan only 40%. Most of postpartum blues occurred in high risk age (<20 years and > 35 years). The statistical test showed no significant relationship between age and postpartum blues occurrence. This study also supported by several studies which found no correlation between age and postpartum blues. Based on the parity, postpartum blues in multiparous mother was 81% and 77.8% occurred in primipara mother. The postpartum blues incidence occurred in mothers of any ethnicity, race and parity. Furthermore, there is no significant relationship between parity and postpartum blues. The mother with primipara had high risk suffering postpartum blues than mother with multiparous. Besides, mother with primipara had experienced many difficulties in parents’ role adaption.

Based on education level, 86.8% of respondents with low education level had experienced postpartum blues. The mother with low education level had large number of children and lack in infant’s care quality since pregnancy had occurred during their young age.
There was no significant relationship between education level and pregnancy planning with postpartum blues. A study found higher postpartum blues risk in unmarried or without family planning than mother with good in family planning. The pregnancy planning is correlated to mother’s readiness in physical, mental and economy.11.

Furthermore, the statistical test also found no significant relationship between childbirth duration and postpartum blues occurrence. The result was indicated respondents had normal childbirth duration experienced postpartum blues than respondents with prolonged labour. Hence, childbirth duration is not caused postpartum blues among respondents. The family support also had influenced postpartum blues occurrence among women. The postpartum blues is high risk occurred in mother with lack of family supports. The women easily to be influenced with certain emotional disturbance during their pregnancy, labour and postpartum. A strong and consistent family support is main key factor in postpartum blues prevention.

**Conclusion**

In conclusions, there was no significant relationship between respondent characteristic (age, parity, education level and pregnancy planning) and childbirth duration with postpartum blues occurrence. The fixed screening procedure should be done on postpartum mothers to detect postpartum blues with using Edinburg Postnatal Depression Scale (EPDS) or other recommended instruments.

Abstract

The breast milk is first and best food for the infant since contains various nutrients needed by the infant. However, the working mother become an obstacle giving exclusive breast feeding. This study aimed to determine the internal and external factors that affected exclusive breastfeeding on working mothers. The study was used descriptive correlational with cross sectional study design. The sample sizes were 37 respondents which selected by purposive sampling that met inclusion criteria such as mother who had infant aged more than 6 months until 24 months, working in the formal sector, breastfeeding the infant, the infant was first child and single birth and willing to be a respondent. The data was analysed by using bivariate analysis with chi square test. The result showed internal factors such as maternal knowledge about lactation management had r=0.350 and p=0.033 and maternal psychological condition had p-value of 0.014 and r=0.414 with exclusive breastfeeding on the working mothers. The external factors such as breastfeeding facilities condition had p-value of 0.006 and r=0.454 while time availability factor for the infant had p-value=0.286 and r=0.175 and leadership policy had p=0.666 and r=0.071.

Keywords: Leadership policy; Maternal knowledge about lactation management; Maternal psychological condition; Time availability; Working mothers.

Introduction

Maternal breastfeeding is natural and suitable ways to feed a child in the first months of life to promote sufficient growth and development¹. World health Organization (WHO) began suggested the infants be exclusive breastfeeding in 1990 and stated optimal duration is six months². Exclusive breastfeeding means infants only receive only breast milk³. Meanwhile, breastfeeding is encouraged after 6 months together with introduction of other foods and liquids⁴.

Breast milk is ideal nutrition which providing all of the nutrient including vitamins and minerals that an infant need for first six months of life⁵. The breast milk contains all essential nutrient including carbohydrates, essentials, proteins, minerals and immunological factors⁶. The exclusive breastfeeding has potential to decrease under five death by 11.6% with exclusive breastfeeding prevalence is still relatively low in worldwide and 90% of exclusive breastfeeding practices has decrease the infant death incidence due to pneumonia⁷. Meanwhile, non-exclusive breastfeeding in first six months of life leads in 1.4 million mortality and 10% of diseases in under-fives and contributes to long term impact such as poor school performance, decreases productivity and impaired intellectual and social development⁸.

There was several factors correlated with not initiating exclusive breastfeeding or with discontinue exclusive breastfeeding before 6 months such as lower maternal age, low socioeconomic status and educational level, unsupportive work environment, insufficient care during birth and in the postnatal period, low birth weight, inadequate milk supply, previous negative experiences with breastfeeding or attitudes regarding exclusive breastfeeding before birth among others⁹. Besides, another study found younger women with lower incomes, ethnic minorities and full-time employees were stop breastfeeding within first month of infant’s life, while other studies found breastfeeding duration is longer in better educated mothers¹⁰.

The study has classified that exclusive breastfeeding by working mothers was influenced by two factors such as internal factors including mother knowledge
about lactation management, maternal psychological condition, while external factor such as time availability for infant, breastfeeding conditions and leadership policy. The support for exclusive breastfeeding programs for working mothers is breakthrough that can increase the coverage of national exclusive breastfeeding.

Physiotherapy treatment has wide range of women health role including able to provide education as promotive and preventive step and special interventions related to lactation management to breastfeeding mothers. This lactation management can help to prevent the occurrence of main exclusive breastfeeding failure among working mothers. This study aims to determine the internal and external factors that affect exclusive breastfeeding on working mothers.

Methodology

Study design

The study was used descriptive correlational research with cross sectional design.

Study location and time

The study was conducted in Berua district of Makassar on 12th April until 10th May 2017.

Study population and sample

The study population was all mothers working in the formal sector, domiciled in Berua district and had infant aged more than 6 months until 24 months. The study samples were 37 mothers who met the inclusion criteria such as mother who had infant aged more than 6 months until 24 months, working in the formal sector, breastfeeding the infant, the infant was first child and single birth and willing to be a respondent.

Data analysis

The data was analysed using SPSS program and bivariate analysis was done to determine the relationship between dependent and independent variable using chi square test.

Results and Discussion

Univariate Analysis

In Table 1, there were 21 respondents (56.8%) aged between 26 years old and 30 years old and 9 respondents (24.3%) aged between 31 years old and 35 years old. There were 20 respondents (54.1%) who were completed degree and 10 respondents (27.0%) were completed master. Meanwhile, 20 respondents (54.1%) were working less than 8 hours per day and 17 respondents (45.9%) had working hours between 9 hours and 11 hours. In additions, 14 respondents (37.9%) had salary less than Rp. 5,000,000, while 15 respondents (40.5%) had earned salary between Rp. 5,000,001 and Rp. 10,000,000. Besides, only 8 respondents (21.6%) had earned more Rp. 10,000,001.

**Bivariate Analysis**

Furthermore, 17 respondents (45.9%) had good knowledge in lactation management, while 3 respondents (8.1%) had medium knowledge in lactation management for exclusive breastfeeding mothers. Meanwhile, 9 respondents (24.3%) had good knowledge and 8 respondents (21.6%) had medium knowledge about lactation management for nonexclusive breastfeeding mothers.

In additions, 17 respondents (45.9%) had good psychological condition and 3 respondents (8.1%) had poor psychological condition for exclusive breastfeeding mothers. Meanwhile, 8 respondents (21.6%) had good psychological condition and only 9 respondents (24.3%) had poor psychological condition.

There was correlation between internal factors and exclusive breastfeeding included maternal knowledge about lactation management ($p=0.033<0.05$) with correlation value ($r=0.350$) by 12% which the relationship between two variables is strong enough. Meanwhile, there also correlation between psychological condition and exclusive breastfeeding with $p=0.014<0.05$ with percentage of correlation coefficient value ($r=0.414$) by 17% proved the relationship between two variables is strong enough.

Meanwhile, 14 respondents (37.9%) had time availability and 6 respondents (16.2%) had no time availability for their babies in exclusive breastfeeding mothers. There were 9 respondents (24.3%) had time availability and 8 respondents (21.6%) had no time availability with their babies for non-exclusive breastfeeding mothers. There were 16 respondents (43.2%) had sufficient breastfeeding condition and 4 respondents (10.8%) had insufficient breastfeeding conditions for exclusive breastfeeding mothers. In additions, 6 respondents (16.2%) had sufficient breastfeeding condition, while 11 respondents had insufficient breastfeeding conditions for non-exclusive breastfeeding mothers. Furthermore, 12 respondents (32.4%) were supported in leadership policy and 6 respondents (21.6%) were not supported in leadership policy for exclusive breastfeeding mothers. There were 9 respondents (24.3%) had supported in leadership policy and 8 respondents (21.6%) were not supported in leadership policy.

The external factors associated with exclusive breastfeeding in mothers were breastfeeding conditions ($p=0.006<0.05$) with percentage of correlation coefficient ($r=0.454$) of 21% indicated the relationship between two variables was strong enough. Another two other external factors did not show any relationship with exclusive breastfeeding such as time availability for the babies ($p=0.286$) with percentage of correlation coefficient ($r=0.175$) at 3% showed the relationship between two variables was weak and the leadership factor ($p=0.666$) with the percentage of correlation coefficient value ($r=0.071$) which greater than 0.05 indicated the relationship between two variables was very weak.

Overall Discussion

The high women participation and participated in all working areas as one reason that most mothers to provide the formula milk. Hence, working mothers often go for work or involved in social tasks that formula milk ins considered only way out in the food provision for the infants.

In this study, exclusive breastfeeding mothers proportion was reached 54% which relevant that majority of respondents were well-informed, good psychological conditions and sufficient breastfeeding means. The maternal knowledge of lactation management is associated with exclusive breastfeeding in working mothers where the relationship between these two variables is strong enough. Suryani (2016) found the relationship between knowledge and exclusive breastfeeding mothers (p=0.041) which higher maternal knowledge with higher exclusive breastfeeding behaviour.

The breastfeeding knowledge is important role in maintaining human life. The mother will losing confidence to provide best care for the infant, infant would losing vital food resource and optimal care means. This study showed there was relationship between the maternal psychological condition and exclusive breastfeeding in the working mothers which two variables are strong enough. The result indicated better maternal psychological condition and better breastfeeding behaviour.

Utari et al. revealed maternal psychological condition did not showed correlation with exclusive breastfeeding. The time availability for infant is not correlated to exclusive breastfeeding in the working mother which the relationship between two variables is quite weak. In this study, most respondents (54.1%) had working hour less than 8 hours per day. Meanwhile, some respondents claimed short distance from house and workplace, so the respondents managed go back home every few hours to feed their infants and often brought their infants to their workplace.

This study showed there was relationship between breastfeeding condition and exclusive breastfeeding in the mothers which the relationship between two variables was strong enough. The high sufficient breastfeeding means in the workplace, more likely the mother is to give exclusive breastfeeding. In this study, insufficient lactation support was found in some respondents since less breastfeeding room in the workplace. There is also have no refrigerator available for storing the breast milk as well as lack of rest period for breastfeeding. In additions, some respondents brought their infants to workplace claimed need to build own space for their infants to play and rest in form of box at the room corner.
The statistical test also showed no significant relationship between leadership policy and exclusive breastfeeding in the working mothers which relationship between two variables were very weak. Most corporate leaders were not concerned with working women who wanted to breastfeed their infants at the workplace leads some working mothers felt ashamed and hiding in certain area for breastfeeding or simply pumping breast milk.

Acknowledgement: The author would like to thank to all respondents in Berua district of Makassarand Faculty of Medicine, Hasanuddin University for unconditional support.

Conclusion

In conclusion, there was correlation between internal factor, maternal knowledge about lactation management and psychological condition with exclusive breastfeeding in the working mothers. In external factors, there was relationship between breastfeeding conditions and exclusive breastfeeding in the working mothers. Meanwhile, other factors such as time availability for the infant and the leadership policy did not have any relationship with exclusive mother breastfeeding. The maternal knowledge of lactation management was most dominant factor in giving exclusive breastfeeding to working mothers. This study is expected to be reference source for future study and should identify more diverse factors related to exclusive breastfeeding in working mothers as well as controlling confounding variables that may affects the study result.

Influence of Oxytocin Massage on Oxytocin Concentration Level and Involution on Postpartum Mothers in Siti Khadijah I Maternity Hospital, Makassar City

Asyima¹, Nasrudin A. M¹, Irfan Idris¹

¹Faculty of Medicine, Hasanuddin University, Jl. Perintis Kemerdekaan Km.10, Makassar, 90245.
Sulawesi Selatan, Indonesia

Abstract

The study aimed to determine influence of oxytocin massage on oxytocin concentration levels and uterine involution on postpartum mothers in Siti Khadijah I Maternity Hospital, Makassar city. The study was used quasi experimental research design with two groups post-test included intervention and control groups. The study population were all postpartum mothers at Siti Khadijah I Maternity Hospital, Makassar city. The samples sizes were 40 respondents which divided into two group included 20 respondents in intervention group and 20 respondents in control group that met the study criteria. The samples were obtained by using purposive sampling method. The data was analysed using SPSS program. The univariate analysis is represented as frequency distribution for each variable. The bivariate analysis is used to determine influence of oxytocin massage on oxytocin concentration changes and uterine involution among postpartum mothers. The statistical test in oxytocin concentration and oxytocin massage level among postpartum mothers had obtained p=0.005. Meanwhile, Mann Whitney test in oxytocin massage and oxytocin hormone concentration among postpartum mothers with p=0.005.

Keywords: Fundal height; Maternal parity; Oxytocin hormone; Postpartum period; Uterine involution.

Introduction

The postpartum period known as “fourth stage of labour and had three distinct but continuous phase: initial or acute period which included first 6-12 hours postpartum, subacute postpartum period which lasts 2-6 weeks and delayed postpartum period which last up to 6 months”. Meanwhile, Ozturk et al. mentioned postpartum period is transition period for women to adapt difficulty after birth, new order in the family and differences in the body image. The postpartum period was time that changes in external and internal occurred especially psychic transformations which women required protection and care. Besides, this period was period which uterine involution and restored ovarian function for new pregnancy.

The uterine involution is referred to the return of uterus size to non-pregnant size as normal as oestrous cycle. The uterus involution had been determined by fundal height and its difficult in uterine myoma and obese women. The oxytocin hormone is important to increase uterine contraction after labour which avoid postpartum haemorrhage occurrence and maternal oxytocin levels also was related to uterine atony occurrence. The oxytocin hormone had released into bloodstream through posterior pituitary during labour, after sexual stimulation, stress, lactation and social interaction and uterine dilation. The oxytocin hormone levels was observed higher in pregnant women than non-pregnant women. The oxytocin massage is spinal massage from fifth or sixth costa until scapula which stimulated parasympathetic nerves so that prolactin and oxytocin hormone are released. The aim of study to determine influence of oxytocin massage on oxytocin concentration levels and uterine involution on postpartum mothers in Siti Khadijah I Maternity Hospital, Makassar city.

Methodology

Study design

The study was used quasi experimental research design with two groups post-test included intervention
and control groups to determine influence of oxytocin massage for oxytocin concentration enhancement and uterine involution.

**Study location and time**

The study was conducted from February to March 2016 at Siti Khadijah I Maternity Hospital, Makassar city.

**Study population and sample**

The study population were all postpartum mothers at Siti Khadijah I Maternity Hospital, Makassar city. The samples sizes were 40 respondents (20 respondents in intervention group and 20 respondents in control group) which met the study criteria: i) third day postpartum mothers who had normal labour, ii) no any systemic disease and good mental health. The samples were obtained by using purposive sampling method.

**Data analysis**

The data was analysed using SPSS program.

**Results and Discussion**

**Univariate Analysis**

Based on Table 1, 27 respondents (67.5%) were aged between 26 years and 30 years old and only 3 respondents (7.5%) were aged between 31 years and 35 years. There were 23 respondents (57.5%) had low education level and 17 respondents (42.5%) had high level education level. Most respondents were housewives represented 60% of respondents, while 10 respondents were worked as civil servants and 6 respondents (15%) were private employee. Meanwhile, 21 respondents (52.5%) were multigravida mothers and only 1 respondent (2.5%) were grand multiparous mothers.

Multivariate Analysis

The data was using Mean CAT analysis to obtain oxytocin hormone category. The postpartum mothers who performed oxytocin massage with oxytocin hormone category 2, while postpartum mothers without oxytocin massage was in category 1. In additions, uterine involution among postpartum mothers with oxytocin massage was in category 1 and uterine involution among postpartum mothers without oxytocin massage in category 3.7.

Overall Discussion

The results showed most respondents were aged between 26 years and 30 years and these respondents were primigravida and multipara mothers which had knowledge and experience in pregnancy and childbirth. Besides, most respondents were housewives, low education and multiparous mothers. The parity also influenced in uterine involution process. The uterine involution process tends to decline in multiparous mothers than primigravida mothers due to lack of elasticity of uterus muscles. The results also found there were significant influence of oxytocin massage toward oxytocin hormone concentration and uterine involution among postpartum mothers. The oxytocin massage helped to stimulate uterine contractions during labour and after labour to accelerate the uterine involution.
The mean differences of oxytocin hormone levels between postpartum mothers with oxytocin massage and postpartum mothers without oxytocin massage. The postpartum mothers who did not received oxytocin massage had 5 times greater risk in having abnormal uterine involution than postpartum mother had oxytocin massage. The oxytocin hormone levels also had influenced by other factors such as early breastfeeding initiation which help in improve uterine contraction. Dyna et al. found oxytocin massage increased prolactin hormones levels and production of breast milk among respondents with post caesarean section mothers. Meanwhile, Sari et al. mentioned combination of endorphin massage and oxytocin massage accelerated uterine involution in normal postpartum mothers. The oxytocin levels are higher in women with normal childbirth than women with caesarean delivery.

Besides, oxytocin levels are slowly increased until birth delivery and slow down up to 8 weeks postpartum period. Lothian et al. suggested oxytocin ease placenta separation and maintain uterus contraction to prevent excessive bleeding. In additions, Kosova et al. also mentioned oxytocin help uterus to return to its pre-pregnancy dimension by uterus contraction. The oxytocin massage had increased oxytocin hormone levels which improve uterus contraction and prevent the bleeding occurrence.

Acknowledgement: The author would like to thank to Siti Khadijah I Maternity Hospital, Makassar city for information support and Faculty of Medicine, Hasanuddin University for unconditionally support.

Conclusion

In conclusions, there was influence on oxytocin concentration levels and uterine involution among postpartum mothers who had received oxytocin massage. The nurses and midwives should improve their knowledge in oxytocin massage technique, while the hospital need to apply oxytocin theory during massage on postpartum mothers to accelerate the uterine involvement occurrence.

Utilization of Home Care Services among the Fishermen Community at Makassar City

Citra Ayu Lestari Hanisu¹, Suriah¹, H. Watief A. Rachman¹

¹Faculty of Public Health, Hasanuddin University, Jl. Perintis Kemerdekaan Km. 10, Tamalanrea Indah, Tamalanrea, Tamalanrea Indah, Tamalanrea, Kota Makassar, Sulawesi Selatan 90245, Indonesia

Abstract

A care which allows a person with special needs to continue staying in their house is called home care. It is beneficial for people who are chronically ill, disabled or getting older. The aim of this study to determine the utilization of home care services in fishermen community at Makassar city. The study type was qualitative research with phenomenology design. The study informants were determined by using purposive sampling method. The informants included 4 patients, 12 patient’s family members, 3 home care staffs, and head of basic service and referral section of Makassar city Health Office. The data was obtained through in-depth interview and observation and then analyzed using content analysis and represented in the narration. The results found that fishermen community who utilized home care services has lack of knowledge but with positive attitude towards home care services. The home care staffs were friendly, kind and alert in serving the patients included fishermen communities. In additions, home care services are more effective and efficient in term of time, accessibility to health center and economy.

Keywords: fishermen; home care; health care; service

Introduction

The ageing population is growing rapidly worldwide. The world population over 60 years would be double from 12% to 22% between 2015 and 2050¹. The older adults aged 65 years and above are expected to represent at least of 28% of population in Switzerland². According to World Health Organization (WHO), the number of people utilizing health services in India was 60.4 million people, 98.5 million in China and 38.4 million people in other part of Asia countries³. In United States, older adults aged 65 years and above had utilized 36% of health care which only representing 13% of population⁴.

Based on National Health Survey (SUSENAS) showed 32.4% of population with poor status had utilized health services and integrated health post were most visited for health services with 61.6%⁵. The health services utilization is influenced by several factors such as socio demographic conditions, attitudes, beliefs and social culture, socio economics, distance to health facilities, health service cost and service time⁶.

Several studies were conducted to determine factors impacting health services among community. A study found several factors included individual characteristics (age, education and illness perception), availability of health workers, distance to health centres and availability of transportation are associated toward utilization of health centres by the community⁷. In Manado city, a study found significant correlation between perception, accessibility to health services and health workers behaviour toward health service utilization by social insurance administration organization participant⁸.

Makassar city has 46 public health centres (Puskesmas) in 2015. Makassar city Health Office had implemented several programs such as Telemedicine and E-Puskesmas to encourage community in health service utilization. Home care was aimed for people who had limitation on accessing health centres due to several factors such as long distance to health centre, limitation of accessibility of transportation and socio-economic
status. In 2016, there were 2170 people had utilized home care services where 2058 people had been treated and 112 people are referred. The fisherman community conditions in term of economy and demography is very influential on health services utilization in Makassar city. The geographical location of fishermen community on the island leads to limitation of accessibility on health facilities. Home care services is one of health services which helps in health status improvement in the fishermen community of Makassar city, especially Ujung Tanah sub district. Hence, the aim of this study is to determine the utilization of home care services among fishermen community in Makassar city.

Methodology

Study Type

This study type was qualitative method by using phenomenology design.

Location and Time

This study was conducted from March 2016 to April 2016 at Ujung Tanah sub district in Makassar city.

Study Informant

The informants were determined by using purposive sampling technique. The informants were selected according to study criteria i) fishermen community living in Ujung Tanah sub district; ii) utilizing home care services; iii) patient or patient’s family. In additions, home care staffs and head of basic service and referral section of Makassar city Health Office also were selected as informants in this study.

Data Collection and Data Analysis

The data was obtained through in-depth interview and observation. Subsequently, the data was analysed using content analysis and represented in the narration.

Result and Discussion

Result

The result found some informants were not aware about home care services despite receiving home care services. The nurses mentioned socialization had been done to the community and home care services call centres also have been affixed in some locations. Besides, some informants called home care services as home visit services after further explanation. The head of basic services and referral section of Makassar city Health Office revealed home care services are home visit done by contacting nearby health call centre. Home care services had divided into 3 types; visiting patients, patient follow up patient and emergency. Based on this study, most informants had received home care services information from their surrounding such as neighbours, communities and own initiatives. The accessibility on home care services varied ranging from informants visit to Puskesmas, request or advice from Puskesmas staff and head of village. The informant had informed Puskesmas staffs that patients have home care services but facing difficulty go to health centres. Informant’s knowledge level on home care service is summarized in Table 1.

<table>
<thead>
<tr>
<th>Variable</th>
<th>Informant’s answer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Understanding toward home care services</td>
<td>Some informants are not aware on home care services despite receiving home care services. According to home care staffs, home care is defined as home visit services by contacting health call centre.</td>
</tr>
<tr>
<td>Information resource</td>
<td>Most of informants received information about home care services from their neighbour and their own initiative. Meanwhile, home care staffs mentioned most of communities had utilized home care services before socialization.</td>
</tr>
<tr>
<td>Accessibility on home care</td>
<td>The accessibility of home care services varied ranging from visiting Puskesmas itself, advice from Puskesmas staff and head of village.</td>
</tr>
</tbody>
</table>

Most of informants gave a positive feedback on home care services as shown in Table 2. The informants claimed home care services made their life more convenient and very helpful in accessing health services by calling health centre via phone. Most of informants found home care staffs were friendly and kind. Besides, there were no complaints from patients regarding the services provided by home care staffs. In contrast, some informants still dissatisfied with service provided even staffs had friendly and kind attitude.
Table 2. Informant’s feedback towards home care services in fishermen community at Makassar city

<th>Variable</th>
<th>Informant’s answer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Feedback</td>
<td>Good feedback from informants toward home care service</td>
</tr>
</tbody>
</table>

Based on study, some informants found fast response from home care staffs to serve the patients after contacting the health centres. Nonetheless, there are informants who also claimed delay in services from staffs itself due to several factors such as hot weather, lot of patients in health centres and limited transportation. Informants’ feedbacks about home care staff’s behaviour towards home care services can be found in Table 3. The informants claimed home care services are more effective and efficient in term of time, transportation and economy as tabulated in Table 4. The geographical conditions, transportation and illness lead patients to prefer home care services. Based on in-depth interviews, most informants felt home care services fulfilled their needs for physical health by receiving free treatment. The drugs and services from home care staffs are without any charges. However, some informants claimed that home care services did not fulfil their health needs since treatment did not concentrate on chronic illness.

Table 3. Home care staff’s behaviour toward home care services in fishermen community at Makassar city

<table>
<thead>
<tr>
<th>Variable</th>
<th>Informant’s answer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Friendly</td>
<td>Home care staffs were very friendly and kind. Even though, some informants dissatisfied with services provided by staffs there were no complaint from patients itself regarding the services.</td>
</tr>
<tr>

</thead>
<tbody>
<tr>
<td>Reason for utilizing home care</td>
<td>Some informants found home care services are more effective and efficient in terms of time, transportation and economy.</td>
</tr>
<tr>
<td>Benefit and need from home care services</td>
<td>Home care services fulfilled informant’s need for their physical health.</td>
</tr>
</tbody>
</table>

Overall Discussion

The result found that the community still have lack of understanding or knowledge concerning home care services. The informants never know about home care either from mass communication or Puskesmas. The fishermen community regarded home care services as home visits after further explanation on home care definition is given. Besides, none of the informants utilized home care services by contacting health call centre. Some informants still use home care services but had no knowledge on home care services. Hence, knowledge had no influenced in home care services utilization. A study found correlation between confidence and interest at inpatient services of Stella Maris Hospital due to health workers ability in treatment.

Based on in-depth interviews, all informants have a positive attitude towards home care services. Home care services increased informant’s opportunity in obtaining health services from health centres. The perceptions and attitude had correlated with health services utilization in Bhayangkara Hospital at Makassar city. However, there is also a study that found no relationship between attitude and health services in Dr Haulussi Ambon Hospital at Maluku province.

Most informants were satisfied with services provided by home care staffs. The home care staffs are friendly and kind towards informants. Besides, there exist a good communication between home care staffs and patients. The staffs always contact the patients to enquire updates on their health conditions. Furthermore, these staffs are always alerted on informants request for the services. Limitation of transportation, high number of patients in Puskesmas and hot weather has led to staffs arriving late to patient’s house. The good communication, friendliness and kindness have made
patients felt comfortable and willing to receive home visit from health centres.

Most informants who utilized home care services due to lack of physical conditions. Besides, informants considered home care services more effective and efficient in term of time, transportation and economy. Moreover, most patients who utilized home care services suffered chronic diseases such as stroke, diabetes mellitus and pulmonary tuberculosis.

Conclusion

In conclusions, the fishermen community who utilized home care services have lack of knowledge but with positive attitude toward home care services. The home care staffs were friendly, kind and alert in serving the patients including the fishermen communities. In additional, home care services are more effective and efficient in terms of time, accessibility to health centre and economy.

The Relationship between Asymptomatic Urinary Tract Infections in Pregnant Women with Preterm Labor in RSKD IA Siti Fatimah Makassar

Dahniar¹, St.Nurasni², Irfan Idris³
¹Faculty of Medicine, Hasanuddin University, Jl. Perintis Kemerdekaan Km.10, Makassar, 90245. Sulawesi Selatan, Indonesia

Abstract

Urinary Tract Infection (UTI) is the growth of microorganisms in the urinary tract that is not normally contains bacteria, viruses or other microorganisms. Urinary tract infection is an infection that often occurs in pregnancy which is around 4-10%. This study aimed to assess the association between asymptomatic urinary tract infections in pregnant women with preterm labor. This research method is quantitative research with cross sectional. Sampling using purposive sampling as many as 28 respondents to preterm labor with gestational age <37 weeks in the delivery room RSKD IA Siti Fatimah Makassar. The results of the study indicated that there were 28 babies born prematurely in RSKD IA Siti Fatimah Makassar. 8 (26.6%) premature infants were born with asymptomatic urinary tract infection and 20 (71.4%) of premature infants did not experience urinary tract infection. The weight of mothers who experience asymptomatic urinary tract infection had significant relationship (p = 0.03) compared to the weight of women who did not have urinary tract infection, while the average weight of infants was lower among mothers with asymptomatic urinary tract infection in comparison to the baby weight of mothers who did not experience UTI has no significant difference (p = 0.195). In conclusion there are 8 (28.6%) of preterm birth with asymptomatic urinary tract infection in RSKD IA Siti Fatimah Makassar in 2016 and is generally caused by the bacterium Klebsiella pneumoniae.

Keywords: bacterium Klebsiella pneumoniae; infant; premature delivery; urinary tract infections

Introduction

Urinary Tract Infection (UTI) is the development of microorganisms in the urinary tract which normally do not contain bacteria, viruses or other microorganisms. The human urinary tract is the organs that work to collect and store urine and release urine from the body. Asymptomatic bacteriuria is most commonly found in cases of UTI which is around 2-10%

WHO defined premature labor as labor that occurs before the 37th week of gestation. While in Indonesia, 24% of cases of UTI were found in women. This figure is worrying considering that 30% of premature parturition was caused by UTI in 2013. Based on the data from the South Sulawesi Provincial Health Office, the incidence of preterm birth caused by UTI in 2007 was 530 cases (0.29%) from 137,984 deliveries, in 2008, 490 cases (0.34%) of 145,769 births assisted by health workers, and in 2009 there were 20 cases (0.1%) of 145,769 deliveries.

Premature labor is dangerous because it has a potential impact on increasing perinatal mortality. The lower the gestation period and the smaller the baby is born, the higher the risk of morbidity and mortality. According to the data, preterm labor reaches 75-80% of all causes of babies who die in neonatal (age less than 28 days).

Loynd et al. reported there were 2-7% cases of pregnant women developed urinary tract infections and as many as 40% of them developed asymptomatic bacteriuria.

Untreated asymptomatic bacteriuria causes premature birth and low baby weight (LBW) around 1.5
to 2 times. A study conducted in Cairo by Elsokkary\(^5\), concluded that the prevalence of pregnant women with asymptomatic bacteriuria who delivered premature birth was quite high (23.5%). These findings reinforced the results of research conducted in the country by Haider\(^6\) which found 35% of women with UTI gave birth to premature baby. He conducted a study with 232 pregnant women in Hyderabad Pakistan and concluded that the increasing frequency of UTIs in pregnant women is related to the factors of multiparity, the presence of UTI history, low socioeconomic status, frequent sexual activity, and low education\(^7\).

According to Krisnadi et al\(^8\), in Sarwono if this asymptomatic bacteriuria is not treated, about 25% of the patients will then experience acute symptomatic infection during the pregnancy. In some studies, bacteriuria has been reported to cause a number of adverse effects in pregnancy. Asymptomatic bacteriuria in pregnancy is often forgotten as one of the causes of pregnancy complications in the mother and fetus such as preterm labor.

From some literature and hypotheses it has been suggested that one of the predispose factors is due to infection, including urinary tract infections. Although still controversial, bacteriuria conversion has been linked to several studies. Schieve et al\(^9\). did a multivariate analysis of perinatal outcomes with a cohort design in 25,476 maternal and child pairs, reporting that there was an increased risk of LBW, preterm birth, hypertension or preeclampsia, and anemia in the mother. Asymptomatic urinary tract infections in pregnancy with the incidence rate were 4-10%, whereas in Indonesia ranges between 20-25% and about 10-20% can cause premature labor\(^3\). The type of bacteria that causes asymptomatic urinary tract infections in pregnant women with preterm labor is Klebsiella pneumonia. The aim of this study was to investigate the significance difference between asymptomatic UTI and the baby’s weight and the significance of the relationship between asymptomatic UTI and the mother’s weight.

**Methodology**

**Research Location and Design**

This research was carried out on May 23-June 18 of 2016 at IA Siti Fatimah Hospital, South Sulawesi. This study used a cross-sectional quantitative approach, which looked at the relationship between asymptomatic UTI in pregnant women with preterm labor in IA Siti Fatimah Makassar Hospital.

**Population and Sample**

The population in this study was all pregnant women who had preterm labor in IA Siti Fatimah Makassar Hospital, as many as 30 people. The sample size used the Isaac and Michael formula, which are 28 people with purposive sampling technique that meets the inclusion and exclusion criteria.

**Data collection and analysis**

Data on the implementation of direct observation with observation and history sheets, consisting of respondents’ identities, and objective data of pregnant women who experienced preterm labor with asymptomatic urinary tract infections. Urine collection while examining urine culture (mid-stream) was done in University Hasanuddin RSP laboratory. The distributed data was tested using the t-independent statistical test for significant level (\(\alpha = 0.05\)).

**Results**

**Univariate analysis**

Based on Table 1, the highest numbers of respondents are those with no risk age and no UTI, as many as 17 respondents (85%) and asymptomatic UTI respondents are not at risk as many as 7 respondents (8.75%). While the lowest respondents were at risk with no UTI as many as 3 respondents (15%) and asymptomatic UTI respondents were at risk as many as 1 respondent (12.5%). In terms of education, 13 respondents (65%) with low education level had no UTI whereas 6 respondents (75%) had asymptomatic UTI. Among those mothers with high education, 7 respondents (35%) had not UTI while as many as 2 respondents (25%) had asymptomatic UTI. From the highest respondent parity, there were 12 (60%) multigravida respondents with no UTI but 3 (37.5%) multigravida respondents with asymptomatic UTI. The lowest parity in primigravida with no UTI was 8 respondents (40%) whereas primigravida with asymptomatic UTI as many as 5 respondents (62.5%). With reference to the low socio-economic respondents, 12 respondents (60%) do not have UTI but then 1 respondent (12.5%) had asymptomatic UTI. In the category of moderate socioeconomic, 5 respondents (25%) had not UTI but as many as 6 respondents (75%) had asymptomatic UTI. On the other hand, the number
of respondents in high socioeconomic category with no UTI and asymptomatic UTI were 3 respondents (15%) and 1 respondent (12.5%) respectively.

The data from Table 2 indicated that the bacteriuria is found mostly in the 20 respondents (71.4%) who were not infected with UTI, and only a small amount was detected in the 8 respondents (28.6%) who experienced asymptomatic UTI.

In the same Table 2, it is also shown that preterm labor that was experienced among the majority of respondents (19 people) was late preterm. 28.6% of the mothers had very preterm while the remaining 3.6% had extremely preterm labor.

Based on Table 3, the types of bacteria that cause asymptomatic urinary tract infection were Klebsiella pneumoniae bacteria which infected 4 people (50%), while each of these bacteria (*bacterium E, Pseudomonas aerogenosa bacteria, Alkaligenes faecalis bacteria and Acinotobacter baumanni*) infected 4 person in total but only with 1 cases of infection for each bacteria.

Bivariate analysis

From Table 4, the respondents with preterm labor who were late preterm experienced asymptomatic UTI as many as 15.8% and no UTI as many as 84.2%. 62.5% respondents with very preterm experienced asymptomatic UTI while the balance 37.5% had no UTI. Those mothers that had extremely preterm, none of them had asymptomatic UTI but 1 person had no UTI. Thus, for asymptomatic urinary tract infections in pregnant women with preterm labor, there were significant differences.

Discussion

This study shows that 8 people (28.6) with asymptomatic UTI and as many as 20 people (71.4%) without UTI. This is because most of the non-UTIs cases do not occur in preterm labor unlike those with Asymptomatic UTI.

Asymptomatic bacteriuria is the presence of 100,000 bacteria or more per milliliter of urine from patients without complaints of urinary tract infections. This bacteriuria may not be accompanied by symptoms, called asymptomatic bacteriuria and may be accompanied by symptoms called symptomatic bacteriuria. Based on Table 5, the weight of infants with asymptomatic UTI had a mean weight of 2023.7 g and standard deviation of 478.84 whereas weight of infants without UTI had a mean weight of 2246.6 g and standard deviation of 367.96. The p value which equaled to 0.195 showed the presence of significant difference between UTI and baby’s weight. While the weight of mothers with asymptomatic UTI averaged 54.3 kg and standard deviation 4.06. Average weight and standard deviation of mother’s weight without UTI were 57.6 kg and 1.22 respectively. Value of P = 0.03 showed a significant relationship between UTI and maternal weight.

Premature labor can be triggered by several conditions such as infection, ischemia in the fetus and accompanied by the uterus, because on the surface of the placenta and amniotic membrane contains a lot of macrophages. Based on the theory that preterm labor is dangerous because of the potential of increased in perinatal mortality by 65% -75%. Low birth weight can be caused by premature birth and inhibited fetal growth. Both should be prevented because of the negative impact of not only perinatal death but also morbidity, potential for future generations, mental birth and economic burden for the family.

Late preterm (32-36 mg) about 98% of babies born at this age can survive. Most of them weigh 3 to 5 pounds,
but still look thinner than babies who are old enough, whom can breathe themselves, but many of them also need oxygen support to breathe. These babies are less at risk of developmental delays than babies born earlier. However, they still have a high risk of experiencing learning and behavioral development problems. It is estimated that at 35 weeks of pregnancy, the weight of baby’s brains is only about two-thirds of babies who are old enough.

Very preterm (28 - <32 mg) in this group, babies looks similar to babies born with ages less than 28 mg, although their body weight is greater (usually between 2 to 4 pounds), and is more likely to live longer (around 96% ). Some of them could also cry and they could move more, although their movements were like jerks. They can hold their fingers, open their eyes, and start to be awake for a short period. Nevertheless, babies born in the womb age from 28 to <32 weeks, remain at risk of experiencing medical complications.

Extremely preterm (<28 mg) there is only less than 1% of babies born at the age of less than 28 mg. Most of these babies are born with a really low body weight (< 2 pounds, 3 ounces). Almost all of them would require treatment with oxygen, surfactants, and mechanical assistance to facilitate breathing. Babies of this category are very immature to be able to suck, swallow and breathe at the same time, so they must be fed through an intravenous therapy (IV) so they can develop their abilities. Their skin is wrinkled and reddish purple and very thin to the extent the blood vessels under their skin are visible.

Research done by Gustina, stated that parity with the incidence of premature parturition had a significant relationship (p = 0.000), whereby patients who had given birth more than 3 times had a 4 times greater risk of having preterm labor compared to patients whose parity was less than 3. Some literature says preterm labor is more common in multiparous patients, caused by the presence of uterine scarring due to pregnancy and previous labor. Thus, the increased levels of arachidonic acid trigger the release of inflammatory mediators such as histamine, cytokines, leukotrienes and prostaglandins. The inflammatory mediators released cause an inflammatory reaction with intermediaries of white blood cells including macrophages, neutrophils, and lymphocytes to carry out phagocytic processes in bacteria. Active molecules such as prostaglandin E2 (PGE2) and prostaglandin F2 (PGF2) are involved in the normal birth process. Certain cytokines such as interleukin-1 (IL-1), interleukin 6 (IL-6), tumor necrosis factor alpha (TNF-α) stimulate PGE2 synthesis from the placenta and chorioamnion. In normal pregnancy, the intraamnion mediator increases physiologically until the threshold is reached at the point of birth, causing cervical dilation and labor.

In this study, Klebsiella pneumonia in preterm labor had infected 8 people and is present in the airways and feces around 5% of normal people and can cause bacterial pneumonia. The main disease caused by this bacterium is pneumonia. Klebsiella pneumonia can cause disease because it has two types of antigens on the cell surface including O antigen is lipopolysaccharide which is found in 9 varieties and K antigen is a polysaccharide surrounded by capsules with more than 80 varieties. These two antigens increase the pathogenicity of Klebsiella Pneumonia.

This is in line with the research of Dewi, entitled sepsis test in children with germ pattern and sensitivity. The study aimed to obtain the type of bacteria that causes sepsis and antibiotic susceptibility testing, so that it can be used as a guideline for treatment of sepsis. A total of 21 samples obtained cultures with positive results with the most bacteria were Klebsiella pneumoniae (24%), Serratia marcescens (14%), and Burkholderia cepacia (14%). The most common cause of sepsis in children is Klebsiella pneumoniae, Serratia marcescens, and Burkholderia cepacia with antibiotics that are still sensitive are cefepime and levofloxacin.

Conclusion

There is a relationship between asymptomatic urinary tract infections in pregnant women with preterm labor. In addition, there were significant differences between the baby’s weight and asymptomatic urinary tract infection. Weight of the mother with asymptomatic urinary tract infection with no urinary tract infection too, seemed to have a significant relationship. The type of bacteria that caused asymptomatic urinary tract infections in pregnant women with preterm labor is Klebsiella pneumonia bacteria with 30% of the babies having UTI.

The Behaviour of Consuming Alcohol of Adolescents in South Bolaang Mongondow Regency of North Sulawesi Province

Dalviyani¹, Ridwan M. Thaha¹, Sukri Palutturi¹
¹Faculty of Public Health, Hasanuddin University, Jl. Perintis Kemerdekaan Km. 10, Tamalanrea Indah, Tamalanrea, Tamalanrea Indah, Tamalanrea, Kota Makassar, Sulawesi Selatan 90245, Indonesia

Abstract

The aim of this study is to determine the behaviour of consuming alcohol among adolescents in South Bolaang Mongondow Regency. The study was conducted using qualitative method with phenomenological design. There were 52 participants involved in this study included 20 adolescents were alcohol consumers, 14 adolescent’s parents consumed alcohol, 6 health officers, 4 community leaders, 3 police officers and 5 alcohol sellers. The results of study indicated average adolescents consuming alcohol ranged from 6 to 15 years old since influenced by their friend when met up at night. The adolescents consumed alcohol during hang out with friends, looked cool, forgot their problems, and increased their self-esteem. The type of alcoholic drinks consumed were “cap tikus”, “cap tikus” mixed with Pepsi, coke, “komix” mixed with M150. Besides, adolescents had stew cowhide fungus and inhaled glue brand “Fox”. The adolescents only know alcoholic beverages are intoxicating beverages. The parents who consumed alcohol greatly affected their children to consume alcohol, too. The role of health officers, community leaders, and even police officers are important since their efforts haven’t reduced number of adolescents who consume alcohol.

Keywords: Adolescents; Behaviour of consuming alcohol

Introduction

The adolescent is transition period from childhood into adulthood period which aged 10-19 years¹. This period is critical period since biological, cognitive, social and emotional that affected their life. The adolescent is defined in ranged of age of 10-18 years and ended between age 19 and 24²-⁴. The adolescence among rapid development phased in human life⁵. In this period, adolescence had involved in academic and professional decision, identity develops, orientation toward future and expectation from family and teacher⁶.

Social issues are major problem among adolescence⁷. The social issue lead problem in adolescence is alcohol consumption. In 2010, worldwide per capital alcohol consumption was 6.2 liters of pure alcohol consumed by every person aged 15 years or older⁸. Based on National Institute on Alcohol Abuse and Alcoholism (NSDUH)⁹, estimated 623, 000 adolescence aged 12-17 years had alcohol use disorder in United States (National Institute on Alcohol Abuse and Alcoholism, Alcohol facts and statistics). The alcohol is caused many health problems such as liver cirrhosis, mental illness, cancer, pancreatitis and fetus damage among pregnant women¹⁰,¹¹. The alcohol consumption in adolescence was interfered with adolescent brain development and increased development risk of alcohol use disorder. Besides, alcohol consumption in adolescence is contributed in consequences action such as injuries, sexual assaults and death.

Several factors had influenced alcohol consumption in adolescent such as inadequate childhood attachment, insecure, parental figures, poor self-esteem, environment triggered, easy accessibility, peer influence, anxiety, and family problem¹². The adolescent also claimed rewarding value was part of alcohol consumption such as cope or escape unpleasant emotions, to be sociable, and enjoy mood enhancement³. In a study, peer and parental factors in shaped friendship tie choice and alcohol consumption
behaviour. Meanwhile, a study suggested adolescent with parent had alcohol problem also likely to drink more alcoholic beverages compared adolescent that parent without alcoholic problem.

In Indonesia, 18.1% of total population aged 10-19 years in 2012. The prevalence of alcohol consumption in last one month was 4.9% in male and 0.3% in female. The beverage types consumed by men in urban areas were 33.6% beer, 14.4 % liquor, 27.1% wine and 25.0 % traditional alcohol. Meanwhile, men in rural area had consumed 18.6% beer, 6.6% liquor, 19.4% wine and 55.4% traditional alcohol.

In North Sulawesi province, alcohol consumption rate is increased lead to health problem and crimes cases. From initial observations, 10 adolescents consumed alcohol because peer and environment influenced. The alcohol types consumed in adolescents was traditional hard (cap tikus) with M150 and beer. The study was conducted to find out behaviour of consuming alcohol among adolescents in South BolaangMangondow Regency.

**Methodology**

The study was conducted using qualitative method with phenomenological design. There were 52 participants involved in this study included 20 adolescents were alcohol consumers, 14 adolescent’s parents that consumed alcohol, 6 health officers, 4 community leaders, 3 police officers and 5 alcohol sellers. The data were obtained through in-depth interview, non-participant observation, and Focus Group Discussion (FGD). In this study, observation was conducted on adolescents toward their behaviour, knowledge and attitude toward alcohol consumption. Besides, role of family, community leaders, authorities (police) and alcohol distributor also observed in this study.

The questions that prepared for interview are:

1. Understanding toward alcohol
2. Type of alcohol and type most consumed by adolescents
3. Age for adolescents to start consuming alcohol
4. Background of adolescents consumed alcohol for first time
5. Place used to consume alcohol
6. How to get alcohol?
7. The adolescent’s behaviour toward alcohol consumption
8. Impact of alcohol consumption behaviour on the adolescents
9. Behaviour of adolescents after alcohol consumption
10. Role of families toward alcohol consumption behaviour in adolescents
11. Understanding toward the alcohol
12. Understanding toward the alcohol
13. The experience in alcohol consumption for parents
14. Prohibition of parent toward alcohol consumption
15. Knowledge toward law or value about alcohol consumption
16. Understanding toward alcohol
17. Response and opinion about alcohol consumption behaviour in adolescent
18. Response and opinion about alcohol consumption behaviour in adolescents
19. The supported factors and inhibitors to overcome alcohol behaviour in adolescents
20. The knowledge of health officer about alcohol and alcohol type consumed by adolescents
21. The response and opinion from health officers about alcohol consumption behaviour in adolescents
22. The efforts were done by health officer to prevent alcohol consumption behaviour in adolescents
23. The program introduced by health officers to reduce alcohol consumption behaviour in adolescents
24. The reason of alcoholic seller to sell alcohol
25. Understanding about alcohol and prohibition toward selling alcohol
26. The response and opinion toward alcohol consumption behaviour in adolescents
27. The response and opinion toward alcohol consumption behaviour in adolescents
28. The efforts had been made in control alcohol consumption behaviour in adolescents

**Result and Discussion**

The understanding toward alcohol consumption was one of predisposed factor encouraged alcohol consumption behaviour in adolescents. Based on
interview result, teenagers only understood that alcohol is intoxicating drink. The adolescents had same understanding level about meaning of alcohol, average of teenagers understood alcohol had consumed is intoxicating and reduce consciousness. Most of adolescents said their own family and friend’s invitation and lead them to consume alcohol. The FGD results showed main reasons for alcohol consumption were friend’s invitation, relieved stress and looked cool in their friend group.

Most common type of alcohol consumed by adolescents was “cap tikus” alcohol as same as FGD results. In additions, adolescents also preferred consumed mixture of “cap tikus” with Pepsi and beer, “komix” mixed with M150, cowhide fungus and inhaled glue brand “fox”. “captikus” alcohol brand was a type of liquor contained 40% that produced by distillation process. Several adolescents bought alcohol by their own money. Some of adolescents also obtained alcohol by shared with their friend because they have no enough money to buy alcohol by themselves. Most of adolescents bought alcohol in stall or directly bought from retailer or sellers.

The behaviour was a predisposing factor that affected alcohol consumption pattern. The interview result showed that adolescents had positive attitude related to alcohol consumption. The teenagers also agreed that they felt happy, relieved stress, looked cool in their friend group when they consumed alcohol. The adolescents had experienced differences effect after alcohol consumption such as dizziness, shortness of breath, vomit, and became lazy. Based on FGD results, most of adolescents felt dizzy and vomited after consumed alcohol. The impact of alcohol consumption such as yelling, fights, some of adolescents had tried kill people and burn the house.

The adolescent’s father had experienced in alcohol consumption, their children tended to consume alcohol as their father. The parent inability to control their emotional made their children became bad temper and had an opportunity to consume alcohol to relieve burdens faced by their parents. The adolescents that lived together with their parents had good relationship with parents. The parent knew their children consumed alcohol would be controlled and supervised by their parents. Some of parents gave punishment to their children if they were consumed alcohol.

The community leader knew clearly alcohol consumption behaviour was very serious problem as many cases of accidents and death from alcohol consumption. An approach was introduced to community by optimized role of community leaders before new policy was drafted to limit sale of alcohol. In additions, there was cooperation with health officers also important to provide counselling about impact of alcohol consumption so that community aware harm of alcohol to their health. The lack of attention from community would create dilemma in new policy introduction.

Based on interview result showed health officer had good understanding toward alcohol. Many cases such as accident and death were due to alcohol consumption. The alcohol consumption in adolescents was serious issue and effort was needed to prevent increasing in number of teenagers consumed alcohol. The program was introduced for alcohol consumption behaviour prevention such as counselling in school to adolescent. There were many obstacles faced in program implementation because lack of cooperation from community itself. In additions, health officers claimed that they were faced difficulty to overcome alcohol consumption in community because their habit in consumed alcohol that had been adopted in their life.

One factor leads to alcohol consumption in adolescents because of availability of stalls and shop that sold alcoholic beverages. The access availability of alcoholic beverages leadsto the adolescent toward alcohol consumption behaviour. The number of shop and stalls that sold alcohol in public was due to high demand from community. The shops were often raided by police officers but there was nothing since socialization was given to alcohol seller. There was no official rule or regulation on prohibition of selling alcohol in public, so sellers were continued their alcohol selling to adolescents.

**Conclusion**

The cooperation from all peoples such as family, community leader, health officers and police officers were needed to control alcohol consumption behaviour in adolescents. The local government was suggested to introduce regulations about limitation in sale of alcohol publicly in stalls or agents that secretly sell alcohol to adolescents. The parent’s supervision toward their children’s activities at outside and their commitment
related to alcohol distribution in community. The health program about alcohol hazard was suggested to adolescents from local health officers.

Abstract

The aim of this study to observe effect of passion fruit juice could change lipid profile (high density lipoprotein (HDL) and low density lipoprotein (LDL)) in diabetes mellitus patient. The study was conducted using quasi experiment with non-randomized pre and post study with control group. The sample was selected using purposive sampling method consisting of 40 participants and is divided to 2 groups included treatment and control group. The treatment group was given yellow passion fruit peel juice 250 ml/day with passion fruit juice recipe for 15 days and control group was only given passion fruit juice recipe. HDL and LDL levels were measured during pre and post study. HDL level in intervention group was increased about 6.85 mg/dL and in contrast, HDL level in control group was decreased of 8.50 mg/dL. There was no difference between treatment and control group. In treatment group, LDL level decreased in mean of 6.15 mg/dL and control group had increased with average of 2.8 mg/dL. The campaign on food consumption especially highlights the important for diverse and high fiber food in their daily dietary. The frequency of profile checks on diabetes patient to avoid greater risk of death from cardiovascular diseases (CVD) known as dyslipidemia. Further action will be taken with larger number of samples with longer duration of yellow passion fruit juice consumption.

Keywords: Diabetes mellitus; Lipid profile; Yellow passion fruit.

Introduction

Diabetes mellitus (DM) is classified by chronic hyperglycemia and impaired body metabolism causes by lack of insulin action1-3. The chronic hyperglycemia is correlated with long-term damage, abnormal, failure on many organs such as eye, kidneys, heart, nerves and blood vessels that lead to mortality and morbidity4. The diabetes cases had increased from 108 million in 1980 to 422 million in 20145. There is estimation of 1.6 million deaths due to diabetes diseases in 2015. Meanwhile, estimated 2.2 million deaths were due to high blood glucose6. DM risk was due to genetic, metabolic, ethnicity, family background in diabetes, age, obesity and overweight, unhealthy lifestyle, lack of physical exercise and smoking habit6.

The diabetes is main cause in premature mortality, due to correlate with cardiovascular (CV) disease also known as dyslipidemia7. An estimated 31.4% of death was due to CV diseases in 2012. Dyslipidemia is classified by presence of triglycerides, LDL and HDL8. The coronary artery disease risk in diabetes patients had contributed by abnormalities of serum lipid and determination of serum lipid levels in diabetics was considered standard of diabetes care10-12. In Sudan, a study found 250 DM patients had low HDL and high in triglycerides13. In few studies had found triglycerides, total cholesterol and LDL level are higher in people with diabetes mellitus compared control group14-17.
Passion fruit (Passiflora edulis) is native of tropical America belonged to Passifloraceae family had 530 species. In Indonesia, passion fruit found in South Sulawesi and North Sumatra and make syrup or juice. The passion fruit was contained high fiber help in body digestion and used in heartburn treatment about 65.22 gram of total fiber; 48.12 gram of insoluble fiber and 17.11 gram of water soluble fiber. Some studies had found passion fruit skin had positive result on glucose level and lipid profile. Based on benefit passion fruit, the authors had interested to conduct a study on effect of passion fruit juice changed lipid profile (HDL and LDL) in DM patients.

**Methodology**

The study was conducted using quasi experiment with non-randomized pre and posttest with control group. The sample was selected using purposive sampling method consisting of 40 participants and is divided to 2 groups included treatment and control group. The treatment group was given yellow passion fruit peel juice 250 ml/day with passion fruit juice recipe for 15 days, while control group was given passion fruit juice recipe. The passion fruit was selected and used proximate test such as ash, moisture, fiber, protein and carbohydrate content measurement. Fiber test, sugar test and pectin concentration on yellow passion fruit originated in Malakaji-Gowa. The formula for juice making was 40 gram of passion fruit albedo (this passion fruit albedo was gone through organoleptic test under preliminary study) with sugar and 200 milliliters. This mixture was blended and boiled for (±2 minutes). This fruit juice was given to intervention group with DM to observed effect of yellow passion fruit juice on lipid profile (HDL and LDL). HDL and LDL levels were measured before and after intervention. The data were analyzed by comparing result of lipid profile pre and post study using paired T test/ Wilcoxon and comparing treatment between two groups with independent T test/ Mann Whitney test.

**Result And Discussion**

**Univariate Analysis**

Table 1 showed the HDL level on intervention group was reduced from 50% to 35% after intervention period. Meanwhile, respondents had high HDL in pre study found increment in HDL level in post study from 50.0% to 65.0 %. Table 2 illustrates the LDL level was remaining unchanged for intervention group on before and after intervention period at 60%.

**Bivariate Analysis**

In Table 3, the mean change of HDL level in intervention group was increased from 52.40 to 59.25, but statistically increment is not significant (p>0.05), which meant no difference in HDL levels before and after intervention. In control group as shown in Table 4, the mean HDL level was decreased from 70.55 to 62.05, but statistically not significant (p>0.05), which means no difference in HDL level before and after intervention. The mean rate of change in LDL level for intervention group was decreased from 146.6 to 140.45, but statistically reduction is not significant (p>0.05), no difference in LDL level before and after intervention. Meanwhile, mean of LDL level in control group was increased from 156.70 to 159.50 but statistically not significant (p>0.05), which meant no difference in LDL level before and after intervention. There was no difference changes for HDL and LDL between group after intervention (p>0.05).

Table 5 was showed mean difference of changes in HDL and LDL level between intervention and control group was not statistically significant, no difference of average difference of HDL and LDL level between intervention and control group.

**Overall Discussion**

In this study found mean HDL level in intervention group after passion fruit peel juice of 250 ml increased from 52.40 mg/dL to 59.35 mg/dL, but statistically not significant (p>0.05). Meanwhile, mean of LDL level was decreased from 146.4 mg/dL to 140.45 mg/dL, but statistically not significant (p>0.05). A study found women aged 30-60 years had cholesterol level of ≥200 mg/dL showed decreased in LDL and total cholesterol after given passion fruit for 60 days25. In addition, another study also showed significant decreased in triglycerides and a significant increase in HDL level, but no reduction in total of cholesterol and LDL level in patients with diabetes mellitus after given yellow passion fruit flour26. Besides, mean of HDL level was observed increased, while LDL level was reduced in intervention group compared control group. This was due to effect of soluble fiber content in yellow passion fruit skin especially pectin. The pectin is formed a gel-like substance in stomach and provided a feeling of anxiety and delayed carbohydrate absorption27. In additions, pectin is helped in reducing total plasma cholesterol level, triglycerides and LDL and increased HDL level. Therefore, fiber consumption was reduced risk for diseases such as dyslipidemia, diabetes, obesity and cardiovascular diseases (CVD) 28, 29. The fiber had significantly reduced LDL level and increased HDL level20, 31. In additions, another study demonstrated passion fruit juice increased HDL levels and reduce total cholesterol, LDL level and free fatty acid level27. The presence of flavonoids in passion fruit had contributed in HDL level increment.

The pectin content in the passion fruit juice given to the intervention group was 2.75 grams which was theoretically gave the effect on the lipid profile. In this study, intervention was done for 15 days and result showed no tendency in LDL level decreased and increased in HDL level significantly. Therefore, short intervention period was one factor caused no significant change in the lipid profile result as hypothesized. Besides diet, nutritional status and physical activity also affected to lipid profile27. The nutritional status and physical activity between two groups was no changed. Thus, trend of increasing HDL levels and decreased LDL levels occurred in the intervention group compared with control group was due to effect of yellow passion fruit juice.

**Conclusion**

In conclusions, HDL level in intervention group was increased about 6.85mg/dL and in contrast, HDL level in control group was decreased of 8.5 mg/dL. There was no difference between treatment and control group. In treatment group, LDL level decreased in mean of 6.15 mg/dL and control group increased with average of 2.8 mg/dL. The campaign on diabetes patient to avoid greater risk of death from cardiovascular diseases (CVD) known as dyslipidemia. Further action will be taken with larger number of samples with longer duration of yellow passion fruit juice consumption.

The Effect of Giving VCO (Virgin Coconut Oil) on the Nutritional Status of Under Nutrition Children Aged 24-58 Months Old in Bontoramba Subdistrict Jeneponto Regency

Diesna Sari¹, Rahayu Indriasari¹, Andi Zulkifli¹
¹Faculty of Public Health, Hasanuddin University, Jl. Perintis Kemerdekaan Km. 10, Tamalanrea Indah, Tamalanrea, Tamalanrea Indah, Tamalanrea, Kota Makassar, Sulawesi Selatan 90245, Indonesia

Abstract

The aim of this study to determine effect of VCO on nutritional status based on body weight and nutrient intake among under nutrition children aged 24-58 months old in Bontoramba subdistrict, Jeneponto regency. The study was conducted as a true experiment that using randomized pre and post test with control group. The samples (72 under-nutrition children aged 24-58 months) were selected using probability sampling method based on the indicator of bodyweight/age. The respondents were divided into two groups: treatment and control groups. The treatment group was given Virgin Coconut Oil (VCO) and supplement biscuits; while control group was just given supplement biscuits for two months. The body weight and nutrient intake were measured before the intervention; and at the first month and second months after intervention. The result showed that treatment group experienced an increase of bodyweight of 0.68 kg on average; while control group experienced an increase of body weight of 0.58 kg on average. The nutrition intake (energy, protein, fats, carbohydrates and fibre) in treatment and control group increased significantly on average (p ≤ 0.05), and a significant difference between two groups (p≤ 0.05). Therefore, no difference between treatment and control group in bodyweight, but difference was observed in nutrient intake for both groups.

Keywords: Children under five years old; Under nutrition; Virgin coconut oil.

Introduction

Under nutrition is determined in malnutrition. There are 4 types under nutrition such as wasting, stunting, underweight and vitamins and minerals deficiency¹. Under nutrition leads children in more susceptible to disease and mortality. An estimated 3 million children were died due to under nutrition for every year². There was also 45% of death in children age under 5 years old due to under nutrition occurs in low- and middle-income countries. In South Asia, high prevalence had observed for stunting (38%), underweight (32%) and wasting (16%) compared to other region in world³. The children malnutrition was health problem in the children that contributed to increment in morbidity and mortality, disrupted the intellectual development, non-productive in adult and even increased risk for many diseases⁴.

The malnutrition is due to several factors: poor in dietary intake and/or infectious diseases, environmental and socioeconomic factors⁵,⁶. Few studies in China and Vietnam found low birth weight, parities, pre term birth, maternal education, and low family income are correlated with malnutrition in children⁷,⁸,⁹. Meanwhile, factors such as gender, age, marital status, maternal education, family income, decision making, parities, feeding mode, accessible to clean water and house condition had influenced malnutrition in children under 5 years old in Ethiopia¹⁰,¹¹. In addition, a study suggested risk factors for under nutrition among children were livestock dispossession, food taboo and wrong eating in families, poor and early marriage of mothers and lack of health/nutrition education, had contributed in malnutrition among children under 5 years old¹¹.

In contrast, a study found male sex, parents’ educational status, preterm babies, monthly family...
income, diarrhoea, and respiratory infection and had no antenatal follow-up was no significantly influenced malnutrition among children in Northwest Ethiopia\textsuperscript{12}. In a study determined high probability boys experienced underweight, while girls were common with stunting since boys had higher weight and height compared to girl at same age\textsuperscript{13}. The malnutrition for children under 5 years had assessed by height and weight measurement. Based on World Health child growth standard 2006, malnutrition was determined by weight for age (underweight), height for age (stunting) and weight for height (wasting)\textsuperscript{3}.

The virgin coconut oil (VCO) is defined as oil from fresh and mature kernel of coconut (Cocosnucigera L.) through mechanical or natural\textsuperscript{14}. VCO had chain fatty acid that maintained healthy heart and resource for energy and fat-soluble vitamins\textsuperscript{15}. The impact of coconut oil on health included cancer, cardiovascular diseases, brain, liver, body weight, and infection\textsuperscript{16,17}. An experimental study showed animal fed with VCO had increment in high-density lipoprotein (HDL) and reduced in low-density lipoprotein (LDL) and total cholesterol\textsuperscript{17}. Meanwhile, VCO had increased body weight compared to soybean oil among children\textsuperscript{18}.

This study was aiming to determine effect of VCO on nutritional status based on body weight and nutrient intake among under nutrition children aged 24-58 months old in Bontorambasubdistrict, Jeneponto regency.

**Methodology**

The study was conducted as a true experiment by using randomized pre and post test with control group. The samples (72 under-nutrition children aged 24-58 months) were selected using probability sampling method based on indicator of bodyweight/age. There were divided into two groups: treatment and control groups. The treatment group was given Virgin Coconut Oil (VCO) and supplement biscuits; while control group was just given supplement biscuits for two months.

In pre-intervention, data in form of characteristics, body weight, nutritional status, dietary intake and appetite were taken for both groups. The VCO was consumed for 3 times per day with supplement biscuits in treatment group. The first and second months, measurement of bodyweight, nutritional status, dietary intake and appetite were taken for both groups. The primary data was obtained directly from observation during intervention period, while secondary data were collected from health centre such as nutritional status report, demographic conditions, village and sub district profile from related government agencies.

The data were analysed using SPSS program to find out change of bodyweight and nutrient intake after intervention by using Repeated Annova/Friedman test. In addition, treatments of groups were compared by using independent T-test/mann Whitney. Hypothesis test of analysis result used 95% confidence level ($\alpha = 0.05$), where hypothesis was accepted when $p<0.05$.

**Result and Discussion**

**Bivariate Analysis**

The study was carried out on 76 under-nutrition childrens that aged under 5 years old and those samples were grouped into two groups: treatment group (39 childrens) and control group (37 childrens). This study found treatment group experienced an increase of bodyweight of 0.68 kg on average; while control group experienced an increase of bodyweight of 0.58 kg on average. Both groups showed significantly decreased in average Z-score at ($p<0.05$). However, difference in average reduction in Z-score was higher in treatment group of 0.33. Table 2 showed there was significant increase in body weight (p<0.05) in treatment group and control group after intervention. Based on Diagram 2, proportion of body weight changes in treatment group was higher than control group for 1%. The body weight was higher in treatment group, 0.68kg compared to control group, 0.58 kg.

Table 3 showed ratio of body weight of sample in pre, post 1, post 2 between treatment and control group did not showed statistically significant result ($p>0.05$) which meant no significant difference in body weight between both group. Table 4 showed there was increased of median mean score in treatment group significantly ($p<0.05$) but control group’s result obtained was not significant ($p>0.05$). The test result among group showed a significant increased (p <0.05) in treatment group compared to control group related to dietary behaviour (appetite). Table 5 showed significant differences in dietary change in both treatment and control group between pre-intervention, during first month intervention (Post 1) and after second month intervention (Post 2), indicated by p-value<0.05. There was no significant difference between treatment group and control group.
The nutrition intake (energy, protein, fats, carbohydrates and fiber) in treatment group and control group increased significantly on average (p ≤ 0.05), and there was a significant difference between two groups (p<0.05). Therefore, there was no difference between treatment group and control group in bodyweight, but difference was observed between treatment and control group in nutrient intake.

Overall Discussion

There was significant increase in p<0.05 p=0.05 in average change of sample weight in treatment group compared to control group. However, average difference of children weight gain is higher in treatment group, 0.68 kg with proportion of change of 6.3% with difference of 1% from control group. Besides, there was a changed of mean Z-score according to body weight/age before and after intervention. Both groups experienced a significant decrease in mean Z-score (p<0.05). The treatment group had achieved high score about 0.33. Meanwhile, VCO consumption had reduced body weight and fat in adult19, 20. In contrast, a study had found that heated VCO had increased body weight in rats compared to non-heated oil-fed group21.

The comparison of body weight before pre-intervention, one month after intervention (post 1), and second month after intervention (Post 2) between both group had increased but not statistically significant (p>0.05), no real difference between two groups in term of body weight. This study also found significant differences in dietary change in treatment and control group prior to pre intervention, during first month intervention (Post 1) and after second month intervention (Post 2) (p<0.05). There was an increment in nutrient intake which included energy, protein, fat, carbohydrates and fibre in both groups. VCO supplement had improved nutritional status by increased body weight among children less than 5 years. VCO is suitable for children had indigestion and difficulty in nutrient absorption. VCO had improved body metabolism system for better nutrient absorption22. VCO had non-hydrogenated fatty acids such as lauric acid, medium saturated with medium carbon chain was called medium chain fatty acid (MCFA). The MCFA absorption was faster and efficient compared long-chain fatty acids (LCFA)20. The
lauric acid was most effective in antimicrobial agents for foods and cosmetics.

Furthermore, the comparison of average intake among treatment with control group during second month (Post 2) found mean comparison of all intake included energy, protein, fat, carbohydrate and fibre experienced significant difference between groups in second month after intervention (Post 2) with p<0.05. There was no significant difference in intake between treatment and control group before intervention with p>0.05. Form this study, virgin coconut oil consumption in these underweight children increased nutritional intake and had better appetite than control group. A study showed no significant difference in body weight gains and liver for VCO consumption.

The virgin coconut oil might be an alternative way to provide enough nutrients for children under five years old that experienced malnutrition.

Conclusion

In conclusions, average changes in body weight occur in treatment and control group after intervention period, with statistically significant test result for both groups. The difference in mean children’s weight gain is higher in treatment group but statistically did not showed significant result. There was a change of average of nutrition intake (energy, protein, fat, carbohydrate and fibre) with statistical test result obtained significant result. Besides, difference also observed in average changes in nutrition intake (energy, protein, fat, carbohydrate and fibre) showed significant increase in nutritional intake in treatment group. Hence, VCO had recommended increasing nutritional intake and appetite of children under five years old.

Relationship between Yoga Exercise for Trimester III Pregnancy and Fetal Outcomes at Restu Maternity Hospital Makassar

Eggy Widya Larasati¹, Nasrudin A. M¹, Budu¹
¹Faculty of Medicine, Hasanuddin University, Jl. Perintis Kemerdekaan Km.10, Makassar, 90245. Sulawesi Selatan, Indonesia

Abstract

There are 5 million neonatal mortality had recorded in developing countries every year with neonatal mortality rate (NMR) 39 per 1000 live births compared to more developed countries with 7 per 1000 live births. Several factors contributed to neonatal mortality such as maternal weight, age and neonatal factors included infants’ birth weight, hypothermia, asphyxia, gap from previous pregnancy and congenital disorder. The study aims to determine relationship between yoga exercise for third trimester pregnancy and fetal outcomes (birth weight, at Restu Maternity Hospital Makassar. The study was used quasi experiment with two group post-tests. The study population were primigravida women who were in their third trimester pregnancy, performed pregnancy yoga and gave birth in June to July 2015. The sample sizes were 50 respondents which selected by using purposive sampling. The data was obtained by using observation sheet of pregnancy yoga exercise, infant birth weight, APGAR score and ballard score in intervention group. The data were analysed using Spearman’s rho and Mann Whitney. The statistical test showed birth weight had obtained p=0.004 and ballard maturation, p=0.002.

Keywords: APGAR score; Ballad maturation score; Birth weight; Yoga.

Introduction

There are 5 million neonatal mortality had recorded in developing countries every year with neonatal mortality rate (NMR) 39 per 1000 live births compared to more developed countries with 7 per 1000 live births¹. Half of neonatal mortality occurred in DR Congo, Nigeria, Ethiopia, Uganda and Tanzania². Several factors contributed to neonatal mortality such as maternal weight, age and neonatal factors included infants’ birth weight, hypothermia, asphyxia, gap from previous pregnancy and congenital disorder³⁴. Yoga is defined as “union” in Sanskrit word which originated from India and written in Yoga Sutra by Patanjali⁵⁶. The yoga practices lead balance in emotional, mental, spiritual dimension and physical which involved postures (asana), breathing exercise (pranayama), concentration and meditation (dharana and dhyana)⁷⁸. The yoga benefit in helped mother well-being and improved normal pregnancy and birth labour chances⁹. An estimation of 35% of women aged between 28 years and 33 years who practiced yoga had reduced maternal experience of anxiety, pain, stress, discomfort as well as birth delivery and fetal outcomes¹⁰. The study aims to determine relationship between yoga exercise for trimester III pregnancy and fetal outcomes at Restu Maternity Hospital Makassar.

Methodology

Study design

The study was used a quasi-experimental research design with two groups post-test (intervention and control groups) to determine relationship between yoga exercise for trimester III pregnancy and fetal outcomes (birth weight, APGAR score and ballard score).

Study location and time

The study was conducted from June to July 2015 at Restu Maternity Hospital in Makassar.
Study population and sample

The study population were primigravida women who were in their third trimester pregnancy and performed pregnancy yoga exercise during the study. The sample sizes were 50 respondents (25 respondents in intervention group and 25 respondents in control group) by using purposive sampling technique.

Data collection

The data was obtained by using observation sheet of pregnancy yoga exercise, infant birth weight, APGAR score and Ballard score in intervention group.

Data analysis

The data was analysed using SPSS program. The bivariate analysis had used Spearman’s rho and Mann Whitney test to compare differences in outcome between mothers who practice pregnancy yoga and mothers who did not practice pregnancy yoga.

Results and Discussion

Univariate Analysis

Based on Table 1, 7 respondents (28%) who did not practice pregnancy yoga had infants with low birth weight which less than 2500 gram. Based on Spearman’s Rho test, there is significant relationship between birth weight with pregnancy yoga exercise on third trimester pregnant at Restu Maternity Hospital in Makassar.

There were 24 respondents (96.0%) had normal APGAR score and a respondent had mild asphyxia in the intervention group, while 16 respondents (64.0%) had normal APGAR score and 9 respondents (34.0%) had mild asphyxia in APGAR score. The statistical test found significant relationship between pregnancy yoga exercise on third trimester pregnant women with APGAR score at Restu Maternity Hospital Makassar.

Bivariate Analysis

Based on Table 3, there were 25 respondents (100%) who had normal or mature Ballard maturation score for respondents with pregnancy yoga exercise, while 17 respondents (68.0%) had normal or mature Ballard maturation score for respondents who did not practice pregnancy yoga exercise. Meanwhile, 8 respondents (32.0%) had dysmature Ballard maturation score for respondents who did not practice pregnancy yoga exercise. The statistical test showed significant relationship between pregnancy yoga exercise on third trimester pregnant women and Ballard maturation score at Restu Maternity Hospital Makassar.

There were differences on fetal outcomes (birth weight, APGAR score and Ballard maturation score) between respondents who practiced pregnancy yoga exercise and respondents who did not practiced pregnancy yoga exercise. Based on Mann Whitney statistical test showed p 0.004 <0.05 with mean rank in control group of 29.0 which higher than mean rank in intervention group which is 22.00. Besides, mean rank in control group was higher than mean rank of intervention group by different of 0.800. The difference of mean rank in Ballard score between respondents who practiced pregnancy yoga exercise and respondents who did not practiced pregnancy yoga exercise.

Overall Discussion

The study found 25 respondents (100%) who practiced pregnancy yoga exercise gave birth to infant with normal weight which birth weight ranged between 2500 and 400 grams. Meanwhile, 18 respondents (72.0%) who did not practice pregnancy yoga exercise had deliver infants with normal birth weight and only 7 respondents (28.0%) had delivered infants with low birth weight. A study by Narentran, et al. showed pregnant women with yoga exercise for one hour daily had significant increased in birth weight more than 2500 grams and lower rate in premature labour16.

APGAR score is simple method used by midwife to assess health of new born infants. APGAR score is rated from zero to ten. Majority of respondents had normal APGAR score, 24 respondents (96.0%) and only one respondent had mild asphyxia for respondent who had practiced pregnancy yoga exercise. Asphyxia
is condition where infants had difficulty in breath after births. The asphyxia also occurs due to lack of blood flow through placenta lead to low oxygen to the fetus. The birth asphyxia also caused by maternal age, multiple births, lack in antenatal care visits, low birth weight infants, prolonged membrane ruptures, meconium stained fluid, malpresentation, partum haemorrhage, pre-eclampsia and severe eclampsia, intrapartum anaemia and ante partum.\textsuperscript{17}

The ballard maturation score is accurate assessment tool on fetal maturity degree for precise interpretation which not gestation age calendar once beyond 36 weeks.\textsuperscript{18} The study found all respondents who practiced pregnancy yoga had normal or mature Ballard maturation score and 8 respondents (32.0\%) who did not practice pregnancy yoga exercise had dysmature Ballard maturation score. There is significant relationship between pregnancy yoga exercise on third trimester pregnant women and Ballard maturation score.

Furthermore, the statistical test result showed differences between fetal outcomes (birth weight, APGAR score and Ballard maturation score) between mothers who practiced pregnancy yoga and mothers who did not practiced pregnancy yoga. Several studies found pregnancy yoga exercise had influenced fetal outcome which using different method and comparison standards. The pregnancy yoga is effective therapy in decrease hypertensive complications and improving fetal outcomes\textsuperscript{14,19}. In additions, another study also suggested yoga had shorten first stage of birth delivery duration and total time of birth delivery\textsuperscript{20}. The regular yoga exercise during last 10 to 12 weeks of pregnancy had increased maternal comfort during birth delivery and improved birth delivery process\textsuperscript{21}. The pregnant women who performed regularly exercise helped in maintain pelvic ligament strength, hips and legs muscles, hence reducing pain during labour, improving maternal comfort at 2 hours post-saline and facilitate the birth delivery. Meanwhile, a study found practicing yoga in early second trimester pregnant women helped in reduced physical pain but increased pain among third trimester pregnant women\textsuperscript{22}. In additions, yoga also decreased stress, anxiety and depression among pregnant women\textsuperscript{23-25}. The yoga exercise also improve concentration, reduced fatigue, increase stamina and reduce stress by 32%.

Acknowledgement: The author would like to thank to Restu Maternity Hospital in Makassar for information support and Faculty of Medicine, Hasanuddin University for unconditionally support.

Conclusion

In conclusions, the pregnancy yoga exercise on third trimester pregnant women helped increased birth weight, APGAR score and Ballard maturation score although several other factors also contributed to fetal outcomes.

Relationship between Premenstrual Coping and Premenstrual Syndrome (PMS) among Female Midwifery Students in Kendari Health Polytechnic

Farming¹, Nasrudin A. M¹, Budu¹

¹Faculty of Medicine, Hasanuddin University, Jl. Perintis Kemerdekaan Km.10, Makassar, 90245. Sulawesi Selatan, Indonesia

Abstract

The study aims to determine relationship between premenstrual coping and premenstrual syndrome among midwifery students in Kendari Health Polytechnic. The study was used an observational study with cross sectional study design. The study population were all female midwifery students in Kenari Health Polytechnic. The sample sizes were 155 respondents and selected by using stratified random sampling method. The data were analysed using statistical test by Spearman correlation test. The statistical test showed premenstrual coping with PMS among female midwifery students had obtained p=0.020. Meanwhile, premenstrual coping dimension of avoiding harm had obtained had obtained p=0.014, awareness and acceptance of premenstrual (p=0.016), adjusting energy (p=0.064), self-care (p=0.003) and communicating (p=0.991).

Keywords: Adaptive; Body mass index; Malative; Menstrual cycle.

Introduction

Most women of reproductive age had experienced some physical dysphoria or discomfort in the weeks before their menstruation¹. Premenstrual syndrome (PMS) is defined by intermittent, moderate-to-severe affective, physical and behavioural symptoms which occurred during luteal menstrual cycle and disappear within a few days of menstruation². PMS is very common among adolescence and young women. PMS had affected 20% until 80% of women of reproductive age and varies among women in term of severity and duration of PMS from cycle to cycle³. The cause of PMS is still unknown and many researchers believed PMS was due to estrogen and progesterone hormone level changes.

There are more than 200 symptoms are related with PMS⁴. Most common physical symptoms for PMS included pimples, abdominal bloating, breast tenderness, fatigue, appetite changes, sleep disturbances, headaches, while emotional symptoms included mood swinging, crying, anxiety, irritability, oversensitivity, tension and depression³⁵⁷. Severe of PMS is known as premenstrual dysphoric disorder (PMDD). About 2% to 6% of women were suffered with PMDD in their lifespan⁵. Women with PMDD had experienced anger, irritability and other mood symptoms included sleep disorders such as insomnia, non-restoration of sleep and frequent night time awakening which affected their daily life⁸.

Few studies had been done to determine relationship between coping ways with premenstrual syndrome, coping with premenstrual changing and correlated psychosocial factors in premenstrual dysphoria with coping process⁹¹³. In this study, Premenstrual Coping Measure (PMCM) consisted of five subscales such as Avoiding Harm, Awareness and Acceptance of Premenstrual Changes, Adjusting Energy, Self-care and Communicating had been examined to correlate with PMS among female midwifery students in Kendari Health Polytechnic.

Methodology

Study design: The study was used an observational study with cross sectional study design.

Study location and time: The study was conducted in November to December 2014 at Kendari Health Polytechnic.
**Study population and sample:** The study population were all female midwifery students of Kendari Health Polytechnic. The sample sizes were 155 respondents which obtained by stratified random sampling method.

**Data analysis:** The bivariate analysis was used to determine dependent variable (PMS) and independent variable (premenstrual coping) by using Spearman correlation test.

**Results and Discussion**

**Bivariate Analysis**

Based on Table 1, 51 respondents (66.2%) who had maladaptive in premenstrual coping were experienced PMS, while 48 respondents (61.5%) had adaptive in premenstrual coping did not experienced PMS. The statistical test found there was significant relationship between premenstrual coping and PMS among female midwifery students in Kendari health Polytechnic.

For avoiding harm, there were 48 respondents (64.0%) had maladaptive avoiding harm and 33 respondents (41.2%) had adaptive avoiding harm with PMS. Meanwhile, 25 respondents (32.5%) had maladaptive and 49 respondents (62.8%) had adaptive in awareness and acceptance of premenstrual without suffered PMS. There were 45 respondents (68.2%) had maladaptive and 36 respondents (40.4%) had adaptive in adjusting energy with suffered in PMS. There were 52 respondents (58.4%) had adaptive with suffered PMS and 37 respondents (41.6%) had adaptive without suffered PMS in self-care. In additions, 44 respondents (58.7%) had maladaptive in communicating with suffered PMS and 31 respondents (41.3%) had maladaptive in communicating without suffered PMS.

Multivariate Analysis

Based on Table 3, half of respondents had PMS aged 20 years old, 40 respondents (51.3%) and none of respondent had PMS who aged 16 years old. There was no significant relationship between age and PMS among female midwifery students in Kenari Health Polytechnic. Meanwhile, 65 respondents had first menstrual bleeding below than 12 years old with suffered PMS and 16 respondents (53.3%) had first menstrual bleeding above than 12 years with suffered PMS. Based on statistical test found no significant relationship between age of menarche and PMS. In additions, there were 65 respondents (52.0%) had menstrual cycle between 21 days and 35 days and 3 respondents (42.9%) had menstrual cycle less than 21 days. None respondents had menstrual period less than 3 days and most of respondents had menstrual period between 3 days and 7 days with suffered PMS, 76 respondents (53.1%). There were 57 respondents (50.4%) had their frequency in changing period pad between 3 times and 5 times per day and only 3 respondents (60%) had their frequency in changing period pad more than 5 times with suffered PMS. Furthermore, respondents who suffered PMS, there were 51 respondents (50.5%) had normal nutritional status and only 6 respondents with obesity status. Based on statistical test, menstrual cycle, menstrual bleeding duration and menstrual bleeding quantity had no significant relationship with PMS. In contrast, only nutritional status had significant correlated with PMS.

**Overall Discussion**

The result found respondents who had maladaptive in premenstrual coping suffered in PMS (66.2%), while respondents with adaptive in premenstrual coping did not suffered PMS (61.5%). Good premenstrual coping helped adolescence in reduce physical or emotional symptoms during luteal phase of menstrual cycle. Based on Spearman correlation value, there was negative relationship between premenstrual coping and PMS among female midwifery students, r = -0.187. This result showed higher score in premenstrual coping reduced premenstrual syndrome. The premenstrual coping had been used among women with PMS were varies depending on their problem and ability in problem solving. In Turkey, a study among 379 women volunteers found 28.9% preferred listening to music, 33.3% resting and 38.8% crying to overcome depressive mood swings. In additions, study by Tumkur et al. found most respondents had preferred sleeping (63%) and resting (62.3%) in relieve PMS symptom due to fatigue among PMS respondents.

Besides, there was significant premenstrual coping dimension of avoiding harm, awareness and acceptance of premenstrual change and self-care with PMS. Meanwhile, adjusting energy and communicating had no significant relationship with PMS. Avoid harm is defined way how women avoiding situations, people, conversations and thought that lead distress during premenstrual period. The avoiding harm is among effective ways for women to solve problem during premenstrual period which contained social withdrawal such as avoided annoying situation with family and friend by reduced social interaction. Meanwhile, women are tending to accept any premenstrual changes to handle other behaviours. Women with PMS contributed in lack of work productivity, interference with hobbies and missed numerous working days for health reason. The acceptance in stressors also related to severity of premenstrual syndrome. In previous study found self-care had benefits during premenstrual period especially for women with PMDD. The adjusting energy subscale is referred as how women copes by adjusting behaviour to manage physical and emotional condition included emotional outburst, sugary food consumption, lack of exercise and other involvement. The dietary behaviour, emotional dysregulation, environmental, personality and culture also influenced PMS in women.
communicating is a coping method based on finding support and sharing their feeling and need from others. Adolescence who use social support and communication in premenstrual needs lead in premenstrual syndrome improvements.

The result showed nutritional status had correlated with PMS, while age, age of menarche, menstrual cycle, menstrual bleeding duration and menstrual bleeding quantity had no correlated to PMS. The respondents aged 20 years were more experienced PMS (58.3%). The study by Thu et al. found age is correlated with PMS since this symptom are more severe in older women especially aged between 20 years and 35\textsuperscript{18}. The inconsistency result might due to the samples from different background and the relationship between age and PMS is still not fully understood. For age of menarche, respondents with age of menarche aged below than 12 years more likely to have PMS than respondents with age of menarche more than 12 years. The respondents who had menstrual cycle more than 35 days more prone to PMS than respondents had menstrual cycle between 21 days and 35 days and less than 21 days. The menstrual cycle had related to hormone functions such as follicle stimulating hormone (FSH) and Luteinizing hormone (LH) which released from the pituitary gland and sex hormones such as estrogen and progesterone. The study also found respondents who experienced menstrual period between 3 days to 7 days were more suffered PMS than those who had menstrual period more than 7 days. Furthermore, respondents who needed to change period pad more than 5 times per day had suffered PMS than respondents who changed period pads between 3 times and 5 times and less than 3 days per day. Lastly, respondents who were obesity more likely suffered PMS than respondents who were underweight, normal and overweight. Obese women tend to be experienced PMS. Many studies found women with high BMI had risk in PMS than women with low BMI\textsuperscript{9,20,21}. In obese women, estrogen levels is higher than non-obese women. The fat intake had influenced estrogen levels in the bloods. Reed et al. found women with PMDD had high desire in high fat contains food during their luteal phase of menstrual cycle\textsuperscript{12}.

**Conclusion**

In conclusions, there was significant relationship between premenstrual coping with premenstrual syndrome, more adaptive in premenstrual coping and less or decreased in premenstrual syndrome incidence. Besides, there was significant relationship between premenstrual coping dimension of avoiding harm, awareness and acceptance of premenstrual change, and self-care with premenstrual syndrome. Meanwhile, there was no significant relationship between adjusting energy and communicating with premenstrual syndrome. The nutritional status had significant relationship with premenstrual syndrome, while age, age of menarche, menstrual cycle, menstrual bleeding quantity and duration had no significant relationship with premenstrual syndrome.

Risk Factors of Obesity among Pregnant Women in Biringkanaya Sub District at Makassar City from 2014 to 2015

Febry Ramadhani Suradji1, H. Andi Zulkifli1, Indra Dwinata1

1Faculty of Public Health, Hasanuddin University, Jl. Perintis Kemerdekaan Km. 10, Tamalanrea Indah, Tamalanrea, Tamalanrea Indah, Tamalanrea, Kota Makassar, Sulawesi Selatan 90245, Indonesia

Abstract

The aim of this study is to determine the risk factors of obesity among pregnant women in Biringkaya sub district at Makassar city. The study type was case control study design with pregnant women who had medical record in public health centres (Puskesmas) Sudiang, Sudiang Raya and Paccerakkang in year 2014-2015 as subject. The body mass index (BMI) tool is used in order to measure the index of weight for height as to classify underweight, overweight and obese adults. Total samples were 152 pregnant women with 38 cases and 114 controls. The samples were obtained by using exhaustive sampling technique for case group and purposive sampling techniques for control group. The result found Odds Ratio (OR) of obese pregnant women is influenced by age (OR= 4.632; CI 95% = 2.119- 10.126), parity (OR=3.107; 95% CI = 1.262-7.649), family background (OR=3.4; 95% CI= 1.578-7.527), socioeconomic status (OR=3 .612; 95% CI= 1.189-10.973) and attitude (OR= 0.838; 95% CI = 0.401 – 1.753). In conclusions, pregnant women’s age ≥ 35 years old, parity ≥ 35, family history, high socioeconomic status are risk factors contributing towards obesity among pregnant women.

Keywords: obesity; pregnant women; risk factor; socioeconomic

Introduction

Obesity is major health problem in global since it had impacted on mortality and morbidity in the adult population1. Obesity had contributed to diabetes mellitus (DM), hypertension, high blood cholesterol and cardiovascular diseases2. Furthermore, obesity prevalence is higher in developed countries and increasing in developing countries due to lifestyle changing3. Several factors had contributed in obesity such as genetic, socioeconomic, environment, demographic, lifestyle and culture4,5,6.

Meanwhile, maternal obesity prevalence also increasing and contributed to several complications during pregnancy, birth delivery and post-delivery3. In the United States, half of pregnant women are categorized as obese and 8% are considered as extreme overweight7. The obesity in pregnancy had increased the risk in gestational DM, preterm delivery, spontaneous abortion, postpartum weight retention, congenital anomalies8,9,10.

In Indonesia, obesity prevalence on population aged more than 18 years old is 15.4%, while women had obesity with BMI more than 25 aged 18 years old is 32.9% in 2013. Based on Indonesian National Survey (Riskesdas), South Sulaweswi province was among highest obesity prevalence in Indonesia. In 2013, obesity in women (aged more than 18 years old) was 31.4%.

The maternal age, parity, family history, socioeconomic status and attitudes were related to obesity incidence among pregnant women. Thus, the aim of this study is to determine the risk factors of obesity among pregnant women in Biringkaya sub district at Makassar city.

Methodology

Study Type

The study type was a quantitative research with analytic observational research and case control study design.

Location and Time

This study was conducted from September 2015
to March 2016 at some Puskesmas working area which included Puskesmas Sudiang, Sudiang Raya and Paccerakang in Biringkanaya sub district of Makassar city.

**Population and Sample**

The population for this study were all pregnant women living in Biringkanaya sub district of Makassar city from January 2014 to December 2015. The case sampling used exhaustive sampling technique for case samples and control samples used purposive sampling technique. The sample sizes were 152 pregnant women.

**Data Collection**

The primary data was obtained through questionnaire and secondary data was collected in form of obstetric register data from Puskesmas.

**Data analysis**

The bivariate analysis was performed to determine the relationship of dependent and independent variables. The assessment of risk of each study variable on the obesity pregnant women was done by odd ratio analysis (OR).

**Result and Discussion**

**Bivariate Analysis**

Based on Table 1, the highest proportion of obesity in pregnant women was ≥ 35 years old, 21 respondents (55.3%) and 90 respondents (78.9%) were predominant in non-obesity pregnant women group. The statistical tests OR is 4.632, 95% CI = 2.119-10.126. The risk of obesity in pregnant women aged ≥ 35 years old had 4.632 times greater than mother < 35 years old.

**Table 1. Risk analysis on maternal age of obesity in pregnant women in Biringkanaya sub district at Makassar city 2014-2015**

There were 31 respondents (73.5%) had parity more than 2 among obesity in pregnant women and 47 respondents (41.2%) had no parity or one in non-obesity pregnant women as shown in Table 2. The statistical test result found OR = 3.107, CI 95%= 1.262- 7.649. The risk factors in obesity pregnant women were more than 2 with 3.107 times greater than non-obesity pregnant women.

**Table 2. Risk analysis on maternal parity of obesity in pregnant women in Biringkanaya sub district at Makassar city 2014-2015**

</table>
Overall Discussion

The results found pregnant women aged ≥ 35 years old are more likely to be obese than pregnant women < 35 years old. Age is correlated with obesity. The studies also found high obesity prevalence in women aged of 35 years and above\textsuperscript{2,11}. The body metabolism was reduced with increasing age had lead to difficulty for burning calories and contributed to obesity\textsuperscript{12}.

The high parity also contributed in maternal obesity risk factors. Women who had high parity and age were associated with obesity\textsuperscript{13}. The pregnant women had family history of obesity had risk of 3.4 times greater than pregnant women who did not have family history on obesity. In the United States, a study found mother who is overweight would give birth to obese children\textsuperscript{14}. The obesity prevalence is higher in women than male. Meanwhile, a study suggested married women had 3 times higher risk for obesity than unmarried women\textsuperscript{15}.

In additions, pregnant women with high socioeconomic status are 3.6 times greater than pregnant women with low socioeconomic status on obesity. People with high socioeconomic status affect the purchasing power level which impacted on excessive food intake. In developing countries, obesity prevalence is higher in urban area than rural areas which obesity is common in high socioeconomic society.

Based on this study, it is also found that attitude was not a risk factor for obesity incidence in pregnant women in Biringkanaya sub district of Makassar city. The respondents have knowledge and this influence their daily practice on achieving good nutritional status. Meanwhile, attitude had not been automatically manifested in practice. Hence, attitude is not influenced in obesity incidence among pregnant women.

Conclusion

In conclusions, the pregnant women’s age ≥ 35 years old, parity ≥ 35, family history, high socioeconomic status are risk factors towards obesity among pregnant women. Meanwhile, attitude is not significantly related towards obesity among pregnant women in Biringkanaya sub district at Makassar city.

Risk Factors of Preeclampsia Women in Dr. Wahidin Sudirohusodo Hospital at Makassar City 2015

Fitri Cicilia¹, Muhammad Ikhsan¹, H. M. Tahir Abdullah¹

¹Faculty of Public Health, Hasanuddin University, Jl. Perintis Kemerdekaan Km. 10, Tamalanrea Indah, Tamalanrea, Tamalanrea Indah, Tamalanrea, Kota Makassar, Sulawesi Selatan 90245, Indonesia

Abstract

Preeclampsia or formerly known as toxaemia is a condition of high blood pressure that develops in pregnant woman who have not had high blood pressure before. It usually happens late in pregnancy although it can happen earlier. The aim of this study is to analyse risk factors on maternal age, parity, hypertension history, diabetes mellitus history (DM) toward preeclampsia. The study type was an analytic observational with case control study design. The sample sizes were 80 respondents selected based on simple random sampling. The data was analysed using available SPSS program. The univariate analysis was represented in form of frequency distribution. The bivariate analysis used Odds Ratio (OR) statistic test. The result found that maternal age and parity were not risk factors for preeclampsia with: age variable OR=1.855 95% CI= 0.692-4.973 and parity variable OR= 1.842, 95% CI= 0.755-4.493. Meanwhile, hypertension history and DM history were not calculated since only cases group had hypertension history and DM history.

Keywords: Age; Parity; Preeclampsia; Pregnant Women

Introduction

The preeclampsia and eclampsia contributed to maternal mortality for every 3 minutes in global¹. In the United States, 15% to 17.6% of maternal mortality is caused by preeclampsia². Preeclampsia was diagnosed by increasing in blood pressure (BP) and proteinuria after 20 weeks of pregnancy and ~ 2% to 7% occurred on nulliparous women³.

The preeclampsia was categorized as hypertensive disorder⁴. Chronic hypertension had contributed about 30% of hypertensive disorder cases and 70% cases were caused by preeclampsia⁵ gestational hypertension. Preeclampsia affected body organ and systems which caused by genetic, paternal factors and auto immune⁶. Besides, several factors such as DM, personal or family history with preeclampsia, multiple pregnancy, obesity and chronic hypertension⁷.

Methodology

Study Type

The study type was an analytic observational with case control study design. This study intended to determine the relationship between maternal age, parity, hypertension history and DM history and preeclampsia.

Location and Time

This study was conducted from January to June 2016 at Dr. Wahidin Sudirohusodo Hospital in Makassar city.

Population and Sample

The population for this study were all pregnant women, birth delivery and postpartum in Dr. Wahidin
Sudirohusodo Hospital at Makassar city. The sample sizes were 80 respondents whereby 40 respondents for case group and 40 respondents for control group.

Data Collection and data analysis

The data was obtained from hospital medical record and was analyzed using SPSS program. The univariate analysis was represented in form of frequency distribution, while bivariate analysis was represented to determine relationship between independent and dependent variables.

Result and Discussion

Univariate Analysis

Table 1 tabulated the frequency distribution based on maternal age, parity, hypertension and DM history of the respondents. Based on Table 1, 26 respondents (65.0%) were aged between 20 years and 35 years in the case group and 31 respondents (77.5%) in the control group. Meanwhile, 5 respondents (12.5%) were aged less than 20 years old in the case group and 6 respondents (15.0%) in the control group. Most of respondents were with nulliparous, 21 respondents (52.5%) in case group and 18 respondents (45.0%) in the control group. Meanwhile, 15 respondents (37.5%) with primipara and multipara in the case group and 21 respondents (52.5%) in the control group as shown in the table. There were 30 respondents (75.0%) who had no hypertension history in the case group and 40 respondents (100.0%) in the control group. Besides, there were 10 respondents (25.0%) had hypertension history in the case group. As for DM history, 39 respondents (97.5%) had no DM history in the case group and 40 respondents (100.0%) in the control group. However, only 1 respondent (2.5%) had DM history in the case group.

Bivariate Analysis

Table 2 showed risk analysis on maternal age toward preeclampsia in Dr. Wahidin Sudirohusodo at Makassar city. There were 14 respondents (35.0%) with age had risk in the case group and 9 respondents (22.5%) with age had risk in the control group. The OR equal to 1.855 and CI 95% = 0.692- 4.973. There were 25 respondents (62.5%) with parity had risk in the case group and 21 respondents (52.5%) with parity had no risk in the control group as shown in Table 3. Based on statistical test result, OR= 1.842 and 95% CI = 0.755-4.493. Based on Table 4, 30 respondents (75.0%) with hypertension history had no risk in the case group and 40 respondents (100.0%) with hypertension history had no risk in the control group. The statistical test result had zero value since no any samples in the control group. There were 39 respondents (97.5%) had no DM history in the case group and 40 respondents (100.0%) had no DM history in control group. There is no OR and 95% CI for DM history with preeclampsia since control had no sample based on Table 5.

Overall Discussion

The maternal age of less than 20 years old and more than 35 years old are high risk age group. The reproductive age for pregnancy and childbirth is age between 20 years to 30 years old. Thus, pregnant women aged less than 20 years old and more than 35 years old are at high risk for preeclampsia and eclampsia. The respondents in this study are aged range from 15 years until 42 years old. Based on statistical test result shown OR= 1.855, meant maternal age was not risk factor in preeclampsia. A few studies found no significant relationship between maternal age and preeclampsia\textsuperscript{9,10}. The factor contributing to preeclampsia among pregnant women aged less than 20 years old is due to maternal reaction on initial trophoblastic invasion\textsuperscript{11}. Meanwhile, pregnant women aged more than 35 years old have susceptible with preeclampsia due to chronic hypertension.

Most of pregnant women experienced preeclampsia was commonly in nulliparous mother (parity 0) and multiparous mother (parity 1-3) had low risk in preeclampsia. In this study, maternal parity was not a risk factor for preeclampsia. This study found nulliparous women had 1.842 times risk on preeclampsia same as study done by Opitasari et al. in Jakarta with nulliparous women had 1.8 times of risk in preeclampsia in Jakarta\textsuperscript{12}. Most common complications in grand multipara were preeclampsia, postpartum haemorrhage and foetal distress compared to primipara\textsuperscript{13}.

Hypertension is most common problem during pregnancy and cause of maternal mortality and morbidity. Hypertension in pregnancy is defined by diastolic of 90 mm Hg or greater and systolic of 140 mmHg or greater\textsuperscript{9}. Several studies found hypertension history is correlated to preeclampsia\textsuperscript{14,15}. In this study, OR value was not available since no sample on control group for hypertension history and DM history. Higher BMI during first and last trimester of pregnancy period are correlated to insulin resistance increment at 28 weeks\textsuperscript{3}. In Kendal regency, a study found correlation between DM and pregnancy with preeclampsia at Dr. H. Soewondo Hospital\textsuperscript{16}. In additions, women’s parental history with chronic hypertension also correlated with preeclampsia\textsuperscript{17}. The study by Kobashi et al. found women with parental history of chronic hypertension is at 2.7 times with risk in preeclampsia\textsuperscript{18}.

Conclusion

In conclusions, age and parity were not risk factors for preeclampsia. The hypertension history and DM history has been not calculated since only cases group had hypertension history and DM history.

Abstract

The study aim was an observation on effect of Moringa Oleifera leaf biscuit on increment of body weight, upper arm circumference and nutrition intake on chronic energy deficiency pregnant women in Bontoramba District of Jeneponto Regency. The study was a quasi-experiment pre and post test one group design. The samples were selected using purposive sampling method and involved 34 people for this study. The treatment group was provided Moringa Oleifera leaf biscuit and biscuit from Health Department. The body weight and upper arm circumference were measured before and after the intervention. The data was analysed by using the Wilcoxon test for the upper arm circumference, T-paired test for body weight and nutrient intake used Friedman test with a confident level 95% (p=0.05). The result showed average change of body weight in pregnant women was 7.67 % and upper arm circumference was 1.59 cm. The average change in protein intake was 49.57± 19.77 before intervention, 70.26± 40.63 after 1 month intervention, and 53.56± 20.66 after the intervention (2 months). These variables indicated statistically significant result; p=0.000 for the changes in body weight and upper arm circumference and protein intake with value p=0.037. Thus, Moringa Oleifera leaf biscuit had increased body weight, upper arm circumference and protein intake in chronic energy deficiency pregnant women in Bontoramba district.

Keywords: Body weight; Chronic energy deficiency; Moringa Oleifera leaf biscuit; Protein intake; Upper arm circumference.

Introduction

Malnutrition is public health problem occur in children and pregnant women. In Kenya, high prevalence in malnutrition had observed in pregnant women compared children¹. The malnutrition was in form of under nutrition (wasting, stunting, underweight), micronutrient-related (lack of important vitamin and minerals) and overweight, obesity and diet-related non communicable diseases². A study found that malnutrition had affected one of every five pregnant women studied³. An estimated 200 million pregnant women in developing countries suffered nutrition deficiencies each year⁴.

The sufficient nutrient in pregnant women is important for their health and fetus development. The pregnant women had chronic energy deficiency lead to risk of low birth weight in infants. The low birth infants also are factor associated with neonatal mortality and morbidity and contributed to health problem⁵,⁶. The underweight infants tend to be under-fives with malnutrition status with slower growth and development⁷,⁸. Based on Indonesia Riskesdas(primary health care survey), prevalence risk in pregnant women with chronic energy deficiency aged 15-49 years old, as much as 24.2%⁹. In South Sulawesi, chronic energy deficiency risk prevalence was 32.4%. Overall, prevalence of chronic energy deficiency risk rose in all age group included pregnant and non-pregnant women. In non-pregnant women aged 15-19 years, the prevalence had risen 15.7 percent. Similarly, in pregnant
women aged 45-49 years increased to 15.1%.^{10}

MoringaOleifera was growing in tropical and subtropical region of world.^{11,12} The local people consumed MoringaOleifera as their daily vegetable and potential in therapeutic and dietary supplement to deal with malnutrition.^{13} The MoringaOleifera contained micro-nutrient need by pregnant women such as vitamin C, vitamin A, calcium, potassium, protein, iron, sodium and essential amino acid.^{14,15} The biscuit is utilized from moringa flour became more practical and formulated with other food ingredients commonly use in Supplemental Food Plan (SFP) with reference to standard procedure by the Ministry of Health 2010.

The study aims to observe effect of MoringaOleifera leaf biscuit on the increment of body weight, upper arm circumference and nutritional intake on the pregnant women with chronic energy deficiency in Bontoramba District of Jeneponto regency.

Methodology

This study was a quasi-experiment with pre and post test design. There were two groups in this study: treatment and control group. In pre and post study, the body weight and upper arm circumference measurement was taken for both group. In intervention period, the physical activity and Iron and other multivitamin consumption was observed. This study was conducted in Bontoramba district. The proximate test was done on MoringaOleifera leaf biscuit at Health Laboratory central of Makassar, South Sulawesi. The samples were selected using the purposive sampling method and involved 34 people for this study. The independent variable was MoringaOleifera leaf biscuit and dependent variables were respondent’s body weight and upper arm circumference measurement. The respondent in treatment was given MoringaOleifera leaf biscuit and biscuit from Supplementary Food Program from Health department. The data was analysed by using the Wilcoxon test for the upper arm circumference, T-paired test for the body weight and nutrient intake used the Friedman test with a confident level 95% (p=0.05).

Result and Discussion

Univariate Analysis

Based on Table 1, 6 respondents had pregnant at 2nd trimester and 28 respondents were pregnant at 3rd trimester. Most of respondent, 15 respondents (44.1%) were aged between 19 years and 24 years. There were 3 respondents (8.8%) aged between 13 years and 15 years. Meanwhile, 12 respondents had completed primary school and only 2 respondents had completed diploma. Besides, 32 respondents (94.1%) were unemployed and worked as housewives. There were 33 respondents (97.1%) had undergone pregnancy check up with midwife and only 1 respondent had pregnancy check up with doctor.

Bivariate Analysis

Based on Table 2, there were significant different between body weight and the pregnant women’s obedient in MoringaOleifera leaf biscuit consumption. There were difference of 7.7kg between pre and post study for chronic energy deficiency pregnant women that
fully consumed MoringaOleiferaleaf biscuit and only 7.54 kg for respondent that less in MoringaOleiferaleaf biscuit consumption.

Table 3 showed pregnant women’s body weight had increased from 44.98 kg to 52.63 kg with body weight changes of 7.65 (10.9%). The MoringaOleiferaleaf biscuit had influenced the pregnant women’s body weight with (p=0.000<0.05).

The study had observed changes in the upper arm circumference in the pregnant women with chronic energy deficiency before and after intervention for 2 months which shown in Table 4. The upper arm circumference in pregnant women was increased from 21.75 cm to 23.34 cm before and after intervention. Based on Wilcoxon test, there was difference in the upper arm circumference measurement before and after the intervention (p=0.000<0.05).

Table 5 showed comparison of energy and nutrients intake in pregnant women in Bontoramba district. The energy intake between pre intervention (week 0), during the intervention (week 4) and after the intervention (week 8) was showed with p=0.098>0.05. The mean before intervention was 1712 increased to 2320 (week 4) and dropped at 1717 kg after the intervention. There was no statistically significant difference in consumption. The protein intake with p value=0.037<0.05 meant the MoringaOleiferaleaf biscuit consumption had contributed in the protein intake for the pregnant women. The fat intake (p=0.085>0.05) was not significant and not contributed in the nutrition intake for the pregnant women.

Overall Discussion

The Moringa Oleifera leaf biscuit is tested for protein content used semi-micro Kjehdal method based on Health laboratory of Makassar Standard of Operation (SOP). The screening process is done in twelve villages in Bontoramba district for six weeks and 61 pregnant women suffered chronic energy deficiency. However, only 38 pregnant women were willing to be subjects for this study. The respondent in treatment group is given 56 Moringa Oleifera leaf biscuit per week and consumed as many as eight pieces per day. During intervention period, the author would have visited respondent’s house for given biscuit and hearing the feedback. In 5th week, food frequency questionnaire (FFQ) was conducted to understand food consumption types in past month. In 8th week intervention, body weight and upper arm circumference and FFQ measurement were carried out.

In the study, chronic energy deficiency pregnant women had attended only primary school and lack of knowledge in pregnancy. The respondent had difficulty to consume Moringa Oleifera leaf biscuit since this biscuit had distinctive flavour. The pregnant women completed minimum education were generally more aware compared pregnant women had no education in nutritional status improvement. The education level had significant influence on nutritional status among pregnant women in India.
The study found Moringa Oleifera leaf biscuit consumption among chronic energy deficiency pregnant women for 2 months increased body weight and upper arm circumference. The study also found 17 respondents had increment in upper arm circumference to normal measurement (upper arm circumference ≥ 23.5 cm). Moringa Oleifera leaf biscuit had statistically increased upper arm circumference (p = 0.000) with an average increased from 21.75 to 23.34 cm. Many assumptions suggested body weight of pregnant women increased due to growth of fetus even though no additional food consumed by pregnant women. The pregnant women had consumed Moringa Oleifera leaf biscuit had experienced in body weight gain of 7.77 kg whereas pregnant women less consumed Moringa Oleifera leaf biscuit only gain 7.54 kg in body weight. The body weight gain had met body weight gain criteria that proposed by Directorate of Community Nutrition (2010) stated chronic energy deficiency pregnant women had gain body weight ranged between 4.5 and 6.5 for 2nd trimester and 3rd trimester for 6.5 kg to 9.5 kg. The nutritional status in pregnant women had affected the infant birth weight. The studies suggested chronic energy deficiency in pregnant women was related with low birth weight18, 19.

Moringa Oleifera leaf biscuit consumption is acted as alternative food since this biscuit had provided additional energy of 264.7 Kcal and met daily protein intake. In addition, this biscuit also increased appetite among chronic energy deficiency pregnant. The nutrition contribution of Moringa Oleifera leaf biscuit included energy, fat, carbohydrate, fibre and iron was not statistically significant different before and after intervention. Lack of energy and proteins among pregnant women especially iron and folic acid lead to pregnant women suffered anemia18. Besides, Moringa Oleifera leaf also helped in DNA damage prevention in pregnant women since Moringa Oleifera leaf had high antioxidant activity20. Meanwhile, Moringa Oleifera leaf had increased haemoglobin level and no low birth weight in pregnant women21. A study had suggested pregnant women consumed Moringa Oleifera leaf and flower had increased milk for infant22. The study was indicated that statistically Moringa Oleifera leaf biscuit had increased the body weight, upper arm circumference and protein intake before and after the intervention in chronic energy deficiency pregnant women in Bontoramba Jeneponto District.

Conclusion

In conclusion, Moringa Oleifera leaf biscuit affected increment in body weight and upper arm circumference in chronic energy deficiency pregnant women at Bontoramba Jeneponto District. Besides, Moringa Oleifera leaf biscuit also affect nutrition intake especially protein in pregnant women. Moringa Oleifera leaf biscuit maintained as additional food in supplemental food plan program. The upper arm circumference increased due to amino acid in Moringa Oleifera plant and as a source of potential nutrients. In additions, Moringa Oleifera leaf biscuit had suggested to children that had malnutrition problem.

Analysis of Effectiveness in Addition of Coffee and Brown Sugar on Wastewater Treatment in Regional Public Service Agency (BLUD) Haji Padjonga DG Ngalle Hospital at Takalar Regency

Fitriany¹, Anwar Mallongi¹, Syamsuar Manyullei¹
¹Faculty of Public Health, Hasanuddin University, Jl. Perintis Kemerdekaan Km. 10, Tamalanrea Indah, Tamalanrea, Tamalanrea Indah, Tamalanrea, Kota Makassar, Sulawesi Selatan 90245, Indonesia

Abstract

A process of changing wastewater into usable water that can be released into the environment is called as wastewater treatment. Generally, wastewater contains a lot of contaminations such as toxins, chemicals and bacteria. Treatment is important in order to make sure the overall contaminations are reduced to the acceptable specification. The aim of this study is to determine effectiveness in addition of coffee and brown sugar to wastewater treatment in Regional Public Service Agency (BLUD) Haji Padjonga Dg Ngalle Hospital at Takalar regency. The study type was quasi-experimental study using pre and post-test design. The results found that addition of coffee and brown sugar to the wastewater treatment in BLUD Haji Padjonga Dg Ngalle at Takalar is effective based on regulation of Ministry of Environment and Forestry Republic Indonesia no.5 year 2014 in which BOD level is less than 50 mg/l with decrement efficiency of 86.34% (366.03 mg/l dropped to 50 mg/l), COD level less than 80 mg/l with decrement efficiency of 86.76% (600 mg/l reduced to 79.45 mg/l) and TSS level less than 30 mg/l with decrement efficiency of 79.73% (136 mg/l decreased to 27.56 mg/l).

Keywords: brown sugar; coffee; Takalar regency; wastewater treatment.

Introduction

The wastewater composition is defined as substantial quantity of chemical, physical and biological elements present in wastewater¹. The wastewater from domestic, industrial, agriculture and commercial were the ones which harmed human life². World Bank, Food and Agriculture Organization (FAO) and World Health Organization (WHO) had estimated an average annual in reused water volume can raised up to 25 in several countries included the United States, Japan, Spain, Israel, China and Australia¹. Besides, 70% of wastewater generated in developed countries, 38% in developing countries and 28% in undeveloped and only 8% of water is treated⁴.

In general, hospital had produced higher wastewater than household (400-1200 l/bed.d versus 100 l/capita.d)¹. The waste from hospital contained pathogenic microorganisms, pharmaceutical partially metabolized, toxic chemical substances, drugs and radioactive elements¹,⁶. The chemical substances such as anti-tumour agents, antibiotic and organohalogen compounds which left in wastewater treatment plants had contributed to environment pollution⁷. In many countries, hospital wastewater had been treated together with domestic wastewater and released to receiving environment without specific pre-treatment⁸.

Haji Padjonga Dg Ngalle Hospital is a government hospital in Takalar regency. Based on the observation, Haji Padjonga Dg Ngalle Hospital has wastewater treatment plant with biological system by using anaerobic bacteria in wastewater degradation. The bacteria had been cultivated in aero reactor room by giving additional nutrients such as coffee and brown sugar into the bio reactor. The coffee and brown sugar is main source of carbohydrates for microorganisms in degrading wastewater. Several studies have been done on effectiveness of coffee and brown sugar in wastewater treatment.
treatment in few industries\textsuperscript{9,10,11}. The objective for this study is to determine the effectiveness in addition of coffee and brown sugar on wastewater treatment in BLUD Haji Padjonga Dg Ngalle Hospital at Takalar regency.

**Methodology**

**Study Type**

This study used quasi experiment method with pre and post-test design.

**Location and Time**

This study was conducted in October 2016 at BLUD haji Padjonga Dg Ngalle Takalar regency.

**Population and Sample**

The population in this study is wastewater in BLUD Haji Padjodnga Dg Ngalle at Takalar regency. The samples for this study were wastewater portion during pre and post-test.

**Data Collection and Data Analysis**

The primary data was obtained by determining biochemical oxygen demand (BOD), chemical oxygen demand (COD), total suspended solid (TSS) and pH of wastewater pre and post-test with addition of coffee and brown sugar in the wastewater. The effectiveness in addition of coffee and brown sugar was obtained by comparison BOD, COD and TSS levels and Regulation of Minister of Environment No. 5 of 2014.

**Result and Discussion**

**Results**

Based on Table 1, the temperature in the wastewater bio-reactor is ranged between 26 °C to 27 °C, while pH value of this wastewater is within the range of 6.8 to 7.2. BOD observed had decreased during pre and post-test. On the first day, no addition of coffee and brown sugar has led BOD to not meet the quality standard. Besides, BOD is reduced in second day from 114.54 mg/l to 37.35 mg/l with decrement efficiency of 67.39%. BOD content had decreased from 366.03 mg/l to 50 mg/l with decrement efficiency of 86.34%. These results had met government quality standard, Regulation of Minister of Environment Republic Indonesia No.5 year 2014 which is less than 50 mg/l but still not fulfilled Governor Regulation SULSEL Number 69 year 2010 which is <30 mg/l. Figure 1 shows the decrement efficiency of BOD level of wastewater from day 1 to day 3.

**Table 2. BOD content of wastewater pre and post-test with addition of coffee and brown sugar (500mg) 2016**
There is no addition of coffee and brown sugar since COD content did not meet the quality standard on the first day. The COD content had reduced from 450 mg/l to 77.02 mg/l with decrement efficiency of 78.04%. In additions, COD content was reduced from 600 mg/l to 79.45 mg/l with decrement efficiency of 86.76%. These result met government quality standard, Regulation by Minister of Environment and Forestry Republic Indonesia no.5 year 2014 which is less than 80 mg/l but still not met standard South Sulawesi governor, Regulation no.69 year 2010 which less than 70 mg/l. Figure 2 shows the decrement efficiency of COD level of wastewater from day 1 to day 3.

Figure 2. Decrement efficiency of COD level of wastewater in BLUD Haji Padjonga Dg Ngalle
Based on Table 4, there was a decrement of TSS from 109 mg/l to 42 mg/l with decrement efficiency of 61.46% on second day. Meanwhile, TSS content reduced from 136 mg/l to 27.56 mg/l with decrement efficiency of 79.73% on third day. These results did not meet the quality standard for both government and governor regulation which is less than 30 mg/l.

The optimal temperature for treatment ranged between 15 °C to 40 °C. High temperature had prevented enzyme activity in the cell and decreased efficiency. The wastewater temperature ranged 26 °C to 27 °C indicated to be suitable for microorganism growth. However, the temperature in bio rector is still below quality standard of wastewater based on Regulation of Ministry Environment and Forestry of Republic Indonesia no.5 year 2014 which is 38 °C and South Sulawesi Governor Regulation no.69 year 2010 which is 30 °C. The acidic wastewater caused toxins which harm to the environment. The good pH is ranged between 6.5 and 8.5. In this study, wastewater pH value was ranged at 6.8 to 7.2. These pH values are still below quality standard of wastewater based on Regulation of Ministry Environment and Forestry of Republic Indonesia no.5 year 2014 which is between 6 and 9 and South Sulawesi Governor Regulation no.69 year 2010 which is between 6 and 9. Figure 3 shows the decrement efficiency of BOD level of wastewater from day 1 to day 3.

Figure 3. Decrement efficiency of TSS level of wastewater in BLUD Haji Padjonga Dg Ngalle

The study showed BOD, COD and TSS levels were decreased during pre and post-test. High BOD content led to less dissolved oxygen since oxygen in water had been consumed by microorganism. The organic composition which is produced by hospital wastewater and high oxygen had led to high BOD levels in first day. Addition of coffee and brown sugar had decreased BOD levels in post study. The result indicated that addition of coffee and brown sugar had accelerated microorganism growth.

Meanwhile, COD level is oxygen demand level in wastewater. COD measurement is more accurate than BOD measurement. In a study by Setyawan\textsuperscript{12}, bio natural system had decreased COD content in anaerobic wastewater treatment up to 60%-70%.\textsuperscript{12} TSS is suspended solid which could be organic and inorganic. The suspended solid had reduced sunlight penetration into the water, thus affecting oxygen regeneration and photosynthesis. A study found that decreased in TSS, BOD and total phosphorus had increased efficiency...
of sewage treatment plant in reduction of organic and nutrient loads from sewage water at downstream Sambul river in Kenya. 

### Conclusion

In conclusions, addition of coffee and brown sugar to the wastewater treatment in BLUD Haji Padjonga Dg Ngalle at Takalar is effective based on regulation of Ministry of Environment and Forestry Republic Indonesia no.5 year 2014 in which BOD level is less than 50 mg/l with decrement efficiency of 86.34% (366.03 mg/l dropped to 50 mg/l), COD level is less than 80 mg/l with decrement efficiency of 86.76% (600 mg/l reduced to 79.45 mg/l) and TSS level is less than 30 mg/l with decrement efficiency of 79.73% (136 mg/l decreased to 27.56 mg/l).

Abstract

The aim of this study to analyze health risk caused by consumed pesticide residues on chilli and tomato in market sellers Biringkanaya Southwestern District of Makassar city. The study was used observational approach to analyze environment health risks. The number of respondent for this study was 53 people who consumed the tomatoes and chilies contained residue profenofos. The data were analyzed with environment health risk analysis method and processed using excel and IBM SPSS program. The profenofos concentration measurement result showed two samples concentrations below 1 mg/kg. The highest profenofos residual concentration in tomatoes is 0.4234 mg/kg and 1 tomato samples was not detected. The highest profenofos residue in chillies was 2.722mg/kg and lowest concentration was 2.521 mg/kg. The mean of Target Hazard Quotient (THQ) real time and life time among respondents who consumed profenofos residues on chilli and tomato <1. This means there is no risk to health. The mean of Hazard Index (HI) real time and life time among respondents who consumed profenofos residues on chilli and tomato <1, which means there is no risk to health. The mean of Risk Quotient (RQ) real time and life time among respondents who consumed profenofos residue in tomato and chilli real time <1, which means there is no risk to health. The mean RQ in tomato life time> 1, which means health risk if consumed.

Keywords: Analysis of environment health risk; Chili; Profenofos; Tomato

Introduction

The pesticide residues are chemical substances contained in the agricultural products, food or animal foods. The residue in plant comes from spraying on the plants. The insecticidal residues are present in all plant bodies such as stems, leaves, fruits and roots. The pesticide residue is still present in fruit and vegetable even though these fruit and vegetable was washed or cooked¹. The pesticide residues had an indirect effect on the customer and caused the health problem on long-term consumption such as neurological disorder and enzyme metabolism. The pesticide residue in the food was accumulated in the body tissues and leads to impair liver, kidney, nervous system, immunity system, birth defect, allergies and cancer².

The profenofos is one type of organophosphate insecticide with maximum limit of residue in accorded with Indonesian National Standard which is 5 mg/ kg in the red chilies. The profenofos is used to kill pest in tomato and red chili plants. The maximum residue limit (MRL) is allowed is 0.05ppm in vegetables; 0.10 ppm in water and 0.005 ppm on the soil³. Based on Ministry of Agriculture regulation, the pesticide was allowed in red chillies were carbendazim, profenofos and quinoxifen. Curcron was one of pesticide product that controlled pest on chili had active ingredient of profenofos⁴.

The proponofos is one type of organophosphate contamination is found in red chili, lettuce and onion at Bandungan and Brebes⁵. Based on the study conducted by the Agricultural Research and Development Agency showed unwashed tomatoes contained profenofos average 0.096 mg/kg, while the washed tomatoes contained 0.059 mg/
The organophosphorus pesticides were most toxic pesticides compared to other types of pesticide because it attacked the nervous system. The pesticide was lead negative impact toward environment and human health. The profenofos is impact biodiversity ecosystems and caused biological population unbalanced.

A study showed 13 respondents had severe poisoning and 37 respondents had mild poisoning among 50 respondents worked as farmers in Bandungan district. In Malaysia, the pesticide residue was highest found in tomato (30%) and lowest was found in capsicum (4.5%). Meanwhile, pesticide residues (Diazinon and Quinalphos) was detected in long yard bean was 66.7% that over limit Acceptable Daily Intake (ADI), (Quinalphos, 0.002 mg/kg body weight and Diazinon, 0.004 mg/kg body weight).

Daya market is located in Biringkanaya sub-district, Makassar city which was central for tomatoes and chilies sale. The author would like to study profenofos residue exposure to the sellers and buyers of tomatoes and chilies in the market. There was potentially at risk for pesticide exposure in Daya market with certain doses and exposure duration to the pesticide caused both acute and chronic disease. Based on these problems, the author had conducted a study on people who consumed tomatoes (lycopersiconesculentum) and chilies (Capsicum annum L.) contained profenofos residue in Daya market at Biringkanaya sub-district, Makassar city.

**Methodology**

The study was used observational method with Environmental Health Risk Analysis Design which observed on the samples to understand the studied variables namely Organophosphate pesticide active substances profenofos in Daya market. The sample results had analyzed used formula to determine health risk. This study was conducted at Daya market in Biringkanaya sub-district, Makassar city, South Sulawesi Province. This study was conducted within 3 months from March 2016 until May 2016. The population for this study was vegetable sellers in Daya market, Biringkanaya sub district, Makassar city, South Sulawesi Province. The samples were selected based on purposive sampling method. The numbers of respondents selected for this study were 53 people who consumed tomatoes and chilies contained profenofos residue. The tomatoes and chilies were obtained from Daya market that wrap with aluminum foil and plastic. The sample criteria for this study are consumer and the sellers in Daya market, Biringkanaya sub-district, Makassar regency, South Sulawesi province.

The primary data was obtained from observation through measurement such as profenofos residue concentration on tomatoes and chilies. Meanwhile, secondary data was obtained from Biringkanaya district office, Makassar health office for health data, and vegetables and pesticides data had obtained from Makassar agriculture department and South Sulawesi department of Agriculture Food Crops and Horticulture. The questionnaires data were obtained from interview with respondents who consumed tomatoes and chilies contained profenofos residues. This data used to calculate profenofos residue in tomatoes and chilies that consumed by the respondent. The data were analysed with environment health risk analysis method and processed using excel and IBM SPSS program. The data analysis method used was Environment Health Risk Analysis method to determine hazard identification and exposure analysis. The risk analysis was calculated intake for daily and weekly to determine health risk. This study used formula estimated weekly intake (EWI) and target hazard quotient (THQ). The EWI calculation was proposed to understand average tomatoes and chilies consumption calculated for a week. Meanwhile, THQ calculation was dangerous potential occurred in the respondent that consumed contamination tomatoes and chilies.

**Result and Discussion**

**Result**

From Table 1, the profenofos concentration in tomato sample I was undetected. Meanwhile, tomato sample II contained 0.4234 mg/ kg. The chilies contained high profenofos concentration, chilies sample III contained 2.521 mg/kg and chilies sample IV contained 2.722 mg/kg.
Table 1. Profenofos residues in the tomato and chili were consumed by Biringkanaya Camatan’s resident in 2016.

Source: Primary Data, 2016

Conclusion

The profenofos residue concentration in tomatoes was 0.4234 mg/kg and average was 0.26215 mg/ kg. Based on these results, concentration of profenofos residue in tomatoes was still below the MRLs that specified by SNI in 2009 that was 2.0. The study showed profenofos residue concentration had passed standard of RFD US-EPA in 2006 that was 0.0001 mg/ kg/ day. In contrast, the profenofos concentration in chilies was exceeded the specified standard. The average target of real time for tomatoes was 0.000138 and average real time for chilies was 0.00085. The 30 years life time for tomatoes was 0.000568 and chilies were 0.0001505. There was no risk in non-carcinogenic disease because of profenofos residue exposure due to THQ<1. Meanwhile, average total real time for HI was 0.000990 and 30 years life time was 0.002074. There was no any non-carcinogenic risk due to HI<1. The average real-time risk for chilies was 0.369540 and tomatoes was 0.571353. The risk of life time for chilies showed non-carcinogenic health risk due to profenofos residue exposure (RQ>1). The average total risk (RQ cumulative) real time for chili and tomato was 0.507901 and life time was 2.076492. It had showed health risk of non-carcinogenic affected at life time because RQ<1. The limitation of chili and tomato consumption needed reduced to avoid profenofos residue and other active substances on health. The chilies and tomatoes needed to be wash well before cooking. Besides, the farmer needed to enrich their knowledge about their high quality of chilies and tomatoes production without using the pesticides.

Correlation between the Level of Von Willebrand Factor (VWF) and Blood Pressure of Pregnant Women in Makassar City

Hardianti1, Abdul Razak Thaha1, Burhanuddin Bahar1

1Faculty of Public Health, Hasanuddin University, Jl. PerintisKemerdekaan Km. 10, Tamalanrea Indah, Tamalanrea, Tamalanrea Indah, Tamalanrea, Kota Makassar, Sulawesi Selatan 90245, Indonesia

Abstract

The aim of this study to analyses the correlation between the Von Willebrand factor (VWF) and blood pressure of pregnant women in Makassar. The study was used cross sectional study which is conducted in community health center (Puskesmas) of Makassar city from August to November 2015. The subjects were primigravida pregnant women ranged from 17 to 35 years old and had no history background on chronic hypertension. The data collections were the sample characteristics, anthropocentric data and blood pressure data. The blood sample was examined at Nechri Laboratory of Hasanuddin University. The data were analyzed used Chi-square by SPSS programmed to analyze the correlation between the level of Von Willebrand Factor(VWF) and systolic and diastolic blood pressure. The study was indicted that the average systolic and diastolic blood pressure of the samples was respectively 101.08 mmHg and 70.81 mmHg. The mean level VWF of the samples was 363.41 ng/ml. There was no significant correlation between VWF level and systolic (p=0.09) and diastolic (p=0.643) blood pressure.

Keywords: Blood pressure; Pregnant women; VWF

Introduction

Hypertension during pregnancy contributed to maternal morbidity and mortality around the world. The hypertension is affected 20%-30% of adult population and more than 5%-8% of pregnant women. The hypertension in pregnant women increased the risk for pregnancy complications such as cerebral hemorrhage, intravascular coagulation (DIC), liver dysfunction and acute renal failure. In United States, an estimated of 15% of maternal mortality was due to hypertension.

The hypertension occurs in forms of preeclampsia or known as gestational hypertension. The hypertension was clinical diagnosis as systolic blood pressure ≥140 mm Hg and/or diastolic ≥ 90 mm Hg. The maternal age and obesity and ethnic profile changed were among risk factors that leads hypertension.

The Von Willebrand factor (VWF) is an acute-phase protein and a market of endothelial damage. The VWF deficiency was related with bleeding tendency that increased evidence thrombogenesis. In a study, number of active in VWF was observed related with acute endothelial cell activation and decreased ADAMTS13 activity.

The study was conducted on pregnant women to analyze correlation between Von Willebrand factor (VWF) and blood pressure of pregnant women in Makassar.

Methodology

Study Type

The study design was cross sectional study by measurement or observation at same period (one point approach) to understand relationship between variables.

Location and Time

The study was conducted in August until November 2015. This study was conducted at public health center, Puskesmas in Makassar: PuskesmasLayang, PuskesmasMalimonganBaru and PuskesmasKalukuBodoa.
Population and Sample

The population in this study was all pregnant women in PuskesmasLayang, PuskesmasMalimonganBaru and PuskesmasKalukuBodoa. In this study, the samples were 37 pregnant women. The samples was using nonrandom (non-probability sampling) with “consecutive sampling” technique that that met criteria included:

i) Aged 17-35 years

ii) Primigravida or first pregnancy

iii) No history of chronic hypertension

Data Analysis

The univariate and bivariate analysis were used in this study. The univariate analysis included respondent characteristic, blood pressure and VWF level. The bivariate analysis was used chi-square used to analyze relationship between variable levels of VWF and blood pressure variables by SPSS program. The T test was used to determine mean difference of blood pressure based on respondent's VWF level. The blood samples were examined at Nechri Laboratory of Hasanuddin University.

Result and Discussion

Univariate Analysis

Based on Table 1, there were 31 respondents aged between 20-35 years and only 6 respondents aged less than 20 years. Meanwhile, 15 respondents (40.5%) were completed high school level. Meanwhile, 29 respondents (78.4%) were unemployed and only 2 worked as teacher or government sector. There were 19 respondents (51.4%) had pregnancy period in trimester II and only 18 respondents (48.6%) was pregnant in trimester III.

Based on Table 2, maximum systolic and diastolic blood pressures on pregnant women were 120 mmHg and 80mmHg. Meanwhile, minimum systolic and diastolic blood pressures were 85 mmHg and 60mmHg on pregnant women. The mean for the systolic and diastolic blood pressure were 101.08mmHg and 70.81 mmHg. Besides, median for both type of blood pressure on pregnant women were 100 mmHg and 70mmHg.

In Table 3, the maximum and minimum value of (VWF) content in pregnant women was 568.79 ng/ml. Besides, median for VWF content was 358.71 ng/ml.

**Bivariate Analysis**

Based on Fisher test which shown in Table 4, the pregnant women with VWF level below median mostly and systolic blood pressure above median (66.7%). Besides, the pregnant women with VWF level above the median, most had systolic blood pressure above the median (89.5%). There were 6 respondents that their VWF level was above median had tended with systolic blood pressure below median. Meanwhile, only 2 respondents with VWF level above median had systolic blood pressure below than median. In additions, 17 respondents had VWF level above median also had systolic blood pressure above median. There was no significant relationship between Von Willebrand factor (VWF) and systolic blood pressure in the pregnant women (p=0.09>0.05).

Based on Fisher test which shown in Table 5, the pregnant women with VWF level below median mostly and systolic blood pressure above median (83.3%). There were 15 respondents that their VWF level was above the median had tended with systolic blood pressure below the median. Meanwhile, only 3 respondents with VWF level above median had systolic blood pressure below than median. There was no significant relationship between Von Willebrand factor (VWF) and diastolic blood pressure in pregnant women (p=0.0643>0.05).

Based on Table 6, pregnant women in trimester II had systolic blood pressure above median (73.7%). Meanwhile, pregnant women in trimester III had systolic blood pressure above than median (83.3%). This study showed there was no significantly relationship between pregnancy trimester and systolic blood pressure on pregnant women (p=0.379>0.05).

Overall Discussion

In this study, pregnant women are aged between 17 years and 35 years and most of respondents were aged between 20 years and 35 years old (83.8%). In a study, young primigravidae aged less than 20 years and over 30 years had high risk in hypertension\(^1\). In additions, a study suggested labor and delivery complication were related with maternal age\(^1\). Meanwhile, a study found hypertension in mother had correlated with hematological profile of infants\(^1\). Most of pregnant women had high education level was completed high school or equivalent (40.5%). This study had assumed pregnant women had knowledge in antenatal care and hypertension risk. In China, a study found low education level influenced hypertensive disorders in pregnancy through multivariate logistic regression analysis\(^1\).

All respondents had systolic and diastolic blood pressure in normal level (normotension). The results also found mean of systolic and diastolic blood pressure were 101.08 mm Hg and 70.81 mm Hg. The minimum values of systolic and diastolic blood pressure were 85 mmHg and 60 mmHg.

The blood pressure data was obtained did not vary (homogenous) since all respondents were in normotension level. The probability was due to blood pressure measurement error. Besides, blood pressure measurement was due to different blood pressure measurement tool. The Von Willebrand factor (VWF) was examined by ELISA method. The average of VWF content of respondent samples was 363.41 ng/ml. The minimum VWF content was 133.18 ng/ml, while maximum of VWF level was 568.79 ng/ml. Based on this study, there was no significant relationship between VWF level and systolic and diastolic blood pressure in pregnant women. This result due to all blood pressure samples was in normotension level. Although, there was tendency that VWF level increased in pregnant women with systolic blood pressure that above median.

Conclusion

In conclusions, no significant relationship between Von Willebrand factor (VWF) and systolic blood pressure in pregnant women in Makassar. The pregnant women with VWF level below or above median both had systolic blood pressure above median. In additions, no significant relationship between Von Willebrand factor (VWF) level and diastolic blood pressure in pregnant women. Besides, pregnant women with VWF level below or above median both had diastolic blood pressure above median. The Von Willebrand factor (VWF) on pregnant women suffered preeclampsia was suggested becoming biomarkers on preeclampsia prevention and treatment.

Correlation between Body Mass Index and Physical Activity on Menstrual Cycle in Young Adult

Hasmawati Rasyid¹, Andi Besse Ahsaniyah¹, Ita Rini¹

¹Faculty of Medicine, Hasanuddin University, Jl. Perintis Kemerdekaan Km.10, Makassar, 90245. Sulawesi Selatan, Indonesia

Abstract

Menstrual cycle disorder are an important indicator showed the presence of reproductive system disruption. The body mass index (BMI) and physical activity are among factors caused menstrual cycle disorders. This study aimed to determine relationship between BMI and physical activity and menstrual cycle in young adults. This study was used analytic observational research design by using cross sectional method. The study population were female students in Faculty of Medicine, Hasanuddin University which total of 306 students in 2014. Meanwhile, the study sample sizes were 76 female student that met the inclusion criteria such as students in 2014 and willing to be study respondents. The data was collected included BMI level using Asia Pacific Cohort Collaboration classification table, physical activity was using International Physical Activity Questionnaire and the menstrual cycle using the observation sheets. The result found relationship between BMI toward menstrual cycle had p-value=0.001. Meanwhile, the statistical test on relationship between physical activity toward menstrual cycle had p-value=0.023.

Keywords: Female students; International physical activity questionnaire; Oligomenorrhea; Obesity; Polymenorrhea; Underweights

Introduction

Menstrual cycle plays important in women reproductive health which have 4 dimensions consists of regularity, menstrual frequency, menstrual duration and menstrual blood volume¹. In general, first menstrual cycle occurs on female aged between 12 years to 15 years old and end around age of 50 years². Most female have their menstruation between 2 days and 7 days and normal cycle ranges from 21 days to 45 days³.

Factors that plays role in the menstrual cycle regularity and flow such as hormone changes, genetics, serious medical conditions, body mass index (BMI) and psychological well-being also affects menarche age and common menstrual problem⁴. Menstrual disorders are an important indicator of reproductive system function disruption which associated with increasing risk of various diseases such as uterine and breast cancer, infertility and bone fracture. The menstrual disorder such as irregularities menstrual cycle are major problem among female adults especially teenagers that leads anxiety⁵. Approximately, 87% of female with irregular menstrual cycles suffers the polycystic ovary syndrome (PCOS), oligomenorrhea (>35 days) and contributed to ovarian dysfunction and insulin resistance among PCOS women⁶.

Body Mass Index (BMI) is calculated based on weight and height (weight/ (height)²). In worldwide, there are more than 1 billion overweight adults and approximately 300 million people are under obesity⁷. There are more than 35% of men and nearly to 40% of women are overweight or obesity and increase among people age between 20 years and 40 years⁸. Several studies found the correlation between obesity and the reproductive system problem such as high risk in menstua disorder and anovulation which obese women had risk of 3 times of anovulation compared to normal weight women⁹.

The physical activity is also associated with the menstrual cycle regularity. Besides, benefit of physical activities for women health such as reduces risk of cardiovascular disease, breast and colon cancers diabetes mellitus, osteoporosis and other diseases¹⁰. Based on the observation, there were 41 female students had BMI that above normal limit and some female students also
suffered abnormal menstrual cycles. This study aims to determine relationship between BMI and physical activity and menstrual cycle in young adults.

**Methodology**

**Study design**

The study was used analytic observational research design with cross sectional design.

**Study location and time**

The study was conducted in Faculty of Medicine, Hasanuddin University on 23rd February until 28th February 2017.

**Study population and sample**

The study population was all female students in Faculty of Medicine, Hasanuddin University in year 2014. Meanwhile, the study samples were 76 female study that met the inclusion criteria such as student in the faculty in 2014, willing to be respondents, no any reproductive medicine consumption and no any diet program joining.

**Data Collection**

The data was collected by using the questionnaire which the question about the physical activity performance in last 7 days and BMI measurement. The weight and height data were obtained through direct measurement. The BMI value was measured by body weight data using one-med scales and body height measurement using stature meter. BMI value was interpreted according to Asia Pacific Cohort Studies Collaboration table. Meanwhile, physical activity was measured using International Physical Activity Questionnaire (IPAQ). The menstrual cycle data was recorded in observation sheet.

**Data analysis**

The data was analysed used descriptive bivariate analysis to determine relationship between BMI and physical activity toward menstrual cycle in young adults. The chi square test also performed with SPSS program. The data was presented in the tables and narratives form.

**Results and Discussion**

**Univariate analysis**

In Table 1, 27 respondents (35.5%) were obesity I and 18 respondents (23.7%) were normal in BMI. Meanwhile, 11 respondents (14.5%) were underweight and 4 respondents (5.3%) were at risk for obesity. In additions, 53 respondents (69.7%) had less physical activity and 10 respondents (13.2%) were active in the physical activity. The menstrual cycle was divided into 3 categories such as oligomenoreoa, normal and polimenoreoa. Meanwhile, 37 respondents (48.7%) were normal in menstrual cycle and 27 respondents (35.5%) suffered oligomenorea. There were 12 respondents (15.8%) suffered Polymenoreoa in menstrual cycle.

**Bivariate analysis**

Furthermore, 1 respondent suffered oligomenorea was underweight and 18 respondents were under obesity I. Besides, 4 respondents suffered oligomenorea were under obesity II. For normal menstrual cycle, there was 16 respondents was normal and 1 respondent was under risk for BMI level. Meanwhile, 5 respondents suffered polimenoreoa were underweight and 3 respondents were obesity II. The chi square test showed there was significant relationship between BMI and menstrual cycle in young adult with p= 0.001<0.005.
In Table 3, there were 6 respondents that very active and 13 respondents had less in physical activities suffered oligomenorea menstrual cycle. Meanwhile, 31 respondents were less active, and 3 respondents were active in physical activities that normal in menstrual cycle. In additions, 9 respondents had less physical activity and 1 respondent who very active in physical activity that suffered polymenorea. The chi square test showed there was no significant relationship between physical activity and menstrual cycle in young adults with p=0.023>0.05.

Overall Discussion

In this study, there were 27 female students (35.5%) had suffered oligomenorea, 36 female students had normal menstrual cycle and 13 female students had suffered polymenorea. These results showed women had high BMI level which high body fat (obesity category) had increment in androstenedione produce. The androstenedione is androgen that served as precursor of reproductive hormones. In the body, androgen is used to produce estrogen with aid of aromatase enzymes. This androgen-induced aromatization process occurs in granulosa and fat tissue. Thus, more fat body percentage, more estrogen is formed which disturb the hormone. Hossain (2011) found the student in one university that had high BMI level is likely to experience menstrual cycle disorder.

In additions, women hormones such as progesterone, estrogen, LH and FSH were closely correlated with hormone disorder. The disruption of hormone system also associate with high body fat percentage. Besides, high body fat affected the estrogen hormone metabolism in the female reproductive system. The menstrual cycle disruption is caused by high rate of estrogen disturbance until Follicle Stimulating Hormone (FSH) did not reach...
the peak. Thus, the follicle was ceases and no ovulation occurs and affected the menstrual cycle period. The rapid in estrogen level leads positive feedback toward the hypothalamus and pituitary gland that contributed increment in L.H. Overweight caused irregular menstrual cycle and estrogen production tens to exaggerate leads to metabolism disorder. Excess body fat causes interference with ovarian function and proliferation phase is longer than classical menstrual cycles.

Furthermore, 6 respondents were active, 8 respondents were medium and 13 respondents were inactive in the physical activities had suffered oligomenorea. Meanwhile, 3 respondents were active, 2 respondents were medium and 31 respondents were less in the physical activities and had normal menstrual cycle. In additions, 1 respondent were active, 3 respondents were medium, and 9 respondents were less active in the physical activities and suffered poligenorea.

The study also showed there was significant relationship between BMI with menstrual cycle in young adults (p=0.001<0.05) Meanwhile, there was no significant relationship between physical activity and menstrual cycle in young adult (p=0.023>0.05). The normal menstruation period were between 3 days until 7 days. Several physical activities affected menstrual cycle disorders and change follicular phase to its normal phase.

This study showed most students have medium of physical activity and suffered oligomenorea menstrual cycle disorder due to overweight or obese. Hence, the physiotherapist roles in women health that provides advice on the food consumption to balance the body energy and to regulate physical activity.

Acknowledgement: The author would like to thank to all respondents and Faculty of Medicine, Hasanuddin University for unconditional support.

Conclusion

In conclusion, there was significant relationship between BMI toward menstrual cycle in young adult. Meanwhile, there was no significant relationship between physical activity toward menstrual cycle in young adults. These results showed BMI factor had more influence on the regularity of menstrual cycle in the young adult compared to their physical activity. This study is expected to be consideration for physiotherapists that needed to focus on the women education especially physiotherapy since the reality showed physiotherapy is more focused on neuropsychiatry and musculoskeletal.

Factor Related to the Occurrence of Anemia and Obedience in Consuming FE Tablets in Pregnant Women at Mamajang Public Health Center, Makassar

Hastuti Husain1, Ema Alasiry1, Irfan Idris1

1Faculty of Medicine, Hasanuddin University, Jl. Perintis Kemerdekaan Km.10, Makassar, 90245. Sulawesi Selatan, Indonesia

Abstract
Anemia in pregnant women is still common and one of factors thought to be the cause is the disobedience of pregnant women in consuming Fe tablets. The purpose of this study is to find out the factors related to the occurrence of anemia and the obedience in consuming Fe tablets in pregnant women. This quantitative study which used the cross sectional design was conducted from November to December 2014 at Mamajang Public Health Center with 60 samples of pregnant women. The data were collected using questionnaires. A statistical analysis with cross-tabulation was conducted after that, followed by a chi-square test. Factors associated with anemia are the size of upper arm circumference (p=0.003) and obedience in consuming Fe tablets (p=0.003) whereas factors related to obedience in consuming Fe tablets are quality of antenatal care (p=0.047). This shows that pregnant women’s obedience in consuming Fe tablet is significantly correlated with the occurrence of anemia in pregnant women.

Keywords: Anemia; Fe tablets; gravid status; midwives; pregnancy

Introduction
Quality of antenatal care can detect the occurrence of risk in pregnancy, getting access to quality pregnancy care, obtaining opportunities in early detection of complications that may arise so maternal death can be avoided1. In Indonesia, prevention programs for anemia in pregnant women provided iron supplements as many as 90 tablets during pregnancy. The Ministry of Health recommends that pregnant women consume at least 90 iron pills during pregnancy which contain 60 mg of elemental iron and 0.2% of folic acid taken 1 tablet a day. Adherence to drinking Fe tablets if ≥ 90% of iron tablets should be taken2. Compliance with pregnant women taking iron pills is an important factor in ensuring an increase in hemoglobin levels of pregnant women. Nonetheless, due to various factors such as lack of knowledge, attitudes and actions of pregnant women who are not good, the side effects caused by the tablet can trigger a person to not adhere to the consumption of iron tablets properly, thus the purpose of giving the tablet is not achieved3.

According to the Indonesian Ministry of Health, the low compliance of pregnant women in consuming iron supplements is one of the causes of anemia prevalence rates to remain high. The results of Sadariah4 study, showed that there were 39.9% pregnant women who suffered from anemia and there were 37.2% pregnant women who did not obey to consuming iron tablets. From research conducted by Purwaningsih5, around 40% - 50% of mothers do not adhere to drinking Fe tablets. Likewise, Maisa’s study stated that out of 30 pregnant women who were anemic, 30% of them did not obey drinking Fe tablets6. Data from Risdiknakes7 showed that iron consumption and variations in the amount of iron intake during pregnancy in Indonesia amounted to 89.1%. From these data, it was found that among those who consumed iron, there were 33.3% of pregnant women who consumed a minimum of 90 days during pregnancy, while 34.4% of pregnant women consumed less than 90 days and the other 21.4% forgot how much Fe tablets they consumed per day8.
Anemia in pregnant women has an impact on the health and safety of the mother also has an impact on the quality of the baby to be born. The incidence of anemia in pregnant women is still high even though in every antenatal examination iron tablets have been given according to the government’s policy of 90 tablets during pregnancy. The purpose of this study was to determine the factors associated with the incidence of anemia and adherence of pregnant women in consuming Fe (iron) tablets.

Methodology

Research Type

The research type is a quantitative study with an analytical survey approach using the cross sectional study design. Independent and dependent variables are observed at the same time and there is no follow-up.

Location and Time of Research

This research was carried out at Mamajang Health Center for 2 months from November to December 2014 until the research sample was sufficient.

Population and Sample

The population in this study was all pregnant women who were examined for pregnancy in November - December 2014. Sampling was done using purposive sampling technique with regard to inclusion and exclusion criteria. The 60 pregnant women who were sampled were those who had repeated pregnancy checks and had obtained Fe tablets at the previous examination and were also willing to become respondents.

Data collection

The data collected are primary data derived from the questionnaire answers of pregnant women along with the results of observations of midwives who conduct prenatal checks. Secondary data is seen in the visit book to see previous inspection history.

Data analysis

Data analysis was carried out in stages, namely univariate analysis which aimed to explain the characteristics of each variable of bivariate research and analysis conducted on two variables that were allegedly related or correlated between independent variables and dependent variables with Chi Square test. The data was analyzed using the SPSS version 21.

Results

Univariate analysis

Table 1 shows the relationship between characteristics of pregnant women and the incidence of anemia. In the age category, the proportion of pregnant women who experienced anemia was 43.75% higher in mothers of high risk age than in mothers of low risk age (43.18%). As for the education category, the proportion of anemia was highest in diploma level (50.00%) and the lowest was in the junior secondary education category (0%). While in the occupational category, the proportion of anemia was highest in civil sector (50%) and the lowest was in traders (0%). For the gestational age category, it was seen that the proportion of pregnant women who experienced anemia in the first trimester of pregnancy (50%) and decreased respectively with increasing gestational age, namely in Trimester II (43.75%) and gestational age III Trimester (42.31%). In the gravida category, it was shown that the proportion of pregnant women who suffered the most anemias was multigravida (47.92%) compared to primigravida (25.00%). For the pregnancy gap category, it can be seen that the proportion of anemia occurrence is more common at high risk pregnancy interval (48.39%) than the low risk group (37.93%). The proportion of anemia in pregnant women with chronic energy malnutrition (CEM) was higher (68.18%) than in the maternal that do not suffer from CEM (28.95%).

Anemia occurs more frequently in pregnant women who state that the quality of antenatal care is according to the standard of 46.81%, while the incidence of anemia in pregnant women who state that the antenatal quality is not standardized is 30.77%. The proportion of anemia occurrences in non-compliant mothers consumed Fe tablets was 72.22% while the incidence of anemia in pregnant women who obeyed consuming Fe tablets was 30.95%.

Table 2 shows the characteristics of pregnant women based on compliance consuming Fe tablets. In the age category, the proportion of pregnant women who obeyed consuming Fe tablets was 75.00% higher in mothers of high risk age than in mothers of low risk age (68.18%). In the education category, the proportion of pregnant women who obeyed consumed the most Fe tablets at the high school level of education were 35.53% meanwhile the lowest were in the junior high school (0%) and diploma (0%) categories. In the occupational category, the proportion of mothers who adhered to consumed the most Fe tablets were housewives (36.73%). The proportion in the work of other pregnant women was 0%. In the gravida category, it was shown that the proportion of pregnant women who consumed the most Fe tablets were multigravida mothers (35.42%) compared to primigravida mothers (8.33%). While in the ANC quality category, it was seen that the proportion of pregnant women who obeyed to consume Fe tablets were pregnant women which stated that the quality of service was not standard (92.31%) compared to pregnant women stated that the quality of service according to the standard was 63.83%.

### Bivariate Analysis

In the results of statistical tests, the characteristics of pregnant women associated with anemia were the measurement of MUAC and compliance to consuming Fe tablets with a p value > 0.05. While maternal age, education, occupation, gestational age, pregnancy distance, gravida status and antenatal quality were not associated with the incidence of anemia.

Statistical test results for MUAC measurement category showed that p value = 0.003 which indicated there was a significant relationship between MUAC and the incidence of anemia in pregnant women. While the results of the statistical compliance test consuming Fe tablets showed that p value = 0.003, which proved there is a significant relationship between adherences to
consuming Fe tablets with the incidence of anemia in pregnant women.

The results of statistical tests of maternal age categories had p value = 0.969 which showed there was no relationship between maternal age and the incidence of anemia. In the education category, p value = 0.390 showed there was no relationship between education and the incidence of anemia. Job category shows p value = 0.770 which means there is no significant relationship between maternal occupation and anemia. In the gestational age category showed that p value = 0.852, referred to as no relationship between gestational age and the incidence of anemia in pregnant women. Gravida status category shows p value = 0.152, which means that there is no relationship between gravida status and the incidence of anemia in pregnant women. Pregnancy gap category shows that p value = 0.414, which point towards no relationship between the period of pregnancy and the incidence of anemia in pregnant women. Antenatal quality categories showed that p value = 0.302 which showed that there was no relationship between antenatal quality and the incidence of anemia.

The results of the statistical test in Table 2 showed that the factors associated with adherence to consuming Fe tablets were the quality of ANC with p <0.05, while age, education, occupation, and gravida status had no relationship with consuming Fe tablets with a p value> 0.05.

ANC quality statistical test results obtained p value = 0.047, indicating a significant relationship between antenatal care quality and the compliance to consuming Fe tablets. In the maternal age category, p = 0.610, proving there was no significant relationship between maternal age and compliance with consuming Fe tablets. For the education category, occupational category and Gravida status category, the results of p value was 0.083, 0.123 and 0.067 respectively which showed that there was no significant relationship between any of these categories and maternal adherence in consuming Fe tablets.

**DISCUSSION**

The results of this study show an overview of the incidence of anemia in pregnant women. MUAC measurement in a group of women of childbearing age is one of the ways for early detection of CEM that can be easily carried out by ordinary people. Compliance with consuming Fe tablets has a significant relationship with the incidence of anemia in pregnant women. The same results were also obtained by Salmariantity, with a value of p = 0.021.

Based on the results of interviews with pregnant women, data was obtained that all pregnant women who were not adherent to consuming Fe tablets because they had complaints on nausea, dizziness and difficulty in defecation. Consumption of iron tablets of pregnant women is sufficient if pregnant women have consumed 90 Fe tablets with each tablet containing 60 mg of elemental iron and 0.2% of folic acid which is taken once a day. Iron supplementation or administration of Fe tablets is an important effort in preventing and overcoming anemia, especially iron deficiency anemia.

The results showed that gestational age did not have a relationship with the incidence of anemia. But there is a difference between the results of research and theory. Consumption of Fe tablets is thought to be the cause of an increase in hemoglobin levels. The same findings were obtained by Windarti, who stated that gestational age was not associated with anemia. But research conducted by Salmariantity disagreed and stated that there is a relationship between gestational age and anemia.

The gravida category showed no relationship between gravida status and the incidence of anemia in pregnant women which is in line with research conducted by Herawati. A mother who often experiences pregnancy and childbirth has a risk of anemia in the next pregnancy if she does not pay attention to nutritional needs. Because during pregnancy, substances - nutrients will be divided for the mother and for the fetus they carry. The research conducted by Nasyidah stated that the gap of pregnancy was related to the incidence of anemia. Nonetheless, the results of the study from Sukasmiyati stated that there was no relationship between the gap of pregnancy and the incidence of anemia.

Anemia occurs more in pregnant women who stated that the quality of antenatal care is in accordance with the standards. If the patient feels satisfied, it means that the health service has quality. Quality services are produced from services performed by health workers in accordance with established standards.

**CONCLUSION AND RECOMENDATIONS**

Factors that influence the incidence of anemia are
MUAC measurement and compliance with consumption of Fe tablets. Quality antenatal care is related to compliance with consumption of Fe tablets in pregnant women. While maternal age, education, occupation, gravida status, and complaints did not have a significant relationship with adherence to consumption of Fe tablets among pregnant women in Mamajang Makassar Public Health Center.

Effect of Communication, Information and Education (CIE) on Knowledge and Decision Making of Married Women with Unmet Need in the Family Planning Program at Marusu District Maros City in 2016

Husnah¹, Masni¹, Veni Hadju¹

¹Faculty of Public Health, Hasanuddin University, Jl. Perintis Kemerdekaan Km. 10, Tamalanrea Indah, Tamalanrea, Tamalanrea Indah, Tamalanrea, Kota Makassar, Sulawesi Selatan 90245, Indonesia

Abstract

The aim of the study was to analyse the influence of Communications, Information, and Education (CIE) on knowledge and decision making of unmet need in family planning in the District of Marusu, Maros. This study was an experimental research design with nonrandomized pre-test and post-test design. Samples were 45 years old or younger spouses with unmet need and 30 people of parity 1 or 2 in each treatment group, selected with purposive method. Data were collected through pre-test and post-test with a questionnaire followed with analysis using paired T-Test sample and One Way ANOVA. The results indicated that there were differences in knowledge before and after the intervention by the lecture method (p = 0.000), media leaflet (p = 0.009) and the combination of lecture and media leaflet (p = 0.000). The results also showed that there were differences in decision-making before and after the intervention by the lecture method (p = 0.000), media leaflet (p = 0.001) and the combination of lecture and media leaflet (p = 0.000). CIE lecture and leaflets affected the knowledge and decision-making of unmet need in family planning.

Keywords: CIE; decision making; family planning; lecture; media leaflet; unmet need

Introduction

Indonesia is among the world’s four largest populations in the world after China, India, and America. Indonesia accounts for about 6% of the population in Asia. This large number indicated the quantity of Indonesian population is a strategic problem and in terms of quality is still relatively low. In 2007/2008 Indonesia’s Human Development Index (IPM) ranked 117 out of 187 countries. In the 11 members of ASEAN, Indonesia’s Human Development Index (HDI) is ranked 7th. If the birth of the population is not well managed, more new-borns will be born with low quality¹.

The explosion of population will bring implications for increased poverty, declining health status, decreased access to education, increasingly limited employment opportunities, increased crime, increased depression, and deteriorating environmental impacts. Population boom control also has implications for achieving Millennium Development Goals (MDG)’s in Indonesia². Maternal mortality and morbidity in Indonesia is still a big problem. When compared with MMR in developed countries, the number of MMR in Indonesia 50 times of that in developed countries³. One of the government’s strategic programs is believed to reduce maternal mortality and reduce population growth rate through the Family Planning program⁴.

The national family planning movement is prepared to build a prosperous family in order to build optimal human resources, characterizing the increasing role of the community in meeting the need to obtain family planning services. Efforts to reduce MMR are also supported by increasing rates of contraceptive use and reducing unmet need through improved access and quality of family planning services and reproductive health⁵. One of the problems in the management of family planning program is the high rate of unmet need of family planning. Unmet need of family planning is defined as a group of women who actually do not want to have children anymore or want to have infant pregnancy up to 24 months but do not...
used contraception to prevent pregnancy. This concept is widely used to identify women who actually need to use contraception because they do not want children anymore or want to delay pregnancy up to 24 months but not using contraceptives. In other words, women are said unmet need if the woman does not use the method of contrary when she did not want another child or want to delay to have more children.

Unmet need has become a global population problem, especially in developing countries. The reasons women of childbearing age do not use birth control because of their concern about the side effects caused after the use of birth control. Access to services that provide various methods of family planning, as well as information and counselling to help women choose and effectively use appropriate methods is essential in helping women unmet need to overcome barriers to contraceptive use. Factors contributing to low use of family planning include partner decision making, service quality, hospitality of service administration staff, and women’s knowledge of family planning.

Mekonnen and Worku found that one of the factors affecting unmet need is low knowledge about family planning especially contraceptive side effects so the government is expected to focus on improving education and public awareness for family planning with health counselling. Health care providers and discussions on family planning issues are key predictors of unmet need.

The highest unmet need rate in South Sulawesi is Selayar regency, which is 32.28%, while the district with the lowest unmet need rate is Maros Regency, which is 7.36%. Although Maros Regency has the lowest unmet need for family planning in South Sulawesi, but in Marus sub-district, the unmet need rate of family planning is quite high (14.37%). One of the important steps to support and awaken the people about the purpose of family planning program, especially in terms of reducing unmet need rate of family planning is through CIE.

Research conducted by Purba, in Rambah Samo sub-district Rokan Hulu district concluded that some of the causes of low use of contraceptives are lack of information about contraceptives, lack of support from health workers, the cost of buying and installing unreachable contraceptives, and contraceptives not available.

According to the data from BKKBN Maros District, Marus District has the highest unmet need in Maros District from year 2011-2013, where in 2011 as many as 694 couples (12.2%), year 2012 as many as 552 couples (12.6%) and in 2013 as many as 880 couples (16.9%). Although there is a decrease in 2014, which is 820 pairs 15.73%, but this figure is still above the average unmet need rate Maros District. Based on the above description, the authors are interested to examine the influence of CIE using lecture and media leaflet method for decision making of unmet need for family planning in Marusu District, Maros Regency.

Methodology

Study Type

This type of research is experimental with the design of nonrandomized pre-test post-test group design.

Location and Time

This research was conducted for one month since January 2016 until February 2016 in Marusu sub-district, Maros Regency.

Population and Sample

Population in this research is all unmet need family planning in District Marusu Maros Regency in 2014 as many as 805 people spread in 7 villages and from the calculation results, obtained a sample of 30 respondents.

Data Collection

Primary data were obtained through structured questionnaires that contained a number of questions where respondents were asked to choose the answer. Questionnaires are used to measure decision making in choosing contraceptives that have to do with Communication, Information, and Education (CIE). Secondary data is obtained from annual reports of field officers of the sub-district of Marusu, BKKBN of Maros Regency, and other sources.

Data Analysis

Data processing is done using SPSS program. Bivariate analysis was done to determine the effect of CIE on knowledge and right decision-making in family planning. Analysis conducted included t-test, One Way-
ANOVA Test and Post Hoc Test.

Result and Discussion

Knowledge

Table 1 shows that there is an increase in the average score of respondents’ knowledge of family planning after CIE intervention, either by lecture method, using leaflet media, or by a combination of lecture and media leaflet methods. The biggest increase was in respondents who intervened with a combination of lecture method and media leaflet (62.63%). Before the CIE intervention, there was no difference in the average score of respondents’ knowledge about family planning in the three methods (p = 0.974). After CIE intervention with 3 different methods, statistic test result showed that there was difference of mean score of respondent knowledge, p = 0.000. This suggested that there is a difference in knowledge of unmet need on family planning using the three CIE methods. Further analysis proved that a significantly different method is a lecture method with a media leaflet as well as a media leaflet with a combination of lecture and media leaflet methods. The most dominant method of influencing the knowledge of unmet need on family planning is the combination of lecture and media leaflet methods. It can be seen on the value of t arithmetic combination of lecture method and media leaflet is bigger than lecture method (15, 20> 11, 68).

Decision Making

Table 2 shows that there is an increase in the mean score of respondents’ decision-making in family planning after the CIE intervention, either by lecture method, using leaflet media, or by a combination of lecture and media leaflet methods. The largest increase was in the respondents who intervened with a combination of lecture method and media leaflet (63.55%). Before the CIE intervention, there was no difference in the mean score of respondents’ decision making in the family planning on the three methods (p = 0.836). After CIE intervention with 3 different methods, statistic test result showed the difference of mean score of respondent decision in family planning (p = 0.000). This indicated that there is a difference in decision making on unmet need in family planning among the three CIE methods. Further analysis proved that a significantly different method is a lecture method with a media leaflet as well as combination of lecture and media leaflet methods. The most dominant method of influencing the decision making of unmet need in family planning is the lecture method. It can be seen on t-value of lecture method is greater than the combination of lecture method and media leaflet (10, 15 > 9, 33).

**Overall Discussion**

This study was conducted by collecting primary data through questionnaires from 30 respondents. Before giving intervention 3 methods of CIE to the respondents, pre-test prior to the knowledge and decision making of respondents in family planning were done. The results showed that all three groups of respondents have scores that are almost the same in the knowledge and decision-making of respondents in the family planning. In accordance with the opinion of Arikunto\textsuperscript{16} who argued that one of the requirements of experimental research is to attempt the three groups of respondents in the same conditions so that the exposure of the final result can really be the result of the presence and absence of treatment.

This is in line with Ganiajri\textsuperscript{17} studies, which found that there is a significant difference in girls’ knowledge of reproductive health before and after health education given by lecture method. This is also in line with Malwenna et al.\textsuperscript{18} study, which found that family planning counselling conducted by community health midwives in Kalutara village of Sri Lanka demonstrated a significant impact on knowledge and attitude of family planning and officers leading to changes in family planning practices and decline in incident of unmet need.

This is in line with Akbar\textsuperscript{19} study which found that there is influence of lecture methods on decision scores to accept family planning in Kecamatan Gondang Mojokerto regency. This is in line with research conducted by Kawuriansari et al.\textsuperscript{20}, which found that leaflet media is very effective in increasing girls’ knowledge about dysmenorrhoea. Research conducted by Wijayanti\textsuperscript{21} found that health education using leaflet media can improve the knowledge of tuberculosis patients. Media leaflets have the advantage that people who read can learn independently, view the content in a relaxed manner, information can be shared with family and neighbours can provide detail by using images for message reinforcement.

This is in agreement with research conducted by Hidayati\textsuperscript{22} who found that the use of leaflet media and decision support tool can assist clients in making implanted decisions.

This is also in line with Suraya\textsuperscript{23} study which concluded that lecture and media leaflet extension can improve mothers’ knowledge and attitude about the pattern of giving breast milk to children aged 6-24 months.

**Conclusion**

Overall it can be concluded that there were differences of knowledge before and after intervention with lecture method (p = 0.000), media leaflet (p = 0.009), and combination of lecture and leaflet method (p = 0.000). Other results also showed that there are differences in decision making before and after intervention with lecture method (p = 0,000), media leaflet (p = 0.001), and combination of lecture and media leaflet methods (p = 0.000). CIE methods of lectures and media leaflets do affect knowledge and decision making for fertile aged couples in their unmet need in family planning.

Influence of Oxytocin Stimulation Massage toward Women Uterine Involution During Confinement Period with Normal Childbirth

Idha Farahdiba¹, A. Wardihan Sinrang¹, Budu¹
¹Faculty of Medicine, Hasanuddin University, Jl. Perintis Kemerdekaan Km.10, Makassar, 90245. Sulawesi Selatan, Indonesia

Abstract

The study aims to determine influence of oxytocin stimulation massage toward women uterine involution during confinement period with normal childbirth. The study was used quasi experimental research design with two group post-tests. The study had been conducted at Public Health Centre (Puskesmas) Batua, Makassar city. The study samples were 82 mothers who in confinement period which intervention group had received oxytocin stimulation massage therapy on 1st, 2nd and 3rd days of confinement period for 10 minutes, while control group had no oxytocin stimulation massage. The fundal height was measured after massage session on 1st, 2nd, 3rd and 7th days of confinement period. The data was analysed using statistical analysis of Mann Whitney U test. The statistical test found stimulation massage toward uterine involution on 1st day (p=0.053), 2nd day (p=0.036), 3rd day (p=0.001), 7th day (p=0.004).

Keywords: Fundal height; Postpartum mother; Oxytocin hormone; Uterine involution;

Introduction

The postpartum period or known as puerperium is first 6 weeks from end childbirth until reproductive organs involution is completed. The postpartum period was period that internal and external changes occur especially psychic transformations which women need care and protection¹. Even though, many physiological changes disappear soon after birth delivery². Besides, this period was period which uterine involution and strengthen ovarian function for new pregnancy³.

The uterine involution is defined uterus size had been return to original non-pregnant size as normal estrous cycle⁴. The uterine involution would be determined by fundal height that difficult in obese women and women with uterine myoma⁵. The lack of uterine contraction during postpartum period affected uterine involution lead to uterine subinvolution⁶. The oxytocin hormone is helpful to improve the uterine contractions after birth delivery for postpartum haemorrhage prevention, while uterine atony occurrence also associated with maternal oxytocin levels. The oxytocin is strongly related with social and affiliative behaviour included beginning of mother-infant bonding and maternal behaviour in mammals⁷. The oxytocin levels are higher in pregnant women and postpartum women than non-pregnant women⁸. The oxytocin massage is spinal massage from fifth or sixth costa until scapula which stimulated parasympathetic nerves so that prolactin and oxytocin hormone are released⁹. The study aims to determine influence of oxytocin stimulation massage toward women uterine involution during confinement period with normal childbirth.

Methodology

Study design: The study was used a quasi-experimental research design with two groups post-test (intervention and control groups) to determine influence of oxytocin stimulation massage on women uterine involution during confinement period with normal childbirth.

Study location and time

The study was conducted from July to August 2015 at Puskesmas Batua, Makassar city.

Study population and sample
The study population were postpartum mother at Puskesmas Batua, Makassar city. The sample sizes were 84 respondents and met study criteria included i) first postpartum mother with normal childbirth; ii) no systemic disease background; iii) good in mental health; iv) aged between 20 years and 35 years. The samples were obtained by using purposive sampling techniques.

Data analysis

The data was analysed using SPSS program. The bivariate analysis had used Mann Whitney U test to compare the women uterine involution between postpartum mothers with received oxytocin stimulation massage and without receiving oxytocin stimulation massage.

Results and Discussion

Bivariate analysis

Based on Table 1, 38 respondents (90.5%) had normal uterine involution and 4 respondents (9.5%) had abnormal uterine involution in the intervention group. Meanwhile, 36 respondents (85.7%) had normal uterine involution and 6 respondents (14.3%) had abnormal uterine involution in control group. The statistical test showed no significant influence between oxytocin stimulation massage and women uterine involution during 1st day of confinement period with normal childbirth at Puskesmas Batua, Makassar city.

Based on statistical test showed there is influence of oxytocin stimulation massage and women uterine involution on 2nd day of confinement period with normal childbirth, $p=0.036<0.05$. There were 3 respondents (7.1%) had abnormal uterine involution in the intervention group and 10 respondents (23.8%) had abnormal uterine involution in the control group.

Meanwhile, the number of respondents had abnormal uterine involution were increased in 3rd day for control group and vice versa. Based on Table 3, there were 14 respondents (33.3%) had abnormal uterine involution, but only 2 respondents (4.8%) had abnormal uterine involution in the intervention group. The Mann Whitney U test found there is influence of oxytocin stimulation massage toward women uterine involution on 3rd day of confinement period with normal childbirth at Puskesmas Batua, Makassar city.

Based on Table 4, the number of respondents had abnormal uterine involution reduced in both groups to 12 respondents (28.6%) in the control group and only 2 respondents (4.8%) in the intervention group. Besides, number of respondents had normal uterine involution were observed increase in the control group from 28 respondents (66.7%) on 3rd day to 30 respondents (71.4%) on 7th day of confinement period. Meanwhile, the statistical result showed there is influence of oxytocin stimulation massage toward women uterine involution during 7th day of confinement period with normal childbirth.

Based on Table 5, mean rank value in the control group was higher than mean rank value in the intervention group on 1st day of confinement period. Based on Mann Whitney U test, there was no difference in women uterine involution between postpartum mother with oxytocin stimulation massage and without oxytocin stimulation massage, p= 0.503>0.05.

In additions, mean rank is observed higher in the control group than intervention group on 3rd day. The Mann Whitney U test found differences on women involution between postpartum mothers with oxytocin stimulation massage and without oxytocin stimulation massage on 3rd day of confinement period with normal childbirth, p=0.001<0.05.

There were differences in mean rank between both groups on 2nd day. The mean rank in the control group was 46.00 higher than 39.00 in the intervention group on 2nd day of confinement period. The statistical test found there was differences in women uterine involution of postpartum mothers with oxytocin stimulation massage and without oxytocin stimulation massage on 2nd day of confinement period with normal childbirth.

On 7th day, the mean rank in the intervention group was 37.50 lower than 47.50 in the control group. There were differences on women uterine involution between postpartum mother with oxytocin stimulation massage and without oxytocin stimulation massage on 7th day of confinement period, p=0.004<0.05.

**Overall Discussion**

The result found there were differences on women uterine involution between postpartum mothers with oxytocin stimulation massage and without oxytocin stimulation massage on 2nd, 3rd and 7th days of confinement period with normal childbirth. Meanwhile, there was no significant differences on women uterine involution between postpartum mothers with oxytocin stimulation massage and without oxytocin stimulation massage on 1st day of confinement period with normal childbirth. Besides, highest number of respondents had abnormal women uterine involution were 4 respondents in the intervention group on 1st day of confinement period with normal childbirth. The normal uterine involution was observed higher in the intervention group on 2nd, 3rd and 7th days of confinement period. These data suggested oxytocin stimulation massage helped in stimulated release of oxytocin hormone among postpartum mothers especially 1st to 3rd days of confinement period. The oxytocin is helpful in uterine involution improvement. The early breastfeeding also helped in production of oxytocin hormone and stimulated uterus contractions. Few studies which using difference methods and application had found breastfeeding help increased the oxytocin levels in postpartum mothers\(^9\),\(^10\),\(^11\). Based on this early observation, the postpartum mothers without oxytocin stimulation massage had 5 times greater risk in having abnormal uterine involution than postpartum mothers without oxytocin stimulation massage. In Semarang Hospital, oxytocin massage had increased prolactin hormone levels and breastmilk production among post caesarean section\(^9\). A study by Sari et al. found combination of oxytocin massage and endorphin massage help in accelerating uterine involution in normal postpartum mothers\(^6\). The low oxytocin was correlated to higher anxiety and depression contributed to perinatal mood disorder\(^12\),\(^13\). Meanwhile, a study suggested oxytocin levels are higher in women who had normal birth delivery than women undergone caesarean delivery and oxytocin was released during normal labour and breastfeeding\(^14\). The oxytocin hormone is important since this hormone helped increase uterus contractions and prevent the postpartum bleeding occurrence.

**Acknowledgement:** The author would like to thank to all respondents and Puskesmas Batua, Makassar city for resources and data input as well as Faculty of Medicine, Hasanuddin University for unconditionally support.

**Conclusion**

In conclusions, there was an influence of oxytocin stimulation massage toward women uterine involution during 2nd, 3rd and 7th days of confinement period with normal childbirth at Puskesmas Batua, Makassar city. Meanwhile, oxytocin stimulation massage was less effective on women uterine involution on 1st day of confinement period with normal childbirth.

Abstract

The aim of this research is to analyse the teachers’ smoking behaviour, knowledge, attitudes and their perceptions regarding smoking and non-smoking area as well as their roles as role models in implementing the smoking free area (SFA) in schools. This is a qualitative case study. The informants of the research were 18 people that consisted of 9 teachers and 9 students. The data were obtained by means of in depth interviews and focus group discussion (FGD). The results show that smoking teachers were no longer smoking in the class except in the teacher’s room and kitchen. The reasons were due to the fact that has not been any ‘No Smoking’ regulation at school and due to difficulty in quitting from smoking. Teachers have actually been aware of the disease cigarettes can generate but they are not yet aware the definition, aim and outcome of the SFA. Majority of the participants agree with the implementation of SFA at school. Teachers who have stopped smoking and non-smoking teachers have perceived smoking as the trigger of serious diseases and even could generate disease to passive smokers. A small minority of smoker teachers perceived that both smokers and non-smokers teachers were vulnerable to disease. Teachers claimed that the implementation of SFA at schools would benefit teachers themselves and other people.

**Keywords:** Attitude; Knowledge; Smoking behaviour; Smoking free area

Introduction

Smoking is one of the main issues that causes of death, disease and poverty. The tobacco epidemic is one of the largest public health threats in the world that has ever been faced for killing about 6 million people per year. More than 5 million of these deaths are due to direct tobacco use. In addition, more than 600,000 are deaths for non-smokers from exposure to second-hand smoke or passive smoking¹.

The direct impact on the individual / smoker can be easily seen in terms of health. Global Tobacco Epidem reported 90% of lung, mouth and respiratory cancers are caused by cigarettes². Cigarettes are also associated with diseases that cause the highest deaths such as ischemic heart disease, cardiovascular disease, lower respiratory tract infections and tuberculosis. Global Youth Tobacco Survey (GYTS) declares Indonesia as the country with the highest teen smoking rate in the world. Most men first smoked at age 12-13 years, and most women first tried smoking at age <7 years and 14-15 years³.

Many studies have studied smoking behaviour in students at school. Research conducted by Apaydin Kaya⁴ found that smoking behaviour in adolescents is influenced by the smoking behaviour of teachers in schools. Teachers are more influential in determining behaviour among young people. Teachers and employees are role models in the School. Teachers and employees interact daily with students so that their group is influential for tobacco control⁵. Middle-income countries can reduce the number of smokers among young people by prohibiting teachers and employees smoking in school⁶. Teachers play a key role in health education for young people, either through the provision of information or as role models for their students. Teachers interact daily with students so that their group is influential for tobacco control in schools.
Data obtained from the interview with one of the teachers found that there are still some teachers and employees who smoke in SMA Negeri 3 Makale. Thus, this study focuses in analysing the teacher’s smoking behaviour at school and evaluating the teacher’s knowledge, attitudes and perceptions about cigarettes and Non-Smoking Areas and their role as role models in the implementation of Non Smoking Areas in schools At SMANegeri 3 MakaleTanaToraja District.

Methodology

Research Design

This research is a qualitative research with case study design. This study is limited by time and place, and cases studied in the form of programs, events, activities or individuals. The case study approach can lead researchers to enter the smallest social units such as associations, groups, families and other forms of social units, which focuses on teachers of SMA Negeri 3 MakaleKabupatenTana Toraja.

Location and Time of Study

This research was conducted at SMA Negeri 3 MakaleKabupatenTanaToraja South Sulawesi Province because there are still smoker in the school area and teachers in the school meet the desired criteria of this study. This study was conducted for 3 months starting from 20 March to 20 May 2015.

Informant Research

Informants in this study are teachers and students in SMA Negeri 3 Makale, TanaToraja District. The main informants in this study were teachers who were divided into three groups namely the group of teachers who are still smoking, teachers who have stopped smoking, and teachers who never smoked. Sampling method used in this research is snowballing method means that the research-informants obtained in the field based on information obtained from the informants.

Data Collection

In-depth interviews were conducted on informants (teachers) related to knowledge, attitudes, and perceptions about the dangers of cigarettes, as well as their role in the implementation of Non Smoking Area in schools. Focus group discussion, FGD is a data collection technique in qualitative research. Researchers ask and stimulate a number of informants at the same time to discuss to answer the questions posed. FGDs were conducted on students to gain students’ views of the role of teachers as role models in SFA implementation.

Data Analysis

Data analysis in this research is based on case study approach. Data obtained from in-depth interviews, observations, and FGD were processed manually in accordance with the instructions of qualitative data processing and in accordance with the purpose of this study.

Informants in this study were teachers of SMA Negeri 3 Makale as the main informant as many as 9 male teachers divided into three groups:

a. Group of teachers who still smoked as many as four people.

b. Group of teachers who have quit smoking as much as two people.

c. Group of teachers who never smoked as many as three people.

Based on the results of interviews with ITM3 it can be seen that in SMA Negeri 3 Makale there are still teachers and employees who smoke in the school. According to ITM3, still often see teachers smoking in the classroom. But with the headmaster’s appeal forbidding smoking teachers in the classroom, no more teachers are smoking in the classroom, but they still smoking in teacher’s room and kitchen. In general smokers still smoke in school because they assume that there is no smoking ban for teachers in the school environment as stated by informant IM1.

The interview result shows the teacher does not known the existence of Regent Regulation no. 31 of 2014 and Permendikbud (Minister of Education and Culture) No. 64 of 2015 which regulates the school as one of the non-smoking areas and prohibits teachers from smoking in the school environment. There are also informants who only smoke while in school but do not smoke at home because their wife not allow and they do assume there is no smoking ban at school. In addition, they do realize smoking can have negative impact to child at home.

The interview found that teachers who have quit smoking reluctantly and hard to reprimand teachers who are still smoking if they smoke in school. The principal had admonished the teacher whom smoke and suggested that they look for a safe place so that cigarette smoke will not disturb others. A study conducted by ApaydinKaya⁴ found that smoking behaviour in adolescents is influenced by teacher smoking behaviour in schools. The results of Abdullah¹⁰ study in Denmark emphasized the importance of a smoke-free school environment and concluded that teacher exposure to smoking during school hours affects teenage smoking behaviour.

Knowledge of Cigarettes

In general, the participants know that smoking can lead to disease and health problems such as lung cancer, disruption of the circulatory system, heart disease, foetus disorders, dental and oral diseases and liver cancer.

The participants know that cigarette smoke is very dangerous for passive smokers. The results of this study are in line with Wang¹¹ results in China that most respondents know that smoking is risky to health but only to learn a little about why cigarettes can cause health risks. The results of this study in accordance with the results of research conducted by Maharani and Julianti¹² at the Faculty of Medicine Undip, that the reason informants do not stop smoking are because it is addicted.

Teacher’s Knowledge of Non Smoking Areas and its Application in SMA Negeri 3 Makale

Informants say the goal of Non Smoking Area at school is to reduce the increment of beginner smokers and to sterilize schools from cigarette smoke. In general, informants say that the goal of Non Smoking Area is to improve public comfort and prevent smoking related illness.

The informants have not known any sanctions for teachers who violate. As for students who have violated, smoke or carry cigarettes will be given a sanctions. The result of this research is in line with Wulandari¹³ where, in Pekalongan City that the implementation of Non-Smoking Area has not run maximally since the policy is still in socialization level and the appeal and sanctions are not yet available.

Teacher’s Attitudes toward Smoking Behaviour

The general smoker informants agree that cigarettes can increase self-confidence, can relieve stress, launch thoughts, and as a tool to socialize with people. There are some informants who have quit smoking has realized that cigarettes did not really benefit them. Informants,
who have never smoked think smoking can result in loss of waste and health. The results of this study are in line with the work done by Komasari and Helmi\textsuperscript{14} that smoking is considered to facilitate concentration, gain a pleasant experience, relaxation and reduce tension or stress.

**Teacher’s Attitude to Applying Non Smoking Area Policy in School**

All informants have a positive attitude towards the implementation of Non Smoking Area policy in schools, although for different reasons. The reason for the smoking informant agreed with the Non Smoking Area policy is from an economic point of view. The reason of the informants who had quit smoking was that the Non Smoking Area policy could reduce the number of smokers as well because the informants were aware that cigarette smoke was harmful to others. While the reason informants who never smoked to agree with the Non Smoking Area policy as it can create comfort free from cigarette smoke and can provide an example to the students to not smoke.

**Perceptions of Teachers about the Dangers of Smoking**

In general, informants who have quit smoking and informants never smoked perception that cigarette smoke is also harmful to passive smokers. Passive smokers are at higher risk of smoking from cigarette smoke than active smokers. The results of this study are supported by research conducted by Yang\textsuperscript{15} in China that smoker respondents agree that cigarettes can cause lung cancer and found that 90% of respondents who never smoked and ex-smokers agree if smoking can cause cancer.

**Teacher Perceptions about the Benefits of Non Smoking Area Implementation in Schools**

All good informants who are still smoking, who have quit smoking, or who never smoked believe that the application of Non Smoking Area in school will provide benefits. Implementation of SFA in schools can reduce novice smokers, keep the environment free of cigarette smoke so that health can be maintained, can reduce the number of smokers, prevent students join smoking, and can reduce expenses for smokers.

**Perceptions about Barriers to Non Smoking Area Implementation**

The smokers’ informants perceive that the obstacles of applying Non Smoking Area policies in schools are barriers derived from themselves. These obstacles are the difficulty of eliminating the feeling of wanting to smoke (dependence) as well as the feeling of uncomfortable, upset, and feeling of lack of enthusiasm when they are not smoking. Also, the rule about Non Smoking Area is not clear.

In general, informants perceived that the obstacles faced in the application of Non Smoking Area in schools are still low teacher awareness, low supervision on the implementation of Non Smoking Area, this is related to the limitations of the Non Smoking Area policy itself and the lack of socialization of the rules underlying the application of Non Smoking Area in schools.

**Perceptions about the Factors Driving Non Smoking Area Implementation in Schools**

All informants perceived that the factors that can encourage the implementation of Non Smoking Area is a regulation that must be established by policy makers who set about the form of sanctions clear to those who violate and improve supervision both to teachers and to students. In addition, teachers, employees, and principals should set an example by not smoking. Also need support from all parties, and the need for socialization of existing policies.

The results of this study are in line with Radwan\textsuperscript{16} where, hospitals in Egypt, found that barriers in the application of smoke-free areas are weak tobacco control law enforcement, lack of penalties for offenders, lack of smoking cessation programs for employees and smoking prevalence among doctors is still high.

**Perceptions about Teacher’s Role as a Role Model in Application of Non Smoking Area in School**

Interviews with smokers informants found that they perceived if the task of the teacher is to socialize about cigarettes and danger to the students, but according to his confession this is never done because it is not related to the subjects they teach. In addition there is also a perceived that he does not have the task associated with the implementation of Non Smoking area policy at school.

In general, all informants perceived that the form of teacher behaviour in the application of non-smoking area in schools is vital as the teachers should provide
an example to students by not smoking and adhere to existing rules to become role models for students as well as educate the student regarding the danger of smoking.

**Conclusion**

Based on the study conducted, it is observed that teachers play a huge role in their school. Every student watches and learns from the behaviour of a teacher. Thus, to combat smoking behaviour and implement Non Smoking Area, teachers them self-have to be Role model and then only students will follow. Implementation of non-smoking area policy in SMA Negeri 3 MakaleTanaToraja District needs the cooperation from every personal and the teachers have the significant role in ensuring it.

Differences in Implementation of Demonstration and Audio-Visual Media Methods on Psychomotor Learning Outcomes among Students for Pregnancy Examination

Ira Jayanti¹, Budu¹, Werna Nontji¹

¹Faculty of Medicine, Hasanuddin University, Jl. Perintis Kemerdekaan Km.10, Makassar, 90245.
Sulawesi Selatan, Indonesia

Abstract

The study aimed to determine differences in application methods such as demonstration and audio-visual media on psychomotor learning outcomes among students for pregnancy examination. The study was used quasi experiment design. Meanwhile, the sample was selected by systematic random sampling design with pre and post-tests which total sample sizes were 120 samples. The data was collected by using respondent assessment sheet in pregnant women examination. The data had analysed by Kruskal-Wallis and Wilcoxon test with confidence level α= 0.05. The statistical test found the demonstration and audio-visual media methods on psychomotor learning outcomes among students for pregnancy examination had obtained p=0.000. The educators should use appropriate methods in assessing intended learning outcomes and assessment of learning outcomes in term of cognitive and affective.

Keywords: Audio-visual media; Conventional; Demonstration; Pregnant women

Introduction

In general, learning objectives had been classified into three domains included cognitive (knowledge), affective (attitude) and psychomotor (skills). Meanwhile, psychomotor learning was classified as learning new things or modified existing actions. Based on Simpson’s psychomotor domain taxonomy, psychomotor domain had involved physical movement, coordination and motor skill usage. In additions, the psychomotor domain had included action (elementary movement), coordination (synchronized movement), formation (bodily movement) and production (verbal and nonverbal movement).

In this study, psychomotor learning outcomes had been discussed among students in pregnancy examination for professional skill achievements in providing midwifery services. Most of Midwifery Academy in Central Java Province were using demonstration and audio-visual media methods. Yapma Midwifery Academy and Mega Rezky Health Science School (STIkes) in Makassar were offered higher midwifery diploma program. Both institutions had applied demonstration and audio-visual media methods in clinical practice.

The demonstration method had been used in physical pregnancy examination. The demonstration method is helpful for low achieving students with high visual and spatial intelligence but limited in cognitive abilities. Meanwhile, media usage also helped in psychomotor learning improvement among students. Audio-visual media is an information delivery type which contains sound and image elements. The study aims to determine differences in application methods included demonstration and audio-visual media methods in psychomotor learning outcomes among students for pregnancy examination.

Methodology

Study design

The study was using quasi experiment method with pre and post-test control group design.

Study location and time

The study was conducted from July until October 2014 at Yapma Midwifery Academy in Makassar city.
Study population and sample

The study population were students who studied in third semester at Yapma Midwifery Academy and higher diploma in midwifery program in Mega Rezky Health Science School (STIkes) in Makassar.

The sample sizes were 120 respondents by using systematic random sampling.

Data collection

The primary data was collected from a respondent assessment sheet in pregnant women examination. Meanwhile, secondary data was obtained from Yapma Midwifery Academy and Mega Rezky STIkes profile reports in year 2012.

Data analysis

The data had analysed by Kruskal-Wallis and Wilcoxon test with confidence level $\alpha= 0.05$.

Results and Discussion

Univariate analysis

Based on Table 1 and 2, there are differences in number of respondents on psychomotor learning outcomes for pregnant women examination which increased after the study.

The pre-test showed number of respondents increased as 20 respondents and constant as 20 respondents for conventional method. The demonstration method also showed increment for 21 respondents and constant in psychomotor learning outcomes, while number of respondents in audio-visual media method had increased as 20 respondents and 20 respondents in constant for psychomotor learning outcomes. Meanwhile, there are none of constant respondents in post-test I, II.

Based on Table 3, mean value for conventional, demonstration and audio-visual media are 22.4, 22.8 and 22.9 during pre-test. The standard deviation of three groups during pre-test are 28.0, 31.6 and 27.7. The mean value was observed increase for three groups in post-test I. The mean values for conventional, demonstration and audio-visual media methods during post-test I are 28.0, 31.6 and 27.7. The standard deviation during post-test I for conventional, demonstration and audio-visual media methods are 1.07, 0.49 and 2.55. and III.

The mean value was increased from pre-test until post-test III for conventional, demonstration and audio-visual media methods. The mean value for these three groups during post-test II were 29.5, 37.9 and 32.0. Besides, standard deviation for these three groups during post-test II were 0.51, 0.3 and 0.68. In additions, the mean value for three groups during post-test III were 29.8, 38.0 and 36.1. The standard deviation for conventional, demonstration and audio-visual media methods during post-test III were 0.41, 0.00 and 1.26.

Figure 1 illustrates there are differences in mean values during pre and post-test using conventional, demonstration and audio-visual media methods. The mean value differences occurred in conventional method are pre-test (22.4), post-test I (28.0), post-test II (29.5) and post-test III (29.8). Meanwhile, mean value for demonstration methods at pre-test (22.8), post-test I (31.6), post-test II (37.9) and post-test III (38.0). The mean value for audio-visual media methods at pre-test (22.9), post-test I (27.7), post-test II (32.0) and post-test III (36.1).

Figure 1. Differences in psychomotor learning outcomes among students for pregnancy examination in each group year 2014

Bivariate analysis

Table 5 showed differences in psychomotor learning outcomes on pregnancy examination for pre and post study which p=0.000 <0.05 due to treatment provision through demonstration and audio-visual media methods on physical pregnancy examination.

There are differences between psychomotor learning outcomes on pregnancy examination for pre and post-test with p value = 0.000<0.05. Meanwhile, the differences had observed after post-test III with p value= 0.014. The pregnancy examination applied through conventional method was using assessment sheet lead to skill limitation among students.

Meanwhile, there were differences in psychomotor learning outcomes among students for pregnancy examination through demonstration methods until post-test II. In post-test II and III, there was no difference in psychomotor learning outcomes through demonstration methods $p=0.157>0.05$.

There were differences between psychomotor learning outcomes among students on pregnancy examination for pre and post-test with $p$ value $=0.000<0.05$. The psychomotor learning outcome was increased due to this method had been frequently using in the student psychomotor learning.

**Overall Discussion**

In pre-test, 20 respondents who applied conventional methods in psychomotor learning outcomes. The gap increment of psychomotor learning outcomes between pre-test and post-test I caused by conventional methods lead respondents memorized step and activities in pregnancy examination contributed to mistakes repetitive on post-test II and III. Based on the statistical test, there was differences in mean value of psychomotor learning outcomes among students in pregnancy examination for pre and post-test. The conventional learning method is less effective since this method tend to be educator centred method and students were assumed have same knowledge level and their ability to absorb learning material at the same progress$^{10}$. The practice helped in students to have in-depth understanding toward course. The conceptual learning with conventional method also easily became verbalism, visual loss and audible listening which students tend to be passive in the learning lesson.

There were 21 respondents had applied demonstration method in pregnancy examination during pre-test. The statistical test found differences in psychomotor learning outcomes among students for pre-test and post-test I and II, $p=0.000<0.05$, while no differences on psychomotor learning outcomes among students with demonstration methods on mean value of post-test II and III, $p=0.157>0.05$. The benefit of demonstration method is clear teaching materials, more concrete and direct involvement among students. The demonstration method had improved cognitive, effective and psychomotor skill. The demonstration method helped in students’ concentration since this method needed attention and observation during their classes.

Based on statistical test found differences in psychomotor learning outcomes among students for pregnancy examination through audio-visual media method. In additions, 20 respondents had met study objective criteria who applied audio-visual media method in their psychomotor learning during pre-test. The demonstration method involved five senses such as sight, sound, smell, taste and touch, while audio-visual media method only used sight and sound senses. The compact disc digital video (VCD) is among material applied in audio-visual media methods. Several studies found audio-visual media method had enhanced students learning outcomes in many study field$^{11-15}$.

Based on statistical result found there is differences on application of demonstration and audio-visual media method toward psychomotor learning outcomes among students for pre and post-test. The demonstration method provided more impressed in depth of class lesson, thus created good understanding among students. Good demonstration methods helped in getting clear picture of things which related in organization, making process, working process, comparison process and differentiation process. The communication also important since no feedback between educator and learners lead in lower understanding of learners toward material representation, experience and impression.

**Acknowledgement:** The author would like to thank to Yapma Midwifery Academy and Mega Rezky STIkes for resources and data input as well as Faculty of Medicine, Hasanuddin University for unconditionally support.

**Conclusion**

In conclusions, there was differences in demonstration and audio-visual media methods application toward psychomotor learning outcomes among students on pregnancy examination. The demonstration method implementation on pregnancy examination was more effective than audio-visual media and conventional methods application. The educators should use appropriate methods in assessing intended learning outcomes and assessment of learning outcomes in term of cognitive and affective.

Effect of Iron and Zinc Substance Giving through Fortification Rice on Stress Level of School Age Children in Islamic Boarding School Annihayahkarawang

Ismi Nurwaqiah Ibnu¹, Razak M. Thaha¹, Suriah¹
¹Faculty of Public Health, Hasanuddin University, Jl. Perintis Kemerdekaan Km. 10, Tamalanrea Indah, Tamalanrea, Tamalanrea Indah, Tamalanrea, Kota Makassar, Sulawesi Selatan 90245, Indonesia

Abstract

The research aimed at analyzing the effect of iron and zinc substance giving through the fortification rice medium on the students stress level. This was a true experimental research with the Double Blind Randomized Control Trial or DB-RCT. The research result indicates that the fortification rice giving has the effect on the iron deficiency anemia status by increasing the hemoglobin content (MD = 0.36 mg / dl, p = 0.000). The ferritin serum content (MD = -10.3±26.44 μg / dl, p = 0.059), and zinc serum (MD = -21.78 mg / dl, p = 0.000) on the subjects decrease. The fortification rice giving decreases stress score (MD = -10.96, p = 0.000) and decreases stress level better compare with the ordinary rice. There is the correlation of the hemoglobin content escalation (r = 0.637, p = 0.000), the ferritin serum content (r = 0.392, p = 0.026) and the zinc serum content with the stress score of (r = 0.377, p = 0.033) before and after the intervention. The research results are in line with the researches concerning the effect of the fortification rice in several other countries. The further research concerning the relationship between the micronutrient and the stress level on the community population should be better in controlling the other intruding variables and stressors (interaction of inter- micronutrients) which have the potential to influence the result.

Keywords: Anemia; Fortification rice; Stress; Zinc deficiency

Introduction

Improving the health and nutritional status of adolescents is one effort to improve the next generation of the nation. The physical growth of adolescents is the most rapid growth. Adolescents not only grow in size, but also progress in functional, especially the sexual organs or “puberty”. In this period, adolescents need nutritional intake, not only macro nutrients but also micronutrients more to facilitate hormonal activity in regulating the growth and development of adolescents¹.

Several studies in developing countries mentioned the presentation of adolescent anemia by 57%. According to Riskesdas 2013 data, the prevalence of anemia in Indonesia is 21.7%, with the proportion of 20.6% in urban areas and 22.8% in rural areas as well as 18.4% male and 23.9% female. By age group, 5-14 years of 26.4% and 18.4% in the 15-24 year age group². In 2010, the government has set a target of reducing the prevalence of anemia in adolescents by up to 20%.

Cannot be denied, nutritional anemia is indeed one of the health problems in Indonesia is quite difficult to overcome. Significant presentations of adolescents in developing countries are anemic, causing serious consequences in this age group³.

Impact of anemia in children and adolescents, including increased of morbidity, decreased physical performance capacity, and impaired cognitive function. This allows decreased learning capacity and school performance in adolescents with anemia⁴.

Iron is an important component of hemoglobin, myoglobin, and many enzymes in cell metabolism and DNA replication and repair. Iron deficiency is associated with fatigue, poor mood, and an inability to concentrate and remember⁴. Chen⁵ states that iron deficiency anemia increases the risk of mental illness, including mood disorders, autism spectrum disorders, hyperactive disorders and developmental disorders in early children and adolescents. The biggest risk factors are depression...
Zlotkin states that fortifying staple foods tend to increase iron intake for those who consume the most (i.e., adult males). Le suggested in a population of children with mild iron deficiency anemia, iron fortification should be the preferred strategy to combat anemia, according to a study of noodles with iron fortification capable of reducing the prevalence of iron deficiency anemia 5.4%, which amounts to more than 50% of the impact of iron supplements in case of adherence. Food fortification should focus on the fortification of locally consumed ingredients, such as the type of fortification can be implemented on a large scale, allowing people to get more nutritional value from the food they consume eg rice which is the staple food of the Indonesian people.

Thus, this work is aimed at analysing the effect of iron and zinc substance giving through the fortification rice medium on the students stress level at Islamic Boarding School, AnnihayahKarawang.

**Methodology**

**Research Design**

The type of research used was true experiment with the design of Double Blind Randomized Control Trial or DB-RCT, which gives treatment on subjects divided into control groups and fortification rice intervention group, then the effects of intervention were measured and analysed including anemia status, zinc deficiency status and stress level.

**Location and Time of Study**

This research was conducted at Pesantren Annihayah in Karawang Regency because it is the largest rice producer in West Java.

**Population and Sample**

Population in this research is 483 santri. Samples are students aged 12-15 years who go to school and live in boarding Pesantren Annihayah Karawang regency. The Inclusion criteria set for the samples were a. Male gender b. Age 12-15 Years c. Has a concentration of Hb ≥ 8 mg% to ≤12 mg%. d. The sample size is determined based on calculation using formula according to Kasjono’s study. The total sample size for both groups was 80 children.

**Data Collection Method**

Data obtained from primary data and secondary data. Primary data is done by interview using stress scale, laboratory measurement for blood sample whereas Secondary data obtained from Pesantren Annihayah Karawang.

**Intervention Description**

In this study the intervention provided is fortified rice. Fortified rice is processed first into rice and given in the form of consumption as much as 2 times (dinner and breakfast) every day for 6 months. In processing, fortified rice is washed and cooked using prescribed pans and stoves to avoid mixing with other foodstuffs. Feeding process to students is started by weighing and giving each rice 200 grams each meal, then put into the launch box that has been determined. Launch box and then distributed by group. In this feeding, the santri are supervised by their respective group enumerators, and after the meal, the remaining unused rice will be weighed.

**Data Analysis**

Data analysis was done using SPSS program. Bivariate analysis of mean difference test was done to test the difference of Hb level, ferritin level, zinc level and score before and after intervention. The statistical analysis tests included are mean test, independent t-test and bivariate correlation test with Spearman rho.

**Result and Discussion**

**Result of examination of bound variable**

The results of measurement of iron deficiency anemia status, zinc deficiency and stress level of intervention on 160 subjects were divided into four groups (two groups of anemia and two non-anemic groups) is shown in Table 1. The zinc status in this anemia group and non-anemic group are significantly different with p = 0.000 (p < 0.05) and p = 0.027 (p <0.05) respectively. The difference in stress level in this anemia group and non-anemic group are not statistically significant p = 0.262(p > 0.05) and p = 0.491 (p > 0.05) respectively.

Hypothesis Test Results

Based on Table 2, it is known that the average hemoglobin level in the intervention group I increased by 0.36 mg / dl after obtaining intervention in the form of fortified rice. Changes in hemoglobin levels and the status of anemia in this intervention group after the intervention provision were significantly significant with the p value= 0.000 (p value <0.05). In the non-anemic group, changes in hemoglobin levels of the intervention group given fortified rice increased by 0.39 mg / dl, changes before and after the administration significantly (p = 0.002).

The effect of the intervention on iron deficiency status with an indicator of serum ferritin levels based on Table 2 was found that among all groups, only the intervention group I decreased serum ferritin levels to 28.56 µg / dl after the intervention. But this change is not significantly significant. Likewise, in the non-anemic group, the intervention of fortified rice and ordinary rice increased serum ferritin levels but not significantly, the second intervention group increased serum ferritin levels by 0.22 µg / dl (p = 0.530).

The effect of the intervention on zinc deficiency status with the indicator of serum zinc level based on Table 2, it is known that serum zinc levels of all groups decreased after intervention. The intervention group I decreased the average serum zinc level to 54.46 µg / dl after the intervention, the study subjects in the intervention group I were included in the zinc deficiency category. And this change is significant based on p value = 0.000 (p value <0.05).

The effect of intervention on stress level with stress score indicator based on Table 2, it is known that the average stress score in all groups decreased. In group of anemia, stress score of research subject of intervention group I decreased to146.56 which included low stress levels. Similarly, the non-anemic group given the fortified rice (the intervention group I) decreased the stress score to151.13 (low stress level). Different test analyzes between fortified rice groups and ordinary rice groups were significant at p = 0.003.

Table 3 shows the correlation study above states that the increase of hemoglobin level before and after intervention in fortification rice group has significant at p = 0.000, closeness of relationship in group the intervention of this fortified rice is higher than that of only ordinary rice of 0.531 or only 28.91% significant at p value = 0.002. At the hemoglobin level, the correlation is positive, meaning that the values of hemoglobin levels move equally, ie between before and after intervention. Compared to stressors, stress scores on the groups given fortified rice intervention were significantly changed before and after significantly significant at p = 0.033. While in the control group I given normal rice, the relationship of stress score before and after intervention of ordinary rice was not significant with the value of p = 0.798. The increase in hemoglobin levels was correlated (correspondingly) with decreased stress score before and after intervention.

**. Correlation is significant at the 0.01 level (2-tailed).

* Correlation is significant at the 0.05 level (2-tailed).

Table 4 shows the correlation study above states that the increase of ferritin levels before and after the intervention in the group given the fortification rice has significant at p = 0.000, the closeness of ferritin the group given this fortification rice intervention is lower than that of only normal rice which significant at the p value = 0.000. At this ferritin level the correlation is positively signified that the high values of ferritin levels before after the same move are increased between before and after intervention.

In the change of stress score between the fortified rice group and the regular rice, only stress score in the group given the fortification rice intervention that changes before and after significantly significant at p = 0.033. While in the control group I given normal rice, the relationship of stress score before and after intervention of ordinary rice was not significant with the value of p = 0.798. The increase of ferritin content was related (correspondingly) with decreased stress score before and after intervention.

*. Correlation is significant at the 0.05 level (2-tailed).

Conclusion

Based on the work done, it can be concluded that there was a significant effect of increased hemoglobin levels, decreased serum zinc levels, decreasing stress score in the group given fortified rice and ordinary rice groups. However, there is no effect of stress reduction on ordinary rice group. In addition, there was no significant effect on serum ferritin levels in the group given fortified rice or the usual rice group. There is a relation of decreasing stress score with increasing hemoglobin level, increase of ferritin level insantri before and after fortification of rice. Finally, there is a correlation of decreased stress score with elevated serum zinc levels in santri before and after fortification of rice.

Abstract

The aim of this work is to determine the effect of giving zinc and food supplement to pregnant women on the status of growth, development and morbidity in children ranging from 13 to 14 years old in Takalar Regency, South Sulawesi Province. The work was an observational study using retrospective cohort design of the subjects in the study done by Taslim in 2004 in order to determine the effect of giving zinc supplement to pregnant women on growth, development and morbidity. Results showed that the group whose mothers were given zinc and food supplement to pregnant women on average have a body length of 48.9 cm and a height of 149.2 cm at this time and the growth of body height for 14 years is 100.3 cm taller than the group with food supplement history and control group with a significant value of p=0.040. For pain occurrence, zinc history group and the giving of zinc and food supplement have a better endurance compared to two groups with only food supplement and control group. In this case, 30 children (68.2%) are not sick but 2 children are sick in other cohort intervention group.

Keywords: body height; menarche; morbidity; zinc supplementation

Introduction

The prevalence of stunting in Indonesia is higher than other countries in Southeast Asia, such as Myanmar (35%), Vietnam (23%), and Thailand (16%). Indonesia is ranked fifth in the world for the number of children with stunting conditions¹. The prevalence of stunting among under-fives in Indonesia is still relatively high compared to the figure in Asia which reached 36.8% with stunting of 19.5% and very short (severe stunting) of 17.3%.

Poor nutritional intake or recurrent infectious diseases may cause short children. In Indonesia more than 36.1% of school-aged children are short-lived when entering school age which is a chronic malnutrition. Children suffering from malnutrition in 2007 were 18.4% and 17.9% in 2010, while stunting in 2007 was 36.8% and 35.6% in 2010².

Zinc is an essential micronutrient and plays a role in various types of enzymes, such as the synthesis and reshuffle of proteins, fats, and carbohydrates. Micronutrients in pregnant women are essential for the development and growth of the foetus in the womb. Zinc which is one of the micronutrients has a function in the immune system and stability of formation³. Thus, if there is zinc deficiency, it can inhibit cell division, tissue growth and repair and eventually cause low birth weight babies (LBW). In addition to zinc also associated with the endocrine system, which supports normal growth, secondary sex characteristic, reproductive function, and thyroid function. Hence, lack of zinc causes not only growth delay but also delayed sexual maturity, hypogonadism, and thyroid dysfunction⁴.

Takalar Regency is the region with the highest prevalence of malnutrition which is 29.78% compared to other area that is Enrekang 17.78% and Maros 11.32%. In South Sulawesi about 44% suffer from extreme malnutrition, 14% malnutrition, and 17.6% with less nutrition⁵.
Based on the results of Basic Health Research (Riskesdas) South Sulawesi Province in 2013 for the prevalence of nutritional status based on TB / U indicators for age 13-18 years in South Sulawesi Province for very short nutritional status of 10.9% and short of 24.8%, while for Takalar regency ie 11.4% for very short and short of 19.0%. The study subjects Taslim (2004) showed that children who were given zinc supplementation and food (group A) had higher stools than zinc supplementation and was given food only. Children who are only given food supplementation (with no zinc supplementation) had a higher rate of height than children who were not given zinc supplementation and food.

Work done by Kusuma showed that the mean rate of weight gain (kg / month) of boys in groups 1, 2 and 3 respectively was 0.181, 0.181 and 0.177. In girls were 0.177, 0.169 and 0.168, respectively. High growth (cm / month) in boys group 1, 2 and 3 respectively were 0.786, 0.786 and 0.773. In girls 0.791, 0.739 and 0.672. Feeding now contributes to weight growth status in 3 groups at a level not significantly different, similar to high growth.

Based on the above background, the authors wanted to continue the study to determine the effect of the history of supplementation zinc + food supplementation for pregnant women (research subjects Taslim on the status of height growth, morbidity, and learning achievement of children at age 12-13 years) in Takalar District, South Sulawesi Province. This study will focus on the effects of zinc and supplementary feeding on pregnant women on high growth status, incidence of morbidity and secondary sex development in children aged 12-13 years.

**Methodology**

**Study Type**

This study was an observational study using a retrospective cohort design (a cohort of subjects studied experimentally by Taslim, which was intended to determine the effect of zinc supplementation to pregnant women (independent variable) with growth, development and morbidity (dependent variable).

**Location and Time**

The study was conducted in North Galesong Sub-District, South Galesong, Pattopakang, Mangarabombang and Patallassang as research sites.

The study was conducted in May 2016.

**Population and Sample**

The population of this study were children aged 12-13 years living in Takalar District, and the samples from this study were children aged 12-13 years living in Takalar District with a history of zinc + food supplementation, history of food supplement pregnancy, and without food and supplements.

**Data Collection**

The data of the research were obtained by collecting primary data and secondary data. The primary data were taken from direct research data in the field before measuring the height of the child (using microtoice), the respondent’s characteristic data (socioeconomic data) and the occurrence of sickness in children that occurred in the range (+ 1 month) and children’s learning achievement (average report score) by using secondary questionnaire.

**Data Analysis**

The collected data was then analysed into bivariate analysis by performing Paired T-Test to determine the mean of the last height of the child during the previous study. This test is conducted to determine the relationship of dependent and independent variables in the form of cross tabulation (crosstab) by using SPSS program with One Way Anova statistical test.

**Result and Discussion**

**Bivariate Analysis**

Table 1 shows the current study subject’s height as well as changes in height calculated from birth (length of birth body). Subjects in the group whose mothers had a history of receiving zinc supplementation and food supplementation while pregnant had a mean of 48.9 cm long birth weight and the current height was 149.2 cm with height growth for 14 years was 100.3 cm. Subjects in the group whose mothers had a history of receiving only food supplementation while pregnant supplementation had a mean birth-length of 49.4 cm and a current height of 147.2 cm with height growth of 14 years was 97.8 cm. While the subjects in the control group had a mean body length of 49.4 cm and a current height of 145.9 cm with a height growth of 14 years was 96.5 cm. Table 2 shows the results of the statistical test
(One Way ANOVA) on the growth rate of height, the value of significance (p value) is 0.046 which means that p value is smaller than α (0.05) it can be concluded that there is very real difference between height growth children given zinc supplementation interventions and food, given food only, and control group). While the rate of growth of body weight, got the value of significance (p value) of 0.308 which means p value smaller than α (0.05) it can be concluded that there is no significant difference between child weight gain given zinc supplementation intervention and food, only given food, and control group.

Table 3 shows the Z-Score comparison based on the type of intervention in the Zinc + PMT group shows the result that the average Z-Score is highest compared to the other two intervention groups, whereby in the male group (0.31) and SD (0.98) and in girls (0.49) and SD (1.27). However, the three intervention groups are at normal values based on the Z-Score standard. Table 4 shows the growth rates of height belonging to the group with a history of zinc + food supplementation with the food group had a mean growth rate with significant values (p = 0.12), whereas for the control group when compared to the history of zinc + food supplementation and history of food average growth rate with significant value (p = 0.014). The average growth rate of children with a history of zinc + food supplementation with food group had high growth rate (p = 0.12) and average growth rate in food and control group (p = 0.64). For the control group and zinc + food group had mean rate of height increase (p = 0.14) and control group and food (p = 0.64).

Based on the incidence of illness shown in Table 5, the history group Zinc and PMT had good body resistance compared to the two groups with a history of PMT alone and the control group. Namely the number of children who were not sick, 30 children (59.1%) compared with 2 other cohort intervention groups. The types of diseases that have been experienced by children based on the intervention and control group can be seen in Table 6 whereby based on the prevalence rate of current illness in the group with a history of zinc + food supplementation (68.2%) and control group (63.9 %) is not too much different, and it can be seen that the role of zinc supplementation still has a significant effect on the child’s body resistance to infectious diseases, so that the number of children who have many types of infectious diseases in the control group and in the history group of food intervention.

Overall Discussion

This study provides information that zinc + PMT supplementation given to pregnant women will improve the supply of macronutrients and micronutrients in pregnant women. In a literature study conducted by Imdad et al. and Rivera et al. who evaluated the effect of zinc on linear growth in children younger than 5 years and adolescents through previous research from various sources it was concluded that there was significant between zinc and the child’s linear growth. Similarly, Palacios et al. suggests that zinc supplements may increase BMI and weight gain.

Based on the results of research conducted by Stammers et al. on the relationship between zinc and the growth of children aged 1-8 years (meta-analysis and literature review study) showed that from nine studies conducted that meet the inclusion criteria, significant of zinc supplements between 2 weeks and 12 months duration in body weight, height for age, weight for age, longevity, weight for height (WHZ) or WHZ score in children aged 1-8 years.

Zinc plays a role in the synthesis of DNA and RNA. In addition, zinc plays an important role in sexual growth and maturation. Although zinc plasma levels decreased during puberty, zinc retention increased significantly during rapid growth rates. This utilization warning might lead to more efficient use of zinc from food. Limited food intake of zinc may affect physical growth and development of secondary sexual characteristics.

Conclusion

Based on the results and analysis of this work, the key findings can be concluded as follow:

1. The height growth rate of children with a history of mother’s zinc + food supplementation and history of food delivery was better than the growth of children with no history of both (maternal groups with a history of food and controls).

2. Sickness events (morbidity) between children with a history of zinc + food supplementation had lower levels of morbidity than the group of children with a history of food and controls.

Female Sex Worker Behaviour against the Risk of HIV and AIDS Transmission in Ambon City

Kalmia¹, H.M. Rusli Ngatimin¹, Muhammad Rachmat¹
¹Faculty of Public Health, Hasanuddin University, Jl. Perintis Kemerdekaan Km. 10, Tamalanrea Indah, Tamalanrea, Tamalanrea Indah, Tamalanrea, Kota Makassar, Sulawesi Selatan, Indonesia

Abstract

HIV and AIDS are two of the health problems that threaten human life in all countries. This study aims to obtain information on the behaviour of female sex workers (WPS) against the risk of HIV and AIDS transmission in Ambon City. This research is qualitative with phenomenology design. The number of informants is 9 people consisting of regular informants and key informants. The obtain information for data collection used in-depth interviews. The results showed that the knowledge of female sex workers on HIV and AIDS can only be transmitted through sex and can be prevented by using condoms during sexual transactions. The workers agree with the usage of condom. However, the usage of condom is not practised by all sexual workers with their customers, especially towards their boyfriends. Only certain workers are consistently using condoms with customers during sexual transactions. Health workers have conducted socialization on HIV and AIDS as well as regular health checks for the sexual workers. Nevertheless, there are some workers who do not follow or conduct the examination. For these sexual workers, it is important for them to earn a lot of money to run their daily lives despite the risk of HIV and AIDS is known.

Keywords: AIDS; HIV; prevention; risk; sexual workers

Introduction

HIV and AIDS can be transmitted through several modes of transmission, such as sexual intercourse of the opposite sex (heterosexual), similar relationships through Male Sex with Men (MSM), the use of syringes alternately, blood transfusions, and from mother to child³,⁴.

Ambon City is the highest in the spread of AIDS cases in Maluku Province, namely 632 people, followed by West Maluku Regency (98 cases), West Seram District (31 cases), East Seram (13 cases) and Buru Island (12 case). In 2010, Maluku occupied the 14th position in Indonesia with 192 cases, the spread of AIDS and 70 people have died⁵.

One of the factors that trigger high HIV and AIDS cases is the knowledge factor⁶. Other research results on the consistency of condom use by sex workers and their customers. Factors that significantly influence the practice of condom use in sex workers and their clients are the knowledge of sex workers on STIs (sexually transmitted infections) and HIV and AIDS, the attitude of sex workers, access to information about STIs and
HIV and AIDS, the ability of customers to engage in safe sex behaviours with the pimp support. Budiono\textsuperscript{7} says this is consistent with Green Theory which states that the most important thing in health behaviour is the issue of behaviour change.

A qualitative study conducted by Jie et al.\textsuperscript{8} on barriers to condom use among female sex workers in China suggested that a major barrier to condom use is related to financial problems. Informants say that some of their clients offer more money even twice as much as not to use condoms during sex. A study by Wulandari et al.\textsuperscript{9} in Jakarta hospital found that knowledge of outpatients on HIV and AIDS is poor even though the HIV and AIDS prevention behaviour is good, and there is no link between HIV and AIDS knowledge with HIV and AIDS risk prevention behaviours. A similar study by Aryani et al.\textsuperscript{10} stated that, low level of education and lack of expertise, makes informants into a woman sex worker. Not all informants are able to reach the existing health services. The ability of informants in reaching health services is different from the ability of informants to reach contraceptives especially condoms. The informants obtained it for free from the health centre and NGOs, both during mobile IMS and extension\textsuperscript{10}.

Based on the stated issues, the female sex worker is one of the groups with the risk of contracting and transmitting HIV and AIDS. Therefore, this work focused on analysing the knowledge, attitudes and actions of the female sex worker against the risk of HIV and AIDS transmission in Ambon city.

**Methodology**

**Research Type**

The research design used is phenomenology design. Phenomenology is a research approach that provides a description of reflection, interpretation and conveys the essence of the life experiences of individuals studied.

**Location and Time**

This research is done at Batu Merah Village, Sirimau Sub-district, Ambon City. The study lasted for approximately one month, from June 9 to July 25, 2016.

**Research Informants**

Informants in this study were women sex workers, local health workers and localization managers of Tanjung Batu Merah Kota Ambon. 9 informants, 7 sex worker women, 1 person manager and 1 health worker were involved in this study.

**Research Instruments**

The researchers used aids such as notebooks, interview guides, questionnaire and documentation tools such as voice recorders and camera phones. Interview was conducted with the informants based on the variables studied.

**Data Collection**

Data collection is done to get as complete information as possible in order to answer the research questions. Data collection effort is done by conducting in-depth interviews with informants.

**Data Analysis**

Processing and presenting data is done by content analysis which is technique used to draw conclusion through effort to determine characteristic of message objectively and systematically. The first thing to do is data reduction. Data presentation is done with narrative text along with its analysis by using facts obtained in the field.

**Result and Discussion**

**Sex worker’s knowledge about the risk of HIV and AIDS transmission**

Based on the answers from the informants, one in seven sex worker informants answered they did not know and never heard about the risk of HIV and AIDS transmission. The informant only consumes antibiotics. The informant assumed the medicine was taken to prevent disease. Other informants who knew about HIV risk answered that HIV and AIDS is a dangerous and deadly disease, and can be prevented by using condoms during sexual transactions. In addition, there are also informants who answered that HIV is a disease similar to syphilis that occurs in the genitals only and HIV can cause death. Thus, to prevent it they must use condom. Another informant replied that HIV is a disease cannot be cured especially if red spots appeared on the skin. Therefore, all informants knew about the risks of HIV and AIDS transmission. Nonetheless, there was one informant who did not know or even heard about HIV and AIDS. Whereas other informants...
know that HIV and AIDS can be transmitted through unsafe sexual relations, and can be prevented by using condoms. Knowledge of informants about the risk of HIV and AIDS transmission of informants is limited since informants think HIV and AIDS can be transmitted only through sexual relations only.

### Attitudes and actions of informants against the risk of HIV transmission

Based on the feedback from the informants, it is known that not all informants who know about the risk of HIV and AIDS transmission ask their customers to use condoms during sexual transactions. One of the informants thought that conducting sexual relations with their customer by using or not using a condom was the same. Another informant responded that they advised to use condoms to their customers to prevent themselves from falling sick. Furthermore, informant also answered that they suggested to the customer to use condoms. However, when it comes to have sexual activity with their boyfriend, they do not recommend using condoms during sexual transactions. Also, another informant replied that she always advised customers to always use condoms because the informant knew the risk of HIV transmission through unsafe sexual intercourse. Informants have also claimed that condoms are available in localization and they also consistently use condoms when transacting sexually with their customers for fear of contracting HIV. Thus, overall informants tend to agree to condom use when transacting sexually but there are some informants do not force their customers and boyfriend to always use condoms and leave the final decision to them.

### Negotiation Capabilities

All informants admitted that the localization provided condoms. Out of seven, there are two informants who remained consistent using condoms for fear of contracting HIV. Other informants claimed to know the risks of HIV transmission will remain for those who use condoms depending on their customers. Another informant replied that condoms are usually available but customers do not like it and there are some customers who offer more pay for not using condoms. A different informant replied that she does not use condoms when it comes to sexual activity with her boyfriend. Nonetheless, if their regular guest still tells them to use condoms to be more secure, they will comply. However, if the informants have suggested to customers to use condoms and the customers still do not want to, then the informant will not force them and will agree with the customer’s request. Another informant stated that she negotiates with the customer by offering that they themselves to wear condoms to customers until the customer agree to use the condom. Overall, all informants claimed condoms were available in the localization, but not all the guests they serve were suggested to use condoms as there were for boyfriend and some customers offered higher pay. There are only a few consistent informants who keep using condoms. Not all who were informants aware of the risks of HIV and AIDS transmission were able to negotiate with the customers regarding condom usage.

### The role of health workers in localization

The role of health workers is to provide understanding and guidance to sex workers on the risk of HIV and AIDS transmission and prevention in the localization. Thus, health education is given to the sexual workers and they are informed to always use condom during sexual transaction. However, there are some sexual workers, if they have been paid more, they no longer force customers to use condoms. In addition, only the senior sexual workers consistently recommend condom usage to customers because they are afraid of falling sick. The younger sexual workers do not force or recommend their customers to use condom, fearing that they will not be able to get money. Finally, only certain sexual workers undergo health examination and the rest do not.

### Overall Discussion

In this prostitution activity, female sex workers provide a significant role in selling sex services. Most informants in this study claimed that their reason for descending into the world of prostitution was an economic reason. This may be due to the fact that most of the informants have high school education, some even dropped out from primary school. Subsequently, to find decent work and get sufficient income for their daily needs and family, they have opted to become sexual workers. This study elevated knowledge as one of the predisposing factors.

Yustina stated that the cause of a person’s behaviour change is due to the reason of thought and feeling in the form of knowledge. Knowledge about
the risk of HIV and transmission will affect informants’ awareness to use condoms to reduce the risk of HIV and AIDS transmission through unprotected sex. This is in line with research conducted by Siswandi which stated that sexual workers know condoms as a tool for prevention of disease.

Efforts to improve the knowledge of women sex workers can be done by means of counselling on a regular basis and educating them on HIV and AIDS transmission in the form of books, magazines, newspapers, brochures, leaflets or other mass media. An attitude according to Yustina is one of the factors driving of a person’s behaviour. In this research, the respondents’ attitude is the tendency of respondents in giving opinions to agree or disagree about the usage of condoms to prevent the risk of HIV and AIDS transmission.

Some informants tend to agree that condom is used to prevent HIV transmission, but do not insist on using condoms on the grounds of their boyfriends. This is in line with research conducted by Aryani et al., which says that sexual workers always invites customers to use condoms but not on boyfriends or people they like. This is because they know their partner well and believe that the partner is healthy. Customers are willing to pay more for not using condoms. Thus, the sexual workers do not use condoms with their customers due to the higher pay and request. This is consistent with research conducted in China by Jie et al. that finance is one of the main reasons sex workers have sex with their customers.

In addition, some informants remain consistent with using condom with their customers during sexual intercourse, as they are afraid of the disease that befell them. This is in line with research conducted by Bui et al. which states that most commercial sex transactions involve workers who actively use condoms, due to fear of illness and pregnancy.

According to Yustina, willingness to offer condoms will be formed if the sexual worker has a positive knowledge of the benefits of condoms usage with customers. The result of this work is coherent with the research conducted by Yustina which stated that only 45.2% do offer and negotiate with their customer to use condom. However, the remaining were not able negotiate with their customers. Many women are helpless when negotiating condom use because they do not have bargaining power. Economic independence is the factor most closely related to bargaining power. The role of health workers is one of the enabling factors. Health workers are expected to provide understanding and guidance on the risks of HIV transmission to direct sex worker women. This guidance can be done through health counselling conducted in the localization.

**Conclusion**

The results showed that the knowledge of female sex workers are limited on HIV and AIDS can only be transmitted through sex and can be prevented by using condoms during sexual transactions. The workers agree with the usage of condom. However, the usage of condom is not practised by all sexual workers with their customers, especially towards their boyfriends. This is because of economic factor, as the worker need money for their daily activity and they are being paid extra for not using condom. Thus, even though the risk of HIV and AIDS is known, the workers opt to neglect it. Only certain workers are consistently using condoms with customers during sexual transactions.

Relationship between Supplementary Minnesota Multiphasic Personality Inventory (MMPI) test toward Competency and Intranatal Care Services among Midwifery Students in Tanawali Persada Health Science School, Takalar Regency

Lince Renden¹, Budu¹, Werna Nontji¹

¹Faculty of Medicine, Hasanuddin University, Jl. Perintis Kemerdekaan Km.10, Makassar, 90245. Sulawesi Selatan, Indonesia.

Abstract

The study aims to determine relationship between supplementary Minnesota Multiphasic Personality Inventory (MMPI) test toward competency and intranatal care services among midwifery students in Tanawali Persada Health Science School (STIkes), Takalar regency. The study was used an analytic observational study with cross sectional study design. The study population were midwifery students who had competence test. The sample sizes were 109 respondents by using consecutive sampling method. The result indicted there is a relationship between supplementary MMPI based on ego-strength (Es), p=0.00<0.05, social responsibility (Re) with p= 0.00<0.05, marital distress (MDS) with p=0.01<0.05, addition admission scale (AAS) with p=0.00<0.05, addition potential scale (APS) with p = 0.00<0.05 and masculine gender role (GM) with p =0.00<0.05, post-traumatic stress disorder (PTSD) (PTSD) with p=0.03<0.05. Meanwhile, anxiety (A), repression (R), dominance (DO), over controlled hostility scale (OH), college maladjustment (Mt), hostility scale (Ho), O (O) and feminine gender role (GF) did not have relationship with competence test of midwifery students. Besides, a significant relationship between intranatal service and competence test.

Keywords: Anxiety; Dominance; Intranatal service; Midwifery

Introduction

An estimation of 830 women died from preventable causes related to pregnancy and childbirth¹. Between 1990 and 2005 found 535, 900 maternal mortality occurred in worldwide and sub-Saharan Africa and Asia had recorded 50% and 45% of cases respectively². Several factors contributed to maternal mortality included infection, haemorrhage, obstructed labour and eclampsia, while non- biological factor such as socio-cultural and economic factors³.

Midwives was primary care providers and their care included primary, gynaecologic and family planning, preconception, pregnancy, childbirth and postpartum period and normal newborn during first 28 days of life⁴. In New Zealand, midwives are provided midwifery care through pregnancy, birth delivery, birth and postpartum period up to six weeks for women who had booked midwifery services⁵.

A well-educated midwifery is important in providing health services quality. The midwifery students are required to equip with adequate theoretical and practical experiences for professional skills development in midwifery register included women health during postnatal period, competence assessment, prevention, identification and prompt treatment of genital tract morbidity in United Kingdom⁶.

In Indonesia, competency test is important to ensure capability of health graduates in their professional duties performance especially their perception and basic knowledge level toward their respective health professional. The competency test had 3 domains are cognitive, psychomotor and attitude. In STIkes Tanawali Persada, only 22.0% of 109 midwifery students had passed for competency test in year 2014. Meanwhile, preliminary observation also indicated 80% of midwifery students had unprepared to sit the competency test due to their lack of knowledge in competency test.
process and need support or motivation so that no any pressure in sitting the competency test. The study aims to determine relationship between supplementary Minnesota Multiphasic Personality Inventory (MMPI) test toward competency and intranatal care services among midwifery students in Tanawali Persada Health Science School (STIkes), Takalar regency.

**Methodology**

The study was used analytic observation method with cross sectional study design by using questionnaire. The study was conducted from September to November 2014 at STIkes Tanawali Persada, Takalar regency.

The study population were all midwifery students in STIkes Persada Takalar, Takalar regency. The sample sizes were 109 respondents by using consecutive sampling technique. The primary data was obtained by observation and interview by using questionnaire. The secondary data was obtained through visits at related agencies. The data was analysed using chi-square test to determine relationship between variables.

**Results and Discussion**

**Bivariate Analysis**

Based on Table 1, there is no significant relationship between anxiety and competency test on midwifery students at STIkes Tanawali Persada. There are 17 respondents had score ≥ 65 and 92 respondents had score less than 6. In additions, 2 respondents (11.8%) were passed and 15 respondents (88.2%) had failed in competency test with score more than 65. 22 respondents (23.9%) had passed and 70 respondents (76.1%) had failed in the competency test with score less than 65.

For social responsibility (RE), the statistical test showed no significant relationship between social responsibility (RE) and competency test among midwifery students at STIkes Tanawali Persada. Meanwhile, 63 respondents (78.8%) were failed in the competency test with Mt score less than 65 and 7 respondents (24.1%) were passed in the competency test with Mt score more than 65. There is significant relationship between Mt and competency test, p=0.04<0.05.

Besides, the statistical test found there is significant between marital distress scale (MDS) and competency test. 67 respondents (78.8%) were failed in their competency test with marital distress scale (MDS) less than 65 and 18 respondents (21.2%) were failed in the competency test with MDS score less than 65. There is no significant relationship between hostility (HO) and competency test. 26 respondents (74.3%) were failed in the competency test and only 9 respondents (25.7%) were passed in the competency test with HO score more than 65.

Based on over controlled hostility (OH), the statistical test found there is no significant relationship between OH and competency test, p= 0.19>0.05. Meanwhile, there is significant relationship between MAC and competency test. The addiction admission scale (AAS) had no significant relationship with competency test.

For repression (R), only 2 respondents (13.3%) were failed and 13 respondents (86.7%) were passed in the intranatal care services. There is significant relationship between repression (R) and intranatal service.

For Es, there only 5 respondents (12.5%) who failed in the competency test with Es score more than 65 and 7 respondents (10.1%) were failed in the competency test with Es score less than 65. The statistical result showed there is no significant relationship between Es and intranatal care services. In additions, 20 respondents (80.0%) were passed with DO score more than 65 and 77 respondents (91.7%) were passed with DO score less than 65. The statistical test showed there is significant relationship between DO and intranatal care services.

Besides, there was no significant relationship between GF and post-traumatic stress disorder (PTSD) with intranatal care services. There were 4 respondents (7.4%) who failed in the competency test with GF score more than 65. For post-traumatic stress disorder (PTSD) MMPI scale, 48 respondents (87.3%) were passed and 7 respondents (12.7%) were failed in the competency test with post-traumatic stress disorder (PTSD) less than 65.

**Multivariate Analysis**

Based on Table 5, only E$\delta$ variable was most related to the competency test with $p = 0.001$. Meanwhile, RE, Mt, MDS and post-traumatic stress disorder (PTSD) showed no significant relationship with the competency test. Meanwhile, APS and AAS had significant relationship with intranatal care services. The APS MMPI scale had statistical value, $p = 0.00 < 0.05$ while AAS MMPI scale had statistical value, $p = 0.02 < 0.05$.

Overall Discussion

The study showed no significant relationship between repression toward competency and intranatal care services among midwifery students. The intranatal care services had influenced by student’s learning and practice outcomes during their study.

The study also showed no significant relationship between dominance (DO) toward competency test and intranatal care services among midwifery students in STIkes Tanawali Persada. The high DO scores are commonly among those who had high responsibility and leadership, secure and self-confident. The study by Hedayat et al. found high DO score among male respondents, while dependency (Dy) and DO score did not vary with duration in day treatment among day-treatment clients.

Social responsibility (RE) is defined as sense of duty, self-confident, strong standard, confidence in others, strong sense of justice and ethical concerns. In this study, social responsibility was correlated with midwifery student’s competency test and intranatal care services.

The midwifery students who scored high Mt scale indicated person who are inefficient, hopeless, procrastinate, anxious, nervous and developed somatic symptom when stress. The study found Mt MMPI score had significant relationship with competency test and intranatal care services. The parent marital distress affected children’s emotional and academic achievement. There was significant relationship between marital distress scale (MDS) towards competency test and intranatal care services among midwifery students in STIkes Tanawali Persada.

The statistical test found no significant relationship between hostility (HO) with competency test and intranatal care services among midwifery students in STIkes Tanawali Persada. The midwifery students who scored high HO score indicated person who had higher anxiety, depression, psychosomatic complaint, poor self-concept, attributed hostility to others and not good adjusted psychological.
High score in overcontrolled hostility (OH) scale to be related with violent and aggressive acts. In this study, statistical test found no significant relationship between overcontrolled hostility (OH) with competency test and intranatal care services. In South California, a study found female college students had higher OH scores than male college students.

The study found MacAndrew alcoholism scale (MAC) had significant relationship toward competency test and intranatal care services. High score in MAC also indicated person who are socially extroverted, self-confidents, enjoy competition and risk taking, lack in concentration, aggressive and potentially in substance abuse.

There was significant relationship between addiction acknowledgment scale (AAS) with competency test and intranatal care services. A study found 8.31% of 385 students had higher scores in AAS who access to internet via cell phone or computers and male students had scored higher mean in AAS than female students. Meanwhile, addiction potential scale (APS) did not correlated with competency test and intranatal care services among midwifery students in STIKes Tanawali Persada. This result showed inability students in determined their potential in apply their theory during their practical period.

The chi square test showed significant relationship between intranatal care services and competency test among midwifery students in STIKes Tanawali Persada, Takalar regency. The well prepared and appropriate curriculum contributed in good competence among students to obtain knowledge in the intranatal care services. The intranatal care services quality was observed from several indicators included technical competence dimension which concerned skills, abilities, appearance or performance among health staffs. This dimension was related to the way that health staffs obeyed health service standards included accuracy, compliance and consistency. The unfulfilled technical competence dimension lead to minor deviation and fatal error which reduced health services quality and can caused dangerous to the patients.

Conclusion

In conclusions, there was significant relationship between supplementary MMPI based on ego-strength (Es), social responsibility (Re), marital distress (MDS), addition admission scale (AAS), addition potential scale (APS) and masculine gender role (GM), post-traumatic stress disorder (PTSD) stress disorder. Meanwhile, anxiety (A), repression (R), dominance (DO), over controlled hostility scale (OH), college maladjustment (Mt), hostility scale (HO), O (O) and feminine gender role (GF) did not have relationship with competence test of midwifery students. Besides, a significant relationship between intranatal service and competence test was a factor which closely correlated to the competency test, while APS was factor closely corrected to intranatal service among midwifery students in STIKes Tanawali Persada, Takalar regency.

Knowledge, Awareness and Perception of Malaysian University Students on Regenerative Medicine and Willingness to Accept and Pay for Regenerative Medicine Therapies

Ramachandren K¹, Tan Ess¹, Tan CK¹, Thiagarajah S¹

¹School of Healthy Aging, Medical Aesthetics and Regenerative Medicine, Faculty of Medicine and Health Science, UCSI University, 56000 Cheras, Kuala Lumpur, Malaysia

Abstract

Regenerative Medicine (RM) is an interdisciplinary field with countless potentials and serves as a solution for the growing rate chronic diseases, communicable and non-communicable diseases in developing countries. For the past 23 years, Malaysia has been exploring this field for the boon RM holds. This study aimed to determine the level of knowledge, awareness and perception of Malaysian university students on Regenerative Medicine. A cross sectional, quantitative pilot study was conducted among 390 Malaysian university students above 18-year-old from government and private universities with science background through convenient sampling. Key results showed that Medical and health science students had more awareness and higher knowledge on RM than engineering and physical science students (p<0.001). Significant association between the types of course enrolled and awareness/knowledge on RM observed (p<0.05). There were significant associations between the level of knowledge and the awareness, willingness to accept and pay for RM therapies/courses (p<0.05). Other demographics did not influence their level of knowledge. Significant association seen between WTP and acceptability of Embryonic stem cell research (ESCR) p<0.05. Students with moderate to good level of knowledge have more awareness, more supportive and showed positive perception towards RM.

Keywords: Regenerative medicine; awareness; knowledge; perception

Introduction

Regenerative Medicine (RM) has been evolving gradually in Malaysia for the past 23 years. This is evident from the established centres for Haematopoietic Stem Cell Transplant (HSCT) in a number of government and private hospitals such as Institute of Paediatrics in Hospital Kuala Lumpur in 1994, Subang Jaya Medical Centre in 1994, Hospital University Kebangsaan Malaysia in 1999. Stem cell therapy one of the major component in RM is considered as a great breakthrough in the paradigm of medicine¹,². Exploration of RM holds the key to solve many growing chronic diseases, infectious diseases and other non-communicable diseases in developing countries³.

University Kebangsaan Malaysia has come out with My Derm, an autologous skin product⁴. Tissue-engineered autologous bladder is been used for patients needing cystoplasty⁵. Numerous RM clinical trials going on which have successfully produced successful therapies that have benefited the developed countries⁶-⁸ countries like Japan, Korea and United States the advancement in RM is astounding⁹. There are substantial evidence supporting the benefits of RM in health and wealth of a nation¹⁰. In line to this, Malaysia should explore more in RM and by evaluating the knowledge, awareness and perception among the Malaysian university students will contribute to this exploration. Approximately 3% of the Malaysia’s population are students pursuing tertiary education according to National Education Statistic Ministry of Higher Education 2015. However, lack of awareness among the Malaysian students on the potential of RM therapies this will impact the health management in future. Hence, interest in RM need to
be instilled among Malaysian youngsters. Besides, education being significant in economic growth and national development, it can be an ideal and powerful tool to create awareness and knowledge related to RM among Malaysian tertiary students. As science and technology is expanding in all fields especially in medicine, our students need to be equally aligned with the growth and aware of global development. In order to assist the growth of RM in Malaysia, a pilot study has been conducted to assess the students’ knowledge, awareness and perception in RM.

**Methodology**

Regenerative Medicine (RM) has been evolving gradually in Malaysia for the past 23 years. This is evident from the established centres for Haematopoietic Stem Cell Transplant (HSCT) in a number of government and private hospitals such as Institute of Paediatrics in Hospital Kuala Lumpur.

**Study Design**

This study was designed as a questionnaire based quantitative study. It was calculated that 384 candidates were required to achieve 95% confidence level and confidence interval of 5% based on SPSS. Informed consents were obtained prior to the distribution of questionnaire. The researcher designed the questionnaire by sourcing from indexed journals, books and reports on RM and vetted by subject supervisor and lecturers from Faculty of Medicine Health and Science (FMHS) in UCSI.

**Study Population**

A sample size of 390 respondents from Klang Valley with science background were targeted. Only Malaysian undergraduate and postgraduate students from both private and government universities with age range of 18-55-year-old were recruited. Both gender whom were English literate were accepted for the study. Students from within and outside the premise recruited with the permission of the Deans of the universities.

**Questionnaires**

The self-administered instrumentation tool used in this survey was formulated based on the literature, journals, reference book, report from reliable sources reviewed on various topics related to regenerative medicine’s components including stem cells, tissue engineering and molecular and genetics with their current therapies and future directions of RM\textsuperscript{11-13}. The questionnaire comprises 5 sections: Section A- Demographics- 12 questions, Section B-Awareness on RM-10 questions, Section C- Knowledge on RM -10 questions, Section D- Perception on RM-12 questions and Section E- Willingness to accept, pay and contribute for RM based therapies, courses and research-8 questions. A combination of dichotomized and trichotomized responses, Likert scale were used to collect data from participants.

**Ethical Clearance:** Ethical approval was granted from the UCSI ethical committee (Proj-FMHS-EC-2016-519). Written informed consent was obtained from each recruited respondent.

**Data Analysis**

All data collected via this study was analysed using the Statistical Package for the Social Sciences (SPSS) version 20. Content validity of the questionnaire was done by conducting a pre-test of the instrument in a small group of university students. Descriptive analysis was used to describe the levels of awareness, knowledge, and perception of the participant groups. Comparison between groups according to their answers and socio-demographics characteristics. Significance for all statistical measures was determined at the p value < 0.05 level.

**Result and Discussion**

Knowledge among University Students on Regenerative Medicine

Level of knowledge on RM was determined through participants’ familiarity with the definition of regenerative medicine, the branches of RM, the disciplines that consider RM application as important as shown in Table 1.

Awareness among University Students on Regenerative Medicine

Only 38.3% of respondents have heard of the term ‘Regenerative Medicine’ and 61.7% have not heard of this before. Among the 38.3%, students from health science were (n=66, 38.6%), Engineering and physical science students (n=25, 30.9%) and medical (n=24, 50%). Besides that, (n=88, 44.4%) government university students were more familiar with RM term than private university students (n=27, 26.5%) (p<0.05). This could be because of active involvement of government universities in stem cell research which is evident through higher number of scientific papers published\textsuperscript{14,15}. However, there is limited information available on the knowledge, awareness and perception on stem cells among Malaysian medical students\textsuperscript{16}. Participants in general, obtained this awareness from a variety of source. It is not surprising that majority of the respondents heard of RM through mass media as this is the easiest and fastest route to disseminate information. The public are able to obtain information easily through the media and internet\textsuperscript{17}.

Perception among University Students on Regenerative Medicine

A total of n=229 (76.3%) of respondents agreed to support regenerative medicine, n=66 (22%) were ‘not sure’ whether they would support and only n=5(1.7%) denied to support RM in Malaysia. Total of 70% male and female respondents agreed to support RM in Malaysia. Respondents in the age range of 18-31 years showed better support than middle age group because most of the respondents in this age group are in health-related courses. Based on the data analysis, undergraduate (n=182, 73.1%) and postgraduate (n=47, 92.2%)(p<0.01). Students from government universities, 79.8% and 69.6% private university students supported RM. Higher support received from health-based students (81.3%) than engineering-based students (63.0%) (p<0.01).When the respondents’ perception on the estimated duration needed for RM to grow in Malaysia explored, 65% respondents commented that RM would be successful in 10 years and 26% of them felt the growth would take about 20 years. RM is growing exponentially in Asia-Pacific region especially in India and China\textsuperscript{9}. Moreover, one third respondents chose Government Funding and Support, Research, Regulatory environment, Legislative constraints, Investors and Public awareness as determinant of RM’s success. Public awareness is one of the influencing factors which would influence the growth of any field\textsuperscript{18}.

Willingness to Accept and Pay for Regenerative Medicine Therapies/Seminars

Based Table 2, the study conducted, 62% respondents were willing to accept RM therapies but only 56% were willing to pay for therapies. The remaining 38% respondents who were not willing to accept the therapies also answered that their religion would influence their perception RM. Respondents whose perception on embryonic stem cell research has the influence of religion and who were not sure if the religion would influence have not accepted nor pay for RM therapies (p<0.01). This shows there is strong religious affiliation among the respondents in Malaysia\textsuperscript{19}. Product/ therapy specification and information ‘halal’ would contribute to increase the acceptability among the public especially for Muslim residents. Apart from this, respondents who
felt RM has numerous potentials to improve wellbeing agreed to pay whereas those who did not have confidence on the benefits disagree to pay (p<0.01).

</tbody>
</table>

Factors associated with Students Level of Knowledge on Regenerative Medicine
Based on this study, there is statistically very significant difference between the knowledge of students from Medical and Health Science with students from Engineering and Physical Science categories on RM components (p<0.05). It is clearly evident that students from Medical and Health Science have better knowledge than the students from the other category. More than 70% of them knew the components better compared to the other group.

Result showed that n=41 female participants have good level of knowledge than male n=11 (p<0.01). As for those who have moderate level of knowledge, the female respondents are more in percentage (58.2%) than male (45.0%). However, there is no significant association between level of knowledge, age range and level of education. (p>0.05) Apart from this, more government university students n=38 have good level of knowledge than private university students n=14 (p<0.01). Medical and Health Science students have higher percentage of moderate to good level of knowledge than Engineering and Physical Science (p<0.01). The existing background on healthcare and life science knowledge could have influence their knowledge level on RM. This is proven among students with life science knowledge whom have better acceptability on genetic testing\(^2\). Students with poor level of knowledge (81.0%) still chose mass media as their main source of information compared to exhibition, education or medical professional. (p<0.01). There is a very significant association between source of information and level of knowledge among the students. Students with moderate to good knowledge have more than one resources on RM.

Factors associated with students awareness on Regenerative Medicine

There is no association between the level of education and the awareness among them as the p-value is 0.09. Association between awareness on the exploitation of ‘stem cell’ words in health products and university students’ demographic factors showed that 85.4% medical students, 74.9% of health sciences students and 48.1% of students from physical science and engineering were aware of the misuse of ‘stem cell’ word in healthcare products. There is a very significant association between this awareness and the categories of courses (p<0.01). More than 66% of undergraduate and post graduate from all 3 categories of courses seemed to be aware of this exploitation (p<0.05). Even though, majority of the students had not heard of regenerative medicine, they were familiar with stem cell related questions. According to\(^4\) study, most of the Malaysian medical students were aware of stem cells and the characteristics but limited awareness noted. Medical students 85.4% (n=41) and 53.2% (n=91) health science students have heard of ill effects of unproven stem cell therapy. Only (30.9%) physical science and engineering students seemed to be aware of this statement. This shows that there is awareness among students across the courses but more awareness is seen in medical and health science students than physical science and engineering students (p<0.01). Students at both level of study and from science background have some awareness on unproven stem cell therapy. Medical and health related students were more aware about potentials of gene therapy than engineering and physical science students (p<0.01). However, there is no association between the level of study and awareness on potential of gene therapy (p>0.05).

Factors Associated with Students’ Perception on Regenerative Medicine

Strong association seen between support received and level of knowledge. Respondents with moderate to good level of knowledge agreed to support than those with poor knowledge. (p<0.01). Students with moderate to good level of knowledge agreed with RM’s potentials and thus became more supportive towards RM. Besides that, any misperception should be carefully handled. Respondents of 40% were neutral about medical tourism leading to misconception because of lack of familiarity about the risks it carries. While 60% of online stem cell clinic use internet as their marketing tool for business\(^3\). The management of public discourse and their misperceptions should be overcome by adequate public education and discussion to see progress in stem cell research\(^20\). There is no significant association among the level of study but medical and health students agreed more than engineering students that television can be the source of exploitation (p<0.01).

Conclusion

This study has yielded positive feedback about RM among students in higher learning. Overall the awareness on RM is low but medical and health science students seemed to have more awareness than engineering and physical science students. Students with moderate to
good level of knowledge have better awareness on RM. Majority were aware of the potentials of stem cells and the risks of unproven therapy compared to potentials of genetic therapy. Significant association has been seen between respondents with moderate to good level knowledge and awareness. Even though there are students with poor knowledge whom were willing to know more about RM, the proportion seemed higher among the students with moderate-good level of knowledge. Students used more than one source of information have moderate to good level of knowledge. Through such knowledge, there was some awareness on RM but inadequate.

Abstract

Menopause is a physiologic phase in women life involving hormonal changes that could lead to severe menopausal symptoms and thereafter affecting one’s quality of life. Moreover, army wives lead stressful lives. In this study, we aimed to determine quality of life among army wives during menopausal transition as well as to investigate possible association between socio-demographics and their quality of life. Seventy-five army wives were recruited. Mean age of menopause reported was 51.7 (± 2.5 SD). Physical domain was the most reported menopausal symptoms followed by psychosocial, sexual and vasomotor. Most army wives reported having lack of energy (78.7%), feeling worn out (77.3%) and decreased in physical energy (76%). Least reported symptom was change in facial hair (25.3%). Menopausal stages were significantly associated with MENQOL domains changes except sexual domain (p<0.05). Army wives in the early perimenopausal stage was most affected in psychological and physical domain. Overall MENQOL scores were associated with household income, spouse’s division and rank (p<0.05). Spouse support is crucial during the menopausal transition. As such, intervention such as awareness, education and counselling can help these army wives to improve their QoL.

Keywords: Menopause; women; hormonal; symptoms; quality

Introduction

Menopause is defined as cessation of menstrual cycle due to decrease secretion of progesterone and estrogen from ovarian¹. The age of menopause is between 45 and 55 years. Menopausal symptoms which are associated with the physiological and hormonal changes include hot flushes, night sweats, mood swings, vaginal dryness and much more. The symptoms broadly divided into vasomotor, physical, psychological and sexual components².

Perimenopause is defined as by World Health Organization as the period of time before the final episode of menstruation³. It extend over 2 to 8 years prior to menopause and 1 year after the last menstruation. During this transition time, women experience different physical, psychological and even social changes that may affect their quality of life in a great degree depend on varities of sociodemographic factors. The cultural, social, economic, religious and educational status might be determinant of impact of these changes in quality of life in perimenopause women.

Besides disturbance due to bothersome menopause symptoms, family environment often influence managing the life during these years resulting in chronic stress in premenopausal women. Military wives have been identified to have a higher level of stress, and depression compare to the nonmilitary wives⁴. There are many studies in association of menopausal symptoms and quality of life in women, but no study had been conducted in this specific population in order to see the degree of menopausal symptoms impacting their life. Thus, this research aimed to determine incidences of menopausal symptoms among the military wives in Malaysia and identifying their impact on the health-related quality of life.

Methodology

Study Design and Subjects and Sample Size

Corresponding author:
M.S. Seghayat
E-mail: marjansadat@ucsiuniversity.edu.my

A cross sectional survey was conducted from November 2015 to March 2017 in an Army Camp situated within vicinity of Kuala Lumpur. Sample were army wives whose husband are serving or had previously served the country. Inclusion criteria were women aged 45 to 85 years old and was experiencing symptoms of menopause. Calculated sample size was 73. Other parameters include 95 percent power at significant level of 5% with assumption of design effect of 2.5.

**Sampling Measurement**

The questionnaire consisted three sections; socio-demographics, history of menstrual cycle and Menopause Specific Quality of Life (MENQOL).

MENQOL was developed and established by and had since been widely used in clinical settings to assess health-related quality of life in the menopausal stage. It is also validated in many populations globally. There are 29 items in the self-administered instrument; vasomotor (3 items), psychosocial (7 items), physical (16 items) and sexual (3 items). Initially, each system is qualitatively evaluated as present or nor present. If the symptom is present, then it is scored from 0 as not bothered to 6 as extremely bothered. Score for MENQOL is the mean total of each domain.

**Ethical Approval**

Permission for conduct of study was granted by the Officer in Command of 712 Pusat Perubatan Angkatan Tentera, Kuala Lumpur. Ethical approval was granted by Faculty of Medicine and Health Sciences, UCSI University via approval code Proj-FMHS-EC-2016-516.

**Statistical Analysis**

Statistical analysis was done using the statistical package for the social sciences software (SPSS Software, Chicago, IL) version 23.0 and statistical significant was deemed at p<0.05.

**Result and Discussion**

**Socio Demographic**

Eighty army wives were approached to participate in this study. Five respondents were rejected due to surgical menopause and history of cancer. Range age of respondents is 45 to 58 years old with median age of 52. Range age for attainment of menarche is 11 to 15 years old with median age of 13. Most respondents received education lower than O-level and were from low income group with 74.7% and 56.0% respectively. Only 22.7% of respondents have husbands who are actively serving. Table 1 shows socio-demographic for this study.

Menstrual Specific Quality of Life (MENQOL) and Domain Scores

The most affected MENQOL domain is psychical with median score of and range from 1.00 to 6.94; which three most commonly reported symptoms were lack of energy (78.7%), worn-out (77.3%) and decreased in physical strength (76%). Psychosocial is the second most affected domain with median of 2.43; which more than half reported experiencing memory loss (62.7%), having anxiety (58.7%) and feeling less accomplished (54.7%). Vasomotor and sexual domains were equally affected with median of 2.33. In sexual domain, more than half experienced changes in sexual desire (62.7%). The least reported symptom was changes in facial hair (25.3%). Scores for each menopausal symptom is listed in Table 2.

Menstrual Specific Quality of Life (MENQOL) and Menstrual Stages

Table 3 demonstrates associations between MENQOL and menstrual stages. Respondents in late perimenopausal stage experienced more vasomotor disorders; median score was 3. Postmenopausal stage was least affected and better quality of life. Vasomotor (p=0.021), psychosocial (p=0.030) and physical domains (p=0.026) were significantly affected by menopausal stages except for the sexual domain (p=0.502).

Menstrual Specific Quality of Life (MENQOL) and Menstrual Stages

Age category was strongly associated with vasomotor domain. Women within the age of 50 to 54 years old experienced more vasomotor symptoms compared to women at the age of 45 to 49 and 55 to 59. Psychological and physical domain was associated with spouse division; which median scores were higher among wives whose husbands were actively serving versus veteran. Sexual domain was associated with household income. No associations were reported for MENQOL domains with ethnicity, religion, occupation and education. Overall, MENQOL score was associated with household income, spouse division and rank.

Overall Discussion

Mean of menopausal age in this study is 51.7 (± 2.5 SD). This result is found to be almost similar to a study conducted in Kuching, involving 356 Sarawakians which mean age of menopause was 51.28 ±2.3 years old. However, other studies in Malaysia reported earlier menopausal age. Mean menopausal age reported in Kelantan and Ipoh was 49.4 ± 3.4 and 47.96 ± 2.5 years old respectively. Indonesia also had an earlier menopausal age. Indonesians were reported to experience menopause at 49.98 old respectively.

A larger study involving seven countries in South-East Asia reported median age of menopause at 51.09. This study encompassed Malaysia, Singapore, Taiwan, Philippines, Indonesia, Korea and Hong Kong. The SWAN (Study of Women’s Health Across the Nation) proposed natural age of menopause to be 51.4 years.
Thus, the mean menopause age for army wives in this study are within proposed normal range.

Variation in menopausal age across different countries can be attributed to several intrinsic factors such as body mass index, educational status, physical activity, smoking habit, alcohol consumptions, better self-rated health and reproductive history. Variation in menopausal age across different countries can be attributed to several intrinsic factors such as body mass index, educational status, physical activity, smoking habit, alcohol consumptions, better self-rated health and reproductive history. In this study, physical domain was the most affected domain with majority of army wives experiencing lack of energy (78.8%), tiredness and worn out (77.3%) and decreased physical strength (76%). Similarly, East Malaysians were also more affected in the physical domain with the highest reported symptoms were muscular skeletal discomfort (80.1%); followed by physical and mental exhaustion (67.1%) and sleeping difficulties (52.2%). Meanwhile, highest reported symptoms were tiredness (79.1%), reduced level of concentration (77.5%) and musculoskeletal aches (70.6%) in Kelantan. These findings are different than those commonly reported in western countries; where vasomotor symptoms like hot flushes were more prominent. In Netherland, 85% women reported having vasomotor symptoms; while less than half were reported in this study. Lower incidences vasomotor symptoms were also found in few other studies in Asian countries.

Table 4 compares menopause symptoms in this study with those in other countries within the Asia Pacific region. Generally, physical domain was most affected with complains on musculoskeletal and tiredness. On the contrary, study conducted in Taipei reported difficulty in sleeping as their highest symptom. Incidences of several menopausal symptoms were found to be higher in this study compared to other studies. Frequent urination due to poor bladder control was found to be higher almost two folds compared to Melbourne study.

In this study, early perimenopausal stage experienced impairment in psychosocial and physical domain; while late perimenopausal stage were affected in vasomotor domain. These findings were in agreement with several other studies. In contrary, several studies found that postmenopausal women experienced more sexual symptoms; but such association was not established in this study.

Our results found no association between household income and menopausal quality of life; which better income actually lead to poorer QoL. Most studies reported the opposite and the norm that menopause women with better economic status were less affected. Army wives seemed to be more influenced by their spouse. Women whose spouse had retired or was serving in the lower rank had better QoL. Vice versa, army wives had higher anxiety and were more depressed. Spouse support is crucial during the menopausal transition. An educational program which comprised of management and health of menopausal transition was conducted for spouse was in Iran; such intervention evidenced significantly lower psychological and physical domains.

As for other domain, women at the age of 50 to 54 were significantly affected the vasomotor menopausal symptoms compared to those at the age of 45-49 and 55-60 years old. It could be explained by the fluctuation of estrogen levels and it reaches the peak during the perimenopausal stage. These findings were in agreement with other studies in the country as well as studies conducted among Caucasian and Australians. Vasomotor symptoms can be as high as 75% during the perimenopausal.

Conclusion

Results showed decreased QoL particularly in physical and psychosocial domains. It was associated with spouse division. Army wives of actively serving spouse were most affected. Therefore, it is necessary to develop effective intervention program such as awareness, education and counselling for these army wives.

Tuberculosis: A Complication after Hematopoietic Stem Cell Therapy (HSCT) and Bone Marrow Transplant

Rafidah Binti Baharudin¹, Marjan Sadat Seghayat¹, Farahnaz Amini¹
¹Faculty of Medicine and Health Sciences, UCSI University, No.1, Jalan Menara Gading, UCSI Heights, Cheras, 56000 Kuala Lumpur.

Abstract

Tuberculosis (TB) is the most common mortality cause among infectious diseases in Malaysia, and is one of the oldest known disease in the world. Generally, TB is uncommon among recipients of Hematopoietic Stem Cell Therapy (HSCT) and Bone Marrow Transplant (BMT); however its infection can be highly fatal if detected late. The objective of the literature review is to identify risk factors and common presentations of Tuberculosis infection (TI) among recipients of HSCT and BMT. Literature searched was done by using different keywords from MeSH in PubMed and Google Scholar. Eligible studies that published from 2005 till 2018 in English language that investigated occurrence of Tuberculosis infection (TI) among HSCT and BMT recipients, have been included. They were appraised and analyzed based on the research questions. All recipients of HSCT reported in 15 studies that developed TI had been exposed to cytotoxic drugs/immunosuppressive drugs. Apart from being immunosuppressed due to the disease and cytotoxicity of drugs, 42% of the recipients had history of exposure to TB prior to therapy; 66.6% of them are treated for Leukemia and 67% of the infections occurred in the lungs; according to the case reports findings. Whether or not TI has certain predilection by donor factor, it is noted in the According to the one of case studies, 7/12 (58%) of TI occurred in HSCT with cell source of allo-related donors. It is noted that tuberculosis in recipients of HSCT presented in the common site of infection i.e. lungs. History of TB exposure has significant contribution to the post HSCT complication of TI. The time from HSCT to diagnosis of tuberculosis (TB) infection ranged from 8 days to 270 days post transplantation. Screening program for Latent Tuberculosis Infection (LTBI) prior to therapy / transplant was not done in most instances.

Keywords: Tuberculosis; Stem cell; therapy; HCST

Introduction

Tuberculosis (TB) is caused by Mycobacterium Tuberculosis. It is an opportunistic agent that is transmitted via air. Often, once transmitted to another person, it remained dormant due to the existing immunity that ‘gated’ them from flourishing; in a healthy subject. At this stage, it is called as ‘latent tuberculosis infection’. Repetitive exposure or poor immune response can lead to active TB disease. It is reported that TB killed 1.5 million of the world’s population in 2014¹. Early case detection and prompt treatment is crucial for controlling TB. Common approved treatment regimen for TB is six months. Due to the long duration, issue such as compliance and treatment interruption due to shortage of supply is identified obstacles in controlling TB. According to Roy et al², chance of having active TB in recipient of Hematopoietic Stem Cell Therapy (HSCT) is 2 times more compared to the general population.

Hematopoietic stem cell is known to cure many types of malignant hematologic and non-malignant hematologic diseases, immunodeficiency diseases and in born error metabolism. Autologous HSCT on the other hand is famous for rescuing bone marrow aplasia secondary to multiple myeloma or high dose chemotherapy for solid tumors¹. HSCT is not just known as the treatment paradigm for blood and bone marrow cancers, it started to gain traction as a treatment for
multiple sclerosis. Tuberculosis Infection (TI) is an uncommon complication in HSCT or BMT recipients. However, its fatality is reported to be 50%. TB may result from Latent TB Infection (LTBI) in either the recipient or the donor or post-transplant infection. There is not sufficient data available to calculate the prevalence of TB in this group to recommend any pre-procedure preventive management prior HSCT and BMT. This review will gather as much information, case reports and analysis done previously and identify frequency of TI and its risk factors in order to suggest few preventive measures that may be considered in the future HSCT and BMT clinical guideline.

**Methodology**

**Research Design**

Literature search was done on electronic articles in PubMed and Google Scholar using MesH terms: STEM CELL, HEMATOPOIETIC STEM CELL, BONE MARROW TRANSPLANT and TUBERCULOSIS. Studies included in the review were chosen according to the following criteria: Published papers from 2005 - 2018, in English case reports, prospective studies, and retrospective studies maximize the data available for the structured review.

Studies were selected according to PICO (Patients, Intervention, Comparison and outcomes) and appraised by Jadad Score and Newcastle-Ottawa assessment tools. Studies with score 2 and above by Jadad - Score and 5 and above by Newcastle Ottawa were considered to have high quality.

Subjects in this study were recipients of HSCT or BMT. Risk factors such as age, illness, concurrent treatment (Chemotherapy, Steroid, Cytotoxic drugs etc.), duration of follow up, possible pre and post HSCT/BMT exposure to TB as well as comorbid factors such as diabetes mellitus, chronic obstructive pulmonary disease, other history of autoimmune diseases have been analyzed. Findings will be tabulated for comparison.

**Result and Discussion**

Total of fifteen (15) studies were selected. Eight studies are case reports (i.e. G Martín-Sánchez et al; Ostendorf et al; Lee et al; E Brial et al; RL Russoet al; Tomaszewska et al; Shima et al; and SC KU et al) and seven are retrospective studies (Fan et al; Jung et al; Ullah et al; Safdar et al; Al-Anazi et al; Hyo-Jin Lee et al; Agarwal et al). Out of fifteen studies, one study (1) Bone Marrow was the source of transplanted cells, while the rest obtained HSCT via other sources (Induced by GSF or Cord Blood).

**Findings from Retrospective Studies**

Safdar et al did a retrospective study on Cord Blood Transplantations (CBT) of 97 patients and categorized them accordingly. This study explored the consecutive infection occurred in 97 recipients of CBT. The sources of cord blood were taken from cord blood banks in the United States and Europe. This study looked into spectrum of infection and surveillance was conducted twice weekly during hospitalization, and weekly within 100 days of discharge. It particularly tested for CMV infection, which is more common than TB.

Active Tuberculosis infection is uncommon among cancer patients in the United States. Higher frequency of TI post HSCT occurs in high endemic country such as India - 2%, Hong Kong - 5.5% and Turkey - 1.4%.

Another retrospective study done for a period of 12 years was conducted in Riyadh Armed Forces Hospital by Al-Anazi et al in which records of patients receiving HSCT for treatment of benign and malignant hematological disorders that developed Tuberculosis infection were scrutinized. Eighteen (18) patients were reported to develop tuberculosis infection (TI). Male to female ratio of 2:1, median age of 48.5 (range 19 – 75) and acute myeloid leukemia (4/18) is the most dominant hematological disorder recorded, among the recipient of HSCT in the hospital.

Exposure to cytotoxic drugs seemed to be the major factor of causing TB infection post HSCT, in view of immunosuppressive property which renders anyone to be susceptible to any opportunistic agents like TB, particularly rampant in high endemic countries. Not just rendering a person to be immunosuppressed, it can even alterate the clinical picture of TBI in recipients of HSCT. Clinical manifestation of TB was reported as wide spectrum from being completely atypical to common presentation of TB. It can involve uncommon site such as skin, bone, central nervous system, urinary tract and most fatally, it can be disseminated and cause multi organ failures and septic shock.
Fan et al\textsuperscript{13} estimated that the annual TB incidence among HSCT recipients was 10 times greater than the general population. Median time to post-HSCT TB diagnosis is 1.22 years with 89.7\% of patients were diagnosed beyond 100 days. Asthma and COPD each are common comorbid diseases occurred in HSCT with TI, whilst 69.2\% of recipients with TI had GvHD\textsuperscript{21-23}.

Two studies (Ullah et al\textsuperscript{15} and Fan et al\textsuperscript{13}) reported its TB incidence of 2.3\% and 3.52\%, respectively. Al-Anazi et al\textsuperscript{17} is focusing on eighteen TI occurred in HSCT recipients only. Safdar et al\textsuperscript{16} reported only one case of TI (\textit{Mycobacterium Tuberculosis}) in 100 HSCT recipients while Ullah et al (2007) reported four cases of TI. It is noted that TI occurred commonly in Lungs by all seven studies and majority of HSCT recipients were treated for Leukemia. TI occurred in various age group with the youngest median age of 14 years and the oldest as 85 years. Two studies (Al-Anazi et al\textsuperscript{17} and Ullah et al\textsuperscript{15}) did not mention period of TI occurrence. However Safdar et al\textsuperscript{16} reported TI after 63 days of HSCT and this is farther in Hyo Jin Lee et al\textsuperscript{18}, where TI occurred 386 days post HSCT.

**Findings from Case Report**

Patients represented in eight (8) case reports are categorized by age (0 – 18 children; above 18 adult), gender, nationality and underlying disease to identify possible risk factors of TB infection post HSCT/BMT. Incidence of TB post HSCT reported different base to the countries. TB infection post HSCT is reported to be proportional to the country’s general population\textsuperscript{2,23}.

It is noted that most of recipients i.e. eight (8) out of twelve (12) patients were treated for Leukemia (66.6\%). Two (2) persons received HSCT for treating Severe Aplastic Anemia (16.7\%) while the other two (2) were treated for multiple myeloma and Beta thalassemia major (16.7\%).This may perhaps depicted that HSCT is very effective in treating Leukemia more than other diseases pertaining to blood; or that Leukemia is treatable with HSCT apart from medical intervention such as chemotherapy. Male seemed to be more susceptible to post therapy infection as compared to female as shown on the table i.e. 66.6\% of TB complications are among male recipients. From the twelve (12) recipients, seven (7) were adults (58\%). This may be due to greater number of diseases requiring HSCT in adult as compared to children\textsuperscript{23-25}.

It is important to explore the history of TB exposure pre and post transplant. From twelve (12) recipient, five (5) had given positive TB exposure (42\%). Two of them as reported by E Brial et al\textsuperscript{9} and SC Ku et al\textsuperscript{12}, had history of Latent TB infection or LTBI. One patient had no clinical evidence of LTBI and diagnosed by Tuberculin Skin Test and Interferon Gamma Release Assay test. E Brial et al\textsuperscript{9} studied, impact of high rate of exposure to TB pertaining to country of origin and possibility of LTBI in recipients. Three (3) recipients had history of contact with patients infected by TB. RL Russo et al\textsuperscript{5} reported the recipient had been exposed to TB a year before therapy, while Lee et al\textsuperscript{8} case was exposed to TB four months after transplant, during inpatient care, and lastly Ostendorf et al\textsuperscript{7} reported the patient whom had contact with his TB infected classmate about a decade prior to HSCT.

All 12 patients received conditioning regimen prior to transplant, which mainly consist of cyclophosphamide and busulfan, beside some of them received total body irradiation (TBI). Patients then had been given GVHD prophylactic treatment that made their body even more immunosuppressed. Six patients recorded to have other infection prior to or concurrent with TI, which 4 of them received allo-unrelated HSCT. All 12 patients had allogeneic transplantation that 7 cases were related (58.3\%).

**Site of Post Transplant Tb Infection**

Tuberculosis infection often involves the lung and its parenchyma. Eight out of 12 infection occurred in the lungs (67\%). The most cases shared common clinical manifestation of TB pulmonary symptoms i.e. cough, fever, night sweats, dyspnea and pleuritic chest pain. Although atypical clinical manifestations of tuberculosis infection and localization could be expected considering confounding factors such as prophylactic, cytotoxic and conditioning regime patients received prior to transplant\textsuperscript{25-30}.

Four cases, had extra pulmonary localization for example disseminated TB in 2 cases of Ostendorf et al\textsuperscript{7} and Shima et al\textsuperscript{11} studies, TB of skin, knee and bone -1 case in Tomaszewska et al\textsuperscript{10}. Study and TB of
lymph node in 1 case in SC Ku et al. study. All cases were treated for acute myeloid leukemia but recipient of TB of lymph node, whom had been treated for Beta thalassemia major.

**Conclusion**

Base to this review in majority of cases TI occurred in the lungs (67% of reported by case reports). This explained that incidence of TI in recipients of HSCT represented the common site of infection as per global population, regardless of nationality. Most TI occurred during Intermediate post-transplant (3 weeks to 3 months). Time of occurrence is important so as to plan ahead on screening and to put an alert on healthcare worker of possible common clinical manifestation that indicates TI. Tuberculosis should be detected and treated as early as possible to avoid dissemination and further difficulties in disease control. Most of the studies, lack environmental evaluation and elaboration on TB exposure were not given much emphasis. Screening for TB pre HSCT / BMT is not made mandatory; hence majority did not do so. Future studies should be more concerned on finding the possible source of TI i.e. previous history of TB exposure and/or nosocomial.

Public Perspective and Engagement in Cognitive-Stimulation Activity to Preserve Cognitive Reserve among Seniors in Malaysia - A Pilot Study

Melisa A.S., Normina A.B., E.S.S. Tan, M.S. Seghayat

Abstract

The loss of cognitive capability is a serious problem affecting the elderly population globally. This study aimed to determine different perspectives on cognitive stimulating activity and the engagement in different types of cognitive stimulating activity in order to preserving cognitive reserve among the elderly in Malaysia. CRI questionnaire and IQCODE had been used to assess the level of cognitive reserve in a lifetime and cognitive decline in the elderly, respectively. Data analysis was done using the SPSS 18.0 version, t-test analysis and Pearson’s correlation. Result showed that, the group aged between 61 and 65 also exhibited higher CRI education (F=6.41, p<0.05), CRI leisure time (F=25.72, p<0.01) and CRI working activity (F=43.61, p<0.01) than the other two groups. Participants aged up to 60 years had higher CRI score (M=109.49, SD=15.20) than those aged up to 65 years (M=99.35, SD=11.45) as well as those aged up to 70 years (M=90.51, SD=16.13). All the post-hoc comparisons were significant at 0.05 level, where F=34.7 and p<0.001. In conclusion, results revealed that the adults who participate in brain stimulation activities such as reading magazines and exercise have reduced chances of developing cognitive related conditions. Elderly people who were found to have worked on the professional and intellectual jobs have low chances of developing cognitive problems than those in unskilled manual jobs.

Keywords: Elderly; population; cognitive simulation; CRI

Introduction

The elderly population has grown significantly due to the rise of life expectancy, and therefore cognitive decline has become a key issue faced by the healthcare system. Age is one of the most important factors that affect the cognitive capacity of the individuals and all human beings record a decline in cognitive capacity as time progresses. Nevertheless, a significant number of elderly individuals do not develop major cognitive impairment such as dementia, even though they show the presence of brain lesions, leading to the model of cognitive reserve.

Cognitive reserve (CR) is an important factor in cognitive health of elderly individuals, according to this hypothesis people presents different level of flexibility and adaptability of brain networks, therefore respond and presentation of age related brain changes are different among elders.

In order to improve the quality of life and preserve cognitive reserve among the elderly, several interventions have been proposed. These activities that are known as cognitive stimulation for adults with different mental conditions, offer a range of activities that provide general enhancement of thinking and concentration. Older adults can benefit from various activities that focus on particular cognitive skills, for instance, memory training can yield significant memory performance. Evidence shows that the elderly can learn new things and that cognitively older people are more likely to preserve their cognitive abilities than the inactive ones.

Taking care of patients with dementia and other degenerative brain diseases has enormous consequences...
for their families in terms of their social lives and finances.

Although the cognitive stimulation intervention and its contribution in preservation of cognitive reserve for the elderly is widely discussed in the literature, little has been done to show the public perception and their engagement in this process. In this study we investigated the public perceptions and engagement in cognitive stimulation to preserve the cognitive reserve among the elderly in Malaysia. Engagement in cognitively stimulating activities to preserve cognitive reserve among the elderly in Malaysia is significant because the country has a growing population of individuals aged 60 years and above. Currently, Malaysia’s population above the age of 60 is close to 10% and is estimated to reach 15% in 2035.

According to a report by the Alzheimer’s disease International report, the occurrence of dementia in the country in the year 2005 was 0.063% with an annual incidence rate of 0.020% in the same year. This figure is projected to increase to a prevalence of 0.126% in 2020 and 0.454% in 2050. With its morbidity and rapid growth, dementia ranks second on the burden of ailments in the Asia Pacific region compared to peptic ulcer, breast cancer, malaria and sexually transmitted diseases excluding HIV/AIDS.

Methodology

Study design and sample

This study is a cross sectional questionnaire pilot study on public perspectives & engagement in cognitive-stimulation activity to preserve cognitive reserve among elderly in Malaysia. The inclusion criteria for this study were: (i) Males and females between ages 55 and 70, (ii) Respondent who did not exhibit any symptom of cognitive disability, (iii) English literate and (iv) Consented for study. The exclusion criteria for this study was (i) Clinically diagnosed cognitive disability disorders (ii) Did not consent for study. Prevalence of dementia among Malaysians is unknown. As such, this study is carried out as a pilot study involving 150 respondents.

Ethical approval: Protocol for this study was submitted to UCSI University, Faculty of Medicine and Health Sciences, Ethics Committee and was approved via code Proj-FMHS-EC-2015-518. This research was carried out in accordance to principles outlines in the Declaration of Helsinki.

Data collection

Subjects were recruited, according to inclusion and exclusion criteria and questionnaire survey had been conducted following explanation on the study and informed consent taking. The questionnaire used in the study was divided into several parts as follows: (i) Social demographic questionnaire, (ii) Cognitive Reserve Index questionnaire (CRIq), (iii) The Informant Questionnaire on Cognitive Decline in the Elderly (IQCODE), (iv) Perspective on cognitive stimulation activity to maintain cognitive function, (v) Engagement in cognitive stimulation activity to maintain cognitive function.

Data analysis

The analysis of data was done using the statistical package for social sciences. The data was analyzed using statistical test SPSS 18.0 (Statistical Package for Social Studies) Descriptive analysis, t-test, Pearson’s Correlation analysis. The t-test analysis was used mainly in the comparison of data sets and was efficient because of the small sample that was used in the study. The level of significance set at p<0.05 and confidence interval, CI=95%.

Result and Discussion

Cognitive Reserve Index Questionnaire (CRIQ)

For CRI Education, results on this area showed that 7 (11%) of the total 66 (44%) respondents reported had spent nine years up to the higher education. Also, 16% and 10% of the total respondents with higher education had spent 3 years and 4 years respectively in school. The rest (7%) had spent six years in school, including higher level education. A total of 104 (69%) respondents had educational training that would help them to secure an employment, which can help them attain cognitive reserve.

For CRI working activity, results on CRI working activity was recorded according to skills of the respondents as skills in manual work, skills in non-manual work, professional occupation and intellectual occupation. Most of the participants (33%) had professional occupation such as teacher, doctor and
qualified freelance professional. This group was followed by skilled manual workers with a frequency of 48 (32%), working in different jobs such as tailoring, hairdressing and cooking. The other group with a significant representation was the skilled non-manual workers with a frequency of 19 (13%). Additionally, those with the low skills such as gardeners and waiters as well as those with intellectual occupation such as university professor, judge and senior managers had the lowest frequency of 17, which is 11% of the total sampled population.

For CRI leisure time, result attained showed that on the monthly basis, gardening, DIY and small-scale operations such as knitting were the most frequently practiced activities (67%), followed by social activities such as associations and recreational clubs (57%) and looking after grandchildren or elderly parents (56%). The least reported activities were artistic activities such as music, painting and writing (68%), followed by cinema/theatre and voluntary with about 65% and 62% of the total sample respectively.

The other frequency was on the annual basis and recorded three main activities; exhibitions/concerts, reading books and journeys. The most frequently recorded activity in one year was reading book (75%). The least activity was travelling/journeys for days with 44% of the respondents. The other significant activity was exhibitions, which was practiced by 66% of the total. Regarding the fixed frequency, the study included children, pet care and managing current account. Respondents with children were 75% while those that always or often care for pets were 77%. Also, 63% of the participants were managing their current accounts.

The scores of the three subsections of CRIq; education, working activity and leisure time were correlated with age. The raw scores for education was r=0.639, working activity with r=0.505 and leisure time r=0.556. The age effect was accounted for by standardizing the raw sub-scores through linear models where each sub-score was the dependent variable and age was the predictor variable. Therefore, it provided standardized scores of CRIq for every section and the total CRIq score. The CRI was transferred to the scale with M=99, and SD=15. The total scores of CRI were categorized into five levels: Low (<70), Medium Low (70-84), Medium (85-114), Medium High (115-130, High (>130).

The Cognitive Reserve Index Score

Among the 150 participants of this study, no subject had low CRI score. The raw score for CRI education was higher in the group aged 55-60 (M=25.93 and SD=7.53) as compared to those aged from 61-65 years (M=18.70 and SD=7.30) and those from 66-70 years (M=7.29 and SD=6.39). Professional work was the most frequent occupation level recorded where those below 60 years accounted for 39% of the total sample while those aged between 61 and 70 years more frequently reported unskilled and skilled manual work (45% and 60% respectively). In CRI leisure time, the frequently reported activities were driving, reading newspapers and magazines, sports, using new technology and domestic chores. Regarding gender differences, women had slightly higher raw score for CRI education, but lower raw scores for CRI leisure time and working activity.

The total CRI score strongly correlated with all the three sub-scores where the correlation with CRI education, CRI working activity and CRI leisure time was r=0.775, r=0.854 and r=0.785 respectively. However, the inter-correlations between sub-scores were low since between CRI education and working activity raw score was r=0.506, between CRI education and leisure time, r=0.352 and CRI working activity and leisure time r=0.529.

All the total scores for CRI as well as each particular sub-score were significantly influenced by age. Those aged up to 60 years had higher CRI score (M=109.49, SD=15.20) than those aged up to 65 years (M=99.35, SD=11.45) as well as those aged up to 70 years (M=90.51, SD=16.13). Also, all the post-hoc comparisons were significant at 0.05 level, where F=34.7 and p<0.001. The group aged between 61 and 65 also exhibited higher CRI education (F=6.41, p<0.05), CRI leisure time (F=25.72, p<0.01) and CRI working activity (F=43.61, p<0.01) than the other two groups. Again, all the post hoc comparisons in the groups were significant at the 0.05 level. The interaction of age accounted for a considerable variance amount of CRI and CRI sub-score.

The IQCODE Assessment

This test offered situations that made respondents use their intelligence or memory to determine whether it has improved, gotten worse or remained the same over the past ten years. The questions had a 5-likert scale,
providing five choices the respondent would choose from: much improves, a bit improve, not much change, a bit worse and much worse. The rating scale was designed deliberately to reflect the cognitive improvement and decline.

After ten years all respondents their ability to remember things have not improved even a bit, but have only either gotten worse, a bit worse or changed a little. Some of the things most respondents could remember were; remembering what day and month it is (88%), knowing how to work familiar machines around the house (85%) and Following a story in a book or on TV (84%). On the other hand, things that respondents could barely remember were; handling financial matters e.g. the pension, dealing with the bank (13%), Making decisions on everyday matters and handling everyday arithmetic (11%) and Learning new things in general (66%).

Perspective on Cognitive Stimulation Activity To Maintain Cognitive Function

Ten questions were used to understand participants’ perspectives regarding how cognitive simulation activity to preserve cognitive function. From the findings most respondents (65%) agreed that CSA helps in promoting good cognitive function and while 85% of the respondents approved that social networking severely promoted cognitive function with age. Also over 80% of the respondents mentioned that mental and physical activity facilitates good cognitive function. As a result, more than 55% agreed that it is important to have mental and physical activities or have hobby or part time activities to improve cognitive function. When asked if cognitive stimulation activities are organized in the community, most (65%) said that a little of them are available while 35% did not know when they existed.

Overall Discussion

This study on public perspectives and engagement in cognitive stimulation activities shows that cognitive reserve is maintained, especially among the older population by involving in activities that improve the brain performance. Some the activities indicated from the results that can preserve cognitive reserve were driving, reading, and playing chess, which promote brain function. These findings are constituent the study of Eckroth-Bucher and Siberski on exercise that improve cognition through training and stimulation programs. The authors indicate that cognitive stimulation has direct effects on the brain substrates, which support cognition. They add that physical exercise and simulating environments promote neurogenesis, enhance neuronal plasticity and prevent cell death.

These results are consistent with the study by Jansen et al. where they mentioned that cognitive impairment is attributed to aging population as compared to a young person. Higher remembrance scores among the older population are on daily easy tasks such as daily chores because they are used to doing them every day.

Most of the participants believed that cognitive stimulation activities such as social networking as well as physical and mental activities facilitate cognitive function with age. Other studies also showed that better cognitive functioning is associated with high levels of social integration and activity. Beside, positive connection between social support and cognate function among the older people, which is consistent with the current study has been reported. Moreover, Wilson et al. found that frequent mental and physical activities positively lead to cognitive function among the elderly, which matches with the results found in this study.

The questions on the engagement in the cognitive stimulation activity were aimed to understand the respondents’ involvement in activities that can maintain cognitive function. Most of the respondents engaged in CSA activities by living a healthy life that prevents poor cognitive function. Most were willing to participate in cognitive stimulation programmes in their community to promote better quality life. Over 50% of the respondents also mentioned that keeping fit and modifying lifestyle can assist in maintaining cognitive function. These results are consistent with other studies who found out that staying fit enhances mental health and cognitive function.

Conclusion

Results were obtained from three instruments and they included the cognitive reserve index questionnaire, the IQCODE questionnaire and questions on perception and engagement in CSA. These different data collection instruments facilitated the production of complex feedback on the relationship between CSA and better cognitive and mental function. From the CRIq, respondents with high education level and vocational training recoded better cognitive function.
On the aspect of working activity, most respondents did skilled annual work as well as professional work, which are associated with high cognitive function. From the IQCODE questionnaire, where the intelligence and memory of respondents was measured shows the events that older people can remember after ten years. The most remembered events are the current day and month and operating familiar home appliances. However, most of the participants hardly remembered handling financial matters and arithmetic. These results indicated that older people are likely to remember activities they do on a daily basis that those involves complex computation of numbers.

Quality of Life in Adults with Androgenic Alopecia

Lim Wan Chyi¹, Eugenie Sin Sing Tan², Chew Kek Lee³, Navedur Rehman², Loh Wei Chao⁴, Tan Chung Keat²

¹Medical Doctor, Crown Clinic, Kuala Lumpur, Malaysia, ²Faculty of Medicine and Health Sciences, UCSI University, Kuala Lumpur, Malaysia, ³Medical Doctor, Pantai Hospital Cheras, Kuala Lumpur, Malaysia, ⁴Faculty of Medicine and Health Sciences, Universiti Putra Malaysia

Abstract

Androgenic alopecia (AGA) is a common hair loss disease with genetic predisposition among men and women. AGA may start any age after puberty and is affecting one’s social aspects as well as significantly impacted psychological and overall of quality of life. Medically, AGA is considered a mild dermalogical illness. However, those suffering from the illness might feel that alopecia is a serious condition with major distress in life and how other people view them as well as their employment opportunities. As hair is a crucial component of one’s appearance and self-identity, patients with androgenic alopecia (AGA) may experience a self-confident distorted and negative feelings of social disadvantages, dissatisfaction, embarrassment, and lack of self-confidence. The purpose of this study was to assess the quality of life among local adults with androgenic alopecia, using 2 validated questionnaires: The Dermatology Life Quality Index (DLQI) and the Hairdex Score System (HSS). Association between quality of life in AGA patients with gender, age group, marital status and employment status was also evaluated. This cross-sectional study was conducted among adults with androgenic alopecia visiting a private clinic in Cheras, Selangor. In this research study, 125 patients (84 male and 41 females) (aged 20 years and above) completed 2 validated questionnaires, DLQI and HSS. Statistical Package for Social Science (SPSS) is used in this study. The results showed that quality of life impairment increases with increasing severity of androgenic alopecia. (p=0. 000). Males had higher impairment of quality of life than females. (p=0. 000) The quality of life in employed patients was more impaired than the unemployed. (P<0.01) The study can conclude that Androgenic Alopecia shows a considerable impact on quality of life among adults.

Keywords: Androgenic alopecia; AGA; hair loss; life; quality

Introduction

Androgenic alopecia (AGA) is a common hair loss disease with genetic predisposition among men and women. AGA may start any age after puberty and is affecting one’s social aspects as well as significantly impacted psychological and overall of quality of life¹.

Medically, AGA is considered a mild dermalogical illness. However, those suffering from the illness might feel that alopecia is a serious condition with major distress in life and how other people view them as well as their employment opportunities².

In women, AGA develop with a diffuse thinning over the scalp producing a “Christmas tree like” pattern. The thinning is from the top of the scalp towards the front, maintaining the frontal hairline. While in most men, AGA commonly develops markedly individually. It can happen with different type of patterned hair line recession³.

However, some of the women with excessive androgen production might also develop a male-like hair loss. And some of the men might occasionally experiencing a female type hair loss. And there is a commonly misdiagnosed in frontal fibrosing alopecia in women, which is a type of scarring alopecia with recessing hairline in women. Where the diagnosis is
in doubt, a biopsy be done. It has been reported that patients with androgenic alopecia have low self-esteem, lack of confidence and impairing their quality of life.

There are also studies reported that dissatisfaction with self image, identity, appearance, lack of self confidence, and embarrassment in AGA patients. AGA patient may also have a negative impact on personal relationships, sports activities, and employment opportunities.

As hair is a crucial component of one’s appearance and self identity, patients with androgenic alopecia (AGA) may experience a low self esteem and negative feelings of social disadvantages, dissatisfaction, embarrassment, and lack of self-confidence. In Malaysia, there are limited data on the impact of androgenic alopecia. In Cheras, Selangor this issue is unknown and would be interesting to study.

Many studies have been conducted previously about quality of life in androgenic alopecia patients. However, in Malaysia, no similar study was conducted among the local population. This study is done to analyze the quality of life among local adults with androgenic alopecia. The analysis was done in terms of its association of androgenic alopecia with age, gender, severity and employment among the local population.

Methodology

This study will be a cross sectional survey with the questionnaire. The total time interval from the identification of topics, data collection, and analysis and until the final submission of the paper will be 6 months. The research proposal and ethics form, patient informed consent, case report form and other relevant forms/permission letters will be sent to the ethical committee for notification purpose. 125 patients will be taken into the study, who fulfill the inclusion and exclusion criteria, visiting the study location which is Crown Clinic, Cheras, Selangor. Sampling method will be based on inclusion and exclusion criteria. The inclusion criteria is, i) Patients who are age above 21 years old, ii) Presence of androgenic alopecia during the survey, iii) Gender: both male and female, iv) Nationality: Malaysian, v) Race: All races vi) Educational level: Able to read and write in English, vii) Patients who have healthy mentally and physically. The exclusion criteria is patients with existing chronic medical illness.

As for data collection, Patients who complain androgenic alopecia and visiting the study location will be identified and screened based on inclusion and exclusion criteria. Patients who are fulfilling the inclusion and exclusion criteria will be informed about the study and if they agree to participate, they will be given consent form, patient information form and case report form to be filled. Severity of androgenic alopecia will be assessed, then by the investigator using Norwood-Hamilton classification for male and Ludwig classification for female and grade will be given. Patients are then given the DLQI and HSS questionnaire to answer. The DLQI and HSS questionnaires consist of 10 and 20 questions each and will not take more than 20 minutes to be answered. Participation in the survey will be voluntary and patients are allowed to change their mind at any time and withdraw from the study without giving a reason if they intend to. Statistical analysis will be performed with Statistical Package for the Social Sciences, SPSS version 19.0.

Result and Discussion

Based on the analysis done, it was found that, 17 (13.6%) patients had Norwood Class Type I and among them 1 patient (0.8%) gave a score of 0-1, 1 patient (0.8%) gave a score 2-5, 15 patients (12.0%) gave a score 11-20. 14 (11.2%) patients had Norwood Class Type II, 13 (10.4%) patients gave a score 11-20, and 1 patient (0.8%) gave a score >20. A total of 28 (22.4%) patients had Norwood Class Type IIa, 1 (0.8%) gave a score 6-10, 27 (21.6%) patients gave a score 11-20. 9 (7.2%) patients had Norwood Class III, all of them gave a score of 11-20. 10 (8.0%) patients had Norwood Class Type III Vertex, 1 (0.8%) gave a score 6-10, 9 (7.2%) gave a score 11-20. 2 (1.6%) patients had Norwood Class IIIa, 2 (1.6%) gave a score 11-20. 2 (1.6%) patients had Norwood Class Type IV gave a score 11-20. 1 (0.8%) had Norwood Class IVa and 1 (0.8%) had Norwood Class V, who gave a score 6-10 and score 11-20 respectively. A total 41 (32.8%) female patients had Ludwig Type 1, all of them gave a score 11-20.

HSS score for Norwood Class I has sample mean of 2.1765 and standard deviation of 0.72761, Norwood class II has sample mean 2.5 and standard deviation of 0.65044, Norwood class IIa has a sample mean of 2.25 and standard deviation of 0.84437, Norwood class III has a sample mean 2.444 and standard deviation of 0.72648, Norwood class III vertex has a sample mean of
2.2 and standard deviation of 0.91894, Norwood Class IIIa has a mean sample of 2.0 and standard deviation of 1.41421, Norwood Class IV has a mean sample of 1.0, Norwood Class IVa has a mean sample of 1.0 and Norwood Class V has a mean sample of 2.0. The Ludwig type 1 has a mean sample of 2.3650 and standard deviation of 0.62274.

In the homogeneity of variances in severity and HSS Score, the P-value or Levene Statistic is 0.009, which is less than 0.0. Therefore the result is significant as shown in Table 1.

From the Table 2, Anova test for severity and HSS score showed the P value of 0.216, which is more than 0.05, therefore the result is significant. The HSS score depends on the severity of androgenic alopecia. In addition, outcome of Tamhane test shows that DLQI scores of different age group significant differs with each other (P<0.05).

Based on Table 4, DLQI score for single patients with a sample mean of 4.00 and standard deviation of 0.00, married patients with a sample mean of 3.9817 with a standard deviation of 0.19157, in a relationship patient with a sample mean of 3.3750 with a standard deviation of 1.18773. Thus, there is a significant association between ages and DLQI in this group.From Table 5, outcome of Tamhane test shows that DLQI score of different status significantly differs with each other (P<0.005).From Table 6, Pearson Chi-Square statistic is 5.765 and degree of freedom is 4. The P-value is more than 0.01. The minimum expected count is 0.37, which is below 1. Thus, there is a significant association between employment status and DLQI in this group.

Thus overall, Androgenic alopecia commonly begins at the ages of 12 to 40 years in both female and male. The severity of androgenic alopecia is highest in Caucasian than Asians and African. In the present study, 125 patients with AGA and DLQI was used to assess their quality of life. The number of Chinese patients were 109 (87.2%) as compared to 11 (8.8%) Malay patients and 5 (4%) Indian patients.

The quality of life patients with androgenic alopecia is measured via the dermatology life quality index (DLQI) and Hairdex Score System (HSS). For the purpose of statistical analysis, both the DLQI and HSS scores are used. Analysis reveals that the severity of androgenic alopecia has significant outcome of the patients’ daily activities. The analysis of DLQI score and severity of AGA showed that DLQI is not dependent on severity, however the results were not conclusive.

From the analysis of HSS score, the mean of HSS score becomes higher when the severity of androgenic alopecia is higher, showing a significant difference between mean score and severity in the study. A similar finding was noted by Cartwright, Endean et al. in their study, which reported a positive association between androgenic alopecia severity and poorer quality of life. This is because when the patients has a more severe form of AGA, he or she may feel more embarrassed, vulnerability and lack of confidence and would avoid social activities such as meeting their friends on leisure time, going shopping, outdoor activities and even engaging in sports. This finding was also supported by the previous research done by SawanChikhalkar et al. in hair clinic of the dermatology outpatient of Hospital in Mumbai. There are a few studies done in which the results showed that impairment of quality of life in female were more than men. There is also supported by a study done by Masmoudi, Sellami et al. where the female more psychological impact compared to male as they believed the physical appearance can indeedly increase a woman’s self-esteem.

In this study, the patient’s age was also correlated to the psychological impact. This finding was also supported by the previous research done by the Korea multicenter study among the local population where the younger age group has a significantly higher impact on their quality of life. A similar finding was also noted in the study done by Bhargava et al. where the quality of life was more pronounced in the younger populations.

The hair loss was indeedly more concern and most vulnerable in the younger age. This result, however, stands in contrast to the previous study done by Sawant, Chikhalkar et al. where older patients seemed to be more severely distressed.

**Conclusion**

The current study concluded that the patients with androgenic alopecia has significantly impact on their quality of life. There is an association between patients’ psychological perception about their illness and the severity of their condition. From the results, it concluded that the strong relation between the severity of androgenic alopecia and patients’ quality of life impairment among local adults. It shows that the patients with increase severity of androgenic alopecia has a significantly decreased their quality of life. As for the gender-based response, the quality of life in males was more affected than female patients and the employed patients more suffered quality of life impairment if compared to the unemployed patient. Not surprisingly, the finding concluded that the younger age group who suffering androgenic alopecia had more impact than older groups. It is strongly believed that physical appearance is important for the younger age patients. With the onset of hair loss could significantly reduce their self-esteem and might face difficulty in finding a life partner or looking for an employment. As androgenic alopecia shows a significant affection of quality of life among the patients, measures should be taken to treat it early and effectively.

Factors Associated with Beliefs and Attitudes in Organic Food Purchase among Adults in Klang Valley

Lee Keat Yan¹, Kavita Chirara¹
¹Faculty of Applied Sciences, UCSI University, 56000 Cheras, Kuala Lumpur, Malaysia

Abstract
Organic food are produced without the use of fertilizers, pesticides, growth hormones, genetic modified, irradiation and antibiotics. The aim of this research is to examine whether there is an association between the four variables (product, lifestyle, regulatory and ethnocentrism) and beliefs and attitudes in organic food purchase among adults in Klang Valley. This research is conducted by quantitative method and using questionnaire with a title of “factors associated with beliefs and attitudes in organic food purchase among adults in Klang Valley” for data collection. Furthermore, this research targeted on adults with age ranging from 18-64 years old. The sample size consists of 350 respondents and all the data were collected in the Klang Valley area. Data analysis were performed by using Software Package for Social Sciences (SPSS) Version 19. Three hypothesis related to product, lifestyle and regulatory was accepted and one hypothesis related to ethnocentrism was rejected. The result shows that there is a significant positive association between the three variables (product, lifestyle and regulatory) on beliefs and attitudes in organic food purchase among adults in Klang Valley.

Keywords: Organic food; factors; purchase; attitudes; adults

Introduction
These days, enthusiasm for naturally delivered nourishment is expanding all through the world because of worries about agrarian practices and their potential consequences for human wellbeing and on the earth¹. As indicated by Sheng et al.², natural sustenance industry has been quickly developed far and wide with the aggregate territory of 30.5 million hectares. Other than that, the worldwide natural market has accomplished 23 billion USD in 2003. In 2005, the market has come to 33 billion USD, constantly expanded to 40 billion USD in 2006². Furthermore, around 90 creating nations, of which around 15 are Least Developing Countries (LDCs) are delivering affirmed natural and picking up the critical offer from the worldwide natural nourishment showcase³.

In Malaysia, the fast financial improvement, increment in way of life, and changes in way of life has changed the structure of agri-nourishment generation so as to take care of the demand by the more rich society. In this way, the interest for natural sustenance is significantly ascending in Malaysia as the populace turns out to be progressively instructed about wellbeing and health issue that prompts a more noteworthy cognizance in the nourishment decisions ⁴. In 2001, for example, just 131 hectares (ha) in Malaysia were natural ranches. In the following five years, the land zone for natural homesteads quickly developed by multiple times to 2,367 ha, of which 962 ha are maybe guaranteed natural,⁵. In any case, The Malaysian Agricultural Research and Development Institute (MARDI) expressed that the neighborhood natural sustenance industry is still of a little source. Moreover, in excess of 60% of natural sustenance items are transported in⁶.

Next, past investigations have demonstrated that the three most concerning components of shoppers in natural sustenance utilization are nourishment security, the insurance of the earth and creature welfare⁷. Other than that, past investigations are concentrating more on how statistic qualities influence shopper acquiring conduct on natural nourishment⁸. In spite of the fact that
there are numerous investigations have been directed and they have recognized different variables or determinants which influencing purchaser acquiring conduct toward natural nourishment. Shockingly, the outcomes that acquired are not steady.

In Asian nations, the interest of natural sustenance isn’t as high as Western nations. In this way, enhancing open mindfulness and discernment towards natural sustenance will build customers’ goals to buy natural nourishment. In Malaysia, there are as yet various individuals who are new towards natural nourishment. The assortment of natural sustenance is lesser contrasted with ordinary nourishments and the greater part of the purchasers are worried about the cost of natural sustenances and not willing to paid for it.

The principle reason for this exploration is to examine how the accompanying measurements: item, administrative, way of life and ethnocentrism related with convictions and frames of mind in natural nourishment buy among grown-ups in Klang Valley.

Methodology

Study Design and Sampling Method

This is a cross-sectional investigation which is led to discover the pervasiveness of the result of enthusiasm inside the populace at a given timepoint. This study meant to assess the variables that related convictions and frames of mind in natural nourishment buy among grown-ups.

Study Location

This research study was carried out in public area of Klang Valley. Thus, this study will be carried out in Mid Valley shopping mall, Aeon Cheras Selatan, Aeon MahkotaCheras, BMS Organic Shop and Carelife Organic Shop.

Study Subject and Sample Size

In this research all the respondents is within the age of 18-64 years old which from Klang Valley area. The sample size of this survey can be determined by using the formula stated below. Therefore the total number of sample size calculated by using the formula was 350 Malaysian adults.

Data Source and Collection

In this examination, every one of the information are gathered from essential sources and optional information. Essentially this survey was isolated into two sections: area A was social statistic profile and general data while segment B was build estimation. In area A, there were an aggregate of eight inquiries asked under the respondents’ statistic segment which included age, sexual orientation, ethnicity, conjugal status, month to month salary, staying condition, instruction level and occupation. In segment B there are an aggregate of 28 questions were adjusted from questions were adjusted from. In this study, 340 of questionnaires were distributed to the respondents. There were 310 usable questionnaires returned for a response rate of 91.2%.

Data Analysis

Data was examined utilizing Statistical Package for Social Science (SPSS) Version 19. Cronbach’s Alpha test was utilized to test the interior unwavering quality of information. Pearson’s connection was led to estimated the connection between the factors.

Result and Discussion

Mean Score of Product

Table 1 shows the respondents reaction towards questions related to product. The question of “Organic food has high nutritional value” has the highest mean of 4.11. The overall mean for all the questions related to product is 3.587 which is the second highest after lifestyle.

Mean Score of Beliefs and Attitudes

The question of “Organic food is good for the environment” has the highest mean of 4.01. Therefore, consumers believe that purchase organic food will benefit to the environment as organic food is produced naturally. Furthermore, question of “I believe organic food has superior quality” has the second highest mean of 3.94. This is consistent to the previous literature review which mentioned that purchase organic food was an event of selecting quality goods. The overall mean for all the questions related to beliefs and attitudes is 3.4430 which is the second lowest among all the factors.

Scale Measurement

In view of Table 5, In this investigation, Cronbach’s alpha was use to analyze the inside dependability of the 28 things and used to gauge the 5 builds. Every one of the builds extended from 0.649 to 0.774. While ethnocentrism had the most noteworthy coefficient (0.774) and item had the least coefficient (0.649). Besides, every one of the builds under scrutiny fall on the moderate solid class.

Inferential Analysis Pearson Correlation Analysis

As indicated by Table 6, it has demonstrated that the relationship network for the four inspected factors which were item, way of life, administrative and ethnocentrism. Every one of the builds demonstrates positive relationships since none of the develops had negative sign.

In this investigation, way of life has demonstrated that $r = 0.558$ which is the most noteworthy among every one of the develops, critical at 0.01 dimension. In addition, way of life falls on the moderate solid class. Next, it was item with a moderate solid relationship $(r=0.509)$, administrative with a frail relationship $(r=0.358)$. In any case, theory 4 was rejected on the grounds that the outcomes show ethnocentrism has a positive relationship $(r=0.208)$ on convictions and dispositions to buy natural nourishment. In this manner, we can infer that ethnocentrism has noteworthy positive effect on convictions and frames of mind in natural sustenance buy rather than negative impact. All connections were noteworthy at 0.01 dimension.

**Correlation is significant at the 0.01 level (2-tailed).**

*Correlation is significant at the 0.05 level (2-tailed).**

**Overall Discussion**

For H1: Organic sustenance item related properties has a positive relationship on the convictions and demeanors in natural nourishment buy among grown-ups in Klang Valley. In light of the outcome appeared, the relationship between item related properties with the convictions and dispositions in natural sustenance buy among grown-ups is huge at 0.01 dimension with a r-estimation of 0.509. Item is the second most critical build that related customer’s convictions and frames of mind after the way of life develop. This present finding is predictable with the result of Chen which they discovered that item related traits have impact on shopper’s buy aim towards natural nourishment.

For H2: Regulations related with natural nourishment has a positive relationship on the convictions and dispositions in natural sustenance buy among grown-ups in Klang Valley. The relationship between administrative with the convictions and frames of mind in natural nourishment buy among grown-ups is critical at 0.01 dimension with arvalue of 0.358. This is predictable with Chen ponder which he discovered that individuals trust that with government bolster, the nature of natural sustenance would be upgraded and their wellbeing would be moved forward.

For H3: Lifestyle has a positive relationship on the convictions and demeanors in natural sustenance buy among grown-ups in Klang Valley. The relationship between way of life with the convictions and frames of mind in natural nourishment buy among grown-ups is huge at 0.01 dimension with a rvalue of 0.558. Way of life is the most vital develop that related shopper’s convictions and frames of mind in natural nourishment buy. The outcome is predictable with an examination led by Gill et al. which they discovered that way of life is an essential factor in clarifying natural nourishment utilization.

Lockie et al. recommend that utilization of natural nourishment mirrors a ‘greening customer ways of life’. They trust that by expending natural sustenance will profit to the earth since natural nourishment don’t have pesticides.

As indicated by Table 3, respondents would love to have a go at something new and in vogue along these lines they might want to attempt more and appreciate the natural sustenance traits. This is bolstered by Rotiner-Schobesberger et al. as they uncovered that the second most imperative intention in the buy of natural nourishment was its fascination as new and in vogue. As more data is attained, shopper will have higher mindfulness and information of their own wellbeing which will make an interest for natural nourishment.

Subsequently, the present examination proposes that way of life has a positive relationship on the convictions and frames of mind in natural sustenance buy among grown-ups in Klang Valley.

For H4: Ethnocentrism has a negative relationship on the convictions and mentalities in natural nourishment buy among grown-ups in Klang Valley. Result showed that Ethnocentrism has a negative relationship on the convictions and dispositions in natural sustenance buy among grown-ups in Klang Valley.

Then, as natural nourishment is seen as earth agreeable, hence customers may will in general buy natural sustenance from nearby sources rather than transported from abroad.

**Conclusion**

Taking everything into account, the fundamental target is to look at the relationship between item,
administrative, way of life and ethnocentrism and shopper’s convictions and demeanors in natural sustenance buy among grown-ups in Klang Valley. This investigation will be noteworthy and helpful to advertisers to advance and expand the offers of natural nourishments by comprehend the purchasing conduct of buyers. As indicated by the last outcomes, all the three autonomous factors (item, administrative and way of life) has positive relationship on customer’s convictions and mentalities in natural sustenance buy among grown-ups. Among the three free factors, way of life is the most grounded factor that related buy goal. As way of life implies the courses gatherings of purchasers invest energy and cash.

Assessment of Knowledge, Attitude and Practice of Malaysian Women towards Cervical Cancer Vaccination

Mohammad Arief1, Loh Jia Ying1

1Faculty of Pharmaceutical Sciences, UCSI University, 56000 Cheras, Kuala Lumpur, Malaysia

Abstract

Cervical cancer vaccination of adolescent girl effectively reduces the risk of developing precancerous lesions caused by the causative agent, Human Papillomavirus (HPV). Cervical cancer is the second leading cause of female cancer in Malaysia despite the availability of HPV vaccine. This study aims to assess the knowledge, attitude and practice (KAP) of Malaysian Women towards cervical cancer vaccination. A cross sectional study was carried out through convenience and purposive sampling method. English literate women with Malaysian citizenship above the age of 18 years old are included into the study. Based on Krejcie and Morgan calculation, a sample size of 384 women is required. Potential women participants were recruited randomly at Klang Valley (which includes Federal Territory of Kuala Lumpur, Selangor districts of Petaling, Klang, Gombak, Hulu Langat) via a self-administered questionnaire that had been validated and pre-tested among 20 women to determine the reliability of the questionnaire. The study result showed that 94.6% of the participants showed good knowledge towards HPV vaccine. On the other hand, the overall attitude and practice level is found to be poor, reported to be 53.1% and 65.1% respectively.

Keywords: Cervical cancer; vaccine; knowledge; attitude; woman

Introduction

Cervical cancer vaccine, also known as HPV vaccine, is an inactivated vaccine that provides protection against Human Papillomavirus (HPV). There are many different types of HPV, categorized into ‘low risk’ and ‘high risk’. Some of high risks HPV leads to cervical cancer1. There are three types of HPV vaccines available in the market, Cervarix®, Gardasil® and Gardasil-9®. These current HPV vaccines work based on virus-like particles (VLPs) which closely resemble the natural virus and stimulate the production of antibodies which will bind to any HPV virus encounter in the future and prevent it from infecting healthy cells. Lacking of virus’s DNA makes VLPs not infectious but remains highly immunogenic thus making the vaccine highly effective2. A total course of 3 doses of HPV vaccination are injected over a 6 months period (at 0, 2, 6 months)3.

All HPV vaccines had been proved to be safe and effective by the US Food and Drug Administration (FDA) prior licensing and marketing through three phases of clinical trials. Post licensure safety of vaccine is closely monitored through the Vaccine Adverse Event Reporting System (VAERS), Vaccine Safety Datalink (VSD), Clinical Immunization Safety Assessment Network (CISA) system. There are no serious side effects shown to date and most common problems like nausea, soreness at injection site, fever and etc are usually mild and short-term4. Multiple studies supported that the vaccines are safe to be used5,6.

HPV vaccines are both effective and safe but yet the US National Data from 2014 shows that the vaccination coverage is low. Less than 40% of eligible female completed the three dose injection course even when 60 % of eligible females received the first initial dose7. It is urge to increase the nation vaccine coverage by The President’s Cancel Panel (PCP) and National Vaccine Advisory Committee (NVAC) through 4 goals established by PCP and an additional 3 recommendations made by NVAC8.
Study conducted in the Saudi Arabia concluded that the knowledge and perception of HPV attributed cervical cancer risk and HPV vaccination was low. Only 34.5% participants were aware of HPV while the other 65.5% never heard about it. Most of the respondents (72.6%) did not know about the role of HPV in etiology of cervical cancer. Only 32.3 % participants were aware of the ability of HPV vaccine to prevent cervical cancer and other HPV-related STDs. However, good news was that the rate of acceptance of HPV vaccine was higher among the participants.

In first world country such as Australia, data found from the National HPV Vaccination Program Register (NHVPR) 2003 showed high vaccination uptake rate (86%) of Australian adolescent girls. United Kingdom and Denmark also reported 87% and 89% of school-aged girls receiving at least one vaccine dose, with 85% and 74% receiving all three doses, respectively. Participants showed high level of knowledge; 97% of them knew HPV causes cervical cancer and 99% knew regular Pap Smears were required after HPV vaccination and 68% knew HPV causes genital warts. HPV vaccination uptake rate by women is assessed in other countries yielding different outcomes of levels of knowledge, attitude and practice that vary in association to multiple demographic and socioeconomic characteristics. Such data, however, is lacking in Malaysia to date. Awareness of cervical cancer and HPV vaccination among rural folks in Penang, Malaysia showed low knowledge about HPV and HPV vaccine (29.3% and 42.2% respectively) even most participants (88.8%) knew about cervical cancer. It was shown that the cost of HPV vaccine is a barrier of public folks getting vaccinated.

In Malaysia, Pap smear screening program launched in 1969, however only about 850,000 women have undergone cervical cancer screening tests out of the eligible 5.2 million female populations. Low Pap smear screening rate and low HPV vaccination rate of the female population despite cervical cancer being the second most frequent cancer among women between age 15 to 44 years of age imply that they would be also less aware of knowledge and practice of HPV vaccination.

Thus, this study aims to assess the knowledge, attitude and practice (KAP) of Malaysian Women towards cervical cancer vaccination.

Methodology

Study Design

A cross sectional survey was conducted in Klang Valley for two months (July and August 2017) with the aim to study the KAP of the targeted population on cervical cancer vaccination.

Sampling and Sample Size

A convenience and purposive sampling method was used in this study. Sample size was calculated using Krejcie and Morgan calculation with 5% margin of error and 95% confidence interval. Based on this, the minimum sample size required was 384 for this study. 482 potential participants were approached but 61 of them refused to participate. Out of the 421 filled questionnaires, 392 were analyzable. The respond rate was 81.3%. The inclusion criteria were Malaysian women citizen whom aged between 18-60 and English literate; exclusion criteria were one who refuse to participate and unfit women. The validated questionnaires were given to respondents after they agreed to participate in the study. An informed consent form is attached along with every questionnaire. Participants were aware that their willingness to participate were fully respected. Their anonymity and confidentiality were preserved.

Study Instruments

A self-administered questionnaire was adapted and modified from previous studies. The questions were constructed into four sections. The first section focused on demographic characteristics of participants. The second section addressed the participants’ level of knowledge towards cervical cancer and its vaccine. The third part measured the attitude of participants towards HPV vaccine and the forth part assessed the practice of participants towards HPV vaccine. All the items in the questionnaire were evaluated by experts. A pilot study was undertaken, during the first phase of which a convenience sample of 20 women were asked to complete the questionnaire. Modifications in the questions were done based on the response of the participants and then it was subjected to second phase of pilot study to determine the reliability. Cronbach’s alpha of the final questionnaire was found to be 0.71.

Statistical Analysis

SPSS Software Version 20 was used to analyze data.
Descriptive analysis was used to tabulate the socio-demographic characters in frequencies and percentages. Chi-square test and logistic regression analysis were adapted to assess the association between the socio-demographic characters and the KAP outcomes. A p-value lesser than 0.05 was said to be statistically significant.

**Result and Discussion**

**Knowledge on Cervical Cancer Vaccination**

Based on the analysis done, 376 individuals (95.9%) have heard about cervical cancer. 355 respondents (90.6%) out of 392 know that cervical cancer can be prevented by taking Human Papilloma Virus Vaccine but only 67 respondents (17.1%) of the respondents knows the beneficial age group whom are eligible to receive free HPV vaccine through the national immunization program. As high as 94.1% of respondents have no idea about the cost of HPV vaccination, 79.6% of them have wrong idea about the protective duration of the vaccination and 52.8% (207 respondents) do not know that a total of 3 doses are required for a complete vaccination course. Table 1 shows the level of knowledge as scored by respondents, 21 respondents (5.4%) are reported poor level (0-9) of knowledge and 371 respondents (94.6%) scored good level (10-14) of knowledge. The outcome ranges between minimum score of 1 to maximum score of 14, at mean score of 7 and standard deviation of 2.725. Level of attitude are divided into two groups, poor (0-3) and good (4-6) as shown in Table 2. 53.1% (208 respondents) are reported to have poor attitude.

Logistic Regression Analysis of Respondents on KAP on Cervical Cancer Vaccination

Binomial logistic regression analyses were conducted to predict the relationships between dependent variables (level of Knowledge, Attitude and Practice) and independent variables (demographic characteristics). Table 4. shows association between level of knowledge and demographic variables of the participants. Based on Table 4, it is seen that the knowledge of participant towards HPV vaccine is almost moderate with results showing almost comparable outcome. Table 5 shows binomial regression between demographic data and the attitude of participants towards HPV vaccine. Based on Table 5 it is seen that the attitude of participant towards HPV vaccine is good among the higher age group compared to the younger age group. Table 6 represents the association between demographic data and the practice of participants towards HPV vaccine. Based on Table 6, it is seen that the practice of participant towards HPV vaccine is good for all range of ages and ethnics.

Overall Discussion

Up to 95.9% of respondents have heard about cervical cancer, this results is slightly lower when compare to one similar study conducted in Eastern Uganda. Response for questions assessing knowledge of respondents on risk factors and signs and symptoms of cervical cancer was fairly optimal, up to 82.1% and 82.4% of respondents knows that women with cervical cancer would get bleeding in between periods.
and periods would be heavier and longer duration, respectively. Similar trend can be observed in Mukama et al. report. In addition, 355 individuals out of 392 respondents answered correctly that cervical cancer can be prevented by cervical cancer vaccination. However, less than half respondents (46.9%) do not know that early sexual intercourse increased cervical cancer risk, which are reported differently from Mukama et al. Knowledge towards the course of cervical cancer vaccination, protection duration provided by a full HPV vaccination course, national immunization program beneficial group and vaccination cost are reported to be low. Only 17.1% (67 individuals out of 392 respondents) know the beneficial age range for free HPV vaccination; while only 20.4% of them know the correct protection duration a completed vaccination course provide. 94.1% of the respondents do not know about the cost of a HPV vaccination course. Nonetheless, the level of knowledge of recruited populations are said to be good. 94.6% of the respondents scored in between 10-14 marks. There are lack of similar studies targeting general public done in Malaysia. However, similar studies which respondents are healthcare providers or healthcare degree students, such as HeshamRashwan et al. and Maharajan et al. reported a good level of knowledge on cervical cancer vaccination.

Overall, slightly more than half of the respondents (53.1%) scored poorly. 86.2% respondents agreed that they would get vaccinated if they are at a high risk in getting cervical cancer regardless the price of vaccines and 95.2% of them would get vaccinated if it is recommended by their physician. This coupled with several studies that suggest recommendation and recognition of HPV vaccination are utmost important factor affecting the vaccination uptake rate. Physicians’ role in future HPV vaccination promoting event should be taken care and maximize. Good attitude was observed when 332 individuals out of 392 respondents (84.7%) stated that they would get vaccinated if they get a free offer for a full course of vaccination.

It is found that respondents from Klang valley have a poor level of practice, with 255 individuals (65.1%) score 4 and below. Only 38.5 percent of respondents had been vaccinated within the optimum age range from 9 years of age to 26 years of age. This low vaccination rate (38.5%) is similar in studies reported by Yam et al. (23.4%) .

**Conclusion**

Age group, marital status, education level and employment status are found to be the factors affecting the KAP levels of Malaysia women, as these socio-demographic characteristics showed significant relationship with the dependent variables (KAP). Logistic correlation analysis also show the correlation between knowledge, attitude and practice levels in terms of HPV vaccination. Despite a good level of knowledge, poor attitude and practice indicate room of improvements for promotion of HPV vaccination. Effective measures are to be taken by efforts contributing from different professions. It is utmost important task to close the gap in between knowledge with attitude and practice so that the HPV protection provided by cervical cancer vaccines can eliminate the high cervical cancer rate among Malaysian women.

Body Dissatisfaction and Risk of Eating Disorder among UCSI University Non-Science Field Students

Joyce Tan Xi Jie1, Shashikala Sivapathy1

1Faculty of Applied Sciences, UCSI University, 56000 Cheras, Kuala Lumpur, Malaysia

Abstract

Body dissatisfaction and risk of eating disorder are problems that are continuing to trouble a large proportion of women and a growing number of men. This study aims to determine the relationship between socio-demographic factors (age and gender), body mass index, body dissatisfaction and risk of eating disorder among UCSI university non-science field students. A self-administered questionnaire which contains four sections was used, including background information, anthropometric measurements, Figure Rating Scale and Eating Attitude Test-26. A cross-sectional study was conducted among a sample of 375 Malaysian students (48.8% males and 51.2% females) between the age of 17 to 28. In this study, there were no significant differences in gender on age (t = 1.626; p > 0.05) and BMI status (t = 1.813; p > 0.05). Also, there was no significant difference found in the total mean score of EAT-26 (t = -1.927; p > 0.05) between genders. However, a significant difference was found in the dieting subscale (t = -2.694; p < 0.05) in which females scored significantly higher than that of males. On the other hand, body dissatisfaction among female students was showed significantly higher than that of males (t = -9.262; p < 0.001). Aside from that, a positive correlation (r = 0.120; p < 0.05) was found between body dissatisfaction and risk of eating disorder. Thus, more adapted interventional programme and a more in-depth studies relating these factors are crucial in order to correct the body image misperceptions among university students and to decrease the occurrence of risk of eating disorder.

Keywords: Body mass index; eating disorder; man; woman.

Introduction

Body dissatisfaction and risk of eating disorder are problems that are continuing to trouble a large proportion of women and a growing number of men. Body dissatisfaction is defined as a person’s negative thoughts or feelings about their body and it has been found to be prevalent around the globe. Whereas, risk of eating disorder is the risk of engaging in eating behaviors that are associated with psychological distress and physical ill-health but are not of a severity to warrant a clinical eating diagnosis. In addition, irregular eating behaviors are extreme dieting, excessive exercising, binge eating, self-induced vomiting, use of laxative and diet pills, as well as negative body image.

The risk of eating disorder is alarmingly prevalent in this modern society and has been getting a great deal of attention. The risk of eating disorder also plays a particularly important role as the most common indicators for the development of an eating disorder. According to obsessive, irregular or chaotic eating behaviors are also belongs to the category of at risk of eating disorder, especially when a person’s life experiences a level of discomfort or disruption. In addition to that, body dissatisfaction was also found as a well-replicated risk factor for the onset of eating disorder, yet not all individuals with body dissatisfaction were at risk of eating disorder.

In 2013, Forney pointed out that body dissatisfaction prospectively predicts worsening risk of eating disorder among young adults in university population. A recent study conducted in Taiwan among the female undergraduates showed that more than one third (43.2%) of the college women were engaging in unhealthy and

Corresponding author:

DOI Number: 10.5958/0976-5506.2019.00863.5
irregular eating behaviours. However, Uzun et al. has proven that 17.1% of the Turkish female college women were identified as at risk of eating disorder.

According to Mitchell and Mazzeo, the relationship between body dissatisfaction and risk of eating disorder has not been sufficiently explored among young adults. Many of them have spent a lot of time to improve their body shape and body weight by engaging in unhealthy eating habits in order to adapt to the trend of thin-culture society. This will eventually lead most of them to be at risk of eating disorder.

Besides, previous researches were conducted mostly among adolescence, especially among females. Only a small amount of studies included males as their study subjects. In addition to that, a majority of the studies were conducted in the Western cultures and only a few studies were done in Asia. This results in a lack of published information on the relationship between risk of eating disorder and body dissatisfaction among Malaysia private university students.

In present study, both males and females will be included as participants. This reason is that recent studies have revealed that at risk of eating disorder was not only a problem for females but also a problem encountered by males. As there is a lack of published information on at risk of eating disorder and body dissatisfaction among young adults, this study was conducted to determine the relationship between socio-demographic factors (age and gender), body mass index (BMI), body dissatisfaction and risk of eating disorder among UCSI university non-science field students.

Methodology

This study comprised of an analytical cross-sectional study was used as the study design. This study was conducted in South Wing UCSI University, Cheras, in Malaysia which is a private university. Convenience sampling method was used in this study. The following formula was used as the sample size calculation for the prevalence of at risk of eating disorder and body dissatisfaction among private university students in Malaysia. Thus, a total sample of 377 students was required to give the prevalence with its 95% confidence interval. The inclusion criteria of this study was aged 17 to 28 years old, Non-science field students and Malaysian nationality. The exclusion criteria was all science field students, all international students and disabled student. Data collection was conducted from mid-October till mid-November 2013 by using a English language self-administered questionnaire. This questionnaire consists of four parts which include socio-demographic factors, anthropometric measurements, the Figure Rating Scale (FRS) as well as the Eating Attitudes Test-26 (EAT-26). The purpose of using this instrument is to assess the relationship between body dissatisfaction and the risk of eating disorder among UCSI University students. As for data analysis, all the data was analyzed using the Statistical Package for Social Sciences (SPSS) software for Windows version 19.

Result and Discussion

Comparison of Variables between Genders and Age

Table 1 showed the mean values, t-values and p-values for the age between male and female students. From this data, the result showed that most of the students were at the age of 19 years old regardless of gender differences. The present study also showed that both males and females had almost the same mean age value with only a slight difference between them. Aside from that, the result also showed that there was no significant difference between males and females in terms of age (t = 1.626; p > 0.05). This finding is consistent with a previous study. According to the statistics in Canada proposed by Dale. The average age of a majority of the students was in their late teens and early 20s. Besides that, Sheldon also proposed that adolescents and young adults are the most vulnerable group to be at risk of developing eating disorder, regardless of gender differences.

Comparison of Variables between Genders and Body Mass Index

Table 2 showed the results from the analysis of independent sample t-test in BMI between male and female students. The result showed that the mean BMI
values for both males and females were almost the same, with males slightly higher than that of females. This finding is consistent with a study in Malaysia conducted by Kuan et al.\textsuperscript{17}. Aside from that, the results also showed that there was no significant difference between males and females in the BMI value (t = 1.813; p > 0.05) although males had a higher mean BMI value than females. This finding is supported by Kruse\textsuperscript{18}, which also found that there was no statistically significant difference in BMI by gender.

Comparison of Variables between Genders and Body Dissatisfaction

Table 3 showed the mean values, t-values and p-values for the current body size, ideal body size and the discrepancy score between male and female students. It was showed that male students had a larger current body size than female students. Besides, the results also showed that males had a higher mean value in ideal body size than females. Nevertheless, females showed a higher mean value in the discrepancy score. One of the reason may be due to females nowadays like to compare themselves to thin media images and sometimes they compare themselves to peers who are more relevant\textsuperscript{19}.

Generally, there were no differences in response to the items between male and female students. From the analysis of independent sample t-test, the differences in the current body size between males and females was not significant (t = 0.992; p > 0.05). However, there was a statistically significant differences for the ideal body size between male and female students in which males were statistically significantly higher than female students (t = 18.909; p < 0.05). This clearly indicated that males preferred a larger body size and females preferred a smaller body size as compared to their current body size. This finding is consistent with a previous research conducted by Baugh\textsuperscript{20}. Aside from that, the results also showed that there was a statistically significant difference between males and females in the discrepancy score, in which females was statistically significantly higher than that of males (t = -9.262; p < 0.05). This finding is supported by Prevos\textsuperscript{21}.

Comparison of Variables between Genders and Risk of eating disorder

Table 4 demonstrated the mean values of the EAT-26 score among males and females. The result indicates that female students had a higher EAT-26 score than male students. Besides that, the independent sample t-test showed that there was significant difference between genders in the dieting subscale (t = -2.694; p < 0.05). However, the independent sample t-test showed that there was no significant difference between the scores of male and female students on EAT-26 score in which the mean EAT-26 score in female students was statistically significantly higher than that of male students (t = -1.927; p > 0.05). Also, there was no significant difference between genders in the bulimia and food preoccupation subscale (t = -1.153; p > 0.05) as well as the oral control
This finding is supported by Nasir\textsuperscript{13} which also found that there was no sex difference the mean EAT-26 score. Similarly, Edman and Yates\textsuperscript{22} also showed no gender difference in the development of risk of eating disorder among Malaysian college students. However, this finding showed that there is inconsistency with a study done by Abbate-Daga et al.\textsuperscript{21}, which also showed that females were more vulnerable to be at risk of eating disorder. Besides that, Tan and Yew\textsuperscript{12} also found significant differences between males and females in the mean scores of EAT-26.

Relationship between Variables

Table 5 presented the relationship between age, BMI, body dissatisfaction and risk of eating disorder. From the table, there was no significant relationship between age and risk of eating disorder ($r = -0.028$, p = 0.592).

A non-significant relationship was found between BMI and risk of eating disorder ($r = -0.008$, p = 0.871). This finding showed inconsistent with a previous research by Martin et al.\textsuperscript{24}, which found that high BMI was associated with risk of eating disorder.

Aside from that, the relationship between body dissatisfaction and risk of eating disorder was also found to be significantly positively related ($r = 0.120$, p = 0.021). This indicated that the more an individual feels body dissatisfaction, the higher the tendency of an individual to be at risk of developing an eating disorder. This is because when a person was dissatisfied with their own body shape, he or she will try to change his or her body shape which may eventually lead to unhealthy practices with food and thus may cause that person to be at risk of developing eating disorder.

Besides, this finding is also consistent with another research which showed that body dissatisfaction was found to be frequently associated with the tendency to be at risk of eating disorder\textsuperscript{12}. Furthermore, the present study showed consistency with past research done by Jonstang\textsuperscript{25}, where a positive relationship was found between FRS and EAT-26 among university students. The occurrence of this phenomenon is due to the stereotypes and standards that has been reinforced by the media that put pressure on most of the young adults and cause them to engaged in draconian diet which can cause harmful effect to their health.

Similarly, Tylka\textsuperscript{26} also revealed that body dissatisfaction can lead an individual to be at risk of eating disorder regardless of gender differences. The possible reason that may explain this finding is due to the changes of body image perception which may lead to a decrease in body satisfaction among university students. At the same time, these changes may also contribute to cause the occurrence of unhealthy eating behaviours. Hence, individual who adapted body dissatisfaction are at increased risk of developing an eating disorder.

Conclusion

The main objective of this study was to determine the relationship between socio demographic factors, body mass index, body dissatisfaction and risk of eating disorder among UCSI university students. A total of 375 university students participated in this study, with approximately an equal number of males and females. About half of the respondents (51.7%) were currently pursuing foundation and degree in Business and Information Science, followed by Social Sciences and Liberal Art (48.3%). The results also reported that there were no significant relationship between age and risk of eating disorder. In this study, the results reported that BMI between males and females did not differ significantly. Also, the results showed that no significant relationship were found between BMI and risk of eating disorder. In terms of body dissatisfaction, the result also showed that most students were dissatisfied with their own current body size regardless of gender differences. In the discrepancy score section, the results showed that females had significantly higher scores as compared to males. However, the results also showed that a significantly positive relationship was found between body dissatisfaction and risk of eating disorder. Furthermore, findings reported that most of the students had a low level of concern about their body weight, body shape and eating. The results showed no significant difference was found in the mean EAT-26 score between genders. However, a significant difference was found in dieting subscale between genders with females having a significantly higher score than that of males.

Abstract

Stem cell research and treatment hold much promise and expectation both globally and locally to date with a lot of interest garnered. The aim of this survey was to assess their knowledge, awareness and perception towards stem cells based on their employment level, as well as insight on healthcare personnel's acceptance of stem cells from religious and moral point of views and the support on the treatment and research. A cross-sectional tool was used on 307 healthcare personnel in Pahang, Malaysia was conducted by using cluster random sampling from six primary healthcare clinics. Ethical approval (NMRR-14-1052-21256) was granted from Malaysian Research & Ethics Committee, Ministry of Health, Malaysia and UCSI Ethics Committee. Based on the result, knowledge on the stem cell among respondents associated with education (p=0.000). Recognizing the low learning in foundational microorganism, the members demonstrated enthusiasm for undifferentiated cell data extremely significant with p < 0.01. The association of awareness on impact of religious and ethical belief over storing and using stem cells for research or therapy among respondents by both education and employment status have very significant p value < 0.01. Overall, the perception of the healthcare personnel based on education to support on stem cell research, in willingness to use medical treatments from embryonic stem cells, using excess embryo during IVF, tax contribution for stem cell research in Malaysia were very significant with p value < 0.01. Taking everything into account, this investigation reflects low level of information, mindfulness and impression of social insurance work force dependent on their business status on the of perspectives relating to undeveloped cells in Malaysia.

Keywords: Stem cell; awareness; knowledge; perception; healthcare.

Introduction

Cells, have been once a study and research mainly in biological and pharmaceutical field. The remarkable evolution embarked the creation of paradigm shift in medical field since the first bone marrow transplants in the 1960s and the isolation of embryonic stem cells from mice in the 1980s followed by many other cell based therapies exclusively stem cell treatment and research has taken place last few decades1.

Organ and tissue donors has always been critically insufficient to supply and replace damaged or dysfunctional part and even then, the compatibility with recipient in another challenge2. The rise of number mortality and morbidity in terminal diseases and degenerative body parts due to the loss or failure of specific cell types function also have been the key for the stem cell field expansion.

Stem cells is one of the main component in regenerative medicine, apparently provide a renewable source for transplantation, and alternative therapies for a multitude of damaged organs as well as many other medical conditions. Accumulated evidences in clinical trials shown there are realistic possibilities with technologies stretching to optimization of stem cells therapies to improve life quality and solve age related factors in near future3.

Chung Keat Tan
sharmanee@ucsiuniversity.edu.my
Stem cells have the ability to self-renew and potential to give rise as specialized cell types. Based on their degree of plasticity, versatility and tissue origin, stem cells have been classified into diverse specialized cell types. The stemness can be categorized in the degree of plasticity from the highest of totipotent, pluripotent, multipotent, oligopotent and unipotent which relatively expressed potential to generate the variety of cell lineages to the lowest. Generally, stem cells come from two main sources whereby embryos formed during the blastocyst phase have encompass embryonic stem cells; ESC and adult tissue have adult stem cells, while induced pluripotent stem cell known as iPSCs are synthetically stimulated to ‘induce’ pluripotency from the somatic cells, besides all these resources able to give rise to cancer stem cells too.

Despite its great potential and high demands, stem cells are surrounded by various social, ethical and legal issues which are shared by stem cell scientists’ globally.

Future impact of stem cells is inevitable, right knowledge especially among healthcare personnel is important as they act as pivotal in educating and disseminating reliable health information where public are confident in the validity. Widespread of information to the public could aid informed decision making and eases comfort with the new technology so as to overcome public misperceptions about stem cell and the research and its social implications. As such, this study aims to determine the level of knowledge, awareness and perception of stem cell among health care personnel in Malaysia based on their employment level. This was done to evaluate the views of each health personnel based on their work experience and employment status.

**Methodology**

A cross-sectional questionnaire was conducted at five major medical clinics in Pahang, Malaysia. Location of sampling are: 3°51’22.8”N, 103°21’57.1”E, 3°49’11.8”N, 103°19’24.6”E, 3°47’20.6”N, 103°14’19.0”E, 3°49’28.6”N, 103°17’13.8”E and 3°45’12.7”N, 103°12’15.2”E. A total of 307 healthcare personnel comprising of doctors, nurses, medical assistants, pharmacists, assistant pharmacists, laboratory technicians, radiographers, dieticians, physiotherapists, occupational therapists and attendants were recruited. Written permission for sampling was obtained from Kuantan District Medical Officer. In addition, ethical approval (NMRR-14-1052-21256) was granted from Malaysian Research & Ethics Committee, Ministry of Health, Malaysia and UCSI Ethics Committee. The questionnaire composed of four sections; demographics (9 items), awareness (11 items), knowledge (17 items) and perception (7 items). All documentations were available in English and Bahasa Melayu (Malaysia’s national language). Translation were verified by professional linguistics of postgraduate qualification.

The data collected were analyzed using SPSS (Statistical Package for Social Studies) version 21. The main statistical analysis was descriptive. The level of significance was set at p < 0.05 and confidence interval = 95% and Chi-square test was used for statistical tests.

**Result and Discussion**

**Knowledge of Healthcare Personnel towards Stem Cells**

Level of knowledge regarding stem cell in general, and their source of information were evaluated. Figure 1 showed none had level of knowledge at the scale of 5 while nearly 40% comprised in scale 3 and 4 while the rest 60% of participants were in scale of 1-2.

![Figure 1. Level of knowledge on stem cells (n=307)(Scale of 1=poor to 5=excellent)](image-url)

However based on the association of respondents who have heard information on stem cells by education level were very significant with p <0.01. Similarly, the association of respondents knowledge on the use of adult stem cell by education level were very significant with p <0.01

Almost 227 (92%) female participants had claimed that they have heard of stem cell from various sources. Notably heard from mass media/internet with 70.7%, followed by cosmetic products with 49.5%, while information from medical healthcare professional and
pharmacy which are more reliable had only 44.3% altogether.

On the type of stem cell sources, participants were more familiar of umbilical cord blood stem cells with having 78.8%, followed by adult human tissue with 53.1%. Only 21.2% of participants have heard of foetal tissue as a source of stem cell. However, based on the Table 1 and Table 2 analysis, the interest of knowledge on stem cell among respondents based on two criteria which were gender, and employment status were statistically very significant with p<0.01.

Awareness of Healthcare Personnel towards Stem Cells

There is no significant association between potential therapeutic applications using stem cells and education level (p= 0.256). However, level of awareness is significantly dependent on education level for both in the doubt of stem cells presence in the commercialized health or cosmetic products (p = 0.006) and stem cell research in Malaysia (p=0.016).

The awareness of the presence of cord blood banking in Malaysia was significantly higher among doctors and medical laboratory technologist compared to others (p=0.000), while the source of information on cord blood banking that the participants chose were mainly from the internet with 37.8% and medical personnel with 29.3%.

There were more than two-third (67.8%) of participants were unsure whether to choose public or private bank for stem cell storage; 17.9 % chose public bank and 14.3% chose private bank. It was found that the main reasons for choosing public bank for stem cell storage were as donation for those in need it with 32.6% followed by for research use with 24.8%. Main reasons in choosing private bank was found with 34.5% participants felt having own cord blood stem cell would be safer and 22.8% participants felt that it is good investment in case if needs.
The p values were very significant among the healthcare personnel’s awareness on the impact of religious and ethical belief over storing and using stem cells for research or therapy by both education level and employment status having p value < 0.01 as shown Table3.

\(X^2=39.629, \ p=0.002\)

Perception of Healthcare Personnel towards stem cells

Overall, the perception of health personnel towards stem cell in this survey have shown very significant finding based on their education level compared to religious level, where education acts as vital role not only disseminating current information but also in comprehending the stem cell in the healthcare. Support for stem cell research among participants based on education level had very significant value with \(p < 0.01\). Health personnel who participated from various level background, also gave very significant value of perception in willing to use embryonic stem cells for medical treatments as well as using excess embryo during IVF for stem cell research in Malaysia based on education level with both having p value < 0.01. However perception on using excess embryo during IVF for stem cell research in Malaysia among respondents based on religion had no significant value, \(p = 0.676\). Also, perception on need of specific legislation and tax contribution for stem cell research in Malaysia among the participants by education showed very significant value with both having \(p\) value < 0.01.

Overall Discussion

Stem cell and its immense potential soon will revolutionize the field of science and especially medicine. However, stem cell-based products have yet to use as main treatment as there are many still at clinical trials studies and FDA has approved only stem cell-based product consist of blood-forming stem cells derived from cord blood and bone marrow. Though many studies have been done in other countries to assess public attitude on stem cells, there is not many study as yet carried out in Malaysia8-11.

Out of 307 participants, 90.9% and mostly females (91.9%) claimed that they have heard about stem cell which mainly from mass media/internet (70.7%) and cosmetic products (49.5%). Marketing via online and manipulating stem cell as seller name over the product especially in cosmetics is a gimmick played by many commercial industries without any or much evident based12,13. As far as mass media and internet in the era of 4th Industrial Revolution are concerned, both contribute to the most effective role in dissemination information. A period which is distinct in the speed, scale and energy at which it transforms production, distribution and consumption. As anticipated, it followed by 38.1%
participants received the information on stem cells from medical health care professional. The response rate for “yes” was more than 80% in all group of employment status except among attendants (73.3%) and statistically significant by education level (p=0.002). Undoubtedly, education level as well employment status almost always play important role in accessing the knowledge.

In the past, hardcopy scientific journals or published articles had been the main sources for scientific information; however, in recent years, the publics are able to obtain the science behind stem cell research easily through the media and internet14, 15.

Among the sources of stem cells, umbilical cord blood was the most popularly heard by the respondents in 78.8%; whereas foetal tissue was not much heard as a source of stem cell (21.1%). The popularity of umbilical cord is much expected as its preservation has been widely promoted especially in maternity hospitals and multimedia.

In this study the participants rated themselves at level of little (24.1%) to moderate (36.2%) level of knowledge. However, majority of more than 75% of participants gave positive feedback on having interest to know more about stem cells and current status on the medical treatment using stem cells, potential benefits and risks of adult and embryonic stem cell research, religion and ethical consideration of stem cells in Malaysia. Therefore this encouraging result of the participants positively in need for further information they are lacking of should not be neglected. Similar outcomes by Mohammed16 and Katz, et.al17 who found in their study that the respondents from other countries had a similar viewpoint thus the respondents considered that the additional information provided by the healthcare professionals was insufficient which this crucial additional information was needed. In terms of occupation, specialists (100%), doctors (86.7%), medical laboratory technician (82.4%) and 80% staff nurses had greater interest in knowledge on stem cells compared to others. Again, employment status further suggesting that education and exposure are the key to cultivate more interest and inquisitive in stem cell with p<0.01.

Many profit driven companies have been manipulating the insignificant data to sell the so-called “stem cells” in their products which claimed to treat many medical condition. Popularly in recent years the exploitation of stem cells in cosmetic and healthcare products that could help to rejuvenate their skin and make them look younger is incredible18. Obviously, female population are easily intrigued by the products and become the victims of their false claim. In contrary, this survey showed that there was a statistically significant majority of respondents who did not have high belief in the presence of stem cells in those products (p=0.006). The level of awareness significantly dependent on education level for both in the doubt of stem cells presence in the commercialized health or cosmetic products and stem cell research in Malaysia with p value < 0.01.

Conclusion

As a summary of the key findings, the results showed that overall the employment status significantly plays a major role in knowledge, awareness and perception on stem cells of health care personal at Kuantan, Pahang. Be that as it may, the key findings likewise demonstrated low level of information, mindfulness and recognition on stem cells among healthcare personnel. Thus, the health care personals have to be well equipped with awareness and knowledge on stem cell by regular exposure to key updates in their field of work. Thus it can be concluded that regardless on the level of education, the knowledge and exposure on stem cell among health personal has to be improved significantly.

Emotional Intelligence As A Mediator Between Personality and Happiness Among Adolescents In Malaysia

Sim MS\textsuperscript{1}, Mohtaram R\textsuperscript{1}

\textsuperscript{1}Department of Psychology, Faculty of Social Sciences and Liberal Arts, UCSI University Kuala Lumpur, 56000 Cheras, Kuala Lumpur, Malaysia

Abstract

Adolescent stage is a duration whereby an individual experiences gradual changes physically and emotionally from childhood to adulthood. During this stage, they will encounter a lot of challenges, ambiguities, obligations, expectations and influences which may affects them emotionally and make them feel unhappy. Individuals who are not happy are more likely to experience severe mental illness and other serious psychological issues that may affect their functioning in the form of social, cognitive and emotional. Present study was carried out to determine the role of emotional intelligence as a mediator between personality and happiness among adolescents in Malaysia. 384 adolescents (13 to 17 years old) from four private institutions were selected as the respondents of this study. The data collected with using Goldberg’s International Personality Item Pool (IPIP) Big-Five Factor Marker, Schutte Self-Report Emotional Intelligence Test (SSEIT) and Oxford Happiness Questionnaire (OHQ). Emotional intelligence partially mediates extraversion and conscientiousness to happiness, and fully mediates agreeableness and neuroticism to happiness. However, emotional intelligence does not mediate openness and happiness. All the Big Five personality, except for openness were significantly correlated to happiness. A significant correlation was found between personality and emotional intelligence. Lastly, emotional intelligence is positively correlated to happiness. Emotional intelligence does play a role in mediating personality and happiness. In order to come out with a more comprehensive and informative outcome, future researcher should replicate this study by using various assessments when evaluating an individual’s happiness for their study.

Keywords: Emotional intelligence; adolescents; happiness; personality

Introduction

There is a worrying trend in mental health issue worldwide and Malaysia is not excluded from this issue. It has been predicted that by 2020, the mental health illness will overtake cardiovascular disease as the second contributing factor that affect the Malaysians’ health\textsuperscript{1}. This can be seen from the increase in number of cases recorded in Malaysia, from 10.7\% in 1996 to 29.9\% in 2015\textsuperscript{5}. Out of 10 Malaysians, four is suffering from mental illness\textsuperscript{5}. Children, especially students, are not excluded from this issue where 12.1\% of 5 to 15 years old children and 29.2\% of individuals who are 16 years old and above were reported to have mental health issues\textsuperscript{6,7}. Students who are depressed have greater suicidal ideation (55.8\%) as compared to students who are not depressed (14.4\%)\textsuperscript{8}. According to the Institute for Public Health\textsuperscript{7}, the high suicide risk group in Malaysia are the individuals aged between 16 to 25 years old as they are most vulnerable to attempt suicide\textsuperscript{9,10}. In the early to mid-development of adolescents, the brain experiences neurological development which encourage transition among the connectivity of various brain sections. The prefrontal cortex is associated with strategizing, problem-solving, and tasks execution\textsuperscript{7}. In view of the worrying trend in mental health issues among Malaysians, it is crucial to have an understanding of the factors that affect individual’s happiness in Malaysia.

Among the mental health issues, researchers\textsuperscript{8-10} have consistently found out that the primary element which lead to depression and suicide are feelings of extreme unhappiness. Individuals who are not happy are more likely to experience severe mental illness and other serious psychological issues that may affect...
their functioning in the form of social, cognitive and emotional\textsuperscript{8-12}.

Happiness is defined by Lyubomirsky\textsuperscript{13} as the feeling of joy, satisfaction or positive affect which come together with a sense of good and meaningful life. A happy individual is able to excel in the workplace as they tend to have better work achievements, organizational citizenship, and are more productive\textsuperscript{14}. When talking about a students’ life factors that usually contributes to their happiness would be academic achievement, satisfying facilities of schools, quality of teachers, teaching methods and development of friendship\textsuperscript{15,16}. People who are more inclined towards personality traits such as extraversion, conscientiousness, agreeableness and emotional stability will experience more constant positive emotions, less recurrent negative emotions and greater life satisfaction\textsuperscript{17-21}.

In recent years, the importance of emotional intelligence (EI) has been reiterated in the dispositional explanations of happiness. Emotional intelligence is the subdivision of social intelligence\textsuperscript{22}. An individual with emotional intelligence are always happy, confident, feel contented with their lives and more likely to think positively\textsuperscript{23}. Emotional intelligence enables a person to be aware of their emotion and govern it in a way which encourages well-being and happiness\textsuperscript{24}.

Most of the past findings have examined on the personality\textsuperscript{12, 25} and emotional intelligence\textsuperscript{26-28} aspects as a direct factor that affect happiness. However, very little has focus on how emotional intelligence play a role in mediating the relationship between personality and happiness. In addition, most of these studies\textsuperscript{26,28,25} were done in the western context rather than in Malaysia. Thus, there is not enough studies to imply the role of emotional intelligence in the relationship between personality and happiness in Malaysia context. Besides, past studies\textsuperscript{12, 29} also do not solely target adolescent as their sample population, therefore, more studies are needed in adolescent stage. Adolescent stage is a duration whereby an individual experiences gradual changes physically and emotionally from childhood to adulthood\textsuperscript{4}. During this stage, they will encounter a lot of challenges, ambiguities, obligations, expectations and influences which may affects them emotionally and make them feel unhappy. Hence, to fill up the research void, present study aims to investigate on how emotional intelligence mediates the relationship between personality and happiness among Malaysian adolescents.

\textbf{Methodology}

The research method carried out in this study is quantitative research with the purpose to examine the role of emotional intelligence as a mediator between personality and happiness among adolescents in Malaysia. The correlational design has been used to collect data.

The first of the three instruments used is Goldberg’s International Personality Item Pool (IPIP) Big-Five Factor Marker\textsuperscript{30}, it is used to examine an individual’s personality in the five domains, namely Openness to experience (O), Conscientiousness (C), Extraversion (E), Agreeableness (A), and Neuroticism (N). A high internal consistency was shown in all of the five domains, for instance, 0.79 (Openness to Experience), 0.81 (Conscientiousness), 0.87 (Extraversion), 0.79 (Agreeableness) and 0.88 (Neuroticism)\textsuperscript{31}.

The second instrument that was used is Schutte Self-Report Emotional Intelligence Test (SSEIT)\textsuperscript{32}, it is used to measure emotional intelligence in the three areas namely, perception of emotions, management of emotions and employment of emotions. SSEIT had a high internal consistency of 0.90 and a high test-retest reliability of 0.87. According to Bastian, Burns and Nettelbeck\textsuperscript{33}, SSEIT has a high convergent and divergent validities.

Lastly, the third instrument that was used is Oxford Happiness Questionnaire (OHQ). This instrument is used to measure an individual’s level of happiness. The internal consistency of OHQ is high which is 0.91\textsuperscript{34}. Based on Pishva, Ghalehban, Moradi and Hoseini\textsuperscript{35}, OHQ has a good reliability and validity.

According to Department of Statistics Malaysia\textsuperscript{36}, the total population of adolescents (10 to 19 years old) in Kuala Lumpur is approximately 356,300. On average, the number of population between 13 to 17 years old in Kuala Lumpur is approximately 71,260. In this study, Cochran’s formula\textsuperscript{37} has used to determine the sample size. Therefore, total number of 384 adolescents of age 13 to 17 years from four private institutions in Kuala Lumpur has participated in this study. To obtain 384 adolescents as the respondents, convenience sampling was used.
Prior from the data collection, approval was sought from the Department of Psychology of UCSI, the school principals, parents and students. Goldberg’s IPIP Big-Five Factor Markers, Schutte Self-Report Emotional Intelligence Test (SSEIT) and Oxford Happiness Questionnaire (OHQ) were used to assess the respondents. 384 set of questionnaires were distributed to the respondents age 13 to 17 years old from the four private institutions. Statistic Package of Social Science (SPSS) version 21 was used for data analysis.

Result and Discussion

According to table 1, most of the adolescents of age 13 to 17 years old in Kuala Lumpur fall under the category of agreeableness (M=32.19, SD=4.441), followed by conscientiousness (M=30.90, SD=4.357), openness (M=30.85, SD=4.465), extraversion (M=29.71, SD=4.362), and lastly neuroticism (M=29.02, SD=4.801).

The connection between the Big Five identity and satisfaction was explored utilizing Pearson-item minute relationship coefficient as shown in Table 2. The discoveries appeared there was a constructive critic relationship among’s satisfaction and the three elements of identity (Extraversion; r=.248, Agreeableness; r=.280, and Conscientiousness; r=.232, n= 384, p < .05). Neuroticism was found to adversely related to satisfaction, r=-.162, n= 384, p < .05. The discoveries are predictable with the past investigations20, 38, along these lines, the elective theories are upheld.

In Table 3, analyst had led different relapse investigation to break down the impacts of enthusiastic knowledge as a middle person on extraversion and bliss. In stage 1 of the intervention show, the relapse of extraversion on bliss was noteworthy, b=.025, t(382) = 4.994, p<.05. Stage 2 demonstrated that the relapse of extraversion on the middle person, enthusiastic knowledge, was additionally noteworthy, b=.354, t(382) = 2.302, p<.05 The aftereffect of this investigation is steady with Chamorro-Premuzic, Bennett and Furnham’s

Concerning the table 5, scientist had utilized various relapse examination to test the go between impacts of passionate insight on honesty and bliss. In Step 1 of the intervention display, the relapse of principles on bliss was critical, b = .023, t(382) = 4.654, p < .05. Stage 2 demonstrated that the relapse of the uprightness on the middle person, passionate knowledge, was likewise huge, b = .638, t(382) = 4.210, p < .05. It was discovered that passionate knowledge incompletely intervened the connection among reliability and satisfaction among teenagers in Malaysia. This outcome is reliable with Chamorro-Premuzic, Bennett and Furnham’s examination⁴¹, along these lines, the elective theory is upheld.

In table 6, specialist had run different relapse investigation to test the middle person impacts of enthusiastic knowledge on neuroticism and bliss. A full intercession was found in the model (z = - 4.791, p<.05) through a Sobel test. It was discovered that passionate insight completely interceded the connection among neuroticism and satisfaction among teenagers in Malaysia and findings is steady with the work of [41].

Conclusion

The data obtained from this study is solely based on adolescent’s self-report. Thus, this may lead to the occurrence of social desirability bias which may affect the accuracy of the results. To obtain a non-bias data, future researcher should consider employing various assessments when evaluating an individual’s happiness rather than solely depending on the respondent’s self-report. Future researcher can utilize memory and reaction time assessment, physical evaluation and reports from informant to assess happiness. Besides, this study is correlational in nature, researcher could not explore the causal relationship among the variables and could not examine behaviour over an extended period of time. In order to establish causality, future researcher should carry out a longitudinal study to let the researchers and readers to have an in-depth understanding on the causal
relationship between the variables.

Chronic Kidney Disease-Mineral and Bone Disorders Laboratory Profiles in Chronic Haemodialysis Patients

Djoko Santoso1, Nirapambudi Devianto1, Pranawa1, Moh. Yogiantoro1

1Faculty of Medicine, Airlangga University, Surabaya 60115 Indonesia

Abstract
Chronic kidney disease-mineral and bone disorder (CKD-MKD) has describe more clinical syndrome which develops as systemic disorder of mineral and bone metabolism as result of CKD. The study aims to determine chronic kidney disease-mineral and bone disorder laboratory profile in chronic haemodialysis patients in Dr. Soetomo Hospital, Surabaya. The demographic and laboratory data (calcium, phosphorus, intact parathyroid hormone and alkali phosphatase) were collected from 150 chronic haemodialysis patients. The study was used descriptive research using cross-sectional design. This study had been implemented in Dr. Soetomo Hospital and conducted between March and April 2007. The samples had been selected by consecutive technique method. The blood serum for calcium, phosphorus and total alkaline phosphatase and albumin were analysed. The result found intact parathyroid hormone level (iPTH) decreased with age. The phosphorus level was observed lower in respondents with diabetes mellitus (DM) than non-DM but higher with longer haemodialysis duration. The corrected calcium met the optimal range of 8.4 mg/dl to 9.5 mg/dl and 38% of respondents had optimal of CaxP product less than 55mg2/dl2. There were 27.3% of respondents had optimal iPTH level with range of 150 pg/ml and 300 pg/ml. The intact parathyroid hormone level in diabetes mellitus (DM) tended lower than non-DM and increased by longer haemodialysis duration. Low turnover prediction (iPTH< 60pg/ml) was 11.3% and high turnover prediction (iPTH> 200 pg/ml with total alkali phosphatase >207 IU/L) was 22%.

Keywords: Calcium, Chronic Kidney Disease, Diabetes Mellitus, Haemodialysis, Phosphorus, Total Alkaline Phosphatase

Introduction
Chronic kidney disease (CKD) is public health problem which 5% to 10% of world population suffered CKD. In the United States, 16% of the adult population is suffering CKD. The main cause of CKD mortality such as cardiovascular diseases which mortality rate reaches 52%. The haemodialysis is provided an additional life expectancy for late-stage of CKD. Furthermore, there is still high rate of cardiovascular morbidity and mortality in late stage CKD patients undergone haemodialysis. In general, late-stage CKD patients with haemodialysis less than 65 years old had cardiovascular mortality of 10-500 times higher than healthy person. Besides, cardiovascular mortality in young adult patients aged between 24 years old and 37 years old undergone haemodialysis has similar cardiovascular mortality number in general population aged 70 years old to 80 years old1,2,3.

The cardiovascular risk factors such as diabetes mellitus, hypertension, smoking and dyslipidaemia but insufficient in explained increment of cardiovascular morbidity and mortality in CKD patients. There are metabolic and bone mineral disorders conditions such as calcium (Ca), phosphorus (P), hormonal such as parathyroid hormone (PTH) and calcitriol (1.25 (OH) 2D3) or called as secondary hyperparathyroidism. The mineral and bone disorder in CKD patients occurs during stage 3 of CKD and gained weight with decline in kidney functions. The mineral and bone disorder are estimated suffered by more than 300,000 in late stage of CKD patients undergone haemodialysis. The longer

haemodialysis process and drug such as calcium-based phosphate binder and vitamin D lead increasing in complications of mineral and bone disorders complex. If therapeutic intervention is improper managed will contribute to the complications.

The mineral and bone disorder is associated with changes arterial elasticity in form of cardiovascular calcification and identified as major cause of cardiovascular morbidity and mortality in late stage of CKD patients. The etiology of CKD due to diabetes mellitus provide more specific or relative hypoparathyroid profile than non DM.

The study aims to determine chronic kidney disease-mineral and bone disorder laboratory profile in chronic haemodialysis patients in Dr. Soetomo Hospital, Surabaya. The data obtained can be used as reference for treatment and prevention of CKD-MBD syndrome in sustained haemodialysis patients.

Methodology

This study was used a descriptive research with cross sectional design. This study had been implemented in Dr. Soetomo Hospital, Surabaya. The study was conducted between March and April year 2007. The study population was all chronic kidney patients who undergone haemodialysis in Dr. Soetomo Hospital, Surabaya. The study samples were 150 respondents which met the study inclusion criteria. The samples were selected by consecutive technique method. The data was collected through primary data which presented and analysed descriptively.

Result and Discussion

The lowest age was 17 years and highest age was 78 years. The highest proportion was between 50 years and 59 years with 36.7% (55). 84% of respondents with age less than 60 years and 16% of respondents were aged more than 60 years as shown in Figure 1.

There were 48 respondents (32%) had suffered diabetes mellitus and 102 respondents (68%) were non-DM and consisted 73 respondents (48.7%) due to hypertension, 11 respondents (7.3%) caused by glomerulonephritis, 13 respondents (8.7%) caused by urine tract stones and 5 respondents (3.3%) caused by polycystic kidney disease (Figure 2).

Figure 1. Distribution of respondent based on age

Figure 2. Respondent distribution based on the etiology of chronic kidney disease

In Figure 3, 34 respondents had undergone haemodialysis less than 6 months, 70 respondents (46.7%) had undergone haemodialysis between 6 months and 18 months, 46 respondents (30.7%) undergone haemodialysis more than 18 months as shown in Figure 3.

Figure 3. Respondent profile period for haemodialysis

The phosphorus level distribution was categorized as 6 respondents (4%) had less than 3.5 mg/dl, 33 respondents (22%) had optimal level between 3.5 mg/dl and 5.5 mg/dl and 111 respondents (74%) had phosphorus level more than 5.5 mg/dl (Figure 4).
Meanwhile, older age group had phosphorus less than 3.5 mg/dl and more dominant in respondents less than 60 years old. In additions, there were 5.9% had haemodialysis less than 6 months with phosphorus less than 3.5 mg/dl and 67.1% of respondents had haemodialysis between 6 months and 18 months for phosphorus more than 5.5 mg/dl. The phosphorus levels tend to increase with longer haemodialysis duration.

In Figure 5, 83 respondents (55.3%) had optimal levels of calcium between 8.4 mg/dl and 9.5 mg/dl and 32 respondents (21.3%) had calcium levels more than 9.5 mg/dl.

In Table 1, mean age was 48.97 with standard deviation of 11.76. The minimum and maximum of age were 17 years and 78 years. There were male respondents (67.3%) and 49 female respondents (32.7%) involved in this study. In additions, 48 respondents (32%) had suffered diabetes mellitus and 102 respondents (68%) were non-DM. Furthermore, 82 respondents (54.7%) had haemodialysis once per 5 days and 36 respondents (24%) had haemodialysis of twice per a week. Meanwhile, phosphorus mean was 7.4 mg/dl with standard deviation of 2.6 mg/dl and calcium had mean of 8.7 mg/dl with standard deviation of 1.3 mg/dl. The iPTH had mean and standard deviation of 191.6 pg/ml and total alkaline phosphatase had mean and standard deviation of 308.80 IU/L and 270.7 IU.
**Discussion**

In this study, there were 22% of respondents had optimal phosphorus level between 3.5 mg/dl and 5.5 mg/dl. Besides, there were 4% of respondents with hypophosphatemia had phosphorus level of less than 3.5 mg/dl and 74% of respondents found hyperphosphatemia with phosphorus more than 5.5 mg/dl.

Besides, number of haemodialysis machines was limited the study result on haemodialysis which haemodialysis was affected in dispose of phosphorus. Every week, the phosphorus was detected positive or exceed the balance, so the restriction of protein diet and phosphorus binder was very reliable. However, this restriction lead malnutrition and dilemma among CKD patients with haemodialysis. The respondents had attended the diet counselling and its difficult since most respondents had low socio-economic. The inability to use phosphate binder was more effective and expensive.

In this study, tendency of phosphorus level decreased in older age group. The previous studies in Iran and Spain found significant negative correlation between phosphorus level with increment of age. Lorenzo et al. (2006) found older age had low calorie and protein intake. In additions, the respondents with DM appeared more dominant in phosphorus less than 3.5 mg/dl than non-DM group. Meanwhile, 81.4% of non-DM and 58.3% of DM had obtained phosphorus more than 5.5 mg/dl. The DM group tended more proportion of low phosphorus than non-DM group.

There were respondents had phosphorus level more than 5.5 mg/dl experienced long haemodialysis duration. Hyperphosphatemia was more dominated in CKD patient with long haemodialysis with tendency increment in phosphorus level. Furthermore, corrected of calcium level among the respondents who under the control target range of 8.4 mg/dl to 9.5 mg/dl was 83 respondents (55.3%). The calcium level decreased in 35 respondents (22.3%) below optimal level less than 8.4 mg/dl. The study also found 20 respondents had hypercalcemia more than 10 mg/dl. There were 137 respondents were used calcium based phosphate binder (CaCo3) and only available at health insurance providers and relatively affordable in Indonesia. Besides, no patients were using calcitriol in hospital.

The correct calcium more than 9.5 mg/dl found in respondents aged 30 years and 39 years old but there was no apparent trend of certain calcium level in age changes. The corrected calcium more than 9.5 mg/dl in haemodialysis with range of percentages of 17.6%, 14.35% and 34.8% with haemodialysis duration of less than 6 months, 6 months to 18 months and more than 18 months consecutively. In this study, there was tendency for elevated level of corrected calcium to decrease over the haemodialysis duration. Steven et al. found significant increment in corrected calcium level with haemodialysis more than 18 months. The phosphorus serum fluctuated more than calcium so the product of CaxP is strongly influenced by phosphorus level. The CaxP product was only practical clinical guide to the change of phosphorus and calcium.

In this study, recommendation of optimal control range of iPTH level between 150 pg/ml and 300 pg/ml of 27.3%. There was tendency for low of iPTH levels in developed countries due to high calcitriol usage with calcium based phosphate binders. In develop countries, non-calcium based phosphate binder was widely used, calcimimetic preparation as well as vitamin D analogues that have less effectiveness on hypercalcemia which helps prevent hypercalcaemia and secondary hyperparathyroidism. In this study, no any calcitriol or vitamin analogues did not used to suppress iPTH since these preparations are relatively expensive for most patients and did not belong to any health insurance provider.

The respondents with aged more than 30 years old and above had dominated proportion of iPTH less than 150 pg/ml level with highest proportion in respondents aged 66 years old group with percentage of 66.7%. Furthermore, iPTH less than 300 pg/ml is more dominated in less than 60 years old and iPTH levels more than 800 pg/ml was dominated in respondents of 30 years old and 39 years old. The tendency in increment of iPTH levels with increased age.

There were 56% of respondents had iPTH less than 150 pg/ml which more than respondents with iPTH above 300 pg/ml of 16.7%. The trend of increment of iPTH levels was observed with high in albumin level. There was indirect relationship between iPTH level and albumin level which low albumin levels correlated with low ionized calcium level. Low albumin levels was caused malnutrition and wasting syndrome.
In addition, 11.3% of respondents had iPTH less than 60 pg/ml with low turnover prediction while 47 respondents (31.3%) had iPTH more than 200 pg/ml with high turnover prediction. Meanwhile, 33 respondents had total alkaline phosphatase more than 207 IU/L that involved with high turnover bone diseases. The increment in total alkaline phosphatase in high iPTH level group will strengthen prediction of high turnover type.

This study obtained diversity of abnormality CKD-MBD laboratory profiles experienced by other studies that influenced by differences in CKD, percentage of etiology CKD, differences in haemodialysis duration, difference dialysis profiles and accompanying therapy, weekly haemodialysis duration and sufficiency of dialysis dose achievement. Besides, other consideration were differences in tolls, laboratory methods as well as research forms that were part of cross-sectional. In additions, the biological and clinical effects causes also considered in laboratory result. The mineral metabolism management also required the complex role of dialysis therapy, phosphorus binding usage, calcimimetics and vitamin D analogues, dietary interventions, patients and family education, communication and compliance. There was difficulty for hospital to achieve good in the CKD-MBD syndrome management.

**Conclusion**

In conclusions, respondent age mean was 48.97 years with age distribution less than 60 years with more male respondents in this study. The phosphorus level was reduced in older age group and tended to be lower in respondents with diabetes mellitus than non-diabetes mellitus. Besides, the phosphorus level also observed to increase in respondents with longer haemodialysis duration. The correlated calcium level and iPTH were lower in the respondents with DM than non-DM. Furthermore, iPTH and albumin levels increased in the respondents with longer haemodialysis duration.

The Relationship between Estimated Glomerular Filtration Rate (eGFR) with Hepcidin in CKD Patients That Have Not Undergone Dialysis

Decsa Medika Hertanto¹, Ami Ashariati¹, Nunuk Mardiana¹, Djoko Santoso¹
¹Faculty of Medicine, Airlangga University, Surabaya 60115 Indonesia

Abstract

Functional iron deficiency anemia is anemia that often occurs in CKD but is frequently not well diagnosed. Measurement of hepcidin may show an earlier functional iron deficiency status. The relationship between hepcidin and eGFR has not been widely studied. This study is to determine the association between eGFR and hepcidin in patients with CKD who have not undergone dialysis. 37 patient with CKD stage 3 to 5, age 20 - 80 years old, both male and female gender, who control at Outpatient Clinic of Dr.Soetomo Hospital were the subjects of study. Levels of hepcidin and eGFR were measured in patients with CKD. Sampling is done by consecutive sampling. The data obtained is then analysed using spearman parametric test. The results showed that among 37 subjects, 67.6% were male with average age 56.84 ± 12.27 years. Among them the common cause was hypertension (75%). Stage 3 (43.2%) is the common stage in this study. The mean hemoglobin level in this study was 10.88 ± 2.21 g / dl, with BUN 33.94 ± 21.1 mg / dl, and serum creatinine 3.42 ± 2.25 mg / dl. Average eGFR was 26.72 ± 16.12 ml/min/1.73m2. The median hepcidin level was 48.58 ng/ml (0.12 - 439.07 ng/ml). eGFR levels correlated negatively with hepcidin level (r = -0.633; p-value 0.000). In conclusion, lower eGFR level is negatively associated with hepcidin level which indicated that when eGFR decreasing, the hepcidin level will be increasing.

Keywords: eGFR, Hepcidin, Anemia, Chronic Kidney Disease

Introduction

Chronic kidney disease (CKD) is a chronic inflammatory disease with a low grade. The inflammatory causes of CKD are decreased cytokine secretion, increased oxidative stress, and recurrent infections. Inflammation secreted several cytokines, IL-6, which stimulates the liver to produce the hepcidin hormone¹,². The hepcidin hormone functions as a regulator of iron hemostasis, which inhibits iron secretion in macrophages. As a result of this condition causes an increase in the hepcidin hormone and a decrease in peripheral iron, but iron in the tissues and macrophages is actually high. This condition is known as functional iron deficiency⁵. In CKD, there is a lot of functional iron deficiency but so far it has not been noticed, as a result of CKD anemia⁴,⁶. Anemia at an advanced stage often causes resistance to erythropoietin which is thought to be due to high hepcidin levels⁷,⁸. Gupta et al.⁹ reported a decrease in kidney function followed by an increase in proinflammatory cytokines. Other researchers Mercadel et al.¹⁰ stated that patients with stage 1-5 non hemodialysis CKD had an increase in hepcidin and a not-so-high increase in CRP indicating low grade of inflammation. Atkinson et al.¹¹ in stage 1-5 CKD patients, functional iron deficiency anemia was found to correlate with hepcidin. In the study by Wagner et al.¹², it was reported that in CKD stage 3-5, hepcidin levels increased accordingly to a decrease in hemoglobin level. The decrease in eGFR in CKD will be followed by an increase in inflammation characterized by an increase in cytokines such as IFN, TNFa, IL-1, IL-6, and IL-10. This surge in cytokines is caused by a disruption of the elimination of these cytokines in the kidneys, in addition to repeated infections, increased oxidative stress, uremic conditions, metabolic acidosis also affects the increase in inflammatory conditions⁸,¹³. These cytokines will
later increase hepcidin production in the liver which is suspected as the cause of anemia deficiency in CKD\textsuperscript{5,8,14}.

To determine the relationship of decreased kidney functions to hepcidin synthesis, hepcidin research was carried out in CKD stage 3-5. In order to prove the presence of inflammation, inflammatory parameters were assessed, namely IL-6, LED and CRP in a cross-sectional manner with a population of kidney poly patients at Dr.Soetomo Hospital.

**Methodology**

The study design was an observational analytic study which aimed to determine the relationship between eGFR and hepcidin in CKD patients who had not yet undergone dialysis. The study was carried out in the Outpatient Hospital Dr.Soetomo Surabaya, by taking blood samples from August 1, 2017 to March 1, 2018. The study sample was part of the affordable population included, which was in accordance with the inclusion criteria.

Inclusion criteria: All patients who were the study sample were male or female, ages 20 - 80 years, and willing to take part in research and sign an informed consent.

Exclusion criteria: Exclusion was carried out in patients infected with hepatitis B, hepatitis C, liver cirrhosis, diabetes mellitus, obesity, and patients who were receiving erythropoietin / steroid / iron therapy / blood transfusion / or hormonal therapy (in 3 months).

Sampling was carried out by consecutive sampling, to obtain a predetermined number of samples, 37 samples.

**Results**

**Clinical Characteristics**

The results of the measurement of clinical data of 37 CKD patients obtained information revealed that most CKD patients had a hemoglobin level of 10.88 with a standard deviation of 2.21 as shown in Table 1. The distribution at each stage found that the average hemoglobin in stage 3 was 12.11 with a standard deviation of 1.79, the mean in stage 4 was 11.28 with a standard deviation of 2.32, and the mean at stage 5 was 8.95 with a standard deviation 1.14. BUN level measurements in this study obtained an overall average of 33.94 with a standard deviation of 21.1. The characteristics of BUN levels at each stage, namely in stage 3, obtained a mean BUN level of 21.06 with a standard deviation of 7.15, mean BUN in stage 4 of 27.2 with a standard deviation of 7.74, and in stage 5 an average of 56.16 with a standard deviation of 22.96. The measurement of creatinine serum levels in this study obtained a total mean of 3.42 with a standard deviation of 2.25. Creatinine serum levels at each stage were stage 3 at 1.71 with a standard deviation of 0.24, mean at stage 4 at 2.78 with a standard deviation of 0.87, and a mean at stage 5 of 6.19 with a standard deviation 1.74.

eGFR Value in Each CKD Stage

Table 2 shows the distribution of eGFR values according to the CKD-EPI formula for 37 patients of the study sample based on the stage of CKD. Distribution of examination of eGFR values among 37 CKD patients based on the recorded stage degree from the results of the stage 3 eGFR examinations was 42.81 with a standard deviation of 7.61, mean of stage 4 eGFR of 22.11 with a standard deviation of 4.45, and mean eGFR in stage 5 at 8.75 with a standard deviation of 3.27. The average characteristics of eGFR values in the overall results of this study amounted to 26.72 with a standard deviation of 16.12.

Hepcidin Levels in Each CKD Stage

The distribution of hepcidin serum values in 37 patients of the study sample based on the stage of CKD is shown in Table 3. Distribution of examination of hepcidin levels in 37 CKD patients based on the recorded stage degrees from the results of median hepcidin examination at stage 3 was 23.17 ng / ml with a range of 0.12 - 70.14, median hepcidin at stage 4 was 83.02 ng / ml with ranges from 1.08 - 254.87, and median hepcidin at stage 5 is 118.86 ng / ml with a range of 9.96 - 439.07. The control value of hepcidin levels in this study was 20.65 - 42.89 ng / ml. The median characteristics of hepcidin values in the overall results of this study amounted to 48.58 ng / ml with a range of 0.12 - 439.07.

Relationship between eGFR value and Hepcidin level

The test results of the analysis of the relationship between eGFR values and hepcidin levels showed that there was a relationship with a correlation coefficient with a negative value of -0.633. The relationship in this study is also significant, indicated by the value p = 0,000. The meaning of this negative correlation coefficient shows an inverse relationship, if the eGFR value decreases, the hepcidin level will increase.

Discussion

Average eGFR value in each CKD Stage

The results of the CKD-EPI eGFR values were averaged at each stage, namely in stage 3 of 42.81 ml / min / 1.73 m² with a standard deviation of 7.61, stage 4 of 22.11 ml / min / 1.73 m² with standard deviation of 4.45, and stage 5 of 8.75 ml / min / 1.73 m² with a standard deviation of 3.27. The average total eGFR in this study was 26.72 ml / min / 1.73 m² with a standard deviation of 16.12. In the study conducted by Mercadel
et al.\textsuperscript{10}, the obtained mGFR values in stage 3a (45-60) at 18.1 ml / min / 1.73 m\textsuperscript{2}, stage 3b (30-45) at 33.7 ml / min / 1.73 m\textsuperscript{2}, stage 4 as high as 28.1 ml / min / 1.73 m\textsuperscript{2}, and in stage 5 it is 7 ml / min / 1.73 m\textsuperscript{2}. The total mean mGFR value at all stages was 35.3 ml / min / 1.73 m\textsuperscript{2}, whereas if the GFR was measured the estimation using the CKD-EPI method was 34.2 ml / min / 1.73 m\textsuperscript{2}. The results of the Mercadel et al.\textsuperscript{10} with this study only differed slightly.

**Hepcidin Level in Each CKD Stage**

The results of this study found that the median of total hepcidin level was 48.58 ng / ml with a range of 0.12 - 439.07 (Control value of hepcidin levels 20.65 - 42.89). The median division of hepcidin levels that are in accordance with CKD stages is in stage 3 of 23.17 ng / ml (range 0.12 - 70.14), stage 4 is 83.02 ng / ml (range 1.08 - 254.87) , and at stage 5 of 118.86 ng / ml (range 9.96 - 439.07). The results of this study do not differ greatly from the research conducted by Zaritsky et al.\textsuperscript{18}; Mercadel et al.\textsuperscript{10}; and Manolov\textsuperscript{20} that is an increase in hepcidin levels occurred as the stages progress. Zaritsky et al.\textsuperscript{18} divided the study sample into controls, stage 2 to 4 CKD, and stage 5 CKD. In this study the median control group was 72.9 ng / ml, in the 2-4 stage CKD group it was 127.3, and the Dialysis CKD stage 5 group is 652.4 ng / ml. On the other hand, in a study conducted by Mercadel et al.\textsuperscript{10} did not explain hepcidin levels at each stage but, the researchers included an increase in hepcidin levels from 23.3 ng / ml to 36.1 ng / ml if there was a decrease in mGFR values from > 60 ml / min / 1.73 m\textsuperscript{2} to <15 ml / min / 1.73 m\textsuperscript{2}. In the study done by Manolov\textsuperscript{20}, the levels of hepcidin in the 3 groups were in the stage 2-4 CKD group with a score of 90.74 ng / ml, in the CKD 5 group which had chronic dialysis of 282.49 ng / ml and in the control group 12.7 ng / ml. This is not much different from the results of this study.

**Relationship between eGFR and Heparidin in CKD Patients**

The test results of the analysis of the relationship between eGFR and hepcidin levels in CKD patients showed a significant relationship (correlation coefficient value of -0.633; p-value of 0.000) indicating that a decrease in eGFR was found to be inversely proportional to increasing hepcidin levels. The results of this study are consistent with the results of a study conducted by Zaritsky et al.\textsuperscript{18} and Uehata et al.\textsuperscript{19} who concluded that there was a negative relationship between eGFR and hepcidin levels. Zaritsky et al.\textsuperscript{18} conducted a study of the importance of the role of hepcidin as a novel biomarker for iron status in CKD patients and their relationship with eGFR. In this study using stage 2-5 CKD samples found a negative relationship between eGFR and hepcidin with R of -0.61 (p = 0.001). The method used in the measurement of hepcidin is ELISA 23. Uehata et al.\textsuperscript{19} did an observational cross-sectional study of the relationship between hepcidin and anemia related to CKD. In this study also the relationship of hepcidin with eGFR was observed which showed a negative correlation between eGFR and hepcidin with r = -0.27 (p <0.001). The sample used did not exclude erythropoietin> 2 weeks and diabetes mellitus. The method of measuring hepcidin levels using liquid chromatography tandem mass spectrometry (LC-MS / MS) 25. In the study carried out by Troutt et al.\textsuperscript{17} examined hepcidin-25 which increases with increasing kidney stage and negatively correlates with eGFR. There was also a negative correlation between hepcidin and eGFR using the Cockcroft-Gault formula with R = -0.32 (p = 0.001). The difference in the results of this study can also be caused by the use of different methods of measuring hepcidin namely ELISA and Mass spectrometry-based methods\textsuperscript{7}.

**Conclusions**

The profile of general characteristics in this study found that the highest sex average was male (67.6%) with an average age of 56.84 years. Most of the CKD stages in this study were stage 3 (43.2%) with most common cause of was hypertension (75%). The mean hemoglobin level in the subjects of this study was 10.88 g / dl, with a mean BUN of 33.94 mg / dl, and a mean creatinine serum of 3.42 mg / dl. The mean and standard deviation of eGFR values in the subject of this study amounted to 26.72 ± 16.12 ml / min / 1.73 m\textsuperscript{2}. The obtained mGFR values in stage 3a (45-60) at 18.1 ml / min / 1.73 m\textsuperscript{2}, stage 3b (30-45) at 33.7 ml / min / 1.73 m\textsuperscript{2}, stage 4 as high as 28.1 ml / min / 1.73 m\textsuperscript{2}, and in stage 5 it is 7 ml / min / 1.73 m\textsuperscript{2}. The total mean mGFR value at all stages was 35.3 ml / min / 1.73 m\textsuperscript{2}, whereas if the GFR was measured the estimation using the CKD-EPI method was 34.2 ml / min / 1.73 m\textsuperscript{2}. Median deviation of eGFR values in the subject of this study amounted to 26.72 ± 16.12 ml / min / 1.73 m\textsuperscript{2}. The mean and standard deviation of eGFR values in the subject of this study amounted to 26.72 ± 16.12 ml / min / 1.73 m\textsuperscript{2}. Median hepcidin levels in the subject of this study amounted to 48.58 ng / ml with a range of 0.12 - 439.07 ng / ml. In this study, there was a significant negative relationship with moderate strength between eGFR and hepcidin levels (r = - 0.633; p-value 0.000) which showed that if there was a decrease in eGFR values, there would be an increase in hepcidin levels. Increased levels of hepcidin which is most likely affected by inflammation since the beginning of the CKD stage need to be watched out for because it has the potential to result in functional iron deficiency anemia.

Association of Glomerular Filtration Rate with Intact Parathyroid Hormone in Non-dialysis Chronic Kidney Disease Patients

Djoko Santoso¹, Ach Syaiful Ludfi¹, Nunuk Mardiana¹, Widodo¹
¹Faculty of Medicine, Airlangga University, Surabaya, 60115 Indonesia

Abstract

Hyperparathyroidism is one of mineral and bone metabolism disorders in chronic kidney disease currently known as chronic kidney disease-mineral and bone disorders. The study aims to analyse the association between glomerular filtration rate and intact parathyroid hormone levels in non-dialysis chronic kidney disease patients at Internal Medicine Outpatient Clinic in Dr. Soetomo Hospital. The study was used observational analytic study with cross sectional design. The samples were 62 non-dialysis chronic kidney disease patients who met the inclusion and exclusion criteria. In this study, the variables were glomerular filtration rate calculated by the CKD-EPI formula and intact parathyroid hormone measured by Electro-chemiluminescence immunoassay (ECLIA) method. The data was analysed using Pearson or Spearman non-parametric tests. The Pearson or Spearman non-parametric tests obtained r=-0.518 and p=0.000.

Keywords: Calcium, Chronic Kidney Disease, Diabetes Mellitus, Hypertension, Phosphorus

Introduction

Chronic kidney disease (CKD) are risk for bone, vascular, and death abnormalities due to calcium, phosphorus and parathyroid hormone disorders¹. The management in patients with impairment of minerals metabolism especially parathyroid hormone which more focus on severe CKD patients. The unbalance of calcium and phosphate leads to secondary hyperparathyroid affects the vascular calcification and bone abnormalities. Minor metabolism and bone disorder will occur in person with reduction in kidney function at early stage. The symptoms are asymptomatic and often unnoticed².

Secondary hyperparathyroidism is mineral and bone metabolism disorder in CKD and known as mineral and bone disorder in chronic kidney disease. The mineral and bone disorder in CKD is characterized by several factors such as metabolism disorders, calcium, phosphorus, vitamin D and parathyroid hormone³,⁴. In CKD with decrement of hyperphosphatemia occurs due to reduction of phosphorus excretion in kidney and increases of fibroblast growth factor-23 level (FGF23). The glomerular filtration rate decreases also lead reduce in 1.25 (OH) 2D3 which important for calcium absorption in the gut.

The hyperphosphatemia, FGF23, 1.25 (OH) 2D3 and calcium level has influence secondary hyperparathyroidism. The secondary hyperparathyroidism increases vascular calcification due to calcium-phosphorus deposition. In additions, secondary hyperparathyroidism causes renal osteodystrophy, immune dysfunction and anaemia⁵. Slinin et al.⁶ stated increment in cardiovascular diseases risk and mortality with hyperthyroid levels> 480 pg/mL.

Approximately, 2 million to 4.7 million people suffers CKD with secondary hyperparathyroidism need treatment costs of $ 52 billion to $122 billion per year in the United States⁷. Secondary hyperparathyroidism is often overlooked, undiagnosed and insufficient treated by clinicians due to lack of studies in non-dialysis CKD patients⁸. Owda et al.⁹ had found 78% of CKD patients undergone dialysis also experiences with secondary hyperparathyroidism. Meanwhile, Young et al.¹⁰ found 50% of dialysis patients had secondary
hyperparathyroidism\textsuperscript{10}. In additions, there was an increment of 24\% of stage 3 and 4 CKD patients in secondary hyperparathyroidism\textsuperscript{11}. Levin et al.\textsuperscript{12} also found pre-dialysis patients had hyperparathyroidism in glomerular filtration rate < 60ml/minute/ 1.73 m\textsuperscript{2}.

Several studies stated decreasing in glomerular filtration rate will increase risk of secondary hyperparathyroidism. Hence, early parathyroid hormone detection test is helpful in CKD patients since secondary hyperparathyroidism caused blood vessel calcification and risk of cardiovascular diseases\textsuperscript{13, 14}. The study aims to analyze the association between glomerular filtration rate and intact parathyroid hormone levels in non- dialysis chronic kidney disease patient at Internal Medicine Outpatient Clinic in Dr. Soetomo Hospital.

Methodology

The study was used observational analytical research with cross-sectional design. The study was conducted at Internal Medicine Outpatient Clinic in Dr. Soetomo Hospital. The study population was chronic kidney disease patients in Internal Medicine Outpatient Clinic in Dr. Soetomo Hospital. The samples were 29 respondents which met the inclusion criteria. The samples were selected by consecutive sampling method. The data was analysed by using SPSS program and tested by Kolmogorov Smirnov test.

Result and Discussion

In Table 1, most respondents were male (85.5\%) and only 9 respondents (14.5\%) were female with mean age of 52.05 years old. Meanwhile, body mass index (BMI) mean included mean upper arm circumference within normal limits. The mean of creatinine serum was 5.8 with standard deviation of 4.28. The hypertension was most comorbid disease included mean of calcium or phosphorus levels within normal limits. The comorbid diseases found in CKD patients were diabetes mellitus (DM) with 41 respondents (66.1\%), hypertension with 48 respondents (77.4\%) and combination of DM and hypertension with 32 respondents (51.6\%).

Based on Table 2, median of glomerular filtration rate were 14 ml/minutes. Meanwhile, smallest glomerular filtration rate was 2 ml/minutes and highest of glomerular filtration rate was 59 ml/minutes.

The comparison of intact parathyroid hormone levels intake in glomerular filtration rate by using Kruskal Wallis test due to abnormal data distribution. Kruskal Wallis test was obtained $p=0.000$ that concluded there was significant differences of intact parathyroid hormone in each of glomerular filtration rate group. The median of intact parathyroid in glomerular filtration rate of 30 ml/minutes to 59 ml/minutes equal to 57.26 pg /ml and glomerular filtration rate of 15 ml/minutes to 29 ml/ minutes was equal 92.08 pg /ml.

An association hypothesis test between glomerular filtration rate and intact parathyroid hormone was performed. In the normality test data with Kolmogorov- Smirnov can be concluded data has spread normally if $p$ value obtained is greater than significance level of 5%. The normality test of glomerular filtration rate and intact parathyroid hormone was obtained $p$ value of 0.000 and 0.000 which concluded that glomerular filtration rate and intact parathyroid hormone distribution was abnormal as shown in Table 5.

Discussion

The result found mean of respondent age were 52 years which highest group proportion was between 41 years and 60 years. In additions, most male respondent with male to female of 5.9:1. The influence in gender toward CKD is still unknown even the ratio of CKD patients between male and female was different. Previous study suggested female had lower progression of CKD than male$^{15}$. Jafar et al.$^{16}$ mentioned that progression of CKD in post-menopausal female was higher than male.

In this study, glomerular filtration rate was calculated using CKD-EPI formula with median of 14 ml/minutes that lower than previous studies. In De Boer study$^{11}$ found mean of glomerular filtration rate of 34 ml/minutes per
1.73 m² with used MDRD formula. Meanwhile, Sinha et al. obtained mean of glomerular filtration rate of 37.2 ml/minutes per 1.73 m³. Besides, low median of glomerular filtration rate was obtained due to abnormal patient distribution which 50% of respondents with glomerular filtration rate less than 15 ml/minutes.

The mean body mass index (BMI) was 23.43 kg/m² within normal category. De Boer et al. found mean of BMI was 26.9 kg/m² or in overweight (pre-obesity). Albumin mean was 3.89 g/dl which not much different from De Boer et al. with albumin mean was 3.7 g/dl. Besides, upper arm circumference was normal with 27.09 cm. Creatinine serum mean was 5.89 mg/dl similar to Malawadi et al. study showed 5.5 mg/dl. The creatinine serum mean was high due to uneven distribution of patients which most patients had low glomerular filtration rate less than 15 ml/minutes.

Furthermore, comorbid diseases in CKD only focused on diabetes mellitus and hypertension obtained by anamnesis patients. The hypertension was 77.4% and diabetes mellitus of 66.1% obtained in this study. Joly et al. (2011) found 86% of respondents suffered hypertension and 45% of respondents suffered diabetes mellitus in Asia population.

In this study, mean of normal phosphorus level was 4.79 mg/dl which slightly higher than other studies by De Boer et al. and Fajtova et al. were 4.2 mg/dl and 4.16 mg/dl. The difference in mean of phosphorus level which relatively higher than other studies due to differences in the patients distributions.

Meanwhile, calcium concentration was 8.49 mg/dl within normal range due to most patients had calcium levels below optimal value (43.5%). This condition may occur caused by decrement 1.25-dihydroxyvitamin D3 in CKD patient at glomerular filtration rate ≤60 mL/minute / 1.73 m².

In this study, glomerular filtration rate was calculated using CKD-EPI formula with median glomerular filtration rate 14 ml/minutes. There were 50% of respondents with glomerular filtration rate less than 15 ml/minutes. The glomerular filtration rate was small which related to the health insurance system policy in Indonesia which most CKD patients with stage 5 in Dr. Soetomo Hospital.

Besides, insufficient intact hyperthyroid hormone levels were probably due high number of patients suffered DM (66%). The patients with DM had lower of intact parathyroid hormones than patients without DM. Insufficient of intact parathyroid hormone also influenced with normal of calcium and phosphorus levels of 51.6% and 53.2%.

Furthermore, it also appears that the median HPT intact value will increase with the decrease in kidney function. Median HPT intact at LFG <15 ml/min higher than LFG> 15 ml/min. These results are similar to those of Levin, et al. where the median HPT intake value will increase as LFG decreases. The intact parathyroid hormone serum increased to be initial of CKD-MBD. The intact parathyroid hormone level in CKD was important as predictor of cardiovascular morbidity and mortality, endothelial dysfunction or systemic inflammation.

The correlation between glomerular filtration rate and intact parathyroid hormone in non-dialysis of CKD patients with p value= 0.000<0.05 in Dr. Soetomo Hospital, Surabaya. The spearman correlation coefficient value of -0.518 meant correlation between glomerular filtration rate with intact parathyroid hormone among non-dialysis CKD patients was medium. The negative or opposite direction of correlation meant decreased in glomerular filtration rate and increased in the intact parathyroid hormone.

**Conclusion**

In conclusions, there was significant correlation between glomerular filtration rate and intact parathyroid hormone. In additions, there was tendency that reduction in glomerular filtration rate and followed by increment of intact parathyroid hormone which calcium and calcium levels were still normal limits that could be consideration in management of mineral and bone disorder with CKD.

Water Soluble Protein Optimized Extraction from Microalgae Spirulina Platensis

Cynthia Dwi Anggraeni¹, Sudarno¹, Mochammad Amin Alamsjah¹
¹Faculty of Fisheries and Marine Universitas Airlangga, Surabaya 60115, Indonesia

Abstract

This research aimed to determine the factors influencing extraction of water soluble protein from Spirulina platensis which included the ratio of Spirulina platensis and aquadest, incubation time, and interaction of those two factors. This research contained two factors (ratio and incubation time) using factorial complete randomized experimental design with nine treatments and three replications. Ratios of Spirulina platensis and aquadest used were 1:40, 1:50, and 1:60, while the incubation times were 1, 2 and 3 hours. Parameter observed in this study was water soluble protein content of Spirulina platensis. Ratio of Spirulina platensis and aquadest significantly affected water soluble protein content (p<0.05). The highest content of water soluble protein was observed at the ratio of 1:50 (85.4742 μg/ml), while the highest water soluble protein content based on the incubation time was observed at 3 hours treatment (p<0.05). These results indicated that ratio and the incubation time influenced water soluble protein content on the extraction process of Spirulina platensis with the optimized extraction should be at the ratio of 1:50 for 3 hours.

Keywords: extraction, optimization, Spirulina platensis, water soluble protein.

Introduction

Spirulina platensis is one of the microalgae that has the potential as a food source. Complete nutrient content of Spirulina platensis and the presence of antioxidant compounds of ficocyanin pigments have been used as a dietary supplement¹. The utilization of Spirulina is to have the value of high protein content mainly on dried Spirulina protein and blue pigment (ficocyanin), reaching 20% of dry weight². The high protein content on Spirulina platensis, reaching 60 – 71%, could be used as a protein source³. Protein in Spirulina was composed of several amino acids, such as methionin, lysin, and systein, compared with the protein content in egg and milk⁴. Spirulina, which is a single cell organism, has other benefits as the source of carotenoids, chlorophyll, and other micronutrients⁵.

Protein source in Spirulina was one of nutrient types that could potentially provide important functional properties, such as maintaining the food product characteristics for an emulsifier, thickener, natural dyes, gel-forming, and others⁶. Spirulina is produced in the form of drugs, supplements, juices, tablet, as well as functional food. Spirulina also served as a food source of food for better immune system and Super Oxyde Dismutase (SOD) content⁷.

The utilization of Spirulina in the industry is not yet optimum. Optimization needs to be done to optimize the utilization of Spirulina. The existence of high-protein potential content in Spirulina could be developed quickly, as it had the ability to proliferate fast, season independence, not requiring an extensive land for culture⁸. The optimization process is done to make an important protein extracts by determining the maximum variables and interaction on the various parameters that influenced the extraction outcome. Based on the research background, further research needed to be conducted for obtaining the optimum process conditions of extracting water soluble protein in Spirulina platensis which will be done in this study. Protein produced is expected to be widely exploited, one of which was the application of water-soluble protein in fruit juice.

DOI Number: 10.5958/0976-5506.2019.00869.6
**Methodology**

This research used factorial complete randomized design (FCRD) experimental method with two factors, such as the ratio of *Spirulina* powder with aquadest and incubation time. These factors were divided into 9 treatments and 3 replications. The ratio treatments are 1:40, 1:50 and 1:60, while incubation time treatments are 1, 2 and 3 hours. These treatments were based on Safi et al.\(^8\), who used 0.5 g of *Spirulina platensis* to dissolve in 25 ml aquadest and incubated for 2 hours.

Sample preparations:

Water Soluble Protein Extract Production from *Spirulina platensis*

Protein extract production was done by measuring *Spirulina platensis* powder into the Erlenmeyer tube filled with aquadest and incubated based on the treatments given. Solutions made were homogenized using vortex and centrifuged at 6,000 rpm for 15 minutes.

Protein Content Measurement using Lowry Method

This measurement analysis was begun with preparing 2000 ppm of BSA (*Bovine Serum Albumin*) as the main standard solution. This solution was made from 0.5 g solid BSA added with 250 ml aquadest. This solution was diluted using 40, 80, 120, 160, and 200 ppm concentration series. This solution was then added with 5 ml of modified reagent for 10 minutes and 0.5 ml of Follin-Ciocalteu reagent, while being shaken for 30 minutes. Solution was measured using 760 nm spectrophotometer\(^9\).

Water Soluble Protein Content Analysis from *Spirulina platensis*

20 μl supernatant of *Spirulina platensis* was added with 1000 μl aquadest. This solution was added with 5 ml of modified reagent for 10 minutes and added with 0.5 ml of Follin-Ciocalteu reagent, while being shaken for 30 minutes. Solution was measured using 760 nm spectrophotometer\(^9\).

Blueberry Juice Production

Fruit juice production was done using 5 concentration treatments of water soluble protein based on Yusmarini et al.\(^10\), containing 0%, 25%, 50%, 75%, and 100% modification. Juice was produced using blender by mixing all ingredients needed, such as blueberry, lemon, water, sugar, and honey. Blueberry juice was added with the water soluble protein from the optimized extraction of *Spirulina platensis*.

Hedonic test is done using 30 non-expert panellists from Faculty of Fisheries and Marine, Universitas Airlangga, students. Indicators tested were appearance, colour, taste, aroma, and texture. Water soluble protein content result data was analysed using FCRD Analysis of Variance (ANOVA) statistical analysis with SPSS 16.0 software. Data containing significant difference was analysed continuously using Duncan’s Multiple Range Test (DMRT). Hedonic test and juice protein content were analysed using descriptive method.

**Results**

Concentration Measurement Results of BSA (Bovine Serum Albumin)

Measurement of protein levels is carried out using the Lowry method. The method uses a solution of BSA as a comparison solution by measuring uptake on UV-VIS spectrophotometers at a maximum wavelength of 760 nm. The BSA concentration series used are 40, 80, 120, 160, 200 ppm and the results are tabulates in Table 1. Making standard solutions with various series aims to determine protein levels in a sample using straight line linear regression obtained from a standard solution graph\(^9\). Absorption values of UV-VIS Spectrophotometry from BSA obtained absorbance figures which became the y-axis and BSA concentration as x-axis in the form of a curve. The BSA curve and calibration equation can be seen in Figure 1. The measurement results of BSA solution absorption produced a curve with a positive slope approaching 1 (0.9945) with a linear regression equation \( y = 0.0934x - 0.004 \). The absorbance results of *Spirulina platensis* extract using UV-VIS Spectrophotometry were included in the equations and calibration curves of the BSA.

Water Soluble Protein Content Analysis based on Ratio of *Spirulina platensis*: Aquades

Based on Table 2, the different ratio of *Spirulina platensis* and aquades affected the water soluble protein content is exposed. The highest water soluble protein was obtained from 1:50 ratio, while the lowest was observed at 1:40 ratio. Analysis result which had the closest level with 1:50 ratio was 1:60 ratio with 78.2769 μg/ml. However, 1:50 showed the highest water soluble protein content which used less solvent, making the extraction process using 1:50 ratio was more effective and efficient.

Water Soluble Protein Analysis based on The Interaction of *Spirulina platensis*: Aquades Ratio and Incubation Time

Based on Table 4, it is shown that the difference in the ratio of *Spirulina platensis* and the different incubation times for each treatment affected the levels of water soluble proteins produced. Water soluble protein content from *Spirulina platensis* extraction was produced from two factors interaction, which was *Spirulina platensis*: aquades ratio with incubation time. DMRT analysis showed that p value was 0.000 or smaller than 0.005 (p< 0.05), resulting a significant difference between treatment interactions. 1:50 ratio and 3 hours incubation gave the highest level of water soluble protein content with 115.99 μg/ml.

Hedonic Test of Water Soluble Protein Application on Blueberry Juice Product

Figure 2 is the graphical representation of the hedonic test results. The concentration of water soluble protein added to blueberry juice includes treatment A (0%), treatment B (25%), treatment C (50%), treatment D (75%) and treatment E (100%). Appearance of blueberry juice with the addition of water soluble protein which has the highest value is in treatment A with a value of 7.53. This shows the value of 8 which means it is very much liked by the panellists. Treatment A with the addition of 0% water soluble protein has a good appearance.

In the colour parameters, the highest average value given by the panellists is in treatment A and D with a value of 7.03. This shows a value of 7 which means that treatments A and D have the colour preferred by the panellists. Treatment A with the addition of 0% water soluble protein has a purple colour produced from blueberries, whereas in treatment D it has blue-purplish colour due to the dominant addition of water soluble proteins produced from extraction Spirulina platensis contains dark blue.

The assessment of the aroma of blueberry juice with the addition of water soluble proteins is an assessment carried out based on the sense of smell. In the graph in Figure 2 shows the aroma parameter has the highest value of 6.87 in treatment D with the addition of 75% water soluble protein which means the aroma of blueberry fruit juice is favoured by panellists.

Assessment of taste parameters in blueberry juice is based on taste buds so the panellists are required to taste the product in order to provide an assessment. On the graph of the hedonic test the highest value is found in treatment D with a value of 6.70 which means that treatment D has a feeling that is favoured by panellists.

The hedonic test results on the texture parameters of blueberry juice which have been added to water soluble protein showed the highest value in treatment B with the addition of water soluble protein by 25%. Treatment B shows a value of 6.77, which means the texture of the preferred blueberry juice is treatment B. The average value of all parameters in the hedonic test shows numbers 6 and 7, which means that fruit juice which has been added to water soluble protein from the resulting Spirulina platensis and well received by panellists.

Protein Content Analysis on Blueberry Juice

Based on Table 5, it can be seen that the addition of different water soluble proteins to each treatment affects the protein content of the blueberry juice products produced. The highest protein content was obtained in treatment E, while the lowest was in treatment A. This shows that the higher the concentration of water soluble proteins added, the higher the protein content produced.

**Discussion**

Different Spirulina platensis: Aquades Ratio against Water Soluble Protein

Data result analysis showed that there was a significant difference at the ratio of Spirulina with incubation time ratio, making them as generated water soluble protein content. Table 2 showed more aquades solvent used would make an increased product of water soluble protein. This was because Spirulina platensis content would be solved only at the polar soluble solvent for Spirulina platensis.

Solvent selection was very important, as it determines the bioactive compound which was taken in the extraction process. Extraction process included the maceration process, the larger ratio of simplicial against the extracting, the higher content result obtained.

Different Incubation Time against Water Soluble Protein Extraction Result

Data analysis of protein from Spirulina platensis water-soluble based on 1, 2, and 3 hours showed longer of incubation time would produce more water soluble protein. The treatment time of incubation for 3 hours has a value of 90.8870 μg/ml. According to Wang et al., longer extraction time would produce more time between solvent and main materials, making them into mass diffused precipitation until reaching a balance of excluding material extraction, thus incubation time influenced the extract production process obtained.

Interaction of Ratio and Incubation Time against Water Soluble Protein Content

The interaction of these two factors, namely the ratio of Spirulina platensis: aquades and incubation time showed significant difference on all treatments that produced water soluble protein. Table 4 shows that the treatment ratio of 1:50 with 3 hours incubation time had the highest water soluble protein content with 115.99 μg/ml. This research used aquades as a maceration solvent. Long and non-movement maceration process allowed many protein compounds got extracted.

Soaking process would crash the cell walls and membranes due to the difference pressure on the inside and outside of the cell. According to Safi et al., cell wall of Spirulina platensis had a characteristic that was fragile, as it was composed by the absence of peptidoglycan cellulose.

**Hedonic Test**

Hedonic test resulted blueberry fruit juices with addition of water soluble proteins a preferred mark from all panellists. All treatment showed blueberry juice with the addition of water soluble protein was acceptable by the panelists. Protein content on juice increased along with the increased protein concentration. According to Febriantiet al., protein content in drinks with protein added would be more appropriate for people who had food restrictions. People suffered kidney failure was more advisable to get the diet food by way of reducing the protein intake.

**Conclusions**

Different ratio, incubation time, and indicators between those two factors affected the water soluble protein content produced. Optimum ratio was observed at 1:50, while incubation time was observed at 3 hours incubation. The best protein content was also observed at the interaction of 1:50 ratio for 3 hours incubation.

Abstract

There is high prevalence of bone disease due to abnormalities of parathyroid hormone (PTH) in chronic kidney disease (CKD). The study aims to determine correlation between iPTH and subperiosteal erosion and b-ALP toward phalanx manus in pre-dialysis CKD patients. The study was used analytical observational research with cross-sectional design. The samples were 60 pre-dialysis CKD patients. iPTH levels was measured using ECLIA method and subperiosteal erosion on phalanx manus was assessed using X-ray. In additions, b-ALP levels were measured using ELISA method. The correlation between iPTH with subperiosteal erosion and b-ALP were analysed using contingency coefficient test. Median of iPTH level was 102.19 pg/ml (12.46-477.30 pg/ml). Subperiosteal erosion was found in 76.7% pre-dialysis CKD patients. Meanwhile, median of b-ALP level was 29.88 ng/ml (12.79-110.38 ng/ml). The contingency coefficient test of iPTH with subperiosteal erosion found r=0.103 and p-value=0.727. Meanwhile, contingency coefficient test of iPTH with b-ALP showed r=0.167 and p-value=0.424.

Keywords: b-ALP, Calcium, Chronic Kidney Disease, Diabetes Mellitus, Phosphorus.

Introduction

The complication of chronic kidney disease (CKD) is characterized by impairment in metabolism of mineral and bones and caused mineral and bone disorder in chronic kidney disease (CKD-MBD). CKD-MDB is describes a clinical syndrome that includes abnormalities of minerals, bone and vascular calcification due to CKD complications. The bone abnormalities in CKD patients contributed to high fracture risk and decrease the quality of life. This bone abnormalities is associated with secondary hyperparathyroidism with hyper parathyroid bone diseases in response to hypocalcaemia⁴⁻⁵. More than 50% of patients with CKD with decrease in glomerular filtration rate which up to 50% have bone histologic abnormalities, although clinical sis not shown any bone abnormalities symptoms⁴.

The bone abnormalities lead potential which caused complication such as fractures, bone pain, bone structural abnormalities, muscle weakness, tendon rupture and extracellular calcification especially cardiovascular calcification¹⁻³. These conditions will degrade quality of life and increasing morbidity and mortality of CKD patients⁶⁻⁷. The incidence rate of fracture is quite high at 2.9 per 1000 patients among CKD patients undergone dialysis in CKD patients undergone dialysis and occurs in younger age than normal population⁸⁻⁹.

Meanwhile, the pelvis fracture in dialysis patients had 2 times mortality risk higher than normal population¹⁰. The fracture incidence in CKD patients have high economic and clinical implications which medical costs for fracture range from $14,000 to $20,000 per incidence¹⁰.

Meanwhile, the pelvis fracture in dialysis patients had 2 times mortality risk higher than normal population¹⁰. As glomerular filtration rate in CKD, hyperphosphatemia and decreased production of 1.25 (OH)² D will cause hypocalcaemia.
The hypocalcaemia presence will lead to increment parathyroid hormone (PTH) or secondary hyperparathyroidism that will trigger bone resorption to release calcium and phosphate\(^{12}\). Hyperparathyroidism lead to increase bone turnover by increasing both bone resorption and formation. Bone specific alkaline phosphatase (b-ALP) describes the osteoblasts activity because osteoblast activity is intertwined during bone turnover and b-ALP represents an overall bone turnover. The combination of b-ALP and iPTH will increase sensitivity, specificity and predictive value in diagnosing bone turnover types\(^{13}\). Bone mediated osteoclast resorption of secondary hyperparathyroid leads to radiographically visible cortical depletion as subperiosteal erosion. The subperiosteal erosion is most consistent radiological feature of secondary hyperparathyroidism. The subperiosteal erosion presence is correlated with PTH serum and b-ALP\(^{12,14,15}\).

The renal osteodystrophy (ROD) is bone abnormality in CKD patients. The ROD is required non-invasive diagnostic techniques included bone radiology as well as biochemical markers for bone turnover such as iPTh and b-ALP\(^{16}\). iPTh showed good correlation with bone turnover rate\(^1\). PTH is major regulator of bone metabolism affecting bone formation and resorption which can affects changes in bone turnover. The study aims to determine correlation between iPTh and subperiosteal erosion toward phalanx Manus and correlation between iPTh and b-ALP in pre-dialysis CKD patients.

### Methodology

The study was used analytical observational research with cross-sectional design. The study was conducted at Dr.Soetomo Hospital, Surabaya between August 2015 and October 2015. The study population were all non-dialysis CKD patients who treated in Dr. Soetomo Hospital, Surabaya. The samples were 60 samples who met the inclusion criteria and selected by consecutive sampling method. The data was analysed Kolmogorov Smirnov test with SPSS program. The correlation between iPTh and subperiosteal erosion and b-ALP were analysed using contingency coefficient test.

### Result and Discussion

In Table 1, there were 51 male respondents (85%) and 9 female respondents (15%) involved in this study. The youngest respondent was aged 27 years old and oldest respondent was aged 65 years old. The mean of body mass index (BMI) was 23.42 kg/m\(^2\) with standard deviation of 3.49 kg/m\(^2\). The BMI was considered in normal BMI range. Meanwhile, mean of upper arm circumference was 27.11 cm with standard deviation of 3.85 cm which considered as normal upper arm circumference. There were 41 respondents (68.3%) suffered diabetes mellitus (DM) and 19 respondents were non-DM.

The corrected calcium serum mean was within normal range. The phosphorus serum level and glomerular filtration rate (GFR) values had abnormal data distribution. The corrected calcium serum had mean of 8.58 mg/dl with standard deviation of 0.63 mg/dl. The median of corrected calcium serum was 8.60 mg/dl with minimum and maximum were 6.9 mg/dl and 10.16 mg/dl.

Discussion

In this study, mean age of respondents were higher. The mean age among respondents was 52.12 years which highest number of respondents were between 50 years and 65 years. Besides, more male respondent than female with ratio of 5.6:1.

The ratio of DM patients and non-DM was 2:1 and most respondents had BMI was in normal ranges. In additions, highest number of respondents were in stage 5 of CKD with GFR median of 12.5 ml / min / 1.73m². The iPTH mean was lower due to higher number of respondents with CKD, older age and lower phosphorus level. The glycaemic status is one determinant of iPTH level in CKD patients with DM. The mechanism caused low iPTH levels in DM patients with Advanced Glycation End Products (AGEs) that inhibited PTH secretion.

The pathophysiology of decrement of iPTH levels together with increased age is still unclear. Kiss et al.17 found negative association between iPTH with age which lower phosphorus serum levels found in older age respondents. These results suggested lower phosphate intake among older patients than younger patients. Besides, older CKD patients had lower parathyroid gland response which correlated with greater uremic toxin accumulation at older age18.

Furthermore, iPTH levels had abnormal data distribution so the median iPTH was used to analyze the data. The ROD histopathology in pre-dialysis CKD patients is unknown than dialysis CKD patients due to lack of skeletal symptoms and definitive indication for bone biopsy. Most common ROD histology type in CKD patients was hyperthyroid bone disease. Early detection for bone abnormalities in ROD is important such as presence of bone related hyperparathyroidisresorption. Subperiosteal resorption was earliest pathognomonic feature of hyperparathyroidism.

In this study, 76.7% of respondents had experienced subperiosteal erosion which detected with plain manus images. High bone erosion due to increased bone resorption caused by secondary hyperparathyroidism included osteoporosis and mixed bone diseases19.

The PTH measurement had several limitations, so alternatives approach was introduced using bone-specific alkaline phosphatase (b-ALP) which is directly related to bone turnover and bone histometric. The b-ALP is an ectoenzyme located on the osteoblast membrane13.

iPTH level were important predictor of bone histology type and used as non-invasive tool to distinguish between high turnover bone disease with low turnover bone disease or normal bone.

The statistical test showed no correlation between iPTH levels with subperiosteal erosion in phalanx manus. In CKD, bone metabolism disorders often caused imbalance between resorption and formation. There was increment in bone resorption included secondary hyperparathyroidism, osteoporosis, mixed bone diseases and β2- macroglobulin osteoarthropathy. The bone lesions showed decreased bone resorption was found in low-binding diseases correlated aluminum, osteomalacia, adynamic osteopathy and extracellular calcification20. The bone abnormalities condition was obtained in CKD patients and found these bone abnormalities affected bone erosion image.

The X-ray helped identified bone characteristics but did not distinguish bone abnormalities type. The subperiosteal resorption was radiological feature of hyper parathyroid bone disease which found in osteomalacia found in CKD patients21. In this study, most respondents were stage 5 of CKD patients leads to increase of IL-1, IL-6, TNF-α and growth factor cytokines. Bone histologic changes in secondary hyperparathyroidism was commonly found in stage 3 or 4 of CKD patients who had lower plasma PTH.

Although, PTH had important effect in bone turnover, PTH serum concentration did not considered as substitute marker for bone turnover. The iPTH level in diagnosed bone disease was higher in dialysis patients than pre-dialysis patients.In this study, there was no significant correlation between iPTH level and b-ALP levels which indicated presence of other factors. The correlation between b-ALP and iPTH represented an uncoupling between bone formation and resorption. Both
iPTH and b-ALP did not correspond to an increment in bone turnover. Low plasma b-ALP also represented decreased in b-ALP synthesis by uremic osteoblasts. Poor osteoblast response to low PTH and b-ALP plasma resulted down regulation of PTH receptors in uremic cells. The osteoblast function defect can be obtained in the respondents which affect the b-ALP synthesis.

**Conclusion**

In conclusion, there was no significant correlation between iPTH levels with subperiosteal erosion and b-ALP. The subperiosteal erosion of phalanx manus and b-ALP levels cannot describe bone due to iPTH abnormalities. The study need to be done to determine bone abnormalities in CKD with using the bone biopsy and other factors such as cytokines IL-1, IL-6, TNF-α and growth factor, calcitriol level, PTH receptor level, vitamin D receptor, calcium-sensing receptor and other bone abnormalities.

Erythropoietin Potential as an Antiapoptotic Agent in ISCEMIC Stroke using Unilateral Right Common Carotid Artery Occlusion (RUCCAO) Model

Junaidi Khotib¹, Ika Ayu Mentari², Mahardian Rahmadi³, Suharjono⁴

¹Faculty of Pharmacy, Airlangga University, Surabaya 60115 Indonesia

Abstract

Ischemic stroke is insufficient or interrupted of blood flow to an area of the brain, typically caused by blockage of an artery and can result in brain damaged. This study was aimed to investigate the efficacy of Recombinant Human Erythropoietin (rHuEPO) as a neuroprotection (antiapoptotic agent) on rat with ischemic stroke induced by right common carotid artery occlusion. Animals were divided into five groups included sham group, ischemic stroke group and treatment group of rHuEPO. rHuEPO was administered intravenously once a day for 7 days at dose 1000, 5000, 10000 IU/Kg a week after induced by right common carotid artery occlusion surgery. The repair of brain damage was evaluated by Y maze for cognitive repair, ladder rung walking and forelimb asymmetry test for motor repair, measured on day 0, 1, 3 and 7. The result showed that treatment with rHuEPO significantly enhanced spatial memory at 5000 and 10000 IU/Kg in day 7 compare to ischemic group (p = 0.0260, p = 0.0286 respectively) and improved motoric function in day 7 compare to ischemic group (p = 0.0064, p = 0.0102 respectively). rHuEPO significantly reduce area infarct at 1000 IU 5000 IU and 10000 IU/Kg compare to ischemic group (p = 0.0265, p = 0.0016 p = 0.0024 respectively). Furthermore, there were significant differences on caspase 3 expression in each group.

Keywords: Anti Apoptotic, Caspase 3, Ischemic Stroke, rHu Erythropoietin

Introduction

Ischemic stroke is a condition where the blood vessels of the brain experience blockage (lack of blood supply) caused by the presence of thrombus or embolism. Death in ischemic stroke involves two processes namely necrosis and apoptosis. Both of these processes depend on the duration of exposure and ischemic intensity experienced. In focal ischemia, necrosis is the main cause of cell death in the core, and in the core area is surrounded by penumbra, where neurons mainly die by apoptosis, which is governed by a programmed cell death mechanism, because the apoptosis process is regulated by certain signal elements so that it takes time for neuronal cell death there is therefore an opportunity to save the penumbra area from ischemic stroke¹.

The lack of supply of blood flow and energy to the brain, which triggers at least some mechanisms that cause cell death, namely excitotoxicity and ion imbalance, inflammation and apoptosis². Ischemia and reperfusion trigger a complex cascade of brain injury mediated by overloaded intracellular glutamate and Ca²⁺. Depletion of oxygen and glucose in cells causes a decrease in the Na⁺ -K⁺ -ATPase function which will cause Na⁺ concentration in cells to increase so that cell swelling arises¹.

To avoid greater neuronal cell death, a neuroprotectant is needed. Erythropoietin is thought to be neuroprotectant by increasing cell resistance through activation of phosphatidylinositol 3-kinase / Akt and the NFkB pathway resulting in regulation of antiapoptotic proteins and blocking the activation of specific death cell proteases leading to apoptosis, Sharawy et al.³ had mentioned erythropoietin effect as neuroprotectant by targeting ROS through activation of antioxidant enzymes and their ability to reduce TNF.
Based on the description above, it is necessary to conduct research on the potential of erythrolein to reduce the number of cell deaths caused by ischemic stroke. It was proved that this was done by testing in mice that were conditioned to suffer from ischemic stroke by using the right unilateral common carotid artery occlusion (rUCCAO) experimental model. rUCCAO (right unilateral common carotid artery occlusion) is a method of inducing stroke by binding or blocking the right carotid of the communist artery, where the artery directly drains blood to the brain, for 90 minutes, this method will produce hypoxic conditions in brain tissue. To see the improvement of the improvement of ischemic stroke using erythropoietin, it will be seen the extent of infraception, cellular changes, caspase 3 expression in the brain and seeing improvements in memory and motor function in experimental mice.

Methodology

This experimental research was conducted at the Animal Pharmacy Laboratory of Airlangga University started from February to August 2017. The study design used was randomized design, pretest-posttest and controlled group study. As many as 30 Wistar breed mice aged 8-10 weeks were randomly divided into five groups included sham group, stroke model group and rHuEPO administration group with three different doses of 1000, 5000 and 10000 IU kg/BW. Prior to stroke induction, baseline measurements were taken for behavioral tests (Y-maze, ladder rung walking, Forelimb used Asymmetry Test -FUAT) which aimed to determine the cognitive and motor function of mice before and after induction. Administration of rHuEPO in the treatment group was given for 7 consecutive days while the sham group and stroke model group were given normal saline for 7 consecutive days. Observation of behavior was carried out on days 1, 3 and 7. Termination was carried out on the 14th day by looking at the area of infarction using TTC staining, observation of the cellular changes in brain tissue using hematoxylin eosin staining, and observation of caspase 3 activities in the brain with immunohistochemical staining using antibodies caspase 3. The experimental data were then statistically analyzed with ANOVA, post hoc Bonferroni’s and post hoc Tukey’s HSD in order to identify the differences between the experimental groups.

Result and Discussion

FUAT method was tested using a cylinder task to observe the effect of rHuEPO toward motor function improvement. The purpose of this method was to determine the tendency of the mouse to use ipsilateral or contralateral when the mouse stands in a transparent plastic cylinder, mice that experience injury to their brains will experience contralateral malfunction if the ipsilateral part is induced by stroke. To find out the differences between groups, it was analyzed using one way ANOVA analysis, Tukey’s HSD post-hoc presented in Table 1. Table 1 showed a significant difference in the percentage of FUAT between each group with p = 0.0324 using the Two Way Anova test with a 95% confidence interval. The effect of rHuEPO on the improvement of motor function by FUAT method exhibited a significant difference on the 7th day between the sham vs stroke model (p = 0.0139), the stroke vs stroke model group + EPO 5000 IU / kgBW (p = 0.0064), the stroke vs stroke model group + EPO 10000 IU / kgBW (p = 0.0102) using the Tukey’s HSD post hoc test.

Figure 1 shows the cross section of brain organ. Based on Figure 1, the brain was taken and then prepared histochemically with hematoxylin-eosin staining. The images showed morphological changes that occur in neuron cell bodies in the thalamus area of the brain after receiving rHuEPO treatment at 1000 IU, 5000 IU and 10000 IU / KgBW doses once a day for 7 days. The body shape of a dead neuron cell indicated that the nucleus of the cell is seen to saturate its boundaries irregularly and is dark-colored in contrast to the living neuron cells which are still visible in the nucleus and children of the cell nucleus and the shape of cells that look brighter than dead cells.

![Figure 1. Cross section of brain organ with hematoxylin-eosin staining (a) sham group (b) stroke model group (c) stroke + EPO 1000 IU / kgBW (d) stroke + EPO 5000 IU / kgBW (e) stroke + EPO 10000 IU / kgBW](image)

To determine the occurrence of caspase 3 expressions in the mouse’s brain after the administration of rHuEPO in the condition of ischemic stroke, mice from each sham group, stroke model group, and treatment group were operated. The brain was taken and then prepared by immunohistochemistry with caspase antibody 3. In Figure 2 it can be seen that immunoreactive cells were clearly depicted as cells that absorb medium to strong
intensity brown color in the stroke model group, also seen quite dramatic changes in the cell image irregular shape with a smaller size.

Discussion

Inducing ischemic stroke models using the rUCCAO (right unilateral common carotid artery occlusion) method, the rUCCAO method was chosen because it was easy to implement and not complicated. The principle of this method was to inhibit blood flow to the brain by clamping the common carotid artery using a bulldog clamp, clamping takes place for 90 minutes, the communal carotid artery was located adjacent to the trachea. Brain ischemia causes gradual changes in neuronal cells included first stage of decreased blood flow, reduction of oxygen levels which results in energy failure resulting in terminal depolarization and failure of ion homeostasis. The second stage of failure is ion homeostasis, the third stage of inflammation and fourth stage of apoptosis.

The initial step of surgery is administration of anesthesia (ketamine 80 mg / kgBW and xylazine 10 mg / kgBW). Ketamine is a mixture of a depressant (NMDA antagonist) and analeptic (one of which is by increasing the binding of AMPA receptors) as its molecular action, with a mechanism like this it will be difficult to achieve full anesthesia and ketamine is an unfavorable muscle relaxation agent, it is necessary to add another agent, xylazine. Xylazine is an α-2 adrenergic agonist whose effects produce interactions between the central and peripheral α-2 adrenoreceptors which result in muscle relaxants. Both of these drugs are complementary combination agents between analgesic and muscle relaxation effects, ketamine provided an analgesic effect while xylazine causes good muscle relaxation.

Mice which have been given antithesis are then dissected by making an incision 2-3 cm long in the middle of the neck, then pinching the common carotid artery blood vessels located adjacent to the trachea. The reason for the use of clamping using bulldog clamp rather than binding with nylon thread is the strength of inhibition of blood flow in the common carotid artery using a stronger clamp and uniform release time compared to using a thread.

The day before surgery, observations were performed on the cognitive and motor functions of each treatment group. The cognitive functions were tested using the Y-maze test. Y-maze also known as spontaneous alternation is a method used to measure spatial working memory, short-term memory and general locomotor activity. There are three arms on the Y-maze tool, where the principle of this test is that each mouse will be placed in one of Y-maze’s arms then the mouse will move to the other arm until the mouse’s tail enters the arm, the movement of the mouse to each arm will be recorded and tested for 5 minutes. Each arm will be labeled A, B and C, for a score of 1 if the mouse enters the ABC arm, if the mouse moves from ABA then the score is 0, the
overall score will be changed in percentage form\textsuperscript{13,14}.

The next test was the measurement of infarct area. Slicing brain organs using brain blockers with bregma -2 interaural cutting position. The choice of Bregma-2 because in the position of Bregma -2 has a significant infarct compared to the position of the other Bregma. In the brain, the Bregma -2 regions is dominated by the hippocampus, hypothalamus and thalamus region where this area affects cognitive function\textsuperscript{9}. The central role of the limbic system included memory, learning, motivation and emotions. A brain structure that includes a system limbic include the amygdala, hippocampus, parahipocampus gyrus, cinguli gyrus, fornix, hypothalamus, thalamus, dentatus gyrus and entorhinal cortex.

The mechanism of cell death caused by ischemic stroke involved two death processes included necrosis and apoptosis, necrosis is the main cause of death in the core and in the core area is surrounded by penumbra, where nerve cells (neurons) mainly die by apoptosis and are regulated by cell death mechanisms programmed, because the apoptotic process is regulated by certain elemental signals so that it takes time for neuronal cell death, therefore there are opportunities to save the penumbra area from cell death due to ischemic stroke\textsuperscript{1}.

Apoptosis caused by ischemic stroke is divided into two intrinsic and extrinsic pathways, the intrinsic pathway caused by a lack of oxygen and glucose supply in cells causes a decrease in Na\textsuperscript{+}-K\textsuperscript{+}-ATPase function and neurons become depolarized causing “neuronal excitability” and massive release glutamate, when glutamate binds to the NMDA receptor causing an increase in Ca\textsuperscript{2+} in the cytosol (due to the opening of Ca\textsuperscript{2+} ion channels). This increase triggers translocation of Bax (proapoptotic agent) to the mitochondrial membrane and joins the PTE (permeability transition pore complex) resulting in increased mitochondrial membrane permeability and cytochrome C release\textsuperscript{1,9}.

The ability of erythropoietin to protect and prevent the brain from cell death can be seen from histology and immunohistochemical results. The results of brain histology using hematoxylin eosin (HE) staining showed the normal number of neuron cells in the sham group, and the rHuEPO treatment group was more compared to the stroke model group which can be seen in Figure 6 more visible cells in the ischemic stroke group dark color and shows no cell nucleus. HE stains is often used and able to smear the core and cytoplasm, HE staining using 2 kinds of staining substances, namely hematoxylin which functions to dissolve the nucleus of the cell and give blue color and eosin which is used to penetrate the cell cytoplasm\textsuperscript{15}.

Immunohistochemical testing of brain organs from each sham group, stroke model group, and treatment group was to determine caspase 3 expression which is caspase effector (caspase executor) one of the molecular regulators of apoptosis. The method used in this examination is a quantitative method, where the number of apoptotic cells in each sample was determined by adding up all apoptotic cells found in 5 (five) different fields of view, at 400 times the magnification.

The suspected mechanism for erythropoietin as an antiapoptotic agent is when EPO binds to EPO receptors in the brain (EPO receptors found in neurons, astrocytes, and microglia) will activate several pathways such as phosphatidylinositol 3-kinase / Akt and the NFκB pathway\textsuperscript{1,12,13}. Wu et al.\textsuperscript{14} stated that Akt is a survival agent and is activated by phosphorylation of ser473 via the PI3K (phosphatidylinositol 3-kinase) pathway which is considered as one molecule that can prevent the apoptosis process, the main regulatory mechanism of this enzyme is phosphorylation: Akt is activated while GSK-3β is inhibited by phosphorylation, inactivation of GSK-3β can cause prevention or reduction of apoptosis in neurons. GSK-3β participates in the mechanism of apoptosis GSK-3β has been shown to induce caspase-3 activation and activate pro apoptotic tumor suppressor genes, p53\textsuperscript{15,16}. GSK-3β also promotes the activation and translocation of members of the Bcl-2 pro apoptotic family, Bax in mitochondria thereby inducing cytochrome c release\textsuperscript{17,18}. Meanwhile, the activation of the NFkB path in his study states that the activation of NF-KB serves as the main mechanism to protect cells against the stimulus of apoptosis by promoting the expression of anti-apoptosis proteins such as XIAP (X-linked inhibitor of apoptosis proteins) and cIAP2 (c-inhibitor of apoptosis-2) in which cIAP2 can suppress the expression of caspase 3 and 9. Chong et al.\textsuperscript{19} stated that exogenous administration of erythropoietin can increase the expression of Bcl-xL (anti-apoptotic agent) in cerebral endothelial cells.

**Conclusion**

Overall results indicated that the administration of rHuEPO had neuroprotectant potential as an antiapoptotic agent in ischemic stroke with the administration of rHuEPO in line with efforts that continue to be developed.
as the latest strategy in the treatment of ischemic stroke. For this reason, it is necessary to further study the mechanism and other markers related to inhibition of brain cell death due to rHuEPO.

The Effect of Finasteride on Vascular Endothelial Growth Factor (VEGF) Expression in the Prostate Tissue and Bleeding Volume during Trans Urethral Resection of the Prostate (TURP)

Kartiko Sumartoyo¹, Budiono², Ketut Sudiana³, Soetojo¹, Sunaryo Hardjowijoto¹

¹Department of Urology, Faculty of Medicine, Airlangga University, Surabaya 60115 Indonesia, ²Department of Public Health, Faculty of Medicine, Airlangga University, Surabaya 60115 Indonesia, ³Department of Anatomical Pathology, Faculty of Medicine, Airlangga University, Surabaya 60115 Indonesia

Abstract

This study was evaluated the efficacy of Finasteride as a neoadjuvant therapy in reducing bleeding volume in patients with Benign Prostatic Hyperplasia (BPH) and urinary retention with prostate volume 30-50 mL who underwent Trans Urethral Resection of the Prostate (TURP). The study respondent consisted 26 patients with BPH and urinary retention who planned to undergo TURP. The study sample was randomly split into 2 treatment groups, 13 patients received Finasteride 5 mg once daily for 2 to 4 weeks before the operation and 13 others defined as control group. The therapy efficacy is evaluated by comparing the Haemoglobin pre-post operation difference, bleeding volume, bleeding volume per gram prostate tissue resected and the Vascular Endothelial Growth Factor (VEGF) expression within the prostate tissue. The treatment group indicated difference Haemoglobin between pre and post operation and average bleeding volume has less significant than the control group. The treatment group showed less amount of bleeding volume per gram of prostate tissue resected compare to control group. The treatment group also found significant lower VEGF expression within prostate tissue than the control group. This study demonstrated Neoadjuvant therapy with finasteride 1 x 5 mg for 2 to 4 weeks can reduce the VEGF expression in prostate tissue and reduce bleeding volume due to TURP.

Keywords: Benign Prostatic Hyperplasia (BPH), Bleeding Volume, Finasteride, Urinary Retention, Vascular Endothelial Growth Factor (VEGF)

Introduction

Benign prostatic hyperplasia (BPH) is a benign tumor that is most commonly suffered by men. The risk of men suffering from symptomatic BPH in the age between 50 - 59 years old is 25% and increases to 43% in men over 60 year old of age¹.

BPH is one of the causes of the lower urinary tract symptoms (LUTS) in elderly men, whereas in the group of men less than 30 year old benign prostate enlargement has not occurred so that LUTS complaints related to BPH have never been found².

Bleeding is a major complication of TURP. During the 1970 - 1990 periods, TURP-related transfusion rates were reported at 20%³. The development of technology in high frequency generators and improvement of techniques in continuous-flow instruments, video-TURP significantly reduced the number of transfusions due to bleeding in TURP where in 2000 and after that the transfusion rate was less than 10%³. Heavy bleeding with an open venous sinus is a risk factor for TUR syndrome. Other risk factors related to the incidence of TUR syndrome are length of time of surgery, large prostate volume and a history of smoking. Approximately 2 - 5% of bleeding due to TURP requires transfusion, while the percentage of need for transfusion in open prostatectomy is higher, between 7-14%³. S. Madersbacher et al.⁴ found an incidence of TURP-related transfusions of 8.6%.
The mechanism of action of Finasteride in reducing or preventing bleeding is estimated through its role in reducing the influence of androgens, which with no DHT formation will result in barriers to various growth factors including Vascular endothelial growth factor (VEGF). VEGF is androgen dependent and has a very important role in the process of angiogenesis and regulation of prostate blood flow. Reduced DHT will reduce VEGF expression so that the process of angiogenesis is inhibited and there is also a decrease in prostate blood flow and eventually the density of blood vessels in the prostate tissue will decrease.

With this circumstantial a study was conducted on the effect of Finasteride 5 mg once daily for 2-4 weeks before surgery on the amount of bleeding and VEGF expression in prostate tissue in BPH retention patients undergoing TURP compared without Finasteride as a control group.

**Methodology**

This study is an experimental study with a post-test only controlled group design with variable measurements such as Hb before TURP, Hb after TURP, Irrigation Hb and weight of VEGF prostate resection. The respondents were the patients who were diagnosed with Benign Prostate Hyperplasia (BPH) with indications that the TUR Prostate was performed at RSUD Dr. Soetomo Surabaya. There were 26 patients involved in this study. The sample study was randomly and equally split into two groups. One group is treated daily with 5 mg of Finasteride. Meanwhile, others group did not treat with Finasteride. The respondents were under observation for 2 to 4 weeks after treatment until the TURP operation.

The study was conducted during April 2014 to September 2014 with 26 patients who met the inclusion criteria. 26 patients were obtained after selected among the 39 BPH patients with urinary retention who undergone TURP surgery at RSUD Dr. Soetomo Surabaya. There were 26 BPH patients with urinary retention who met the inclusion criteria were grouped randomly into two groups. In additions, 13 patients who received 5 mg of finasteride therapy once a day for 2-4 weeks before TURP surgery as a treatment group and another group of 13 patients did not receive therapy as a control group. All patients in the treatment group completed therapy 2-3 weeks. The average duration of taking medication was 15.6 days (14-20 days) before surgery. There are no patients who meet the criteria for drop out. Unpaired t-test is used for parametric data in this study. While, Mann Whitney test is sued to test the different from non-parametric data. The data analysis is performed using SPSS V.21 with a significance level of 0.05.

**Result and Discussion**

All data were tested for normality by the Shapiro-Wilk test and the result is shown in Table 1. The results of normality test showed that the variables of age, preoperative hemoglobin, initial systolic blood pressure, the amount of bleeding, the weight of the resected prostate tissue and the duration of operation were normally distributed with a significance value of more than 0.05. Thus, the statistical test used is parametric statistics. An independent t test is used to test the differences between finasteride and control groups. There were two types of independent t tests, the pooled or equal variance t tests were assumed and the t separate or equal variance test is not assumed. The selection of the type of independent t test is based on homogeneity between groups. Levene test is used for homogeneity test, if the Levene test significance value is above 0.05. The data of both homogeneous groups and the t test used are pooled or equal variance t test assumed. Whereas if the significance value of the Levene test is below 0.05, the data of the two groups is not homogeneous and the t test used is the t separate or equal variance test not assumed.

Whereas in prostate volume variables, a long history of urinary retention, pre-postoperative hemoglobin difference, Hb irrigation, volume of irrigation, bleeding per gram of resection tissue, mean systolic blood pressure and VEGF expression of prostate tissue were abnormally distributed with a significance value of less than 0.05. Since the data is not normally distributed, the statistical tests used are non-parametric statistics. Different tests for non-parametric data used Mann-Whitney test. For the variable residual history, history of hematuria, urine culture and postoperative hematuria is nominal data so that the Chi square test is used.

Ten patients in the treatment group and 9 patients in the control group were examined for PSA serum. Patients who were not tested for serum PSA due to age>70 year old and no suspicion of malignancy on physical examination were found. Table 2 shows the mean serum PSA value in the treatment group was 6.53 ng /mL while the control group was 10.14 ng /mL. Six of the 10 patients in the treatment group were treated with prostate biopsy with the guide trans rectal ultrasonography (TRUS), in the biopsy control group performed in 6 of 9 patients who were examined for serum PSA. Biopsies in these 12 patients were carried out between 1-2 months before surgery. The results of biopsy pathology examination in both groups did not show any prostate malignancy.

Table 3 showed the information of residual cases, history of hematuria and urine culture for finasteride group and control group. In the finasteride group there were 2 cases of residual BPH while in the control group only 1 case of residual BPH. TURP’s operating history in the three residual cases is more than 7 years. There were 4 treatment group patients who had a history of hematuria before surgery and 3 patients in the control group. All patients were examined for urine culture, there were significant amounts of germs in urine in 6 treatment group patients and 7 in the control group, the rest were patients with sterile urine culture. The most
common type of germs found is Klebsiella pneumonia, in 4 (30.7%) patients. The differences in the three variables in the two study groups were not statistically significant (p> 0.05).

Discussion

Finasteride is a 5α-reductase type 2 enzyme inhibitor that converted testosterone to 5α-dihydrotestosterone (DHT). With a single dose of 5 mg Finasteride will rapidly reduce serum DHT levels, consequently blood flow and vascular endothelial growth factor (VEGF) expression will decrease and inhibit the process of angiogenesis, so that the density of the vascular tissue or microvessel density (MVD) will decrease5,8, 9, 10. Through this mechanism Finasteride can work to reduce hematuria due to BPH and bleeding in prostate surgery3.

The dose of finasteride given was finasteride 5 mg once daily for 14-20 days (2 - 3 weeks) before TURP surgery. One day before surgery the patient will be examined for serum hemoglobin and repeated after surgery while still in the recovery room. Blood mixed with irrigation fluid in containers was taken for inspection of irrigation Hb after the operation was completed. The volume of irrigation, blood pressure during surgery, the incidence of hematuria and postoperative retention clots in the room were recorded. Prostate scraping tissue was sent to the Anatomy Pathology section to find out histopathology and for VEGF expression examination.

Neoadjuvant treatment effect by administering finasteride 5 mg once daily for 14-20 days (2 to 3 weeks) before surgery in this study was found to have significantly lower pre-postoperative Hb (g/dL) than the control group (ρ <0.001 ) with a median of 0.2 and 0.3 respectively. The mean of bleeding (mL) of treatment group was significantly smaller compared to the control group which are 260.65 ± 94.86 and 523, 39 ± 156.49 with ρ = 0.014. The amount of bleeding per 1 gram of tissue (mL/g) resected of treatment group was significantly smaller than the control group (ρ <0.001) with a median of 9.53 and 21.25 respectively. The presence of VEGF expression in prostate tissue (per 15,625 μm2) in treatment group was significantly lower compared to the control group (ρ <0,0 001) with a median of 1.9 and 6.5 respectively.

The amount of bleeding in TURP is estimation because blood coming out of the prostate tissue mixes with irrigation fluid so that the exact amount of bleeding cannot be measured precisely. Estimation of the amount of bleeding in the study was obtained by calculating a formula involving variable Hb irrigation, serum Hb preoperative and the volume of irrigation used during surgery. The formula for estimating the amount of bleeding (mL) equal to the multiplication of volume of irrigation (mL) with the fraction of Hb irrigation (g/dL) and the preoperative blood hemoglobin (g/dL)11.

In this study, the range of Hb irrigation was 0.1 - 0.3 gr/dL in the finasteride group and 0.2 - 0.6 gr/dL in the control group with statistically significantly different. Irrigation HBs obtained from blood samples mixed with irrigation in containers, factors for fluid homogenization and sensitivity of examination instruments affect differences in results. Not all other researchers have included the results of irrigation Hb examination. The volume of irrigation fluid used will affect the final result of the amount of bleeding but not all other studies include the amount of irrigation fluid used.

The mean number of hemorrhages of the finasteride group in this study was 260.65 ± 94.86 mL, significantly different compared to controls. Bleeding parameters in Donohue’s study differed from this study and other studies, in which Donohue defined bleeding with the loss of gram Hemoglobin in irrigation fluid. However, different tests with the control group had the same results as this study, which was the amount of bleeding was significantly different compared to the control group.

Bleeding per gram of resected prostate tissue is assessed as a more appropriate criterion for assessing and comparing the amount of bleeding that occurs. In this
study, bleeding per gram of resection was significantly different compared to controls, median 9.53 (5.03 - 11.39) vs. 21.25 (9.72 - 28.20), mean 8.77 ± 2.17 vs 19.67 ± 5.82; ρ <0.001.

Besides, the study also found the VEGF expression of finasteride group was lower than the control group with median 1.9 (1 - 3.2) vs 6.5 (3.9 - 8.7) mean 1.81 ± 0.7 vs 6.34 ± 1.27 per area of 15,625μm², this difference was statistically significant (ρ <0.0001). VEGF-index is obtained from the number of cytoplasmic cells that react positively multiplied by the intensity score of the positive. This index is measured on the grounds that VEGF staining is difficult to uniform in each cell.

In this study VEGF expression was the mean of the positive number of VEGF expression of cytoplasmic cells of prostate tissue seen with a 100x, 400x magnification microscope and counted in graticule in each area of 15,625μm² in 10 random locations on each slide. However, the difference in measurements did not influence the results of the study because the same results were obtained where the VEGF expression of the finasteride group was lower than the control group.

The results and several other studies above were in agreement with the theory that VEGF is androgen-dependent, where the administration of finasteride will inhibit the formation of DHT, an androgen that is stronger than testosterone, which will reduce VEGF production. Reduction in VEGF will inhibit the process of angiogenesis so that blood flow and density of blood vessel tissue (microvessel density / MVD) in prostate tissue will be reduced\(^2,5,6,10\).

**Conclusion**

In conclusions, this study indicated a significant decrease in Hb difference before and after TURP, significant decrease in the amount of bleeding, decrease in the amount of bleeding per gram of prostate resection tissue and decrease in VEGF expression in prostate tissue treatment with neoadjuvant therapy with 1 x 5 mg finasteride for 2-3 weeks before surgery in BPH retention patients.

Effectiveness and Mechanism of Action of Vanadyl Sulfate in Increasing Pancreatic β Cell Proliferation of DM Mice Due to Streptozotocin Induction

Khoirotin Nisak¹, Junaidi Khotib¹
¹Faculty of Pharmacy, Airlangga University, Surabaya 60115 Indonesia

Abstract

Diabetes mellitus (DM) is a metabolic disorder characterized by hyperglycemia as a result of damage to insulin secretion, insulin action, or both. Vanadyl sulfate is one of the form of vanadium which has begun to be used to treat diabetes in humans. In this study, investigation on the effectiveness of vanadyl sulfate in increasing pancreatic β cell proliferation of diabetes mice due to streptozotocin induction. There were 30 healthy mice were subjected to this experimental study. Findings from this experiment proved that administration of vanadyl sulfate at various doses can significantly increase the amount of pancreatic β cell proliferation and eventually reduced blood glucose levels in a meaningless manner. However, those mice that administrated of vanadyl sulfate at a dose of 30 mg / kgBW had a higher amount of Langerhans Islet than those in the vanadyl sulfate group at a dose of 5 mg / kgBW and 100 mg / kgBW. Similar observations were obtained for the Ki-67 expression. The highest Ki-67 expression was obtained at a dose of 30 mg / kgBW but it decreased with a dose of 100 mg / kgBW of vanadyl sulfate.

Keywords: Diabetes Mellitus, Langerhans Islet, Streptozotocin, Vanadyl Sulfate

Introduction

Vanadium has been used since 1800 because of its nutritional benefits, in people with diabetes mellitus (DM), atherosclerosis, anemia and so on¹. In the 1900s, vanadium began to be used to treat DM in humans. The mechanism of vanadium action is that it can mimic the work of insulin so that stimulation of glucose uptake, glycogen synthesis, glucose oxidation in adipose, hepatocytes in an in vitro trial². In vitro and in vivo studies have shown that vanadium has the effect of insulin on the liver, skeletal muscle, and fat tissue both in humans and animal models²³. Studies have also reported the effects of glucose reduction due to vanadium salts, making them potential agents for blood glucose control purposes¹⁵.

The development of DM therapy since the last 2 decades has led to efforts made to induce pancreatic β cell regeneration. These efforts are carried out both by using stem cells and developing compounds that can induce pancreatic β cell proliferation⁶⁷. One of the compounds used is vanadyl sulfate. Vanadyl sulfate is a compound that has the potential to be used in the development of DM drugs because it can induce pancreatic β cell proliferation, this is evidenced by studies that have been conducted. In a study conducted by Missaoui et al.⁸ results were obtained that vanadyl sulfate can induce β cell proliferation in both normal and diabetic experimental animals.

In line with the latest direction of DM therapy development and has been widely researched for the past 20 years namely by induction of β cell proliferation using both stem cells and compounds that can induce proliferation, this study is expected to provide a mechanism description of the effect of vanadyl sulfate in increasing pancreatic β cell proliferation of DM in mice due to streptozotocin(STZ) induction.
Methodology

This study was conducted at the Animal Laboratory of the Faculty of Pharmacy, Airlangga University, Anatomical Pathology Laboratory, Faculty of Medicine and Dr.Soetomi RSU Diagnostic Center (GDC) Building. The animals test used were mice (Mus musculus) obtained from Gajah Mada University, Yogyakarta. The albino male mice, derived from one strain (BALB/c), healthy, no congenital abnormalities and had normal random blood glucose levels), male sex (age 8-10 weeks, body weight 25-30 grams), adapted for 14 days before being used for experiments. The 30 mice were kept in the cage throughout the experimental period at a constant room temperature of 25 ± 1 °C.

Before giving the mice vanadyl sulfate, the blood glucose reading were taken. On the first day of the experiment all the mice (except normal control) were induced intra peritoneally with streptozotocin dose of 100 mg / kgBW which was made in citrate buffer of pH 4.5 to induce the occurrence of DM. Followed by induction of the second dose 50 mg / kgBW on day 14. The blood glucose of the mice was evaluated on days 0, 7, 14, and 21. Those mice that experience DM had blood glucose levels> 300 mg / dl. When DM conditions occur at the time of blood glucose measurement, mice are then grouped into 5 random groups (control, healthy mice-no DM, mice with DM and vanadyl sulfate treatment group at a dose of 5 mg / kgBW, 30 mg / kgBW, and 100 mg / kgBW). For the treatment group, the mice were given vanadyl sulfate suspension for 7 days orally. Whereas in the control group, given CMC Na 0.6%. On day 8, after administration of vanadyl sulfate suspension, the mice were sacrificed by the cervical dislocation method, then surgery and removal of pancreatic tissue of mice from each group.

Histochemically, cross-sectional preparation of pancreatic tissue is performed with fuchsine aldehyde staining to observe the morphological characteristics, the number of Langerhans islets, and the number of pancreatic β cells of the mice. Results of the immunohistochemical examination are determined by Ki-67 antibody. To compare the differences in blood glucose levels of mice between normal groups, control of diabetes and treatment, one-way ANOVA test was carried out. Meanwhile, the effect of vanadyl sulfate at various doses observed on day 2, day 4 and day 8 after treatment, the One-Way ANOVA statistical test and followed by post-hoc Tukey’s HSD were done.

Result and Discussion

Table 1 presented blood glucose reading of the mice after consuming vanadyl sulfate for a week. From the table, the vanadyl sulfate could reduced blood glucose levels in DM mice. The results of measurement of blood glucose levels in groups of mice who developed DM and received vanadyl sulfate treatment at a dose of 5 mg / kgBW, 30 mg / kgBW, or 100 mg / kgBW showed decrement in blood glucose levels along with increased vanadyl sulfate doses compared to the DM group who only given 0.6% CMC Na solution orally.

| TABLE 1. Characteristics of blood glucose levels in different animal groups |
|---------------------------------|-----------------|-----------------|-----------------|-----------------|
| Group                          | Blood glucose level (mg/dL ± SE) |
|                                | Post STZ ± SE   | Day 2 ± SE      | Day 4 ± SE      | Day 8 ± SE      |
| Mice + DM                      | 413.00 ± 50.97 | 552.83 ± 30.55  | 493.83 ± 40.71  | 471.5 ± 49.05  |
| Mice + DM + VS 5 mg/kgBW       | 343.00 ± 47.08 | 414.17 ± 81.28  | 431.5 ± 50.10   | 369.17 ± 48.47 |
| Mice + DM + VS 30 mg/kgBW      | 444.17 ± 40.00 | 514.5 ± 29.09   | 363.33 ± 75.9   | 294.67 ± 73.68 |
| Mice + DM + VS 100 mg/kgBW     | 452.67 ± 106.36| 343.67 ± 177.41 | 269.2 ± 210.07  | 255.75 ± 229.64|

Statistical results showed that there were significant differences in the group as indicated by p = 0.0129 (p <0.05). In addition, there was a significant difference in blood glucose levels between normal animal groups and DM animal groups, but there were no significant differences in other groups. There was a trend towards a decrease in blood glucose levels as the dose of vanadyl sulfate increases.

Furthermore, One-Way ANOVA showed significant differences between normal mice group, DM, and treatment (p = 0.0065). The normal group of mice who did not get streptozotocin induction had an average number of Langerhans Islets of 8.00 ± 1.1 units and were significantly lower than the DM group to 3.78 ± 0.58 units (p = 0.0263). In the vanadyl sulfate group, the dose of 5mg / kgBW also showed a significant decreased compared to the normal mice group which indicated that the administration of vanadyl sulfate at a dose of 5mg / kgBW was not able to increase the amount of Langerhans Islet specified by its value which was not difference with DM mice (p = 0.9831).

Based on Table 4, the mean scoring of pancreatic β cell counts in the normal mice group was 5.03 ± 0.26 units, significantly decreased in the DM mice group to 1.87 ± 0.43 units (p = 0.0001). The decreased in this number justified the effectiveness of streptozotocin in damaging β cells in the Langerhans Islet.

In the treatment group 5mg / kgBW, 30mg / kgBW, and 100mg / kgBW, there was a significant increase in the number of pancreatic β cells compared to DM mice (p = 0.0000). The administration of vanadyl sulfate caused an increase in the number of pancreatic β cells from 2.67 ± 0.24 units for a dose of 5mg / kgBW, increasing to 4.07 ± 0.18 units for a dose of 30mg / kgBW, and the largest increase is 4.27 ± 0.27 units at a dose of 100mg / kgBW.

Based on Table 5, Scoring results using the Allred method showed that administration of vanadyl sulfate at a dose of 5mg / kgBW, 30mg / kgBW, or 100mg / kgBW showed an increase in Ki-67 expression compared to the DM groups. From these calculations, the largest Allred score is obtained at a dose of 30mg / kgBW was 3.89...
± 0.25 units. This showed an increase in proliferation in β cells when compared with the DM group with a dose of 5 mg / kgBW or 100 mg / kgBW. The One-Way ANOVA test results on immunohistochemical observations with Ki-67 expression calculation showed that there were no significant differences between groups in Ki-67 expression (p = 0.0720). The mean expression of Ki-67 in the normal mice group was 4.06 ± 0.29 units and decreased not significantly in DM mice to 3.28 ± 0.18 units.

Discussion

Over the past 20 years, the development of studies on transcription control of genes involved in β cell proliferation in both humans and mice has been studied. Recently, progress has been made in the development of human embryonic stem (ES) cells and induced pluripotent stem (iPS) cells for the development of pancreatic β cell studies. Replacement or regeneration of pancreatic β cells is expected to counteract the DM process. New cells developed theoretically can counteract the progression of diabetes both in humans and in rodents. This concept has encouraged efforts in various research groups to make new human β cells use stem cells to transdifferentiate or reprogrammed non-β cells to β cells or to find macromolecules or fields for the development of other compounds that can induce human β cell proliferation.

In this study, after induction of streptozotocin blood glucose levels then checked every 7 days to see the increase in blood glucose levels. The occurrence of DM in experimental mice was not simultaneous, at 36% of all experimental groups experienced DM conditions on day 7, 52% of DM mice occurred on day 14, and 12% of experimental mice experienced DM on day 28. Experimental mice models with blood glucose checks every 7 days also reported by other studies. Variable results are estimated due to different individual response factors to streptozotocin, mice strain factors, or due to intraperitoneal delivery route factors. Streptozotocin injection in experimental animals is best done when fasting and streptozotocin animals are made new by dissolving them in citrate buffer pH 4.4 to 4.5. After mice have diabetes, a dose of 5 mg / kgBW, 30 mg / kgBW, or 100 mg / kgBW is given for 7 days and their blood glucose levels are measured. The statistical test showed that there were significant differences in the normal mice group and DM mice group, but there were no significant differences in the treatment group on different doses of vanadyl sulfate. From Table 1, there was a trend of decreasing blood glucose levels as the dose of vanadyl sulfate increased. Based on this result, it can be seen that the administration of vanadyl sulfate in the treatment group compared with the DM group was able to reduce blood glucose levels in mice, namely at a dose of 5 mg / kgBW decreased blood glucose from 430.00 ± 47.08 mg / dL to 369.17 ± 48.47 mg / dL, at a dose of 30 mg / kgBW there was a decrease in blood glucose levels from 444.17 ± 40.00 mg / dL to 294.67 ± 73.68 mg / dL (p = 0.2618), whereas at a dose of 100 mg / kg BW there was a decrease in blood glucose from 452.67 ± 106.36 mg / dL to 255.75 ± 229.64 mg / dL (p = 0.1904).

In Table 3 showed that there was no significant difference in the amount of Langerhans Islet in the administration of vanadyl sulfate at various doses compared to the DM group of mice. From these results, it can be observed that the administration of vanadyl sulfate at a dose of 30 mg / kgBW had increased amount of Langerhans Islet better than the dose of 100 mg / kgBW.

The results also indicated that there was a significant effect between the administrations of vanadyl sulfate at various doses with the number of pancreatic β cells, with an increase in the number of pancreatic β cells as the dose of vanadyl sulfate increases. From these results it can be concluded that administration of vanadyl sulfate can increase pancreatic β cell proliferation which is characterized by an increase in the number of pancreatic
β cells as vanadyl sulfate dose increases. Considering that the amount of Langerhans Islet did not increase significantly, it can be concluded that the pancreatic β cell proliferation process due to the effect of vanadyl sulfate is likely to occur due to hyperplasia or an increase in the number of pancreatic β cells.

Conclusion

Overall the results of this study indicated that administration of vanadyl sulfate has the potential to stimulate pancreatic β cell proliferation. Stimulation of pancreatic β cell proliferation with the administration of vanadyl sulfate is in line with continued efforts in efforts to stimulate pancreatic β cell proliferation as the latest strategy in the treatment of diabetes mellitus. The results of this study can be used as a reference for other researchers in terms of pancreatic β cell proliferation studies using Ki-67 proliferation markers, pancreatic β cells and number of Langerhans Islets that have been scaled using reliable Allred method. It is recommended that further research be carried out to examine the mechanism of pancreatic β cell proliferation due to the administration of vanadyl sulfate with other proliferative markers.

Differences of IPSS, Q Max and Prostate Volume Before and After Treatment with Combination of Dutasteride and Tamoxifen in BPH Patient without Urine Retention

Kurnia P. Seputra¹, Doddy M. Soebadi¹, Hedromartono Widayat¹, Widoda J. P.¹, Soetojo¹

¹Department of Urology, Faculty of Medicine, Airlangga University, Surabaya 60115 Indonesia

Abstract

Benign Prostate Hyperplasia (BPH) is the common benign enlargement that found in men who suffers from urinary difficulties and the incidence increases as they are getting older. This study compare the IPSS, Q max and volume of the prostate between pre and post treatment of 5α Deductase inhibitor and Tamoxifen in patients BPH without urine retention. About 40 patients who had been diagnosed BPH without urine retention is participating in this study. The study has classified them into 4 groups, each group contain of 10 patients and were given Tamoxifen, Dutasteride, Combination (Tamoxifen with Dutasteride) and Placebo. The collected data includes the IPSS, uroflowmetry and volume of the prostate before and after 3 months of treatment. The data is analyzed by SPSS 12. The obtained results show Q max and IPSS have significantly improved in Dutasteride and combination group. While, Tamoxifen treatment group shows no significant improvements in Q max and IPSS. All the treatment groups show significant decreasing of prostate volume except Placebo group.

Keywords: Benign Prostate Hyperplasia (BPH), Dutasteride, Lower Urinary Tract Symptom (LUTS), Placebo, Tamoxifen

Introduction

Urinary difficulties are a problem in older men. Although this has long been known by people but Benign Prostate Hyperplasia (BPH) has not been identified as a disease until the early 19th century. Only in the last decade, the information about epidemiology and the course of this disease has become popular¹. BPH is the common benign enlargement found in men, and the incidence is related to age. Symptoms that occur in BPH are known as Lower Urinary Tract Symptom (LUTS). It is estimated that nearly 50% of men in their lives experience symptoms of symptoms caused by BPH and 10% will develop into malignancy²,³.

In some developing countries, the death rate due to BPH has decreased. In the period 1950-1954 the highest mortality rate was found in Denmark, amounting to 22.9 out of 100,000 sufferers, while 17 of 24 countries had a mortality rate of 10 out of 100,000 people suffering from BPH. At General Hospital Dr. Soetomo, the incidence of BPH during the period January 2005 to December 2005 has found 123 BPH patients who underwent surgery for the Trans Urethra Resection of the Prostate (TURP). From the 123 patients with BPH, 70 patients with BPH were accompanied by urinary retention while the remaining 53 patients were BPH patients with LUTS. The prostate is composed of components of the stroma and epithelium, each or a combination of the two will produce BPH symptoms. Prostate growth regulation is influenced by intrinsic and extrinsic factors. Intrinsic factors are signals from within the prostate itself. While extrinsic factors consist of testis, systemic, environmental, and genetic factors⁴.

Current BPH treatment includes watchful waiting, medical therapy, conventional surgical therapy and minimally invasive therapy. In medical treatment or medicine, a lot of variations are given, starting from the alpha blockers, 5α reductase inhibitors, combination of both or by using phyto preparations. This study identify
the effect of Dutasteride on a 5 α reductase inhibitor (Dutasteride) and estrogen inhibitor (Tamoxifen) in BPH patients who experience LUTS, based on the International Prostatic Symptom Score (IPSS), Q max, and prostate volume.

**Methodology**

The experimental research was conducted with the pre and post-test control group design. The study respondents were BPH patients who experienced uncomplicated LUTS and visited the Urology Polyclinic, Dr. Soetomo Surabaya between August 2006 and January 2007. The respondents were examined for IPSS scores. The test on uroflowmetry and trans rectal ultrasonography or TRUS were examined at InstalasiInvasif Minimal Urogenital (IIU) at Dr. Soetomo Surabaya.

The sample sizes were determined with Rule of Thumb guideline with a total of 10 samples for each case and control group. Hence, total sample sizes were 40 samples which divided into four group randomly. First group were patients with BPH who experienced uncomplicated LUTS who were given Placebo for 3 months and evaluated for pre and post treatment, second group was patients with BPH who experience uncomplicated LUTS were given 5α reductase inhibitors (Dutasteride 0.5mg) for 3 months and evaluated pre and post treatment. Meanwhile, third group was patients with BPH who had uncomplicated LUTS who were given anti-estrogen (Tamoxifen 20mg) for 3 months and evaluated for pre and post treatment and fourth groups was patients with BPH who had uncomplicated LUTS given 5α reductase inhibitors (Dutasteride 0.5 mg) and anti-estrogen (Tamoxifen 20mg) for 3 months were evaluated pre and post treatment.

The dependent variables in this study were IPSS, uroflowmetry and TRUS. The independent variables were 5 α reductase inhibitor (Dutasteride) and anti-estrogen (Tamoxifen). Meanwhile, control variable was LUTS patients due to uncomplicated BPH. The IPSS score, Q max, and TRUS were calculated for pre and post of the study. SPSS program is used to analyze the collected data.

**Result and Discussion**

Table 1 showed there was an increment in Q max after Tamoxifen treatment from 7.75 +/- 3.5538 to 9.15 +/- 2.9448. The Q max increase of -1,400 was then tested by t test shows the t value of –1.416 and a significance of 0.190. There was no difference in uroflowmetry before and after Tamoxifen treatment. This also reflected there was an insignificant increase in Q max after treatment of Tamoxifen.

In Dutasteride treatment, there was an increase in Q max from 9.55 +/- 3.2793 to 15.12 +/- 4.3522. Q max increased by -5.57 and tested by t test showed the t value of -3.444 and a significance of 0.007. There was a difference in Q max before and after Dutasteride treatment. This result indicated there was a significant increment in Q max after Dutasteride treatment.

In combination (Tamoxifen and Dutasteride) treatment showed an increase in Q max from 6.55 +/- 2.5435 to 8.86 +/- 4.4475. The Q max increase of -2.31 was then tested by t test showed the t value of -2.752 and a significance of 0.022. There was a difference between Q max before and after combination (Tamoxifen and dutasteride) treatment. This result also showed there was a significant increase in Q max after combination (Tamoxifen and dutasteride) treatment.

The Placebo treatment showed decrement in Q max from 9.4 +/- 4.077 to 8.91 +/- 3.8731. The Q max decreased of 0.49 was t test showed t value of 2.784 and a significance of 0.021. Hence, there was a difference in Q max before and after giving Placebo treatment. Although the results of the t test shows a significant value, but decrease in Q max, so the Placebo treatment could not increase the Q max of LUTS patients with uncomplicated BPH.

Table 2 showed full results of the Wilcoxon Signed Rank Test. In the Tamoxifen treatment group, post IPSS score lower than pre-IPSS had 5 patients, then post IPSS higher than pre IPSS had 1 patient and equal IPSS between pre and post score is about 4 patients. This result indicated there was no difference in IPSS scores before and after Tamoxifen treatment since the significance level was more than 0.05.

The group that received combination treatment for post IPSS lower score than pre IPSS were 6 patients. There were 4 patients contributed by the equal pre and post IPSS score. Since the significance level is less than 0.05, thus there was a difference in IPSS scores before and after the combination treatment.

The group that received Placebo treatment found no patient for post IPSS score lower than pre IPSS. Whereas, the post IPSS score higher than pre IPSS were 2 patients and equal IPSS score between pre and post were 8 patients. Since the significance level is more than 0.05, thus there was no difference in IPSS scores before and after the Placebo treatment.

\(^c\)IPSS pre = IPSS post

Table 3 showed there was a decrement in prostate volume after treatment of Tamoxifen from 40.124 +/- 7.9129 to 36.323 +/- 8.2573. The decrease in prostate volume of 3.801 was then tested by t test showed a value of 3.053 and a significance level of 0.014. Since the significance level is less than 0.05, thus there was a difference in prostate volume before and after Tamoxifen treatment. This result also reflected there was a significant decreased in prostate volume after Tamoxifen treatment.

The Dutasteride treatment showed decrease in prostate volume from 30.93 +/- 9.0031 to 24.506 +/- 7.3267. Decrease in prostate volume by 6.424 is calculated. The t test showed the t value of 3.292 and the significance level of 0.009. Since the significance level is less than 0.05, thus there was a difference in prostate volume before and after Dutasteride treatment. This result also meant that there was a significant decrease in prostate volume after Dutasteride treatment.
The Placebo treatment showed an increase in prostate volume from 32.42 +/- 9.5974 to 33.68 +/- 9.6177. Prostate volume increase of 1.260 and then tested by t test showed the value of 1.371 with significance level of 0.204. Since the significance level is greater than 0.05, thus there was no difference in prostate volume before and after the Placebo treatment.

Discussion

From this study, 3 months of Tamoxifen treatment showed the result increased in Q max of LUTS patients because of BPH, although it is not statistically significant (p> 0.05). The improvements that occurred were 1.4 cc / sec. The treatment period of 3 months may also affect the results of this study. Tewari A. et al. has found that there was no significant association with Q max changes with total prostate volume but found a significant relationship in the reduction of transitional zone volume and the ratio of prostate transitional zones with Q max improvement in finasteride therapy. Two components that played a role in the occurrence of LUTS were mechanical and dynamic components. Dynamic components were prostate growth and mechanical components are smooth muscles in the prostate and urethra.

The effect of Dutasteride on LUTS patients because of BPH showed a Q max improvement of 5.57 cc / sec and statistically significant (p <0.05). The previous studies had found a Q max improvement of 2.2 cc / sec and after 12 months giving finasteride 5 α reductase inhibitor, the uroflowmetry improvement is about 1.6cc / sec compared to Placebo treatment which is 0.7 cc / sec.

The combination effect of Dutasteride and Tamoxifen on Q max showed that uroflowmetry improved about 2.31 cc / sec, which based on the statistics approach that there was a significant improvement (p <0.05). The same behaviour also occurred in IPSS. In the combination (Dutasteride and Tamoxifen) group also found a statistically significant improvement (p <0.05). Tamoxifen worked by blocking estrogen receptors. Estrogen is known to suppress TGF β1 which functions to stimulate the apoptosis process. When the estrogen is blocked, the end result of the cell will be driven by TGF β1 to apoptosis. Likewise, Dutasteride works by inhibiting the enzyme 5α reductase inhibitor, which converts testosterone to dihydrotestosterone (DHT). DHT is what will stimulate prostate growth. If a blockade is done on these two hormones, there will be a decrease in prostate volume and there will be an improvement in the urinary stream even though study of Kaplan S. A. has obtains the relationship between prostate volume and urinary emission is still a question.

IPSS in the Tamoxifen group showed no statistically significant improvement (p> 0.05) in the LPS patients with BPS. From the 10 patients, there were improvements in IPSS in 5 patients, 1 patient did not experience improvement in IPSS, while the rest had
no improvement. This is consistent with the results of uroflowmetry in patients with LUTS because of BPH given Tamoxifen. Time of only 3 months treatment period may also influence the results of this study. Symptoms of LUTS in BPH may influence by prostate factors and other factors such as diabetes mellitus. In this study these factors were not excluded. Therefore, there could be no significant improvement in uroflowmetry due to this factor.

The Dutasteride shown significantly improve of IPSS (p <0.05). From 10 patients, there were improvements in IPSS in 9 patients and 1 patient with IPSS score did not experience improvement. This is agreed with the results of Q max where significant improvements are obtained. Dolder C.R. found that Dutasteride treatment can improve the symptoms of BPH and reduce the risk for urinary retention and surgery in patients.

In prostate volume, Tamoxifen turned out to have a significant decrease in prostate volume (p <0.05). The decrease is about 3.8 cc within 3 months. Liu J. et al. has found that Tamoxifen treatment can decrease the prostate cell proliferation that will decrease prostate volume. In vitro Tamoxifen treatment also affects the metabolism of testosterone, which is through induction of resistance to the activity of 5α reductase and 17β hydroxysteroid dehydrogenase in the prostate gland. Tamoxifen shifts the position of androgen from its bond with sex hormone binding globulin in the blood.

Prostate volume in the Dutasteride treatment group obtained a significant decrease of 6.424 cc and statistically obtained a significant value (p <0.05). Clark R.V. claimed that Dutasteride can reduce prostate volume up to 26% of the previous volume as this study show about 20.8%.

There was a decrease in prostate volume of 4.623 cc in 3 months of the combination of Dutasteride and Tamoxifen, and statistically there was a significant decrease (p <0.05). In Dutasteride treatment, the decrease occurred was 6.424 cc while in the Tamoxifen group shows the volume decrease was 3.8 cc. A clinical trial may need in order to determine the effectiveness and efficiency of all three.

In the Placebo group the results obtained were a decrease in Q max before and after Placebo treatment, which is statistically significant. While in prostate volume and IPSS, there were no statistically significant differences between before and after treatment.

Conclusion

In conclusions, there was significant difference in Q max before and after the combination of Dutasteride and Tamoxifen in patients with LUTS because of BPH. Besides, there were also significant differences in Q max in Dutasteride treatment. In contrast to the treatment of Tamoxifen there was a difference but not significant at Q max. In additions, there was a significant difference in IPSS before and after the combination of Dutasteride and Tamoxifen in patients with LUTS because of BPH. Similarly, the treatment of Dutasteride also had significant differences in IPSS. In contrast to the treatment of Tamoxifen there were no significant differences in IPSS. Besides, there was a significant difference in prostate volume before and after the combination of Dutasteride and Tamoxifen in LUTS patients because of BPH.

Effect of Erythropoietin Administration on Spermatogonium Amount, Sertoli Cell and Leydig on Rats Testis (Wistar Strain) After Vas Deferens Ligation Released

Muhammad Surya Negara¹, Soetojo¹, Doddy M. Soebadi¹

¹Department Urology, Faculty of Medicine, Airlangga University, Surabaya 60115 Indonesia

Abstract

The study aimed to determine the effect of Erythropoietin on spermatogonia number, Sertoli cells and Leydig cells in white rat Wistar strain testis after ligation vas deferens release. Twenty-four Wistar strain eats were grouped into four group. The control group only performed an orchiectomy for testicular examination, ligation group vas deferens, group performed release ligation of vas deferens and group performed release ligation of vas deferens and given EPO injection with dose of 1000 iu/kg BW intraperitoneally for a week (three times per week). The observation of spermatogonium, Sertoli cells and Leydig cells by determined amount on 5 cross sections of seminiferous tubules used 400x light magnificent microscope with Hematoxylin Eosin staining. The result showed ligation of vas deferens had significant decreased spermatogonia number and Sertoli cells (p<0.05). There was no significant difference Leydig cells number after ligation of vas deferens (p>0.05). Meanwhile, release ligation of vas deferens had no significant different in spermatogonia, Sertoli cells and Leydig cells with ligation of vas deferens group. Besides, treatment ligation of vas deferens release and an EPO injection for a week also no significant different in number compared ligation release group of vas deferens.

Keywords: Vasectomy Reversal, Reactive Oxygen Species (ROS), Erythropoietin, Spermatogonium, Sertoli Cell, Leydig cell

Introduction

Vasectomy is most reliable form of male contraception and estimated 40 million to 60 million men worldwide had undergone vasectomy. Even though, vasectomy is very effective method but various problem can arise related to unclear patient information before action, surgical procedures, post-operative follow up and success rate¹. Most common long term complications of vasectomy are scrotal pain with 1% reporting post-operative pain and spontaneous recanalization of vas deferens which occurred between 0.03% and 1.2% after vasectomy procedure was performed.

There were 2% men who had vasectomy choose to have vasectomy reversal because their desire to have children. The vasectomy reversal request are increased in men who undergo vasectomy at young age¹². Most men had vasectomy reversal will faced reducing in their semen quality and require additional reproductive techniques to achieve conception. The success rate in vasectomy reversal patients is around 90%. Longer interval from patient undergoing vasectomy to reversal vasectomy, success rate for pregnancy is also getting lower³.

There are many hypotheses mentioned that vasectomy will result in obstruction of vas deferens which increasing intratesticular pressure in testis and resulted decreasing in testicular blood pressure and increased oxidative stress in the testis⁴⁵⁶. Vasectomy will result in high hydrostatic pressure due to obstruction, excessive sperm accumulation and stimulate local inflammatory reaction process which is characterized by increment in leukocytes in sperm. The abnormalities of sperm in the seminiferous tubules which contribute to Reactive Oxygen Species (ROS) increment⁷.

Corresponding author:

E-mail: soetojo@fk.unair.ac.id
In contrast, vasectomy reversal will result in ROS increment which is greater than patients who do not have a vasectomy or those who have vasectomy. When vasectomy reversal, long standing chronic inflammatory process activates even greater leukocyte activity in the vas deferens. Besides, pre-existing immune mechanism which is formation of anti-sperm antibodies which stimulate another inflammatory reaction resulted in increment leukocyte activation. Reactive Oxygen Species (ROS) content in vasectomy reversal action is higher than for patients who have vasectomy resulting in disturbances in sperm motility and spermatogenesis.

There was decreased in Sertoli cells, spermatogonia and spermatids and increased in apoptosis in spermatogenesis process. Lue et al. indicated that testicles weight and testosterone hormone had no significant changes but spermatogonia number and Sertoli cells decrease significant after 6th weeks and tubular atrophy occurred at 12th weeks.

Erythropoietin (EPO) is most important growth factor produced in kidney and works on Erythroid progenitor cells in bone marrow to prevent programmed cell death and response to hypoxic conditions. In additions, Erythropoietin receptors in the body also found in the brain, liver, digestive system, lungs, testicles and Leydig cells. EPO can affect steroidogenesis of mouse testicular Leydig cells by stimulating testosterone production and EPO intravenously can increase testosterone production in renal failure.

Besides, Erythropoietin has function as anti-apoptosis, anti-inflammatory and antioxidant by inhibiting ROS. The EPO given to mice testes had improved morphological testicular structure and repair germ cells by reducing apoptosis process and preventing inflammatory process so that ROS process could be inhibited. EPO have benefits by increasing spermatogonia number, Sertoli cells and Leydig cells. Hence, EPO is expected to be alternative therapy for vasectomy reversal. The study aimed to determine the effect of Erythropoietin on spermatogonia number, Sertoli cells and Leydig cells in white rat Wistar strain testis after ligation vas deferens release.

**Methodology**

The study was used experimental study with post test only control group design used male Wistar white rats (Rattus norvegicus). In additions, the treatment was in form of vasectomy (ligation of vas deferens) which observed for seven weeks, release ligation and left for one week and EPO injection for one week (3 times per week). The effect on spermatogonia number, Sertoli cells and Leydig cells in the testes was observed after ligation of vas deferens.

In the study, a post-test only control group design study was used with assumption that variable measurement were only obtained after treatment and had criteria for random allocation. The sample used was Wistar strain of white rats (Rattus Norvegicus) which had criteria included aged between 10 weeks and 12 weeks, body weight between 150 gram and 200 grams, healthy and not disabled. The white rats was obtained from breeding laboratory at Faculty of Veterinary Medicine, Airlangga University.

The samples were divided into four groups randomly with random numbers. Overall samples were 36 Wistar strain (Rattus norvegicus). The treatment consisted 3 groups included one group treated with a vasectomy and observed for 7 weeks; one group with vasectomy and release ligation performed at 7th weeks and then observed for another one week and another group with vasectomy treatment and release ligation was carried out at 7th weeks and given EPO injection was give for one week (3 times per weeks).

The study was conducted at Reproductive Embryology section of Faculty of Veterinary Medicine, Airlangga University for experimental animal rearing places and Pathobiology section of Anatomical Pathology section of Faculty of Veterinary Medicine for anatomical pathology examination and immunohistochemistry of testicular tissue examined.

The independent variable was EPO administration in Wistar strain rats after release ligation of vas deferens. Meanwhile, dependent variables was spermatogonia number, Sertoli cells and Leydig cells and control variables included Wistar strain (Rattus norvegicus), rats age, weight, cage type, feed, temperature, air pressure, cage humidity, artificial reversal vasectomy by release ligation of vas deferens, vasectomy duration and EPO dose.

The normality and variance test were used as basis for determined hypothesis test to determine the differences in spermatogonia number, Sertoli cells and Leydig cells in the control group and treatment group. All
data process techniques were analyzed computerizable used SPSS software program.

**Result and Discussion**

The data was analyzed used One Way ANOVA test. The result showed there were significant differences in Sertoli cells in each group with p<0.05. The analysis continued with Post Hoc test to determine differences in each group. There was significant difference in Sertoli cells number in the control group compared to group who received vasectomy (p<0.05), where Sertoli cells number in the control group was higher than in vasectomy group. In this study, the vasectomy had reduced Sertoli cells significantly. Besides, group with release ligation and group with release ligation and EPO found did not significantly affected Sertoli cells number (p>0.05). In additions, group with release ligation and group with release ligation and EPO found that there was no significant difference compared group with only vasectomy. The group with release ligation of vas deferens was observed had lower Sertoli cell than group with vasectomy which is released by ligation.

Based on Post Hoc test, there was significant differences in spermatogonia cells number in the control group compared to group with vasectomy (p<0.05). In additions, spermatogonia cells number in control group is higher than group with vasectomy. This result showed vasectomy had reduced spermatogonia cells number. Meanwhile, release ligation did not affect spermatogonia cells number as well as release ligation and EPO given with p<0.05. The group with release ligation had low spermatogonia number than group with vasectomy while group with release ligation and EPO given had higher number of spermatogonia cells than group with vasectomy and release ligation.

Discussion

A reversal vasectomy was an act of returning vasectomy by reconnected vas deferens either by vasovasostomy or vasoepididymostomy. The reversal vasectomy is usually performed in 2-6% men who had a vasectomy before. The success rates for reversal vasectomy were determined by several factors included duration between vasectomy and reversal vasectomy, operator skills and intra-operative and pre-operative factors. The patency rate and success of pregnancy after reversal vasectomy was around 97% and 76%. Meanwhile, between 3 years and 8 years intervals the patency and success rates were around 88% and 53%.

Vasectomy was resulted in high hydrostatic pressure due to the obstruction, excessive sperm accumulation and stimulated local inflammatory reaction process which characterized by an increment in leukocytes in the sperm and abnormality of sperm in seminiferous tubules that played a role in increased Reactive Oxygen Species (ROS).

The inflammatory process had increased leukocytes and secrete pro-inflammatory cytokines such as TNF-α, IL-6, IL-8, NF-κB and TGF-β which increased ROS and iNOS (Inducible Nitric Oxygen) activity species. In the testis, the cells expressed TNF-α receptors and IL-6 were sensitive to hypoxic conditions were spermatogonia. The leukocytes and IL-6 concentration in seminiferous tubules remained stable during release ligation of vas deferens treatment due chronic inflammatory process of vasectomy.

In this study, vasectomy significantly reduced spermatogonia and Sertoli compared to control group (p<0.05) because vasectomy in vas deferens tract was blocked so that obstruction occurred and there was an increase in intratesticular pressure in the testis. The inflammatory process had increased leukocytes and secrete proinflammatory cytokines such as TNF-α, IL-6 which mediator had bind to TNF-α receptors (TNF-αR) and IL-6-R found in spermatogonia. Chronic inflammatory reactions due to vasectomy obstruction caused an increment in macrophages resulted in leucocyte infiltration into the plasma seminal. The apoptosis activation process also increased ROS and NOS resulted in degeneration of the seminiferous tubules, the blood testicular barrier was damaged and spermatogonia number and Sertoli cells also decreased. Meanwhile, there was no significant difference in Leydig cells after vasectomy with control group (p>0.05). Naik et al. had stated vasectomy did not affect significantly in the FSH hormones, LH and testosterone while Leydig cells plays a role in producing testosterone. Leydig cells were interstitial compartment of testes along with macrophages and lymphocytes which were located in Leydig cells between seminiferous tubules.

In this study, the reversal vasectomy was analogized to release of vasectomy ligation since vasectomy had performed also an artificial vasectomy by double ligation of vas deferens of mouse testes for 7 weeks with non-absorbable threads and no any cutting either proximal to ligation of vas deferens or distal from ligation of vas deferens.

In group with vasectomy for 7 weeks and release ligation with left for one week, there was no statistically significant difference from spermatogonia number, Sertoli cells and Leydig cells with group with vasectomy for 7 weeks (p>0.05). The spermatogonia number, Sertoli cells and Leydig cells after release ligation of vas deferens had lower number than group with vasectomy. In reversal vasectomy, leukocytes and IL-6 in seminal plasma was remain stable due to chronic inflammatory vasectomy process and increased which affected ROS activities.

Furthermore, group with EPO injection after release ligation of vas deferens showed no significant difference in spermatogonia, Sertoli cells and Leydig cells compared to group with vasectomy. The number of spermatogonia cells, Sertoli cells and Leydig cells were observed increased on group with EPO injection after one week observation. EPO had function as an anti-inflammatory, anti-apoptotic and antioxidant which also known that there were EPO receptors in the testes.

Conclusion

In conclusions, Sertoli cells and spermatogonia number less than the control group. Meanwhile, Leydig cells number in vasectomy group was higher than control group. Sertoli cells, Leydig cells and spermatogonia in vasectomy and release ligation of vas deferens was higher compared group with vasectomy. Besides, Sertoli cells, Leydig cells and spermatogonia in vasectomy group and release ligation of vas deferens with EPO for one week also higher than group with vasectomy and release ligation of vas deferens. The administration
of EPO for one week did not affect spermatogonia, Sertoli cells and Leydig cells numbers in release ligation of vas deferens treatment.

Abstract

The purpose of this study is to determine the substitution of rice bran with phytase enzymes in commercial feed on the performance of broiler. The experimental design used in this study was complete randomized design. Thirty five male broilers strain CP 707 were randomly divided into five treatments. The treatment consisted of: P0 = 100% commercial feed (control), P1 = 95% commercial feed + rice bran with phytase enzymes 5%, P2 = 90% commercial feed + rice bran with phytase enzymes 10%, P3 = 85% commercial feed + rice bran with phytase enzymes 15%, P4 = 80% commercial feed + rice bran with phytase enzymes 20%. Treatment was given to chickens aged 20 - 35 days. Carcass weight and abdominal fat was measured at 35 day of age. The results of data analyzed using Anova and Duncan Multiple showed that substitution of rice bran with phytase enzymes 15% in commercial feed affected weight gain, feed conversion, percentage of carcass and abdominal fat that give good performance broiler.

Keywords: Phytase Enzymes, Broiler, Weight gain, Feed conversion, Percentage of Carcass, Abdominal Fat.

Introduction

Feed costs in a livestock business, especially broiler, are the largest component in the total production costs that must be spent by farmers during the production process, which is around 60 - 70\textsuperscript{1}. Rice bran is one of the feed ingredients that are often used to fulfill broiler nutrition. By using rice bran in large quantities, the cost of broiler feed can be reduced, but the increase in the amount of rice bran in feed can also increase the content of phytate compounds while poultry does not have the ability to digest Phytate compounds due to the absence of phytase enzymes in the digestive system of poultry. Therefore, broilers need additional phytase enzymes in their feed to increase digestibility\textsuperscript{2}. Anti-nutrient substances (phytate) have a negative effect on nutrients absorbed because phytic acid will bind proteins and minerals that function for the growth of broilers\textsuperscript{3}.

In feed also need to be added supplements in the form of fish oil. Fish oil is a fat fraction obtained from fish extraction or as one of the byproducts of the fish canning industry produced due to heating and sterilization during the process\textsuperscript{4}. Lemuru fish oil can be added to feed broilers to meet high energy needs. Lemuru oil contains very high omega-3 unsaturated fatty acids so that it can be used as a broiler feed supplement\textsuperscript{5}. Meat with high cholesterol and fatty acid content can increase the risk of atherosclerosis. Feeding sources of unsaturated fats can reduce meat cholesterol levels\textsuperscript{6}. With that said, this study intends to investigate the effect of substitution of rice bran with phytase enzymes in commercial feed on the performance broiler.

Methodology

This research was conducted in June - August 2017 at the Faculty of Veterinary Medicine, Airlangga University in Surabaya. Feed processing and proximate analysis were carried out at the Animal Feed Laboratory of the Department of Animal Husbandry. Maintenance of experimental animals was carried out in experimental cages.
The materials used in this study were 35 male broilers of CP 707 age two weeks from PT. Charoen Pokphand. The commercial feed used is commercial broiler feed (BR1). Drinking water uses water mixed with vitamins as recommended. Lemuru fish oil is obtained from a distributor in Surabaya. Vitamins for broilers are obtained from poultry shops in Surabaya while phytase enzymes are obtained from single colonies of rumen isolates which have the highest phytase activity, Actinobacillus spp and Bacillus pumilus. As for the broiler immune system, the ND (Newcastle Disease) vaccine is applied by means of eye drops and gumboro which are applied by means of mixed feed. The tools used in this study are tools for making feed, digital scales, cage cleaning tools, battery cages made of ram wire and places to eat and drink made of plastic.

Rice was fermented for five days with a dose of phytase enzyme 0, 2, 4, 6, 8% which was diluted by adding 25% distilled water. All treatments were fermented for five days and after that a laboratory analysis was carried out to measure dry matter, organic matter, crude protein, crude fiber. According to Nugroho et al., the results of this experiment obtained the right level of phytase enzyme which is 6% for the preparation of broiler feed formulas which will be applied in vivo. Formulations to be given to broilers:

- P0: Commercial feed (BR1) (control)
- P1: Commercial feed (BR1) 95% + fermented rice bran 5%
- P2: Commercial feed (BR1) 90% + rice bran with 10% enzyme
- P3: Commercial feed (BR1) 85% + fermented rice bran 15%
- P4: Commercial feed (BR1) 80% + fermented rice bran 20%

All treatments were supplemented with 2% lemuru oil and the feed formula was made isoprotein. This study used a completely randomized design (CRD) method.

One week before the cage is used, the cage is cleaned then sprayed using disinfectant evenly. The eating and drinking equipment to be used is cleaned and then prepared in a cage. Incandescent lights are installed in the center of the cage. The broilers are put in the prepared cage. The sugar water is given to the broilers to restore the fluid to the body that was lost during shipping and prevent stress from occurring in the broilers. For two weeks, the broiler was given commercial feed, whereas in the third week was used for adaptation to the adjustment of the treatment. When vaccinated on the 4-day, the active vaccine was dripped in the eye and repeated on the 21st day by mixing it. The gumboro vaccine is given at the age of 14 days by mixing it with drinking water.

Broiler feed is given in ad libitum in the form of mash. Drinking water that has been added with vitamins is also given in ad libitum and replaced every day. The balance is carried out at the beginning of the treatment in order to find out the initial weight before the treated feed is then recorded. Weight of before being slaughtered (5th week) and after being slaughtered and with no internal organs is then recorded. The data is used to calculate the percentage of carcass weight by comparing the carcass weight with life weight then multiplying by 100%. Whereas after being slaughtered, abdominal fat is taken and weighed and then recorded for the calculation of the percentage of abdominal fat.

**Results and Discussion**

**Weight Gain**

Based on data analysis using ANOVA, it was shown that there was a significant effect (p <0.05) on the substitution of enzyme fermented rice bran to broiler weight gain among the treatment studies. The weight gain in the average obtained for each treatment can be seen in Table 1. Treatment P0 has the highest weight gain with 1251.14 g, P1 at 1117.43 g, P2 at 1115.14 g, P3 at 1026.14 g and the lowest P4 was 853.43 g. The energy and nutrient content which includes protein, carbohydrate, fat, crude fiber, calcium, dry weight, BETN and metabolic energy which has little difference can also affect weight gain. Phytase enzyme supplementation in feed increased the crude protein content in the fourth feed of treatment P1 (23.31); P2 (23.70); P3 (23.77); P4 (23.88) while at P0 which does not contain the phytase enzyme protein it is roughly lower P0 (23.01). The increase in crude protein in rice bran is caused by the presence of phytase enzymes which degradedphytic acid that affects the nutrient content of rice bran. Addition of phytase enzymes to reduce phytic acid, thereby increased the availability of calcium and phosphorus while increasing the nutrient content of rice bran is to increase crude protein and reduce crude fiber.
The use of phytase in broiler rations has been reported to be able to increase feed energy metabolism\textsuperscript{9,10}. The content was higher in P1 (2943.80), P2 (2920.74), P3 (2924.89), P4 (2910.06) compared to P0 (2896.17) without phytase enzymes, in this study when viewed with an average P0 has the highest weight gain with 1251.1 g after that followed by P1 treatment of 1117.4g, then P2 1115.1g, then P3 1026.1g and the lowest is P4 with 853.4 g. If it is associated with higher crude protein in P4 but the lowest weight gain, according to Nugroho et al.\textsuperscript{8}, an increase in crude protein is due to the addition of the enzyme itself. The enzyme has a major component in the form of protein. The enzyme is a protein that acts as a catalyst in biochemical reactions or as biocatalysts. Catalysts are compounds that can accelerate chemical reactions, are required in small amounts and in chemical reactions and at the end of the reaction will be recovered but the catalyst does not change the balance constant only accelerates the balance\textsuperscript{11}. It can be concluded that as a catalyst, enzymes do not participate but only accelerate the reaction process. The higher the dose of the enzyme used in the treatment, the higher the crude protein content in rice bran. Therefore, high crude protein does not function to increase weight gain but only to degrade phytic acid contained in rice bran and as a catalyst for the integration process. This is consistent with the results obtained whereby P4 had the lowest metabolic content of energy which eventually result in lower weight gain compared to treatments P1, P2, P3.

Feed Conversion

Based on the data analysis using ANOVA, it was shown that there was a significant effect (p <0.05) on the substitution of enzyme fermented rice bran to the value of feed conversion between treatments. The average results and standard deviations of feed conversion values from each treatment are listed in Table 2. When viewed from the average feed conversion during the treatment, it showed that the lowest feed conversion obtained at treatment P0= 1.67, P1=1.80, P2=1.90, P3=1.99 and the highest feed conversion in treatment P4= 2.43. Feed conversion in broilers is a comparison between the amounts of feed consumed with weight gain produced at a given time. The efficiency of feed use by the body is indicated by feed conversion. The lower feed conversion is the more efficient, because the less feed needed to produce per unit of weight gain in a certain period of time\textsuperscript{13}. This is also in accordance with Rokhana et al.\textsuperscript{14} opined that high feed conversion rates are caused by the difference is greater or smaller in the ratio between feed consumed and body weight gain achieved. According to Coon\textsuperscript{15}, the main factors that influenced feed conversion are genetic, ventilation, sanitation, feed quality, type of feed, use of additives, water quality, disease and treatment and maintenance management. Feed conversion values are also influenced by body size, chicken population, energy and protein levels in feed and environmental temperature\textsuperscript{16}.

</tr>
</tbody>
</table>

Based on the results of statistical calculations using the Duncan Multiple Comparison Test (DMRT), there was no significant difference (p> 0.05) between treatments P1, P2, P3 and P0. Nonetheless, P4 was significantly different (p <0.05). The highest average feed conversion in this study occurred at P4 with 2.43 and the lowest at P0 with 1.67. The high value of feed conversion in treatment P4 is suspected because at the time of treatment, many feeds were dropped and mixed with feces so that they were not counted. Moreover, large amount of feed consumption did not offset by
weight gain. According to Risnajati\(^7\) the value of feed conversion in chicken maintenance broiler is much related to economic value and the amount of feed that is more certainly will reduce the benefits obtained.

### Carcass Weight Percentage

The results from ANOVA showed that there was no significant effect (\(p > 0.05\)) on the substitution of enzyme fermented rice bran to the percentage of carcass weight between treatments. The mean carcass percentage in the treatment is presented in Table 3.

Broilers will show good growth with feed which has a high energy and protein content\(^8\). The level of energy metabolism in the treatment ration P0, P1, P2, P3, and P4 respectively is 2896.17 kcal / kg; 2943.80 kcal / kg; 2920.74 kcal / kg; 2924.89 kcal / kg; 2910.06 kcal / kg. In order for the broiler to achieve maximum growth, metabolic energy content in feed should not be less than 2,900 kcal / kg of feed\(^9\). The statement above shows that the metabolic energy in the treated feed still meets the normal needs of chickens. According to Faraj\(^9\) the quality requirements for broiler ration standard for crude fiber content is a maximum of 6%. Coarse fiber is needed to stimulate the digestive tract movement. Lack of crude fiber in feed causes digestive disorders, and excess amounts of crude fiber can also reduce feed digestibility\(^20\). According to Bharath et al.\(^21\), fiber can interfere with the absorption of feed and cholesterol in the small intestine, so that intestinal movements increase and cause food containing fat and cholesterol to be quickly wasted through feces. Agreeing to Faraj\(^9\), the standard quality requirements for broiler rations are roughly 19% for the starter protein and a minimum of 18% for the finisher. The proximate analysis of crude protein in the treatment rations P0, P1, P2, P3, P4 respectively was 23.01%, 23.31%, 23.71%, 23.77%, 23.88%. The proximate analysis shows that the amount of crude protein between treatments is not much different. This is due to this research using isoprotein feed formulas by means of fish meal.

### Percentage of Abdominal Fat

The average percentage of abdominal fat in the treatment is tabulated as in Table 4. Based on data analysis using one way ANOVA, it can be seen that the substitution of enzyme fermented rice bran in different doses of broiler feed showed no significant effect (\(p > 0.05\)) on the percentage of broiler abdominal fat. The accumulation of total body fat and its spread on the body parts of broilers is influenced by feed. The composition in feed is a factor that influences body fat content. The formation of body fat in chickens occurs because of the excess energy consumed\(^22\).

The results showed that the average percentage of abdominal fat between treatments was P0, P1, P2, P3, P4, respectively was 1.31%; 1.34%; 0.94%; 1.03%; 1.26%. Santoso\(^23\) stated that under normal circumstances, the percentage of abdominal fat broilers ranged from 1-2.5% of life weight. Based on the statement above, it can be concluded that the percentage of abdominal fat broiler in this study is normal. The data above shows that the highest percentage of abdominal fat was P1 at 1.34% and the lowest percentage of abdominal fat in P2 was 0.94%.

Treatment of P1 has the highest percentage of abdominal fat of 1.34%. The high percentage of abdominal fat is in line with the high crude fat and metabolic energy in the feed content. According to Pasi and Nahak\(^24\), the excess energy in the body of the chicken will be stored in the form of fat, while the metabolism of fat formation requires a lot of energy, and then indirectly there is waste of feed energy. While abdominal fat accumulation is included in the follow-up results, it is energy scattering and reduction in carcass
weight, because the fat is removed in the processing. Abdominal fat is one component of body fat, which is found in the abdominal cavity. The P2 treatment has the lowest abdominal fat percentage of 0.94%. The low percentage of abdominal fat is in line with the low crude fat content and metabolic energy in feed. So that the energy consumed is more used to meet the needs of basal broiler energy in normal growth and development and only a little is used for fat formation and accumulation.

Total Cholesterol and C-reactive Protein (CRP) Levels as Prognostic Markers for Urosepsis

Septa Surya Wahyudi1, Budiono1, Tarmono1, Soetojo1, Doddy M. Soebadi1, Sunaryo Hardjowijoto1

1Department of Urology, Faculty of Medicine, Airlangga University, Surabaya 60115 Indonesia

Abstract

This study was aimed to determine and compared the total cholesterol and C-reactive protein (CRP) levels as a prognosis in urosepsis patients treated at the RSUD. Dr. Soetomo Hospital. There were 30 patients involved in this study and was assigned to the test for total cholesterol and CRP level at the day of admission, three days later, and on the last day (14th days) of sepsis or on the day of the death. The variables were tested using the Spearman’s rho test with software SPSS 20. This study found 15 patients who were in septic condition, 14 patients had severe sepsis and one patient had septic shock. There were statistically significant between total cholesterol and CRP levels in determining the outcome of urosepsis patient. The coefficient correlation of total cholesterol was better than CRP. The low total cholesterol levels and high CRP levels can be used as predictors of worsening urosepsis prognosis. Total cholesterol levels showed better performance than CRP as a prognostic marker for urosepsis.

Keywords: Cholesterol level, C-reactive Protein (CRP), Prognostic Marker, Urosepsis

Introduction

Urosepsis was a sepsis that originates from urinary tract infections with symptoms of SIRS1. Sepsis that was not adequately treated can fall under severe sepsis with MODS and even septic shock2,3. The sepsis can change body hemodynamics, hematology and metabolism body by involving immune system responses and many organ systems1,4. In severe sepsis and septic shock there can be circulatory distress syndrome at the micro and mitochondrial levels. Hemodynamic and severe circulation disorders can cause disruption of oxygen transport and cell respiration which can cause failure of many organs. Mitochondrial dysfunction plays an important role in sepsis where the rate of mitochondrial respiration dysfunction was related to the patient’s outcome. Mitochondrial failure associated with sepsis role in respiratory distress, especially in areas of hypoxia and can cause distress networks that can progress to organ dysfunction5,6.

There were several clinical and laboratory variables that can be used as markers to determine and assess the severity of sepsis and determine its prognosis. One of them was total cholesterol. Cholesterol involvement in this sepsis condition allows cholesterol to be used as a biomarker for urosepsis. Decrease in total cholesterol in sepsis occurs from the first time bacterial toxins enter the patient’s blood (host) and will further reduce the decrease in patients with severe sepsis accompanied by MODS7,8.

The reduction in total cholesterol was basically a decrease in HDL cholesterol, LDL cholesterol and VLDL cholesterol. The total cholesterol was decrease due to multi factorial factors including increased cholesterol usage in the sepsis process, decreased synthesis and changes in metabolism9,10,11. The use of cholesterol in sepsis occurs since bacterial toxins enter the patient’s body. Both endotoxins (lipopolysaccharides) from gram-negative bacteria and lipoteichoic acid (LTA) from gram-positive bacteria will bond between lipopolysaccharide (LPS) and cholesterol (lipoprotein) known as lipopolysaccharide binding protein (LBP)12,13. This cholesterol bond with lipopolysaccharide (LBP) aims to neutralize germ toxins and reduce cellular response caused by gram-negative and gram-positive
bacteria\textsuperscript{10, 14}. In addition to reduce the cellular response of the host to endotoxin, LBP also aims to present endotoxin monomers (LPS) in membrane bound CD 14 in monocytes, neutrophils and macrophages\textsuperscript{15, 16}. Thus, the invasion of germs can be prevented and overcome\textsuperscript{4, 17}. Decreased cholesterol synthesis in liver also occurs in sepsis, this was related to an increase in cytokine mediators in the form of TNF α, IL-1 and interleukin 6\textsuperscript{10}. Decreased lipoprotein (cholesterol) was seen after liver cells were exposed to TNF α, IL-1 and IL-6. This study was aimed to determine and compared the total cholesterol and C-reactive protein (CRP) levels as a prognosis in urosepsis patients treated at the RSUD. Dr. Soetomo Hospital.

**Methodology**

This study was a prospective study of the type of diagnostic test which highlight on the comparison of total cholesterol levels and C-reactive protein (CRP) in assessing urosepsis prognosis through observational analytic research designs. The study sample focused on the patients who were diagnosed with urosepsis (sepsis caused by urinary tract infection) and treated at the RSUD. Dr. Soetomo Hospital. The samples were calculated based on the formula of the sample size for correlative analytic test research. All respondents were required to sign an approval sheet following the research. On the first day, the respondents were classified based on the results of assessment for clinical severity, total cholesterol, CRP, MAP, blood leukocytes, urinalysis, urine culture and blood culture, BGA (blood gas analysis), SGOT, SGPT, BUN, and serum creatinine level. On the third day the patients were reassessed for their clinical severity, total cholesterol, and CRP. Patients were continuing follow this study until the last day of the patient’s death, recovery or a maximum of 14 days of treatment. The correlation test was performed between total cholesterol and CRP against the prognosis (outcome) of patients with the Spearman’s rho test. The correlation coefficients of each variable was determined to compare the correlation strength between CRP and blood cholesterol against the prognosis (outcome) of patients with urosepsis.

**Result and Discussion**

Table 1 showed the CRP score and total cholesterol based on outcome. The average results of the first day CRP examination in patients was $177.18 \pm 107.37$ mg/L, worsening $146.74 \pm 62.82$ mg/L, whereas in patients with improved outcome showed low average CRP score which was $88.10 \pm 74.41$ mg/L. The mean CRP values on the third and last day of patients with clinically improved decreased from $56.28 \pm 50.15$ mg/L to $31.58 \pm 37.37$ mg/L. The mean CRP of patients died on the third day was $127.10 \pm 106.28$ mg/L and on the last day was $141.88 \pm 105.61$ mg/L. The difference (Δ) of CRP between last day and first day showed positive value in the patient with outcome deteriorated which was $38.76 \pm 59.02$ mg/L, while the negative value in the patient improved and died were $-56.52 \pm 70.20$ mg/L and $-35.3 \pm 97.53$ mg/L respectively.

Examination of total cholesterol based on outcome at the end of the study showed lowest average total cholesterol examination results on the first day in patients with death outcomes that was equal to $63.25 \pm 14.15$ mg/dL and then increased follow by worsening patients which was $101.38 \pm 20.51$ mg/dL and improved patients which was $119.5 \pm 17.81$ mg/dL. Meanwhile, patients with outcome worsening and dying clearly seen total cholesterol values continued to decline. In patients worsening the total cholesterol value for the third day was $93.62 \pm 10.68$ mg/dL and the last day was $82.25 \pm 10.9$ mg/dL. In patients who died in third day, total cholesterol value was $56.0 \pm 6.98$ mg/dL and the last day was $51.0 \pm 6.16$ mg/dL. The difference (Δ) of cholesterol between the last day and first day showed positive mean value which was $35.3 \pm 21.46$ mg/dL for patients improved. While, negative mean values in patients who worsened and died were $-19.13 \pm 18.45$ mg/dL and $-12.25 \pm 11.59$ mg/dL.

The correlation test was performed using Spearman’s rho method in order to determine the significance and strength of correlation (correlation coefficient). Correlation test was performed between first day CRP, third day CRP, last day CRP, delta (Δ) CRP (14th CRP – 1st CRP), total cholesterol of first day, third day, last day, and delta (Δ) total cholesterol (Δ 14th Chol -1st Chol)) against the outcome of patients with urosepsis. CRP and total cholesterol statistical tests were conducted in all study samples. All study samples were observed and assessed on the outcome or the condition of the patient until the last day the patient was declared cured or died.

Based on Table 3, the value of the correlation test of CRP levels on outcome in patients with urosepsis using the Spearman’s rho formula was shown in Table 3. Based on statistical tests it was found that CRP levels on the first, third, fourteen days, and delta CRP (day 14 minus the first day) in patients with urosepsis showed a significant correlation (p <0.05) to the outcome with a significance value of 0.011, 0.002, 0,000 and 0.047 respectively and the correlation coefficients (r) were 0.459, 0,543, 0.686, and 0.365 respectively.

Discussion

Increased CRP levels require a minimum of 12-18 hours and CRP increased slowly during sepsis and reaches peak levels in 36-50 hours. The concentration will drop rapidly with a half-life of 19 hours if the stimulus was removed. This causes CRP to be independent and only affected by therapy and actions to eliminate the inflammatory process. In this study, 4 patients died with varying initial CRP levels of 53.0 mg/L, 156.0 mg/L, 186 mg/L and 313.7 mg/L. The high level of CRP can be a description of the number of organ systems that have failed their function.

In this study, the first day CRP levels in patients with improved outcomes had the lowest average compared to the first day CRP levels in patients with worsening and dying outcomes, which was 88.10 ± 74.41 mg/L compared to 146.74 ± 62.82 mg/L and 177.18 ± 107.37 mg/L. On the third and final day examination, a very clear pattern was seen that in patients with improved outcomes there was a lower CRP level of 56.28 ± 50.15 mg/L and 31.58 ± 37.37 mg/L. Whereas the worsening of patients continued to increase, 148.88 ± 63.15 mg/L on the third day and 185.50 ± 88.71 mg/L on the last day. In patients with death outcomes, the mean on third day CRP level was 127.10 ± 106.28 mg/L and on the last day it increased to 141.88 ± 105.61 mg/L. The results of the correlation test of CRP levels with the outcome obtained significant values (p <0.05) on the examination for the first, third, and last days were 0.459, 0.543, and 0.686 respectively. These results reflect that low CRP levels were associated with a good prognosis, whereas high CRP levels were associated with a poor prognosis even to death both on the first day, third day and last day examination.

This study was determined that total cholesterol and CRP concentration can be used as predictors of outcome and prognosis of urosepsis. Serial total cholesterol and CRP measurement (periodically) will be more helpful in identifying the patient’s condition so that it can provide additional information to increase the aggressiveness of the action to be given. From the results of data analysis in this study it can also be determined that the total cholesterol level compared to CRP showed a higher correlation with the outcome of patients with urosepsis. So that the measurement of total cholesterol levels in patients with urosepsis was better in predicting outcome or prognosis when compared with CRP levels.

Conclusion

In conclusions, total cholesterol levels can be used as a marker of prognosis (improved / worsened / died) in urosepsis patients both on the first, third, and last day examination with a significant correlation (p <0.05). The lower the total cholesterol level the worse the prognosis of the patient and vice versa. CRP levels can be used as a marker of prognosis (improved / worsened / died) in urosepsis patients both on the first, third, and last day examination with a significant correlation (p <0.05). The higher the CRP level the worse the prognosis of the patient and vice versa. Plasma total cholesterol levels showed a greater correlation coefficient than CRP levels on patient outcomes with urosepsis both on the first day examination (-0.633 vs. 0.459), third (-0.755 vs 0.543), and the last day (-0.874 vs 0.686). So that total plasma cholesterol levels can be used as a better prognosis indicator than CRP levels.

Application of a Photogrammetric Kinematic Model for Prediction of Lung Volumes in Adults: A Pilot Study

D. Malarvizhi¹, Aruna Ramanan Sekar²

¹Dean Incharge, ²Final Year Student, SRM College of Physiotherapy, SRM Institute of Science and Technology, Kattankulathur

Abstract

Background: The use of equipment such as spirometers in respirometry and analysis of respiratory muscle strength are some of the methods of evaluation for lung volume. Advancement in technologies aims to measure and evaluate the respiratory performance which is Vital for health professionals. The aim of the study find out the correlation of lung volumes between spirometry and the values obtained in AutoCAD® software.

Methodology: The study was Non-experimental design, observational type. Total 15 subjects, age group of 18-24 years with no history of respiratory illness were included and subjects using bronchodilator were excluded at SRM Medical College Hospital and Research Centre, SRM Institute of science and technology, Kattankulathur. There was five-point mapping for anatomical modeling and photogrammetry with each evaluated for Spirometric values. A video was taken during the procedure and filmed then the film was extracted into images for the proof of maximum inspiration and expiration. With the use of AutoCAD® software the defined respiratory volumes were obtained.

Results: Statistical analysis shows that correlation between the upper abdomen inspiration the mean and S.D value 116.93±11.8, and the FVC mean and S.D value 2.77±75, FEV₁ is 3.96±64 respectively. The correlation is significant at p< 0.05 (2-tailed).

Conclusion: The study concluded, the FVC and FEV₁ lung volumes may predict which are co-related with the abdominal inspiration of the 3-dimensionalexploration.

Keywords: Photogrammetry, Spirometry, adults

Introduction

Lung volumes are subdivided into static and dynamic lung volumes. Static lung volumes are measured by methods which are based on the completeness of respiratory maneuvers so that the velocity of the maneuvers should be adjusted accordingly. The measurements taken during fast breathing movements are described as dynamic lung volumes and as forced inspiratory and expiratory flows¹.

Factors which determine the size of the normal lung include stature, age, sex, body mass, posture, habitus, ethnic group, reflex factors and daily activity pattern. The level of maximal inspiration is influenced by the force developed by the inspiratory muscles, the Vital capacity. Hence the vital capacity alone is of little use discriminating against restrictive, obstructive and mixed ventilatory defects. In some cases of cystic fibrosis, which primarily affects the airways, temporary decreases in TLC have been described, possibly due to partial atelectasis².

The respiratory performance is the result of many sets of organs, where the respiratory muscles and bony structures especially the thoracic cage that works simultaneously to generate the phenomenon called ventilation which is vital for humans³. The thoracoabdominal surface respiratory movement is found to be effective to evaluate the performance of the pulmonary function. The equipment used such as spirometers, peak expiratory flow meter and assessing the respiratory pattern of the individual are some of themethods of evaluation. Advancement in technologies aims to measure and evaluate the respiratory...
performance which is Vital for health professionals. Using the advancement in the technologies this study aims to correlates the spirometry values with the lung volumes measure using the AutoCAD software. The need for the study is to find the most cost-effective, reproducible and reliable method. The objective of this study was to find the lung volume using photogrammetric model. Photogrammetry, it is processed dating from the 9th century which gives the quantitative information about the system evaluated by inserting metric dimensions into images which is available in AutoCAD software by the extrusion tool.

**Methodology**

The study was Non-experimental design, the observational typewas carried out with 15 sample, which the 15 samples are healthy adult males who had no history of respiratory illness aged between 18-24yrs, informed consent form and Institutional Ethical committee approval also obtained before starting the study. Samples were undergone the photogrammetric analysis, anthropometric analysis, and spirometric analysis in long sitting position and the respective values were obtained. The anthropometric analysis includes height (cm) weight (kg) and the thoracic length, the thoracic length is obtained by the anthropometric caliper which is positioned in line with the xiphoid process, then the samples were asked to take a deep inspiration with their arms stood up and the thoracic length was measured.

A camera was used to record the moment of maximum inspiration and expiration during the spirometric analysis in the long sitting position which is placed 2m away from the participant and the tripod is used to position the camera accordingly. The reflective markers are used to indicate the anatomical points in the photogrammetric analysis, the reflective markers are placed on the following anatomical points of the samples, the projections of the umbilicus (COD), the inferior angle of the 10th rib (ACd), the xiphoid Process (AXd) and the right anterior superior iliac spine (EId).

The windows movie maker was used to extract the frames from the video for the moment of maximum inspiration and expiration. Then these images are transferred into AutoCAD for three-dimensional model the thoracic and abdominal values were obtained. The 3-dimensional model was obtained from the AutoCAD 2012 by inserting the thoracic length into the 2D model through the extrusion tool which is available in the software.

**Results**

The data analysis of co-relation between upper abdomen inspiration and spirometric values were analyzed by IBM SPSS version 20

**Table 1. Co-relation between Upper abdomen inspiration and spirometric values of FVC and FEV<sub>1</sub>**

Table-1 shows the mean value, r-value and p-values of upper abdomen inspiration and FVC, FEV<sub>1</sub>
Results

According to the Table-1, Graph 1 and 2, there is a correlation between the upper abdomen inspiration, the mean and standard error value 116.93±11.8, and the FVC mean and standard error value 2.77±75, FEV\textsubscript{1} is 3.96±64 respectively. The correlation is significant at the 0.05 (2-tailed)

Discussion

The objective of the study is to find the lung volume using the bio-photogrammetric model by Autocad software for the three-dimensional exploration in long sitting position and to find the cost-effective method in predicting the lung volume using the advancement in the technology.

Spirometry assesses the integrated mechanical function of the lung, chest wall, and respiratory muscles by measuring the total volume of air exhaled from a full lung (total lung capacity [TLC]) to maximal expiration (residual volume [RV]). The spirometry is used to diagnose the chronic lung disease such as chronic obstructive lung disease and emphysema.

The Autocad uses the movement of the chest wall and the breathing pattern of the individuals to measure the volume of the lung because the movement of chest wall and pattern of the breathing also influences the volume of the lung\textsuperscript{6,7}.

The pulmonary function test is usually done to find the pulmonary impairment this can be done with various instruments such as spirometry, peak expiratory flow meter. Spirometry – measures the FVC, FEV\textsubscript{1}, FEF values, forced inspiratory flow rates (FIFs). Using autocad method the values of FVC, FEV\textsubscript{1}, FEF values were found but the values of FVC, FEV\textsubscript{1}, correlated with spirometry hence the values of FVC, FEV\textsubscript{1} can also found using AutoCAD method.

Ripka, W. L., et al concluded that 2D photogrammetry analysis can identify the breathing pattern of the children. The advantages of two-dimensional analysis are the possibility for locally testing due to ease of resources transportation, low cost of involved material and the lack\textsuperscript{3}.

Wagner L Ripka, et al concluded that the photogrammetric model using the 3-dimensional exploration can be used to find the thoracoabdominal movements in the adolescent’s age group between 14-17 years\textsuperscript{10}.

Statistical analysis of the study showed that there is a relationship between the upper abdomen inspiration, FVC, and FEV\textsubscript{1}.

Conclusion

The study concluded that FVC and FEV\textsubscript{1} lung volumes are predicted which is co-related with the abdominal inspiration of the 3-dimensional exploration and lung volumes can also be predicted by photogrammetric kinematic model adults.

The limitations of the study the use of the AutoCAD software should be in precise and the positions of the subject should be changed and can be evaluated. The study does not include the adult female due to anatomical points mapping over the body, for the successful prediction of lung volumes using a photogrammetric model more number trial and error should be done in the study.

The components in the study can be added in a single application by coding the components for making the apps for measuring the breathing pattern and thoracoabdominal movements.

Pysiotherapy in Wilson’s Disease –A Case Report

Suresh.J 1, Janani 2

1Assistant Professor, 2BPT Student, SRM College of Physiotherapy, SRM Institute of Science and Technology, Kattankulathur, India

Abstract

Wilson’s disease, it is also known as Hepatolenticular degeneration which is an autosomal recessive disorder which results in abnormal metabolism of copper. It leads to accumulation of copper in the organs such as liver, central nervous system, kidney, cornea and other tissues, which results in impaired function, these are caused by mutation of the ATP7B gene. The symptoms usually develops in the late adolescence but the deposition of copper begins immediately after birth. Liver disease or neurological symptoms are the two common presentation which typically manifests Wilson’s disease. Liver related pathologies will tend to experience in symptomatic adolescents, while neurological signs and symptoms will occur in older adults. This is a rare condition affecting only one person in 30,000 in most. This disease has been found to be 56% of gene frequency with a carrier frequency of 1 in every 90 people. Recent studies has shown an increase incidence of this gene mutation which has been found in isolated populations.

Keywords: Wilson’s Disease, physiotherapy treatment, dysarthria.

CASE PRESENTATION

Name: Mrs B.RAMYA

Age: 13

Gender: Female

A 13 year old female patient was diagnosed with neurological Wilson’s disease. There is no family history regarding same disease. In 2016 at the age of 11 the patient is admitted for presenting a clinical picture of bradykinesia, rigidity and gait disturbance for which required assistance. A brain study was conducted which showed hyper intense lesion in basal ganglia together with the presence of kayser fleischer ring, in 2016 the patient was diagnosed with Wilson’s disease and the patient started medication.

The patient has generalised dystonia with her lower limbs of hindered gait which caused recurrent fall according to the patient’s report. The patient present with hand–eye coordination, emotional and behavioural changes and neurological involvement which present Athetoid movements and unsteady gait.

The central nervous system symptoms includes tremors in hand, facial and muscular rigidity and dysarthria.

The patient was under medication with strict control of her neurologist, the medication remained the same before start or during the physiotherapy treatment.

ASSESSMENT TOOLS

TUG

10 Meter Walk Test

Functional Gait Assessment Scale

Activity Balance Confidence Scale

PHYSIOTHERAPY MANAGEMENT

The treatment goals was to reduce the risk of falls and the difficultly to overcome architectural barriers.

The treatment was based on static and balance exercises and on functional capacity training.

The treatment frequency was 6 days a weeks for 6months.

Exercise aimed at improving static balance:
The training began with sit to stand exercises, on a stable surface, with feet together on the floor with hand support of the therapist. In this position the patient was trained to hold for maximum 20 sec to improve static balance. These exercises were performed in 5 series of 5 minute duration with 3 minutes breaks.

**EXERCISE AIMED AT IMPROVING DYNAMIC BALANCE**

This training was done on swiss ball with back extension and flexion with legs supported, it is carried out for 25 repetition. so the goal was to stabilise the spine. Once this has achieved the gait training was performed with walker initially. In later stage of the treatment the patient was trained to walk without walker with the help of back support and the main aim was to stabilise the lower limbs. Simultaneously stretching was done for both upper limbs and lower limbs, pelvic bridging is also done for 4 series of 3 minute duration with 4 breaks in between. The dosage was delivered according to the patient’s tolerance with breaks of 5 minutes this type of training lasted approximately 1 hour per session.

**EXERCISE AIMED AT IMPROVING FUNCTIONAL CAPACITY TRAINING**

This training stage was aimed at patient daily activities in which she found some difficulties, for instance walking up and down stairs or ramps, picking up objects from the floor, writing in notebook to improve handwriting skill and to distract psychologically. The patient was dosed according to his tolerance, with rest periods in between 5 to 8 minutes with a total of 30 minutes. Speech training is also given to reduce the risk of dysarthria, which is followed by stretching of facial and oral muscles.

The treatment presented no problems or associated injuries in its development. On the other hand the patient reported being satisfied with it.

In the final evaluation the patient showed a genuine self reported improvement in balance confidence.

TUG: Time up and go; 10MWT: 10 Meter walk test; FGA: Functional gait assessment; ABC Scale: Activity balance confidence scale

**Discussion**

The kinesic approach to this pathology is still based on empirical principal due to limited evidence available, as works consulted do not provide information about physiotherapy treatment.

After the treatment the patient achieved stability of spine which showed the patient development from muscular rigidity.

Athetoid movements and unsteady gait were controlled at the maximum possibilities.

Tremors in hands and facial rigidity has been reduced.

Hand-eye coordination, emotional and behavioural changes has been modified.

The risk of fall has been reduced.

**Conclusion**

This case report is to our knowledge, the first to describe an approach to physiotherapy management on movement disorders present in Wilson’s disease more specifically on gait and balance disorders. We consider necessary to carry out further research on different interventions that serve to justify and improve the physiotherapy approach in movement disorders.

Effect of Living Arrangements on Health Status of the Elderly in Malaysia

Norehan Abdullah¹, Shamzaeffa Samsudin¹

¹School of Economics, Finance and Banking, Universiti Utara Malaysia, 06010, Kedah, Malaysia

Abstract

Malaysia needs to prepare now to address the ageing society problem, which is expected to account for 15% of the population by 2035. The increasing number of the elderly in the total population means there is an increasing incidence of ill health and chronic diseases. The World Health Organization in 1977 has described elderly people living alone as an ‘at risk’ group. Living alone in later life is often seen as an undesirable state and as a potential health risk. It is therefore crucial to understand the relationship between living arrangement and health status for the old age. Using a sample of 1,414 elderly from the northern Peninsular of Malaysia, this paper aims to examine the effect of living arrangement of Malaysian elderly’s on the health status. The study found that living alone nor living with spouse, children or others is not significant in affecting the health status of elderly, but the physical aspect of living in own-home does matter to the probability of perceiving good health.

Keywords: Elderly, living alone, own-home, self-perceived health, and long-standing illness

Introduction

Like any other country, Malaysia is heading towards an aging society. The Malaysian Statistic Department (2016) estimates that Malaysia is expected to reach ageing population status by year 2035, at which point 15% of the total population will be 60 years and older and it is roughly 16 years from now¹. Many are concerns over the socioeconomic effects of population ageing, namely its effects on economic growth, availability of public funds, and financing of the healthcare system². Furthermore, the increasing numbers of older adults derive a challenge to maintain quality of life and well-being of Malaysian elderly.

As Malaysia’s population is ageing and decreasing birthrates, we expect to exert extra pressure on healthcare resources³. Mounting number of old-age population are actually posturing enormous health care threats and social challenges. There are many factors that may determine health status of the elderly, and one of the factors is living arrangement. Although the Malaysian government has played a substantial role in providing elderly’s living arrangement and welfare, there will be a changing necessity that may require public provision, thus understanding the living arrangements of older adults is imperative.

Due to the recent trend of nuclear family structure, decline in extended family, and increasing life expectancy, there is a high tendency for Malaysian older adults to live alone at their own home. Many epidemiology studies have shown strong relationships between insufficient family supports with deprived health among elderly⁴. In addition, the World Organization⁵ has described elderly people living alone as an ‘at risk’ group. Living alone at the old age is undesirable state, as potential health risk and needs specific care.

In examining the effect of living arrangement on health status in India, a study by Agrawal found that elderly who are living alone have poorer health status, in term of self-reported prevalence of acute and chronic ailments, than elderly who are living with their family⁶. In this aspect, by living alone, feeling of loneliness and social isolation will worsen health problems and it may be unnoticed. In the United States, using data sampled from National Health Interview Survey 2009-2014,
Weissman and Russel found that elderly living with others have the poorest health; and less likely to report excellent or very good health, compared with older adults living with spouse or life-partner.

In a developing country like Bangladesh, the impact of living arrangements on self-reported general health are different according to gender. For older men, controlling for age, education and household assets, a co-resident spouse does not have any impact on self-reported general health. In contrast, for older women, living with spouse has a significant positive impact on self-reported general health. The presence of co-resident son have no impact on self-reported health for older women.

In China, older people are trended to choose formal home care. There was an interaction and joint effect between degree of disability and living arrangements. Thus, it was suggested that the policymakers to be more attentive to care for those living alone and focus on construction of facilities in rural areas.

In the context of Malaysia, a substantial number of the elderly are associated with financial problem and poor health conditions. This highlights the need of elderly to rely on their spouse or children as founded in one study based in Pahang state. Living with children is the commonest type of living arrangement for older adult in Peninsular Malaysia. Compared to living alone, living with spouse, and living with both spouse and children is associated with better life satisfaction. Although living at own home is preferred, but older Malay women are more likely to live with children, compared to older men as a second choice of living arrangement. Furthermore, Malaysian elderly who are low educated, female, Malay, not in good health, need long term medical treatment, no medical insurance and low income, are more likely to live with their adult children as compared to other living arrangements.

A study among pre-elderly Malay, aged 40 to 59 from three economic corridors of Peninsular Malaysia found that majority (83%) of the respondents prefer to live in their own homes in their old age. Among factors influence the probability to choose own home includes age, household size, gender, marital status and level of education. Income on the other hand has limited influenced over the choice.

Generally, there has been a trend change in the living arrangement preferences at old age among the current generation, but the effect of such arrangements on health status requires continuous investigation as the effect may differ due to different settings and social environment of the population under study. Furthermore, current evidence on the effect of living arrangement among the elderly on their health status is important in designing effective welfare policies for this vulnerable group. Therefore, in this study we aim to investigate the effect of living arrangements on health status among the elderly residing in northern states of Peninsular Malaysia. We use two indicators to proxy health status – the self-perceived health and whether or not the respondent is living with at least a long-standing illness. The self-perceived health measures one’s own perception while long-standing illness refers to physical health, which is the objective status of one’s health We use two distinct indicators, as people may sometimes feel good and healthy despite of having long-standing illness.

**Data and Method**

**Data**

A cross-sectional survey was used to obtain the required information from the respondents aged 60 and above in the northern peninsular Malaysia (Perlis, Kedah, Penang and Perak). The interviews were conducted from 1 September 2012 to 14 February 2013. A combined cluster, stratified and snowball-sampling design is used. For each state, we divided the targeted population into three clusters: rural, urban (city) and urban (big city) which then we randomly selected one big city, city and rural from each state. In obtaining appropriate ethnic representation in the sample, we stratified housing estates into Malays and Non-Malays majorities. A total of twenty four housing estates were chosen from the three clusters and respondents were obtained by snowball sampling. Once the elderly voluntarily agreed to participate in the survey, he or she was asked to recommend other elderly in the housing estate. We pre-determine the targeted sample size based on the number of population in each state and managed to interview 1,420 respondents.

**Empirical specification**

This article aims to examine the effect of living arrangements on health status of elderly. We measured health status using two indicators: (1) self-perceived health (SPH) and (2) the existence long-standing illness.
Thus, two separate probit models were used in determining the effect of living arrangement on SPH and LSI. Respondents were asked on how they perceived their health, either good or otherwise (SPH) and whether they have a long-standing illness (LSI).

Assume that for each elderly, there is a latent variable that represents an unobserved health status. This unobserved health status is associated with variables such as living arrangements, socio-demographic characteristics of the elderly and other relevant variables, denoted by \( x_i \).

Let, for each individual \( i \), \( y^* \) represent the latent variable and assume that \( y^* \) is a linear function of \( x_i \), then,

\[
y^*_i = \sum_{i=1}^{n} \beta x_i + u_i
\]

where
\( y^* = \) unobserved health status (SPH) or (LSI)
\( x = \) independent variables including living arrangement
\( u = \) error term

Let \( y \) be the random variable that represents the observed outcomes such that value of \( y \) is observed as:
y = 1 if the elderly perceived as good health or have long-standing illness
y = 0 if otherwise

Assume that the error term in the latent equation (1) follows a normal distribution, we have the probit model. The probability that the elderly have observed outcome of good health or long-standing illness (\( y = 1 \)) or otherwise (\( y = 0 \)) are as below:

\[
\text{Prob}(y = 1) = \text{Prob}(y^* > 1) = \text{Prob}(x \beta + u > 0) = \text{Prob}(u < x \beta) = \Phi(x \beta)
\]
\[
\text{Prob}(y = 0) = 1 - \text{Prob}(y = 1) = 1 - \Phi(x \beta)
\]

The \( \Phi \) is the cumulative standard normal distribution function. The maximum likelihood parameter estimates (MLE) are obtained by maximizing the following log likelihood function with respect to \( \beta \):

\[
LF(\beta) = \sum_{i=1}^{n} y_i \ln(\Phi(x \beta)) + (1 - y_i) \ln(1 - \Phi(x \beta))
\]

The model is estimated with the robust variance estimates (Huber/White/sandwich estimator of variance).

**Findings**

List of variables with the summary statistics of independent variables used for empirical analysis is presented in Table 1. From Table 1, it shows that 61.1 percent of respondents are Malay), the mean age is at 69 years old, and majority of the respondents have been retired and married. Their highest education attainment is post degree education.

**Table 1. Summary Statistics of Dependent Variable and Independent Variables N=1,414**

</tbody>
</table>
About half of the respondents perceived their health as good while 66 percent reported of having long standing health problems. About 31 percent of respondents declared that they currently living at their own home. Living arrangement is constructed as in Table 2, which show that around eight per cent of the elderly is living alone. On the other hand, there are around 35 per cent of the elderly living with spouse only; around thirty-two percent with spouse and other family members; around 25 per cent with other family members only. It appears that to some extent, majority of respondents do not live alone.

The probit model was estimated for the self-perceived health, *goodhealth*, and the existence of long standing illness, *long_ill*. The estimated probit model fits the data significantly with p-value of almost zero (prob>chi2 =0.0000) and pseudo R square of 0.0781 and 0.0422, respectively. The estimation from the probit models is shown in Table 3.

</tr>
</tbody>
</table>
The variables that represent living arrangements in the analysis are alone and own-home. The analysis shows that variable alone has no influence on the health status of elderly, neither perceived or physical health. In short, living alone nor living with any member of family is not significant in determining the health status of elderly in northern states of Malaysia. This finding is in contradiction of previous studies by Agrawal and Weissman and Russell, which concluded older adults living alone, will have poor health status as compared to living with co-resident. Nevertheless, living at their own-home has a positive impact on good self-perceived health, but not actual health status, measured by long_ill. The elderly are more likely to perceive themselves as in good health if they stay in their own home. This may be because the attachment to own home gives more living satisfaction, empowerment and happiness.

In terms of demographic variables, the influence of education and economic activities on perceived and physical health are comparable. The level of education has a positive impact on the probability of perceived good health and negatively affect the probability of having long-standing illness. In other words, the more educated these elderly’s are, the higher the probability of perceiving good health and the lower probability of having long-illness.

From Table 3, it demonstrates that retired, exercise and chat affects significantly the probability of having good health. As the elderly actively involved in exercise activities and spending more time to chatting with friends and neighbors, they have higher probability to perceive themselves as in good health. Furthermore, this type of social support enhanced the relationship between living arrangements and life satisfaction.

The results of the probit model for long-standing illness, it shows that retired, exercise, smoker and income are significant in affecting the health status of elderly. Being a retired elderly and has a certain amount of income increase the probability of having long-standing illness. However, living a good live through doing exercises and not smoking, has lower the probability of having longstanding illness. Other variables such age, gender, ethnicity and living with co-residents are not statistically significant in determining health status in this analysis.

**Conclusion**

Health status can be distinct in terms of perceived and physical. How you assess your health is more of a perception of conceptual but having a long-standing illness is more of an objective measures. This study has provided some evidence on the effect of living arrangement and other factors on health status, measured
by both perceived and physical health of the elderly in northern states of Malaysia. It was found that living alone is not significant in affecting their health status, be it perceived or physical. On the other hand, they are more likely to perceive of having a good health if living at the comfort of their own-home. While the effect of living in own-home is significant on perceived health, it is not on the probability of having long-standing illness. This reflects that the choice of health indicators has somewhat influence understanding on this issue. Feeling of having good health does not necessary mean that one is physically healthy and conclusion may differ based on different health indicators. Although, living alone has positively influenced the likelihood to be in good health status among the elderly in this study, social support by the society is still essential. By promoting social engagement of older persons, such as volunteerism, it may yield important benefits for them and for the productivity of society. Health care facilities should be properly designed as to ensure easy access and meet the expectation and demand of the old generation.

Study on Heart Rate Visualisation Using Combination of Real Time Heart Rate Detection and Augmented Reality

Norazlin Mohammed1, Junaidah Binti Idrus1
1Center for Advanced Computing Technologies (C-ACT), Faculty of Information and Communication Technology, Universiti Teknikal Malaysia, Melaka (UTeM), Melaka, Malaysia

Abstract

Heartbeat is a natural process which the heart continuously beating without any control from the living thing while heart rate is the speed of the heartbeat measured by the number of contractions of the heart per minute (BPM). There are few methods that can be used to check heart rate. Traditionally, heart rate is check by placing a finger on wrist or temple area and the pulse is counted in one minute. There are few devices that can be used to check the heart rate such as a stethoscope, electrocardiogram (ECG) and chest strap. This paper presents the study on the comparison of these devices that are commonly used nowadays. As analysis being done, none of the existing devices provide visualization features that enable user to see how the heart beating process happen in a human’s body. This paper also presents the study on providing visualization of heart beating process by using Augmented Reality in delivering health information to improve the understanding on user heart condition whiles getting their real-time heart rate. Since AR is one of the new emerging technologies, it can be used to visualize the user heart beat in real time and user can interact with the application to get details of their heart condition. This project also aimed to encourage the user to do frequent heart rate checkup in order to let them monitor their health by providing interactive features of ‘Lean Touch’ where heart model can be scaled, moved, and zoomed.

Keywords: Augmented Reality; Beats per minute (BPM); Heartbeat; Interactive; Visualization;

Introduction

Heart rate is the speed of the heartbeat measured by the number of contractions of the heart per minute (BPM). Every living thing need heart beat to pump blood and supply oxygen to whole body. Traditionally, heart beat measurement usually taken at pulse point of the body. The measurement is count based on how many beats per minute. There is few point from our body that enable us to take detect heart rate such as wrist, inside of your elbow, side of neck or top of your foot. Pulse is rhythmical throbbing of the arteries as blood is propelled through them and it used to help us get a picture of our health. Very low or fast heart beat is a signal of few diseases that need further check up with doctor. The problem raised when it comes to visualization part as patient and doctor cannot see the heart pumping. As the doctor used statoscope, doctor can only hear and count the heart rate. As for patient, they just get the result from doctor observation as we as person with normal hearing, when it comes to pitch the human hearing range starts low at about 20 Hz and ability to hear it is different for each individual. This project goal is to solve the current limitation of visualization of the heart rate for the patient. Augmented reality technology will be used to develop this application in order to produce a functional heart beating model associated with the real time heart rate reading.

Literature Review

Heart rate or pulse is a vital signed used to measure basic function of human body. Heart rate is measure on how much beating in a minute. Heart rate is taken to check rhythm and strength of the heartbeat. This is due to uneven rhythm or weak pulse might be a sign of a heart problem. Heart rate usually measured by using
your index finger any pulse point on your body and count the beats for set period of time. Example of pulse area include wrist, neck, temple area, groin, behind the knee, or top of the foot. Although this traditional method of counting the beats in second and then multiply the result by two is simple, it is not accurate and it could lead to error in counting when the heart rate is high. Other sophisticated method is created like a smartwatch for pulse detection, digital pulse reader and etc. By using all this new device or technology, the accuracy of the heart rate reading is higher and the risk of error can be reduced.

The latest technology has used mobile phone as the heart rate reader. The camera flash from mobile phone will get the measurement of the heart rate and give result to the user less than 10 second. The main idea of how the heart rate is measured is by detecting the change of skin colour and brightness of the surface of skin due to blood pulsation. However, this raw signal cannot be simply taken as it may contain noise or fake peaks or data loss due to movement of the finger during the reading is taken.

In medical sector, the most crucial instrument for checking the heart beat is a stethoscope. Stethoscope is a medical instrument that is used to check the performance of the heart and the lung. If there is any murmur; a condition where the heart sound is unusual that may reflect disease or malformation of the heart, further check-up is needed by using other instrument. There are many forms of murmurs and each of them represent a variety of heart condition.

Other example in medical sector is the Electrocardiograms (ECG). Electrocardiograms (ECG) is a test that is used to identify the underlying heart condition by measuring the electrical activity of the heart. Condition that may be diagnosed an ECG test are abnormal heart rhythms whether the heart pumps too fast or too slow, abnormal conduction of cardiac impulses that may indicate metabolic disorder, presence of a prior heart attack, occurrence of abnormal blood electrolytes such as potassium, magnesium and calcium.

Other than all stated above, there also few wearable gadgets that have been invented to fulfil the needs of our modern culture. This wearable device includes wristband heart tracker, chest strap and also fitness tracker. Other than that, there is also heart rate monitor integrated with headphones which allow the user to listen to their favourite music while doing physical activity. This headphone is connected to the user smartphone via Bluetooth and the heartbeat of the user is send to the smartphone during the activity.

Augmented reality (AR) is one of the technology that allows a level of immersion for user but the immersion level is not a fully immersion like the virtual technology provide. Augmented reality objective usually is simplifying the user’s life by providing virtual information immediately in the user’s real world surrounding. Augmented reality technology have been used in many sector or applications such as surgery, inspection of hazardous environments, and engineering. Currently the augmented reality technology basically covers for indoor activity within small areas. However, with the advances of the computer, and present of wireless technology, development of wireless augmented reality for outdoor application could be made. There are six different types of augmented reality that fall under two basic categories which is marker based and markerless based augmented reality. Marker based augmented reality are one that use marker or object to initiate the augmentation. Marker Based Augmented Reality can be easily recognized and does not require a lot of processing power to read. The other types of augmented reality are markerless based AR; these types of AR allow the user to experience augmentations without marker. Markerless Based Augmented Reality also known as location-based or position-based or GPS. Wide availability of smartphones and location detection enhance the Markerless Based Augmented Reality. This technology used detection technology to recognize something or pattern before the scene is display.

As the Internet of Things (IoT) rapidly develop, this project is one of a IoT project that used Particle Photon as one of the hardware. Every Photon can easily be connected to the cloud by claiming each device in the Particle Cloud. With this Particle Cloud, developer can know the last time that the Photon active, and even to test the functionality of the photon by flashing LED on photon using flash function available in the web IDE. Other than Particle Photon, pulse sensor also used in this project in order to detect the pulse of the user hence getting the heart rate of the user. Pulse sensor is a plug-and-play heart rate sensor for Particle Photon compatibles. Pulse sensor usually used with Arduino to get the heart rate of the user.
**Existing System**

There are three existing systems that can be used to get heart rate which are stethoscope, electrocardiogram and chest strap. In medical sector, stethoscope is the most crucial device which doctor will use to check the patient’s heartbeat. Listening to the heart and lung need different listening skill to distinguish one another. Uses of stethoscope is painless and it give information on how the body function and if there is any further treatment to be done.\(^1\)

ECG is an ambulatory electrocardiogram monitors if the heart in normal state. It helps to detect abnormal heart rates or rhythms of the patient. ECG can detect if there is previous mild heart attack that did not show any symptoms or demonstrating heart disease that has not been suspected.\(^2\)

Chest strap should be worn directly under the breast and strap need to be adjust as tight enough to ensure constant contact with your skin. Although the uses of chest strap may cause uncomfortable affect, somehow the chest strap have the highest accuracy compare to other heart monitor device as it implements the ECG-style sensor where the sensor detect the electrical impulse in the heart and the result is shown in beat per minute (BPM). The algorithm and improvement are made to ensure that interference is reduce to improve the accuracy.\(^8\)

**Comparison of existing system**

</table>
HARDWARE REQUIREMENT

The devices used in this project were Particle Photon, Pulse Sensor, USB 2.0 Micro-B 5 Pin, and Solderless Breadboard.

Particle Photon (Header)

Particle’s IoT (Internet of Things) hardware development board, the Photon, use to build a connected project. Particle has combined a powerful 120MHz ARM Cortex M3 microcontroller with a Broadcom WiFi chip in a tiny thumbnail-sized module called the PØ (P-Zero).

These specific Photons come with headers, making prototyping easy as each board can plug directly into standard breadboards and perfboards, and may also be mounted with 0.1” pitch female headers on a PCB. The small form factor is ideal for IoT projects with cloud-connectivity. To get you started quickly, Particle has added a rock solid 3.3VDC SMPS power supply, RF and user interface components to the PØ all on a small single-sided PCB.

Pulse Sensor

The Pulse Sensor Amped is a plug-and-play heart-rate sensor usually used for Arduino. It essentially combines a simple optical heart rate sensor with amplification and noise cancellation circuitry making it fast and easy to get reliable pulse readings. Also, it sips power with just 4mA current draw at 5V so it’s great for mobile applications. Simply clip the Pulse Sensor to your earlobe or fingertip and plug it into your 3 or 5 Volt Particle and it will read the heart rate.

Solderless Breadboard

Solderless breadboard is a construction base for prototyping of electronics and used to connect two electronic components which is Particle Photon and Pulse Sensor. Solderless breadboard has 400 tie-point, 2 power lanes with tie-point 100 and 1 double strip with tie-point 300. It size is 8.2x5.5x0.85 CM. It made up from plastic housing associated with metal contact clips. It accepts wire with diameter 20-29AWG. Voltage/Current: 300V/ 3-5A.

USB 2.0 Micro-B 5 Pin

USB 2.0 Micro-B 5 Pin is a connector cable with type A end that connect Particle Photon with to the power supply in order to make the particle photon work and able to link to application.

SOFTWARE REQUIREMENT

Unity and Vuforia are the main platform of building application for this project. In addition, particle application also used to monitor the particle photon.

Unity

Unity is a cross-platform game engine developed by Unity Technologies, which is primarily used to develop both three-dimensional and two-dimensional video games and simulations for computers, consoles, and mobile devices. In this project, Unity version 2017.3 has been used to develop the application.

Vuforia

Vuforia is an Augmented Reality Software Development Kit (SDK) for mobile devices that enables the creation of Augmented Reality applications. It uses Computer Vision technology to recognize and track planar images (Image Targets) and simple 3D objects, such as boxes, in real-time. In this project, Vuforia 7 has been used to develop the project.

Particle

Particle is an application to setup the particle photon to the Wi-Fi. The application allows us monitor our particle photon and provide information of the device such as ID of the device, IP address of the device and the time of the last activity is recorded. It also provides action for user to flash thinker and refresh the data.
PROJECT DESIGN

The main menu of this application consist of four option which are PLAY, HELP, TIPS, and QUIT.

Refer to Fig 2 to see the flow of application.

Refer to Fig 3. System Architecture for ARHeartRate application

SYSTEM ARCHITECTURE

In the system architecture, there is four main parts which is User, Hardware, Software and the Output of the system. For user part, the most crucial element is to get the input from user in term of getting heart rate from the user. In hardware part, there will be three components which is button badge, laptop’s camera, and composite device which is combination of pulse sensor and particle photon. In this system, button badge will act as a marker for detection to project the model in the scene. Pulse sensor and particle photon were linked and integrated with coding to make it both of the component works. Laptop’s camera is used to produce superimpose effect where the ribcage and the heart will be reflected on user body. The real time heart rate of the user will detect by using the pulse sensor where it uses infrared light to read the heart rate.
Advantages And Limitation

The main advantage of this ARHeartRate is provides a visualization of upper part of human body which is ribcage and the heart model. To improve the experience of the user, the ribcage has been set to maps the user body once the marker is scanned. Moreover, the heart has been animate and the user can see and hear the heart beating. To make the application easier to use, the marker of this application has been design in form of button badge, where it allows the user to interact with application without the need to hold the marker.

![Figure 5. 3D model maps to user’s body and Marker design for ARHeartRate application](image)

Although the application has its own advantage, this application also has its flaws. The main limitation of this application is the pulse sensor is over sensitive where value of the heart rate often changes during measurement if the pulse sensor is move and expose to noise.

Conclusion and Future Work

In conclusion, this project has been successfully developed to achieve certain objective in visualizing heart beating process using real time heart rate detection. By having this project, we hope that user is motivated to do frequent check of their heart rate hence they can monitor their health as well. User can also get information about best practices to ensure their heart is healthy. For future work, the application should include the ability to store history of user heart rate and allow the user or doctor to monitor the heart rate of the user remotely. The proposed model will be further evaluated by using usability evaluation (heuristics evaluation and questionnaire).

Protective Effect of Various Lyoprotectant on the Survival of Antineoplastic Drug Producing Serratia Marcescens

Kavitha.R¹, Damodharan.N²
¹Associate Professor; ²Professor, Department of Pharmaceutics, SRM College of Pharmacy, SRMIST, Kattankulathur

Abstract

More effective method of long time storage of the microbes is lyophilisation and cryopreservation. To enable cell survival rate of bacteria during the drying process, lyoprotectant usually added before freezing. Serratia marcescens is a bacterium recognised as the producer of prodigiosin drug which showing promising antibacterial, antifungal, immunosuppressant and anti-proliferative activity in hematopoietic cancer cells. The aim of this current research to investigate the influence of lyoprotectant on the viability of Serratia marcescens during lyophilisation. Several additives were tested as protective agents like sucrose, mannitol, skim milk, bovine serum albumin and sucrose with BSA combination. The effect of drying adjuncts on survival was correlated to their interaction with the bacterial membrane by determination of cell viability by plating and SEM images. Cellular viability during storage of exponential phase cells remained highest for cells dried in the presence of 10%silk milk and 10%sucrose with 5%BSA combination. The result suggested that the possibility of achieving a good formulation system influenced by the type of lyoprotectants used.

Keywords: Lyoprotectant, Serratia marcescens, Mannitol, Bovine serum albumin, SEM analysis.

Introduction

Starter culture plays an essential role in the fermentation process of dairy, food and fermentation industries. Awareness is increasing about culturable diversity, and the development of modern cultivation approaches is continuously improving the numbers of new and previously uncultivated taxa of microorganisms in culture collections. Cultivation and characterisation of microorganisms alone are not adequate without preservation techniques that do not alter the morphology, phenotypic or genotypic stability of pure strains. Careful preservation is imperative for future research, teaching and industrial applications¹,².

Members of genus Serratia well recognised as the producer of bioactive compounds. Serratia spp are gram-negative bacteria, classified in the large family of Enterobacteriaceae some strains of Serratia marcescens produce a water-soluble pink pigment pyrimidine, L-2-(2-pyridyl-D/-pyrroline-5-carboxylic acid) [Prodigiosin]³,⁴. Prodigiosin has antibacterial, antifungal, antimalarial and cytotoxic properties and it has suggested for the treatment of autoimmune diabetes and collagen-induced arthritis⁵,⁶. The chitinolytic machinery of S. marcescens is of great interest because it is one of the best characterised chitinolytic machinery known to date⁷. A synergistic inhibitory activity of prodigiosin and chitinolytic enzymes was observed against spore germination of Botrytis cinerea⁸.

Metabolically active preservation methods such as subculture and maintenance under oil can lead to a decrease in the production of these valuable secondary metabolites. Since secondary metabolite synthesis only decreases during effective preservation methods, utilising inactive methods are necessary. However, cell damage occurs during the preservation process and even during the storage of inactive cultures. Therefore, the preservation of highly productive variants even at efficient conditions can impede the production of the biologically active substance⁹. Lyophilisation is the preferred long-term preservation method in most culture collection process due to the low-cost maintenance and ease of transportation of lyophilised cultures. It gives satisfactory results for the preservation of many microbes¹⁰.
Lyophilization is the sublimation of water from a frozen sample, and it comprises (i) freezing, (ii) primary drying, and (iii) secondary drying\(^8\). Lyophilisation exerts stress on the cells during vacuum desiccation and cells raised under stress many respond better to lyophilisation\(^8\). A culture at stationary phase and low pH condition survived better during lyophilisation than did cells in log phase grown at circumneutral pH. In general, a suspension medium with \(1 \times 10^8\) cell mL\(^{-1}\) or more gives a better recovery, whereas glass-forming cryoprotectants preferred over a eutectic crystallisation salt\(^1,11\).

The major causes of loss of cell viability during freeze-drying are attributed to ice formation high osmotic shock due to the high concentration of internal solutes with membrane damage, macromolecule denaturation and the removal of water, which affect the properties of many hydrophilic macromolecules in cells\(^12,1\). The survival rate of bacteria during this process, cryoprotective is usually added before freezing to prevent or reduce cell death during freeze-drying and subsequent storage\(^13\). An ideal cryoprotectant should meet all of the following criteria: be highly water-soluble, penetrate inside the cell, have low toxicity, be non-reactive, and not precipitate at high concentrations\(^14\).

Traditional classification of cryoprotectants additives (CPAs) depends on the rate of penetration: i) Additives which enter rapidly, in 30 minutes approximately, Eg: methanol, ethanol, ethylene glycol (EG), Dimethylformamide. ii) Additives which penetrate slowly, Eg: glycerol, mono-, oligo and polysaccharides, mannitol, dextran, sorbitol, albumin, protein, gelatin, polyethylene glycol (PEG) at 10-40%. Some cryoprotectants additives only penetrate the cell wall and do not penetrate the cytoplasmic membrane and categories: 1) Cryoprotectants penetrating both cell wall and cytoplasm membrane- glycerol and MeSO. 2) Cryoprotectants penetrating the cell wall but not the cytoplasm membrane: mono and disaccharides, amino acids. 3) Cryoprotectants were not penetrating cell wall: dextran, PEG-6000 polysaccharides\(^15,16\).

The application of a variety of chemical compounds either alone or in addition to skim milk has reported. The mono and disaccharides glucose, sucrose, maltose, lactose and trehalose, as well as maltodextrins, increased the viability of lactic acid bacteria during freezing and freeze-drying\(^17,18,19\). The fructo-oligosaccharides significantly increased survival of stationary phase cells of Lactobacillus reuteri TMW1.106 after freeze-drying and storage by increasing membrane fluidity. The addition of the prebiotics FOS, inulin and polydextrose also enhanced survival of Lactobacilli rhamnosus during spray-drying\(^1\).

At the combination of sucrose and monosodium glutamate and sodium caseinate, skim milk shown higher viability on freeze-drying of Streptococcus thermophiles NCIM 2904\(^20\). The optimum protective medium for Lactobacillus bulgaricus LB14 was reported with the combination of sucrose, glycerol, sorbitol, and skim milk\(^12\). Consequently, some studies have examined the potential role of additives in suspensions of microorganisms such as sugars, polyols, amino acids, peptides and proteins in their survival throughout freezing and drying of lactic acid bacteria and Streptococcus thermophiles\(^13,20\). Although techniques of lyophilisation well established, optimisations of lyoprotectants are still necessary for certain microorganisms.

In this research work comprehensively investigated the preservation of aerobic bacteria by lyophilisation process. The bacterial fitness evaluated by viability using different non-toxic protectants like sucrose, skim milk, mannitol, BSA and sucrose and BSA combination to improve freezing and freeze-drying resistance. The efficient cryoprotection of Serratia marcescens reported at the first time.

**Materials and Method**

**Microorganism**

*Serratia marcescens* KR isolated in our laboratory from SRM Institute of Science and Technology, Kattankulathur. The microbe obtained from the marine crustaceous soil sample. The strain was characterised and confirmed as *Serratia marcescens* then maintained in nutrient broth.

**Culture Condition**

The culture was initially passed on solid nutrient agar and then in liquid nutrient broth. After inoculation, the cultures incubated for 24hr at 37°C followed by a new seeding a liquid medium, Then again were incubated for 24hr at 37°C.

**Protective Agents**

The substances used to protect cells during
lyophilisation were bovine serum albumin (BSA) at the concentration of 5%, mannitol, sucrose and skim milk at a concentration of 10% and the combination of sucrose and BSA at 10% and 5% as respectively. The protective media were prepared by suspending these agents in distilled water and were sterilised at 121°C for 15 minutes.

Preparation Procedure

Cells in the early stage of the stationary phase were harvested under aseptic conditions by centrifugation at 10,000rpm for 10min at 4°C in a cooling centrifuge. The growth medium was decanted, and the harvested cells were washed twice in aseptic distilled water and centrifuged again. Each pellet was resuspended in the experimental protective medium to make a cell suspension containing approximately $1.0 \times 10^{10}$ CFU/ml. The suspension was incubated for 20 minutes at room temperature and shaken continuously to allow cell adaptation.

Lyophilization

Aliquots (5ml) of each suspension were transferred into three sterilised vials (8ml) and were frozen at -20°C overnight. After overnight storage in the freezer, samples connected to a lyophilizer operating at 1Pa pressure and -70°C for 24hrs.

Rehydration

After freeze-drying, samples were immediately brought to their original volume (5ml) with each rehydration medium at 25°C. Then, samples were homogenised for 1 min with a Vortex mixer and incubated at room temperature for 9 minutes.

Determination of Cell Viability

The number of viable cells before and after freeze-drying determined as colony forming units (CFU). Decimal dilutions were prepared from the suspension before freezing, and suitable dilutions were plated on nutrient agar consisting of yeast extract 5g, beef extract 5g, peptone 5g, sodium chloride 0.5g and agar 15g (pH 7.20.2), by the drop count technique. The suspended samples were plated and incubated at 37°C for 24 hr and colonies were counted.

The viability of cell suspension for each protective medium was calculated using the following equation:

$$Viability\% = \frac{\text{Viable cells after freeze-drying (CFU/ml)} - \text{drying (CFU/ml)}}{\text{Viable cells before freezing (CFU/ml)}} \times 100$$

Scanning Electron Microscopy

The small amounts of matrix/bacteria take out of the vials and fix it on an SEM stub. Load the SEM holder in the sputter-coater (Thermo VGScientific Polaran SC7640 used in the present work) and coat the sample with a few nm of Au/Pd for Pt. In these experiments, the sputtering parameters were 1,900 V, 20mA and 20 sec, for a 5-10nm Au/Pd coating. The coating reduces electric charging during image acquisition. It is recommended to start with a thin coating and, if charging persists and causes
image artefacts, the sample should be coated again. Load the SEM holder in the SEM chamber. Appropriate imaging parameters selected. For the instrument 5kV accelerating voltage, spot size 3, a working distance of 5mm and the secondary electron detector used.24,25,26

Result and Discussion

Microbial culture preservation is currently limited to the bioresource centres or culture collections. Different groups of microorganisms give widely varied responses to the same preservation method. Even the different strains of the same species may show different responses regarding survival and durability with the same preservation strategy. Microbiologists should consider the preservation of medically, ecologically and industrially important strains as paramount or representative members from each group should be optimised for routine preservation. Preservation and storage of microorganisms by various methods used from decades. From a large number of methods used of storage of microorganisms, the more effective methods are long-term cryopreservation and lyophilisation. The objective of the current study to determine the influence of various lyoprotectants used on the survival rate of Serratia marcescens strains during the lyophilisation process. The most efficient protectant for longer survival and maintenance of genetic stability required in the production of secondary metabolites evaluated following preservation stress.

Lyophilisation is one of the most common methods for the conservation of micro-organism in the collections due to storage conditions is 1-4°C which affords easy transportation of microbes. Membranes are primary targets of freezing and desiccation injury, and membrane damage is a catalyst of cell death during drying and dry storage. The membrane integrity, as well as the viability of stationary phase cells, remained higher compared to exponential phase cells. The acquisition of increased freezing and drying resistance in stationary phase Lactobacillus reuteri TMW 1.106 were studied.

The critical factor for a formulation to support cell survival is the capability of the formulation ingredients to replace water during dehydration, thus maintaining the structure of the proteins and membranes of the cell also in the dry state. Our experimental result shows the mannitol and BSA forms an amorphous powder with high quantitative formexhibited eminent cake properties whereas skim milk formed porous structured the quantitative amount, sucrose produced semi-solid end product not given any powder with our lyophilisation condition (Table:1). It has predominantly hypothesised that sucrose acts by verification process, forming a thick, viscous layer around microbes and require high activation energy for sublimation. In this context, the observed melt-back phenomenon could be possibly due to inability to achieve very high activation energy, which led to the formation of a stagnant viscous layer of sucrose around microbes resulting in melt-back of cake. This phenomenon was regarded as critical stability and is generally unacceptable for the lyophilised sample. These products often result in loss of viability and reduced stability of Serratia marcescens. In this regard, the lyophilised product of sucrose incorporated with Serratia marcescens renounced for further characterisation studies.

When the sucrose added with 5%BSA, it produced amorphous structure and easy to quantify- the images of the lyophilised samples represented in fig:1, without any lyoprotectant act as blank in this study. The amorphous structure was beneficial for shielding and keeping cells separated. Fortunately, our result showsmannitol, BSA, Sucrose and BSA combination formulations become amorphous after lyophilisation.

![Figure 1. Lyophilized form of Serratia marcescens with different lyoprotectants.](image)

i) Blank (without any protectant) ii) 10% mannitol iii) 10%skim milk iv)5% bovine serum albumin
v) 10% sucrose + 5% BSA
vi) 10% sucrose

The difference exhibited in cell survival in this study indicates that certain additives are more effective than others in protecting *S. marcescens*. The current research shows that sucrose with BSA and skim milk had the most lyoprotectant activity among the other tested lyoprotectant for Serratia marcescens in the freeze-dried state. Compatibility and availability of skim milk, in addition to its low cost, justify its selection as a suitable protectant for large-scale preservation of industrial strains. Since skim milk contains 32.0%–35.7% protein and 48.4%–54.1% lactose, it is a preferred protectant in the preservation of bacteria (Fig:2)

![Figure 2. Comparative effect of different lyoprotective agent on *Serratiamarcescens* viability after freeze-drying and rehydration](image)

BSA it gave noticeable protective for the viability of the microbes lyophilised sample. The final cell viability obtained using mannitol as protectant was only 40%, even though this compound provided the lyophilised material with a light and amorphous structure which makes rehydration easy.

![Figure 3. SEM images of *S.marcescens* in five different formulations: a) and b) –Blank (Water), c) and d)- 10% mannitol, e) and f) 10%skim milk g) and h) 5% BSA i) and j) 10%sucrose+5% BSA](image)
formulation leading to a uniform alignment of microbes despite its intermolecular variations and ensured cake formation with crystalline structure in electron microscopy. The image of the lyophilised formulation with skim milk, BSA and Sucrose with BSA combination formulations showed the discernible microbes in the sheets of lyoprotectant. Per Wessman et al.\textsuperscript{3} stated that whether the protectant and bacteria dispersed as crystals of dissolved in the polymer, does not correlate with cell survival. The viability of microbes may relate to the type of protectant added, and our result explained as same.

In conclusion, this study has shown that the recovery of cells of \textit{S.marcescens}, when subjected to lyophilisation, is dependent on the lyoprotectant used, the formation of amorphous solid which make the rehydration easy with higher productivity. An appropriate selection of these factors seems to be essential to ensure the long-term viability of these microorganisms. Future research must focus on demonstrating more lyoprotectant effect with their combinations in the survival of microbes. It would also be essential to study the shelf-life of lyophilised cells. These findings are necessary for the industrial development of microbial preservation.

Comparison between Dry Needling Versus Kinesio Taping in Patients with Tennis Elbow

K.Guru Karthick¹, D.Malarvizhi², Komal Bhagat³

¹SRM College of Physiotherapy, MPT Second Year Post Graduate Student (Sports), ²Dean Incharge, SRM College of Physiotherapy, SRM Institute of Science and Technology, Kattankulathur, India, ³SRM College of Physiotherapy, MPT Second Year Post Graduate Student (Neuro), SRM Institute of Science and Technology, Kattankulathur, India

Abstract

Background: Tennis elbow or lateral epicondylalgia is a common painful condition of elbow which leads to pain over common extensor origin, muscle weakness, and reduction in upper limb function. There are very few researches are on muscle activity in the tennis elbow and the treatment of dry needling and Kinesiotaping. Objective: To examine the effectiveness of dry needling versus kinesio taping in patients with tennis elbow. Design: Quasi Experimental design

Methodology: It has two groups: Group A – Dry Needling and Ultrasound therapy (n = 5) and Group B – Kinesiotaping and Ultrasound therapy (n = 5), age: 17 to 50 years, genders, SRM medical college hospital and research center, Kattankulathur.

Outcome Measures: Pain Pressure Threshold and Patient Rated Tennis Elbow Evaluation (PRTEE)

Result and Conclusion: From the results this is found that there was no significant difference of Pain Pressure Threshold and Patient Rated Tennis Elbow Evaluation between the Group A and Group B but there was significant difference of Pain Pressure Threshold and Patient Rated Tennis Elbow Evaluation within the Group. This concludes that there was effect in both dry needling and Kinesiotaping among patients with tennis elbow

Keywords: Tennis elbow, Dry needling, Kinesiotaping, Pain pressure threshold, PRTEE

Introduction

Tennis elbow is a common painful condition in which outer aspect of the elbow becomes sore and tender at the lateral epicondyle. It often occurs after the strenuous overuse of muscles and tendons of forearm near the joint. Tennis elbow is responsible in affecting daily activities and job due to pain. Not surprisingly, playing tennis or other racquet can cause this condition. However several other sports activities can also put you at risk.

Lateral epicondylitis involves the muscle and tendons of the forearm. Forearm muscle extends the wrist and fingers. The forearm tendons are the extensors which attaches to the bone on the lateral epicondyle. The tendon usually involved is extensor carpi radialis brevis. The overuse of extensor carpi radialis brevis leads to this condition¹, ², ⁴, ⁸, ¹⁰.

Lateral epicondylitis is directly related to activities that increase the tension and hence the stress of the wrist extensor and supinator muscles resulting in muscular contractile overloads that may occur concentrically or eccentrically. This clearly describes an overuse syndrome that is characterized by excessive forearm use with respect to intensity and duration¹¹.

Also known as myofascial trigger point needling, dry needling is the invasive procedure of the use of either filiform needles or hollow-core hypodermic needles for releasing the tension and myofascial pain.

Corresponding author:
Prof. D. Malarvizhi
Mail id: malarvizhi.d@ktr.srmuniv.ac.in
It is a physiotherapy procedure which helps in treating abnormality caused due to trigger points. It is an effective therapy to treat muscular tension and spasm. Many researches prove to be beneficial in treating lateral epicondylitis. Several articles concludes that 5-6 additional follow ups improves the pain and ADL activities.  

Kinesiology tape is a thin, stretchy, elastic cotton strip with acrylic adhesive which is mainly used for treating athletic injuries and many of the physical disorders. For the first decade after introduction, practitioner in Japan were the main user of this therapy and by 1988 the tape had been adopted by Japanese Olympic and professional athletes. It relieves pain, reduces swelling and inflammation, accelerates recovery from bruises and contusions, prevents muscle spasm and cramping etc. Kinesio taping has proved to be effective in treating pain intensity, grip strength and also increasing functional performances of the patient.

So the purpose of the study is to compare the effectiveness of Dry needling versus Kinesiotaping among tennis elbow patients.

**Methodology**

This study was a quasi experimental study; the type of the study was pre and post type. The inclusion criteria were based on population with both genders, patients presenting with pain over lateral side of the elbow, subacute patients (7th to 45th day). The patients with positive mills maneuver were included and with any of the trigger points over extensor carpi radialis, extensor carpi radialis brevis, Supinator and Brachioradialis. Therapist has to check for trigger point and needling has to be done on those muscles for 1 – 2 minutes. After the dry needling procedure over the muscle attachment and myofascial trigger points of muscle belly and musculo-tendinous junction the areas were examined for post needling bleeding.

**Group A: Dry Needling**

The patient position was in sitting with forearm in mid prone position. The needle size was 25 mm. Most commonly Affected Muscles: Extensor digitorum, Extensor carpi radialis longus, Extensor carpi radialis brevis, Supinator and Brachioradialis. Therapist has to check for trigger point and needling has to be done on those muscles for 1 – 2 minutes. After the dry needling procedure over the muscle attachment and myofascial trigger points of muscle belly and musculo-tendinous junction the areas were examined for post needling bleeding.

**Group B: Kinesiotaping**

The kinesiotaping technique was Inhibitory technique (insertion to origin) and the tension was Paper – off tension (15 – 25%). Placing the base of kinesio Y strip near the wrist in the region of the radius styloid process, with no tension. The elbow should be in slight flexion with wrist in neutral position. Have the patient move in to elbow and wrist extension with wrist ulnar deviation. The inferior strip should follow the inferior aspect of the common muscle group. The superior strip should follow the superior aspect of the common muscle group. Both tails should end directed towards the lateral epicondyle of the humerus. Lay down the distal 1 – 2 inches with no tension. Initiate glue activation prior to any further patient movement. Apply a space correction technique, tension on base, for the area of pain. Being by placing the base of the kinesio Y strip below the area of pain with the elbow in neutral position. Do not cross over the lateral border of ulna – this may cause pain in this region.

After two weeks of treatment the post test will be assessed.

**Data Analysis**

The observed data were calculated and
Graph 1: Pre and Post test values of Pain pressure threshold test among Group A subjects treated with dry needling and Group B subjects who treated with kinesiotaping.

This graph shows that there exist a significant difference between Pre and post-test of Pain Pressure Threshold among Group A and B.

Graph 2: Pre and Post test values of PRTEE among Group A subjects who treated with Dryneedling and Group B subjects who received Kinesiotaping

This graph shows that there exist a significant difference between Pre and post-test of Patient Rated Tennis Elbow Evaluation among Group A and B.

Graph 3: Comparison of PPT and PRTEE between Group A and Group B

This graph shows that there is no significant difference between comparison of PPT and PRTEE between group A and group B.

Discussion

The aim of our study is to find out the effect of dry needling and Kinesiotaping in patients with tennis elbow, and compare the effectiveness of dry needling versus Kinesiotaping in patients with tennis elbow.

Our study results show that there was significant difference in PPT and PRTEE within groups of A and B. The Group A PPT values are Pretest M=1.12±0.36 and Post test M=2.60±0.49, t=-22.31 and P=.000. The PRTEE values are Pretest M=72.2±11.07 and Post test M=41±6.67, t=12.69 and P=.000. The Group B PPT values are Pretest M=1±0.36 and Post test M=1.66±0.42, t=-6.887 and P=.002. The PRTEE values are Pretest M=58.80±14.41 and Post test M=41.80±13.55, t=-6.208 and P=.003.

Our study results show that there was no significant difference in PPT and PRTEE between Group A and Group B. The PPT values of Group A was M=2.6±0.49 and Group B was M=1.6±0.42, t=3.205 and P=.013. The PRTEE values of Group A was M=41±6.67 and Group B was M=41.8±13.55, t=-0.118 and P=.909.

Sukumar et al (2014)\(^1\) concluded that both dry needling and low level laser therapy shows improvement in functional performance and reducing in pain. In this study also there was a improvement within group which is significant and between group it was no significant which same like our study.

Paras Joshi (2017)\(^2\) done a single case study using Tailor Made Physiotherapy Protocol with Dry Needling And Kinesio Taping and he found the results Pain came down to 0.5 from 9 on NPRS. Full ROM achieved at elbow. There was absolutely no complaint in performing daily activities. Chronic tennis elbow can be treated with tailor made physiotherapy treatment.

In our study most of the patient felt immediate pain relief after the dry needling treatment when compare to Kinesiotaping undergone patient. Our protocol was 3 session for 1 week, if it may keep for 2 weeks we could able to drastic improvements.

Conclusion

This study concluded that there was effect in both dry needling and Kinesiotaping among patients with tennis elbow.
Limitations

Limitation of this study was the sample size was small and the duration of the treatment session was less.

Recommendations

The future recommendation was to have larger sample and longer duration. They can analyze the pre and post of muscle activity after the dry needling and Kinesiotaping in tennis elbow patients using EMG.

Effect of Incentive Spirometry and Balloon Exercises to Improve Pulmonary Function for Type 2 Diabetes

D Malarvizhi1, Geetha Anandakrishnan2
1Dean Incharge, 2BPT Final Year Student, SRM College of physiotherapy, SRM institute of Science and Technology, Kattankulathur, India

Abstract

Background: Diabetes is a systemic disease with well-known complications involving eyes, kidneys and nerves. Patients with diabetes mellitus may present pulmonary abnormalities associated with chronic hyperglycaemia due to extensive pulmonary micro vascular circulation and abundant connective tissue raising in the lung. The possible reduction in the lung function is due to respiratory muscle weakness that is due to non-enzymatic glycosylation of connective tissue protein such as collagen in pulmonary tree and chest wall. Objective: The purpose of this study was to see the effect of both incentive spirometry and balloon exercise on pulmonary function for type 2 diabetes. Method: 30 samples (15 diabetic group and 15 control group) with age group between 40-60 yrs., with 6 month-10 years duration of diabetes were included in the study. Pulmonary function test was performed using computerized spirometry. PFT values were less in diabetes when compared to controlled group. Intervention was Incentive spirometry and balloon exercises were given for one month of duration. Outcome measures were computerized spirometry. Results: After one month of intervention pulmonary function test was again taken it shows that there is increase in the PFT values for both group A and B when compared to the pre-test. Conclusion: As with statistical result the people who were given incentive spirometry and balloon exercises have shown a significant improvement in pulmonary function. So, it is concluded that these exercises have effect on lung function in diabetes.

Keywords: diabetes, spirometry, pulmonary function.

Introduction

Diabetes mellitus is a chronic systemic disease that is due to the deficiency of insulin produced by the pancreas or the insufficient use of insulin by the cells in the body. There are two types of diabetes in which type 2 Diabetes are most common for about 90% of the total population mostly with age group of above 45 years. Diabetes can only be managed and not cured. Usually its importance is not recognized until people suffer from diabetes1.

Diabetes is associated with the dysfunction and damage of organs namely kidneys, nerves, heart, lungs due to micro vascular and macro vascular damage of blood vessels that supplies these organs2. The etiology of type 2 Diabetes may be due to lack of physical activity, improper diet (higher intake of saturated fatty acids results in insulin resistance), obesity, malnutrition, alcohol, viral infection, stress3.

The impaired glycaemic control in diabetes may lead to reduction in lung function that is due to increased systemic inflammation4. Pulmonary dysfunction is due to thickening of walls of alveoli, alveolar capillaries and pulmonary arterioles5. It is also due to immune function impairment6.

Pulmonary function test is the test that is done to rule out pulmonary problems. Computerized spirometry is used to evaluate the lung function of the diabetic. Spirometry assess the lung volumes and flows suited to describe the effect of obstruction or restriction on lung function7. Forced Vital Capacity (FVC), Forced Expiratory Volume in one second (FEV1) and ratio of Forced expiratory volume in one second and Forced...
Vital Capacity (FEV$_1$: FVC) are the parameters that were assessed. Meo et.al reported that FVC, FEV$_1$, FEF were impaired in diabetic patients when compared to the normal people with no diabetes$^8,9$. It is also said that subjects with reduced lung function are at the high risk of developing diabetes mellitus. Engstrom and Janzon predicted that presence of diabetes may be due to decreased FVC, FEV$_1$, which are inversely proportional$^{10}$. The incidences of diabetes are most commonly associated with restrictive lung diseases than obstructive type of lung diseases. In restrictive lung disease both the values of FVC and FEV$_1$ will be low but the ratio of FEV$_1$ and FVC will be increased$^{11}$.

Normally breathing exercises can increase the pulmonary function. Rafaqat, Mushtaq Z, Tahir A, Shahzad MF has compared and proved that both incentive spirometry and balloon exercises are equally effective in patients with chest intubation after trauma$^{12}$. So the aim of this study is to show the effect of incentive spirometry and balloon exercises to improve the pulmonary function of diabetes.

Earlier they were studies that are done to retrain the inspiratory muscles in diabetes as there may be diaphragmatic paralysis that is due to phrenic neuropathy$^{13}$. And there were study done to report that there is reduced pulmonary function in diabetes$^{14}$. But there were no studies done to improve the pulmonary function of diabetes. So this study was done to find out the effect of incentive spirometry and balloon exercises on the pulmonary function of type 2 diabetes.

**Methodology**

Study design was experimental design, pretest and posttest type, 30 subjects between the age group of 40 to 60 years (15 – controlled group, 15 – chronic type 2 diabetes) and with the history of diabetes in duration of above 6 month to 10 years were included. Study setting was SRM medical college hospital and research Centre. History of exercise induced asthma, Osteoarticular disease, infectious disease, cardio pulmonary disease, regular alcohol tobacco consumption in last 6 month were excluded in this study. Outcome measure was computerised spirometry.

According to the inclusion and exclusion criteria 30 subjects were selected and divided into two groups, 15 in Group A – Experimental group and 15 in Group B – controlled group. The procedure was explained, and informed consent was taken to participate in the study and Institutional Ethical Committee approval also obtained before starting the study.

**Procedure**

On application of inclusion and exclusion criteria subjects were selected and pulmonary function test was done using computerised spirometry. The participants were asked to keep the mouth piece fully covered by the mouth and then to take deep inspiration followed by forceful expiration and then again inspire. Three tests were done and maximum of it were considered. Pulmonary function of both group A and B were evaluated. The values were then compared, and it showed that there were reduced FVC and FEV$_1$ in group A than group B.

Incentive spirometry and balloon exercises were taught and were asked to follow up for one month. Subjects were asked to inspire to their maximum in incentive spirometry. They were encouraged and motivated to increase the inspiratory capacity on seeing the raise of the balls. On progression they were asked to maintain the balls in the peak for five seconds and then relax.

The procedure for balloon exercise was, subjects were asked to sit straight, hold the balloon in front and asked them to blow to the maximum after the deep inspiration. This was repeated for 5 times in one sitting/10 repetitions/day. After one month of interventions posttest was done evaluating the pulmonary function using computerized spirometry.

Discussion

In this study there were total of 30 subjects in this mostly were female population as most of the males were excluded due to smoking history. Duration of diabetes ranged from 6 months to 10 years.

Diabetes mellitus produces changes in structure and connective tissues that affects eyes, kidneys, nervous system etc. Lung may be the target organ for diabetes as there is extensive circulation and abundant connective tissues. Several changes including non-enzyme glycosylation of connective tissue might be responsible for organ damage and diabetic myopathy. These lead to loss of elasticity, altered perfusion and also weakness of the respiratory muscles that is responsible for ventilation. Lung function may provide useful measures of the progression of systemic micro-angiopathy in diabetic. The possible reduction in the lung function is due to respiratory muscle weakness that is due to non-enzymatic glycosylation of connective tissue protein such as collagen in pulmonary tree and chest wall. so lung is exercised to increase its function and capacity by incentive spirometry and balloon exercises.

The Study was to find the effect of incentive spirometry and balloon exercises to improve the pulmonary function of diabetes. Incentive spirometry is basically an inhalation based method of breathing that encourages participants to increase their lung volumes. Whereas balloon blowing exercise is the exhalation technique that produces resistance to muscles of expiration. This increases strength of the respiratory muscles. Recently there is a study proved that incentive spirometry and balloon blowing exercise are equally significant in improvement of pulmonary function.

These exercises improve the pulmonary function of participants. Along with exercise, healthy food, eating at correct time, using stairs can help in the prevention of diabetes. Further dynamic breathing exercise can be taught for the improvement.

This study goes in hand with Mandava v et .al int J adv med (2016) which is concluded that there is pulmonary function changes in type 2 diabetes lungs. The changes include with reduced values of FVC, FEV1.

Ana paula, S CORREA and et.al stated that diabetes mellitus may present with pulmonary functional abnormalities associated with chronic hyperglycaemia. Engstrom and Janzon predicted that the presence of diabetes may be due to decrease in Forced Vital Capacity and Forced Expiratory Volume in one second.

All Rafaqat, Zaharamushtaq, AdilaJahir and FarrutchShahzad M has experimentally proved that incentive spirometry and balloon exercises are equally effective in patients with chest intubation after trauma. Incentive spirometry improves the elasticity in the lungs and balloon exercise increases the strength of the respiratory muscles by providing resistance.

Jackie A Thomas had recorded that incentive spirometry had significant effect in people health versus no physical activity. Meo et.al reported that FVC, FEV1, FEF were impaired in diabetic patients when compared to the normal people with no diabetes.

Conclusion

The study concluded that incentive spirometry and balloon exercise has significant effect to improve the pulmonary function in type 2 diabetes.

Limitation of this study was short duration; small sample size and only chronic type 2 diabetes were given exercises. Recommendations are type 1 diabetes can also be studied, sample size can be increased to see mass effect and the duration of intervention can also be increased to see the great difference in pre and post test.

Abstract

Generally in critical case patients should be monitored continuously for their Heart Rate, Body position and in body temperature. In the present paper, we are utilizing an original thought for nonstop monitoring patient’s health conditions. The health care scheme is concentrate on the estimation and observing different natural parameters of patient’s body like heart rate, body position and temperature utilizing a web server and video monitoring, where doctor can constantly monitor the patient’s condition on PC using an Internet. This paper depicts the implementation and evaluation of the execution of a health care monitoring system using Internet. To ensure quality and accuracy the proposed system has been field tested. The test results demonstrate that our system can measure the patient’s physiological information with a high accuracy. This project aims to design and demonstrate an innovative web based remote healthcare diagnostic system that provides vital medical data and live video images of a patient situated in rural area accessible to a health professional available elsewhere in urban centers resulting in better analysis and treatment of that patient.

Keywords: Video Monitoring, DCMI, RTOS and Multitasking.

Introduction

At present, patient physiological parameter embraces timing artificial estimation style at most hospital. For example, nurse goes to ward and measures patients’ body temperature consistently, manual records and draws body temperature evolving figure, which can be broke down by doctors as reference of disease determination. This term of conventional not only wastes nurses’ massive manpower, but also aggregation, query analysis to measurement result is varied, as well as cannot feedback in time when patient appear special condition, which can cause postpone of treatment time. Through analysis we can see, this kind of style has bigger limitation, especially, to those patients with infectious diseases, monitoring personnel is inconvenience to contact. So, aiming to this problem, by sensor technology, single chip microprocessor technology, etc, we design a wireless remote concentration system. This system uses wireless communication and serial communication interface technology to design, which makes up tradition system shortcoming. Through monitoring in real time, as well as communicating with monitoring computer, we can increase work efficiency, and has active function in saving medical source, etc.

Related Works

Wireless health monitoring system (WHMS) has drawn significant considerations from the exploration group and in addition industry among the most recent decade. Various and yearly expanding innovative work tasks have been posted in the paper. The health tracker, that can monitors user’s fundamental signs; for example, heart rate or heartbeat, blood pressure and breath rate could be actualized utilizing pressure sensors¹. The coordinated patient monitoring combining with electronic patient records, the principle difficulties to expanding strength of “e-health” application to a level at which clinically helpful. The disadvantages of electronic patient record are extremely time consuming and costly to overcome this problem, using novelty detection task that allows a direct comparison without integrated, automatics methods².
The heart logo in beat sensor reaches skin and little LED sparkles at posterior of heartbeat sensor. For the most part Pulse sensor can be put on the fingertip or ear cartilage of the human body. The basic information sends to the mobile health care unit utilizing GSM communication. Heartbeat sensor communicated with the microcontroller which is arduino Undistinguishing proof (RFID) advancements enters the human services condition. Key information rates and the measure of the information collection in an assortment of smart health care utilize cases are talked about. At last they created fix sort wearable imperative observing device that numerous quantities of essential sensors, a performance processor and a dual mode Bluetooth receiver are incorporated.

The microcontroller based persistent non invasive cuff less blood pressure measurement system with a caution circuit for medicinal services observing system. Accuracy of the system is found in acknowledgment range by contrasting the results and the current regular systems. Heart rate or body temperature exceeds the standard range for any patient; the system can inform utilizing a disturbing circuit. The entire system is controlled by microcontroller ATMEGA8L.

The quick improvement of wireless technologies and the increases in communication transfer speed encourages the improvements of android based health care systems. Remote and flexible patient observing systems not just expand the portability of patients and therapeutic staff additionally enhance the nature of health care. In the improvements of remote patient monitoring frameworks, concentrated on patient’s details transmitting physiological signs by means of the Zigbee innovation. A few analysts have utilized the individual personal digital assistant (PDA) to gain and transmit physiological signs from patient’s space to the focal administration unit in the medicinal facility utilizing the remote advances utilizing remote monitoring system.

**System Architecture And Working Principle**

This project aims to design and demonstrate an innovative web based remote healthcare diagnostic system that provides vital medical data and live video monitoring of a patient situated in rural area accessible to a health professional available elsewhere in urban centres resulting in better diagnosis and treatment of that patient.

Various medical sensors are used to collect patient medical data and sent to the monitoring station for interpretation.

3-channel ECG

Body temperature

Body position

The system includes an advanced camera sensor to give live video pictures of the patient. In this architecture appeared in figure 1, three distinct sensors are utilized for monitoring the patient health services, for example, ECG sensor, Temperature sensor and body position sensor and which can directly connected with microcontroller and camera is used to interface the microcontroller. In this paper proposed video monitoring. So that effortlessly recognizes the patient’s health conditions.

**Figure 1. Health Care Monitoring System**

ECG sensor AD8232is used to monitor the regular heart beat of the patient’s which is used to find whether the patient’s heart rate is normal or abnormal. MEMS accelerometer is a body position sensor is used to find out the patient’s body position. Temperature sensor LM35 is used to find out the patient’s body temperature.

**Camera Image Acquisition using DCMI**

A project of this sort needs an extremely fit microcontroller with extensive measure of RAM memory. Along these lines STM32F429 from STMicroelectronics is picked as the fundamental MCU, which is one of the powerful microcontrollers right now accessible in the market. Figure 2 demonstrates that the hardware implementation. All the components connected in microcontroller.
The system comprises of a camera sensor to stream a live video feed. At the point when ask for is made the onboard microcontroller catches the JPEG pictures from the camera utilizing the implicit DCMI peripheral and begins to stream it once again the web in MJPEG pressure organize at an adequate rate between. The picture determination is settled at 470 x 272. The microcontroller has an extensive RAM memory region, around 256KB, which is an unquestionable requirement for this sort of use.

**Embedded Web Server**

The project utilizes an ARM Cortex-M4 based microcontroller that act as a web server that sends information to the customer side application. Any device with an Internet program, for example, advanced cell phone or PC/Laptop can be utilized to monitor the data feed. The customer side client is confirmed with an extraordinary client name and secret word before getting to streaming content.

**Security**

Before associating with the framework the client needs to enter the login username and secret word which is a genuinely necessary safety effort to keep others from getting to the substance. Once logged in, the user allowed accessing all the data including the video feed.

**Software Design**

Real Time Operating System (RTOS) is a multitasking working system planned for continuous applications. Real Time shows a hopeful reaction or response to a moment of its development. The expectant response describes the logical correctness of the result produced. The instant of the events evolution describes deadline for producing the result.

**RTOS Architecture**

The architecture of a RTOS is reliant on the many-sided quality of its organization. Great RTOSs are adaptable to meet distinctive arrangements of necessities for various applications. For simple applications, an RTOS as a usually comprises only a kernel. For more complex embedded frameworks, a RTOS can be a blend of different modules, including the kernel, organizing convention stacks, and different parts.

A working system large comprises of two sections: kernel space and user space. Kernel is the smallest and focal segment of a working framework. Its administrations incorporate overseeing memory and devices and furthermore to give an interface to programming applications to utilize the resources. Additional services such as managing protection of programs and multitasking may be included depending on architecture of operating system.
During the execution of an application program, particular tasks are insistently changing beginning with one state then onto the following. In any case, only a single task is in the running mode (i.e. given CPU control) whenever of the execution. In the process where CPU control is change beginning with one undertaking then onto the following, setting of the to-be-suspended task will be saved while setting of the to-be-executed task will be recovered. This technique of saving the setting of a task being suspended and restoring the setting of a task being proceeded is called context switching.

In this paper describes preemption. Preemption defines the capability to identify the task that needs a resource the most allocate it the control to obtain the resource. In RTOS, such capability is achieved by assigning individual task with appropriate priority level. Figure 6 and 7 shows that the priority level.

The kernel of a RTOS gives an abstraction layer between the application programming and equipment. This abstraction layer contains six primary sorts of normal administrations given by the portion to the application programming. Figure 4 demonstrates the six common service of an RTOS kernel.

**Task Management**

To achieve continuously real time application program, the application is decompose into small, schedulable, and consecutive program units known as “Task”. In real-time context, task is the basic unit of execution and is governed by three time-critical properties; release time, deadline and execution time. Deadline is the point in time by which the task must complete. Release time refers to the point in time from which the task can be executed and Execution time denotes the time the task takes to execute. Each task may exist in any of the four states, including running, ready, or blocked and dormant as shown in Figure 5.

**Figure 5. Possible States Transition of Tasks**

**Figure 6. RTOS Implementation**

**Figure 7. Task Description**
This paper describes about Ethernet task, Control task, sensor and local task. From this analysis it concludes that multitasking which plays an important role in health care RTOS.

Results and Discussion

The program is developed using Atollic True Studio IDE. Webpage is created for displaying the patient’s health information through doctor’s login. Only authorized users can login into the webpage. The doctor’s can access the patient’s information. In this project data are displayed by PC using Internet. After login into webpage, user can see the patient’s health records are shown in Figure 8.

![Real Time Patient Health Status Monitoring](image)

**Figure 8. Real Time Patient Health Status Monitoring**

Figure 9 describes video monitoring. This technique is very easy to identify the patient health related parameter details. Doctor can able to view the patient status and give the instruction to further improvement through the camera by video monitoring.

![Video Monitoring](image)

**Figure 9. Video Monitoring**

### Conclusion

This paper concludes that health care monitoring is done by utilizing sensor devices and reports all the sensor information to the doctor. Using four sensors identified with human health monitoring, for example, ECG sensor, body position sensor, temperature sensor and video monitoring which is controlled by microcontroller and brought information from sensors and all the sensor information through the doctor by using internet. Through this way, real-time remotely monitoring is achieved. With the developed system, achieve video monitoring but also an early treatment is possible. Thus, the proposed system makes the human’s daily life easier and more comfortable.

Artificial Voice for Speechless

K.S.Thivya¹, M.Anand²
¹Associate Professor, Dr.M.G.R Educational and Research Institute University, Chennai,
²Professor, Dr.M.G.R Educational and Research Institute University, Chennai

Abstract

Background: Communication is a must for human beings to express and those who cannot communicate are isolated in this society. This work finds a solution for human race, where people are dumb but not deaf. Objective: The Main purpose of the work is to create an artificial voice based on the tongue movement and with the help of the Phones of the language mapping table for the dumb person in order to meet their personnel and societal needs. Method: In this work the main features involved are tongue, lip movements and air flow. These features are fed in to the computer via parallel port. These features are in turn converted as data and mapped with the recorded Tamil phones. Results: In this work the mapping table is being done choosing Tamil as a language using Tamil grammar laws. Whereas the mapping table can be done for other languages also, using their own grammar laws. A device which fits inside the mouth is used to extract the tongue, lip movements and the air flow inside the mouth. This device in turn is connected to a computer to produce the artificial voice. Conclusions: As a test many letters and phrases were pronounced without making any sound. The computer pronounced the letter and phrases correctly via speaker.

Keywords: Parallel port, Mapping table, Tamil phones, Tamil fusion laws.

Introduction

In ancient days communication was very poor because it was done only through actions, later on language came in to existence. So people started to communicate orally with each other by means of language. There are around 6909 languages in existence. This statistical figure shows the importance of communication. There are three categories of dumb people. (i) Dumb by birth (ii) dumb due to accidents (iii) dumb due to cancer and other diseases. Generally cancer and especially throat cancer has been a disease of the older men with history of tobacco and alcohol use. However, with the rise in HPV infections, incidence in younger people is rising. In Tamilnadu alone 12,260 people are affected due to throat cancer per year. Mostly 70% of the patience with throat cancer looses their voice. Since they cannot speak they loose their communicating power and start feeling isolated, which in turn leads to mental depression. This work is focused only on dumb people in order to provide artificial voice for the speechless.¹

Dumb only

This device can only be used for dumb people. The device cannot be used for deaf and dumb people since deaf people cannot hear sound and are not aware of the language phones. The main criteria of the work are based on the language phones and the movements of tongue, lip, and air flows. For the above reasons this device cannot be used for deaf and dumb people. The actual process involved in the speech is the usage of organs such as the lungs, vocal cord, the mouth, tongue and teeth etc. The main objective of the work is to produce artificial voice even if the vocal cord is removed due to any reasons.¹, 6, 11, 13, 14

Tamil language

In this work a mapping table is done using Tamil phones. Tamil is an ancient language. It is one of the official language in Indian union territory of Pondicherry and a state in India is named as Tamil Nadu as majority of tamilians reside there. Tamil is also an official language of Sri-Lanka and Singapore. In 2004, Indian government declared Tamil as a classical language and it is considered to be one of the 22 scheduled languages of India.²⁰ More than 55% of the epigraphically inscriptions (about 55,000) found by the Archaeological Survey of

DOI Number: 10.5958/0976-5506.2019.00886.6
India are in the Tamil language. There are 247 phones in Tamil grammar including 12 vowels and 18 consonants. In the mapping table the 12 vowels and 18 consonants covers all the 247 phones. For these reason thirty phones only has to be covered in the mapping table (12 vowels and 18 consonants).  

Method

The work starts with a ceramic hard palate. The ceramic hard palate contains metal points. The metal points are in turn connected with the NOT gate IC 7404. When the tongue touches the metal point 5v signal is produced. One end of the electrode is connected to the ground and the other end is placed on the hand. This detection circuit detects the input. Two mikes are used, one to detect the airflow in the mouth and the other one to detect the air flow in the environment. According to the environmental noise the threshold value is set. By using the movement of the lip, tongue and air flow the corresponding thirty phones can be identified. These thirty phones are further simplified by taking only seven vowels and thirteen consonants in to account. By using wonderful fusion laws given in Tamil grammar book like NANNOOL we are able to derive all the words pronunciation from these twenty phones. The airflow in the nose and the mouth can be differentiated using the mike. By this way we can further simplify six phones called as MELLINAM. In remaining fourteen phones two phones have unique positions of lip touch with incisors teeth and tongue touch with incisors. Out of the other twelve phones three can be identified with lip contraction and dilation. One phone can be identified by the touching of both upper and lower lips. After, all the simplifications only eight different positions of the phones has to be identified. According to the Tamil fusion law even though two phones produce same sound, one metallic point is enough in the ceramic palate, because the two phones can be differentiated by airflow. These data are sent to computer via parallel port. Using mapping table the computer pronounce the corresponding phones.

Block diagram

The following block diagram (fig 1) can simply explain the process involved and hardware setup in this work. The ceramic hard palate is connected to detection circuit which detects the position of the tongue touching on hard palate. The output of detection circuit is connected to the multiplexer circuit. This circuit allows all the eight inputs in to computer via parallel port by allowing four inputs at a time. By scanning two times all the data’s are registered into the computer.

Parallel Port

Eight moulds are drilled on the ceramic palate. The drilled holes are filled with metal and insulated wire which is connected to the metal point. The other end of the insulated wire is connected to the detection circuit. The ceramic hard palate is categorized as (I) front (II) lower middle (III) middle and (IV) back side. In these fronts, lower middle, middle and backside ceramic hard palate two holes are drilled in each one. The position where the tongue touches on the hard palate can be identified using the detection circuit.

Air flow detection

As mentioned earlier, six phones are originated from nose. This can be identified by detecting the airflow. This detection of air flow may be confused with the normal breathing. In order to avoid the confusion, the air flow in the mouth is detected. For detecting this air flow,
microphone is used. The microphone is connected to the computer via audio jack. The microphone is faced towards the mouth for detecting the air flow. Another microphone is used to set the threshold value which is placed facing the environment.

Detection circuit

The detection circuit is used for finding the tongue position on hard palate which in turn is interpreted as binary data. When tongue touches any metal point in ceramic palate, the corresponding data will be logical 1(5v). The NOT gate pins are connected by 330 kΩ series with 110 kΩ. The 330 kΩ is connected to earth and 110 kΩ is connected to +5v voltage source. When the tongue touches the metal point, body resistance comes parallel with 330 kΩ and the voltage drops across it. It gives logical 1 (+5v) as output. The detected output is sent to multiplexer circuit.

Multiplexer circuit

Multiplexer circuit can select 4 input data’s at a time and send to computer via 4-bit gates. When the selection line is 0 the lower four bit is selected and when the selection line is 1 the upper four bit is selected. For single movement the data is given as 8 sets of 4 bits into computer through parallel port, because parallel port can send only 5 bits at a time to a computer. The status port pins 10, 11, 12, 13 and 15 only can send data to the computer from external device. Here we are choosing pins 10, 11, 12, 13 for sending data to computer from 2-line to 1-line selector. The pin 15 is used as direct control by the user, when user is in mode of talking this will be enabled, so computer starts speaking, when this pin is disabled the computer will not give voice for the ordinary movement of mouth. Usually there are four sets of selectors or switches, these movements are synchronized i.e. All switches are ON or all the switches are OFF. When logical zero is given to selection probe all the switches selects the first four input, so first four is produced as outputs and then when logical one is given to selection bit all the switches selects second set of four inputs. So the remaining four inputs are displayed as output. By giving selection input as zero and one we get all eight inputs as two set of four outputs.

Opto-coupler

This is worn by the user inside the mouth. When the multiplexer circuit is connected to the computer via parallel port, there is a possibility of electrocution which will be more fatal. In order to avoid this situation an opto-coupler is used which in turn provides an electrical isolation. The outputs from multiplexer and computer is connected to the opto-coupler, which senses the voltage change and transforms the data in the form of light and then converts this change of light in to electrical signal. By this way there is no electrical contact between the two ends.
Parallel port

The parallel port is used for sending data between the computer and multiplexer circuit. In multiplexer there are 4 inputs and 1 independent input, totally 5 inputs. These 5 inputs are connected with the pin number 10, 11, 12, 13 and 15. Here the pin 15 is inverted i.e. if input is given then 0 is displayed on the screen. XOR logic is used to correct the data. The pin 2, 3, 4 and 5 is used to send data from computer to multiplexer for the scanning purpose. The parallel port with the pin details are shown in the figure 6.

![Figure 6. Parallel port connection diagrams](image)

Mapping

247 phones are stored in the computer as data. The 247 phones are simplified in to 8 phones are mapped accordingly. Based on the users tongue and mouth movements the phones are pronounced by the computer via speaker\(^5\). The flow chart decision making is shown in the figure 7.

![Figure 7. Flow chart of software part](image)

Results

The entire work was aimed to sound as natural as possible\(^6\). But the actual result obtained was successful in pronouncing the individual letters correctly. As a test while pronouncing different words, some letters got repeated and some letters were missed. This was due to the difference in time taken for actual pronunciation and the time fixed in the algorithm. These errors can be corrected by the usage of effective algorithm and the usage of many more fusion laws in order to avoid the repetitions of letters.

![Figure 8. Picture of complete setup](image)

Software used

Matrix laboratory is used to develop algorithm for the fusion of 8 phones in order to make all the 247 phones by using fusion law given by NANNIOOL. The data is transferred between the computer and the device via parallel port and is programmed by using Matlab software.

Discussion

Using some advanced devices for tongue, lip movement and air flow detections, results can be improved. Using microcontroller and wireless devices the work can be made compatible and suitable for real time use. If this work is improved and made suitable for real time usage many gets benefited and an improved quality of life can be provided to the dumb people. In this work, the mapping table was done only for Tamil language. The mapping table can also be created for the other languages using their grammar and fusion laws. Usage of wireless devices, microcontroller and effective algorithm can make the work more effective.

Conclusion

In this work the movement of tongue; lips were identified by using ceramic hard palate and detection circuit. The data’s were transferred to the computer via multiplexer circuit and parallel port. The air flow was detected using the mike. Tamil phones were recorded, edited, and stored. The mapping table was created. As a final result the entire device was fixed and tested. As a test many letters and phrases were individually
pronounced without making any sound. The computer pronounced the letters and phrases correctly via speaker. The work can be extended, by making use of improved algorithms, microcontroller and the wireless device, in order to make it compatible for real time use.

Comparative Analysis of Automated Applications using Fetal Ultrasound Images

Bahbibi Rahmatullah

National Child Development Research Centre (NCDRC), Universiti Pendidikan Sultan Idris, 35900 Perak, Malaysia

Abstract

Computer-assisted technology plays an important role in helping to reduce risk during pregnancy, particularly serious risks associated with intra-uterine growth restriction (IUGR). Fetal gestational age estimation and fetal weight estimation are two crucial factors in evaluating fetal growth and detecting any abnormality of growth, in order to identify IUGR risk to the fetus. The estimation is made through serial measurement of fetal anatomy comprising the length, diameter and circumference of multiple segments in the fetus scanned through an ultrasound machine. The computing method helps to overcome human subjectivity in assessment that is prone to variability in measurement. Automatic measurement methods carried out by the computer can help in producing fast, accurate and reproducible measurement and assessment of the fetal anatomy. This study presents an analysis of techniques attempted by researchers in conducting automated fetal biometric anatomy measurements using ultrasound images. Chronological comparative analysis presented in this paper will aid other researchers who are keen to explore on computer-assisted technology especially in the field of fetal ultrasound imaging.

Keywords: Computer technology; fetal ultrasound; automatic method.

Introduction

Historically, X-ray was used to measure fetal dimensions (e.g. fetal head, pelvic dimension) (Shenton21) before the development of ultrasound. The development of two-dimensional (2D) ultrasound made the measurement of fetus soft tissue structures and bones faster and more reliable than with X-rays. 2D ultrasound is currently considered to be the first choice for a safe, non-invasive, accurate and cost-effective investigation in the fetus. In obstetrics care, it has gradually become a crucial apparatus and plays a significant role in the care of every pregnant mother.

The need to visualize structures or anatomical regions that are difficult to see with normal 2D ultrasound opened the path for three-dimensional (3D) ultrasound to be applied in obstetric care. Improvements in ultrasound transducer, display technique, reconstruction algorithms, and computer power account for 3D ultrasound being seriously considered for everyday clinical use. Diagnosis of fetal abnormalities such as cleft lip is improved with the accurate surface rendering capability in 3D ultrasound (Pretorius and Nelson13). Recent studies have shown that the use of 3D ultrasound results in accurate assessment of the fetal biometry (Mercé et al.9, Chan et al.5) and structural volumes (Moeglin et al.10, Chang et al.6). Another advantage is shorter patient examination times where 3D volumes data can be stored on a computer and repeatedly examined off line without continual scanning.

Problem Statement

Although ultrasound imaging has several advantages over other image modalities like MRI and CT, it suffers from many problems. For example, ultrasound suffers from acoustic shadowing, attenuation, motion effects and speckle. In addition, anatomical definition is poor when compared with MRI or CT. Due to this, some organs are very hard to be visualized and others cannot be seen. Moreover, the quality of the acquired
images highly depends on the sonographer experience. Acquisition reproducibility is a major problem in ultrasound imaging in which intra or inter-sonographer acquisition may highly affect the quality and the details in the acquired images. The problem becomes harder when using ultrasound for imaging fetuses because of the movement of the fetus and differences in maternal fat thickness and volume of amniotic acid. Figure 1 shows a screen shot of the femur bone for a 34 weeks fetus. The figure also reveals some challenges in ultrasound images such as like poor anatomical definition, shadowing from the bottom part of the femur, loss of signal at the two epiphysis ends and low signal to noise ratio. On the other hand, ultrasound imaging is real-time, less expensive and radiation free, which makes it the main choice in imaging modality in pregnancy care.

Figure 1. Ultrasound image of the fetal femur. The white linear segment within the thigh tissues represents the femur

SEARCH METHODOLOGY

Relatively, there has been fewer efforts at automating the analysis of fetal ultrasound images in comparison to other fields in medical ultrasound such as diagnostic cardiac ultrasound, breast ultrasound etc. The SCOPUS database (www.scopus.com) is used to find studies involving automation in fetal examinations with ultrasound devices. Table 1 shows chronological arrangements for studies related to the automation method in the measurement of the fetal biometric structure selected to be analyzed.

Morphological operators had been the basis for many of the initial approaches for automatic segmentation in fetal ultrasound images (Zador et al.\textsuperscript{23}, Lu et al.\textsuperscript{8}). A sequence of phases were used in order to perform femur and head segmentation including edge linking, Hough transform and edge detection. Active contour model was employed by Chalana et al.\textsuperscript{4} and Pathak et al.\textsuperscript{12} for fetal head and abdomen segmentation. Active contour method has its disadvantages and among them is that it might require manual correction when it get stuck at local minima.

The initial methods used for femur segmentation have been refined and improved through the watershed method experimented by Rahmatullah et al.\textsuperscript{14, 15}. This method combines the use of femur extraction algorithm and threshold method. Results obtained through this method demonstrate an increase in performance and a faster computational time for the segmentation and measurement of femur bones.
A database-guided segmentation technique for the detection and measurement of head, femur and abdominal structures were proposed by Carneiro et al.\textsuperscript{1,2} that utilized the discriminative constrained probabilistic boosting tree (PBT) classifier. Adaboost were used to train the strong classifiers at the nodes of the binary tree. The method was extended to measure the crown-rump length (CRL) and also the humerus length (HL).

Rahmatullah et al.\textsuperscript{16,18,19} conducted experiments for the detection of objects such as the abdominal and umbilical veins found in the abdominal image. Large databases that contain positive images and negative images for both objects are used to train AdaBoost classifier to detect both objects more accurately. This method is enhanced by the use of local phase features that are combined hybrid with the classifier.

Rahmatullah et al.\textsuperscript{16} attempted an automated anatomical structure detection as the first step towards the development of a fast and reproducible assessment of fetal biometry scan. Quantitative and qualitative evaluations of all the algorithms were obtained using 2384 images of fetal abdominal scans retrieved from the INTERGROWTH-21st project image database study (Rahmatullah et al.\textsuperscript{18}). The proposed “hybrid” detection method was evaluated in two potential application scenarios. The first application was clinical scoring in which both the computer algorithm and four experts were asked to record occurrence or nonappearance of the stomach and the umbilical vein in 400 ultrasound images (Rahmatullah et al.\textsuperscript{19}). The second application concerned selecting the standard image plane from 3D abdominal ultrasound volume (Rahmatullah et al.\textsuperscript{17}).

A computer aided detection system was proposed by Konur\textsuperscript{7} for detecting the neural tube defect of spina bifida because currently manual segmentations has been the ground truth in its implementation. Magnitudes of Zernike moments utilized in the system were computed from the normalized skull shapes acquired in ultrasound scan. At a sampling rate of synthetic minority oversampling technique (SMOTE) of 400% followed by 50% random undersampling (RU), the test result achieved an accuracy of 94% and 98% in specificity.

</table>
There have been fewer related works in fetal 3D ultrasound. Automatic extraction of the frontal surface of a fetus from a 3D fetal ultrasound volume were the focus in Nguyen et al.\(^\text{11}\) where the texture classification method proposed used a support vector machine (SVM). Improvement in the visualization of the fetus frontal surface were evident in the results and achieved through the removal of some amount of abdominal fluids and walls.

Carneiro et al.\(^\text{2}\) extended their probabilistic boosting tree method to finding anatomies in 3D ultrasound volume of fetal head based on semantic keywords. The method presented in this work would let the user to decide the selection of anatomical landmarks (i.e. cistern magna, cerebellum) in fetal brain and not based on any pre-defined clinical protocol.

Rueda et al.\(^\text{20}\) investigated the problem of segmenting the adipose tissue on the fetal arm which is proposed as a fetal nutrition indicator. Fuzzy connectedness framework was the basis in their segmentation approach which utilized an affinity function using edge and structural information acquired from local phase features extraction. Quantitative and qualitative results obtained indicates the superiority of the method compared to the framework that was based on intensity images only.

A fully automated semantic segmentation of fetus, placenta and gestational sac in 3D ultrasound volumes was developed by Yang et al.\(^\text{22}\). To address the challenge presented by variations in image quality, shape and scale, they utilized a 3D fully convolutional network (FCN) that are embedded with deep supervision and transfer learning. RNN was adapted as a common module to encode varying contextual dependency in order to balance the spatial concurrency exploited in 3D FCN. They performed extensive validation of their proposed method by comparing it with other methods. Encouraging quantitative results were accomplished (0.64 in Dice for placenta and 0.9 for gestational sac and fetus) and they presented qualitative results through their large datasets.

**Conclusion**

The outcome of the literature search and comparison in the field of fetal image ultrasound analysis indicates that researchers had been mostly focused and limited to the area of (semi)-automated segmentation of particular fetal anatomical structure for producing biometric measurement that is of high accuracy. The poor quality of ultrasound image has been recognized by all the papers as the major hurdles in their algorithms implementation.

The extensive manipulation needed to be performed by the clinician in finding the standard planes to assess the fetal biometric measurement in a 3D ultrasound remains to be the main challenge for promoting the widespread use of the volumetric ultrasound. The learning curve to understand the manipulation steps is quite large even for an expert user (Mercé et al.\(^\text{9}\)). Therefore, standardized planes localization scheme would be of tremendous benefit in progressing the application and usage of 3D ultrasound for clinical diagnosis.

An Analysis on Social Support and Community Commitment in the Investigation of New Cases of Smear Positive Pulmonary TB in the Work Area of Donggala Health Centre, Donggala Regency, Central Sulawesi

Miradiantri Tule¹, Muh. Syafar¹, Alimin Maidin¹

¹Faculty of Public Health, Hasanuddin University, Jl. PerintisKemerdekaan Km. 10, Tamalanrea Indah, Tamalanrea, Kota Makassar, Sulawesi Selatan 90245, Indonesia

Abstract

The study aim was to analyze social support and community commitment in the investigation of new cases of smear positive pulmonary tuberculosis in the work area of community health center (Puskesmas) of Donggala. This study was used qualitative method with phenomenological approach. The informants were those who recovered from pulmonary tuberculosis patients and who were had pulmonary tuberculosis disease treatment, health workers and community. The data were analyzed with content analysis done through some steps such data collection, data reduction/ethic data, data presentation, drawing conclusion/concept. The study was indicated that social support in investigation of new cases of smear positive pulmonary tuberculosis came from family such as transportation, cost, and motivation to access the health facilities from health workers and community: information on pulmonary tuberculosis and motivation for medical treatment to facilities of health service. The commitment in investigation of new cases of smear positive pulmonary tuberculosis such as community agreement to form community caring pulmonary tuberculosis in work area of Donggala health center supported from district government.

Keywords: Community commitment; Pulmonary tuberculosis; Social support

Introduction

The pulmonary tuberculosis is infectious disease caused by mycobacterium tuberculosis and main health problem in global and Indonesia especially poor community¹. The bacteria are transmitted through mouth or nose and through respiratory system². India, Indonesia and China had high pulmonary tuberculosis cases³. There is an estimated 1 million of new pulmonary tuberculosis per year in Indonesia¹. Based on Millennium Development Goal (MDGs), efforts in disease prevention included tuberculosis that indicated to increase Human Development Index (HDI) based on tuberculosis with high incidence rates and fluctuate each year⁴. The pulmonary tuberculosis had disadvantage effect such as stigma and even ignored by the community⁵.

Based on Indonesia Health Profile in 2014, new positive pulmonary tuberculosis cases in Central Sulawesi province reached 40%. This result showed MDG target had not reached 70%². Donggala regency had recorded low positive pulmonary tuberculosis cases was 43%. The health profile data within 4 years showed new positive pulmonary tuberculosis cases which ranged 41% to 43%.

The social support is important and made individual felt calm, confident, competent, and loved⁶-⁹. The social support was important for chronic disease patients such pulmonary tuberculosis diseases because support affected individual behavior such as reduced anxiety, helpless, and hopeless that improved health status¹⁰. The community participation and health worker influenced and communication helped in pulmonary tuberculosis cases in Cambodia⁷. The villages with high community participation and health worker influenced and communication helped in pulmonary tuberculosis cases in Cambodia⁷. The villages with high community participation and health worker influenced and communication helped in pulmonary tuberculosis cases in Cambodia⁷. The villages with high community participation and health worker influenced and communication helped in pulmonary tuberculosis cases in Cambodia⁷. The villages with high community participation and health worker influenced and communication helped in pulmonary tuberculosis cases in Cambodia⁷.
participation that exceed case detection rate (CDR) target ≥ 70%, 7.5 times greater than in villages with low community participation\textsuperscript{11}. The community perception on pulmonary tuberculosis was due to offspring and cursed\textsuperscript{12}. The study aim was to analyze social support and community commitment in the investigation of new cases of smear positive pulmonary tuberculosis in the work area of Donggala health centre.

**Methodology**

**Study Type**

The study is used qualitative research design with phenomenology approach. This study design was used to analyze social support and community commitment in new smear positive pulmonary tuberculosis cases discovery in the work area of Donggala community health center of Donggala regency, Central Sulawesi province.

**Location and Time**

The study was carried out from March to May 2016 in the work area of community health center (Puskesmas) of Donggala regency, Central Sulawesi province since PuskesmasDonggala had found new cases that program target (≥70%).

**Population and Sample**

The respondent determination method used was purposive sampling method. The sampling criteria in this study included:

a) Smear positive pulmonary TB patients: The new smear positive pulmonary TB patient were informants in this study which is diagnosis by health workers and undergone treatment. The patients provide information about their experience such as initial symptom of pulmonary TB, accessibility to health facilities and treatment.

b) Community: The regional leaders, community leaders and people who are influential in the work area of PuskesmasDonggala.

c) Health officer: The head of DonggalaPuskesmas, manager of PuskesmasDonggala, midwives and health officer of community health service program.

**Data Collection**

The primary data was obtained was conducted observation, in-depth interview and focus group discussion (FGD). Meanwhile, the secondary data was obtained from health office of Central Sulawesi province, Donggala health office and PuskesmasDonggala.

**Data Processing and Data Analysis**

The data were analyzed with content analysis done through some steps such data collection, data reduction/ethic data, data presentation, drawing conclusion/concept.

**Result and Discussion**

**Result**

Table 1 shows the informant’s answer toward pulmonary tuberculosis. Based on this study, understanding toward tuberculosis symptom was long term cough, body weight loss, sleepless and sweat on night time and fatigue. The risk factor of pulmonary TB was due to bacteria, smoking habit and job risk as factory workers. Most of informants understood pulmonary TB was spread through cough. Besides, some of informants did not understand about pulmonary TB transmission. The pulmonary TB required 6 months treatment and some of informant had repeated treatment. In general, informant understood tuberculosis disease prevention effort from separated the cutlery, maintained house cleanliness, good air circulation, lighting and keep body’s stamina to be always fit. The community was still interacted with tuberculosis patients since no prohibition among healthy person with pulmonary TB patients. The perception toward pulmonary TB was common cough, no longer as curse disease and transmitted through infected person to healthy person. All informants had positive response toward effort made by health worker in the control of tuberculosis pulmonary. The availability of health care facilities in the village area was easy for villagers to get access on health service. The informants had received moral support from families and community in form of informational, tangible and emotional support.

Source: Primary data

Table 2 illustrates the health worker and community leader’s answer toward pulmonary tuberculosis. The community participation was improved from year by year in support pulmonary tuberculosis cases since community understood pulmonary tuberculosis was cured with proper treatment. The availability and accessibility of health service facilities in Pustu, Poskesdas and PuskesmasDonggala is sufficient for villages and easily access by public transportation. The informant made supportive effort in pulmonary tuberculosis cases as well as efforts to support pulmonary tuberculosis findings such as cross-sector cooperation and program, performed supervision on program, logistic management and treatment included budget policies for program. The commitment from each sub-district on PuskesmasDonggala was important in pulmonary tuberculosis disease prevention.

Overall Discussion

Based on this study, the informants understood early pulmonary tuberculosis symptoms are continuously cough up blood, weight loss, and night sweats. The understanding in pulmonary tuberculosis disease is varies among the informants. Most of informant had stated pulmonary tuberculosis is caused by smoking habits and their work duty in coconut factory and construction area. The education was among factor influenced informant’s understanding toward this disease was education level. Based on focus group discussion, informant had mentioned pulmonary tuberculosis disease is due to bacteria. The informant understood pulmonary tuberculosis transmission because informant had obtained information from the health worker or mass media. The new information provided cognitive foundation formed new knowledge.

The informant understood pulmonary tuberculosis disease treatment is 6 months. Before treatment, informant had consumed cough medicine bought from pharmacy. In this study, informant tend to have late treatment because their late awareness on early pulmonary tuberculosis. Most of informants are examined their illness after suffered continuously cough for a month or two months. The lack of awareness among patients on symptom and late visit to health center is referred as patient delay. Most delay occur in first step represented decision to seek help and through interaction with non-pulmonary tuberculosis health care staff. The program was introduced to strengthen their understanding and health examination regulation on pulmonary tuberculosis diagnosis.

Besides, informant understood effort in this disease prevention. The house cleanliness, good air circulation and maintained body stamina was best way to avoid from this disease. The pulmonary tuberculosis is due to mycobacterium tuberculosis very sensitive to heat, sunlight and ultraviolet light. Most germs were died after direct exposure with sunlight within few minutes. The focus group discussion concluded community understanding in PuskesmasDonggala toward pulmonary tuberculosis which transmitted disease from suspected to health person due to bacteria especially in crowded area. The pulmonary tuberculosis symptom commonly was cough more than 1 month, body weakness, vomiting blood and chest pain. The pulmonary tuberculosis patient was given 6 months treatment. This disease was prevented by maintained house hygiene.

The informant showed positive attitude toward the pulmonary tuberculosis disease and still interacted with pulmonary tuberculosis patients. The informant understood pulmonary tuberculosis (TB) was a contagious disease since no stigmatization about this disease. The pulmonary tuberculosis patient was stated still interacted as usual with healthy person. The community was stated interaction was usual with...
pulmonary tuberculosis patients and still maintained family relationship between them. The social interaction included relationship between individual with physical and surrounding psychological environment. There were small people who still antipathy toward pulmonary tuberculosis patient. The positive attitude toward pulmonary tuberculosis disease had influenced community participation in pulmonary tuberculosis discovery. The people had encouraged to visit the health centre if initial symptom was detected.

Based on Focus Group Discussion showed community was still interacted with the pulmonary tuberculosis patient. The study also showed that the personal attitude and behavior toward pulmonary tuberculosis disease was much influenced prevention successful. The understanding and knowledge in patient, family, community and health workers also played important role in treatment performance. The person suspected suffered pulmonary tuberculosis disease needed immediate treatment to avoid the disease transmission.

The study showed informant perception toward pulmonary tuberculosis disease was common cough disease based on symptom. The informant went to seek treatment at health center once symptom was persisted for long time. Besides, informant was assumed this disease was not curse disease. The pulmonary tuberculosis patients are still interacted with healthy person because still has family relationship. Based on focus group discussion, pulmonary tuberculosis patients were not offended by the community and need to be support. The treatment and prevention step were needed by maintained house cleanliness and body stamina. In west Lombok, community stigma was still strong and assumed embarrassed as pulmonary tuberculosis patients.

The community beliefs toward pulmonary tuberculosis disease affected attitude in seek treatment for pulmonary tuberculosis. In this study, informant believed this disease was not curse disease, but infectious disease caused by bacteria. There was belief that this disease transmitted between healthy people with patients. The informant said there was no transmission between them and children suffered pulmonary tuberculosis disease. The belief was a manifestation with various perceptions that developed in human thinking. The community had believed on pulmonary tuberculosis was a contagious disease cured if treated properly. Besides, community believed that this disease was curse disease caused by evil spirits.

Based on this study, there was good coordination between health worker in PuskesmasDonggala and health worker in other Puskesmas in effort for pulmonary tuberculosis cases. The examination record was reported had highest cases discovery in Puskesmas. The health program was conducted and well implemented in the village where program officers from Puskesmas were also actively implemented health program. The home visit by the health worker was found some pulmonary tuberculosis cases. The experience in work was contributed positive influence on work performance. Besides, the informant worked better because their experience and characteristic of the working area of PuskesmasDonggala. The improvements in health program and health service mobilization were needed to increase the new cases discovery. The promotion on the health program was needed in the community so more participation and cooperation for new pulmonary tuberculosis disease discovery in the community. The good coordination between the informant and health program officers at Puskesmas was well established. Based on Focus Group discussion, the health worker role in pulmonary tuberculosis cases was quite good but still needed improvement for future. The program implementation was needed competency person to achieve the program objectives.

The health facilities availability such as wheelchair was available in the health center Donggala. Most of work area of PuskesmasDonggala had Poskesdes or Puskesmas building in each village. There were only four villages that did not have health service facilities. In Cambodia, availability of health facilities and severity of disease was determinant in search for health care. The health care facilities were utilized by community if health workers were on duty. Besides, there were health worker also in charge at the Puskesmas and Poskesdes. Head of PuskesmasDonggala also mentioned village did not have Puskesmas but still had midwives on duty for villagers. There were total 22 midwives served in the village in the work area of PuskesmasDonggala. The accessibility to health service facilities either Puskesmas or Poskesdes easily access by community and transportation. However, there were midwives served in the village. PuskesmasDonggala was one of microscopic referral Puskesmas in Donggala district. The focus
group discussion had been done on community showed that availability on midwives in the village especially villages that did not have Puskesmas or Poskesdes. The women had high risk in pulmonary tuberculosis disease since no accessibility on health facilities in Ethiopia\textsuperscript{18}.

Based on this study, informant had revealed there was social support from families, health workers and neighbors. The family member was important in pulmonary tuberculosis patients especially their financial support\textsuperscript{8}. The supports were in form of information, motivation and transportation. There was relationship between social support and life quality in pulmonary tuberculosis patients\textsuperscript{19}. The focus group discussion showed community support was important toward pulmonary tuberculosis patient. Besides, support from community toward health worker in health program for 6 months treatment. The social support was one function in social ties that positively related to health\textsuperscript{6}. The participation of district government in health program was very supportive in handled pulmonary tuberculosis disease in the work area of PuskesmasDonggala.

The commitments in this case were from sub-district leadership and community commitment. The health worker found that number of disease cases in Banawa sub-district was higher than in Central Banawa district. The factor related with case detection rate (CDR) included identifying need, mobilizing program resources and leadership\textsuperscript{10}. The focus group discussion showed there was community commitment in pulmonary tuberculosis cases in the working area of PuskesmasDonggala. The commitment was an agreement to establish pulmonary tuberculosis care community in the work area of PuskesmasDonggala.

**Conclusion**

In conclusions, community had good understanding about pulmonary tuberculosis disease and symptom, causes, transmission, treatment and efforts to prevent pulmonary tuberculosis disease. Besides, there was positive attitude among community about pulmonary tuberculosis disease. The community was still interacted with pulmonary tuberculosis patient as usual. The perceptions in pulmonary tuberculosis were infectious disease which cured with completed 6 months. There was no longer belief in community that this disease was cursed disease. The health worker had good role in this pulmonary tuberculosis cases discovery. The availability and accessibility of health facilities in work area of PuskesmasDonggala was good. Most of village had Pustu and Poskesdes in work area of PuskesmasDonggala. PuskesmasDonggala was microscopic referral clinic equipped with laboratory that supported pulmonary tuberculosis disease examination. The social support was coming from families, health worker and community. The social support was in form of instrumental, informational and emotional support.

Healthy Life Pattern Behind Related To the Movement Program First 1000 Days of Life in Gowa Regency of South Sulawesi Province

Muh Zaifullah¹, Ridwan M. Thaha¹, Suriah¹
¹Faculty of Public Health, Hasanuddin University, Jl. Perintis Kemerdekaan Km. 10, Tamalanrea Indah, Tamalanrea, Kota Makassar, Sulawesi Selatan 90245, Indonesia

Abstract

This study aims to analyse in depth the healthy lifestyle of pregnant women related to the movement of the first 1000 days of life in Gowa Regency of South Sulawesi Province. The method used in this work is qualitative method with phenomenology design. Determination of informants was done using purposive sampling method and 17 informants were obtained. Data were collected through depth interview and observation. Data analysis was done using content analysis and presented in narrative form. The results showed that the frequency of feeding that the mother applied during pregnancy varies, ranging from 5 times to only 1 time per day. Several types of dietary restrictions according to informants are pineapple, mango, squid, shrimp, crab, and moringa leaves. Physical activity carried out such as washing, sweeping and other household chores. Meanwhile, the form of personal hygiene during pregnancy is showering, shampooing, and brushing teeth. Informants stated that they had health information from books and maternity class. Informants stated that they have used ANC services supported by the role of health workers in providing service fulfilment strategies. In addition, the informant was assisted by midwives and doctors during labor period. There some informants continued to have neonatal and low baby weight (LBW) neonatal deaths despite receiving the ANC services. Therefore, one of the obstacles to the movement’s first 1000 days of life is the practise of healthy lifestyle of mother during pregnancy.

Keywords: Healthy Life Pattern; Movement Program; Pregnant women

Introduction

Pregnant women, nursing mothers, new-borns and children under the age of two years are the target group to improve the quality of life through the First 1000 Days of Life program. This program is a thousand-day period from the time of conception to a two-year-old child. A thousand days consists of 270 days during pregnancy and 730 days of first life since the baby is born. This period is called the golden period or also called a critical time, which if not properly utilized there will be permanent damage to the child or new-born.

Maternal and neonatal complications and deaths often occur during labor. Therefore, interventions that emphasize the safe delivery of help are provided by health personnel. This is to demonstrate the level of ability of the government in providing quality delivery services assisted by skilled health personnel including pregnancy examination, maternity delivery and delivery assistance. According to Yenita (2011) it is expected that every pregnant woman utilizes health workers like doctors, midwives and nurses in the delivery aid. By choosing a health worker as a maternity helper, the mother will receive health services in accordance with the principle of germ-free and standard procedure of care.

Nutrition problem is a public health problem, especially in pregnant women and is an important cause of maternal mortality and child mortality indirectly that actually can still be prevented. A good nutritional condition is a major prerequisite in realizing healthy

DOI Number: 10.5958/0976-5506.2019.00889.1
and qualified human resources. If traced, nutritional problems occur in every life cycle, beginning in the womb (fetus), infant, child, adult, and old age. Therefore, the occurrence of nutritional disorders in those days can be permanent and cannot be recovered even though nutritional needs in the future are met.

Pregnant women who exercise regularly experience less weight gain and less body fat than women who are less active. The weight keeps rising normally and the baby remains in excellent health. In addition, pregnancy and the birth process of active women will tend to be problematic. By exercising, the demands of pregnancy on the body and fulfilled well.

Antenatal Care (ANC) is an examination conducted by health officers to pregnant women and their fetus periodically to monitor the condition of maternal health and growth and development of the fetus in preparation for delivery. The purpose of ANC services is to optimally prepare physically and mentally the mother and child during pregnancy, childbirth and childbirth so as to get mother and son.

The Government of Indonesia’s commitment to resolve the issue has been declared through Government Regulation no. 42 of 2013 on the National Movement for the Acceleration of Nutrition Improvement and on 30 October 2013. The President of the Republic of Indonesia has launched the National Movement for the Acceleration of Nutrition Improvement in the First Thousand Day of Life (1000 HPK). The first thousand days of life is a golden period for a child to grow and develop optimally. Disorders occurring during this period, especially proper nutritional intake and healthy life behaviors of mothers during pregnancy will have an impact on survival and development of children that is permanent and long-term and more difficult to repair after 2-year-old child.

Gowa regency is one of the districts with high maternal and infant health problems. The maternal mortality rate in Gowa regency in 2013 is 10 cases, while the neonatal mortality rate is 72 cases. The case of neonatal death in Gowa Regency is the highest in South Sulawesi Province. Therefore, this study aims to analyse the healthy lifestyle of pregnant women related to movement program of first 1000 days of life (1000 HPK) in Gowa Regency.

Methodology

Design and Type of Research

The research method used in this research is qualitative research method. According to Sarwono (2006) qualitative research is a process that tries to gain a better understanding of the complexity that exists in human interaction. This study aims to determine the pattern of healthy behaviours of pregnant women against the program movement First 1000 Days of Life. The techniques used are observations and in-depth interviews.

Time and Place of Study

This research is located in Palangga sub-district working area of Palangga and Kampili health center of Gowa regency. The location of the study was chosen due to the prevalence of infant mortality, low nutrition and high low weight birth rate. The information to be extracted in this study is a healthy pattern of pregnant women against the program movement of the first thousand days of life.

Informant Determination Method

The method used in this research is purposive sampling that is sampling technique of data source with certain consideration. Certain considerations such as those who are considered most know about what we expect to facilitate researchers to explore the object / social situation under study. The informants in this study were mothers who had given birth, immediate family and local health personnel. Thus, Informants in this study were mothers who had given birth with nutritional problems; the mother’s family who gave birth to it, as well as health care workers in Kecamatan Palangga (working area of Puskesmas Palangga and Puskesmas Kampili). The number of informants interviewed was 17 people consisting of 11 maternal informants who had given birth with nutritional problems, 2 family informants, and 4 health worker informants.

Data Collection

Primary data is obtained by way of observation and in-depth interviews on pregnant women, families and health workers. Observations were made by researchers before and after in-depth interviews by observing the closest health facilities accessible to informants and handling of health services including the availability.
of health information supporting the healthy life-style of informants related to the first 1000 days of life program. In addition, triangulation technique is done by cross checking between information obtained by direct observation at research location and information from the in-depth interview.

Data Analysis

Data obtained from in-depth interviews are done manually in accordance with the instructions of qualitative data processing, as well as in accordance with the purpose of this study.

Result and Discussion

Balanced Diet during Pregnancy

Based on the results of in-depth interviews, informants recounted the frequency of eating done during pregnancy. The answers expressed by the informants vary, ranging from more than five times a day to only one meal per day, but the reasons for such behaviour vary, for example economic reasons, habits, and laziness. The informants who eat up to 5 times each day due to the feels of increased appetite during pregnancy. In addition, there are informants eating once per day due to laziness. In addition to the economic factors and influences of pregnancy, the informants explained that the frequency of eating during pregnancy was irregular and it depends on the condition and appetite at the time.

Regarding the healthy foods taken during pregnancy, informants said that the food menu consumed by mothers during pregnancy is rice, vegetables, fruit, fish and egg consumption is only done if the financial condition is sufficient. They would prefer chicken but limited by the financial condition. They do consume fruit if the garden season arrives.

Informants also explained that the type of food at risk that is often consumed is meatballs and sambal, although the type of food is not recommended by health workers. There are informants who love to consume the type of meatball food, instant noodles, and coto. However, they have refrained from consuming them as direct by the health workers as the food may cause hypertension. Some informants have abstinence foods during pregnancy such as pineapple, mango, durian, and certain beverages. Some informant’s prohibition are shrimp and squid which could lead to difficult labour process and the prospective baby will be born with a weak condition.

Maternal Physical Activity during Pregnancy

The type of activity performed during the pregnancy according to the informant was washing and walking. Another informant performs sweeping and lifting activities up to the time before delivery. The reason that many more pregnant women who do not do physical activity is the assumption that without exercising informants are still sweating. In addition, there are some informants who choose not to exercise for reasons of history of pregnancy disorders. Other informants also did not do much physical activity during pregnancy due to the availability of facilities such as washing machine and vehicle to move around. In addition, there are informants who do not engage in physical activity during pregnancy due to a sense of laziness.

Personal Hygiene during Pregnancy

Based on the results of in-depth interviews to informants, explained that the informant diligently perform self-hygiene such as brushing teeth and using shampoo bathing as much as 2 (two) times a day due to hot weather conditions. In contrast to other informants, there are informants who perform self-hygiene activities only once a day for cultural reasons adopted by her family.

Mother’s Role Model during Pregnancy

Informants revealed that informants do not have role models during pregnancy because the informant is the first child and live alone, so that if there is a complaint during pregnancy, the informant will go directly to the health service. In addition, some informant revealed that they selected their neighbour’s as role model due to experience and proximity in terms of distance. Some informant revealed not to follow the advice of role models because they may lack of experience in certain situation.

Resources during Pregnancy

Informants explained that the informants were easy in reaching the existing health facilities due to the close proximity of both the health centre and the village midwife. Besides that, the informants said that the presence of village midwives who opened 24 hours gives the opportunity for pregnant women to check their health at any time. The book of Mother and Child Health
(MCH) also provided to informants, but they have never read them.

**Antenatal Care (ANC) Compliance**

The informants routinely check the content even every month, so if there are complaints related to ANC content, the informant directly goes to health facilities. The other informants also provided the view that their pregnancy check-up routinely and always hear the directions from health workers. The informant also said that ever get vitamins and formula milk.

**Birth Support**

Informants explained that the childbirth performed by midwives in health centre. Other informants stated that her childbirth was helped by medical personnel such as doctors at the hospital through a caesarean process.

**Overall Discussion**

A good diet for pregnant women should meet the source of carbohydrates, proteins and fats as well as vitamins and minerals. For the sake of the success of pregnancy, the mother’s nutritional state at the time of conception must be in good condition and during pregnancy should get additional protein, minerals, vitamins and energy. While Hardinsyah and Briawan (2005) explain when the body lack of nutrients, especially energy and protein in the early stages cause hunger and within a certain period of weight will decrease and accompanied by decreased work productivity. The outcome of this study is in line with what was stated by Praditama (2011) in a study conducted in the village of Tiripan that there are still some people who do abstinence against some foods that are considered harmful to the condition of pregnant women, such as miscarriage or bleeding.

Clap et al.’s research in Shaw (2003) explains that pregnant women’s activity also influences nutritional status of pregnant women, the relationship between physical activity with nutritional status impact on pregnant women is complex seen from the burden of pregnant women will reduce the growth and birth weight and can be a factor that affects many pregnant women with chronic energy shortages.

As for the personal hygiene care, work done by Potter and Perry’s (2005) stated that culture or personal value affects the ability of personal hygiene care.

Someone from a different cultural background follows different personal hygiene practices.

Informants’ satisfaction in utilizing health facilities as described by Swastha (2005) which explains several factors influencing the utilization rate of health services are factors that come from health care providers and factors of the healthcare user community. The three factors of health care providers are health facilities, service costs, and distance. Whereas two factors from health service user community are education factor and socioeconomic status of society.

Many factors influence maternal compliance in ANC services regularly, including from individual characteristics that include age, education, economics, and knowledge. This is irrelevant to the condition of some informants who married at a young age, with low education and economics but still utilizing ANC services on a regular basis.

**Conclusion**

Based on the obtained results, the balanced diet that mothers apply during pregnancy varies. Starting from the frequency of eating the mother, healthy food consumed, to the type of food at risk during pregnancy. Physical activity patterns according to informants during pregnancy are done with different forms and reasons, the type of physical activity performed during pregnancy such as washing, sweeping, working in rice fields, raised water, and some other household chores. The forms of behaviour that informants present during pregnancy in maintaining personal hygiene are bathing regularly, shampooing, and brushing teeth. Maternal role models during pregnancy are health workers located in the nearest health service; this is because the majority of mothers will directly utilize health services in case of complaints during pregnancy. Support resources such as health service facilities and health personnel according to informants are considered good. Maternal compliance during pregnancy in utilizing antenatal care has support. Lastly, the informant agreed agrees that the birth helpers by medical personnel were good.

Awareness, Knowledge and Attitude towards Nutrigenomics among Health Care Workers in Indonesia: A Preliminary Exploration

Widyawaty N1, Tan C.K1, Tan E.S.S1, Seghayat M.S1, Normina A.B1
1School of Healthy Aging, Medical Aesthetics and Regenerative Medicine, Faculty of Medicine and Health Sciences, UCSI University

Abstract

Chronic diseases are rising in number and have become the leading cause of mortality in the world. These diseases can be controlled via diet and lifestyle modifications. Nutrigenomics recently emerge as a study area endeavoring to understand one’s response to diet at molecular level. Despite its rapid development, limited number of health care workers were exposed to nutrigenomics. Therefore, this study aimed to provide a preliminary insight on the baseline of awareness, knowledge, and attitude of nutrigenomics among health care workers in Indonesia. A questionnaire consisting of 18 questions was developed and distributed to nutritionists, general practitioners, and specialists in selected hospitals. Total of 114 questionnaires were completed and analyzed using SPSS software. Approximately 19.3% of participants have heard about nutrigenomics; awareness among nutritionists (55%) was significantly higher (p<0.05) compared to 7.1% for general practitioners and 13.6% for specialists. Furthermore, less than 15% of participants had good knowledge of nutrigenomics. Majority of participants acknowledged benefits of nutrigenomics and have strong interest to incorporate nutrigenomics into their clinical daily practice. Lack of knowledge and limited clinical evidences were considered as the first and second limitation. However, high eagerness to pursue a higher education and to embark nutrigenomics research were found. In conclusion, participants reported to have limited awareness and knowledge, but had positive attitude towards nutrigenomics. These findings are encouraging for future development and application of nutrigenomics in daily clinical practice.

Keywords: Awareness and Knowledge, Nutrigenomics, Health Care Workers.

Introduction

Nutrition takes an essential part in maintaining health and controlling disease in each individual. It is generally recognized that there is a significant association between diet and its function for health promotion and disease prevention1. Throughout the last century, nutritional science was only centered on presumptions that all individuals have similar nutritional requirements2. With focus mainly on vitamins and mineral, their use and requirements were researched and later defined by Recommended Dietary Allowance (RDA) for deficiency prevention which express the amount of a nutrient that is daily needed for general public to maintain healthy1,2.

With advancing awareness and knowledge on importance of nutrition as well as easy accessibility to food especially in urban and developed nations; international health issues shifted from undernutrition to include obesity and overnutrition1. According 2005’s report by World Health Organization (WHO), chronic diseases such as heart disease, stroke, cancer, chronic respiratory diseases and diabetes, are leading causes of mortality in the world, representing 60% of all deaths4.

It is generally accepted that lifestyles and choosing food habits have a significant contribution in the development of non-communicable diseases. Thus, these kinds of disease are largely preventable through lifestyle changes, including diet modification3. Furthermore, many genes are considered to be interconnected with
certain chronic diseases. Consequently, focus of nutritional science changed to prevent the raise of these types of disease by investigating how diet and nutrition can maintain human health at cellular, tissue and organ level. In order to prevent the development of disease, increasing knowledge of nutrition at the molecular level are required. The rapid breakthrough of human genome has facilitated scientists and researchers to explore more about interaction between diet, gene expression, health and disease. As a result, partnership between nutrition and genomics science emerged leading to the development and advancement of nutrigenomics.

Nutrigenomics is a science of determining relationship between nutrients and genes' responses and consequently, its effect on human health. It was previously shown that nutrigenomics, which is frequently represented as most recent applications of genomics advancement in the field of personalized health interventions, had been connected with the idea of individualized dietary management based on personal’s specific genes. Regardless, nutrigenomics does not aim only individual with specific predisposition of genetic disorders that could be intervened with diet modification. Other than genetics, there are still various factors which can influence the response to diet such as age, sex, physical activity, and smoking.

Researchers agree that nutrigenomics will shift therapeutic approaches from curative to preventive. In addition, Fenech et al. argued that advancement in nutrition genomic technologies had increased expectations involving predictions of diseases and development of new prevention as well as therapy approaches.

It is anticipated that nutrigenomics could possibly boost awareness of the detection of contributed factors of metabolic mechanism at the genome or molecular level, which will be used to inhibit the onset and development of vary of cancer, diabetes, and cardiovascular disease that chronically developed and may have multifactorial etiologies. Personalized nutrition may offer prevention against onset and progression of these chronic diseases. It is acceptable that everyone are likely to be concerned about maintaining their health and well-being. This has made the increasing expectation of nutrigenomics application regarding the rising possibility for customization of personalized diet for wellness and disease prevention.

Rapid establishment of nutrigenomics has been anticipated for development of preventive health approaches. Unfortunately, the level of awareness towards this field has been found to be low with research on nutrigenomics are mainly roaring in developed countries. In addition, despite the field’s potential for development of preventative health approaches, exposure on nutrigenomics among healthcare professionals is limited.

With that in mind, this study aimed to provide a preliminary insight into the awareness, knowledge and attitude towards nutrigenomics among health care workers in Indonesia.

**Methodology**

**Research design**

This research is a cross-sectional, quantitative and self-administered questionnaire. This study focused on health care workers currently employed in selected target hospital in Jakarta, Indonesia. The participants of this study consisted of different groups of health care workers including nutritionists, general practitioner, and medical specialists. The questionnaire was designed to identify the baseline information of awareness, knowledge, and attitude towards nutrigenomics amongst health care workers in Indonesia. While some of the questionnaire items were adapted from previous studies.

**Research Instrument**

The demographic section consisted of four items: participant’s age, gender, occupation, and length of experience in nutrition field. Respondents’ awareness regarding the term of nutrigenomics was measured by using single “Yes/No” question. The questionnaire also included questions on how the participants acquire knowledge about nutrigenomics and questions evaluating their knowledge regarding nutrigenomics including knowledge on definitions, disciplines which might be relevant with nutrigenomics application and conditions which might be beneficial from nutrigenomics science. The questions also asked what would be the most reliable source to acquire knowledge about this field. The questionnaire will comprise of questions regarding the participants’ agreement toward benefits that nutrigenomics may offer by using questions with a five point Likert – type response scale (1= Strongly Disagree, 2= Disagree, 3=Uncertain, 4= Agree, to 5=...
Strongly Agree).

Questions to measure attitude towards nutrigenomics include the participants’ attitude towards including nutrigenomics in their practice and their outlook on further trainings, higher education and academic activities in this field. The questionnaire also contained “Yes/No” questions regarding the participants’ actual trainings and academic activities in nutrigenomics.

The last question was intended to determine the main limitation of applying nutrigenomics into their daily practice according to participants. Participants can select one or more answers among: high cost, no facilities, lack of evidence, knowledge limits, poor accuracy, ethics and medico-legal issues. In addition, participants were allowed to specify “Others” if they have another issue as a limitation.

**Ethical Approval**

This study had been approved by the ethical committee of the hospitals. All recruited participants were required to read and understand the information provided in participant information sheet outlining the purpose of study and benefits of participating in the research. Confidentiality and anonymity were warranted as well as no remuneration for participation. All participants were required to sign the informed consent indicating the participant’s voluntary completion of the questionnaire. This research is conducted in accordance to ethical principles in Declaration of Helsinki.

**Data Analysis**

Data analysis were done using Statistical Package for the Social Sciences (SPSS) software. Descriptive statistics were used to describe the levels of awareness, knowledge, and attitude of the participant groups. Cross tabulation chi-square analysis were used to make a comparison between groups according to their answers and socio-demographics characteristics. Significance for all statistical measures was determined at the 0.05 level.

**Result and Discussion**

A total of 163 questionnaires were distributed with a total of 114 questionnaires were returned and completed; actual response rate was 69.9%. Level of experience was divided into four categories. The most common duration of experience in the field of nutrition was less than 5 years (n=45, 39.5%). The number of participants who have been experienced for 6-15 years and 16-25 years were 33 (28.9%) and 28 (24.6%) respondents, respectively. While only seven percent (n=8) of them had been working in nutrition field for more than 25 years.

Questionnaires in part two comprised of questions determining level of awareness, sources of information as well as the participants’ knowledge. In order to assess Indonesian health care workers’ awareness about nutrigenomics, participants were asked “Have you heard of nutrigenomics?” Results reported that approximately four-fifths of participants (n= 92, 80.7%) had never heard about nutrigenomics. Only 19.3 % (n= 22) of participants had heard of nutrigenomics. However, those who had never heard about nutrigenomics were still able to answer the knowledge and attitude questions.

Occupation was significantly associated (p<0.05) with awareness of nutrigenomics. Among nutritionists, more than half of them (n=11, 55%) had heard about nutrigenomics compared to 7.1% (n=2) for general practitioners and 13.6% (n=9) for specialists (p<0.05). Association between awareness of nutrigenomics and other demographic characteristics were examined but not statistically significant. Table 1 outlines awareness of nutrigenomics among healthcare workers according to socio-demographic characteristics.

According to respondents, the most common sources of information were scientific meetings and conferences (n= 16, 72.7%). Meanwhile, others heard about nutrigenomics either from sharing among colleagues (n= 6, 27%) or as a part of their undergraduate studies (n= 5, 23%).

*p<0.05 on chi-square analysis

Level of nutrigenomics knowledge was determined through participants’ familiarity with definitions of nutrigenomics. This suggested description of nutrigenomics was agreed by 81.6% (n= 93) of respondents. 4% (n= 3.5%) of participants rejected this definition and 14.9% of respondents chose to answer “don’t know”. Good knowledge regarding definition of nutrigenomics was only significantly associated with age. All respondents aged 25 years and below agreed with the definition of nutrigenomics given (p<0.05) as shown in Table 2.

Overall score obtained from knowledge-related questions was calculated to determine participants’ total knowledge score. The maximum score is 12 and participants scoring above 11 were considered to have good knowledge. Of the 114 participants who completed the knowledge section, the mean knowledge score was 9.59 out of 12 (SD= 1.54, Median= 9.79).

Only 14% of respondents (n=16) were classified as having good knowledge of nutrigenomics based on this criteria. There were no significant association found between level of overall knowledge and sociodemographic characteristics. Nevertheless, knowledge level was much the same between females than males, with 14.3% of females and 13.6 % of males indicating they had good knowledge of nutrigenomics prior to the survey whereas knowledge level was approximately ten percent higher for them who had been experienced in nutrition field for more than 25 years compared to another groups. Result also indicated that level of knowledge was mostly homologous between age groups, with approximately 10-15% for each group had obtained good level of nutrigenomics knowledge. General practitioner showed the least percent of respondents (3.6%) with good knowledge about nutrigenomics, in comparison with 16.7% of specialists and 20% of nutritionists as shown in Table 3.

</table>
In order to determine participants’ attitude toward nutrigenomics in the future, they were asked to indicate their willingness to include nutrigenomics into daily practice and pursue a higher education on nutrigenomics. Slightly more than four-fifths of participants (81.6%, n=93) reported a willingness to incorporate nutrigenomics into their practice. Concurrently, nearly three-fourths of participants (74%, n=73) indicated willingness to pursue a higher education on nutrigenomics.

Willingness to integrate nutrigenomics into daily practice was not found to be significantly associated with any socio-demographic characteristics. Meanwhile, there was significant association between willingness to pursue higher education with age as well as occupation. Compared to another occupation, almost all of nutritionist (95%, n= 19) felt like to get better knowledge of nutrigenomics through formal higher education (p<0.05). Among age group, willingness to pursue higher education was extremely higher in “<25 years” group (90%) than in other age group (p<0.05). No statistically significant association were found with the other two socio-demographic characteristics.

The result showed only 14% (n=16) of participants had recently attended training, scientific meetings and conferences in nutrigenomics. Participants were being asked about their interest for nutrigenomics-related training, scientific meeting and conferences with 18.4% (n= 21) respondents were extremely interested and 70.2% (n= 80) participants were interested. Other than training and any scientific events, participants were being asked about their actual involvement in research and academic activities on nutrigenomics with only 1.8% (n= 2) of respondents were currently involved in nutrigenomics-related research and academic activities. When being probed about their interest; 8.8% (n= 10) respondents were extremely interested and 48.2% (n= 55) respondents were interested to be involved in research and academic activities on nutrigenomics.

Curiosity to participate in scientific meeting and conferences in nutrigenomics was only found to be significantly associated with gender. Association between excitement to know more about nutrigenomics through scientific meetings and other socio-demographic characteristics were tested but no statistically significant associations were found. On the other hand, there was no significant association between excitement on nutrigenomics research and sociode mographic characteristics.

Participants were also asked what challenges that limiting the nutrigenomics application in daily practice. If applicable, they were allowed to choose more than one answer. Most of the survey participants thought knowledge limits as a limitation of nutrigenomics application which was accounted for a little more than 30% of responses (n= 66), followed by lack of evidence (22%), lack of facilities (19%) and then high cost (19%). Ethics medico-legal issues and poor accuracy accounted for 7% and 2% of responses, respectively.

Thus overall, this appears to be a pioneering questionnaire conducted among healthcare personnel in Indonesia to gauge their awareness, knowledge, and attitude about nutrigenomics. Health care workers were primarily targeted because public tends to consult their physician for information and guidance on nutrigenomics service6,7. Nutrition has a tendency to be associated with preventive medicine; thus, it is considered to be fundamental for nutritionists and medical practitioners (general practitioner and specialist) as well as geneticists to be competently educated in this field2. Therefore, having awareness and adequate knowledge of nutrigenomics are important so that their trustworthiness and practice are appropriately applied and not violated. Moreover, rising popularity of preventive medicine

Results revealed significant association between awareness and occupation; nutritionist were reported to have highest awareness. With regard to occupation, nutritionists/dietitians tend to more aware about nutrigenomics which was similar to previous research which reported that approximately half of registered dietitians in Canada were aware about nutrigenomics11. One plausible explanation may be that nutritionists or dietitians focus on diet-management for treating the patients.

Measurement of knowledge regarding agreement on definition of nutrigenomics in this study suggested that majority of health care worker agreed with the proposed definition of nutrigenomics, followed by its significant association with age of respondents. Health care workers aged 25 years and below were found to be more appreciative regarding definition of nutrigenomics. Other than better accessibility to information, Cormier et al11. argued that young health care worker had more
opportunities and probabilities of being exposed during their academic activities.

It is challenging for health care professional to gain awareness on nutrigenomics, to delay onset of disease as well as to prevent progression of disease. Moreover, Weir et al. argued that this inadequate proficiency might lead to skepticism towards nutrigenomics. Thus, it is not surprising that most of health care workers had low level of knowledge on nutrigenomics based on results obtained from this research. Despite nutritionists having a higher level of awareness, it is interesting that level of overall knowledge was not significantly associated with occupation as well as other socio-demographics characteristics such as age, gender, and experience. However, this result might be due to small sample in this study.

Assuming better level of knowledge would be gained through exposure of these topics during training programs, only a small minority of health care workers in Indonesia had recently attended training, scientific meetings and conferences in nutrigenomics. This might be the reason for low awareness of nutrigenomics in this study, as learning process definitely will affect knowledge and awareness on the subject matter. Interestingly, high willingness to attend training, scientific meetings and conferences in nutrigenomics was reported which suggests positive attitude towards increasing awareness and knowledge among health care workers in Indonesia.

Knowledge limit will restrain healthcare workers to integrate nutrigenomics into their daily practice. To overcome this, evidence-based approach is postulated to be one of the effective ways to give health care workers an assurance that nutrigenomics would be applicable in clinical practice. Thus, more research and other academic activities in this field is urgently needed to boost the number of evidence.

Conclusion

Despite of the fact that the participants shown limited awareness and knowledge, they had positive attitudes towards nutrigenomics. These data imply that majority of respondents acknowledged benefits of nutrigenomics and have a strong interest to include nutrigenomics in daily practice. Knowledge limits was considered as main limitation of nutrigenomics application in daily practice. A comprehensive education program may be necessary to increase healthcare workers’ knowledge of nutrigenomics and assist in the application into their practice in the future. The lack of evidence was also noted as second limitation, which should inspire researchers to conduct more research to gain more convincing evidence in this field. In conclusion, these findings are encouraging for future development of nutrition and genomics collaboration to prevent or treat many kind of diseases including chronic diseases on health care professionals’ daily practice when applicable.

Abstract
All around, natural medication is an undeniably sought after elective drug. They had been expended for ages to enhance one’s prosperity. In Malaysia, Malay home grown medications (MHMs) are ordinarily expended amid pregnancy and baby blues by moms of the Malay people group. This investigation is a similar poll consider including 106 baby blues Malay moms; comprising of 64 customers and 42 non-shoppers. Respondents were met amid their postnatal visits to decide their socioeconomics, example of MHMs’ utilization and pregnancy and neonatal qualities. Top three MHMs devoured were Ubat Periuk (12.5%, n=8), Manjakani (26.6%, n=17) and Nona Roguy repression set (20.3%, n=13). Utilization of MHMs amid pregnancy did not impact preterm conveyance and in addition neonatal birth weight, birth length, and head boundary. The revealed chances proportion for neonatal jaundice and requirement for phototherapy were 1.03 and 2.78 separately. Then, moms who did not expend MHMs amid pregnancy revealed bring down occurrences (p<0.05) and bring down hazard (OR=0.25) of undermined premature births. Higher dangers of neonatal jaundice were found for baby blues utilization. As an end, family unit salary was an affecting statistic factor for MHMs utilization. Requirement for phototherapy about tripled with pregnancy utilization; while, non-utilization seems, by all accounts, to be defensive against undermined fetus removal.

Keywords: Herbal medicine; malay medicine; pregnancy; postpartum

Introduction
Herbal medicine is a debatable method of treating diseases nowadays. It becomes very popular and some say as the safest approach to cure diseases in our society. The popularity is indeed overwhelmed in Malaysia itself. According to World Health Organization1, in Malaysia, offers of customary and reciprocal/elective meds are evaluated to be 1000 million Malaysian Ringgit yearly. Clearly, this occasion isn’t just in Malaysia yet in addition to every single creating nation for the most part.

At last, it is verifiable that home grown drug is started from plants. As indicated by Firenzuoli and Gori2, home grown prescription is the utilization of therapeutic plants for counteractive action and treatment of ailments. This has related to Saad et al.3 when they quote that home grown drug is a custom go about as they have referenced; in light of the data acquired from different investigations, the status of information concerning wellbeing and adequacy of restorative plants utilized in our district.

Addo4 concurred that home grown medications are regularly advanced as ‘characteristic’ and ‘safe’ and these cases may essentially pull in pregnant ladies

Corresponding author: E.S.S. Tan

who are frequently worried about their unborn kid’s prosperity. Malay’s way of life has a convention, which they are custom and have incredible regard towards the elderly individuals in their family. These more seasoned ladies frequently fill in as guards and assume an essential job in transmitting conventional qualities and works on encompassing pregnancy, labor, and baby blues care.

Another fascinating aim that prompts this gathering of moms to devour Malay home grown drug is because of the impulse to give the best to their infants. Louik et al. depicted as uneasiness leads pregnant ladies more remote lean toward home grown prescription paralleled to current medications. This conduct is a common mother intuition concerning the tyke they conveying with.

The main wellspring of Malay home grown prescription utilization is dominantly from the nearest and closest individual alongside the pregnant and baby blues moms. As indicated by Mothupi in his examination, family and companions speak to the social and social condition in which the pregnant lady lives and to some extent impact wellbeing looking for conduct amid pregnancy. Another investigation done by Tang et al. likewise concurred that family particularly the more established age, for example, maternal mother and relative, was the primary wellspring of referral on home grown utilization. Most pregnant ladies trust that these prescriptions are ‘normal’ and ‘safe’ contrasted with present day drugs. As per Bayisa et al., customary prescription is accepted to treat restorative issues and enhance the wellbeing status amid pregnancy, birth and baby blues care in numerous country territories of the world.

Studies have demonstrated the relationship between utilization of natural meds and neonatal jaundice, and utilization of home grown prescriptions with lead focus in bosom drain. These examinations are not made for a wide range of home grown medications, which we know there will never be finishing rundown of Malay home grown meds moving over the counter. We require some solid and satisfactory further research for an explicit kind of home grown medications to set up the adequacy and security of these home grown drugs utilization.

With that in mind, this study aimed to justify the herbal medicine consumption effect among pregnant and postpartum mothers who are breastfeeding particularly. This study focusing on Kuala Lumpur area where there is a modern community of Malay population targeted here.

**Methodology**

**Research Design**

This research was a pilot study, where a total of 106 participants were taken for sampling. Consent was taken before the sample collection begun for participation of this study. Upon consent, the respondents were given a set of questionnaire. The purpose of the questionnaire was for data collection of socio-demographic, maternal, pregnancy, postpartum and infant characteristic, as well as frequency and usage of herbal medicine. All questionnaires answered will be reviewed and analyzed.

**Research Participants**

This study dedicated on pregnancy and postpartum mothers at Klang Valley, Malaysia. The participants of this study are housewives and working mothers. The inclusion criteria for this study are Malaysian, women less than 3 months of post partum duration, term pregnancy and consented. The exclusion criteria for this study are age below than 18 years old and not more than 60 years old. Mentally and physically not fit to participate in the research. Free from occupational hazard and metal exposure.

**Data Collection**

The questionnaire was designed to get the information regarding consumption of Malay herbal medicine (MHMs) during pregnant and postpartum mothers. The questionnaire consisted of seven sections, which the data including socio-demographic, maternal characteristics, pregnancy characteristic, postpartum characteristic, infant characteristics, use of herbal medicine, and herbal medicine consumption frequency. Aggregate of members were 106 with 42 from control gathering and 64 from respondent gathering. All members have finished the survey effectively.

**Data Analysis**

Statistical Package for the Social Sciences (SPSS) software was utilized for statistical data analysis. Data analysis was done with descriptive analysis and Chi-squareross tabulation test. The characteristic of Malay herbal medicine consumption during pregnancy and postpartum as well as maternal characteristics and
infant characteristics were used for descriptive statistics. Significance level at 0.05 was used for all statistical measures.

**Result and Discussion**

Consumption During Pregnancy Versus Maternal Characteristics

Based on Table 1, remarkable changes notable towards Malay herbal medicines consumption pattern during each trimester of pregnancy as well as during confinement. According on previous pregnancies question divided into four categories: “0”, ”1”, ”2”, and ”≥3”. Respondent group showed 51.6% (n = 33) of amount for category “≥3”, followed by 17.2% (n = 11) for category “1” and “2” and only 12.5% (n = 8) for category “0”. The control group showed 47.6% (n = 20) for category “≥3”, followed by 21.4% (n = 9) for “1”, 16.7% (n = 7) for “0” and only 14.3% (n = 6) for “2”. Respondent group showed the total of 51.6% (n = 33) for “≥3” category. 31.3% (n = 20) and 17.2% (n = 11) for category ”2” and ”1”. Control group also showed the same pattern with category “≥3” brings the highest number of non-consumption 42.9% (n = 18), followed by 31.0% (n = 13) and 26.2% (n = 11) for category ”2” and ”1” each. Weight gain category showed average amount for both respondent and control group with 13.54 ± 11.6 and 13.7 ± 7.6 increments. Weight loss category similarly showed the same average of reduction of 9.8 ± 6.0 and 10.3 ± 4.7 from respondent and control group each. This showed consumption and non-consumption of Malay herbal medicine displayed no significant influenced of weight increment or weight reduction.

Consumption During Pregnancy Versus Pregnancy characteristics

Based on Table 2, it showed that threatened abortion cases with respondent group 53.8% (n = 7) otherwise for control group showed 22.6% (n = 21) for “yes” category and “no” category reported respondent group showed 46.2% (n = 6) and for control group with 77.4% (n = 72) as shown in Table 4.4. Pregnancy related illness category showed 30.8% (n = 4) of respondent group and 21.5% (n = 20) of control group with “yes”. Result showed 69.2% (n = 9) of respondent group and 78.5% (n = 73) of control group with the answer “no”. Chronic illness category, “yes” category showed same result for both respondent group and control group with total of 50% (n = 3).

Consumption During Pregnancy Versus Infant Characteristic

Notable for control group based on Table 3, the number of full term baby delivered showed 95.7% (n = 89) whereas for respondent group showed 100% (n = 13). 0% (n = 0) for respondent group showed “no” for full term baby and 4.3% (n = 4) from control group. Baby weight, length of baby and head circumference categories showed no significant changes of result for both respondent and control group. Respondent and control group showed birth weight result of 3.2 ± 0.3 and 3.1 ± 0.5 each. For length of baby category showed 47.2 ± 5.5 and 48.3 ± 3.8 each for respondent and control group result. Respondent group and control group for head circumference category showed 34.5 ± 4.8 and 33.4 ± 2.7. For the jaundice occurrence, respondent and control group each showed not a significant changes for neonatal jaundice, phototherapy and exchanged transfusion event with 76.9% (n = 10) and 77.4% (n = 72), 61.5% (n = 8) and 36.6% (n = 34), 0% (n = 0) and 4.3% (n = 4).

Consumption During Confinement Versus Postpartum Characteristics

Based on Table 4 breastfeeding showed 94.3% (n = 50) for respondent group and 88.7% (n = 47) for control group to “yes” answer. “No” for breastfeeding question showed 5.7% (n = 3) and 11.3% (n = 6) for respondent and control group. Respondent group showed 5.7% (n = 3) and control group showed 1.9% (n = 1) for “yes” to confinement in a postpartum nursing center. Whereas option “No” for respondent group showed 94.3% (n = 50) and control group showed 98.1% (n = 51).

Overall Discussion

Malay populace is among populace in Malaysia who devour home grown drug alongside Chinese and Indian populace. This investigation appeared, an aggregate of 64 members out of 106 members who have expended the Malay natural meds. This reality is appropriate with Holst et al.\textsuperscript{10} revelations that, half of the ladies expended natural drugs amid pregnancy or in the wake of conceiving an offspring. The pregnancy and baby blues moms who expended the herbs generally have the possibility that it is protected and trusted that the herbs were gotten from a characteristic source. As per Sooi and Keng\textsuperscript{12}, the high pervasiveness of natural meds use may most likely be because of the solid trusts that these herbs are sheltered. Tang et al.\textsuperscript{8} in their writing overmuch guaranteed that higher instructive dimension was connected to a higher commonness of home grown utilization, which this contradicted to our finding in this investigation. Over this, as indicated by Mothupi\textsuperscript{7} he held oppositely, which the utilization of natural medication was related with a lower dimension of instruction (p = 0.007). As indicated by Nordeng and Havnen\textsuperscript{12}, they concurred that clients of elective medications were factually altogether more frequently from a higher social class.

The utilization example of this Malay home grown prescription amid pregnancy in this examination obviously isn’t with any mindfulness on the security side of the herbs. This announcement endorsed by Sooi and Keng\textsuperscript{11} in their writing that decree ladies kept on devouring home grown medications over their pregnancy period without the absence of information about its security and advantage. As indicated by Zeng et al.\textsuperscript{14} amid pregnancy specifically, the pervasiveness of CAM (Complementary and Alternative Medicine) use was as high as 73.2% in china.

The most expended Malay home grown prescription in this examination is coconut oil (69.2%). This compared to Sooi and Keng\textsuperscript{11} count for the most normally utilized home grown prescriptions in pregnancy were Anastatica hierochuntica L. (60.1%) trailed by coconut oil (35.4%). Coconut oil, halba, ubat periuk, manjakani and spirulina...
unmistakably to be the most expended home grown for Malay populace and this contrasted with Kennedy et al.\textsuperscript{15} revelations that the best home grown prescriptions utilized in Western Europe have incorporate ginger, cranberry, raspberry, chamomile, valerian, and echinacea.

Utilization of Malay natural medication demonstrated no huge relationship to past pregnancies and number of youngsters in this investigation (p < 0.05). This finding is in opposition to Tang et al.\textsuperscript{8} as it was uncovered that ladies who had been pregnant before would in general utilize home grown cures amid pregnancy.

**Conclusion**

The entire participants reaction towards this study is overpowering. Despite there are few hurdles to get great number of control group to contribute in this study yet the objective can be achieved conclusively. This study and the data collection are the reflection of Klang Valley Malay community towards the Malay herbal medicine consumption pattern among pregnancy and postpartum mothers. The limitation here is the number of participant, which is relatively small to certainly construct a prodigious conclusion for this study. However, the need to create more awareness regarding herbal therapy is mandatory. This awareness is essential and need to be done from the education level, social activities coverage and media involvement. Despite of the Malay culture and tradition that play a big role and the main influence that build it embedded in this Malay population, the challenges unquestionably await for future research and study and must be taken profoundly. In conclusion, this study intensely looked-for further and greater sampling size for better outcome and result for the future study conduct.

Abstract

Anti-aging medicine cultivates a target for medical intervention. However, it is still a controversial topic which needs more research to provide a better understanding of safety and efficacy of anti-aging medicine. This study is aimed to evaluate Malaysians’ demand and awareness of anti-aging medicine. A questionnaire with 17 questions in four parts was developed to identify demographics profile, general health status, awareness of anti-aging medicine and treatment. Questionnaire was randomly distributed to the patients in a clinic in Kuala Lumpur. There were 200 consented volunteers (126 female and 74 male) who participated in the survey. Majority of participants were 25 to 34 years old. Overall, 70% of participants were aware of their general health status, 69 % (n=138) believed that Anti-aging medicine is a future lead in medicine. However, 30 % of participant were worried about unexpected adverse reaction. Almost half of participants (46.5%, n=93) acknowledged that they had no exposure to Anti-aging medicine previously. Half of the participants (n=100) indicated age group from 25 to 34 would be the best age to start anti-aging treatment. About 60% (n=120) believed that the ideal timing to see anti-aging effect is between 1 to 3 months. There were a total of 84.5% (n=169) participants who expected the pricing of anti-aging medicine and treatment to be less than RM500. A positive view and high demand toward anti-aging medicine and treatment was observed in this study. In light with the high degree of interest upon anti-aging medicine, it is foreseeable that the demand will increase in the future.

Keywords: Anti-aging; medicine; efficacy; safety.

Introduction

Aging is defined as a gradual changes in the structure of any organism that occur with the passage of time, in which it does not result from any disease of gross accidents¹ According to United Nation (UN) population division, the number of people aged over 60 years old is getting increasing from under 800 million to over two billion by 2050, which means representing about 11% to about 22% of the world population².

In Malaysia, by 2035 it is estimated to reach the ageing population status, with those above the age of 60 constituting 15% of the population³. The elderly population of Malaysia has shown a steady increase over the past years, and this is expected to continue⁴. Life expectancy among Malaysians has also risen to 71.51 years for men and 77.24 years for women, meanwhile total population life expectancy is 74.28 years in 2013⁵. It implied that, human nation demographics is going to shift to predominant aging nation.

With increasing numbers of aging population around the world, health care strategies is needed to cope with the rising numbers in order to maintain good physical and mental health of the society⁶ as well as emphasis on comprehensive health care system in the aspect of health, social security, housing, environment that includes the family and community⁷,⁸.

Study on public perception of longevity in relation to anti-aging medicine found supportive outlook towards

marjansadat@ucsiuniversity.edu.my
anti-aging research with potential to increase maximum human lifespan by slowing aging\(^9\), particularly in older generation\(^10\).

Anti-aging medicine consumers preferred the results that last a long time versus immediate results as well as gradual results which last for two years compared to immediate results which could only last for six months\(^11\). The cost of treatment seems to be of less importance compared to longer lasting results. Physician training and expertise, duration of effect, cost, and recommendation by the physician are among the factors affecting decisions towards anti-aging treatment use\(^11\).

On the other hand, the most commonly voiced negative personal outcome of anti-aging technologies was that it would extend the number of years a person spent with chronic illnesses and poor quality of life\(^9\). In parallel, public also has their concerns about the possible adverse side effects of anti-aging drugs\(^9\).

Evidence of human life extension is sparse and at current time suggests that quality of life is maintained in laboratory animals with extended lifespan\(^12\). While life-extending effects of interventions in animal models are invoked as arguments for supporting anti-aging research, there is uncertainty in these interventions whether will also extend healthy lifespan in human\(^12\).

This research aimed to establish the relation between the public perceptions regarding anti-aging medicine in the cultural context of aging in Malaysia. With regards to the attitude and demand toward this related trend, the research will establish the future prospective of the anti-aging medicine in general practice setting.

**Methodology**

This is a cross sectional survey. The participants selected are Malaysians aged 18 and above residing in Kuala Lumpur. The questionnaire is set out to establish the participant’s demographics profile such as age group, gender, marital status, ethnicity, and monthly income and education levels.

The questionnaire was developed in English language and consisted of 23 questions in 5 different sections:

i. Demographic profile (6 questions),
ii. Respondent general health status (5 questions),
iii. Perception of Anti-aging medicine, (3 questions)
iv. Expectation on Anti-aging treatment (5 questions)
v. Respondent’s preference in getting Anti-aging treatment in future (4 questions)

Likert scale was used to rate the interest in related issue. The questionnaires were distributed randomly to respondents who visited the clinic during consultation from May to November 2013. Questionnaires were handed to respondents by the researcher and they would then be given a brief explanation regarding the intent and purpose of research. Thereafter, informed consent was obtained. The survey lasted for about 10 minutes. Collected data was analyzed using SPSS 20.0

**Result and Discussion**

A total of 200 participants were recruited in the survey. Majority of the participants were female (n=126, 63%). Age structure was divided in five categories: age below 25 years (n=55, 27.5%); age 25-34 years (n=85, 42.5%), age 35-44 years (n=40, 20%); age 45-54 years (n=15, 7.5%); and age above 55 years (n=5, 2.5%). Different ethnic groups were involved in the study with Malay population (n=115, 57.5%); Chinese (n=90, 45%); Indian (n=17, 8.5%); and others (n=8, 4%). Monthly income were categorized into income lesser than RM1000 (n=10, 5%); income RM1000-RM2999 (n=120, 60%); income RM3000-5999 (n=64, 32%); income RM6000-9999 (n=4, 2%); and income more than RM 10000 (n=2, 1%). Table 1 summarizes socio-demographics of participants.

Out of the 200 participants, 70% of them are aware of their apparent general health status. They have given optimum rating upon their current health status. Most of them have been putting effort to improve their health status, including having regular exercise, adequate quality sleep, healthy organic diet with supplement, regular health check and healthy lifestyles. This health conscious group has their regular medical health check in their individual preference of health center. Around 30% of the participant has been found to be less aware of their health status at the moment with half of these participants were within the age group of 35-44. Hustle working lifestyle with family commitment as well as social circle engagement may be the factors that take up most of their time. On other aspect, most of the participants who were less aware of their health status are within the monthly income range of RM1000-2999. Table 2 outlines the awareness of participants on their general health according to socio-demographic characteristics.

Most of the participants gave similar perception upon Anti-aging medicine. Majority of participants (n=138, 69%) referred Anti-aging medicine as a future lead in medicine field. However, some participants have low confidence on the new emerging medicine with 30% (n=60) of them anticipating unexpected adverse reaction. Participants also believed that anti-aging treatments are applicable to older people (n=30, 15%) and the treatments and consultations are too costly (n=108, 54%). Some participants were skeptical on this new medicine, with 36% (n=72) of them alluding the current influences as a trend; and 45% (n=90) claimed it as a money making business. Table 3 summarizes the perception of participants towards anti-aging medicine.

More than half of the participants (n=107, 53.5%) reported previous exposure towards anti-aging medicine information, with health screening and medical consultation topping the list of the most common type of services anti-aging medicine could offer, according to the participants. Majority showed positive acceptance towards anti-aging medicine with 72% (n=144) indicated possible future need for anti-aging treatment, while 28% were not keen for the treatment at the moment. Table 4 shows the participants’ awareness towards anti-aging medicine.

Majority of participants reported decreased in energy and vigor, menopause or andropause; and decreased sexual function (n=150, 75%). as the main concerns about aging (Table 5). In addition, participants perceived that anti-aging medicine could results in prevention and delay of age-related diseases (n=156, 78%), optimization of aging process (n=144, 72%) and improvement of facial aging appearance (n=144, 72%) (Table 6).

Half of the participants (n=100, 50%) indicated age range of 25 to 34 years old as the best age to start anti-aging treatment. On average, most of participants reported the ideal timing to observe the therapeutics effects at one to three months (n=120, 60%) while 19% (n=38) of participants expected the effects within four to six months and 15% (n=30) expected the effects within one month.

Majority of participants were willing to pay for anti-aging treatment at the cost of less than RM50 (n=74, 37%), while 25% (n=50) at the cost of RM50 to RM199, and 22.5% (n=45) at the cost of RM200 to RM499. The participants showed positive interest on the anti-aging treatments, with 55% (n=110) foresee rapid increase of demand within five years, while 41% (n=82) foresee the demand to moderately increased (Figure 1).

Majority expressed moderate interest in anti-aging medicine (n=122, 61%), while 35% (n=70) were very interested to pursue anti-aging treatment modalities (Figure 2).

Thus overall, A total of 200 respondents were recruited in this study. Most of the respondents believed that anti-aging medicine is the future of medicine with majority of the respondents indicated keenness for anti-aging treatment. This is similar to previous studies done in Australia and Canada which showed overall positive interest towards anti-aging medicine.

Public perception and interest seem to be positive towards emergence of anti-aging modalities as part of medicine. However, despite the positive outlook, concerns on negative impact and unexpected adverse effects of anti-aging medicine remains in mind of the participants. One of the potential common issues in between will be the advocates failed to persuade or educate the public regarding the human life extension updates. Thirty percent of respondents anticipated possible adverse effects from Anti-aging medicine.

![Figure 1. Participants’ expected demand of anti-aging medicine within five](image1)

![Figure 2. Participants’ interest in anti-aging medicine](image2)
However, throughout the study, some participants had shown interest by prompting for more information about Anti-aging medicine including availability of Anti-aging treatment in the clinic, proven safety and efficacy of the Anti-aging medicine, as well as price and cost of the treatment. Excellent Willingness to Accept for Anti-aging medicine was also reported. Only 1% of respondent was not interested in Anti-aging medicine. This is in line with the findings of a study in Canadian population which elicited a strong predictor of support toward this new emerging science. The researchers concluded that the population acceptance level is so supportive that encouraged further contribution of the life extension science in the society.

In this study, age group of 25 to 34 was the most indicated target group (50%) to receive anti-aging treatment. A previous study done in University of Toronto found that both middle age and older age groups were more favourable towards Anti-aging treatments compared to younger age group. This might be due to financial ability of older age groups.

Most of respondents indicated that Anti-aging medicine played a role in prevention and delay of age related diseases (78%), aging optimization (72%), facial aging (72%), physical fitness (51%), sexual satisfaction (51%) and sleep quality (27%). In regards of future prospective, more than half of them (55%) anticipate rapid increase of development in the next five years.

When comes to factors influencing patients to go for Anti-aging treatments, the expected duration to see effects as well as cost of the treatment were main factors of consideration for the treatment. In addition, 60% of participants thought that ideal timing to see effects was between 1-3 months. Meanwhile, 84.5% of the participants expected Anti-aging treatment to cost less than RM500. Contrary to the first world countries, long-lasting results and physician training as well as expertise were more influential than cost of treatment.

**Conclusion**

Positive views alongside high demand towards Anti-aging medicine and treatment were observed in this study. Although almost half of respondents had expressed concerns regarding possible adverse effects resulting from Anti-aging treatments; the dissemination of information and knowledge might help to enlighten the public with both benefits and side effects. Physicians should also look into public expectations of Anti-aging treatment outcomes as well as pricing to ensure mutual satisfactions following Anti-aging treatments. In light with high degree of interests in Anti-aging medicine, it is foreseeable that its demand will increase in the future.

Predicts the Successfulness of a Trial Voiding Without Catheter (TWOC) Through Urine Retention Volume, Detrusor Wall Thickness (DWT) and Intravesical Protrusion of Prostate (IPP) on Acute Urinary Retention (AUR) Patients Due to Benign Prostatic Hyperplasia (BPH)

Abstract

This study aimed to identify the successfulness of Trial Voiding without Catheter (TWOC) on acute urinary retention (AUR) patients due to Benign Prostatic Hyperplasia (BPH), based on urine retention volume, Detrusor Wall Thickness (DWT) and Intravesical Protrusion of Prostate (IPP). The 24 patients over 50 years old underwent catheter per urethra and recorded urine volume at retention. Transabdominal ultrasound was performed several days later to evaluate the thickness of the Detrusor Wall Thickness (DWT) and intravesical protrusion (IPP), and detrusor IPP is classified as free de 1 (0 -<5 mm), grade 2 (5-10 mm) and grade 3 (> 10 mm). Trial voiding without catheter (TWOC) was carried out on day 5 and was considered successful if the patient was able to spontaneously micturition during first 6 hours, post voided residual volume (PVR) <100 ml, and maximum flow rate (Qmax)> 10 ml / second . Data will be analyzed by simple and multiple logistic regression test with significance level (α = 0.05). The result demonstrate the detrusor muscle thickness examination and IPP degree can be used to predict TWOC success, while urine retention volume does not affect the success of TWOC.

Keywords: Acute urinary retention (AUR), Benign Prostatic Hyperplasia (BPH), Detrusor Wall Thickness (DWT), Post Voided Residual Volume (PVR), Protrusion of Prostate (IPP), Trial Voiding without Catheter (TWOC)

Introduction

Benign prostate hyperplasia (BPH) is a benign tumor in men whose incidence is related to age. The incidence of BPH in autopsy research in men are aged 41-50 years is 20%, age 51-60 years 50%, age 61-70 years by 65%, age 71-80 years 80%, and obtained 90% BPH in men age 81-90 years¹. Urine retention is the condition of patient cannot remove urine collected in the bladder so that the maximum capacity of the bladder is exceeded. Urine retention can be classified as acute urinary retention (AUR) and chronic urinary retention (CUR)². Urologists generally divide urine retention episodes based on: the patient’s ability to excrete urine (complete or partial), duration (acute or chronic), symptoms (with pain or painless), mechanism (obstruction or non-obstruction), and examination findings urodynamic (high pressure or low pressure)³.

Acute urine retention (Acute Urinary Retention / AUR) is a urological emergency characterized by an inability to remove urine (voiding) accompanied by lower abdominal pain, and usually can be overcome by catheter placement. The management of AUR due to BPH can be treated by perform surgery and use of a long-term catheter. Besides that, the Trial voiding Without Catheter (TWOC) accompanied by medical therapy demonstrates...
increases success rate. A selective TWOC is needed to minimize the suffering of patients due to long-term catheter use and reduce total cost of care. If the success of TWOC can be predicted beforehand, then the patients who are expected to succeed can be continued with medical therapy, whereas if it is predicted to experience failure, it can be immediately planned for active action for definitive therapy, without having to do a TWOC trial first. However, the standard protocol on TWOC is still unclear. Research on factors that can predict the success of TWOC to date has not been widely studied.

The modalities that are estimated to affect success of TWOC are the amount of urine volume during retention, which according to Drasa obtained a cut-off point value of 500 ml, with a sensitivity of 100%, a volume of 750 ml with a sensitivity of 76% and 1000 ml with a sensitivity of 18.3%. Whereas in the Reten-Survey, univariate regression analysis showed that the urine volume at retention of <1000 ml was related to the success of TWOC (p <0.001).

Another modality that can be used and non-invasive is the detection of detrusor muscle thickness or Detrusor Wall Thickness (DWT) and Intravesical Protrusion of the Prostate (IPP) using transabdominal ultrasonography. The detrusor will thin only until the volume of bladder is 250 ml, and then the detrusor thickness will stabilize until the maximum capacity of the bladder is reached. The degree of IPP is divided into three, namely: grade 1: IPP <5 mm, grade 2: IPP 5-10 mm, and grade 3: IPP> 10 mm.

Meanwhile, the relationship between urodynamic parameters, outcomes of therapy management and improvement of symptoms, is still controversial. With these considerations it is necessary to have a diagnostic modality that is non-invasive, easy, fast and more efficient when compared to urodynamic examinations in predicting the outcome of TWOC in patients with acute urine retention due to BPH so that a more selective assessment will be obtained in determining the choice of therapy in BPH sufferers. One of the non-invasive diagnostic modalities is the measurement of the amount of urine volume during retention, intravesical protrusion of the prostate (IPP) and detrusor wall thickness (DWT) tests that are carried out using ultrasonography, which in some studies shows that only two of the parameters are used to estimate the obstruction and success of the TWOC. This study used the three mentioned parameters to determine and prediction the successfulness of the TWOC.

Methodology

The study was conducted using an observational analytic study design with cross sectional form. The sample size was the patients with acute urine retention due to BPH that admitted to the Emergency Room, Urology Polyclinic and Urological Minimally Invasive Installation (IU), Dr. Soetomo Surabaya Hospital. There were 24 patients participated in this study during December 2014 and March 2015.

The respondent criteria included first time admitted patients that caused by BPH and catheter placement was done per urethra. Besides that, the respondents aged above 50 year old and willing to participate by fill out and sign the study approval statement form. This study did not consider as BHP patients with recurrent urinary retention, had prostate surgery and have alpha blocker therapy, 5 α reductase inhibitors in the past 2 weeks. Besides that, the patients with pathology other than BPH, such as bladder and urethra stones, prostate malignancy, bladder malignancy, urethral stricture, diabetes mellitus, neurological disorders as well as urinary tract infection will not considered in this study.

The variable examined in this study is the amount of urine volume during retention (initial urine when installed catheter), detrusor muscle thickness / detrusor wall thickness (DWT), and intravesical prostatic protrusion (IPP). TWOC is declared successful, if after the catheter is equipped, the patient can spontaneously micturition in less than or equal to 6 hours, and the ultrasound and uroflowmetry examination show the post void residual urine (PVR) <100 ml, and $Q_{\text{max}} > 10$ ml / sec.

The independent variables consisted the urine volume during retention, detrusor wall thickness (DWT), and intravesical prostatic protrusion (IPP), while the dependent variable was TWOC success outcome. The data was analyzed descriptively and analytically. Non normality test is performed as the dependent variable is categorical dichotomous. Besides that, simple and multiple logistic regression test with significance level ($\alpha = 0,05$) is considered in order to determine the effect of the amount of urine volume at retention (RV), DWT, IPP on the incidence of BPH with urine retention and the success outcome of TWOC.
Result and Discussion

The study was conducted on 24 patients with acute urine retention due to BPH and underwent TWOC. Table 1 showed the data included urine volume during retention, mild muscle detrusor, IPP levels, and TWOC success indicators. The average age of the participants is about 64.5 year old ranging from 53 to 82 year old. The TWOC’s success was identified by 13 (54.2%) patients, while the remaining 11 (45.8%) patients were unsuccessful. Patients who succeeded TWOC had an average prostate volume (37.1 +/- 8.2 ml) which was significantly lower compared to patients who failed TWOC (61.9 +/- 25.5 ml). A significant difference between successful and failed TWOC groups is seen in the average thickness of detrusor muscles and grade IPP. Patients who succeeded TWOC had an average detrusor muscle thickness (1.8 +/- 0.3 mm) which was smaller compared to patients who failed TWOC (2.8 +/- 0.4 mm). For the IPP grade variable, patients who managed TWOC tended to have Grade 1 or 2 IPP, while patients who failed TWOC were more likely to have grade 3 IPP. The variable of initial urine volume when catheter was installed or urine volume during retention did not show any differences between successful and failed TWOC patients groups. The average initial urine volume when installed is 975 ml catheter which ranges from 400 ml to 2000 ml.

a Statistical test to compare between TWOC successful groups and TWOC failed group using chi square for Grade and Micturition IPP variables and student t-tests for other variables.

The relationship between urine volume during retention and success of TWOC was tested by Spearman correlation test. The Spearman correlation test results are shown in Table 2. From the results of correlation test observed that the relationship between urine volume during retention and success of TWOC was not proven significantly. The correlation value with 0.158 and a significance level of 0.461 (p> 0.05).

The relationship between thickness of the detrusor muscle and success of the TWOC was tested by the Spearman correlation test. Spearman correlation test results were shown in Table 3. From the results of the correlation test it can be seen that the relationship between the thickness of the detrusor muscle and the success of TWOC is proven to be significant. This can be seen from the correlation value of -0.840 and a significance level of 0.000 (p <0.05). The number of correlations approaching one shows a strong relationship between the detrusor muscle thickness and the success of the TWOC. A negative correlation sign indicated that the increase in the thickness of the detrusor muscle, smaller the success rate of TWOC.

** Correlation is significant at the 0.01 level (2-tailed).

Based on Table 1, IPP in the group that succeeded TWOC was (4.5 +/- 2.4mm) while in the group that failed TWOC was (17.1 +/- 8.8mm). The average difference between the two groups was tested by t test and showed a significant difference (p <0.000). Comparisons between two groups were tested by the chi-square test and showed significant differences (p <0.001) as shown in Table 1. The relationship between Grade IPP and
TWOC success was tested by Spearman correlation test. Spearman correlation test results are shown in Table 4. From the results of the correlation test it can be seen that the relationship between Grade IPP and the success of TWOC is proven significantly. This can be seen from the correlation value of -0.717 and a significance level of 0.000 ($p < 0.05$). Correlation figures that approach one indicate a strong relationship between Grade IPP and TWOC success. A sign of a negative correlation indicated that increased in Grade IPP will decreased the success rate of TWOC.

**Correlation is significant at the 0.01 level (2-tailed).**

The results in this study indicated that Grade IPP can be used to predict the success of TWOC in patients with acute urine retention due to BPH. From the results of simple logistic regression showed the confidence interval value of the odds ratio is 0.008 to 0.497. This result showed that every 1 degree increase in the IPP grade will tend to have the odds of a maximum TWOC success of 50.3% lower or in other words any decrease in 1 IPP grade would increase the odds of success of the TWOC by 2.01 times.

A multiple logistic regression urine volume at retention, DWT, and IPP grade on the success of TWOC was conducted. The deviance value (-2 Log likelihood) model was very small below 0.000. The result indicated the occurrence of over dispersion / under dispersion so that the Wald test statistic becomes invalid. This is possible because of the interaction between independent variables or the existence of independent variables that are not mutually independent.

According to result of correlation test shown in Table 5, there was a close relationship between the variables DWT and Grade IPP. Thus, the model needs to be changed.

**Table 5: The correlation test of the DWT and Grading IPP**

**Correlation is significant at the 0.01 level (2-tailed).**
From the results of multiple logistic regressions in Table 6 and Table 7, if separated between the variables DWT and Grade IPP it does not cause over dispersion. Wald test statistics concluded that DWT had a significant effect on success of TWOC with a significance level of 0.033 (p <0.05) and Grade and IPP significantly influence the success of TWOC with a significance level of 0.009 (p <0.05).

* Variable(s) entered on step 1: urine volume during the retention, IPP Grade

This result suggested that prostate configuration such as IPP that described the medius lobe and/or lateral lobes of the prostate which protrudes into the bladder base, contributes to the occurrence of obstruction. So, the higher the degree of IPP, the heavier the degrees of obstruction, which will result a low success rate of TWOC.

**Conclusion**

In conclusion, the urine volume during retention could be used as a predictor to observe TWOC success. Based on the simple logistic regression analysis demonstrated that DWT and IPP degrees suitable to use as predictors of TWOC success. The IPP degree/grading had affected TWOC outcome where patients with grade 3 IPP had a low TWOC success rate are require for surgical procedures such as Transurethral resection of the prostate (TURP).

Effectiveness of Virtual Reality Using PS4 Gaming Technology in Stroke Rehabilitation for Improving Upper Limb Function-A Pilot Study

Suresh J¹, Harish C²
¹Assistant Professor, ²BPT Student, SRM College of Physiotherapy, SRM Institute of Science and Technology, Kattankulathur-603203

Abstract

Background: Hemiparesis resulting in functional limitation of an upper extremity and lower limb is common among stroke survivors. Virtual reality is one of the way of improving motor function in stroke, limited evidence is available on the efficacy of virtual reality for stroke rehabilitation. Methods: In this pilot study 2 parallel groups involving stroke patients, we compared the feasibility, safety and efficacy of virtual reality using the sony PS4 gaming technology to evaluate upper limb motor improvement. The primary feasibility outcome was the total time receiving the intervention. The primary safety outcome was the proportion of patients experiencing intervention-related adverse events during the study period. Efficacy, a secondary outcome measure, was evaluated with wolf motor function test and Spasticity Grading at 4 weeks after intervention. OUTCOME MEASURE: WOLF Motor function test and Box and Block test. Result: This study shows that mean values obtained from WOLF motor function test showed no statistical significance and the mean values of Box and Block test showed statistical significance. Conclusion: This study concludes that the PS4 gaming technology is a feasible, safe, and potentially effective intervention to enhance motor function recovery in patients with a recent stroke.

Keywords: Virtual reality, PS4, wolf motor function test, Box and Block Test.

Introduction

Stroke is a devastating, serious and leading disease which causes disability and rehabilitation plays an important role in patients care. More than 80% of stroke victims experience hemiparesis immediately after the stroke of which 55-75% suffer from associated motor deficit and reducing the quality of life¹. Recent researches of neural plasticity and motor retraining suggests that repetitions of movement for multiple times plays a major role in regaining motor function. Jaron Lanier in the 1980s introduced Virtual Reality (VR). It consists of vital components such as external tools, internal tools, software and the database. The external tools (visual, auditory, and haptic), creates a virtual environment and allows the user to interact with it, and the internal tools (trackers, gloves, joysticks and exoskeletons, mouse), which tracks and senses position and motion of the user in a virtual environment and it connects the user to the virtual environment. In the field of motor rehabilitation, VR offers a convinient and affordable environment for rehabilitation, which makes way for the repetition of exercise effectively, evaluation of the effects, and provides motivation for maximum exercise repetition, which is the vital component in the field of rehabilitation³.

McComas et al. suggested that VR can be used for practicing new skills and learning of motor and cognitive functioning and to enhance their social participation and quality of life. It is a gaming technology which offers 3 dimensional virtual reality world, engaging the mirror-neuron system. The evaluation gaming industry has provided a variety of VR system like play station, xbox for home use, making it reasonably priced and also it can be easily modified according to the community needs. These technology allows bilateral observation.
of wonderful moments displayed on the monitor and combines the quality of increasing demands, required for the induction of neural plasticity.

Need for the Study

There are very few research involving the use of VR technology particularly the PS gaming console in the field of neuro-rehabilitation. There is an identified need for to establish the welfare, viability and efficiency of VR system as therapeutic option in stroke rehabilitation. The objective of this study is to examine the feasibility and safety of the PS4 gaming console compared with conventional physiotherapy in the facilitation of upperlimb motor function of the upper extremity required for activities of daily living among stroke patients.

Methodology

The study design was Experimental design, study type was experimental type, sampling method was convenient sampling and sample was 5, study setting was in and around Chennai. The participants 18-60 years of age having an ischemic or hemorrhagic stroke were included in the study. Participants involved in the study had acute stroke confirmed by the imaging and met a level of function of the upper extremity derived from the Chedoke-Mcmaster scale >3 in the arm at the time of enrollment. Participants were excluded who were medically unstable, or uncontrolled hypertension, severe illness, unstable angina, seizure and shoulder subluxation.

Procedure

The participants were selected based on the inclusion and exclusion criteria, the procedure was explained and the consent were taken to participate in the study. The participants were divided into two groups Group-A and Group-B. Group-A was treated with PS4 gaming session and conventional Physical Therapy and Group-B was treated with conventional Physical Therapy only. Participants received an intensive training program consisting of 12 interventional sessions of 60minutes each for a period of 4weeks. The arm movement involved in the use of PS4 included flexion and extension of shoulder(tennis), internal and external rotation of shoulder (tennis), elbow flexion and extension, forearm supination and pronation, flexion and extension of wrist as well as flexion of thumb involved in all activities. Participants were instructed to use their affected arm mainly in these activities in sitting position. There may be risk of photosensitive induced seizures to avoid these the patients were made to sit at a distance ≥6 feet away from the screen and lights were kept on.

Results

According To Table 1: shows there was no statistically significant difference between pre and post test values of WOLF Motor Function Test among Group-A (P>0.05)

According To Table 2: shows there was statistical significance difference between pre and post test values of WOLF Motor Function Test among Group-B (P<0.05)

According To Table 3: shows there was statistical significance difference between post test values of Forearm to table, Forearm to box, Elbow extension, Hand to box (P<0.05). There was no statistical significance difference between post values of Elbow extension (weight), hand to table and grip strength (P>0.05)

According To Table 4: shows there is a significance statistical difference between pre and post test values of Box and Block Test values among Group-A.

According To Table 5: shows there was a statistical significance difference between pre and post test values of Box and Block Test (P<0.05)

According To Table 6: shows there was a statistical significance difference between post test values of Box and Block test among Group-A and Group-B (P<0.05)

Discussion

Nowadays the virtual reality technology is evolving in the stroke rehabilitation. The current paradigm of stroke rehabilitation strategy is to refine the motor function. Participation and maintaining a regular exercise has been regarded as the most important aspect in the field of stroke rehabilitation, there by preventing and halting the progression of the disease. Limited activities leads to disuse atrophy and decreased cardiovascular efficiency, which affects the functional gains, which is achieved during the rehabilitation. Virtual reality gaming technology allows the user to communicate with virtual environment and receives a feedback based on their real time performance. Limited evidence are available on VR gaming system in stroke rehabilitation, two recent systematic review reports focused in the lower extremity especially in gait training and very few studies are available in the upperlimb. Lnghorne. P, Coupar F, Pollack A. stated that the extent of VR system can support conventional therapy currently in use. The gaming and music are incorporating in the rehabilitation, it enhance enjoyment and the motivation and it also facilitate participation in the regular exercise. Heller et al. stated that hand strength is directly related to hand function. Sunderland et al. reported that hand strength improves according to the probability of complex motor task ability of the upper extremities and stated that hand strength is an important measure to indicate functional recovery in stroke. The result of the study shows that there is statistically significant difference in grip strength and box and block test between both the groups but when comparing both the groups, Group-B is highly significant than Group-A. Moreover several studies compared an intervention plus conventional physical therapy versus conventional physical therapy alone, which by necessity allowed for more rehabilitation time in the experimental group.

Conclusion

On seeing the result we can conclude that there is significant improvement in WOLF Motor Function Test and Box and Block Test in Group-B when compared to Group-A. The limitation of our study was a pilot study with small sample size, limiting any definitive conclusion about the efficacy of VR. This study was single blinded, it may subject to bias in those patients because of the use of new technology, that has been motivated them by the use of this treatment and also may have inadvertently disclosed their treatment allocation to the examiner.

Despite these limitation PS4 gaming technology is a feasible, safe, and potentially effective intervention to enhance motor function recovery in patients with a recent stroke.

Abstract

The identification of human beings is based on their physical body parts such as the face, eyes, nose, iris, ear, fingerprint, voice plays an important role in electronic applications and has become a popular area of research in image processing and in many face recognition related fields. Facial Expression Recognition (FER) is a decisive technology and a challenging task for human-computer interaction. Out of all the above-mentioned body parts, the face is one of the most popular traits because of its unique and differing features. In fact, individuals can process a face in a variety of ways to classify it by its identity, along with any numbers of other characteristics, such as gender, ethnicity, and age.

The classification has become prominent as a leading technique for problem solution and optimization. The classification has been used extensively in many problems that are controlled by a particular ruler or government. It is an area of great significance and has great potential for future research for future gender classification. It offers more than two but not many industrial applications in near future such as monitoring, surveillance, commercial profiling, and human-computer interaction. Many different methods have been proposed for gender classification like gait, iris and hand shape. However, the majority of techniques for gender classification are based on facial expression recognition. The proposed system uses skin tone extraction, facial feature exaction and feature extraction are done using LBP. Classification is done using Artificial Neural Network from that male and female is recognized.

Keywords: Facial Expression recognition, self-organizing map, Artificial neural network, artificial intelligence.

Introduction

Automatic analysis of data in video is a very challenging problem. It is used to a particular object in a video stream and automatically decides if it belongs to a particular class or not, one should utilize a number of different machine learning techniques and algorithms, solve object detection, tracking, and recognition tasks. The automatic human face and body parts recognition tasks differ. It is based on pattern recognition⁶ and artificial intelligence (AI).

Artificial Intelligence uses different biometric body parts, such as the face, fingerprint, gait, iris, and voice. Of all body parts, the face is one of the most popular distinguishing quality because of its unique features and impression among all other body parts. Using face recognition it can be performed without the cooperation and knowledge of the person being identified. Basically, recognizing a person becomes very difficult because of the variations in the poses, illumination, occultation, expression and so many. Using the human identification face is critical because it considers multiple parts of the facial structure, and the face of a person changes because it changes with the passage of time (time to time). In fact, individuals can categorize the faces in a variety of ways to show their identity, along with a number of other demographic characteristics, such as gender, ethnicity, and age. In particular, recognizing human gender is important because people respond differently depending to gender. In this, a successful gender classification approach can boost the performance by many other applications, including person face

DOI Number: 10.5958/0976-5506.2019.00895.7
recognition and tidy human–computer interfaces\(^4\). Face detection is disapproving comments to the final result in many applications, such as face processing (i.e., face, expression, gender classification, and gesture recognition), computer-human interaction, human crowd surveillance, biometrics, video surveillance, Artificial Intelligence, and content-based image retrieval. Facial expression recognition can be viewed as a preprocessing step for obtaining the object region. Recent researches are carried out for face detection by using a various color-based algorithm where the segmentation of skin-colored regions becomes robust only when a proper color model is picked out. Several color models exist on RGB(Red, Green, Blue), YCbCr(), and HSV (Hue, Saturation, Value) color models and each has a specific work field and strength. The RGB color space consists of the three primary color elements that make up white light: red, green, and blue. The RGB model makes easy to design of computer graphics systems but is not ideal for all applications. The YCbCr color space was defined in response to increasing demands for digital algorithms in handling video information and has since become a far apart used model in digital videos. Given that hue, saturation, and intensity (HSI) value are properties used to describe color, a corresponding color model, HSV, logically exists. When using the HSV color space, knowing what percentage of blue or green is required to produce a color is not needed; the hue is adjusted to get the desired color.

**Face Recognition Using BFGS**

The fact of being identified of human beings is based on their physical body parts, such as the face, fingerprint, gait, iris, and voice plays an important role in electronic applications and has become admired by many people, this area of research in image processing. FER is also one of the most successful applications of computer-human interaction and understanding. In these above-mentioned body parts, the face is one of the most popular a distinguishing quality because of its unique features. In fact, individuals can process a face in a variety of ways to classify our face by its identity, along with a number of other characteristics, such as gender, ethnicity, and age. Specifically, validity human gender is important because of human response differently according to gender. In this, we present a robust method that uses global geometry-based features to classify gender and identify age and human beings from video sequences\(^5\). The distinctive attributes are extracted based on face detection using skin color segmentation and the computed geometric features of the face ellipse region. These geometric features are used to form the face vector the path followed by it, which are put a data to a time delay neural network and are trained using the Broyden–Fletcher–Gold–Shanno (BFGS) function\(^6\). When using the HSV color space, knowing what percentage of blue or green is required to produce a color is not needed; the hue is adjusted to get the desired color\(^1\).

In facial feature extraction, unlike in natural methods applied to extract the features from image or video sequences: geometry-based, template-based, color-based segmentation and appearance-based methods. In this geometry-based method, it extracts features using geometric information, such as the relative positions and sizes of the facial components. This facial feature extraction method requires the classifier to use a large number of features. The techniques proposed to extract geometric features, such as left eye width, right eye width, nose width, left eye center to mouth left edges meet, right eye center to mouth right edges meet, left eye center to mouth right edges meet, and right eye center to mouth left edges meet, mouth left edges meet to middle of chin, and mouth right edges meet to middle of chin. This method proposed using geometric features, such as the distance between eyebrows to an eye, eyebrow to nose uppermost point, nose uppermost point to mouth, eye to mouth, left eye to right eye, nose width, and mouth width, all of which are removed using the Viola–Jones algorithm. And then this is applied as a combination of global and grid features. Worldwide features include inter-ocular distance, the distance between the lips to the nose tip, the distance between the nose tip to the line connecting the two eyes, the distance between lips to the line connecting two eyes, an eccentricity of the face, a ratio of dimension, and width of the lips\(^1\). Grid distinctive attribute includes skin color, mustache region, lip region, eye tail, forehead, eyelid, and nose wing of the face image. The pattern-based approach matches facial components to previously designed templates using an appropriate energy functional. The best match of a pattern in the facial image will yield the minimum energy; this approach can be many different due to the extensive computation involved and produce an intended result when query and model images have the same scale, orientation and illumination properties. Color-segmentation makes use of skin color to deal the face separately and any non-skin color region. In
this approach, the quality of the image coupled with lighting and hue plays an important role in image recognition and rate of classification. For a complicated background, face detection method on the skin color feature is identified. The pattern in the appearance-based method differs from the simple facial features, such as eyes and mouth, used in other approaches. Any extracted particular of the image refers to a feature. In methods such as principal component analysis (PCA), which was proposed by many applications, a face image is beentitled as a two-dimensional N by N array of intensity values or a vector of the dimension N2. The principal component analysis finds an M-dimensional subspace whose basis vectors correspond to the intensity as possible variance direction in the original image spaces. Introducing basis vectors define a subspace of face images called face space. All images of known faces are estimated onto the face space to find sets of weights that describe the contribution of each vector. The face can be identified through an equivalent set of weights for the unknown face and the sets of weights of known faces. It is applied as an adaptive pattern generation algorithm trained by means of the optimization procedure according to the LDA principle. Gabor wavelets were also used to extract the pattern vector. These approaches are commonly used for facial expression recognition rather than person identification. An applied Gabor filters at five scales and eight orientations for detecting skin regions. In this Fourier–Gabor filter was applied to extract features from the face images. In this not the same size, orientation, and scale values were adopted. Despite the prevailing circumstances of the above-mentioned methods, a variety of classification techniques can be used for recognition, such as decision trees, neural networks, nearest neighbours classifier (NNC), support vector machines (SVMs), Bayesian networks, fuzzy logic and genetic algorithms and many others useful algorithms. These are trained and tested three classifiers SVM, back propagation NNs (BPNNs), and KNN. These classifiers are then optimized through the GA (General Arrangement) using this, approach they got promising results in terms of the classification error rate and the minimization of computation time. This proposed a variant of the decision tree algorithm for gender classification of frontal images owing to its distinctive features. Their especially the execution is showed robustness and relative scale invariance for gender classification. This got high accuracy by using SVMs for gender classification. Many applications produced very promising recognition rates for three applications face recognition, facial expression recognition, and gender classification, and reasonable results in all databases with the same set of features and (NNC) classifiers. The system also had a real-time capability, and it was automatic. It is used an unsupervised learning technique to classify DCT-based feature vectors into groups and identify if the subject in the input image was present or not present in the image or video database. After training for approximately 850 epochs, the system achieved a recognition rate of 81.36% for 10 repeating trials. The main advantage of this execution is its high-speed processing capability and low computational requirements in terms of speed and memory utilization. In classification algorithm, PCA matrixes with different numbers of components (40, 50, and 60) were passed to the Neural Network, which conducted the framework with not same layer number, not same learning algorithms, and not same number of neurons in each layer, and achieved a high correct classification rate of approximately 83.5%. This is used as a posterior class probability and Artificial Neural Network is used to classify gender and age, respectively. The outcome achieved was 100% for face recognition, 98% for gender classification, and 94% for age classification. The recognition step was applied by SVM. A good concert of the gender classification test was also achieved on a relatively large-scale and low-resolution video database. In this FER applied the Artificial Neural Network for the face, facial expression, and gender classification, and produced reasonable results in all databases. This proposed system using SVM and presented the experimental results gained on a large image dataset. More than 90% accuracy of the viewer’s gender recognition and their classification was achieved. The social phenomena of a successful real-time gender classification depend greatly on the right choice of features and classification method. In the previous paper, an algorithm is introduced to enhance real-time gender classification. The face region is detected using skin color segmentation with HSV (HUE, SATURAION, VALUE) color space, and the features are extracted using global geometric properties. A Time Delay Neural Network (TDNN) algorithm is used for classification tasks and this implement for further gender classification.
The proposed system uses skin tone extraction, facial feature extraction, and feature extraction is done using LBP. Classification is done using Artificial Neural Network from that male and female is recognized.

**Block Diagram**

The steps of the proposed method can be summarized as follows:

1. Extract video frames.
2. Delete abnormal images from the start and the end manually.
3. Detect the face region from each frame using skin color segmentation.
4. Extract features from each image using the geometry based approach.

**Conclusion and Future Work**

A real-time classification system using TDNN is described according to Broyden Fletcher Goldfarb Shanno training algorithms and used for gender and age classification and human identification. This developed system implies that we can arrange gender, age, and human being with promising recognition rate by using global geometric features from video. It uses skin tone extraction, facial feature extraction, and feature extraction is done using LBP. Classification is done using Artificial...
Neural Network from that male and female is recognized.

The developed method based on worldwide geometric facial features achieves a high classification rate of 100% in the training set for all application, as well as 91.2% for gender classification, 88% for age arrangement, and 83% for human’s action in the testing set. Future work will be devoted to put into effect and examining the other features extracted from face parts by various with real-time application.

Abstract

Tooth caries or also known as tooth decay or cavities is one of the most common and widespread oral disease. However, this disease is also preventable if a good oral care and habits are practiced on daily basis since at the young age. Due to this, this study is conducted with the aim to identify the caries severity among the elementary pupils of Puskesmas Keputih. Random samples of 120 students were selected as the subject of study. Questionnaires, interviews and oral examination were done as means of data collection. The results had revealed that there were a few factors which increased the risk of caries development among the students. These factors are age, cariogenic food and drinks consumption, psychological and physical disorders, dental visits, toothache problems and lastly the behavior of mothers in handling their children’s toothache problems. In addition, the severity of caries when specified by Body Mass Index (BMI), the groups of subjects with a total number of DMF more than 5, tend to have BMIs with abnormal categories. Thus, in order to prevent and reduce cavities, a proper oral care needs to be taken since severe caries could contribute to poor body growth and BMI.

Keywords: Body Mass Index (BMI), Cariogenic Food, Dental Caries, Elementary Students

Introduction

Tooth decay or caries is one of the biggest problems faced by the people of Indonesia and other developing countries. Dental caries is considered a public health problem that is common throughout the world because of its high prevalence with significant social impacts1. The results of the 2013 Baseline Health Research (RISKESDAS) showed that the caries prevalence of the population in Indonesia was 72.6%, the dental and oral problem population of those who received treatment and medication was 31.1% and the tendency of the decayed, missing, filled tooth (DMF-T) index was 4.5. 2013 RISKESDAS data also showed that the DMF-T among 12-year-olds was 1.38, whereas World Health Organization (WHO) expected the targets for DMF-T by Global Goals for Oral Health 2020 to be less than one for the 12 years old children. The high prevalence of dental caries and unsuccessful attempts to overcome it are influenced by several factors including population distribution factors, environmental factors, behavioral factors and different dental health factors in Indonesian dental caries.

Dental caries can attack all people from toddlers to adults. Caries experience in the period of primary teeth is considered to affect permanent teeth later. In children, especially at the young age, the tooth structure includes the type of teeth mixed between milk teeth and permanent teeth, making them susceptible to dental caries2. Dental caries among children will cause pain, discomfort, sleeping difficulties at night and this can cause children to be absent from school. Children who experience caries do not always feel pain, but it is reflected on the changes in children’s eating and sleeping habits. The primary effect of caries is pain due to an infection. Nonetheless caries also has an effect on

Dramawan Setijanto
E-mail: r-darmawan-s@fkg.unair.ac.id
the general health of the child, one of which can occur due to abnormality of body weight since the presence of growth and development disorders\(^4\).

Puskesmas Keputih is located in Sukolilo Subdistrict and consists of 2 Sub-districts, namely Keputih Village and MedokanSemampir Village. Based on the preliminary survey conducted among 245 children from Keputih School and 100 children from MedokanSemampir, the mean of caries prevalence was found to be 89.5% and had a DMFT value of 5.42. Furthermore, 73.6% of the students with an abnormal BMI also experienced caries.

These results implied that high degree of DMF-T value which had an impact on BMI abnormalities and children’s lack of knowledge on dental and oral health as well as the participation of parents in maintaining a healthy teeth and mouth is a serious problem that must be immediately overcome and made as priority in solving the problem. Thus, this research intended to study the relationship between BMI and status of caries among primary school children in Puskesmas Keputih\(^3\).

**Methodology**

The type of research method used is observational descriptive research with cross sectional approach. This research was carried out in Keputih Elementary School and MedokanSemampir Elementary School, Surabaya in September 2017. The total populations in this study were all students from both schools in the 2017/2018 school year with a total of 821 students. Based on the population, using the simple random sampling technique, the calculation for the sample size for this study was 119. The equipment and materials utilized in this research were a) DMFT (WHO) examination sheet; b) Interview sheets and interview guidelines for subjects; c) Questionnaire sheets for parents; e) WHO Probes; f) Cotton and alcohol; and g) Gloves and masks.

The needed data and information for this research is gathered by means of questionnaires and interviews. The subject of study (students) answered the interview questions on the WHO questionnaire form relating to caries risk factors and questionnaire forms related to BMI supporting factors. This is followed by measuring body weight (kg) and height (cm) of the research subjects. Next, the researchers examined the condition of the oral cavity, namely the number of caries according to the WHO form using WHO probes. Lastly, questionnaire forms are distributed to the parents of the subjects to be filled up and collected the following day. Once all the distributed questionnaires are collected, the data is processed and cross-tabulated using the SPSS 17 application on several risk factors aforementioned.

**Result and Discussion**

In this study, cross tabulation analysis was made in the form of a 2x2 table. This is due to the small number of research subjects. The following is a cross tabulation between the risk factors of the impact of caries severity in Keputih and MedokanSemampir elementary schools on BMI.

Caries severity is measured through DMF-T values which are categorized into the DMF-T value is less than 5 and the DMF-T value is above 5. In Table 1, the result found that children with DMF-T values more than 5 tend to have a body abnormal mass index which is 76.5% of the total sample. P value obtained was 0.218 which showed no significant difference between caries severity and body mass index.

An abnormal body mass index of the children is regrouped based on thin and fat bodies. From Table 2, the result showed that children with a DMF-T score of more than 5 tend to have a thin body mass index with a frequency of 78 children and a percentage of 94%.

Large food composition in one day is categorized into complete food composition and incomplete food composition. In Table 3, the results proved that children with large food composition in one day were incomplete and those with abnormal weight were 93 children with a percentage of 77.8%. P value was 0.9 which showed no meaningful results between the compositions of large food in one day with BMI. Cross tabulation between the compositions of large meals in one day with BMI has an odds ratio of 0.42.

The amount of large meals in one day is categorized into a large number of three or more meals, and less than three times a day. In Table 4, the presented findings found those 16 children with large amounts of food less than three times a day, had abnormal weight. A p value of 0.445 was obtained which showed insignificant results between the number of large meals in one day and BMI. Cross tabulation between large meals in one day and BMI has an odds ratio of 0.79.

The frequency of children eating snacks in one day is categorized into 3 times a day or less, and greater than 3 times a day. Table 5 showed that children who had snack frequency less than 3 times a day with an abnormal body mass index have the highest frequency of 59 children with a percentage of 78.7% of the total sample. P value was obtained for 0.693 which reflected no significant difference between frequency of eating snack and body mass index. Cross tabulation between BMI based on frequency of eating snacks in one day had an odds ratio of 0.40.

The duration of sleep in one day is grouped to sufficient (9-11 hours) and lack (less than 9 hours). In Table 6, the total number of the study subjects found that children with enough sleep duration in one day but had abnormal BMI values were 75 people with a percentage of 82.4%. P value was 0.024 which showed a significant difference between sleep duration and BMI. Cross tabulation between sleep duration in one day and BMI had an odds ratio of 0.022 which showed the difference between sleep duration in one day and BMI.

**Discussion**

In this study, there were no significant results between the severity of caries in the study subjects and the frequency of consumption of cariogenic foods and beverages. This is very likely to occur because caries is a multifactorial disease, meaning that many factors can cause caries. The children with good habits will immediately drink water after consuming cariogenic foods and drinks. This is very effective for caries prevention because it will reduce the attachment of foods containing sugar to the surface of the teeth.

Based on the results, the severity of dental caries among elementary school children in the work area of Puskesmas Keputih Community had no significant difference to the body mass index which can be seen from the P value greater than 0.05 and those with DMF-T values are more than 5 inclined to have an abnormal BMI. These results are consistent with the theory that children with dental caries have less weight since dental caries can cause extreme pain till the children tend to avoid hard foods and main meals. This condition can lead to weight loss and malnutrition. The absence of a significant difference between caries severity and body mass index was probably due to additional factors such as eating habits and duration of sleep in a day and physical activity after school.

Findings related to the frequency of eating snacks in one day did not have a significant difference to the body mass index which can be seen from the P value greater than 0.05. The children whose had frequency of snacking was less than three times a day but having a thin body, can be influenced by the type of snack. Most types of snacks that children often eat are snacks that are part of unhealthy food and lack of nutrients. Whereas children who have a frequency of eating snacks less than three times a day but having a fat body was probably due to the children’s tendency to eat the main or large food portion more often than snacks, so the calories obtained from large foods greatly affected the child’s weight.

Those children with incomplete large food composition in one day were and those with abnormal weight as many as 93 children with a percentage of 77.8% the P value was obtained at 0.9 which showed that there was no significant difference between the incomplete composition of large food in one day which with BMI. The composition of food eaten by children every day can affect a child’s weight, if the composition of foods that are eaten excessively or less which can cause weight to be abnormal (obesity or underweight). Multifactor that contribute to the occurrence of obesity are food intake (macro nutrients, fibre intake, breakfast intake, fast food consumption patterns, and consumption patterns of sweet foods / drinks); physical activity factors; psychological factors (self-esteem); and genetic factors.

In addition, 16 children ate large amounts of food (<3x in one day) and have abnormal weight. The P value was 0.445 which showed no significant difference between the number of large meals <3x in one day with BMI which was proven with the theory that to get enough energy, everyone should pay attention to
their diet by getting used to eating three times a day (morning, afternoon and evening) regularly. Especially the habit of eating breakfast is very important because our activities during the day need a lot of energy. Based on the research on eating behaviour of obese students, it was concluded that the main eating behaviour of 86% obese students were more 3 times a day and had a habit of adding portions of food at mealtime, eating their favourite food which was high in calories and low in fibre.

Based on the results of the study showed that the level of sleep duration in one day had a significant difference to the BMI with a P value less than 0.05 and the results obtained showed that 82.4% of the students despite having enough sleep in a day, still had abnormal BMI. This sleep disorder is judged by the way a person wakes up when he/she sleeps in the middle of the night or wakes up too early, wakes up to the bathroom, has difficulty breathing, coughs or snores loudly, feels cold or feels hot, experiences nightmares, feels sick and excuses others that disturb sleep. Sleep disturbances can cause hormonal changes in the body, one of which is growth hormone (GH). GH is secreted at the beginning of a period of deep sleep, stages 3 and 4 but is inhibited during sleep in the REM phase, which is related to dreams. GH is secreted during sleep, and three times more secreted than when awake. This hormone is also very instrumental in the child’s growth process, namely as a stimulator of cell growth and division in every part of the body and cartilage, improving the process of bone mineralization, increasing body protein synthesis, and stimulating insulin like growth factors that function in the growth and development of body cells. Lack of physical activity causes a lot of energy stored as fat, so that people who do less activity tend to be fat.

**Conclusion**

In the study the severity of caries in elementary school students in the work area of the Surabaya Puskesmas Keputih based on several risk factors measured using the DMF-T index had a total range of 0 to 15 with an average of 5 which according to WHO was categorized in high status. The severity of caries when specified by Body Mass Index (BMI), the groups of subjects with a total number of DMF more than 5, tend to have BMIs with abnormal categories. BMI with an abnormal category, if further specified did not have a significant difference between fat and thin.

Abstract

The study aimed was to determine risk factors in severity of dental caries among primary school students in working area of Keputeh Health Centre (Puskesmas). The study was used descriptive observational research with cross sectional approach. Besides, the study was conducted in September 2017 at primary school in working area of Keputih Health Centre (Puskesmas) included Keputih and MedampirSemampir primary schools. The population were all students who attended Keputih and Medoka primary schools. The sample sizes were 119 students who meet the inclusion criteria. The tool and material were DMFT (WHO) checklist sheet, interview guideline, questionnaire, mouthpiece, WHO probe, cotton, gloves, masks and study instrument. The questionnaire forms were distributed to respondent parents. The collected data were processed and cross-tabulated used SPSS software program. The result found, the students had higher risk of severity dental caries such as aged between 6 years old and 8 years old, those had experienced lower severity caries, those felt there was a psychological and physical disorder and visited dentist in past 12 months.

Keywords: Dental Caries, Cariogenic Food, Dental Visit, Brushing Teeth

Introduction

Dental caries is one most common dental and oral diseases in society which does not only occurs in adult but also in children. Dental caries affects 60-90% of school-age children and most of adult1. Dental caries is known as main cause of oral pain and tooth loss2. Besides, dental caries also defined as post-eruptive, localized, pathological process of external origin involving softening of hard tooth tissue which forms cavity3. Dental caries is progressive irreversible microbial disease which affecting tooth hard tissues4. Teeth are one part of body that functions to chew, speak and maintain face shape, thus it is important maintain dental health as early as possible so that teeth can long lasting in the oral cavity4.

The dental caries is strongly correlated with lifestyle included frequent in sugar consumption, less toothbrushing, lack of dental floss usage and less visiting a dentist regularly6. In Indonesia, dental caries is biggest problem faced by Indonesian which considered as public health problem with significant social impacts. Based on World Health Organization (WHO), developing countries have caries index of 1.2 which WHO target is 1.0.

High prevalence of dental caries and unsuccessful efforts to overcome dental caries among Indonesian are influenced by several factors such as population distribution, environment, different behavior factor and dental health factors7. Dental caries lead pain, discomfort, sleep difficulty among children which affects their life quality [2]. The children who suffering dental caries might not have tooth pain but can observe their changes in eating and sleeping habits. The primary effect is pain due to infection which results in abnormal weight because disruption of growth and development8. The study aimed was to determine risk factors in severity of dental caries among primary school students in working area of Keputeh Health Centre (Puskesmas).

Methodology

The study was used descriptive observational research with cross sectional approach. Besides, the study was conducted in September 2017 at primary school in working area of Keputih Health Centre (Puskesmas) included Keputih and Medemampir Semampir primary schools. The population were all students who attended Keputih and Medoka primary schools. The sample sizes were 119 students who meet the inclusion criteria. The tool and material were DMFT (WHO) checklist sheet, interview guideline, questionnaire, mouthpiece, WHO probe, cotton, gloves, masks and study instrument.

In this study, DMF-T and def-t which aimed to determine dental caries status. The data needed from interviews. The oral cavity was examined according to WHO form used WHO probes. Meanwhile, the questionnaire forms were distributed to respondent parents. The collected data were processed and cross-tabulated used SPSS software program.

Result and Discussion

The age of the subjects is categorized into the age range 6-8 years and 9-13 years due to the age of primary school children generally aged 6-13 years. In Table 1, the number of study subjects aged 6-8 years who had a DMFT score > 5 of 89.1% and a group of 9-13 years of 100% had a DMFT score of > 5. P value was 0.004 which showed a significant result between age and severity of caries.

A person’s self-assessment on dental and oral health is categorized into students’ assessment of their teeth and gums that are considered bad or good. In Table 2, the number of study subjects who had good self-assessment of teeth and gums with DMFT score > 5 (75 children) was greater than the group that had poor self-assessment of teeth and gums (40 children) of 93.8% of the total sample. P value was 0.106 which showed insignificant results between a person’s independent assessment of oral dental health and caries severity.

The frequency of brushing teeth is categorized as twice a day or more, and less than twice a day. With reference to Table 3, the percentage of the results of the study subjects group who brushed their teeth less than twice a day has a DMFT score of more than 5 compared to those who brush their teeth more than twice a day at 98% of the total sample. P value obtained was 0.333 which reflected there were no significant results between the frequency of subjects brushing their teeth and the severity of caries. Cross tabulation between the
frequency of brushing teeth and the severity of caries had an odds ratio of 2.866.

Psychological disorders due to health problems of the teeth and mouth of the students are categorized into there are disorders (there are) or no interference. In Table 4, the number of study subjects who had physiological distress due to dental and oral health disorders had a DMFT score of > 5 (47 children) compared to groups that did not have psychological disorders due to dental and oral health (68 children) of 97.9% of the total sample. $P$ value obtained was 0.351 which showed insignificant results between psychological disorders due to dental and oral health and the severity of caries. Cross tabulation between psychological disorders due to dental and oral health and severity of caries had an odds ratio of 2.765.

Physical disturbances due to health problems of the teeth and mouth are categorized into disruption (there is) or no interference. In Table 5, the results of the study implied that physical impairments due to dental and oral health disorders that had a DMFT score of more than 5 compared to the group that did not have physical impairment due to dental and oral health amounted to 96.2% of the total sample. $P$ value was obtained at 0.8 which showed insignificant results between physical disturbances due to dental and oral health and the severity of caries. Cross tabulation between physical disorders due to dental and oral health disorders and severity of caries has an odds ratio of 1.154.

**Discussion**

In this study assessment of caries severity among the public elementary school students of Puskesmas Keputih was done using a DMFT / deft measuring instrument which is an index of measurement of damaged dental caries (cavities). The severity of caries can be affected by several associated risk factors. The number of research subjects was 120 students. The data obtained in the study showed that the DMFT score was 5 and the median is 5, with 89.5% of children having caries.

Among children aged 6-8 years, the caries severity was higher than the 9-13 year old age group. In the cross tabulation, p value <0.05, where there was a significant relation between age and severity of caries. For the 6-8 years age group, 41 children had a DMFT score of >5. This was consistent with the theory that as the child ages, the child will have better knowledge in maintaining the cleanliness of his/her teeth and mouth. Lack of knowledge among children about dental health compared to adults affected them in cleaning their teeth.

Physical disorders when cross-tabulated with DMFT, 96.2% (with a significance test of p> 0.05 with odds ratio is 1.154) of the students had high caries severity that caused a mastication disorder and eventually absent from school due to dental pain. Dental caries that occur in children’s teeth will cause pain till the children will become lazy to eat whereby this can affect the BMI. Based on the odds ratio, it is illustrated that children who have physical impairments due to dental and oral health problems are at risk of 1.1 times to be affected by caries.

Psychological disorders such as embarrassment with the condition of his/her teeth when cross-tabulated with DMFT, was found that 97.9% with a significance test of p> 0.05 with an odds ratio of 2.765 that those suffering from high caries severity had a psychological disorder which caused the feeling of shame with his/her teeth. Oral health in children will affect the growth of teeth and jaw, speech function, aesthetics, acute infection, sleep disturbances, and severe caries at risk of taking longer breaks. From this study it can be justified that in groups with a higher number of dental caries experience (DMFT > 5) also agonized from a high psychological disorder of 97.9%.

Dental and oral health among children is an important factor that must be considered at early stage because tooth decay that occurs in the young age of children can affect the tooth growth at a later age. Besides that, childhood is the beginning of the formation of behaviour. Health behaviour is formed from several factors such as knowledge, attitudes, belief, physical environment, health facilities and infrastructure availability and health programs availability.

**Conclusion**

In conclusions, the students had higher risk of severity dental caries included aged between 6 years old and 8 years old, those had experienced lower severity caries, those felt there was a psychological and physical disorder and visited dentist in past 12 months.

Medical Diagnosis using Machine Learning

Kiruba.J¹, Visalakshi.R², Vaishnavi.A², Ahalya.R², Keerthi.Ra²
¹Assistant Professor, ²Student, Department of CSE, Karpagam College of Engineering, Coimbatore-32

Abstract

Machine learning is one of the fast growing aspect in current world. Machine learning (ML) and Artificial neural network (ANN) are helpful in medical diagnostic task, detection and diagnosis of various disease. The information required for diagnosis is typically gathered from a history and physical examination of the person who is in need of medical care. The aim of this paper to examine the applications of machine learning and artificial neural network in medical and data science field. In specific, we have chosen the disease dengue. This targets on dengue fever prediction, symptoms of a patient, using a data mining tool for the accurateness. Climate change is the main cause of dengue. There is a need for active input from health sector to ensure development and prevention about local and global environment.

Keywords: Machine Learning, Artificial Neural Network, Dengue, Health Sector

Introduction

Contrary of dengue infection has increased since early 1940’s. This is due to increase in population growth, ineffective mosquito control, climatic change³. Today, approximately 45% of people live in regions of the world where they have the risk of getting affected by dengue. The dengue virus spread easily by transmitting to humans via a small bite of an infected mosquito⁴. When a mosquito bites a person who is already affected by dengue in his or her blood, mosquito becomes infected with a dengue virus. Dengue cannot be spread directly from one to one, mosquitoes are needed for transmission of the dengue virus.

Artificial Neural Networks

An artificial neural network attempts to account for the parallel nature of human brain. An (ANN) is high network of interconnecting processing elements. Subgroup of processing element is called as layer. The input layer is first layer and output layer is last layer. Between input layer and output layer there is also a hidden layers. Medical diagnosis using (ANN) is a very active research in medical field. By the classification Artificial neural networks classified into categories such as supervised and unsupervised. In supervised, network is trained by its own input and output while unsupervised is as self-organizing map and provided only with its input. The network needs to develop its own input stimuli. The self-organization by clustering input is to inherent the problem description⁴.

Creating the database

In the process of creating the database for neural network it needs idea that clinical status of patients. The data which contain inaccurate information about the patient cannot be used. Often these days basic information
about the patient, results of biochemical analysis and symptoms to detect the correct disease. Database should contain sufficient amount of details about the patients and reliable patterns which characterize the diagnosis. This will enable you the training process of neural network in data science and to used to generalize patient’s diagnostics4. The database structure has a form of table or matrix containing information about patient’s health condition and their diagnosis.

MLP NETWORK STRUCTURE FOR DISEASE CLASSIFICATION

Initial idea of medical diagnosis with MLP to be used in hidden layer and output layer. Inputs are represented as medical parameters in medical field. Hidden neurons are experimented and evaluated successfully. If hidden neurons are large and its able to generalize. Details of patient’s diagnosis are applied to MLP. And it is suitable to training, testing, evaluation and validation.

Case Study about dengue disease

The dengue virus is spreading everywhere through a mosquito-to-mosquito-to-human cycle of transmission2. After 3-5 days being bit by mosquito, a person gets infected. Aedes aegypti develops vitamin, where there is a possibility of high level dengue virus in blood level. Mosquitoes have a difficult life cycle. Aedes aegypti is the primary vector. Dengue have the great risk in high population areas6.

Aedes aegypti principal vector of dengue disease is seen between the latitudes 35°N and 35°S. The annual case of dengue fever in South East Asia is found to be 200000 in 90s6. Dengue virus antigen can be found in different tissues of our body but it is mainly found in liver and reticuloendothelial system2. Travellers travelling to endemic areas are found to be affected by dengue disease. Travellers are advised to protect themselves from mosquito bites while travelling to endemic areas. During genotype cycle the mosquito takes more than one meal blood. Dengue epidemics are happened during the warm, rainy and humid season which is favor for the mosquito.

Figure 2. MLP Network Structure

Figure 3.1. Case study

Clinical diagnosis and Features

Clinical diagnosis may vary based on the age of the patient and clinical in apparent infections. Clinical in apparent infection is classified into five different types: Classic dengue, dengue haemorrhagic fever, febrile illness, dengue shock syndrome and other syndromes such as fulminant liver failure and encephalopathy. Dengue is seen more commonly among adults and older children compared to school children (children under 15 years). The symptoms are: Headache, High fever, vomiting and nausea.

Diagnosis using Neural Networks

The Artificial neural networks (ANN) have distinct advantages over statistical classification methods. The ANNs are suitable in cases, where traditional classification methods fail, because of noisy or incomplete data. Neural networks also benefit in multivariable classification problems with a high correlation degree in medical diagnosis. Based on the generalized model, we
can then classify input patterns based on symptoms of diseases. The disease diagnostics process can be divided into training and diagnostic part. The neural network is trained using database. The patient’s data are processed by the neural network which is determined by the probable diagnosis methods. The final diagnosis is the result of physicians decision who evaluates all aspects of the disease and results in neural network classification.

Figure 4. Training & Diagnosis

Surveillance of vector borne disease

There are several surveillance for different type of vector borne disease. But early warning systems are not yet found due to the environmental factors, dynamic and complex nature of the disease. Early warning system includes targeting surveillance, detecting potential threat and control methods3. To create early warning system using information like environmental, climate, host and vector through different process such as mathematical modeling and geographical information system been used to enhance surveillance system.

Overview of ANNs in medical Diagnosis

There are many reviews about the application of ANNs in medical field. The general application of ANNs is of data and diagnostic classification of patient’s with uninvestigated dyspepsia in gastroenterology and in search of biomarkers. The amount of data coming from instrumental and clinical analysis of these diseases quite large. So that development of tools to facilitate diagnosis is of great relevance.

Dengue disease

The clinical features of dengue vary with the age of patient. It can be classified into five presentations: non-specific febrile illness, classic dengue, dengue haemorrhagic fever, dengue haemorrhagic fever with dengue shock syndrome and other unusual syndromes such as encephalopathy and fulminant liver failure.

Classic dengue is more commonly seen among children and adults. Dengue is abrupt in onset, typically with high fever accompanied by severe head ache. Recovery may be prolonged and include depression. Dengue haemorrhagic fever is primarily a disease children under 15 years in hyperendemic areas. The disease is characterized by increased capillary permeability and haemostatic changes. Enlargement and tenderness of the liver has been reported in up to 50% of patient’s. Mortality can be high as 20-30% without early appropriate treatment, but it is as slow as 0.5% in hospitals with staff experienced in the disease. Warnings that dengue syndrome include vomiting, abdominal pain, level of consciousness and fever to hypothermia and decrease platelet count1.

Figure 5. Classification

Cancer

According to the survey, there will be more than 2 million newly diagnosed cases of cancer in US. Diagnosis is essential for the clinical management of cancer including more suitable therapeutic approach. The application of neural networks on defined data sets was evaluated in 1994 for cancer. Moreover, advanced analytical method, mass spectrometry can offer suitable information for clinical relevant ANN analysis. This technique has been applied successfully in the diagnosis of cancer. The integrated feed-forward ANN classifier showed an overall sensitivity of 98% and a specificity of 96% in medical field. Therefore ANNs have been used in various primary data, ranging from clinical parameters to bio-chemical values and provide increased diagnostic accuracy for various kinds of cancers.
Diabetes

It represents a serious health issue in developed countries. The most common kind of diabetes is type II, in which cellular response to insulin is impaired leading to disruption of tissue homeostasis and hyperglycemia. The ANNs extrapolate glucose concentrations from spectroscopy to monitor glucose level. For this particular purpose biological variables such as age, weight, gender fasting plasma glucose where used as input data. Results were compared with those from traditional statistical methods. As a control strategy trajanoski and colleagues combined ANNs and non-linear model predicted controlled. A sensitivity of 79.30 and specificity of 60.53% was actually, better values than those obtained using other approaches such as statistical method³.

Overall Analysis of Dengue Prediction

Figure 6. Overall Analysis of dengue

Conclusion

Dengue is a most threatening disease caused by mosquitoes. In our research work and dengue disease prediction is done using ANN in medical diagnosis¹. ANNs represent a powerful tool to help physician perform diagnosis and other enforcements. ANNs have proved to be suitable for satisfactory diagnosis of various diseases. Methods of summarizing and elaborating and intelligent data and on informative data are continuously and can contribute greatly to effective, precise and swift medical diagnosis. ANN shows significant results in dealing with data represented in symptoms. Thus, the results demonstrate the effectiveness of proposed system⁵.

A Study on Relationship between Internet Usage and Anxiety among Primary School Students

Mohd Rustam Mohd Rameli¹, Loh Shu Wen² & Najua Syuhada Ahmad Alhassora¹, Mohamad Rasidi Pairan³

¹Senior Lecturer, ²Master Student, School of Education, Universiti Teknologi Malaysia, Malaysia

Abstract

The main objective of this study was to investigate the difference in internet usage and the anxiety level of Chinese primary school students in Johor Bahru, Malaysia across gender. The study was also carried out to identify the correlation between the internet usage and anxiety level among students. A total number of 396 primary school students from the Chinese primary schools in Johor Bahru, Malaysia have been involved in this study who are sampled by using stratified simple random sampling technique. From the study, it was found that excessive internet usage could occur in students of any gender depending on their patterns, purposes or motivations of using internet. However, male students tended to involve in excessive internet usage. There was no significance difference between the mean of total Internet Addiction Test (IAT) score of male and female students. There was a significance difference between the mean of total and Child Anxiety Symptom Checklist (CASC) score of male and female students. Female students tended to be troubled by the anxiety symptoms. Internet usage could predict the prevalence of anxiety problem although the correlation was weak. The findings of the study are to create awareness among parents, teachers, schools and community regarding the issue of excessive internet usage and anxiety in children, as well as to enrich the current empirical research data and theoretical evidence in Malaysia especially for primary school students.

Keywords: Internet usage, anxiety, correlation, primary school students

Background of Study

In Malaysia, there is 76.9% of Internet users reported in 2016 according to a survey administrated by MCMC CATI Centre in Cyberjaya ¹. The survey found that 83.2% of children aged between 5 and 17 are Internet users ¹. Most of the children spend their time online in text communication, social networking, online gaming, searching tools and videos viewing ¹,². As children grow up, the purposes of using Internet will also be varied and expanded³,⁴. Some students, especially children, spend plenty of time on using Internet because they gain more satisfaction on Internet compared to their daily real life⁵. This scenario is not a good sign and should be highly concerned by parents or caregivers.

In Malaysia, a study has been carried out by Ke, Wong and Marsh⁶ on the problematic Internet usage among university students. The results showed that majority of the students (57.5%) were having moderate Internet addiction and most of them were addicted to the social networking sites (SNS). These students on the other hand showed the symptoms and behaviours of having depression, anxiety and stress problems. The research also examined on the relationship between pathological Internet usage and mental health and the findings showed that there was a significant, positive correlation⁶. The more addicted the university students in using Internet, the greater the tendency of developing mental health problems such as depression, anxiety and stress⁵,⁶,⁷,⁸.

Excessive Internet usage which causes Internet addiction can result in emotional instability that leads to tension, anxiety or depression ²,⁷,⁸. Internet users who have addicted to Internet are most likely to have
emotional instability where the Internet addiction has shown negative impact as well as disturbance on their mood, tolerance, patience and judgment. They have higher risk of suffering from psychological problems including stress and loneliness which eventually could affect academic performance or lead to cyber bully.

According to the study of Gholamian, Shahnazi and Hassanzadeh, younger generations such as children and adolescents are more prone to excessive Internet usage or Internet addiction and problems caused by the following issue such as anxiety, stress and depression. Children are believed that they are lack of skills and not capable yet to cope with the inappropriate content online, cyber bully and online scam. Long-term exposure to the negative issues from Internet might cause emotional disturbance to them.

The prevalence of Internet addiction is higher in males than females according to most studies, while some show higher rate in females. The differences between male and female in Internet addiction resulted from the patterns, motivations, or purposes of using Internet. On the other hand, the gender difference of the prevalence of anxiety disorder showed that females were usually reported to have higher prevalence of anxiety disorder than males at a younger age of onset. For elder age, females were more easily influenced than males in terms of emotion and they showed higher rate in fear extinction compared to males. According to Lebron and Milad, the anxiety-related neurotransmitter systems and fear extinction are significantly affected by the female gonadal hormones such as oestrogen and progesterone. In contrast, testosterone, the male gonadal hormone, has been found to have the function of reducing anxiety by reducing the reaction of stress. Therefore, the gonadal hormones of females are likely to play a role in increasing the prevalence and severity of anxiety disorders in females.

Research on the impact of excessive Internet usage has been carried out in many countries but lack in Malaysia. Most research regarding the following issue studied on adolescents or students of age above 16 but less in students of age 12 or below. Therefore, further study on this area should be conducted to improve the current empirical research in children.

**Research Objectives**

The main objective of the study is to investigate the relationship between Internet usage and the anxiety level of Chinese primary school students in Johor Bahru. Besides, this study will also investigate the difference in internet usage and anxiety between male and female students.

**Methodology**

The research design of this study takes the form of the quantitative research approach. Statistical analysis of numerical data was done to deduct a conclusion to explain the issue. This research study was administered in 17 Chinese primary schools in Johor Bahru district of Johor state. This research applied stratified simple random sampling to determine the population samples. 386 students of Year 4 to Year 6 from the Chinese primary schools in Johor Bahru district had been randomly selected as the samples of the study.

The survey contained three sections, Section A for demographic background and related information, Section B for Internet Addiction Test (IAT) and Section C for Child Anxiety Symptom Checklist (CASC). The instruments used in this study were adopted from other researchers and had been modified by the researcher according to the cognitive level of the respondents. The constructs that were measured by IAT included salience, excessive use, neglect work, lack of control and lack of social life. The CASC measured the following constructs including generalized anxiety disorder, social anxiety, panic attacks or panic disorder, separation anxiety, specific phobia, emetophobia or fear of throwing up and obsessive-compulsive disorder. Pilot test was carried out on a group of Chinese primary students to measure the validity and reliability of the instruments. Both IAT and CASC showed high reliability, in which the Cronbach’s alpha showed 0.81 and 0.88 respectively. The items in the instruments had been revised for better reliability and validity purpose. All items in the IAT were accepted and remained, while only 32 items were included in the CASC after revising. The instrument IAT and CASC both based on Likert-like scale of 4 points. The total score of the scale were analysed to determine the level of Internet addiction and anxiety symptom the students have.

**Findings**

Table 1 showed the test statistics for the total IAT score of male and female primary school students. The significant value, .093, was greater than the alpha value,
.05, thus failed to reject the null hypothesis. There was no significance difference between the mean of total IAT score of male and female students (z = -1.682, p = .093). The results suggested that there was no significant difference in Internet usage between male and female students.

Table 1: Test Statistics for the total IAT score of male and female primary school students

</tr>
<tr>
<td>Z</td>
<td>-1.682</td>
</tr>
<tr>
<td>Asymp. Sig. (2-tailed)</td>
<td>.093</td>
</tr>
</tbody>
</table>

Table 2 showed the test statistics for the total CASC score between male and female students. The significant value, .000, was less than the alpha value, .05, thus rejected the null hypothesis. There was a significance difference between the mean of total CASC score of male and female students (z = -3.983, p = .000). The results suggested that there was a significant difference in level of anxiety symptom between male and female students.

Table 2: Test Statistics for the total CASC score of male and female primary school students

<td>-3.983</td>
</tr>
<tr>
<td>Asymp. Sig. (2-tailed)</td>
<td>.000</td>
</tr>
</tbody>
</table>

Table 3 presented the correlation between the total scores of IAT and CASC. There were 386 respondents (N) in each condition. The correlation coefficient was .160. This meant that the correlation between the total scores of IAT and CASC showed weak correlation. The significant value of the correlation between the total scores of IAT and CASC was .002, was lower than the alpha value, .05. Thus, the tests rejected the null hypothesis. There was a significant difference between the correlation of the Internet usage and the level of anxiety symptom among students (r = 0.160, p = 0.002). The result suggested that there was a weak, yet positive correlation between the Internet usage and the level of anxiety symptom among students.

Discussion

According to the findings, there was no significant difference in Internet usage between male and female primary school students. The findings showed that male students had higher prevalence of excessive Internet usage than female students as supported by several past studies. This might be due to the low self-controllability of male students in using Internet in which they were more likely to involve in excessive usage of Internet than female students. This study had proven that excessive Internet usage did not necessarily occur in specific gender because there was no significant difference in Internet usage between male and female students. The gender gaps in accessing Internet had been reducing as Internet access at home and school were becoming more common. Both male and female students might show equivalence of Internet usage but the patterns, purposes or motivations of using Internet would be different as supported by Mok and MCMC.
The results suggested that there was a significant difference in level of anxiety symptom between male and female primary school students. The findings showed that female students had higher prevalence of anxiety problem than male students. According to most studies, females were usually found to have higher prevalence of anxiety disorder than males at a younger age\textsuperscript{13-14}. This was probably because females were easier to be influenced than males in terms of emotion due to the gonadal hormones of females in increasing the prevalence and severity of anxiety disorders in females\textsuperscript{15-16}. Females showed fear extinction more easily compared to males\textsuperscript{15}. In contrast, male gonadal hormone was reported to have the function of reducing anxiety by reducing the reaction of stress\textsuperscript{17}. Furthermore, females were more protected by their parents since young age. Therefore, the parenting style of protecting female children physically had increased their feeling of vulnerability\textsuperscript{20}. Male children would be encouraged and praised for their assertiveness and independent more than female children and that gave the males stronger sense of security that they had control over the environment\textsuperscript{20}.

The findings showed that there was a weak, positive correlation between the Internet usage and the level of anxiety symptom among Chinese primary school students in Johor Bahru. There was a positive correlation between the Internet usage and the level of anxiety symptom among primary school students. Hence, Internet usage level of students was able to predict the prevalence of anxiety symptom among them. The correlation was weak as primary school students were less likely to suffer from anxiety problems due to the protective parenting for children at age below 12\textsuperscript{21}. Furthermore, the Internet usage level of students in the study was in average level and that did not precisely predict the prevalence of anxiety problems as followed by the influence of excessive Internet usage.

**Conclusion**

This study focused on the relationship between Internet usage and anxiety among Chinese primary school students in Johor Bahru. It was found that excessive Internet usage could occur in students of any gender as there was no significance difference in Internet usage between male and female students. However, male students showed slightly higher tendency of excessive Internet usage probably due to their lower self-control than females\textsuperscript{18}. Furthermore, female students had higher tendency to be troubled by the anxiety symptoms most probably due to the female gonadal hormones that stimulated the prevalence of anxiety feeling and the overprotecting parenting style that might cause them to be more vulnerable to fear and anxiety\textsuperscript{19,20}. There was a weak, positive correlation between the Internet usage and the anxiety symptom among students in this study. Internet usage of an individual could predict the prevalence of anxiety problem in that individual, although the correlation was weak. It was believed that primary school students were less likely to suffer from anxiety problems due to the protective parenting for children at age below 12\textsuperscript{21}. There were also some implications to enrich the current theoretical evidence in Malaysia and for authorities in concern with the issues. Several recommendations had been suggested for future studies in order to enrich the empirical research data in Malaysia, especially for students of age below 12.

Abstract

The rising issue of food borne diseases due to unhygienic food preparation is burgeoning in our society. The risk of food contamination largely depends on the hygiene practices of food handlers. However, previous studies had shown that hand hygiene practices is often neglected by the food handlers. This study sought to evaluate the perceived hand washing knowledge among food handlers with reference to the proper hand washing procedure as well as the knowledge on appropriate times to wash hands. The study sample is comprised of 146 food handlers who were selected by means of random cluster sampling. The questionnaire used was adapted from previous studies on hand washing. Data were analyzed using descriptive statistics. Findings revealed that hand washing knowledge scores among food handlers were high where 84.9% respondents had good knowledge with score ≥ 70%, 14.4% respondents had satisfactory knowledge with score range of 50 to 69%. Only one respondent had a poor knowledge of hand washing (score below 50%). However, outcome from the study also indicated that there are some misconceptions concerning proper hand washing practices and appropriate times to wash hands. Thus, leads to a conclusion that although food handlers had knowledge of how and when to wash hands, some of them shows that they had a misconception of a certain facts on hand washing.

Keywords: Hand washing, food handlers, school food service.

Introduction

Hand washing is well-known as an important routine to prevent food-borne diseases and cross-contamination from hands to foods. Previous studies had shown that inadequate hand washing by food workers is one of the factors that contribute to the food-borne disease outbreaks in retail food establishments. Previous study proposed that there are two factors which influence microbiological contamination in foods which are poor status of hygiene and poor food handling practices¹. Currently, the importance of food handlers’ hand washing behaviour has prompted a number of studies investigating their knowledge, attitudes and practices of hand washing²⁻⁵. The community was well aware of the unhygienic practices and diseases associated with them, but they failed to apply the principles of hygiene in daily lives⁶. A study on food safety knowledge among food workers found that respondents who were certified in food safety had higher knowledge test scores than those employees who were not certified⁷. Food handling training and education should be targeted to both managers and food workers. Operations with food safety certified personnel practiced a greater number of appropriate food safety practices than those without a certified employee. Knowledge could contribute to the changes in attitude. Realizing the importance of

DOI Number: 10.5958/0976-5506.2019.00900.8
knowledge, other researches in this area also sought to measure knowledge towards hand hygiene. However, evidence also shows that high level of food-related knowledge was not an assurance of good food handling practices. Some studies had proven that food handler’s practices during food preparation process were not always consistent with the accepted standards.

There is a need to explore in-depth factors associated with training effectiveness because training that emphasizes in knowledge acquisition does increases the knowledge level regarding food safety. However, it does not always result in a positive change in food handlers’ behaviour. The results were similar to the various studies on food safety behaviours which indicate that knowledge solely will not ensure compliance to standard food hygiene practices although it is one of the necessary components of behaviour change. Hand washing is often being neglected in actual food handling practices as supported in a study where the authors found negligence as one factor among food workers. Food handlers’ training that emphasized on food hygiene and safety supposed to be one of the best strategies in increasing awareness among food handlers. Nonetheless, the findings from past researches imply that some food handlers who had attended food hygiene educational courses or training may not have understood the real aim of the training. Therefore, prompt action should be taken to encounter these discrepancies. The current study seeks to identify the perceived hand washing knowledge among food handlers in the school food service operations with reference to the proper hand washing procedure and appropriate times to wash hands at workplace.

Method

The sample included 146 food handlers in hostels kitchen from two types of boarding schools in Peninsular Malaysia. A cluster-stratified random sampling method was applied to select the sample from the selected schools. The knowledge assessment instrument was developed using references from the Malaysia Ministry of Health (Food Hygiene and Food Safety Guidelines) and past studies. Frequency analyses were applied to determine respondents’ response on each of the statements in the questionnaire. Knowledge section consisted of 19 statements covering aspects of knowledge about the proper procedure to wash hands and the appropriate times to wash hands. Respondents were asked to choose from among three options – true, false or do not know. A “do not know” answer was considered as wrong answer. Each correct answer was given one (1) mark and each wrong or do not know answer was given zero (0) marks. The score range was between 0 and 19, for there are 19 statements in the knowledge section. This score were then converted to 100 points. The classification for knowledge score of the respondents are “good knowledge” (score equal to or above 70%) and satisfactory knowledge (50-69%). Respondents that scored below 50% for knowledge were considered as “poor knowledge”.

Results and Discussion

Table 1 shows the findings related to food handlers’ knowledge on proper hand washing procedure. Most respondents are aware that there are seven steps of correct hand washing as recommended by Ministry of Health, Malaysia. Majority of the respondents (74.7%) answered item 2 correctly by indicating the statement “soaps should be used for visibly dirty hands only” as “false”. Pathogens cannot be seen on hands and water alone is not always sufficient to remove them. Food handlers should have the knowledge where hands should be washed using soaps as appropriate technique for hand washing includes the use of soap. Most of the respondents answered the statements correctly for item 3, item 4, item 5, item 6, and item 7. For item 8, there are a number of respondents (12.3%) who reported that their apron could be used for drying hands after washing their hands. This shows that some of the respondents lacked of knowledge in terms of the use of a proper medium for drying hands.

Quite a number of food handlers are lacking of knowledge on appropriate times to wash their hands. As shown in Table 2, 17.8% of the respondents indicated “true” response on the statement that they do not have to wash hands before handling dry type of foods. About 8.9% respondents reported wrong answers on an item regarding there is no need to wash hands after washing face at the toilet. Food handlers have to make sure they clean their hands after entering the washrooms even if they just washing their face and not using toilets. Most of the times, they need to touch the dirty doorknob while they leave the toilet. Therefore, if they had entered the washrooms, they have to wash their hands once again before they continue with their task in the kitchen.

</table>
Hands should be considered as dirty after someone touches their mouth, nose, scalp or any parts of the body. For that reason, good hand washing practices should always be adhered. However, findings suggest that 11.0% of the respondents think that this practice is unnecessary. Hands must be washed each time after handling raw food. However, 17.8% of the respondents perceived they do not have to wash hands after handling raw food. About 15.8% respondents perceived that there is no need to wash hands after handling dry trash such as paper. About 11.0% of respondents gave wrong answers on the statement that hands must be washed each time after re-entering the kitchen at designated break. There are 19.2% respondents who agreed that there is no need to wash hands after cleaning and disinfecting the workstation. This is contradictory to the fact that hands should washed before returning to food preparation after cleaning equipment or food contact surfaces. Several respondents (13.0%) perceived that there is no need to wash hands each time after smoking. This finding is consistent with previous study\textsuperscript{12} which reported a lower proportion of food handlers who wash hands after smoking. Some of the food handlers (24.0%) perceived it is unnecessary to wash hands properly while wearing gloves. Most of the times, wearing gloves may give false sense of security\textsuperscript{24}. Food handlers should aware that they need to change the gloves frequently and properly wash their hands before and after they wear new gloves. There is a need to increase food handlers’ knowledge on the appropriate times to wash their hands properly while performing their job responsibilities in the kitchen.

Overall, the mean for hand washing knowledge score was 15.63 with the standard deviation of 2.17. Figure 1 below shows the hand washing knowledge score obtained by the respondents. About 124 (84.9%) respondents had good knowledge on hand washing with score $\geq$ 70%, 21 (14.4%) respondents had satisfactory knowledge with score range of 50 to 69%. Only one respondent had a poor knowledge of hand washing (score below 50%).

![Figure 1: Hand washing knowledge scores among food handlers](image)

Additionally, food handlers were classified into with- or without certification in order to assess any significant difference between these two groups in terms of their hand washing knowledge. The differences between these two groups of food handlers were determined by independent sample t-test. Result shows that there is no significant difference between food handlers with certification and without certification ($p$>.05).

*The mean difference is significant at the .05 level.*

Inadequate hand washing by food workers is an important factor that contributes to the food-borne disease outbreaks in retail food establishments. Findings indicated most respondents are aware that there are seven steps of correct hand washing as recommended by Ministry of Health, Malaysia which was initially intended for people working at food service facilities, where a lack of such knowledge may lead to a major outbreak of food poisoning. Providing health education in food and personal hygiene to food handlers and incorporating these aspects in existing guidelines for food establishment is important so that food handler’s practices could be improved.

However, outcome of the study indicate that there are many misconceptions regarding proper hand washing practices and appropriate times to wash hands. The results are aligned with previous study which showed that although hand washing knowledge scores were high, hand washing practices were not always consistent with the accepted standard. In the current study, more than half of the respondents had not participated in any food hygiene courses other than Food Handlers Training which is mandatory for them. These show that food handlers have very limited continuous education that specifically targeted on their job practices. Provided that there are no significant differences between food handlers who received formal food hygiene training and those who had not, the finding is quite similar from several studies that found no significant impact from food hygiene education on KAP (knowledge, attitude, and practice) of food handlers. This could be due to the variation in the approach of the training and education.

**Conclusion**

The improvement of existing training and education for food handlers in Malaysia on hand washing practices should be done promptly. As suggested by previous study, incorporating regular education for food handlers is likely to improve the existing practices. Findings on the misconceptions of food handlers regarding hand hygiene knowledge demonstrate that there are several areas where education and training could be improved to promote hand washing. This also aligned with previous studies which concluded that an improved education and training should include a comprehensive on-premise class with detailed explanation of types of food-borne illnesses and its symptoms. The personal hygiene of the respondents can be improved through a better understanding of the factors influencing hand washing and cross contamination from hands to food.

Abstract

The study examined the determinants of marital adjustment among married civil servants in Ogbomosho metropolis, Oyo State, Nigeria. The study also examined the gender difference in respondents’ view of determinants of marital adjustment. Using a descriptive survey, purposive and convenient sampling techniques were used to select 384 respondents who participated in the study. The data collection tool was a self-designed instrument entitled “Factors Influencing Marital Adjustment Questionnaire” (FIMAQ), with 0.72 test re-test reliability coefficient. Factor analysis and independent t-test were used to analyses the data collected and the hypothesis was tested at 0.05 alpha level. The findings revealed that communication, a gap in couple’s age, a gap in couple’s educational attainment, sexual fidelity, personality differences and expectations before marriage are the determinants of marital adjustment among married persons in Ogbomosho metropolis. Also, a significant difference was found between male and female respondents on determinants of marital adjustment. Relevant recommendations were made based on the findings of the study.

Keywords: Marital Adjustment, Married Persons, Self-Designed Instrument

Introduction

Marital adjustment seems complex than it may appear. Basically, in marriage, two persons adjust to each other’s socio-emotional and psychological function. On the personality level, a couple must adjust to diverse marital issues, including such matters on relatives, children, provision and preparation of food, friends and occupation¹. Marital adjustment has four main components including dyadic satisfaction, dyadic cohesion, dyadic consensus and affection expression. According to ², dyadic satisfaction consists of the rate of happiness in relationships and also the frequency of experienced conflicts in communication. Dyadic cohesion is the rate of cohesion couples have over important affairs like managing economical issues of family and making important decisions. Dyadic consensus refers to the fact that how often couples are involved with the common activity and affection expression is also related to the fact that how often couples express affection and love to each other.

Marital adjustment is harmony and empathy in achieving common goals of life between husband and wife that leads to satisfaction from living together. Marital adjustment is one of the expressions used extensively in a family. This expression is related to many other expressions like marital success, marital happiness and marital satisfaction ³. Marital adjustment is a multi-dimensional expression that clarifies different levels
of marriage and it is a process undertaken by couples to understand individuals’ tastes, personality features, the establishment of behavioral laws and forming relationship patterns. Different aspects of life’s quality such as spiritual inclination of couples, satisfaction from life, self-efficacy, satisfaction from a job, educational success and even the length of a lifetime are all indices of marital adjustment.

Researcher explained the realistic indices of marital adjustment as spouse’s agreement on matters critical to maintaining their union, they share common activities and interest that enhance family growth as well as demonstrations of affection and mutual confidences. These would help the marital dyad’s ability to cope with day to day activities and life issues. Couples who are happy and satisfied with their marital life have few complaints about their relationship and few doubts about the certainty of the marriage’s chance of succeeding. Thus, marital adjustment is achieved when spouses get along with each other to achieve a harmonious working relationship in different areas of their life. Adjustment between husband and wife allows them to avoid conflicts or to solve them appropriately, in a way that they both feel satisfied with the marriage and relationship with each other.

There are different factors that may determine marital adjustment among couples. Finance is one of the major factors. Financial problems put an erroneous strain on a family relationship. Variables such as changes in growth and development, individual differences, home conditions, family size, human needs, parental attitudes and child training practices could also be associated with marital adjustment. Poor and weak communication is an index of marital maladjustment, lack of information exchange may itself impede resolution of difference and interpersonal tension. Hence, for couples to overcome diverse marital problems and adjust effectively in their relationship, they need to understand each other in all facets of human dynamism.

Many marriages have ended in divorce or passive relationship as a result of these experiences. Contemporary couples are exposed to frustrating experiences such as social assault from in-laws, the problem of childlessness or barreness, poor communication and a breakdown of a marital relationship. All these constitute a serious threat to marital stability and family cohesion in the country. Based on the meta-analysis of the previous studies such as 6, 10, 11, 12, 13, there are large volumes of studies on marital adjustment of couple but less attention has been paid to factors influencing marital adjustment of married persons, particularly in Ogbomosho, Oyo State. This prompted the researchers to, therefore, examine the determinants of marital adjustment among married civil servants in Ogbomosho metropolis.

**Method**

**Procedure**

The researchers administered the instrument on the selected respondents among married civil servant in Ogbomosho metropolis Oyo state, Nigeria, having sought for their consent to participate in the study. The researcher also assured the respondents full confidentiality to be able to free and to give honest opinion and their names is excluded.

**Sample**

Sample, sample size 384 civil servants participated in the study. Civil servants in 12 different government ministries and Local Government secretariats were purposively located. Convenient sampling technique was used to distribute the questionnaire to every subject that the researchers met in those secretariats.

**Instrument**

The instrument used for this study was a self-designed questionnaire entitled “Determinants Marital Adjustment Questionnaire” (DMAQ). The questionnaire consists of two sections. Section A focused on the demographic data of the respondents. Section B contained twenty (20) items on factors influencing marital adjustment of married civil servants in Ogbomosho metropolis. A test re-test reliability test was conducted on the instrument and a coefficient 0.72 was obtained. Based on this, the instrument was adjudged reliable for the study.

**Data Analysis**

The data collected were analysed using a factor analysis and t-test statistics.

**Research Questions:** What are the determinants of marital adjustment among married civil servants in Ogbomosho metropolis?

Tables 1 showed variables or items on the independent variable subjected to a factor analysis using Principal Axis Factoring and Orthogonal Varimax Rotation. The table shows that all KMO values for the individual items (> .90) were well above .5 and the Kaiser-Meyer-Olkin measure (KMO) was .723, indicating that the data was sufficient for Exploratory Factor Analysis. The Bartlett’s test of Sphericity - \( \chi^2 \) (190) = 2218.964, \( p < .001 \) showed that there are patterned relationships among items 1 to 20 on the Determinants of Marital Adjustment scale. The Eigen-value cut-off of 1.0, shows there are 6 factors that explain a cumulative variance of 20.735% and the factor loadings after rotation using a significant factor criterion of .4 shows that, accordingly, items 1 (.724), 5 (.755), 19 (.786), 10 (.728), 9 (.733) and 14 (.757) are significant variables in the model. The items indicated communication, a gap in couple’s age, a gap in couple’s educational attainment, sexual fidelity, personality differences and expectations before marriage as the determinants of marital adjustment among married persons in Ogbomosho metropolis.

**Ho**: There is no significant difference in the determinants of marital adjustment among married persons in Ogbomosho metropolis on the basis of gender.

*Significant at \( p < 0.05 \)

Table 2 presents the calculated t-value of 3.78 which is greater than the critical t-value of 1.96 (\( p = .000 < 0.05 \)). This indicated that there is a significant difference in the determinants of marital adjustment among married persons in Ogbomosho metropolis on the basis of gender; hence, the hypothesis is rejected.

Discussion

The findings of the study revealed that communication, a gap in couple’s age, a gap in couple’s educational attainment, sexual fidelity, personality differences and expectations before marriage are the determinants of marital adjustment among married persons in Ogbomosho metropolis. The finding of this study is in line with the finding of 11 which revealed that communication is significant to a stable and satisfactory
marital relationship. Generally speaking, communication is the bedrock of every successful marriage. It is also the life wire of marriage relationship or any other meaningful relationship. Poor communication between a couple will lead to poor inter or intra personal relationship, therefore communication is the key to a strong, healthy relationship. It allows partners to feel love and being cared for; thus, enjoying a satisfactory marriage relationship.\(^\text{15}\) equally supported the need for effective communication between couples in order to ensure effective marital adjustment.\(^\text{16}\) also discovered that communication gap is among the causes of marital conflict in families; hence, that good communication network reduces the rate of marital conflict among couples and enhances marital adjustment.

It was also found that a gap in couples’ age at marriage determine their level of marital adjustment. The age difference, in the African context, speaks much about maturity, especially for a male spouse. Couples whose age differences are between 5 to 10 years tend to adjust better than couples who got married at between the age difference of 1 to 2 years. This is in line with \(^\text{17}\) who carried out a study on the relationship between marital satisfaction, age at marriage, and marital role performance. The study found that as the age at marriage increased, marital adjustment increased as well. The finding is in line with the findings of \(^\text{18}\) who reported that older age married individuals have shown statistical significant higher mean scores of marital adjustment than younger age married individuals.\(^\text{17}\) also showed the presence of a positive correlation between age at marriage and an overall score of marital adjustment i.e. older age married individuals had more marital adjustment than younger age married individuals.

Educational attainment\(^\text{21-22}\) of couples goes a long way in influencing marital adjustment the more the level of educational attainment marriage partners has, the greater the probability of good marital adjustment and the lower the probability of divorce. This is in line with the findings of \(^\text{19}\) which revealed that the level of education of couples plays an important role in the husband-wife relationship, especially in the early days of marriage. The study found also found that the female graduates had a closest love relationship with their husbands, while the less educated group did not say that they had a close relationship with their husbands.

There was a significant difference in the factors influencing marital adjustment of literate married adults in Ogbomosho metropolis on the basis of gender. This means that gender has a significant influence on respondent view of determinants of marital adjustment. This finding disagrees with the finding of \(^\text{20}\) who demonstrated that women and men are similar in their predictors of marital adjustment; meaning that positive correlation finding was true for both males and females.

### Conclusion and Recommendations

Based on the findings of the study, it is recommended that:

- Marriage counsellors should equip couples with communication skills that can be employed in their interaction in order to avoid maladjustment in marriage.
- Intending couples should ensure that there is a relative age difference (at least 5 years) between the husband and wife. The husband should be older than the wife so there can be respect for each other, thereby, adjusting effectively to the marriage relationship.
- Couples of similar educational background should get married so that they can adjust effectively to their marital life.
- The counsellors should encourage intending couples to go into marriage at a mature age so as to be mentally and physically prepared for challenges that could lead to maladjustment in marriage.

Relationship between Personality Traits and Preferred Academic Advising Style of Malaysian Public University Students

Norashuha Tajuddin¹, Hamdan Said², Faizah Mohamad Nor³
¹PhD Student, School of Education, ²Associate Professor, School of Education, ³Associate Professor, Language Academy, Universiti Teknologi Malaysia (UTM), Johor, Malaysia

Abstract

This descriptive study identified personality traits, preferred academic advising style, and the relationship between the personality traits and preferred academic advising style of Malaysian public university students. Student personality traits are classified into 15 categories while preferred academic advising style are categorized into prescriptive and developmental advising styles. A total of 401 undergraduate students from three Malaysian public universities participated in this study. The Sidek’s Personality Inventory and Academic Advising Style were employed for data collection in this study. The data was analysed using descriptive and inferential statistics. The finding showed that most students possessed helpfulness personalities and the majority of students preferred developmental advising style for academic advising process. The findings also showed that there is a positive relationship between student personality traits and preferred academic advising style of Malaysian public universities’ students.

Keywords: personality, academic advising, developmental advising, prescriptive advising, university student

Introduction

Academic advising is a process in which an appointed academic advisor assists students to develop their overall potential¹. Academic advising is the only planned and structured development program on campus where each student has the opportunity for one-to-one interaction with an academic advisor¹-². In this process, the academic advisor becomes a source of information related to curriculum and co-curriculum, university policies, and administrative procedures for students¹,²,³,⁴,⁵. They are the intellectuals who can assist students to address issues related to academic, personal, social, and career development⁵,⁶. Due to that effective academic advising is considered one of the best drivers to enhance the development of students and that which can help ensure that students are successful in their studies and possess positive attitudes towards lifelong learning⁶,⁷,⁸,⁹.

Many studies indicated that academic advisors can assist students to overcome various campus life challenges⁶,⁸,¹⁰,¹¹. Thus, students’ readiness to meet their academic advisors affects the process of academic advising³. Unfriendly interactions between academic advisors and students will influence the students’ desire to meet and seek advice from their academic advisors. This situation will affect their relationship and the implementation of academic advising process. Careful, caring and effective academic advisors enhance student-advisor relationships and the implementation of the academic advising process²,⁵,⁶,⁸,¹⁰-¹⁶.

The effectiveness of the academic advising process can be enhanced through the personality of the students. Personality is the qualities or characteristics that form an individual’s distinctive character¹⁷,¹⁸. Those qualities make someone different from others. As reported in many studies, students with different personalities possess different characteristics, thus, they may require different methods, techniques and advising styles¹⁷-²⁰. Thus,
academic advisors need to approach students, understand their personalities, backgrounds and other important things about them to ensure successful implementation of the academic advising process\textsuperscript{21}. Students would be more comfortable meeting and discussing with their academic advisors regarding their studies when they find that their academic advisors are caring, understand their problems, and guide them according to their needs\textsuperscript{22}. In contrast, students would avoid meeting with their academic advisors if there is a lack of compatibility between them and their academic advisors or if they find their academic advisors too serious, fierce, and unfriendly for their liking. Several personality traits including one’s level of extroversion are known to have an influence on relationships between people\textsuperscript{22-24}. Thus, the identification of students’ personality traits makes it easier for academic advisors to develop appropriate strategies to improve the effectiveness of the academic advising process\textsuperscript{24}. Ineffective advising processes will negatively affect students and may lead to students quitting their studies, having a negative view of the university and its staff, and having low academic achievement\textsuperscript{13,25}.

The function of academic advisors in rendering assistance to students continues to get attention and the emphasis on academic advising styles became more apparent\textsuperscript{3,4,6,7}. Much focus is now placed on developmental and prescriptive styles of academic advising\textsuperscript{21}. Studies revealed that the majority of students preferred the prescriptive advising style for activities related to course selection, course timetable planning, registration procedures and requirements for an award\textsuperscript{26,27}. Other researchers indicated that the key to success in academic advising is to implement the advising activity using the developmental style\textsuperscript{27}. This indicates that the implementation of academic advising based on the advising style preferred by students enables academic advisors to make the optimal impact of academic advising and eventually achieve the academic advising goals\textsuperscript{21}.

The above-mentioned findings on academic advising are reported by studies that were mostly done abroad while in Malaysia, research in this area is scarce. What is the academic advising style preferred by students in public universities in Malaysia? Research needs to be carried out to identify the academic advising style preferred by students in public universities in Malaysia as our students have socio-cultural, background and life styles which are uniquely different from other countries. This study identified students’ personality traits and the academic advising style preferred by students at public universities of Malaysia. The objectives of the study are to identify student personality traits, academic advising style preferred by students, and the relationship between student personality traits and their preferred academic advising styles.

**Method**

This descriptive study was carried out by distributing questionnaires to the respondents at three public universities in the southern region of Malaysia. The Sidek Personality Inventory (IPS) was employed to identify students’ personality traits. This IPS examined 15 individual personality traits as follows: aggressive, analytic, autonomy, dependency, extrovert, intellectuality, introvert, versatility, endurance, self-criticism, control, helpfulness, support, structure, and achievement. To identify the academic advising style preferred by the students, the Academic Advising Style Questionnaire was used. This questionnaire was adapted from the Academic Advising Inventory (AAI) developed by\textsuperscript{28}. The questionnaire consists of 14 items used to identify the academic advising style preferred by the students. The questionnaire contains three main components, namely individualized education, academic decision-making and course selection. A total of 401 randomly selected undergraduate students participated in the study. The data were analysed using descriptive and inferential statistics with the assistance of SPSS.

**Results and Discussions**

Table 1 shows a descriptive analysis of student personality traits. From a total of 401 students who participated in the study, the following is a break-down of the number of students for each personality trait: 128 students with helpfulness personality, 79 students with autonomy personality, 77 students with achievement personality, 74 students with dependency personality, 65 student with structure personality, 50 students with analytic personality, 39 students with self-criticism personality, 33 students with extrovert personality, 31 students with versatility personality, 29 students with endurance personality, 29 students with support personality, 27 students with introvert personality, 23 students with aggressive personality, 22 students with control personality, and 17 students with intellectuality personality.

0.664  0.664
Table 3 shows the correlation between student personality traits and preferred academic advising style. The table shows that there is a moderate correlation between student personality traits and preferred academic advising style ($r = 0.664$, $p < 0.05$). If the coefficient of correlation is between 0.50 - 0.69, it reflects a moderate correlation between the variables.

The results of the analysis show that the majority of the students possessed the personality described as ‘helpfulness’, followed by the autonomy, achievement, dependency, structure, analytic, self-criticism, extrovert, versatility, endurance, support, introvert, aggressive, control, and intellectuality personality. Different personalities indicate that they have different characteristics. For example, according to 17, students with dominant autonomy personality enjoy full freedom in all actions and can control and determine their daily activities. Meanwhile students with dominant dependency personality enjoy relying on others. In making any decision, individuals with dependency personality traits usually expect opinions and advice from others, especially those with authority. Thus, students with this personality also always ask other people to point out the direction to go. As such, it is important for academic advisors to understand the personality of the students under their guidance so that the advising becomes more effective and productive.

The finding of this study is in line with 21,24 who found that students with different personalities required different methods, techniques and advising styles. 21 stated that the academic advisor should approach his/her students by understanding their personalities, backgrounds, and important information about themselves to ensure the advising provided meets the students’ needs. 23 noted that several student personality traits such as introvert and extrovert affect their interactions and associations with the environment and community. Identification of students’ personality traits can assist academic advisors to develop appropriate strategies to improve the effectiveness of academic advising 21,24.

The findings show that students preferred the development approach in the implementation of academic advisories. This shows that students prefer to discuss and give their opinions and be given the opportunity to decide. Academic advisors and students will present various options, discussing various alternatives and guidance will focus more on student development as a whole. Therefore, allowing students to choose their own direction will make the students feel more satisfied with the career path they want and they can invest in their own education. The findings are consistent with the study of 22 where a group of UTM students preferred to meet, discuss and seek advice with academic advisors using the developmental style that encourages them to think and be independent. 27,28 also noted that the key to success in academic adherence is to implement an advising activity with developmental styles. The developmental advising style promotes communication and shared responsibility.
in the advisor-advisee relationship; permits students to reach an agreement with their academic advisor; and allows the students to take initiative and responsibility, for how they would want knowledge and skills to be obtained.\textsuperscript{25,27,28}

The study indicated that not all students prefer the developmental approach of academic advising. This finding is in line with the study of.\textsuperscript{21} Prescriptive advising indicates an imbalance in power between students and academic advisors and this may subsequently lead to an authoritarian relationship. Students are assumed to be less motivated.\textsuperscript{21,26} Thus, academic advisors are entrusted to take charge for staying informed regarding rules and regulations to be delivered to the students.\textsuperscript{30,31} Academic advisors may be blamed for unsuccessful initiative for student learning, college choice\textsuperscript{32} and on-campus leadership training.\textsuperscript{33}

**Conclusion**

Ineffective advising processes will negatively affect students. Students may make the decision to quit the university, have a negative view of the university and its staff, and have low academic achievement. Students may also avoid meeting their academic advisors. The identification of students’ personality traits can ease academic advisors to develop appropriate strategies to enhance the effectiveness of academic advising process. Academic advisors need to vary their advising styles between students. Academic advising needs should ideally be person-specific, vary among students, and change over time for individual students. Thus, it is imperative that academic advisors recognize the individual students’ differences and modify their advising styles accordingly.

The implementation of academic advising process based on the academic advising style preferred by the students can ensure optimal impact and higher achievement of academic advising goals. The academic advisors need to implement prescriptive and developmental advising styles according to the student’s personality, situation and needs. The application of academic advising styles based on students’ characteristics and needs can ensure that the sharing of knowledge and responsibility, and positive interactions between students and academic advisors.

Factors Influencing Career Progression of Working-Class Married Women in Oyo Metropolis

Fasasi Lukman¹, Aqeel Khan², Adigun Akeem Ayodeji³

¹PhD Student, School of Education, University Tecknologia, Malaysia (UTM), Johor Malaysia,
²Senior Lecturer, School of Education, Universiti Teknologi Malaysia (UTM), Skudai, Johor, Malaysia,
³Lecturer, Department of Educational Psychology, Ahmadu Bello University, Zaria, Nigeria

Abstract

The objectives of this study were to determine the factors influencing career progression of working-class married women in Oyo metropolis and to examine the influence of demographic variables of age, educational attainment, and job cadre on the respondents’ view. The purposive and convenient sampling technique was used to select 220 participants; out of which, 209 questionnaire forms were adequate for data analysis. The questionnaire was a self-structured type, with a test re-test reliability coefficient of 0.82. A 3-way Analysis of Variance (ANOVA) statistics was used to test hypothesis at 0.05 alpha level. The findings of the study revealed that childcare responsibilities, societal discrimination against women and sexual harassment from men are the factors influencing career progression of working-class married women in Oyo metropolis. Based on the findings of this study, it was recommended that working-class married women should seek the support of their husbands on child care; and the society should avoid discrimination against women in the workforce among others.

Keywords: Career Progression; Working-class Married Women; Implications for Counselling

Introduction

Traditionally, career pursuance and providing home needs (financial needs) is the responsibility of men. The modern, complex and dynamic society has however, led to the influx of women in the labor market. Also, the increase of women taking employment can be attributed to the impact of globalization and the demographic changes to the global workforce. Many women are now gainfully employed either in public or private establishment. This is in contrary to the existing cultural intact family system the society was practicing, where the father engaged in an occupation to provide for the family needs and the wife or mother take adequate care of the children and manage the home. This implies that the society has turned to a situation where a husband and wife are out of the home, engaged in paid job to jointly provide for family needs.

Over the years in the African context, women have been viewed as child-bearers and keepers of home. This age-old mindset has posed many unnecessary barriers on women’s pursuit of their careers. Today, as married women commonly pursue their careers outside the home, concerns as to their ability to achieve equal footing with their male counterparts without sacrificing their families is a contending issue. Women are faced with many challenges in moving up their career ladder, such as non-supportive bosses or colleagues, sexual discrimination and male chauvinism, and still list male prejudice as the main obstacles to their career progress.

Career progression means the process of climbing the corporate ladder, moving upward, or towards high ranks, coupled with higher pay and increased prestige, made possible by the cumulative experience gained in one’s field from more challenging projects and responsibilities. According to researchers, career progression is described as the positive psychological or work-related...
outcomes or personal and professional achievements one has gathered from their working experience. Progression is extremely important to employees, as half of those aged under 35 believed promotion should come every two years. Employees who see a clear progression path are more likely to be engaged and committed to their jobs.

Research showed that increased career prospects are accompanied by job effectiveness (CIPD), reduced absenteeism and unrest, willingness to remain in the organization. Male dominance in the workplace has forced a number of women to adopt a more aggressive model. The constantly reinforced message is that women succeed only if they become more assertive, competitive, dressed for success and more politically and socially astute. This places women in a disadvantaged position because they tend to lose sight of other responsibilities and they sacrifice their personal lives. Male managers have to work harder in order to be noticed and to prove that they can handle the job, the family as well as everything else. Women continue to be disadvantaged in newer management fields. They have been excluded from foreign or international management positions. A lack of women in senior positions who mentor and encourage other women is the single most important issue facing women in business.

In their quest to climb up the corporate ladder, women are facing many challenges. Family responsibility had continued to create barrier for women’s career progression especially for women with marital status and childcare. It is in this context that, women in the civil service need assistance in navigating the challenges of home and work in order to attain success in their career paths. Sexual harassment of female workers by male supervisors is evidently increasing in the workplace. Recent cases in various courts over the world particularly, in the African society give credence to the fact that sexual harassment is on the increase. According to Zippel (2002), while sexual harassment used to be a subject of jokes and ridicule, the behaviors are seen today as illegal. Zippel (2002) stated further that while cases in the past did not attract public attention, more and more women are willing to report incidents today with the expectation that employers will take the necessary action required.

The Nigeria society is patriarchal in nature, which men tend to shy away from giving women leadership responsibilities; especially responsibilities that are perceived to be important and involve making autonomous decisions. Some men also tend to be reluctant in sharing equal partnership with women in business. It is however noted that men are receptive and welcome ideas to purchase properties owned by women, they believe that such properties are in better shape than if they had been owned by women. It is against these backdrops that this study examined the factors influencing career progression of working-class married women in Oyo metropolis.

Method

Procedures

The questionnaire was administered by the researcher with the help of two research assistants, who were trained on the procedure for instrument administration, to the consented civil servants in Oyo metropolis.

Sample

The sample size for this study was 220 working-class married women. In selecting the sample, purposive and convenient sampling techniques were employed. Firstly, the researcher purposively selects 10 different government ministries, secretariats and parastatals in Oyo metropolis. Purposive sampling is a sampling technique employed by a researcher in order to deliberately select subjects because of their peculiar characteristics. On the other hand, convenient sampling technique was used to select the respondents in different locations within the ministries or secretariats.

Instrument

The instrument used in the data collection from the respondents was a self-designed questionnaire entitled “Factors Influencing Career Progression Questionnaire (FICPQ)”. The instrument was a self-structured questionnaire with 20 items. Section ‘A’ deals with demographic data of the respondents such as age, educational attainment, work experience, job cadre and marital status. The other section sought for information on factors influencing career progression of married women. The test re-test reliability method was employed and the co-efficient of 0.82 was obtained which adjudged the instrument reliability.
Data Analysis

A 3-way Analysis of Variance (ANOVA) was used to test the hypotheses formulated at 0.05 alpha level.

Results

Research Question: What are the factors influencing career progression of working-class married women in Oyo metropolis?

</table>

Table 2 shows that all the twenty items were agreed upon by the respondents as factors influencing career progression of working-class married women. This is indicated by mean scores of all the items which are above the average mean values of 2.50 (benchmark) for determining the factors. Among all the items however, items 11, 1 and 2 with mean values of 3.36, 3.16 and 3.11 respectively preceded others and were ranked 1st, 2nd and 3rd. This implies that there are numerous factors influencing career progression of working-class married women in Oyo metropolis but the topmost among them are childcare responsibilities, societal discrimination against women and sexual harassment from men.

Ho: There is no significant difference in factors influencing career progression of working-class married women in Oyo metropolis based on age, educational attainment and cadre.

a. R Squared = .189 (Adjusted R Squared = .063)
Table 2 shows that at the degrees of freedom (df) of 4/180, 4/180 and 1/180 the calculated F-value of 0.815, 0.658 and 1.268 (p = .517, .622 and .262 > 0.05) for age, educational attainment and cadre respectively. This implies that, there was no statistically significant difference in the factors influencing career progression of working-class married women in Oyo metropolis based on age, educational attainment and cadre; hence, the hypothesis is not rejected. The interaction effects of the three independent variables (age, educational attainment and cadre) revealed that no statistically significant effect existed among the three demographic variables.

**Discussion**

The first finding is that childcare responsibilities are one of the factors influencing career progression of working-class married women in Oyo metropolis. Women are known to be responsible for proper care of the children and adequate care of the home. This was reflected in the view of the working-class married women which related that child care as significant barrier to their career progression. This finding is in line with the finding of 13 which indicated that home and family responsibilities are among the factors preventing advancement for working-class in their profession. Similar finding was also reported by previous researcher 14. This implies that combining home responsibilities with work or career becomes a herculean task for working-class women which in turn prevent them from reaching the top decision making status in many enterprises. This thus not mean that there are no married women who are reaching the peak of their profession, but it implies that many working-class married women are finding it difficult to adjust with such situation and cannot reach the power based position before retirement.

Societal discrimination was the second factor identified by working-class married women in Oyo metropolis as factor influencing their career progression. The finding of this study is in tandem with the finding of 15 which revealed that societal discrimination against working-class women is a phenomenon that still exist in this modern time and has invariably contributed to negatively to the career advancement or progression. It was also found in the study of 16 that societal discrimination worked against women in reaching the greater height in their career endeavors. This follows that despite the increase and spread of civilization in this modern society, Nigerians still have the mindset that the role and responsibilities of women should not exceed the home, to the extent that working women are being discriminated against.

It was also found in the study that sexual harassment of women from the men at their working place is among the factors influencing career progression of working-class married women. The finding of this study supports the finding of 12 which revealed that sexual harassment is a common challenge affecting many working-class women from contributing meaningfully to the progress of their work place. It was also found by 16 that sexual harassment has been one of the factors that create barriers to success of many women in the labor force to reaching the administrative position. It might not be strange is different work place where the male boss or colleagues will be harassing women sexually. In some occasions, the women might be threatened with sack letter or severe punishment should they turn down the harasser. This might have made some women to resign, many who do not resign are finding it difficult to cope with the situation, while those who accepted the offer might eventually be disappointed. All these combined, can result in discomfort and discontentment for working-class married women and can invariably discourage them from progressing in their profession.

The hypothesis tested revealed that there was no significant difference in the factors influencing career progression of working-class married women in Oyo metropolis based on age, educational attainment and cadre. The finding of this study corresponds with the finding of 17 which reported that no significant difference exists in the factors influencing career progression of women on the basis of age. The findings of the study suggest that every woman irrespective of their age, educational attainment and cadre are finding it difficult to reach the peak of their career ladder.

**Conclusion and Recommendations**

Based on the findings of this study, it can be concluded that the patriarchal attitude among the African people is pervasively influencing working-class married women to reach greater height in their career of pursuits irrespective of the socioeconomic status. In the light of this, it was recommended that:

Working-class married women should seek the support of their husbands on child care by providing them with house maid or assist them physically on
different house chores; thereby, reducing their volumes of responsibilities in the home to enable them to be more committed to their career of pursuit.

The society should avoid discriminating women in the workforce but rather encourage them through the media and various interaction focused on women; so that they can be allowed to reach greater height in their profession.

Government should make appropriate policies and ensure its full implementation against men who harass women sexually at work in order to serve as deterrent from the act; thereby, given the women the free hand to work assiduously towards achieving the best in the profession of choice.

Counsellors should create awareness for the working-class married women on the likely challenges they may face while at work and equip them with positive coping strategies they can employ to adjust with such situation in order to help them reach advanced level of their career pursuits.

The Influence of Emotional Intelligence and Personality on Career Adaptability among Teachers in Special Education Schools in Johor Bahru

Bay Yan Er1, Mohd Rustam Mohd Rameli2
1Master Student, 2Senior Lecturer, School of Education, Universiti Teknologi Malaysia (UTM), Malaysia

Abstract

Challenging and stressful working environment faced by teachers in special education schools are a reality which cannot be denied. Research showed that teachers’ ability to adapt into challenging working environment is correlated by certain level of emotional intelligence and their dominant personality. However, lack of research has been conducted to predict the role of emotional intelligence and personality towards teachers’ ability in fitting themselves into workplace among teachers in special education schools. This quantitative research investigates the influence of emotional intelligence and personality towards career adaptability among teachers in special education schools. Respondents involved in this research were 108 teachers from three special education schools in the state of Johor, Malaysia. Quantitative data were collected through questionnaire were analyzed inferentially. Research findings indicated that emotional intelligence, extraversion, conscientiousness and openness to experience were significant predictors of career adaptability in linear regression analysis. However, extraversion and openness to experience personalities were the most significant predictors of career adaptability in multiple regression analysis. The research has highlighted the important role of emotional intelligence and personality on career adaptability in the context of special education teachers in Malaysia. The findings of this research is important to provide an insight to teachers, schools and Ministry of Education in selecting suitable teachers in teaching students with disabilities.

Keywords: Emotional Intelligence, Personality, Career Adaptability, Special Education

Background of Study

Working environment has become more complex and the diversity in terms of people and working conditions has been increased in recent years1. School environment also can be considered as challenging working environment. Challenges of school environment is not solely consisting of students’ academic achievement, education quality and students’ misbehavior but it also involves parents’ expectations towards teachers, technology and educational policies2. Teachers are required to cope with these burdens rather than focusing on teaching. Teacher is a profession that involved in a lot of changes3. Teachers are expected to interact with students with different background, recognize their learning needs, communicate with colleagues effectively, handling difficulties appropriately and complete tasks assigned by managers.

The relevancy of studying emotional intelligence among employees had been increased in 21st Century4. Affection and cognitive adjustment abilities are essential for an individual to cope with the stressful working environment that related to unforeseeable changes in the workplace5. Teachers in special education schools are responsible to modify and accommodate instructions, deliver instructions in various ways, liaise with different stakeholders and knowledgeable about legal and legislation related to special education6-7. Hence, there is a need to study emotional intelligence among teachers in special education schools.
Personality of teachers also predicts the success of providing special education to students. Special education teachers responsible to provide variety of teaching strategies to students with disabilities. They need to be patient throughout the teaching processes. Personality affects teaching effectiveness and directly increases students’ achievement. Teacher’s self-efficacy, interpersonal relationship, work commitment and work contentment are influenced by personality. Hence, both emotional intelligence and personality are the factors that needed for teachers in coping with challenging and stressful working environment.

Besides, career adaptability is an important issue that need to be studied in working environment. Career adaptability enables teachers to fulfill the demands of different students. Teachers are also able to take up new assignments given by superior, adhere to changes and always prepare for the uncertainties. Teachers who work in special education schools are required to have certain level of emotional intelligence and personality in order to cope with stressful and challenging working environment.

According to previous researches, teachers who work in special education schools are generally facing greater level of career-related stress or burnout than teachers who work in general schools. This phenomenon has urged the necessity in studying career adaptability issue among special education teachers. Hence, this research will focus on the influence of emotional intelligence and personality on career adaptability among teachers in special education schools in Johor Bahru.

Objectives

The main objective of the research is to investigate the influence of emotional intelligence and personality towards career adaptability among teachers in special education schools in Johor Bahru. Besides, this research will also investigate the influence of each emotional intelligence and personality types on career adaptability among teachers.

Methodology

Quantitative research design that involves survey in conducting research was adopted in this research. Inferential approach was used to determine the influence of emotional intelligence and personality on career adaptability among teachers in special education schools. Respondents involved in this research were 108 teachers from three special education schools in Johor Bahru, Johor, Malaysia. The number of sample is determined based on Krejcie and Morgan’s Table for Determining Sample Size from A Given Population. The participants of each school were chosen by using ratio sampling technique while teachers from each school were selected through simple random sampling. Respondents were briefed on the details of research and were informed on their right to withdraw from this research if they are not comfortable to participate in this research. Respondents who were willingly joining the research were selected as the respondents. Informed consent was given to all respondents. Self-administered questionnaires were distributed to the respondents. The questionnaires were collected at the end of the research. The data were studied and analyzed.

The questionnaire was divided into four parts which included demographic information, emotional intelligence, personality and career adaptability. The instruments involved were Wong and Law Emotional Intelligence Scales (WLEIS) developed by Wong and Law in 2002, Big Five Inventory (BFI) created by John and Srivastava in 1999 and Career Adapt-Abilities Scale-Short Form (CAAS-SF) developed by Maggiori, Rossier and Savickas in 2012. All of the instrument showed high reliability value which ranging from 0.88 to 0.90, 0.83 and ranging from 0.87 to 0.96 respectively.

Findings

Table 1 presented the linear regression result of this research. There are 108 teachers involve in this research. Emotional intelligence ($\beta=0.33$, $p<0.05$), extraversion ($\beta=0.308$, $p<0.05$), conscientiousness ($\beta=0.317$, $p<0.05$) and openness to experience ($\beta=0.426$, $p<0.05$) are the significant predictors of career adaptability. The null hypotheses are rejected. However, agreeableness ($\beta=0.141$, $p>0.05$) and neuroticism ($\beta=0.005$, $p>0.05$) are not the significant predictors of career adaptability among teachers. The hypotheses are failed to be rejected.
Table 1: Linear Regression Analysis

Table 2 showed the multiple regression analysis of this research. The total number of respondents is 108 teachers in special education schools. The finding indicates that openness to experience (β=0.426, p<0.05) is significant to predict career adaptability. It contributes 17.4% (r=0.426) changes of variance in career adaptability [F(1,106)=23.522, p<0.05] among teachers in special education schools. Combination of two independent variables, which openness to experience (β=0.381, p<0.05) and extraversion (β=0.234, p<0.05) contribute 22% (r=0.484) change if variance in career adaptability [F(2,105)=16.087, p<0.05] among teachers in special education schools.

Discussion

Linear regression analysis findings indicated that there was a significant influence of emotional intelligence on career adaptability among teachers in special education schools in Johor Bahru. The finding was supported by past researches. Emotional intelligence is an important factor towards career adaptability among employees. The ability to control own feelings and emotions enabled employees to succeed in their career. Emotional intelligence affected employees’ ability in managing own emotions and readiness in career planning. Employees with high level of emotional intelligence were able to express and comprehend own and others’ emotions. In the context of this research, teachers in special education schools handle students with various
adaptive, cognitive and social capabilities. Beside delivering lessons to students, they are responsible to understand students’ abilities, handling students’ misbehavior and determine the types of interventions and teaching strategies that suit the students the most\textsuperscript{15}. By having high level of emotional intelligence, teachers able to make correct assumptions and stay optimistic on various situations. Hence, teachers are well-fit into the complex environment in special education schools.

Personalities such as extraversion, conscientiousness and openness to experience were significant predictors to career adaptability while agreeableness and neuroticism did not. The research findings were aligned with some previous researches\textsuperscript{16-18}. Extrovert teachers are generally sociable, outgoing, enthusiastic, confident and lively\textsuperscript{16,19}. Extrovert special education teachers adapted better in challenging situations, especially teaching students with disabilities. Teachers claimed that they used humor as strategy to manage students who showed disruptive behavior in classroom and tended to stay positive when facing the problems\textsuperscript{20}.

Agreeableness was not the significant predictor of career adaptability among teachers in special education schools. Finding was aligned with past research claiming that agreeable individual did not show notable curiosity on career interests\textsuperscript{21}. However, the findings were contradicted with most of the past researches indicating that agreeableness was the significant predictor of career adaptability\textsuperscript{16-18}. Agreeable teachers were described as reliable, easy-going, friendly, tenderhearted and open-minded\textsuperscript{16}, also able to cooperate with various stakeholders and willing to compromise when facing problems\textsuperscript{20}. They always able to adapt in different working situations. The finding was contradicted with most of the previous research findings probably due to the age range of research respondents. Majority of the research respondents were young adults. Middle and older-aged adults were more agreeable than younger adults\textsuperscript{22} and thus having better ability in adapting in their workplace.

Findings indicated that conscientiousness was significant predictor of career adaptability. Result was supported by past research\textsuperscript{17}. Conscientious teachers were persistent, goal-oriented, wisdom and committed towards accomplishment. These characteristics helped them to cope with challenging tasks in workplace. Conscientious teachers tended to make self-reflection and improvement on their teaching approach constantly. Hence, they were capable to deliver lessons smoothly in classroom. In the context of this research, conscientiousness scored the highest and was the most dominant personality among teachers. It means they were committed, organized and capable in managing students with different educational needs. Hence, teachers were better able to adapt in their working environment and fulfill their career objectives.

Neuroticism was not significant predictor of career adaptability. The finding was supported by past research claiming that career adaptability was not affected by neuroticism probably because neurotic individuals tended to withdraw from challenging responsibilities\textsuperscript{16}. However, some researches stated there was significant but negative influence between neuroticism and career adaptability\textsuperscript{18}. Neurotic individuals have lower self-evaluation compared to emotionally stable individuals. As a result, adaptive ability in workplace could not be developed.

Moreover, the findings also indicated openness to experience as the significant predictor of career adaptability among teachers. This finding was aligned with several past researches\textsuperscript{16-18}. Teachers in this research are visionary, creative, flexible and high tolerance to unforeseeable situations. They actively looking for opportunities which bring to career success. Hence, they were able to adapt better in unpredictable working environment.

Multiple regression analysis findings indicated that openness to experience and extraversion were the significant predictors of career adaptability while other independent variables (emotional intelligence, agreeableness, conscientiousness and neuroticism) were not. This finding happens may due to some aspects of these variables were captured and proved to be relevant to teachers’ career adaptability\textsuperscript{23}. However, emotional intelligence, agreeableness, conscientiousness and neuroticism were not the significant predictor of career adaptability in this research probably because other personal characteristics may have more roles and were more important predictors than these variables in this research\textsuperscript{23}.

This finding was supported by the research conducted by Zacher\textsuperscript{23} indicating that employees’ curiosity on work affected by openness to experience while extraversion forecasted individual’s control in career development.
Employees with openness to experience personality are visionary, flexible and willing to try new things in workplace. Extrovert employees are enthusiastic, lively, confident, active and sociable.

Moreover, the variables (emotional intelligence, agreeableness, conscientiousness and neuroticism) were not the significant predictors in the multiple regression analysis of this research also had been supported by previous researches. Emotional intelligence and personality varies according to age. Older individuals tend to develop positive emotional well-being and manage emotion better. For the personality, maturity increase as individuals grow older. Maturity causes the formation of personality and professional identity. Older teachers are stable, people-oriented and have well-formed identity and professional development. These characteristics allow them to have higher self-efficacy, self-confidence and more capable to cope with workplace situations. In this research context, more than half of the teachers in special education schools aged between 20 to 39 years old, who were considered as young adults. These young teachers probably still undergo identity exploration. They tend to be self-focus and have unstable personality. These phenomena probably resulted the insignificant effect of independent variables (emotional intelligence, agreeableness, conscientiousness and neuroticism) on career adaptability among teachers in special education schools.

Conclusion

This research concentrates on the influence of emotional intelligence and personality towards career adaptability among teachers in special education schools in Johor Bahru. The research findings had been discussed and aligned with the context of this research. Based on the research findings, all of the independent variables (emotional intelligence, extraversion, conscientiousness and openness to experience) except agreeableness and neuroticism personality showed an influence towards career adaptability. Out of these variables, openness to experience and extraversion personalities are the most significant predictors of career adaptability. More future researches need to be conducted in order to find out the factors that affect career adaptability among teachers in special education schools in Malaysia.

Coping Styles in Group Reality Therapy among Cardiac Women Patients with Depression

Racheal Entayang Kudang1, Mohamed Sharif bin Mustaffa2, Surena Sabil3, Aqeel Khan4, Fatahyah Yahya5

1Master Student, Universiti Malaysia Sarawak (UNIMAS), Kota Samarahan, Sarawak, Malaysia, 2Senior Lecturer, Universiti Malaysia Sarawak (UNIMAS), Kota Samarahan, Sarawak, Malaysia, 3Dean, Faculty if Cognitive Science and Human Development, Universiti Malaysia Sarawak (UNIMAS), Kota Samarahan, Sarawak, Malaysia, 4Senior Lecturer, School of Education, Universiti Teknologi Malaysia (UTM), Skudai, Johor, Malaysia, 5Lecturer, Universiti Malaysia Sarawak (UNIMAS), Kota Samarahan, Sarawak, Malaysia

Abstract

Depression will be the number one major cause of illness by the year 2020. Depression has been the main factor of morbidity since a decade ago. The aim of this study is to investigate the coping styles among cardiac women patients with depression experiencing Reality Therapy. The respondents of this study are taken from Pusat Jantung Sarawak, Kota Samarahan. The respondents are four cardiac women patients waiting four heart surgery. Their age range are from 22 to 64 years old. Three respondents are from Iban ethnicity and one respondent is from Malay ethnicity. The method of the study is Qualitative method whereby four session of Reality Therapy are conducted. The data analysis method is descriptive phenomenology whereby the researcher investigates the important criterion that make up a whole structure of an experience. The findings from this study are the respondents’ coping styles during the WDEP (wants, doing, evaluation and planning) intervention. Their BDI score before and after Reality therapy are also recorded. The implication of this study is Reality Therapy and WDEP intervention can be used to help people with depression. In conclusion, the depression level in cardiac women patients are reduced after experiencing Reality Therapy.

Keywords: cardiac, women, depression, Beck’s Depression Inventory.

Introduction

Existing researches showed psychological effect on human behavior1-5. One of the form of mental illness is depression. Depression interrupts with your daily routine and practice and lessens the quality of one’s life. Cardiac disease on the other hand is several illnesses that affect the heart and nearby blood vessels. People with cardiac disease tend to experience depression than otherwise fit people. Depression has been considered the common cold of psychopathology. The comparison is unfortunate, for it conveys the impression of a frequent but mild complaint. Some depressions end fatally. The objective of this research is to investigate the coping styles of cardiac women patients after experiencing Reality Therapy.

Depression has been the main factor of morbidity since a decade ago. Since women are more prevalent to depression and cardiac disease is getting more and more common in Malaysia, this study is to investigate changes in these patient’s level of depression after experiencing reality therapy. The level of depression is measured using Beck’s Depression Inventory (BDI). The cardiac women patients undergo reality therapy session.

The duration incidence of depression in any country is between 8 and 10% (Yusoff, Rahim and Yaacob, 2011)6. Opposite to the usual conviction, cardiac disease does not only happen in advance country. The case of Malaysia is no exception; in fact, depression is the most frequent mental illness conveyed in Malaysia. Fortunately, it is also one of the very easily treated form
of mental illness, and is expected to influence nearly 2.3 million people in Malaysia, at some point in their lives (Malaysian Psychiatric Association, 2004). In Malaysia, biological theories, and thus, the pharmacological treatment of depression, are commonly used in clinical practices in community settings and hospitals; in fact, this is the main form of treatment for depression in Malaysia (Stahl, 2000). Unsurprisingly, the development of psychotropic medication in Malaysia has tended to ignore psychological aspects in the process of depression recognition and understanding, particularly for depression (Deva, 2006). While psychotherapies for the treatment of depression are applied clinically in Malaysia, it is unfortunate that no empirical evidence to support such use has been established. Further, it is still unknown whether psychological instruments for the assessment of depression and the theories for depression are valid and reliable for use in Malaysia.

Hence, this research will investigate the coping styles of these cardiac women patients with depression at Pusat Jantung Sarawak experiencing Reality Therapy.

**Method**

Psychology Phenomenology assumes human as existent or being that has history and experience that creates the history (Giorgi, 2009). Phenomenology as a philosophy is to understand everything that one’s consciousness on any future events (human, object or certain complexity) based on that one’s perspective that went through the experienced (Giorgi, 2009). As a research, phenomenology is a descriptive research that investigate the important criterion that make up a whole structure of an experience (Ricoeur & Stewart, 1978).

The data of this research depends fully on the verbatim of the respondents. Cresswell (2007) suggests that the minimum number of respondents for a phenomenological research is five respondents. According to Giorgi (2009), who was the founder of Descriptive Phenomenology Analysis, the minimum number of respondents is even more little which is three respondents. The number of respondents for qualitative research is usually depending on the concentration of information acquired from the interview.

The research respondents for this research are from Pusat Jantung Sarawak. They are cardiac women patients who are waiting for heart surgery. They were chosen through Beck’s Depression Inventory whereby they were asked to answer the inventory. The scoring of the inventory is evaluated and the patients with shows the scoring of patients with depression was picked.

Table 1 Summary of Respondents’ Background: The session started as soon as the respondents were chosen. The researcher and the respondent met for a total of six times throughout the process and had four sessions of Reality Therapy. The first meeting was to recruit the respondents by giving out the Beck’s Depression Inventory and explaining the purpose of the research. The Reality Therapy session started on the second meeting onwards until the fifth meeting. In the final meeting, the respondents were given Beck’s Depression Inventory again to check their level of depression after experiencing Reality Therapy.
The Descriptive Psychology Phenomenology uses a five-step method of data analysis based on some principles of phenomenological philosophy (Giorgi, 2009). The first step of the phenomenological psychological method is for the researcher to assume the phenomenological attitude. The phenomenological attitude is different than the natural attitude or everyday way of understanding the world.

The second step in the data analysis requires that the researcher to read the entire “naïve description” to get a sense of the whole experience (Giorgi, 2009). The “naïve description” provided by the respondent was taken in the natural attitude in the way that she would experience things in the mode of everyday living from the commonsense perspective.

The third step in the data analysis is the demarcation of “meaning units” within the narrative so that the data can be dealt with in manageable portions (Giorgi, 2009). The researcher went through the narrative text in a subsequent reading(s) with the purpose of determining where places of meaning shift within it. According to Giorgi (2009), how or where the meaning units are delineated is not absolute. Different researchers may delineate the meaning units in different places in the same data. However, the same or different the meaning units may be among researchers, it is the results that are important to the overall quality of the analysis (Giorgi, 2009).

The fourth step was transforming the meaning units into psychologically sensitive descriptive expressions of each of them. The researcher takes the phenomenon at the psychological level to practice science rather than the transcendent level which is to practice philosophy (Giorgi, 2009). The psychological level is an individuated, worldly and personal level rather than a transcendent (universal, unconditional, and independent of experience) (Giorgi, 2009).

The fifth step in the analysis is the synthesis of the general psychological structure from the psychological constituents of the experience. Constituents therefore cannot be independent of each other, but are necessarily part of the whole structure. The purpose of this procedure is grounded in the phenomenological concept of parts and wholes. Sokolowski (2008) points out that concept of parts and wholes is not original in phenomenology but was developed by Greek philosophers Plato and Aristotle.

After experiencing Reality Therapy (WDEP Intervention):

The table 3 shows the result of the patients after experiencing Reality Therapy. R1 is in normal state, R2 is in borderline clinical depression, R3 is in mild mood disturbance and R4 is in normal state.

The changes in emotional, thinking and behavioral changes are also recorded through their dialogue.

### Discussion

Analysis descriptive of respondents by demographic background.

The total respondents for this research are four respondents. The age range of the respondents are from 22 to 64 years old. R1 is 53 years old, R2 is 64 years old, R3 is 23 years old and R4 is 22 years old. R1 is from Malay descendant whereas R2, R3 and R4 are from Iban descendants.

According to Glasser (1998), patients with diseases are more prone to fall into depression. Especially those patients who suddenly became ill compare to those
where their disease is hereditary. This is due to their world suddenly crumble down when the doctor broke the news to them. Imagine that it was normal, or so they thought, but when they know that they have chronic illness, they will be sad and depress.

This is research is to investigate the coping styles of cardiac women patients with depression after experiencing Reality Therapy. Four questions that were required to be asked during the sessions were:

a. What do you want in the next 6 months?

b. What have you done to achieve what you want?

c. Does it help?

d. If (b) does not help, what else can you do? If (b) did help, what else that you think can help but haven’t being executed?

It was found out in the result that the level of the depression in all four respondents decreased. Even though the score of their BDI does not decreased to zero (normal), most of the respondents only have mood swings and mild mood disturbance.

Coping Style in “Want” among the cardiac women patients.

The results of “want” among the patients were that they all want to be healthy again. They want to be healthy because they do not want to stay at the hospital for too long and be away from their family.

Glasser (1998) states that patient with depression usually will want to be healthy and happy again. Sometimes people do not realize that they are not happy and no action was taken to make them happy and heal them. This result is similar with the past studies because cardiac women patients wants to be healthy and results from past studies also shows that they want to have freedom from the hospitals.

Coping Style in “Doing” among the cardiac women patients.

The results of “doing” among the patients are that they are doing many things such as exercising, reading and praying to God to be feel better about themselves and help to improve their health. They are unable to do more than these things since they are waiting for the surgery. The past studies were also supporting that depression patients are often experiencing over thinking and does not what to do. Through WDEP, these cardiac patients can plan their strategies bit by bit.

Wubbolding (1990) states that depression patients are quite passive when it comes to ‘doing’ something to overcome their depression. They fall into depression in the first place was because they felt helpless. Hence, they feel that there is nothing much that can be done to help them anymore. Fortunately, these patients had each other to support each other. They feel less lonely and is able become more active in doing something for themselves.

Coping Style in “Evaluation” among the cardiac women patients.

Overall, these cardiac patients can evaluate their own thought and mind. They know why they are always feeling sad and they can analyze what should be done to make sure their body will be healthy again. Many of them create their own alternative to become healthy other than taking medicine only. They do exercise and reading. They also change the bad habit that they have such as bad eating or sleeping habit.

Past studies by Glasser (1998) show that depression patient is unable to evaluate their mind with any help. Hence, the WDEP intervention helps them to evaluate themselves. Control is a key issue therapy. Human beings need control to meet their needs: one person seeks control through position and money, and another wants to control their physical space.

Coping Style in “Planning” among the cardiac women patients.

These cardiac patients can plan their action after the evaluate what they have done. Many of them still have other ways that they can think of on how to become healthier. They plan to do more exercise and be more discipline in changing their bad habits. The patients also focus on the present and does not think of their past problems. They focus more on their future and how they can be healthy again.

Conclusion

In conclusion, Reality Therapy helps these women patients with cardiac disease to cope with their depression. They felt better emotionally and the intervention help them to take care of their physical body better. There is
evidence that some progress had been made for women patients with depression.

It is hoped that, with further research and expansion of Reality Therapy, cardiac women patients can be treated and the rate of morbidity caused by depression is reduced.

Coping Strategies as a Mediator Between Stress and Marital Quality among Postgraduate Students

Ahmad Mustaqim Yusoff, Aqeel Khan, Adibah Abdul Latif & Dzilal Abdul Aziz

School of Education and Social Sciences, Management and Science University, Malaysia,
School of Education, Universiti Teknologi Malaysia, Malaysia,
School of Education and Social Sciences, Management and Science University, Malaysia

Abstract

The study was conducted to evaluate coping strategies as a mediator between stress and marital quality among married postgraduate students. During tertiary education, married postgraduate students are exposed by academics and family challenges which bring impact on their marital relationship. A total number of 225 respondents from various universities (UTM=45, UPM=45, UKM=45, USM=45, UM=45) were participated. Data was collected by using purposive sampling technique. All respondents were asked to answer Conflict Resolution Style Inventory (CSRI), Graduate Stress Inventory-Revised (GSI-R) and marital Quality Questionnaire (MQQ). Data were analysed using Smart-PLS Software. Based on Partial Least Squares-Structural Equation Modelling (SEM-PLS), this study showed that there were several factors have been identified as the risk factors toward marital detrimental. In order to counter the stress, coping strategies were integrated in the mediation analysis. The results indicated that coping strategies were suitable to be a good mediator to reduce the negative effect of stress towards marital quality. This study have good implications for psychologist, counsellors and educators to understand married university students’ marital relationship.

Keywords: Academic pressure, marital relationship, mediator, coping strategies

Research Background

Many previous studies have focused on the impact of tertiary education on marital quality. Currently, Malaysia aims to be an educational hub. In this sense, many efforts are done to make sure our educational system keeps improving. One of the efforts is by providing Malaysia Higher Education Blueprint. In this blueprint, Malaysian married postgraduate students also play an important role to enhance the tertiary education. Ministry of Higher Education (MOHE) wants the students to master their own discipline so that the knowledge can bring benefits for the country. However, this kind of aspiration faces challenges as the married postgraduate students are easily exposed to academic pressures. This kind of pressure among married postgraduate students exists due to discomfort response on tension state and the emotional strain during postgraduate level. They are required to accomplish certain academic demands, such as dissertation, examination and assignment. In this sense, they need to seriously consider the role of stress between academic and family. Otherwise, the stress perceived by married postgraduate students tend to reduce their marital satisfaction.

In order to reduce the impact of stress on a marital relationship, several studies marked an increase of empirical and theoretical attention to coping strategies. The ways in which individuals and spouses respond to negative effects, resolve conflicts and provide support for one another will bring benefits to marital bonding. Since a marriage involves a dyadic interaction, married postgraduate students need to know the effective ways to influence each others’ thoughts, feelings and actions. All of these have been viewed to be an important feature of marital happiness. This is due to the reason that coping strategies contribute to family cheerfulness. However less of studies try to integrate coping strategies as a mediator between stress and marital quality among married postgraduate students population. Many of the previous studies were focused more on newlyweds, parenting and arranged married. This study suggests that married postgraduate students also need to be concerned...
as they are facing difficulties to balance between academic demands and family needs\(^1\). Lacking to have adaptive coping strategies always contribute to marital detrimental\(^{11,12,13}\).

Marital detrimental is recognised based on criticism, defensiveness and stonewalling\(^7\). Regarding the criticism aspect, stress individuals treat their spouses by relationship problem\(^{24}\). They become intolerant within their marital relationship\(^{24}\). Next is defensiveness, which occurs when spouses did not take responsibility for even a small part of family problems\(^{25,26}\). Last is stonewalling, which happens when spouses choose to shut down during a conversation\(^7\). All of these aspects need to be regulated. Therefore, this study provides an evidence on the impotency to integrate coping strategies as a mediator between stress and marital quality. Otherwise, it will lead towards dissatisfaction between married postgraduate students and their spouses.

**Research Objectives**

The main objective of the study is to evaluated coping strategies as a mediator between stress and marital quality among married postgraduate students. Before conducting the mediation analysis, the direct relationship of stress towards marital quality also need to be identified. In turn, the factors that need to be mediated by the coping strategies are measured.

**Methodology**

A total of 225 married postgraduate students (105 males, 120 females) were participated from five universities in Malaysia. The universities were from Universiti Teknologi Malaysia (UTM), Universiti Putra Malaysia (UPM), Universiti Kebangsaan Malaysia (UKM), Universiti Sains Malaysia (USM) and Universiti Malaya (UM). Each university consists the same number of respondents (UTM= 45 respondents, UPM=45 respondents, UKM= 45 respondents, USM=45 respondents and UM= 45 respondents) so that the number of sample size was equally selected. This study used purposive sampling technique, therefore the respondents were selected from those who were officially enrolled as postgraduate students.

Three instruments were used, which known as Conflict Resolution Style Inventory (CSRI), Graduate Stress Inventory-Revised (GSI-R) and marital Quality Questionnaire (MQQ). The CSRI was used to measure coping strategies. This instrument had been reported to have a good internal consistency (\(\alpha=.76\))\(^{27}\). Meanwhile, for the confirmatory factor analysis, the value was .014 (RMSEA\(\leq.06\)) and Comparative Fit Index (CFI) value was .99 (CFI \(\geq.95\)). On the other hand, GSI-R was used to measure stressful events. The Cronbach’s alpha for environmental stress was \(\alpha=.85\), familial or monetary stress was \(\alpha=.77\) and academic stress was \(\alpha=.78\). One week test-retest reliability coefficient ranging from \(\alpha=.80\) to \(\alpha=.85\) was also obtained\(^{28}\). Lastly was MQQ in which used to assess marital quality. The item reliability of MQQ was \(\alpha=.94\)\(^7\). In terms of validity, the value of raw variance explained by measure was 77.5\% (\(\geq40\%)\(^7\).

**Findings**

Figure 1 shows the direct path analysis of stress towards marital quality. Based on the figure, the highest coefficient of determination was acceptance (\(R^2= 0.87\)). This result implies that environmental stress, academic stress and family stress contributed to 87\% of total variance in acceptance sub-construct. In addition, another sub-constructs in marital quality also shown the excellent values (\(R^2\geq 0.75\)). Therefore, this results denoted that stressful events played an important role to determine the changes in marital quality among married postgraduate students.

![Figure 1: Direct path analysis of stress towards marital quality](image)

Table 1 indicates the path coefficient and significant value for each sub-construct of stress towards marital quality. The highest path coefficient was the relationship between environmental stress sub-construct towards companionship sub-construct (\(\beta = -0.82\)). In terms of significant value, only six relationships were considered significant (\(\geq \pm1.96\)). The results implied that only acceptable path coefficient and significant value were contributed to predict the relationship of stress towards marital quality among married postgraduate students.

Discussion

The direct relationship between stress towards marital quality has been found to be negative and significant. The direct relationship shows that an increase in stress contributes to low marital quality. In this sense, environmental stress, academic stress and family stress play a vital role on total variance in the companionship aspect. As these stressful events happened, married postgraduate students are suggested to make some adjustment on time, energy, commitment and financial resources. If not, the stress perceived by married postgraduate students tend to threaten the continuation of the marital relationships\textsuperscript{1,2,3}. They might think that postgraduate levels always potentially bring negative impact on their marital relationship. In turn, married postgraduate students tend to view that their marital relationship as disruptive.

In terms of mediation analysis, the result shows that coping strategies can be a good mediator between stress and marital quality. Based on this finding, coping strategies can regulate stress to enhance married postgraduate students’ marital relationship. Higher coping strategies help married postgraduate students to have constructive interaction within their family. Constructive interaction includes all behaviours that can enhance mutual resilience\textsuperscript{29,30}. By having constructive interaction, marital conflicts can be resolved\textsuperscript{29}. Individuals with good constructive interaction are able to have positive communication, cooperation, acceptance, and compromise\textsuperscript{7, 35-36}. These behaviours acts to reduce the problems risk. Therefore, any negative behaviour such as attack, criticism, coercion, and withdrawal can be avoided\textsuperscript{7}. In turn, it leads to emotional support within the marital relationship.

Married postgraduate students who manifest emotional support are easily develop marital awareness\textsuperscript{31}. They become aware that conflict happened might affect their engagement within the family\textsuperscript{31}. They then tend to find an effective way so that their marital interaction can be sustained\textsuperscript{7}. In fact, in this study, married postgraduate students tend to focus on the solution to resolve their marital conflict. This matter is shown based on the significant value of coping strategies to act as a mediator between stress and marital quality. This matter leads them to become supportive in discussing problems. Discussion helps them to avoid judgmental towards their spouses\textsuperscript{32}. This is due to the reason that married postgraduate students who have emotional support are likely to listen their spouses’ point of view before making any decision. In this sense, pro-relationship behaviour has been created within marital relationship. In turn, any harmful marital interaction can be avoided\textsuperscript{33,34}.

Conclusion

In a nutshell, this study shows that married postgraduate students need to well manage their stressful\textsuperscript{1,2,3}. Specifically, there are there types of stress encountered by married postgraduate students, which known as environmental stress, academic stress and family stress\textsuperscript{7}. All of these stress tend to decrease their marital quality. In turn, marital difficulties are internalised in the relationship. Married postgraduate students might think that the stress always threaten the continuation of their marital relationship\textsuperscript{5,6}. Regarding to this matter, coping strategies need to be integrated within marital relationship.

By having good coping strategies, married postgraduate students are able to perform constructive interaction, able to give emotional support towards their spouses and have a pro-relationship behaviour. All of these are needed to counter any marital detrimental during the postgraduate level. The coping strategies then diminish any negative behaviour such as attack, criticism, coercion and withdrawal\textsuperscript{7}. Consequently, married postgraduate students tend to focus more on the solution rather than the problems. They always find an effective way so that their marital interaction can be sustained. Therefore, strong marital engagement can be developed.

An Examination of the Social-Emotional Competencies among Primary School Students

Ng Ching Yee¹, Yeo Kee Jiar²
¹PhD Student, ²Professor, School of Education, Faculty of Social Sciences and Humanities, Universiti Teknologi Malaysia, 81310 Johor Bahru, Johor, Malaysia

Abstract

Social Emotional Learning is an important focus in education that develops the Social-Emotional Competencies (SEC) of students to work and live as productive citizens. The objectives of this study are to examine (i) the overall Social-Emotional composite of Year Three primary students; (ii) the SEC of the students in self-awareness, social awareness, self-management, relationship skills and responsible decision-making; (iii) the specific needs and strengths of the students’ SEC. Non-probability sampling technique specifically purposive sampling was used for this study. 35 teachers with experience in Year Three students from six National type schools in Johor Bahru, Malaysia were recruited for this study. Each teacher rated three Year Three primary students’ (n=105). This study used the Devereux Student Strengths Assessment (DESSA) to examine their social-emotional needs and strengths. The results showed the social-emotional composite is at “Need for Instruction” category. More than 43% of students were in the “Need for Instruction” category and had the lowest level of Personal Responsibility, 44% - 54% of students were in the “Typical” category while less than 9% of students were in the “Strength” category. Therefore this study is valuable in the design and development of Social Emotional Learning Intervention which will re-direct the teachers’ focus on educating rather than managing students’ social and emotional problems.

Keywords: Social emotional competencies, Social-emotional learning, Social-emotional composite.

Introduction

Social Emotional Learning (SEL) has become an imperative component in education and has gained the attention of researchers and educators. It is the process of acquiring fundamental life-skills that enhances the students’ ability to integrate knowledge, attitudes and behaviours that help them cope with daily challenges and tasks effectively and ethically (Collaborative for Academic, Social, and Emotional Learning). The SEL process develops the students’ social-emotional competencies (SEC) which consist of pro-social skills, emotional and behavioural regulation, intra- and interpersonal relationship, problem-solving and emotion coping ability that are critical to a student’s academic engagement and school success. Self-management, self-awareness and coping effectively with others enable the student’s ability to learn and provide them with the support for individual and learning achievements.

A teacher’s responsibility is to teach and shape the students’ characters into well-rounded and well-behaved individuals. However, inadequate support from school places the misbehaved students at risk of developing severe behavioural problems. School plays a vital role in fostering students’ cognitive development, as well as their social and emotional growth. The increase in SEL as preventive and early intervention efforts have been well documented. Studies found SEL programmes are useful in improving students’ attitudes, behaviour, and academic performance. Research-based SEL curricula enhance the successfullness in school and life. Intervention researches have also shown that SEL can be fostered.
Numerous studies have been done to investigate the effectiveness of SEL programmes on behavioural problems in different countries.\textsuperscript{1,2,3} This presents a broad range of research opportunities for researchers to further expand the knowledge base in this important area of education. In view of this, the current study examines the social-emotional development needs and strengths of the student.

Literature Review

The Effect of the Social-Emotional Competencies

Students who do not have adequate SEC to cope with the stress in school will negatively affect their academic performance, student-teacher relationships, and behaviour and emotional development.\textsuperscript{4} Lee\textsuperscript{6} reported students lack the five core social-emotional competencies; self-awareness, social awareness, self-management, relationship management and responsible decision-making. Inadequate SEC may lead to behavioural problems which then form a barrier towards effective classroom instruction.

The inadequacy in SEC does not only affect the individual but the society at large as well as the school system too. Individuals with social-emotional problems are not productive in educational settings and society. Insufficient social-emotional development can eventually affect the academic achievement, productivity and satisfaction with life.\textsuperscript{3} These indicate there is a need to address the social-emotional challenges seen in students.

Behavioural intervention has the ability to improve SEC in a student’s life.\textsuperscript{1,2,7} Prevention and intervention in schools are essential approaches that focus on the needs and strengths of students at diverse stages of social-emotional problems. The Social Emotional Learning Intervention (SELI) appears to address a variety of challenging social-emotional problems. With the implementation of the SELI, teachers may be able to spend more time on instruction and less time reacting to social and emotional problems in the classroom.

The Barrier in Social-emotional Implementation

Although SEL is an organized and practical approach to address students’ social-emotional problems, it is clear there are barriers to the prevention and intervention.\textsuperscript{8} The barriers highlighted by Ng and Yeo\textsuperscript{5} and Lee\textsuperscript{6} and showed teachers have limited training to employ SEL, teachers affirmed they did not have enough time to prepare for SEL lessons, and lack the knowledge on SEL implementation. The results indicate the curriculum and instructional strategies in classroom practices need much improvement in order to overcome the barriers of implementing SEL in classrooms. These critical issues should be addressed as SEL programmes have been found to be effective in developing students SEC.\textsuperscript{9} Without the appropriate training to increase teachers’ awareness of SEL, the implementation of SEL in classrooms is far from satisfactory.

In sum, literature revealed most teachers faced social-emotional problems in their classroom, challenges such as insufficient knowledge in SEL, time constraints and lack of resources in SEL implementation. There is a practical gap between the reality in school and classroom. The disparity is seen amidst the teachers’ SEL practice and training and the inadequacy of teachers’ SEL pedagogical knowledge to optimise SEC. Evidence-based approaches that yield multiple benefits need to be implemented effectively in order to address the time constraints and challenging demands in school. It is recommended to look at SEL intervention to deal with and eventually solve the behaviour problems.

Social-Emotional Learning and Moral Education

In Malaysia, education is a continuing process to educate and shape students into well-rounded and well-behaved individuals as envisioned in the National Education Philosophy. Social-emotional learning and moral education are the two main formal methods adopted in schools to support students’ behaviour. Moral education’s emphasis is on values clarification like right-thinking leading to right behaviour. Conversely, SEL is a parallel effort to moral education in teaching morality and social-emotional competencies.

The education system has the responsibility to teach children into leading a morally-guided life. For this reason, schools promote SEL for the purpose of creating moral and productive citizens. SEL and moral education offer a possible route to learn effective problem-solving skills in handling emotions and relationships. Skills in problem-solving can provide an opportunity for moral action in life. Therefore there exists a potential pathway of convergence between moral education and SEL.

Malaysia Education Blueprint for 2013 to 2025 concentrate on 6 areas of student aspirations: knowledge, thinking skills, leadership, bilingual proficiency, ethics
and spirituality, and national identity. Students need SEC to gain knowledge, think critically and demonstrate their values in ethics, leadership, communication and national identity. However, the lack of SEC among students in schools would require effective improvement strategies to institute the necessary SEC.

Analysis of SEC in Year Three Moral Subject revealed that SEC does exist in Year Three Moral subject. Social-emotional Components are embedded in Year Three Moral subject, regardless of whether teachers realise it or not. Although social-emotional components are implicitly embedded in the Moral subject, effective ways to enhance SEC are still lacking due to the absence of awareness and teaching strategies of SEL among the Moral subject teachers.

Objective

The objectives of this study are to examine (i) the overall Social-Emotional composite of the Year Three primary school students; (ii) the social-emotional competencies of the students in self-awareness, social awareness, self-management, relationship skills and responsible decision-making; (iii) the particular needs and strengths of the students’ social-emotional competencies.

Methodology

Research Design

This research design adopts the quantitative method.

Sampling Procedure

Non-probability sampling involving purposive sampling is used in this study. 35 teachers from 6 Chinese National Type schools with experience in teaching Year Three students rated Year Three students from Johor Bahru on their social-emotional competencies.

Participants

The student participants for this study came from six schools in Johor Bahru. Different schools were selected to obtain the sample from different geographical areas. 35 Chinese National type teachers were recruited for this study, consisting of different gender with different teaching experiences and they rated three Year Three primary school students in Johor Bahru, Malaysia from regular education classes.

Instrument

The Devereux Student Strengths Assessment (DESSA) is used to measure Social-Emotional Competencies in children from preschool through the eighth grade. DESSA is a 72-item strength-based behaviour rating scales instrument and contains a series of questions for raters to examine and measure a variety of behaviours according to a Likert scale. DESSA is a screening, monitoring and evaluating tool and was designed mainly to monitor social-emotional instruction and assess the outcome of the program.

DESSA produces eight scores of social-emotional competencies and an overall total score named the Social-Emotional Composite. DESSA is organized into eight Social-Emotional Competencies. Eight of the DESSA scale scores are results from the items allocated to each scale. A Social-Emotional Composite score comprised of a combination of the eight scales of SEC which include: Decision-making, Personal Responsibility, Self-awareness, Self-management, Social Awareness, Goal-directed Behaviour, Relationship Skills, and Optimistic Thinking. Two of the CASEL domains; Self-management and Responsible Decision-Making were each further categorized into two components. Self-management branched into Self-management and Goal-Directed Behaviour while Responsible Decision-Making branched into Decision-Making scales and Personal Responsibility.

Validity and Reliability of DESSA

DESSA has a high internal reliability. The internal reliability for DESSA ranges from a low .82 to a high of .94: Self-awareness (.89), Social-awareness (.92), Self-management (.92), Goal-directed behavior (.93), Optimistic thinking (.89), Relationship skills (.94), Decision making (.92), Personal responsibility (.92), and Social-emotional Composite (.99). The median value for teacher raters was .92. The Social-Emotional Composite coefficients for teacher raters (.99) is above .90 value for the total score.

Scoring and Interpretation for DESSA

The rater is required to rate on a five-point LIKERT scale ranging from 0 to 4 (Never=0, Rarely=1, Occasionally=2, Frequently=3, Very Frequently=4) on how often the student exhibit each conduct over the past four weeks. The DESSA is administered for 8 to
10 minutes. Each scale score is summed from the scores of the eight DESSA scale items. A Social-Emotional composite score is a combination of the eight scales scores, which gives a general indicator of the student’s social-emotional competencies. Items are first sum up to raw scores which are then converted to T-scores. T-scores of 60 and above signify “Strengths”, T-scores of 41 to 59 signify “Typical” and T-scores of 40 and below signify a “Need for Instruction”. The T-scores provide information about the particular needs and strengths of the students.

**Results**

The results in Table 4 show 100% (102) of Year Three students’ level of social-emotional competencies is at the “Need for Instruction” range for the social-emotional composite. The mean score for the social-emotional composite is 28.01(SD=0.10). More than 43% of students are in the “Need for Instruction” range in every component of SEC, namely self-awareness (45.1%), social awareness (43.1%), self-management (43.1%) goal-directed behaviour (46.1%), optimistic thinking (43.1%), relationship skills (44.1%), responsible decision-making (44.1%), and Personal Responsibility (47.1%). They had the lowest level in the self-awareness item (M=41.93, SD=9.13). Majority of the students are in the “Typical” range (44.1%-53.9%). Less than 9% of the students are in the “Strength” range. The result shows that there is a risk for the students to go into “Need for Instruction” range.

**Discussion**

The findings of the studies indicated that the social-emotional competencies, student-teacher relationships and behaviour development among Year Three students were not satisfactory. A majority of the students will need preventive intervention, although a minority of the students performed well in the social-emotional competencies. Therefore, DESSA can be used to examine students’ particular need for instruction and social-emotional strengths. These results can also be used to assess for social-emotional learning quality improvement and program evaluation. Prevention and intervention in enhancing the social-emotional competencies might benefit the students who are in the “Typical” and “Need for Instruction” range. SEL components do exist in Malaysia Moral Education curriculum, but most teachers are not aware of its existence and therefore did not practice SEL in their teaching. This study provides an insight into the design, development and organization of learning objectives and
content for SELI.

Through SELI, students can learn to master the expected behaviours and the social-emotional skills. The behavioural intervention also helps the students’ to be productive in the classroom. As such, SEC plays a vital role in determining how well the students socialize with peers, engage in learning and benefit from SEL instruction. Durlak et al.² assert that SEL improves achievement, increases pro-social behaviours and reduces depression and stress among student. On top of this, SEL equips the student to manage themselves and others, their relationships, and their work ethically and effectively.¹ Social-emotional learning is a critical component for individuals to be successful in school, workplace and later in life. SEL allows students to control themselves, build a relationship with friends, resolve conflicts, and make ethical and safe choices. Students with strong social and emotional skills make better use of instructional time, their classroom behaviour is less disruptive and they are less likely to be disciplined and suspended.

For students already experiencing significant social-emotional problems, DESSA can uncover strengths that can be nurtured. This study provides a better insight into the students’ social-emotional competencies in order to design and develop the Social Emotional Learning Intervention for Year Three primary school students. There is a need for teachers training programmes on SEL instruction and the application of SEL for managing students with social-emotional problems. SEL programmes should be implemented throughout the school years and aligned with academic achievements and made into an essential element of the school curriculum. Understanding which behavioural problems students faced and the coping mechanism they adopt would assist the Ministry of Education in the formulation of SEL strategies intervention programme in schools. In-service and pre-service teachers can be trained to equip them with SEL teaching strategies that support the development of SEC.

**Conclusion**

The present study indicates that there is still a lot that needs to be done for the students’ social-emotional competencies. The findings of this study highlighted the social-emotional competencies among Year Three students were not satisfactory. Research has indicated that students with social-emotional problems often encounter difficulty in the learning process as well as interrupt the learning process of others. Students who lack SEL skills are unable to learn effectively and over time they drain the educators’ energy. Unfortunately, schools have limited resources for teachers to deal with students’ SEL and schools’ exclusive focus on academic education and behaviour management are inadequate to help students achieve academic success.

Finally, teachers need considerable support and teaching resources on SEL to redress students’ social-emotional problems. Every student deserves the opportunity to succeed in school. Students who acquired social and emotional skills in school will become productive, responsible and satisfied individuals. Therefore existing resources should be used to institute SEL in teaching SEC for social, emotional and academic success.

Parents’ Couple Relationship, Parent-Child Relationship and Emotion Regulation among Malaysian Children

Azlina Mohd Kosnin¹, Tu Chien Hui², Mohd Zaki Daud³

¹Associate Professor; ²Master Student, School of Education, Faculty of Social Sciences and Humanities, Universiti Teknologi Malaysia (UTM) Skudai, Malaysia; ³Lecturer, School of Electrical Engineering, Universiti Teknologi Malaysia (UTM) Skudai, Malaysia

Abstract

Studies have found the importance of parent couple relationship and parent-child relationship in relation to children’s emotional regulation. Nevertheless, these findings are based on isolated studies which do not really reflect the extent to which each factor relates with each other as well as to their children’s emotional regulation. The purpose of this study was to investigate the interactions between parents’ couple relationship satisfaction, parent-child relationship and children’s emotion regulation among children in Malaysia. Couple Satisfaction Index (CSI)-4 was used to measure satisfaction level in couple relationship, PACHIQ-R for parent-child relationship and Emotion Regulation Checklist (ERC) for children’s emotion regulation. Cluster sampling was used to select the sample and a total of 357 parents responded to the questionnaires. The analyses have found that all variables are significantly and positively correlated with each other. In other words, the findings suggest that parent-child relationship is related to parents’ couple relationship and children’s emotional regulation is related to both of these variables.

Keywords: couple relationship; parent-child relationship; emotion regulation

Introduction

Emotion regulation (ER) is emotional self-control and a part of one’s self-regulation¹. The term refers to how emotions regulate the other aspects (regulation by emotions) or to how emotions themselves are regulated (regulation of emotions). ER is defined as a complex process of initiating, restraining, and modulating the conscious emotion in achieving goals effectively. In other words, it refers to one’s ability to control own feelings and manage the behavioural outcomes appropriately in social interactions. According to Thompson², emotion regulation consists of the extrinsic and intrinsic processes responsible for monitoring, evaluating, and modifying emotional reactions, especially their intensive and temporal features in accomplishing one’s goal.

With daily lives and resources congregated, family members are mutually influencing each other through daily interactions³. According to Bowen’s family systems theory, family is viewed as an emotional unit and uses system thinking in describing the complex interactions within the unit⁴. Based on the theory proposition, it is natural that family members are intensely connected emotionally and affect each other’s thought, feelings, and behaviours. Moreover, they tend to seek for each other’s attention and acknowledgement for actions, and as well react to each other’s needs, expectations and upsets. With such connections and reactivity, a change in one party would predictably lead to reciprocal changes in the others⁷.
The relationship between father and mother can incite better emotional experiences for children. Couples who are dissatisfied with their relationships often exhibit frequent conflicts and distress in their marriages or child rearing tends to reason the existence of negative emotions and withdrawal in the communication with their children. At the same time, parent-child relationship also affects children’s ER development. Strong and close relationship between parents and child would build up an important developmental basis for the children’s growth. A securely attached child often exhibited mature and healthy emotional regulation. These insights are based on isolated studies which do not really reflect the extent to which each factor relates to their children’s emotional regulation. It is also important to note that most of the past studies were done in the Western culture. Although there were few researches found in Asian and Malaysian context, these results are far too little to be conclusive with regards to the relationship between couple relationship, parent-child relationship and children’s ER among Asian and Malaysian families.

This study investigates the inter-relationships between parents’ couple relationship, parent-child relationship and their children’s ER development among Malaysian families. Results from this study could further add into the literature regarding the development of children’s performance in regulating their own emotions in relation to parents’ couple relationship and the ways parents’ interaction with their children.

**Methodology**

A total of 357 parents with children aged 11 and 12 years old from Johor Bahru district, Malaysia responded to a set of questionnaire. The questionnaire comprised of (1) the short version of Couple Satisfaction Index (CSI) developed by Funk and Rogge (2007) to measure parents’ couple relationship, (2) Parent-Child Interaction Questionnaire – revised version (PACHIQ-R) by Lange et al. (2002) for parent-child relationship, and (3) Emotion Regulation Checklist (ERC) by Shields and Cicchetti to identify the children’s level of emotion regulation. All instruments have been proven to have high reliability indices. A meta-analysis conducted by Graham et al. displayed an average Cronbach’s alpha of 0.940 from five researches in the analysis for CSI. PACHIQ-R has been found to have high reliability in past literatures with Cronbach’s alpha ranged from 0.90 to 0.93 for Conflict Resolution, from 0.78 to 0.81 for Acceptance scale, and from 0.78 to 0.95 for the total score. ERC has showed high internal consistency in most of the past researches with average Cronbach’s alpha reading 0.89 for overall scale, 0.96 for Negativity and 0.83 for Regulation.

**Results**

Normality test was conducted prior to the statistical analyses to identify the relevant statistical tests to be used. To assess the data normality, both skewness and kurtosis values as well as Shapiro-Wilk reading were identified. According to Rose et al. and Cohen et al., skewness and kurtosis scores shall comply with the rule of thumb applied. For large sample size such as 357 in this study, the skewness and kurtosis values should fall within the range of -1 and +1 to be proved normally distributed. A summary of normality test results in this study is in table 1 below:

**Table 1: Summary of normality test results**

<table>
<thead>

<td>2.74</td>
<td>0.19</td>
</tr>
</tbody>
</table>

**Relationship between parents’ couple relationship and parent-child relationship**

The first family relationship evaluated is the relationship between parent’s couple relationship and parent-child relationship through Spearman correlation as the data were found to be not normally distributed. As shown in Table 1, the Spearman correlation indicated a significant relationship between couple relationship and parent-child relationship among the respondents. A significant weak positive relationship between the variables was proven with $r = +0.248$, $n = 357$, $p = 0.000$ ($p < 0.05$). Analyses based on parent-child subscales also show significant correlations, indicating that better couple relationship is associated with better acceptance towards their child ($r = +0.214$, $n = 357$, $p < 0.01$) as well as better conflict solution ($r = +0.237$, $n = 357$, $p < 0.01$) in parent-child interaction.
Table 2: Correlation (Spearmen’s rho) between parent’s couple relationship and parent-child relationship results

<table>

<tbody>
<tr>
<td>Spearman’s rho</td>
<td>0.248**</td>
<td>0.214**</td>
<td>0.237**</td>
</tr>
</tbody>
</table>

**. Correlation is significant at the 0.01 level (2-tailed).

In this study, the relationship between parent’s couple relationship and parent-child relationship was significant. The variables were positively related to each other that greater marital satisfaction facilitates better parent-child relationship in both the acceptance and conflict solution. However, the relationship was weak. The result was somehow reflected as the trend in similar past researches. From previous research findings, data demonstrated inconsistency with regards to the relationship between parent’s couple relationship and parent-child relationship. For instance, research by Amato\(^24\) found that the consequences of divorce on the family is strongly relied on the couple’s reactions towards the change. Instead, divorce may be beneficial for certain individuals. On the other hand, earlier study concluded that marital status can erode the relationship between parent and child especially when a father or mother leave the family behind\(^25\). In addition, low quality of marriage accounted the parent-child relationship and leads to less affective relationship. Severe marital dissatisfaction and family chaos contribute to non-supportive responses such as rejection and dismissing by the parents, thus defeated the parent-child attachment\(^13,26-27\).

**Relationship between parents’ couple relationship and children’s emotional regulation**

The second correlation has identified the relationship between parents’ couple relationship and children’s emotional regulation. Spearman correlation was once again applied to investigate the relationship. The results has reported a weak yet significant relationship with \( r = +0.107, n = 357, p < 0.05 \).

According to Bowen’s family theory, family members are intensely attached to each other in thoughts, feelings, and actions. They tend to constantly seek for each other’s attention, approval and supports for actions and development. Consequently, changes in one predictably bring changes in the others\(^6-7\). Furthermore, the concept is also advocated in Social Learning Theory by Bandura\(^28\) that children are likely to model the interactions between their parents while learning proper social interactions. Therefore, the marital conflicts between parents and negative family expressiveness will then impair the children’s acquisition of ER\(^1,14,29\). In contrast, if parents displayed greater satisfaction in relationship and warm interactions, positive communication is promoted\(^1,8,14,29\).

Similar result was once again confirmed in this study with the Spearman’s rho indicated significant positive relationship. However, the relationship was very weak though significant. As suggested by past literatures, this weak relationship probably moderated by several factors such as the parent’s gender and the parenting strategies they employed. Merely judging from stressors on parents and their marital relationship are insufficient and inappropriate to conclude the relationship\(^26\).

**Relationship between parent-child relationship and children’s emotional regulation**

The last research objective of this study was to gauge the relationship between parent-child relationship and children’s ER. Since both data were normally distributed, Pearson correlation was carried out. As shown in Table 2, the results showed significant relationships between parent-child relationship and children’s ER. A moderate positive relationship was identified with \( r = +0.532, n = 357, p < 0.05 \). When analysed based on children’s emotional regulation subscales, both parent’s acceptance and conflict solution were highly correlated to parent-child relationship with results \( r = +0.909, n = 357, p < 0.05 \) and \( r = +0.930, n = 357, p < 0.05 \) respectively.
Table 3: Pearson correlation between PCR and children’s ER

<table>
<thead>
<tr>
<th></th>
<th>Accept Score</th>
<th>Con. Sol. Score</th>
<th>Total ER Score</th>
</tr>
</thead>
<tbody>
<tr>
<td>Total PCR Score</td>
<td><strong>0.909</strong></td>
<td><strong>0.930</strong></td>
<td><strong>0.532</strong></td>
</tr>
</tbody>
</table>

**. Correlation is significant at the 0.01 level (2-tailed).

Parent-child relationship is also found to relate to children’s emotion regulation development. Based on the Attachment Theory, effective communication and expression of emotions can only be allowed by a secure attachment between parent and children. Consequently, a child appears to have better ER and better behavioural management skills if he is certain that his guardians would understand and willing to communicate his expressions (Hicks and Korbel, 2013; Kim and Page, 2013).

The results indicated that children’s ER improves along with positive parent-child relationship. Specifically, significant relationships are also found when relating children’s ER to the parent’s acceptance and conflict solution. Comparatively, acceptance is defined to have higher contribution to children’s ER than conflict solution. This result is aligned with most of the previous findings10,15,16,17.

**Conclusions**

Bowen’s family theory was one of the famous theories that explained the emotional attachment between family members. Based on the theory, changes in the either member in the family bring causal reactions in the others7. In this study, this concept was studied through correlations between parent’s couple relationship, parent-child relationship on children’s ER development. For instance, the research findings showed positive and significant relationships for all three variables where better couple relationship relates to better parent-child relationship, and better children’s ER development. The significant findings serve as an extension of knowledge and information to understand the different factors that contribute to the children’s emotional development.

Low Back Pain Risk Assessment for Construction Industry Personnel

Norzarina Othman¹, Yeo Kee Jiar²
¹Postgraduate Student, PhD Ed. ²Professor School of Education, Faculty of Social Science and Humanities, Universiti Teknologi Malaysia, 81310 UTM Johor Bahru, Johor, Malaysia

Abstract

Workers in Construction Industry (CI) are potentially to deal with injuries and illnesses, including Musculoskeletal Disorders (MSDs) in the workplace. Unfortunately, the issues related to Ergonomic Risk Factors (ERFs), that lead to MSDs always being underestimated and little attention been taken from the CI. Therefore, a study will be conducted to obtain the mitigation to reduce Low Back Pain (LBP) affected by ERFs impact to CI personnel. For the purpose of this findings, the objective is to study ERFs that caused LBP, to study Ergonomic Program (EP) that is implemented and to propose mitigation method to reduce LBP for CI personnel.

Keywords: Musculoskeletal disorders, Ergonomic risk factors, Low back pain, Construction industry personnel.

Introduction

The CI listed as a major contributor to the economic development of the country. The importance of this industry can be clearly seen through its involvement in various industries particularly in Malaysia.

However, the safety elements shall be considered and implemented in any construction project. Issues related to MSDs is one of the elements shall not be underestimate because it is common health problems in the working population.

The injury is highly affect the health of workers who exposed to hazard for a long period of working time. These injuries are caused by ERFs such as awkward posture, high force, repetitive motions, contact stress, static loading, segmental or whole body vibration, heat and cold cause, which related to the working conditions that expose the muscles, joints, tendons, ligaments, and nerves.

Literature Review

A MSDs has been recorded as high risk hazards in CI. According to the statistical report released by DOSH Malaysia 2012, indicate a high number of personnel who suffer from the occupational diseases. The increased numbers been recorded significantly since 2005; 3,002 numbers of cases being recorded in 2014 drastically increased from the previous ten years. The gap numbers recorded for the ten years are shown that the cases of occupational diseases are drastically increased with 94%. Large numbers shown the element of MSDs particularly in CI increased due to lack of attention on personnel health safety in the industry.

MSDs at the workplace were greatly increased and become serious in occupational injuries. These rapid increases make the industries suffer from tangible and intangible losses because of increased in medication costs, decreased productivity, work quality and decreased worker morale.

Due to Malaysia moving towards industrialization and the rising average age, MSDs symptoms are on the rise. These rapid increases continue to be a major source of disability, loss of working time, and also linked to serious and costly health risks. There is less emphasis on the health issues due to the nature of construction work, such as sizeable, temporary and mobile workforce, many
impermanent workers which not directly employed lack of health experts within the industry, benefits of health management are not immediate and are consequently difficult to demonstrate⁷.

**Musculoskeletal Diseases (MSDs)**

MSDs are injuries of the soft tissues that affects nearly all tissues, including the nerves and tendon sheaths, and most frequently involve the arms and back. OSH professionals have called these disorders a variety of names, including cumulative trauma disorders, repeated trauma, repetitive stress injuries, and occupational overexertion syndrome.⁶

**Ergonomics**

Ergonomics are related to human and their job. Good ergonomics prevent injury and promote health and safety. Implementation of program that includes guidelines for employees; contributes to an efficient work environment, prevent injuries and helps employees return to work after an injury has occurred.

**Table 1: Advantages of Ergonomics (Shoubi, 2013)**

<table>
<thead>
<tr>
<th>Advantages</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>• Reducing discomforts</td>
<td>by reducing the ERFs</td>
</tr>
<tr>
<td>• Increasing productivity</td>
<td>by providing job satisfaction</td>
</tr>
<tr>
<td>• Reducing absenteeism</td>
<td>Engagement with healthy environment increased productivity</td>
</tr>
<tr>
<td>• Cost &amp; time savings</td>
<td>Minimizing injuries improves productivity and reducing compensation claims</td>
</tr>
<tr>
<td>• Increasing morale</td>
<td>Safer working environment will value to employees</td>
</tr>
</tbody>
</table>

**Ergonomic Risk Factor (ERFs)**

ERFs on CI was in a straight line connected to the job structures; imperfection into interpretation of body structure and also to the MSDs through long period of time. They contribute major job factor which constituted to ERFs. Therefore, understanding in basic ergonomic principles is essential for prevention of injuries. Each employee need to understand the ERFs related to their work tasks and solutions to minimize such risks.

**Methodology**

The research methodology act as systematic way towards achieves the objectives. In this study, the process generally consisted of five stages.

The first phase involves on the background of the study. Problem statement was identified by looking at current trend. Formation of objective, title selection and scope of the study were determined based on problem statement identified.

Second phase is followed by secondary data collection with exploratory research of the literature reviews on related topic for this study.

The third phase is conducting of detail data and information collection. Questionnaire is developed using the information from literature review. Primary data is collected by the developed questionnaire where using Likert scale method on five (5) ordinal options designed. Questionnaire was divided into four (4) sections; Respondent’s Detail; ERFs caused LBP; Factor Affecting LBP; Recommendation to Reduce LBP. Questionnaire had been distributed among construction companies in Johor Bahru.

The fourth phase is data analysis, interpretation and data arrangement of primary data collected from respondent using SPSS. The percentage frequency distribution uses the risk formula from HIRARC and Average Index (AI).

The last phase of the research process mainly involved discussion, conclusion and recommendations for future study.
Results & Discussion

This study was to assess the prevalence of MSDs indicated the highest work-related symptoms which focus to LBP. Questionnaires sets were distributed to 100 respondents and 67 number of respondents returned with completely answered. The results are discussed as below based on the objectives of the study.

**Finding 1: ERFs caused LBP among CI personnel**

Objective one conducted to study ERFs on CI that caused LBP. Six ERFs elements have been categories as repetition, vibration, contact stress, awkward posture, static posture and excessive force. The result for this objective is obtained by analyzing the ERFs based on severity and frequency of personnel exposed to the risk factor. By using the risk formula and risk matrix table, the ERFs for each element have been identified.

Static posture is an element that caused to ERFs and there were four tasks which all in medium risk. Sitting for a long time found as highest risk among the ERFs that caused LBP. Followed by maintaining the same posture for extended duration and standing for a long period of time. Maintaining the same position without taking time off between assignments been identified as the lowest risk involved among the four tasks in static posture element.

Result for Repetition element shows the Performing task in the same motion repeatedly lead to the rank and followed by doing the same movements without taking time off between assignments. Both task being categorized in medium risk

From the result, one medium risk of ERFs indicates for using any body part as a tools to perform task and one low risk of performing task by pressing hard any body part to the sharp edges of workstation. Both of the tasks categorized in Contact Stress element of ERFs that caused LBP.

The finding indicates two tasks in medium risk and one task in low risk for Excessive Force element of ERFs that caused LBP. Lifting with improper posture, carrying, pushing or pulling heavy objects manually become the high ranking among the three. While using heavy or awkward tools to perform task being found as the lowest risk in the excessive force element.

Result indicate for Awkward Posture element were involved two tasks in medium risk and one in low risk. All the medium risk of ERFs that caused LBP; performing task by bending of backs and performing task involve excessive lifting or/and bending of shoulders, elbows and arms. While performing task that involve long reaches indicates as low risk in the awkward posture element.

There were three tasks involved in Vibration element and all of them were found as low risk that caused LBP. The highest risk tasks are performing task using vibration tools, followed by performing task involve vibration from vehicles and performing task involve vibration working surfaces.

Based on Figure 1, ERFs Elements that caused LBP indicated as medium risk and low risk. The average of all tasks exposure to ERFs in medium risk is static posture, repetition, excessive force, contact stress and awkward posture, which requires an approach to control hazard and applies temporary measure. While vibration become low risk that may be considered as acceptable and further reduction may not be necessary. Control measures must be implemented and recorded for any risk that can be resolved efficiently.

![Figure 1: Factor Affecting ERFs Caused LBP](image-url)
Improper motivation; latent error at management level; bad design and maintenance lead to the top three highest average value. The top three factors extremely affecting ERFs that caused LPB in CI. While lack of control by management; undesirable personality; low quality equipment; and lack of understanding followed after the top three ranking. All factors were classified under moderately affected ERFs that lead to LBP discomfort.

**Finding 2: Ergonomic Program (EP) implemented in CI**

Second analysis conducted to obtain the second objective which to determine EP that is implemented in CI. These factor were actually an external factor which may contribute in affecting ERFs that lead to LBP discomfort.

Data of EP for LBP discomfort prevention being analyzed as tabulated in Figure 6. Hazard and reporting; and training become the most important for EP to be implemented, followed by management leadership and employee participation. The least EP implemented is job hazard analysis and control, program evaluation and MSDs management is the most less EP implemented in CI.

**Finding 3: Mitigation Method to reduce LBP for CI personnel**

Third analysis conducted to proposed mitigation to reduce LBP in CI. The ways will be acquired through minimizing the ERFs. Respondent participation for this section includes CI personnel from management and technical representative who directly involved in construction project.

Administrative control element become the most recommended which lead by the setting of proper working time; assigned the correct position and proper instruction for ergonomics; provide training and information regards to LBP awareness; provides convenient working area and working furniture; and keep on records, control and monitor to reduce hazards and accidents at workplace; medical check-up regularly comes after the suggestion to create awareness regards to hazard that affected LBP; while penalties for non-ergonomics compliance comes after the independence inspector to assess safety and health that lead to MSDs.

Two suggestions come from engineering control elements which to provides convenient working tools; and build a computerize system with new technologies about health environment. Element of construction industry itself suggested to create awareness regards to hazard that affected LBP; and independence inspector to assess safety and health.

**Conclusion**

The conclusions of each objective that can be drawn out as follows;

Objective 1: To Study ERFs that caused LBP among CI personnel

The first objective of this study has been achieved through questionnaire survey by analyzing the respondent’s exposure to ERFs that caused LBP.

i. From the result, six ERFs affecting LBP being categories as repetition, vibration, contact stress, awkward posture, static posture and excessive force.

ii. Five ERFs falls onto medium risk while the other being categorized as low risk.

iii. This finding found that none high risk involved due to safety officer provided at most construction project and safety and health data being recorded, controlled and monitored regularly. Besides, most of construction companies have implemented an EP in order to reduce MSDs and injuries at workplace.

iv. Static posture become the high risk exposure toward ERFs to suffer LBP and followed by risk factors of repetition, excessive force, contact stress and awkward posture. Five highest ERFs elements being categorized under medium risk which a planned approach to control the hazard and applies temporary measure is required. Actions taken must be documented on the risk assessment form.
including date for completion.

v. While vibration where the factors may be considered as acceptable and further reduction may not be necessary. However, if the risk can be resolved efficiently, control measures should be implemented and recorded.

vi. The finding also shows all personnel involved in CI are in medium risk and low risk. This indicates that CI personnel were actually exposed to ERFs that may cause to LBP as the nature working condition in CI.

**Objective 2: To Study EP that is Implemented in CI**

Second objective of this study being achieved through questionnaire survey by analyzing the EP that is implemented in CI.

i. The study shows that MSDs management and program evaluation extremely affected ERFs that caused LBP. This result clearly shows management are the underlying causes leading to MSDs injuries, as if management improve their job which define “planning, organizing, leading, and controlling,” the MSDs can be prevent from happening. Management need to take every safety measure available to minimize the ERFs that helps to reduce the MSDs that lead to LBP.

ii. Job hazard analysis and control, management leadership and employee participation, training and hazard information and reporting also contribute in affecting ERFs that lead to LBP. EP are highly preferred to be implemented in construction personnel in both workers and management representative on CI. The organization environment need to continuously implemented the EP to prevent LBP from occur.

iii. The management provides training and information regards to LBP awareness to employees and all parties involved; and build a computerized system with new technologies about health environment. The proposed mitigation may enhance with conducting EP through training and computerize system for hazard information, records, controls, monitors and reporting.

iv. Management may support with financial supply for medical checkup regularly such as once in a month.

v. Management may provide convenient working area and furniture; and proper working tools in creating safe and healthy working environment.

vi. Set up penalties for non-ergonomic compliance to ensure the achievement in reducing LBP due to employees had an undesirable personality especially when comes in complying with rules and regulation. The proposed mitigation, will ensure employees to comply with all the ergonomic instructions.

vii. Finally, the involvement from the third parties such as DOSH represent the CI to provide independence inspector to assess all safety aspects respect to MSDs. This proposed mitigation can be adopted in order to reduce MSDs that lead to LBP.

Impacts of Natural Disaster on Children: Development of the ‘MAIN’ as Inventory

Hafizah Harun¹, Rohaya Talib¹, Habibah @ Norehan Haron², Hamimah Abu Naim¹, Marlina Ali¹
¹Senior Lecturer, School of Education, Faculty of Social Sciences and Humanities, University Teknologi Malaysia, ²Razak Faculty of Technology and Informatics, University Teknologi Malaysia, Kuala Lumpur

Abstract

Children are the most vulnerable victims during natural disaster and majority are neglected from aspect of psychosocial support. A 6.0 magnitude earthquake of June 5, 2015 in Sabah resulted in 18 fatalities, among them 12 year-olds schoolchildren, and disrupted normality of lives. This study investigated impacts of natural disaster on school children. The MAIN (acronym for Measurement of Adverse effect INventory) was developed to collect the required data and consisted two sets of measurement. The first set are instruments assessing children posttraumatic stress disorder symptom (PTSD), and preparedness / awareness of both children and related authorities. The second set consisted of initiative game modules that examine problem solving skills and heart rate (HR) responses during simulated situations. Respondent were 100 school children and 50 mixed populations. Results of the quantitative and qualitative data were triangulated. Low levels of PTSD but high levels of empathy were displayed. Adequate contingency plans and designated emergency centres were needed, A disaster risk education and training drills were proposed, as embedded into existing curriculum. HR variability occurred dependent on positions of the player. And both types of audio interventions significantly decreased the HR to normal levels faster than no interventions procedure.

Keywords: disaster, MAIN, initiative games, HR responses, PTSD, preparedness / awareness

Introduction

Natural disaster is an open problem that affects humans in terms of direct, indirect and intangible losses. Direct losses involved costs such as to repair physical damages due to destructions of amenities. Disruptions to normality of life in terms of economies are examples of indirect losses. Intangible losses include the psychological impairments an individual suffer as a result of both the direct and indirect losses. There have been several approaches and tools used to study these impacts.

Assessment of the disaster is usually done to estimate resources for replacement and mitigate consequence of the damage to the more tangible losses.

Studies examining physical and psychological effects mainly involved single assessments such as standardized questionnaires to collect self-reported information on symptoms and quantified using numerical scores.

Natural disasters are sudden events that negatively impact the immediate wellbeing of humans. Communities and more than half children take years if ever to overcome the adversities. Children that are victims of war and other extreme situations suffers both physically and psychologically if they have limited support from parents or communities. The problem is often comorbid, one affecting the other and illnesses rampant as access to medical care and food supply is cut off or contaminated.

Earthquakes are frightening and stressful experience. Children are less able to express their stresses such as grieves of losing loved ones, looking at parents undergo stress, and seeing damages to their homes. Often undetected and take lapse of time to be identified, they suffer silently from distress symptom...
such as posttraumatic stress (PTSD) and depression. PTSD symptoms include intrusive memories, avoidance, changes in emotional reactions and hyperarousal.

The 6.0 magnitude earthquake that shook Sabah were considered light, but 18 climbers and guides were killed as they were struck by boulders on the slopes of Mount Kinabalu. Seven of the victims were 12 year olds school children from a Singapore school and others were adults including Malaysians and others. Nevertheless the quake caused tangible losses damaging the geographical landscape and economy of the local communities and destroys livelihoods.

Hence, the MAIN inventory was developed to investigate impacts of natural disaster on school children. The purpose of this study was to report the protocol and results obtained. And further discuss implications of the findings.

Method

Permission to run the study was acquired from the Education Department of Sabah. Visits were carried out on the 23 – 30 November 2015. Sample were students and communities from the town of Kundasang and immediate areas located in the district of Ranau from six schools located closest to Mount Kinabalu, the center of the 2015 Sabah earthquake.

The MAIN (acronym for Measurement of Adverse effect INventory) developed to collect the required data consisted of four measurement tools (Figure 1). Two of which comprised instruments (I₁) that assessed students posttraumatic stress symptom (PTSD) and (I₂) the schools’ authorities and communities preparedness - awareness (P-A) using set of questionnaires and interviews. The other two contained modules (M₁) that investigated students’ physiological responses (HR-heart rate in beats per minute) during a simulated game play situations and (M₂) the HR recovery trends using two intervention procedures.

Data for I₁, where only 15 minutes was needed to complete the measure, and all the I₂, M₁, and M₂ were collected during the one week visit

![Figure 1: Design of the MAIN inventory](image)

**Instrument component (I)**

The I₁ is child version of PTSD questionnaire, adapted from the adult scale and developed by Foa et al. This diagnostic scale was adapted into Bahasa Malaysia and Malaysian context from internationally published studies (test-retest reliability of 0.96 and validity kappa of 0.64 - Blanchard et al.².

The I₂ consisted of specific preparedness / awareness (P / A) questionnaires and a structured interview sessions. Test-retest reliability of the P / A was alpha = 0.81. Targeted respondents are school supporting staffs such as teachers, clerical, gardeners and guards and/or students that should be at the schools during the research team visits. The P / A questions pertained to inquiring the level of preparedness and awareness during occurrence of natural disaster. The head of schools and senior administrators were interviewed discussing emergency and contingency plans that ensures safety in case future calamities reoccurs.

**Module component (M)**

The second school visits where appointment had been made to collect the M₁ and M₂ data, group of students came to participate in the simulated game situations. They live in the surrounding areas where tests were completed at the respective school halls and community centres. Since the children came with their families, permission was acquired from parents to participate in the M₁ and M₂ data collection sessions.

M₁ consisted of simulation game situations that tested children high order thinking skills during the process of solving situational stressful problems. Each individual heart rate data were recorded prior to, during and after the simulated game play. The game requires that students worked in groups of five to overcome
prescribed obstacles. The students assigned themselves to positions 1 through 5, besides having their legs tied to each other; the third person was also blindfolded. Video cameras and scorecards were used to record number of mistakes or falls of each person in the group and time for the group to complete the game (Figure 1).

M₂ examined the heart rate recovery response of the students. Directly after completing the M₁ activities, students are randomly assigned to two experimental procedures, recovery response listening to instrumental music audio and the melodious Islamic call of the azan with a control sample (no audio interventions) (Figure 2).

RESULTS AND DISCUSSION

The four components that made up the MAIN produced both quantitative and qualitative data.

Instrument component, I₁ and I₂ inventory:

A total of hundred and one questionnaires had been successfully completed and returned to the investigator consisting samples of thirty-five boys and sixty-six girls (88 % were 12 year olds and the rest 11 to 15 years) whose religions were Islam (52.5 %) and Christianity (47.5 %).

The PTSD checklist is a self-report measure that assessed the severity of symptoms (response format of a low to high 4-point likert scale). The 17 items diagnostic scale indicated the relative frequency to which respondent had been bothered by a particular symptom. In this paper the impact of trauma are clustered into three matrixes of cognitive, emotion and physical symptoms (scores of 1-2 as low, 2-3 moderate, and 3-4 high). The children that participated in this study reported low to moderate posttraumatic symptoms after six months of the Kundasang - Ranau earthquake.

Cognitive symptoms constitute items 1, 2, 3, 8, 15, and 16 - Intrusive Recollect, Flashbacks, Upset by Reminders, Psychogenic Amnesia, Concentration Impaired, and Hyper vigilant. The emotional symptoms are items 4, 6, 7, 8, 9, 10, 11, 12, and 14 - Distressing Dreams, Avoid Thoughts, Avoid Reminders, Anhedonia, Estrangement from Others, Psychic Numbing, Foreshortened Future and Irritability/Anger. And physical symptoms included items 5, 13, 17 - Physical Reactions to Reminders, Sleep Difficulty, and Exaggerated Startle

For the P / A, sample consisted of nine males and forty-one females secondary school students, teachers and other staffs. Seven government officials from the local education department and school administrators participated in the interviews. After the sessions, researchers were given tours of the school areas directly affected during the 30 seconds quakes. Some of the building structures such as the walls and floors in the offices and classrooms, the students hostel and teachers housing complex had minor cracks and deem unsafe by the public works department.

Interviewed staffs had been in their related services ranging from two to twenty-one years. All of them agreed it was fortunate the disaster occurred during the Malaysian school mid-term holidays. Liability was
low for the schools as only about fifty students were in schools, a few teachers and school staffs. These students were having extra classes preparing for their SPM (secondary five) and UPSR (primary six) examinations. From the interviews none of the students suffered any injuries but were terrified and girls crying during the event.

Attendances of students and teachers were low as school reopened on Monday since the earthquake occurred on Friday for the term. Most either had left the affected areas or stayed home with their families fearing that more tremors would occur. However, it increases during the week as talks, emergency drills and safety action plans were given by the Education, fire and meteorological departments.

Towards future natural disasters, results indicated moderate to high levels of P/A among respondents (scale of 2.10 to 2.66). Changes to classroom designation according to students’ age and lessons on disaster should be inculcated into existing curriculum and during co-curriculum.

**Module component, M₁ simulation games and M₂ recovery with audio interventions:**

Participations included six groups (five person per group) of thirty boys and seven groups of thirty-five girls that were matched for age and approximate height and size.

Comparing for gender, the heart rate fluctuations and number of errors committed by the girls were higher than the boys (Figure 4). However, no differences were found in the time (minutes) to complete the tasks in the simulated game situations.

Also, as expected persons in position three (who were blindfolded) exerted larger heart rate fluctuations compared to persons in other positions. Being handicapped by sight would have a disadvantage; both the boys and girls had triggered slightly different physiological response.

M₂ were undertaken immediately after completing the simulated game. Knots at the legs and blindfolds were undone, and the children were taken aside for active rest and recovery sessions. While still attached to the heart rate chest monitors, students were randomly seated and given headsets where two persons were assigned to instrumental music, two to melodious calls of the azan (Islamic prayer) and one person without any audio interventions.

![Heart rate responses](image)

**Figure 5: Heart rate responses**

For the recovery sessions, heart rates were reported every minute for four minutes (Figure 5). The heart rates were compared between the two audio interventions and recovery processes between using audio and no audio. There was no statistically significant difference in the heart rate recovery response between the instrumental music and Islamic azan calls audio procedures. However, the two musical audio interventions significantly decreases the recovery heart rate faster than without any audio sessions (p < 0.5).

The four measurement tools that constitute the MAIN inventory yielded both quantitative and qualitative results. In processing data from the instruments and modules, triangulations would further produce a holistic measure of the psychological and physiological impact of natural disaster affecting school children.

This initial analysis indicated that overall 17 PTSD symptoms were low to moderate. Bonanno et al.\(^3\) suggested that posttraumatic stress symptoms appear to be common in the first months post-event with a decline over the first year or longer. Hence the diagnostic judgments about possible presence of PTSD should consider both temporal and spatial parameters to within a few weeks to a month of the disaster. Compassion might have been overcome with time and daily life activities.
Moreover, association or empathy to who was involved as casualties should be a considered factor since the 12 year olds were not local Kundasang - Ranau children. Samples in the study should have also included younger children, since the earthquake affected their homes and schools.

The interviews and second set of questionnaires disseminated to other than children did reveal the state of preparedness and awareness of the school authorities and adults during a disaster. The sudden occurrence demonstrated implications for safe shelter and medical emergencies to be thoroughly planned. Since the school children have never experienced any kind of disaster and thus lack the skills to face natural disaster, disaster risk education curriculum could be embedded in existing school subjects.

The modules, that is the simulation games scenario or initiative games could suitably train the children on cooperative problem solving skills and teamwork. In training for preparedness to future disaster, these games could be introduced during physical education classes or incorporated in extracurricular activities. Moreover the use of audio interventions demonstrated that increased heart rate response during high levels of fear or nervousness experienced to cope with stressful situations could be better managed rather than without any interventions.

**Conclusions**

Triangulations in terms of approaches (quantitative and qualitative) and respondents (children, teachers, administrators) have given insight of what really happened to the affected children. So, a holistic program (which involve cognitive, affective and psychomotor domains) needs to be planned for a better recovery process. The module can be retested for the other types of disaster victims (earthquake, flood, hurricane) to establish the predictive validity of the inventory.

Addiction Rehabilitation and Structural Family Therapy

Raymond Shoup¹, Diana-Lea Baranovich²

¹Master of Psychology Student, Behavioral Sciences Department, California Southern University, California,
²Associate Professor, Educational and Counseling Psychology Department, University of Malaya, Kuala Lumpur, Malaysia

Abstract

Addiction is a societal problem that has affected people from all over the world. As this is the case, a serious look needs to be taken with regards to treatment. Structural Family Therapy was fathered by Salvador Minuchin, who believed that addictions in the family causes a shift in the dynamic of the family, which is where addiction rehabilitation treatment with family members affected by addictions should begin. When working with clients who have addictions, it is important to view the client through a holistic lens; meaning we must view how the substances/activities, and the stresses in their lives which led them to the substances/activities, cause changes in their psychology and physiology. From there, we can create a treatment plan that works with families that offers a prognosis for the client’s life, not just treating their addiction. Structural Family Therapy is great for this, has part of treatment is looking at the client holistically, and helping heal the various parts of the clients lives, including healing their family unit.

Keywords: Addiction, Rehabilitation, Family Therapy

Introduction

When a person goes through an addiction, every aspect of their life changes, including their role and dynamics with the family. Structural family therapy discusses that dysfunction in families can evolve from three dimensions, boundaries, alliances and splits, and hierarchy of power. Structural family therapy was developed by Salvador Minuchin, who developed the practice from his certifications and practices in child psychiatry and psychoanalysis. When it comes to addiction, all three of these dimensions are changed, and need to be adapted when discussing treatment. With addictions, there are two components that need to be addressed, the physiological, which addresses what the body is going through during addictions and withdrawals, and the psychological, which addresses why the client has addictive behaviors, and how the addiction(s) affect them mentally. Structural family therapy, which in the past has been used to help those with eating disorders, a type of addiction in and of itself, could potentially be a great therapy process for both the person with the addiction, and their family members.

Salvador Minuchin

Born in Argentina in 1921, Salvador Minuchin was a pioneer of family therapy. By 1947, he had received his medical license and began working as a pediatrician; eventually leaving the field to serve in the Israeli army. Once his military service was completed, he moved to the United States to study psychiatry, eventually becoming certified in child psychiatry and psychoanalysis by 1967. While receiving his certifications, he was offered a position as the director of the Philadelphia Child Guidance Center. While working as the director of the Philadelphia Child Guidance Center Minuchin developed a new method of working with the center’s patients¹. This method would later be known as structural family therapy (SFT). Minuchin would eventually use SFT to work with patients who have eating disorders, combing techniques from both SFT and cognitive-behavioral therapy. With eating disorders being a type of addiction, and a common cooccurrence with other types of addictions, it is not a stretch to suggest that SFT would work well when working with clients suffering from addictions, and their family members.
Structural Family Therapy

SFT works along the theory that families need therapeutic intervention when there is dysfunction within the family structure, usually resulting in a problem with communication and family role disruption. SFT assesses three dimensions of family dysfunction; hierarchy of power, clarity/firmness of boundaries, and alliances/splits. Hierarchy refers to the level of authority within the family, who holds this authority, and how this authority is executed. Within hierarchy there are three forms that can manifest i.e Effective, insufficient and excessive. In an effective hierarchy, parents hold authority by setting rules while remaining emotionally invested and connected with the children. Insufficient hierarchy is one where parents are ineffective in raising the children in an appropriate manner, which can often lead to permissive parenting, giving the children the authority, to an extent. Excessive hierarchy discusses strict rules enforced unrealistically and bonding with the children often suffers and/or is lacking. Boundaries describe the level of emotionality and closeness of a family unit. There are three levels of boundaries; enmeshment, which is when family members are too much in each other’s business, clear boundaries are described as a healthy closeness and emotionality, decided by the family themselves, and disengagement, which explains a Laissez-faire approach to child-rearing, usually to the extent of having no emotional closeness. Alliances/splits refer to the act of family members creating cliques with each other. This can often result in family members ganging up on ‘outsider’ members and can sometimes lead to the unintentional ostracization of that member.

Addiction

Addiction is described as seeking positive stimuli, despite negative consequences (3). When a person has an addiction, they prefer their addiction over anything else going on in their lives. As a result of this, those suffering from addictions, tend to unintentionally isolate themselves, and are often ostracized from friends and family. With addictions predisposition exists toward addictive and compulsive behaviors, as such it is important to treat the person, not just to change the addictive behavior, otherwise they may switch out one addiction for another.

Addiction is an extrinsically motivated disorder, usually leading to worsening states of anxiety, panic, paranoia, and disconnection. Therefore, part of treatment should use intrinsic motivation for becoming satisfied with life. This is where family can get involved in the therapy process, as they can learn how to reinforce positive intrinsic motivation within themselves to support each other’s motivation within and outside of the therapy sessions. By doing this, some of the isolation and ostracization may begin to reverse themselves.

Psychology

People have addictions when problems they are facing become burdensome, so they use their addiction to ignore the problem. Unfortunately, as bodies adapt to the highs experienced, it requires larger doses of the addiction to experience the high and delay the come down process. Addictions are often outgrowths of improper attachment, with addiction replacing the feeling of love and belonging. Another common reasoning for addictions, is to regain a sense of control in a life that feels out of control. With this, it is likely that the people turned to the addiction as an act of rebellion from the lack of control, telling themselves no one can tell me I can’t do this. This is common with teens from affluent families, who are involved with many rigorous activities for parents to feel a sense of accomplishment through their children.

Physiology

When a person has an addiction, the body responds to the high from participating in the addiction. This reaction stems from three neurotransmitters, cortisol, dopamine, and serotonin. Let’s use shopping as an example, when a person gets stressed their hormones elevate the levels of cortisol in their body, to cope with this increase, the person shops. The act of shopping decreases the cortisol levels, while increasing the reuptake of dopamine, to experience pleasure, and serotonin to experience happiness, once the dopamine and serotonin stabilizes to the point of homeostasis, the cycle is repeated, and a person will need to shop again.

Another neurotransmitter is norepinephrine, this increases the adrenaline levels to experience thrill and excitement, it is typically this feeling that is the addiction, with the source of the addiction simply being a preference on how to increase norepinephrine. It is for this reason that simply treating the addiction, may cause the person to trade one addiction for another, to get that thrill back. Therefore, it is important to
treat the cause of the addiction, not just the addiction itself. When the body is accustomed to the level of these neurotransmitters, it needs more of the addiction to reach the same level of pleasure. With that, when the person is not participating in their respective addiction, the neurotransmitters begin to return to hemostasis; once this is done over a prolonged period, the body enters the withdrawal process. Withdrawal is a process whereby the body reacts violently to lowered levels of the neurotransmitters it’s used to having copious amounts of. As a result of this, withdrawals can include, convulsion, aggression, febrile symptoms, sweat, severe dehydration, and hypoxia, which is when the skin turns pale and bluish from deprivation of oxygen.

**Families and Addiction**

When a person is going through an addiction, their whole family is affected by the toll it takes on the person. Because of this, treating people suffering from addiction needs to involve the family. In fact, addiction is comparable to a chronic disease; as a result of this, families cope with addictions in a similar manner to the way they would with chronic diseases, including maladaptive coping behaviors. Families often accommodate the person with the addiction, at times even helping to pay for the addiction and avoid intervening in order to not upset the member. Another factor that needs to be discussed regarding families and addiction is attachment. Improper attachment can lead to a hinderance in the ability to develop confidence and a sense of self while growing up. It is this lack of confidence and sense of self that may lead a person to form a dependency on an activity or substance that makes them feel good. As a result of this, work with families affected by addictions should focus on reforming and mending the bonds and attachment of the family.

Insecure attachment correlates to higher levels of anxiety and a tendency to avoid managing the anxiety. These behavioral patterns are common in people with addictions, who use their addiction as a tool to manage their anxiety. The idea that improper attachment can lead to addictions is not strictly social in nature. The combination of depression and long-term drug use leads to the deterioration of white matter in the brain, which holds the chambers of the brain together, and assists in carrying neurons throughout the brain and spinal cord. Deterioration of white matter can lead to severe hinderances in cognitive functioning and memory formation.

Compassion fatigue and secondary trauma are both common reasons for families to experience during rehabilitation. With compassion fatigue the family member is tired of the empathy that goes into supporting a person through addiction treatment. Secondary trauma generally happens during the withdrawal process of rehabilitation; this results from watching the events that occur during withdrawal. Not only can this experience be burdensome to the person going through it but watching someone you suffer can be equally traumatizing. When watching a person experience that kind of pain can cause some to leave because they do not want to witness it.

**Structural Family Therapy and Addiction**

Addictions are psychosomatic in nature, and has origins within the family, stemming from improper attachment and lack of clear boundary development. As this is the case, a combination of behavioral therapy (BT) and STF is encouraged when working with clients who have addictions, emphasizing the need to work with the family of the client during and after recovery. BT works on the symptoms of the addiction and teaches resisting set-backs and relapses. STF, works on the cause of the addiction and works with the clients and their families in order to assess where the dysfunction lies and how to form a healthy relationship with the client and their families. You and Park used STF with families whose child(ren) suffer from emotional and behavioral disorders (EBD). After 16 sessions the psychologists found improvements in family function, relationship, and a more positive prognosis for the children. Given the co-morbidity between EBD and addiction, this study shows STF is an effective strategy when working with families who suffer from an addiction.

Many addicts exhibit aggressive and violent behavior. This can cause alienation between the addict and his/her family and friends. This needs to be addressed and worked through while in therapy. Structural family therapy has been shown to be useful in helping families cope with these violent behaviors and can help to decrease dependency behaviors in clients with emotional and behavioral problems.

When working with clients that have addictions, one must explore how the family effects symptomology. They may negatively challenge the symptoms, causing the client to feel ashamed and guilty or be a beneficiary of...
the symptom, meaning that they gain something positive from that symptom, such as sympathy from peers, or the feeling of being the hero in the family.\textsuperscript{8}

All three dimensions of SFT are brought into the therapy process during sessions with both the person with the addiction and their family members. We first look at how boundaries change; often what we see with addiction(s) is the enmeshment boundaries, the parents of the siblings are too much into their business; trying to get them to stop, trying to change, trying to help with withdrawal. This unfortunately makes the client feel uncomfortable and not supported, but rather makes them feel like his/her life is out of their control. There is also have alliances and splits happening with family members of addiction, it can go one direction, whereby the person suffering the addiction is ostracized from the family unit due to the addiction and being a burden. However, you also have the other extreme, whereby the attention is focused solely on the person with the addiction, which may cause the other sibling(s) to be ignored and pushed aside in order to deal with the “problem”. As for hierarchy of power there’s a shift that occurs with addiction. Specifically, this could happen if a parent themselves is the one that suffers the addiction; when they were once a caring parent that provided order to the house and took care of the kids is now trying to take care of themselves and their addiction, thus making parental duties secondary\textsuperscript{3}. When working with people who have addictions, we must first look at the client’s history of the three dimensions before the addiction, discuss how the shift changed during the addiction, and work on how this is going to improve after recovery.

Conclusion

Addictions take a toll on a person, both mentally and physically. However, the family of that person is also affected, and as such needs to be involved in the healing process, from admittance of the problem, all the way to the last day of rehabilitation. The healing process, involving SFT, includes looking at and working through the dysfunctionality of the family, involving the three dimensions; hierarchy of power, boundaries, and alliances and splits. When it comes to addiction, major changes have occurred in the role that person takes in their family, including how they handle hierarchy of power, boundaries, and alliances and splits. As a result of this, the therapy process needs to acknowledge this new role, and how the role can be adjusted to be healthy for both the client and their family.

A Preliminary Study of the Evaluation on the Dietary Pattern among Obese School Children

Norimah Said¹, Norazmir Md Nor², Siti Khuzaimah Ahmad Sharoni³

¹Postgraduate Student, PhD in Nursing, Centre for Nursing Studies, Faculty Health Sciences, Universiti Teknologi Mara (UiTM) Selangor, Kampus Puncak Alam, ²Deputy Dean & Lecture for Center for Nutrition and Dietetics, Faculty Health Sciences, Universiti Teknologi Mara (UiTM) Selangor, Kampus Puncak Alam, ³Koordinator of Institute of Neo Education (INED) Universiti Teknologi Mara (UiTM) & Lecture for Nursing Studies, Faculty Health Sciences, UiTM Selangor, Kampus Puncak Alam Universiti Teknologi Mara (UiTM), Malaysia

Abstract

The World Health Organization (WHO) has ranked Malaysia as the sixth country in Asia with the highest prevalence of obesity with 38% affecting children. The primary objective of this study is to evaluate the elements of dietary pattern related to behavior with regards to the food, environment, attitude, and knowledge of consumption pertaining fruit and vegetables; presenting a preliminary result. In this study, a quantitative method is utilized where questionnaires are distributed to 200 recipients from primary schools, aged 10 to 12-years-old, and 132 respondents have returned with feedback. This study, it is discovered that the school children are likely to consume more sweetened beverages such as soft drinks causing 67.6% of the school children to reflect an unhealthy score under health practice, 57.1% of them obtain an unhealthy score for their attitude towards snacking between meals and consuming sweet beverages and 85.7% of these recipients showcase low knowledge regarding healthy food such as fruits and vegetables. All the school children do not obtain a healthy score relating to the environment. The Body Mass Index (BMI) shows that water and fruit consumption have a significant relationship p-value >0.05. Therefore, the results of this study are beneficial to create a pre-requisite for the module development of health education centering on childhood obesity management.

Keywords: dietary pattern, healthy food, nutrition, obesity, school children

Introduction

Current trends in the world today has demonstrated the growth of an obese population especially among children. This phenomenon has posed a threat to human beings. The obesity among children often will convey into adulthood, and it also increases children’s risk in developing chronic diseases such as cardiovascular diseases, type 2 diabetes and others in their life¹.

An interactional cause of obesity could arise due to environmental factors, genetic predisposition, and human behaviour were is generally caused by a lack of physical activities, unhealthy eating, social factors such as socioeconomic status, race, ethnicity, media and marketing and the physical environment that influence energy consumption and expenditure²,³. Usually, school children in Malaysia have extremely packed schedules from morning which involves attending extra classes including religious classes. Consequently, they have limited time to play or be involved in sports.

Malaysia was ranked as the first top country that has the highest obesity rate in Asia in the year 2014⁴. This prevalence of obesity among children continues to grow up to 25% in the year 2015 among children aged 10 to 17-years-old as compared to 11.2% in the year 2011⁵.
One of the factors that contributes to the prevalence of obesity includes the dietary intake of school children who are likely to consume fast food; their diet lacking consumption of fruits and vegetables. In addition, adolescents and school children are recommended to consume at least three servings of vegetables and two servings of fruits daily. However, 93.7% of adolescents consumed less than the basic guidelines for vegetable intake, and 51.7% consumed less than two servings of fruits. Besides that, most of the school children aged 6 to 17-years-old informed that they skipped breakfast more than three times per week. They are also consuming an excessive amount of Energy-Dense Nutrients (EDNP) foods such as soft and sweetened drinks, fast and fried food, savoury crisps, confectionaries and spending less time with active physical behaviours. They are also unaware of the food consumption recommended by the Malaysian Food Pyramid. Relatedly, previous research revealed that children with better nutrition knowledge have healthier eating habits and a more positive attitude compared to children with poor nutrition knowledge.

This paper seeks to evaluate the dietary pattern among obese school children and to confirm the association between behaviour towards healthy food, environment, attitude, and knowledge related to BMI and prove the significance to develop the module of health education for childhood obesity management to be beneficial in creating awareness among primary school children.

**Method**

**Data collection**

A cross-sectional study has been conducted among obese school children. This study has been done at two primary schools located at a suburban area of Petaling Jaya, Selangor. The target population was overweight and obese school children aged 10-12 years old. The total number of populations is N= 200. The primary school children from age 10-12 years old were screened to measure their weight, height, and calculate their BMI. Children whose BMI are within range of being overweight and obese were selected as respondents in this study. Based on the BMI-for-age, if a child exhibits a standard deviation (SD) reading 1SD and +2SD reflects to overweight and if reading surpasses +2SD, they are considered obese school children. Furthermore, the sample size determination using Krejcie and Morgan’s Table, when the N=234, the sampling size is n=132. School children with severe disabilities or special needs and are active as athletes who categorise as obese were excluded from this study. In total, questionnaires were distributed to 132 samples among primary schoolers aged 10 to 12-years-old and returned with their feedbacks.

**Design of Questionnaire**

The structured questionnaire was adopted from the Modified Child Nutrition Questionnaire. The questionnaire was translated from English to Malay language by the researcher and then translated back to English to ensure the questions have the same meaning. A pilot study was conducted to validate the questionnaire and the value of Cronbach’s Alpha 0.835 was obtained, indicating that the questionnaire is reliable to be use. On top of that, this questionnaire was utilized with the permission of the original author. The scoring for each item and summation was made by totaling items specific to each category as such in the Table 1 to indicates the health target score for five categories.

**Data Analysis**

All the data will be converted to Statistical Package for Social Science (SPSS) version 22.0. Descriptive statistics were used to determine the dietary pattern, healthy food behaviour, environment, attitude, and
knowledge in relation to BMI

Result and Discussion

EFFECT OF DEMOGRAPHIC OF OBESE PHENOMENON.

A total of 132 respondents made up the samples for this study aged 10 to 12-years-old. A majority of the respondents were girls with 71 or 53.6% followed by boys with 61 respondents or 46.4%. Ages of the subjects ranged from 10 to 12 years old with 28.6% of 10 years old, 32.1% of 11 years old, and 39.3% of 12 years old. Meanwhile, 53.6% of the respondents had a BMI that was overweight and 46.4% were obese.

DIETARY PATTERN, HEALTHY FOOD BEHAVIOUR, ENVIRONMENT, ATTITUDE AND KNOWLEDGE FOR OBESE SCHOOL CHILDREN

Table 2 illustrates the frequency of dietary pattern, healthy behaviour, attitude, environment, and knowledge. The dietary pattern was divided into five categories such as consumption of non-core food, sweetened beverages, diet soft drink, water, fruit, and vegetable. The non-core food consumption result shows that 119 overweight and obese school children obtained an unhealthy score with the percentage of 90.7%. It is only 16 overweight and obese school children who have obtained a healthy score with the percentage of 7.1% for the consumption of non-core food. Moreover, the sweetened beverages result showed that 71 or 53.6% of the overweight and obese school children obtained the unhealthy score and 61 or 46.4% obtained healthy score that regarding less consumption on the sweet beverages. Not only that, 122 or 92.9% of the overweight and obese school children obtained an unhealthy score on the consumption of sweetened beverages of diet soft drink and 10 or 7.1% of the overweight and obese school children obtained an unhealthy score. Meanwhile, the intake of water data shows that 71 overweight and obese school children obtained a healthy score with the percentage of 46.4% and 71 obtained unhealthy score with the percentage of 53.6%. Besides that, for the consumption of fruit, all the overweight and obese school children obtained an unhealthy score. Lastly, for the consumption of vegetable category, 5 overweight and obese school children obtained a healthy score with the percentage of 3.6% and 127 overweight and obese school children obtained an unhealthy score with the percentage of 96.4%.

The practices of the overweight and obese school children related to healthy food behaviour show that a majority of them obtained unhealthy score with 90 or 67.9% and only 42 or 32.1% of them obtained a healthy score. Furthermore, the attitude category for the overweight and obese school children on consumption of fruits and vegetables shows that 75 of them obtained a healthy score with percentage 57.1%, and 57 overweight and obese school children obtained an unhealthy score with percentage 42.9%. The environment factor that influences the consumption of fruit and vegetables shows that all of the overweight and obese school children obtained unhealthy score.

The knowledge related to fruit and vegetables shows that 19 overweight and obese school children obtained a healthy score with the percentage of 14.3%. Furthermore, 113 of them obtained an unhealthy score with the percentage of 85.7%. An increase in knowledge and understanding of nutritional concepts does not necessarily lead to a positive change in making choice of healthy food because people need the extra time to change their preference of food and eating habits. Furthermore, the nutrition knowledge and education will provide enhancements on knowledge on healthy food and then change the attitudes and practice among overweight and obese school children.

The relationship between BMI with dietary pattern, healthy food behaviour, environment, attitude and knowledge of overweight and obese children.

This study examines the relationship between BMI with dietary pattern, healthy food behaviour, environment, attitude and knowledge of overweight and obese children. Table 3 tabulates, the healthy score of intake water with BMI and illustrates the association as p-value which is 0.004 (p<0.05). The data shows that a significant number of obese school children obtained a healthy score on water intake.

The consumption of fruit in dietary pattern group, the data also showed significance with BMI as p-value is 0.046. The relationship of the BMI with non-core food (p=0.157), sweet beverage (p=0.467), sweet beverage-diet soft drink (p=0.564), vegetable (p=0.059), healthy food behaviour (p=0.366), attitude (p=0.405), environment (p=0.083) and knowledge (p=0.705) are not associated with BMI as the p-values are greater than 0.05. Thus, the data showed that water and fruit consumption have a significant relationship with BMI.

As generally, this study shows BMI is associated with dietary pattern. This indicates that dietary intake influenced the BMI of the overweight and obese school children. The result revealed that the children do not practice healthy eating. The types of food intakes were related to BMI such as sweet drinks, fried rice, fried beef. This study identified a weak association of BMI with fruit consumption. This indicates that their intakes were still below the National Recommendation of five servings of fruit and vegetables daily. This is also lower than WHO population goals where the children need to eat more than 400 g of fruit and vegetable daily. The majority of the children reported not consuming fruits, legumes, or dairy every day. This study shows that a low intake of vegetable could be due to food neophobia and dislike of the taste of vegetable amongst school children. Meanwhile, mothers play a vital role in fighting childhood obesity and the mother needs to be motivated and understand healthy eating patterns and exercise that helps her child lead a healthy life. The relationship between food knowledge, preferences, diet, and subsequently with weight status; showed that better food knowledge indicates healthier food preferences and, in conclusion, lead to healthier food choices that are mirrored by a normal weight status. This is concurrent with a previous study in the United States that found children consumed high fast food had a lower intake of milk, dairy, and fruits.

**Conclusion**

This study is beneficial to evaluate the overweight and obese school children’ knowledge, attitude, and eating behaviour and number of obesities among children of 10 to 12 years old in the school. Furthermore, this study gives the ideas for the nursing practice or School Health Nurse (SHN) to plan their health education related to nutrition and physical activity but also to plan school intervention programs to overcome obesity among overweight and obese school children. It will also motivate the government or Non-Government Organization (NGO) to take precautions of obesity epidemic in Malaysia. The health education module or intervention program related to childhood obesity will gives a positive impact while providing children with good nutrition knowledge, improving attitudes and healthy eating habits among the children themselves. This future study can highlight the most useful and accurate results for the research needed by the school, government body and the intervention programme to enhance the knowledge, attitude, and practice among overweight and obese school children.

**Ethical Consideration:** In this study, the children’s parent was given the consent as permission for their children to answer the questionnaire. The parents have their right to decide in allowing the children to get involved in this research and was return to the researcher. Researcher must keep the confidentiality of the participants. This study also was obtained the approval from Ministry Education, Malaysia and State Education Department Selangor.

**Acknowledgment:** Special thanks to Nur Sitarun Nisa Misbah (2013221696), Siti Mardhiyah Muhammad (2013268478), Universiti Teknologi Mara, Ministry Education and State Education Department for the permission.

Examining a Model to Measure Green Packaging Practices Among Consumers in Malaysia: A Sustainable Contributor to Achieving Smart Environmental Goals

Chinnasamy Agamudai Malarvizhi¹, Sreenivasan Jayashree², Shamima Raihan Manzoor³

¹ Senior Lecturer, ² Associate Professor, ³PhD Student, Faculty of Management, Multimedia University, Malaysia

Abstract

This study primarily aims to test the factors in the extended Theory of Planned Behavior (TPB) model and their impact on green purchase intention and green buying behaviour towards green food packaging practices in Malaysia. The research hypotheses are tested accordingly among the restaurants and cafeterias in various places of Selangor, Malaysia. A total of 164 usable sample responses were collected from working and student population in Malaysia by using a self-administered questionnaire based on convenient sampling method. The outcomes of the study reveal that the environmental attitude and internal perceived behaviour have a significant positive impact on green purchase intention. Further results in this research show that subjective norms and external perceived behavioural control also have a substantial impact on green buying behaviour in favour of green food packaging in Malaysia. The finding of this study contributes to the Malaysian government’s environmental policy-making which aims to encourage pro-environmental change among people and business groups for achieving smart environmental goals through their green purchase intention and green buying behavior.

Keywords: Green food packaging, Consumer behavior, Theory of planned behavior

Introduction

Environmental concerns about food production and consumption have become increasingly prominent, which is evidenced by the “dramatic rise in sales of organically produced food products in many countries”.¹³,²⁷ Marketers realize that packaging performs an important role in marketing communications and could be one of the most important factors influencing consumer purchase decision. The combination of green and packaging would be a new choice for consumers in developing markets like Malaysia. In this country, like many other developing countries with abundant resources and minimal development pressures, little attention was paid to growing environment protection and conversation. As far as green packaging is concerned, it is a very new concept in Malaysia. As of today there has been little empirical research on Malaysians’ attitudes and purchasing intention toward green packaging of food items.

The environment issue is often associated with materials used in food packaging. The process of recycling plastic material is more difficult and costly in comparison to other materials.²⁸ Moreover, landfill space is needed for an increasing amount of packaging waste. So the solution needs to be found in a proper model of measuring and influencing customer intention and behaviour towards greed food packaging. This has led to the research question about the factors in TPB that influence the green purchase intention and behavior towards green food packaging in Malaysia. To complement with the research question, the objective of this study is formulated to test the TPB factors that influence the green purchase intention and behavior towards green food packaging in Malaysia.

Literature Review

According to Garnett, food waste affects the environment via its decomposition after disposal in landfills and by the embedded emissions associated with the production, processing, transport, and retailing of food. In Malaysia, “food waste generation in 2002 was reported to be 7,650 tonnes per day. This value is expected to reach 13,500 tonnes per day by 2020.”

Product’s packaging and labelling is often considered as something paid attention to by the consumers. In Malaysia, the most popular food packaging is by polystyrene containers and plastic. Polystyrene containers are non-biodegradable, and studies show that they have harmful side effects when it migrates from the containers onto food primarily from leaching caused by heat. Benzene, a material used in the production of polystyrene, is a known carcinogen and poses a potential risk to human health.

Several studies have adapted attitude models to explain the impact of norms, social influence, and behavioural control on green buying behaviour. In this regard, the ‘theory of planned behaviour’ (TPB) is a widely used attitude model for examining relationships between personal, social norms, and beliefs of individuals with their green buying.

The TPB has added the concept of ‘perceived behavioural control’ (PBC) to the TRA as a third predictor of intention. PBC refers to the perceived ease or difficulty of performing a particular behaviour. Ajzen proposes that personal behaviour depends on behavioural intention, which is guided and predicted by three determinants: the attitude towards the behaviour, the social subjective norm, and the PBC. The TPB posits that positive attitude to increased pressure from social influences (i.e. social norms) and increased control over behaviour leads to increased behavioural intention.

Specifically, in Malaysia, there is limited information about consumers’ perceptions and their practices towards going green. Manget et al. have discovered that almost half of the respondents in a multi-country survey indicate that green products offer comparable or superior quality over conservative alternatives.

Methodology

For this research, the researchers have focused on the two categories of population in Malaysia: students and working people. This is because these two groups of people need to depend on packaged food more than others as they have to remain outside their houses due to study or work-related duties they have less time to cook their breakfast, lunch and dinner at home. Selangor state was chosen to conduct the survey for this study due to its urban and adequate population. Environmental Attitude was operationalised by taking four items from the former studies of McCarty and Shrum and Tanner and Kasti. Subjective norms, internal perceived behavioural control, external perceived behavioural control were

Green purchase intention (GPI) was measured by using a five-item scale from Paul et al.\textsuperscript{21} Green buying behaviour items were taken from Ahn et al.\textsuperscript{1}. A 5-point Likert-scale was utilized to measure all the variables. A self-administered questionnaire was distributed by the researchers using convenient sampling method. A total of 164 usable complete questionnaires were used to analyse the data. Bagozzi & Yi\textsuperscript{8} mentioned that the sample size for a study should be above 100. The data were analysed using Statistical Package for Social Sciences (SPSS) version 22.

**Results**

Among the analysed respondents (N=164), 56.7% are female, and 43.3% of them are male. 71.3% of the respondents are students and 28.7% are working people. Table 1 shows that the R-square value = .352. This means 35.2% of the variation in purchase intention is accounted for by the variation in external perceived behavioural control, environmental attitude, subjective norms, and internal perceived behavioural control.

</tr>
</tbody>
</table>

a. Dependent Variable: GBB

The regression equation based on Table 4 is as follows:

Green buying behaviour = 1.176 + 1.267(EnvAttde) + 3.80(Sub_Norms) + 1.34(IntPerBehavC) + 0.189(ExtPerBehavC)

Based on Table 4 subjective norms(p value=.000<0.05) and external perceived behavioral control(p value=.026<0.05) have significant positive impact on green buying behavior.

**Conclusion**

In conclusion, this study addresses a significant gap in analysing customers’ green purchase intention and green buying behaviour towards green food packaging in Malaysia as a part of consumers’ adoption of sustainable practices through the use of Theory of Planned Behavior²⁻⁴.
Based on this study’s outcomes, it is clear that the environmental attitude and internal perceived behavioural have a significant positive impact upon green purchase intention. This finding is also in line with the previous researchers like Chan & Lau and Seung Bong Ko & Byoungho Jin. Further results in this research show that subjective norms and external perceived behavioural control have substantial bearing on green buying behaviour towards green food packaging in Malaysia. This result is also supported by the findings of the previous researchers Biswas & Roy, Jin & Kang, and Seung Bong Ko & Byoungho Jin.

From a practical viewpoint, pro-environmental attitude among the customers needs to be nurtured in the society. Moreover, various initiatives of the restaurant business owners and food packaging manufacturers along with the support of the Malaysia Government as a whole can create a big difference in the society. Finally, the unsustainable practices triggered by wasteful runaway consumerism will be reduced if each individual makes small changes to his or her lifestyle and consumption habits by selecting green food packaging services practiced by the restaurants and cafeterias. Thus, each individual can make a worthy contribution to achieve smart environmental goals in Malaysia.

Abstract

Many studies have been conducted to examine the involvement of adolescents in sexual misconduct; however, through a literature review conducted, studies on teenage personality traits and sexual misconduct are found to be limited in Malaysia. Teenagers are easily trapped by sexual misconduct due to the process of change between childhood and adulthood. The role of personality traits, religiosity, cultural values of adolescents highlighted to shape the character of youth, which can help to build positive personality for becoming good citizen of the country. As Malaysia consists of Malay, Chinese and Indian diverse cultural societies and diverse religious people living together harmoniously in Malaysia, which has absolutely noble values to develop healthy personality; however, sexual misconduct emerging as challenge, which need to be understand in terms of unregistered pregnancy and social issues. By developing positive values and healthy personality among teenager could serve as best predictor for avoiding sexual misconduct.

Keywords: Personality, Sexual Misconduct, Teenager, Malaysia

Introduction

In this era of modernization, adolescents are involved with a variety of negative activities that contribute to the occurrence of negative social issues that are widely increasing day by day. This issue is not only happening in Malaysia, but this problem also exists globally and its challenge in the development of human civilization (Faizal & Zaki, 2014; Khan) ¹, ². Sexual misconduct among teens is growing social problem around the world regardless of the status of a country, whether developed countries or developing countries ³. In developed countries such as America, adolescents involved in social misconduct are defined as juvenile offenders who live in a social environment that is different from their previous generation. Exposure to various causal factors is either directly or indirectly negatively affecting the development of adolescent psychology, and at the same time encouraging them to participate in social misconduct. This situation becomes more severe when these adolescents face difficulty in changing or removing themselves from these negative effects despite undergoing recovery ⁴. Obtaining 50 percent of teens in America under the age of 17 are actively involved in sexual intercourse ⁵.

In addition, Wendy et al. ⁶, conducted a study of 4135 American Indian teenagers aged between 13 and 18 in Minnesota. Based on the study, 40 percent of teenagers aged between 13 and 15 years old and 69 percent of teenagers aged 16 to 19 have had sexual intercourse. As regards the phenomenon of rising teenage cases in the United States, researchers have pointed out that increased public recognition of out-of-date pregnancies has eliminated the stigma of birth of a child out of wedlock as before⁷. Between the 1950s and the 1960s, more than a teenager who was born out of wedlock would get married before their birth.

The term adolescents refers to a stage of transitional development from childhood to adulthood and experienced significant physical changes related to puberty and also significant cognitive and social changes. Adolescents are adapting to many changes, such as body shape, sexual maturity and social status. This can run smoothly and involve minimum pressure if the most important person in teens’ life provides the necessary support. Teenagers are easily trapped by sexual misconduct due to the process of change between childhood and adulthood. At this stage, adolescent emotions are somewhat unstable, so they are easily pushed with a push towards fulfilling sexual desires. The most significant problem in teen sexual misconduct is the willingness of the adolescent to the effects of these sexual activities while they are still not physically, mentally and economically.

Sexual Misconduct among Teenager

Sex is a basic necessity in human life, without sexuality human civilization will not grow. Sex is seen as a major internal force in directing and influencing human behavior. This means that sex also involves teenagers. The adolescent stage is one of the stages of human development. This is a phase of change or transition from childhood to teenage level which includes biological changes, psychological changes and social change.

There are various factors, which contribute to the increasing sexual misconduct among adolescents throughout the country were discussed by many researches. Additionally, the cause of the increasingly dramatic social spread of the disease has been identified as well as various modules are formulated as a guideline that involves the role of responsible parties as a means of curbing these symptoms. However, every day the malnutrition among teenagers in Malaysia continues to increase. Lack of identity leads to a lack of self-control. When a person loses control over himself, then the individual easily loses direction and then becomes involved with negative elements.

Teenagers in Malaysia are defined as individuals between the ages of 15 and 30 years and this definition has been fully utilized starting in 2018. Statistics by the Department of Statistics, Malaysia (2017) show that Malaysia’s total adolescents between the ages of 15 and 29 in 2016 are 9.3 million people out of the total 31.7 million people in Malaysia. The present scenario shows the growing rate of sexual misconduct among adolescents. Every day many sexual misconduct news reported especially among under-aged teens. There are many crimes committed by adolescents found to be related with involvement of sexual misconduct.

This act in turn contributes to the rise of the case of an out-of-date pregnancy. National Registration Department statistics. From 2000 to July 2008 records show more than 257,000 registered birth certificates without the name of the father. This means that an average of 2,500 cases of out-of-date children are recorded monthly or almost 84 cases per day. The breakdown of birth-offs by state between 2000 and 2008 showed that 70,430 unmarried children were registered. Selangor recorded the highest number of 12,836 babies. This followed Perak (9,788), Kuala Lumpur (9,439), Sabah (8,435), Negeri Sembilan (4,108) compared to Sarawak (617) and Terengganu 574 people. Registration by ethnicity shows the highest number of Malays and Bumiputera in Sabah and Sarawak at 20,949 babies, India 19,581 and China 18,111. Religious breakdowns are 30,978 Muslims, 18,085 Hindus, 17,236 Buddhists and Christians 3,395 people (UKM news portal, June 2010). The out-of-date pregnancy case recorded an increase between 2011 and 2014 where 71,619 cases were registered. In 2011, 18,656 cases were recorded to 18,847 (2012), down to 17,588 (2013) and 16,528 (2014).

The researcher studied about pregnant teenagers without marriage at Nur Hasanah Kuala Lumpur House. The findings showed that the family background and the way the problems are addressed by adolescents with their families and forms of care received after the pregnancy has had an impact on the development of adolescent personality.

The Ministry of Health statistics in 2016 recorded 3980 teenagers or 28.8 percent of 13,831 teenagers aged between 10 and 19 years old. The statistics recorded five states which recorded the highest number of teenage pregnancies in Sabah with a total of 3,084 cases, followed by Sarawak 2,910 cases, Selangor 1,461 cases, Johor 1,319 cases and Pahang of 940 cases. Based on the study of Mohammad Sabran (2003), in Malaysia more than 300 teenagers aged between 13 to 25 years are involved with sexual misconduct and free sex resulting in pregnancy and subsequently abortion.
Many studies have been conducted on sexual misconduct more focused on religious, sociological and environmental aspects. The appreciation of religious values should also be emphasized and applied in the adolescents to shape the character of a superior youth. Studies found that parents contributed to the problems of children’s behavior, which failed to show good behavior in front of their children in addition to ignoring religious teachings. This study proves the involvement of adolescents in social problems is caused by lack of spiritual practice such as performing worship.

**Personality Context**

All adolescent behavior and personality are influenced by the elements within themselves. Al-Ghazali explains that there are three factors that influence one’s personality, heart, lust and sense. In humans (adolescents) there will be interactions between heart, lust and reason. When a tadabbur is mixed with the heart and lust of mardiah, it will create a superior youth personality. However, when the adolescent has the intellect, the heart of obligation and mutmainnah, it will form a balanced youth personality. While teenagers who have common sense, qalban heart and ammarah appetite will give birth to teenage personality.

According to Eysenck personality is a picture of a person’s behavior that is consistent, unique and dynamic. Consistent and consistent means that one’s behavior is unchanged. The personality of the baby’s realm, the stage of childhood, teenage, adult and old are similar. If a person has hard-heartedness and ego at the stage of childhood and adolescence, the nature and attitude will be brought to the old age or to the grave. Changes that occur from the environment only affect the personality, not the overall effect. While Carl Rogers states that personalities are closely related to self-concept, which is how individuals learn about the advantages and disadvantages and feedback from others about themselves. Personality is related to an individual’s environment, where the element of assessment and physical influences on it.

Adolescents are the natural resources of the country and will play an important role in shaping the political, economic and social future of a country. “The youth of the nation’s hope, the country’s pioneers”, this proverb clearly shows how important the role of youth in a country. Adolescents are considered the most productive and passionate in all respects. Quality teenagers can empower the glory of nation and nation. Therefore, every teenager needs to play their part with the responsibility to plan the development of the country. More than half a century we have gained a sense of independence, but teenagers who are the backbone of the country are still plagued by various social troubles. It can be seen that youth mentality in our country has not yet undergone a paradigm shift in line with the flow of our nation’s development. The present scenario shows the rising rate of social misconduct among adolescents. Every day we are served with a variety of sexual misconduct news especially among under-aged teens where this situation has sparked the concern of all parties.

Case studies involving sexual misconduct such as rape, discharge of pregnant and pregnant children out of wedlock show a significant increase from year to year. Utusan Malaysia dated September 10, 2016, in 2015, a total of 3,980 adolescents and youth aged between 10 and 19 years of age have been pregnant with extramarital children. Meanwhile, reports from the Royal Malaysian Police (PDRM) show that the number of baby dumping in Malaysia is 432 cases from 2011 to June 2015 with out-of-pregnancy pregnancy which is the main cause of the growing baby’s cure. PDRM also reported that the lack of awareness on sex knowledge has also been a major cause of rape cases statistics (Utusan Malaysia, September 10, 2016). According to statistics released by (PDRM), 93.5 per cent of victims from 12,473 rape cases in 2011 to June 2015 involved teenagers aged between 13 and 18 years old.

This study showed that the behavior in early adults have studied the effects of certain psychosocial variables (eg norms, attitudes and self-efficacy) on risky sexual behavior, personality can also be important determinants of sexual behavior. While according to Hoyle, Fejfar, and Miller, in particular, impulses seeking sensation and decision are the two main personalities often associated with high-risk sexual activity. Hence, an assessment of the psychological characteristics of individuals is important to identify the tendency of a person to enable them to be caught in the case of sexual misconduct.

Through this study, enlightenment and uncertainty regarding the traits of adolescent personality involved in sexual misconduct will be identified. Five personality traits, assertiveness, concern, integrity, cross culture and delinquency will be analyzed to identify key personality
tricks that contribute to adolescent involvement in sexual misconduct. Subsequently, the findings will assist counselors in designing systematic and more focused interventions after recognizing the teenage personality involved in sexual misconduct. In addition, counselors are also able to interact more effectively with adolescents who may be at risk for sexual misconduct to help them avoid temptations of wrongdoing. Disclosure of knowledge regarding the involving personality of the adolescent is important because there is a difference between the personalities of teenagers now as compared to the past. This is due to the revolution in society at large; therefore counseling adolescents now requires a different approach.

**Conclusion**

Positive personality building is important in building integrity, attitudes and good behavior. Failure to build a good personality causes one to make wrong and harmful choices. In this regard, present research paper showed role of personality traits and sexual misconduct among adolescents. This issue is substantiated by the increasing number of cases of sexual misconduct among adolescents and consequently, the personality traits leading to sexual misconduct among teenagers.

Overcome the Problem of Street Children Through Life Skill Learning in West Java Indonesia

Herwina Bahar¹, Zainudin Hassan², Iswan¹, Hanny Firas¹
¹Lecturer, Education Faculty of Muhammadiyah University of Jakarta, ²Associate Professor, School of Education, Universiti Teknologi Malaysia, Johor, Malaysia

Abstract

This study aims to provide solutions to the problems of street children through Life Skill learning. The research was conducted at Master Depok Primay School, Indonesia. 20 children are active as street children to fulfill their daily needs as family economic demands. Qualitative Research Methods, are case studies, involving teachers who play a role in developing life skills, they are two class teachers and two life skill teachers. Determination of research subjects was carried out by using purposive sampling technique, the results were specifically street children 9 people, five people in grade 4 and four people in grade 6. The techniques of collecting data were through observation, structured interviews, and study documentation. The results showed that street children in Depok Master School were included in the children on the street group, it means, children who had economic activities as child laborers on the road, but they still had strong relationships with their parents. Part of their income on the road is given to their parents. To overcome these problems, the life skill learning process is very instrumental in the life process of street children, for this reason a teacher’s strategy is needed in creating and innovating by continuing to improve pedagogical, personality, professional and social competencies. Support from various parties is needed to participate, both the government and the community to continue to provide guidance and supervision to parents that the act of releasing and letting children on the road, especially demanding them as breadwinners is illegal and violates children’s rights.

Keywords: street children, life skills learning, children’s rights, social problems

Introduction

Depok City Central Bureau of Statistics (BPS), Indonesia noted that the number of neglected children in Depok increased, in 2012 was as many as 49 children while in 2011 was only 30 children. Head of Regional Balance Sheet and BPS Analysis of Depok City Bambang, researcher¹ said that most neglected children were caused by family economic factors, but some are caused because they prefer to live on the streets. The children living on the streets are especially vulnerable to victimization, exploitation, and the abuse of their civil and economic rights (Shahina, 2014).

Street children in Depok City, Indonesia are mostly migrants, the number of street children tend to reducing because of the number of raid programs carried out by the Civil Service Police Unit¹. In 2012, there were only 336 street children, the number decreased from 2011 totaling 430 children. Their involvement in the informal economy sector usually produces a sense of pride and worth because of their ability to contribute to welfare of family. For example, working as a hawker at stations, terminals, selling newspaper, shining shoes, looking for used goods or garbage, traffic light busking, car washers, renting umbrella, and many of them doing criminal to get money. Like child labor in general, street children often start living on the streets at a very young age. These are either “children on the street”, who are engaged in economic activities, but who mostly still go home, or “children of the street”, who live on the streets, but still have occasional contact with their parents.

But this is also proven to eliminate the interest of children to school because they want to get more money. Intervention needs to emphasize three types of change: (a) in awareness of street life for those making little use of the streets; (b) in the capabilities of those using the street as a major resource; and (c) of the condition of those totally dependent on the street environment.

One of the rights of street children is to obtain proper education as stated in Law Article 31 paragraph 1 that education is a right for every citizen. But to deal with the problems of street children must be admitted is not an easy thing. During this time, various actual efforts have been made, both by NGOs, government, professional organizations, and social as well as every person to help street children come out or at least slightly reduce their suffering. In the Convention on the Rights of the Child which has been ratified by the Government of Indonesia, it is stated and recognized that children are essentially entitled to obtain proper education and they should not be involved in economic activities early as stated in Law Number 23 of 2002 concerning Child Protection. However, because everything is done temporarily, segmented, and separated, the results are less than optimal.

The review of Education Environment stated the school, and community environment. Therefore, the role of the school, especially the teacher’s contribution, becomes the supporting force in the progress of the nation’s children. The Master School or Yayasan Bina Insan Mandiri (YABIM) in Depok, West Java is an institution that is engaged in the formal school field, which does not charge a single fee. One of the treatments that is often used is by providing training in the form of life skills accompanied by attitudes, behaviors, and motivations which needed by students at facing life problems.

Life skill learning in the Depok Master School, especially at the Primary School level, is in the high class where the majority of students have been able to develop various abilities among cognitive, affective and psychomotor abilities which are very supportive in their life skills learning process. At Master Elementary School Depok, there are 235 active students, and approximately 20 students at Master Depok Elementary School are still struggling in the street world to just fulfill their daily needs, with the economic demands of the family. Meanwhile, there is very little number of teacher that interest in teaching them. Therefore, the teachers come from volunteers who are willing to spend energy and time to teach. The learning process occurs when the volunteer teacher can spend his time in the midst of other activities.

**Research Method**

This study was used a qualitative or naturalistic method because it is done with natural conditions. Afrizal suggested that qualitative research is a scientific activity using conscious and controlled procedures. Sugiyono suggested that qualitative research methods are methods used to examine natural object conditions, where researchers are key instruments, data analysis is inductive, and the results of qualitative research emphasize the meaning rather than generalization. This research was used data collection techniques, they are observation, structured interviews, and documentation studies. The research is a case study, carried out in Depok, involving teachers who play a role in developing life skills, they are 2 class teachers and 2 life skills teachers. Determination of research subjects was conducted by using purposive sampling technique, the results are specifically street children 9 people, 5 class 4 and 4 class 6 people.

**Research Result**

Depok Master School is one of the schools established to minimize the problem of education in Indonesia, especially for unfortunate children from economic factors, starting from the Early Age Education to the High School level. The Depok Master School is located at Margonda Raya Road, Number 58, Depok Terminal.

The learning conditions are what they are, students are more dominant wearing free clothes such as T-shirts and not wearing shoes but wearing sandals. Observations were carried out in all corners of the school, starting from the school gate which was written by the Foundation, then there was a fairly large school yard for children playing soccer and basketball because of there are basketball goal and basketball hoops and there is also a hall used for students to pray jum’ah together. The elementary school building has two floors with a characteristic. While entering the classroom which is quite unique, students and teachers learn to sit on the school floor and simplicity can be seen in the classroom.
Strategic Role of Teachers in Street Child Life Skill Learning

Based on the results of observations, it appears the urgency of the strategic role of teachers in life skills learning for street children. Life skill learning process means that these skills are needed in career development, innovation skills, also includes skills to do a task, and the skills to create products by using appropriate concepts, principles, materials, and tools. Judging from the conditions of the Depok Master Elementary School, the researchers concluded that it was very different compared to the conditions of other schools, but basically the scientific nature of a child is only children, because the school environment, community environment, and family environment are influential in the formation of children’s character. Therefore, the teacher needs to understand the characteristics of students so that it is easy to carry out educational interactions.

Life skill teachers need to create a pleasant classroom atmosphere. This becomes important for street children because they have a simple understanding, of learning that requires them to think hard becomes unattractive for them. Therefore, teachers are required to create a pleasant classroom atmosphere by providing interesting lessons, not chasing target for the children and not force them to do the will of the teacher, they are given the freedom to choose, the teacher also should provides learning according to their conditions. For example, in life skill learning for the first week they learn to make bracelets from beads, the second week they make headbands with colorful and attractive material colors. In their minds, that’s what is needed to easily bring money.

Street children in Depok Master School are included in the children on the street group stated by Suyanto who have economic activities as child labor on the road, but still have a strong relationship with their parents. Part of their income on the road is given to their parents. Paying attention to the condition of street children as students, the role of the teacher as a planner requires that planning is always reflected in their conditions, learning habits, experience and knowledge, harmonious learning methods, and material that suits their interests. In terms of economics and character of students, it is certainly different from students in general schools. Therefore, the teacher who teaches in the street children class requires high dedication selflessly and needs to have full energy, especially in the process of affective learning. Their people skills are of great use not only in planning and implementation of the projects at the grassroots but also for advocacy and policy-level work.

The learning process was also carried out by volunteers. The school did not demand any provisions about the criteria for volunteers who had to teach at the school due to the lack of human resources especially for teachers. The school only hoped for each teacher to be consistent in teaching and educating students so that the learning process could running smoothly. They consider a challenge to teach and make their students more skilled although there are no wages they receive every month, they are sincere to teach and educate children. So, the learning process requires permanent teachers who have the same commitment and vision so that the learning process is not hampered or disturbed.

Learning Condition of Life Skill for the Street Children

The implementation of life skill learning seems less planned for learning, such as the absence of administration; Learning Plan or learning syllabus. Volunteer teachers who come once a week at Depok primary school make a plan learning is only limited to giving verbal information to homeroom teachers, usually they inform a week before learning. The material given to students is in accordance with their conditions, because the teacher already understands the character and condition of the student. In carrying out the learning process is inseparable from the method used to achieve the learning objectives, but from several data collection techniques the teacher does not understand the techniques and methods, they only apply according to the conditions in the field. The role of the teacher as a diagnosis of student learning progress by way of knowing the development of students gradually through life skill learning by looking at the various results of students’ work from their progress and skills. The benefits of life skill learning are reflected in the activity in learning, the emergence of motivation, good communication, and training their self-confidence. Street children are the causalities of economic woes, war, poverty, loss of traditional values, domestic violence and physical and psychological abuses. They seldom have a choice in becoming a straw in the wind – and going to school is always out of question.
Teachers in making administration as well as reports on student work are limited to physical records of the work, these physical records are not in the form of values but in the form of general descriptions of student development, then the results of notes or information are given to the class teacher who is assigned the value. Tools and materials are prepared directly from the teacher, usually the teacher provides the tools and materials they have for the practice of students who will make skills. They are like scissors and materials from recycled goods. The work of students can be used as a benefit or opportunity to do business by selling and offering their work to guests who come or sell it outside. The experiences gained by students and teachers from life skills learning are so many benefits ranging from communication skills, vocational skills, social skills, and personal skills.

The presence of unsupervised children and adolescents on the streets in developing countries is common and a consequence of unfair politics and poor socio-economic development. The benefits that students get are included in street children who are in grades IV and VI in addition to personal, social, academic, and vocational skills that students can develop the talents they get, sell various kinds of products they make, more importantly they are numbered school because in life skill learning students are more active in using psychomotor so they are happy with the learning and they are more eager to go to school. The work can also be used as a business opportunity. Benefits for students that they can train emotionally, independence, can make work, and no less important is to know their talents. The above conditions indicated that teachers play an active role in preparing life skills learning equipment. Unfortunately, they do not play a role as a planner and leader in the sense of making a final report or teacher administration.

Solution

Barriers of human research are less comparable and the absence of wages received by teachers, requires attention from various parties, including the role of the government in determining policies about teacher placement in social institutions by taking into account the welfare of teachers. All parties involved, both at the central, regional and community levels, synergize with the problems of street children, so that they have the right to study seriously and leave activities on the streets which are dangerous both physically and mentally.

It is good for the government, both the Center, the region or the relevant Institution, to place professional teachers in Educational Institutions that are committed to educating the nation’s shoots, so that the problems of street children can be minimized and even completed with life skill learning strategies.

Conclusion

The life skill learning process which includes personal skills, social skills, academic skills, and vocational skills play an important role in the life process of street children, because of these reasons, the teachers need strategies in teaching them so that they are no longer interested in the streets. In addition, teachers play an active role in knowing their condition, providing tools and materials to be used in skills so that they are more likely to learn and be motivated to create and innovate. The efforts of the teacher for the next time is develop their talents and interests by producing works or products according to their needs, so that students become the center and subject of learning.

Barriers to life skill learning of street children is the academic quality of teachers, who come from housewives and have not fulfilled academic qualifications and certification as in the provisions of the Teacher and Lecturer Law number 14 of 2005. Learning goes as it is according to the students’s needs and desires. Class management, less strict discipline, learning methods, and the absence of teacher administration were indicated that the teacher teaches according to the minimum conditions. Thus, there is a need for efforts from various parties to participate, both the government and the community to continue to provide guidance and training to teachers so that they have pedagogical, personality, professional and social competencies.

Effectiveness of Shaping Technique for Increasing Self Confidence among Minor Autistic Students Banjarmasin, Indonesia

Ririanti Rachmayanie¹, Nina Permata Sari¹, Zainudin Hassan², Desy Nurmiyanti³,
¹Lecturer, Guidance and Counseling of Departement, Lambung Mangkurat of University, Banjarmasin, Indonesia, ²Associate Professor, School of Education, Universiti Teknologi Malaysia, ³Student of Guidance and Counseling Department, Lambung Mangkurat University, Banjarmasin, Indonesia

Abstract

People with autism seem like living in their world, physically they grow normally like children in their age but they have limitations on social relations. The purpose of this study was to describe the self-confidence of minor autistic students before and after counseling with shaping techniques, as well as to determine the effectiveness of shaping technique to help improving the confidence of minor autistic students at Banjarmasin School. This research was quantitative study using an experimental method with a pre-experimental design, using Single Research Subjects. This research was conducted at Banjarmasin, Indonesia. The sample in this study was a student of X Animation class with minor autistic. The research instrument was the treatment material in the form of “Guidelines for Shaping Technique Research to Improve Self-Confidence”.

Key words: Shaping technique, self-confidence, autism

Introduction

In recent years, the world of education in Indonesia has been enriched with the emergence of inclusive concepts in educational settings in an effort to minimize discrimination in educational practice and through inclusive education. It is expected that not only students with special needs, but also other potential students can be educated together with students in general so that there is no gap between them. Inclusive education school not only have students who are classified as non students with special need, but also have students with physical, emotional and economic limitations. Inclusive school generates education for students who are physically, emotionally and economically limited and therefore it is possible for inclusive schools to have disabled students. People with autism are like living in their world. At first glance children with autistic disorders do not seem to have problems. Physically they grow normally like their age in general. However, if examined more deeply, it will be seen that they experience developmental delays (especially in terms of language) and they exhibit ‘strange’ behavior that is not commonly performed by their age “for example, often wagging hands, moving in circles or often looking at the corner eye “.

In this study researchers intended to help autistic students grow their confidence in communicating with their friends first. Self-confidence is one aspect of personality in the form of a belief in one’s own abilities so that they are not influenced by others and they can act according to their will, happiness, optimism, moderately tolerant, and responsibility.

Research Method

Current study used a single subject design. A single subject experimental design (also called a single case experimental design) is a design that can be used if the sample is one. Single subject design is usually used in the investigation of the behavior of someone who arises as a result of several interventions and treatments. Basically the subject is applied to the state of no treatment and by alternating treatments, and performances or achievements are measured repeatedly during each phase. Non-treatment conditions are given symbol A and the condition with treatment is given the symbol B.
This study used research with a single subject with the subject under study that is mild autistic students with low self-confidence by being given a treatment counseling behavior Shaping technique. In research with a single subject method, the design used is a reversal with A-B-A.

The A-B-A design is a development of the basic A-B design where the baseline phase measurements are repeated twice. The basic procedure is measurement in the baseline phase (A1) then in the intervention condition (B) and measurement again in the baseline phase.

This design can be described as follows:

Baseline (A)   Intervention (B)   Baseline (A)

Session (time)

A-B-A Basic Design Procedure [16]

A 1: At first the target behavior is observed indirectly and without being known the student is measured continuously at least 3 and 5 in the baseline condition to a stable condition.

B: treatment with the administration of shaping techniques.

A 2: researching and observing students who have not conducted research is a repetition of the initial conditions of the subject matter in the form of behavioral re-measurement applied to condition A to monitor and evaluate the extent to which interventions can affect the confidence of mild autistic students.

For taking data of students belong to autistic children, researchers use a type of observation research, and interviews.

Shows steps of the shaping technique

Step 1: Analyzing ABC (Antecedent, behavior, consequence)

Activity: a. what kind of problem autistic students face

b. what kind of technique suitable for autistic students

c. what will happen to autistic students after treatment

Step 2: Deciding target of behavior student will achieve

Activity: Counselor deciding what is the problem autistic students face, what kind of problem need to be addressed and what is the target need to be achieved by counselee to help autistic students

Step 3: Deciding what kind of positive reinforcement use with counselee

Activity: Researcher with counselee decided positive reinforcement use in counseling process, decision about positive reinforcement given should be approved by counselee and researcher

Step 4: Making the stage of behavior from beginning until the end

Activity: researchers together with the counselee make the stages of achievement to be achieved at each stage and what are the consequences if these stages cannot be resolved. In this stage the counselee must be able to greet other students, in the first day at least greet one student, the second day greet two other students, the third day also greet three other students, the fourth day greet four other students and the fifth day the counselee greets five students.

Step 5: Planning is able to be modified during the program of shaping technique

Activity: Modification using the ABA model reversal design. At first the target behavior is measured continuously at baseline (A1) with a certain time period then in the intervention condition (B) after that the measurement in the second baseline condition (A2) is given. At this planning stage counselees are trained on how to greet friends first in a good and right way. For example “good morning, good afternoon, hi, etc. while giving a smile to another friend”.

Step 6: Deciding time for giving reinforcement in every stage of program

Activity: The researcher determines when the time to give positive reinforcement counseling to the counselee and the number of attempts to fail experienced by the counselee. After all stages are passed by the counselee the counselee will get a reward. Although in the counseling process the counselee has experienced a failure, the counselee will still be able to continue to the
next stage because when the counselee has tried, even though the counselee will still feel a change in him even if we do not see the changes, maybe the change will only be felt by him because when he failed he had tried to try indirectly what he was trying to imprint on his memory.

For analysis of data from single case experiments, it usually uses graphic that present results. First, evaluations are made regarding design quality. Second, by assuming a fairly valid design, an assessment of the effectiveness of the treatment is made.

**Research Result and Discussion**

Based on the results shown in the Baseline 1 phase, the counselee has not been able to perform the expected behavior formation because the researcher only made initial observations of the counselee in an effort to increase the self-confidence of minor autistic students, so the percentage score obtained was 0%.

Baseline stage 2 counselees are able to show an increase in self-confidence. The following will be described the phases of giving treatment by implementing the steps of the shaping technique contained in the guideline sheet, namely as follows:

The counselee in the 1st day of the Baseline phase has not shown the expected target behavior, namely increasing self-confidence. In this first session researchers only built rapports, determined time and contracted counseling. Based on the results of the agreement in the counseling process, the expected behavior formation target consists of 5 kinds of behavioral formation targets. At this first meeting the counselee had not been given intervention or treatment.

The counselee in the Baseline phase 1 day to 2 days the counselee was not able to show the expected behavioral target even though the second session had given a shaping technique in the form of an introduction so that the counselee was able to tell the problem in more detail, what the counselee felt and the hope of the counselee in the counseling process.

In this second phase the counselee has not been given an order to greet students who are classified as students without special needs and have not been given examples of how to greet friends or students without special needs. Automatically there is no frequency, duration and intensity seen. At this stage the counselee changes behavior by 20%.

At the intervention stage 1 (B1) the researcher starts giving treatment to the counselee. The intervention stage (B) is the treatment stage, at the stage of intervention the counselee is given an example as initial treatment.

Intervention phase 1 (B1) day 3 of the counselee was able to show the expected level of behavior formation in the form of being able to greet friends who belonged to students without special needs. The reason the counselee was able to greet other students because in this phase intervention or treatment has been given by the researcher in the form of giving reinforcement and also the reward to the counselee, besides of his own desire to have many friends, not only friends from fellow students with special need but also students without special need.

The Intervention Phase (B) on day 4 of the counselee showed an increase in behavior change because he was able to greet one friend who was classified as a student without special needs. The reason the counselee was able to greet friends who belong to student without special needs because in this phase the counselee ventured to approach other students. When the counselee greets other students, he saw the student smiling at him so that made him feel happy and finally the counselee wanted to greet other students so that there would be more friends smiles at him again.

In the intervention phase (B) the 5th day the counselee was able to greet 2 students, meaning that the counselee has been able to increase the courage to greet other students. Where initially only 1 person in a day becomes 2 people in a day. So that in this phase the frequency, duration and intensity can be seen.

In the 6th day of intervention (B), the counselee showed an increase in expected behavioral formation, namely not thinking that other students did not care about it, so that in this phase the counselee was able to show 2 behavioral change targets namely being able to greet friends who were students without special needs and not thinking that other students do not care about it, so in this phase the counselee got the same score with day 5, which is getting a score of 4 with a percentage of 40%.

Stage 7 (B) day 7, counselee was able to show the formation of the same behavior as the previous day. In this phase the counselee also showed an increase in the number of greetings namely the counselee who on the 3rd and 4th day was able to greet 1 student, on the 5th
day he was able to greet 2 students, on the 6th day he was able to greet 3 students and finally on the day 7 this counselee experienced more improvement than in the previous days, the counselee was able to greet 4 students within 1 day.

Table 1: The results of recapitulation after obtaining intervention 1 (B1) can be seen in the following table:

<table>

</tbody>
</table>

In the intervention phase (B) it can be concluded that the counselee has been able to increase self-confidence by obtaining a score percentage of 40%, but to test whether the counselee was able to continue to increase self-confidence, the researcher returned to measuring the Baseline 2 (A2) stage.

Stage Baseline 2 (A2) was the stage of measuring the second counselee behavior after being given treatment at the intervention stage (B). In the Baseline 2 stage, observations were carried out again on the 8th day and 9th day.

In the Baseline 2 (A2) phase of the 8th day, the counselee was able to carry out two kinds of expected behavioral targets, namely the formation of behaviors greeting friends who are not students with special needs and do not think that other students do not care. So the score obtained is 4 with a percentage of 40%.

On the 9th day the counselee was still able to greet students without special need and judging from the way of greeting it showed a stable level of previous behavior formation which initially was able to greet 1 student in 1 day to be able to greet 4 people in 1 day and on the 9th day consistently students are able to greet 4 people in 1 day.

The ability to increase confidence in the conditions of Baseline 1 (A1), Intervention 1 (B1), and Baseline 2 (A2), can be seen from the following tables and graphs:

From the results of data analysis in the form of visual data between conditions can be proven Ha accepted hypothesis that was the influence of self-confidence in minor autistic students in Banjarmasin SMKN 2 after being treated with Shaping Technique. Shaping is a therapeutic technique that carried out by learning new behavior gradually. Counselors can divide the behavior they want to achieve in several units, then study it in small units \(^1\). Shaping can be defined as the development of a new operant behavior by strengthening the successive approximation of the behavior, and extending the previous approximation to the behavior until the new final target behavior appears\(^4\).

This study using a single subject (also called a single case experimental design) is a design that can be used if the sample size is only one. Basically the subject is applied to the state of no treatment and by alternating treatments, and performances or achievements are measured repeatedly during each phase. Non-treatment conditions are given symbol A and the condition with treatment is given the symbol B \(^1\).

At the first 1-day baseline the counselee did not bring up the expected behavior because the researcher still approached the counselee in order to build rapport and approached the client (attending behavior) which included components of eye contact, body language, and oral language as the initial steps of individual counseling\(^5\).

On the second day the counselee begins to show behavioral changes, namely the counselee begins to dare to tell the researchers, this was in accordance with the steps to build self-confidence, where a counselee took risks by expressing thoughts, feelings, and reactions to certain situations to other people (counselor). And the counselor must respond with acceptance, support, and cooperation and reciprocate the client’s openness by expressing thoughts, feelings, and reactions to the situation to the counselee \(^7\).

The counselee’s intervention stage was targeting to increase behavior seen from the third day to the seventh day, namely greeting students without special needs, but on the third day the counselee was still given an example.

At the baseline 2 the counselee also targets behavior formation but does not experience improvement, the counselee shows the same behavior formation, seen on the eighth and ninth days. In the A-B-A design after measurement in the intervention condition (B) the measurement in the second baseline condition (A2) is given. The addition of the second baseline condition (A2) is intended as a control for the intervention phase so that it is possible to draw conclusions about the functional relationship between the independent variable and the dependent variable \(^16\).

By giving shaping techniques to minor autistic students to increase their self-confidence, which when referred to with characteristics of high self-confidence that is the belief in self-ability, optimistic, objective, responsible, rational and realistic, autistic children are difficult to form behavior in accordance with the characteristics character of that high confidence. So that for the formation of behavior is only directed to one characteristic of high self-confidence, namely the belief in his abilities, namely by increasing the greeting behavior of without special needs, by being treated through individual counseling using the counseling shaping technique to have confidence in his ability to greet students with or without special needs.

Abstract

The study aims to identify the self-efficacy, self-regulation and academic motivation among students. Research design for this study is case study which used quantitative method. The study involved 140 respondents randomly selected among students Permata Insan in Islamic Science University of Malaysia from Form 1 until Form 4 respondents involved in this study using stratified sampling method which based on their availability to participate. Instruments used are The Self-Efficacy Questionnaire, The Self-Regulation Questionnaire and Academic Motivation Scale. The design of the study uses a survey method. The data were analyzed using descriptive and inferential statistics, independent sample t test and correlation. Research findings shows there is significant relationship between self-efficacy and academic motivation among students, significant relationship between self-regulation and academic motivation among students and significant difference between self-efficacy, self-regulation and academic motivation based on gender among students. Thus, to improve self-esteem, self-regulation and academic motivation among student, there is need of teachers to make diversify in style of teaching when delivering in classroom to ensure delivering are more effective towards students.

Keywords: Self Efficacy, Self Regulation, Academic Motivation, Students

Introduction

Education has been seen because the main issue that contributes to the success of people in life. When a child goes to school, they are under surveillance from parents and teachers to excel in terms of academic fields. Children will work diligently to achieve outstanding results in the lesson. Self-efficacy is the belief in one’s competence in performing particular tasks ¹⁵. It is also perceived as a realistic way of dealing with complications. It is a skill to effectively handle undesired changes². According to Bandura³ described self-efficacy as the belief in one’s capabilities to organize and execute courses of action required to produce given attainments. Self-regulation refers to certain conscious and unconscious processes. It is the human psycho exercises control over the operation of the state and its internal processes. Self-regulation is the key aspect through which the Self acts on the organism. Other authors consider that self-regulation as an individual energy resource. Based on Rashiqah & Siti Azlia ⁴ according The National Morbidity Health Survey (NHMS) the Ministry of Health, shows 11.2 percent of the teens in the group had the idea of suicide, nine percent planned to commit suicide and 10.1 percent committed suicide.

Research Objective

1. To identify the difference between self-efficacy and academic motivation among student.

2. To identify the relationship between self-efficacy and academic motivation among student.

3. To identify the relationship between self-efficacy and academic achievement based on gender among student.

Method

This study used quantitative research design in order to acknowledge the self-efficacy, self-regulation and academic motivation. The target population of this research is students of Permata Insan in Islamic Science University of Malaysia (USIM). Sampling is a process selecting number of individual for a study in such a way that they represent the large group from which they were selected. The sample size involved in this study is 140. In this research, three questionnaires namely self-efficacy, self-regulation and academic motivation questionnaire were applied. The Self-Efficacy Questionnaire was developed in 2015. It has 12 items and 3 subscales which includes academic self-efficacy, social efficacy and emotional self-efficacy. This scale ranges from 1 (Not at all) to 5 (Very well). Alpha Value Self-Efficacy is .720. The Self-Regulation Questionnaire was developed by Cleary. It has 13 items and 3 subscale which includes receiving relevant information, formulating a plan, implementing the plan. Alpha Value of Self- Regulation is .890. While the Academic Motivation Scale (AMS-28) High School Version developed. It contains 11 items assessed on a 5-point scale. Alpha Value of Academic Motivation is .970.

Findings

Table 1: The relationship between self-efficacy (SE) and academic motivation (AM) among students

Significant on level $p < 0.05$

Based on table 4.15 an independent sample t- test has been run between level self-efficacy, self-regulation and academic motivation based on gender among students. Result showed the significant between self-efficacy based on gender among students ( $t = .282, p < 0.05$ ). This means that there is significant difference between self-efficacy based on gender among students. Thus, HO3 is accepted. The significant between self-regulation based on gender among students ( $t = .208, p < 0.05$ ). This means that there is significant difference between self-efficacy based on gender among students. Thus, HO4 is accepted. Then, The significant between self- academic motivation based on gender among students ( $t = .106, p < 0.05$ ). This means that there is significant difference between academic motivation based on gender among students. With this HO5 is accepted.

Discussion

Relationship between self-efficacy and academic motivation among students

This result showed there is significant relationship between self-efficacy and academic motivation among student Perma Insan. This research is parallel with the findings Alkharusi, Hussain. Results of multilevel analysis showed that student academic self-efficacy beliefs were significantly and positively influenced by students’ perceptions of the assessment tasks. That means, teacher is the main role to improve the student self-efficacy compared to other factors. This shows, the self-efficacy are very useful to the students for increase their academic motivation.

Research also supported by Verdi & Lisa which done research in non-medical prescription stimulant use in graduate students relationship with academic self-efficacy and psychological variables to examine the relationship between non-medical use of prescription stimulants with academic self-efficacy and psychological factors. The result shows the sample consisted of 807 graduate students from universities located in five geographic regions of the United States. In development of self-esteem, self-efficacy is a crucial aspect to focus on since the development of a high sense of self-efficacy leads to an increase in one’s self-respect and generally their self-esteem is improved. It proves, the individuals with high level of self-efficacy are inclined to perform activities in a successful way.

Result also supported by Cerino (2014) in research relationships between academic motivation, self-Efficacy, and academic procrastination used sample of 101 undergraduate students (36.6% men, 63.4% women; $M = 20.76$, $SD = 2.54$, years of age) at a Northeastern public liberal arts university participated in the present study. This result suggests that, in addition to self-efficacy developed through previous learning experiences, learners need to know, and be able to employ, effort self-regulation in order to control their learning behavior for successful learning. Attention to
the research will help to clarify our understanding of the role that self-efficacy plays in academic motivation. Teachers are understandably concerned about teaching students skills; however, simply possessing skills does not ensure that students will be motivated to apply them. In their instructional planning, teachers need to take into account how given procedures affect students’ sense of efficacy.

Relationship between self-regulation and academic motivation among students

This result showed there is significant relationship between self-regulation and academic motivation among student Permata Insan. This research is parallel and supported by Thinbodeaux et al. in research first-year college students’ time use relations with self-regulation and Grade Point Average (GPA) show that how students manage their time is critical for academic performance and is an important component of self-regulated learning. Findings showed that students planned and spent less time on academics than socializing and work obligations in their first semester. Students generally planned to spend more time on academics in the second semester. That means, the students that got higher CGPA in the first semester must involve their society to the next semester to improve their self-regulation in their studies. The students who join themselves in the social programmed, they will improve their self-regulation. That shows, the student who can manage their self-regulation will perform their academic performance. The higher self-regulation, the high in studies performance in academic performance.

Result also supported by in research the effect of collaborative learning and self-assessment on self-regulation. Collaborative learning teaching method (Jigsaw and teacher assistant) is used for one group and the other group had also the same as well as learners’ self-assessment for eight 90-min-sessions. The study population included 75 persons who are divided into three groups of 25 subjects (two experimental groups and one control group). Using a learning techniques questionnaire and the motivated strategies for learning questionnaire (MSLQ) as well as a self-developed achievement test to measure the geometry in the lower and upper levels of the cognitive domain, it was revealed that “cooperative learning and self-assessment” have a positive effect on promoting learners’ “self-regulation” knowledge for geometry course. Collaborative learning and self-assessment also have a positive impact on academic achievement at low and high levels of learners’ cognitive domain. That means, it can be seen the effect of self-regulation and academic achievement to collaborative learning and self-assessment. So that, the high the self-regulation the high the academic achievement to collaborative learning and self-assessment.

The difference the Self-Efficacy, Self-Regulation and Academic Motivation based on gender among students

An independent sample t-test has been run between level self-efficacy, self-regulation and academic motivation based on gender among students. The result finding there is significant difference the self-efficacy, self-regulation and academic motivation based on gender among student Permata Insan. The result shows that there is the significant between self-efficacy, self-regulation and academic motivation based on gender among students.

This research also revealed a significant difference of both female and male students’ self-efficacy. This research is support to the difference the self-efficacy, self-regulation and academic motivation among student. This research parallel with the findings an independent sample t-test has between level self-efficacy, self-regulation and academic motivation based on gender among students which shows the significant negative between self-efficacy, self-regulation and academic motivation among student. This research is support by in research level of students self-efficacy based on gender used a quantitative research. The findings of the research showed 42.7% of male students’ self-efficacy is at moderate category and 47.2% of female students are at high category. This research also revealed a significant difference of both female and male students’ self-efficacy. The research shows, that female have higher self-efficacy, self-regulation and academic motivation rather than male the research is it is expected that counselors provide guidance and counseling services to improve and develop self-efficacy.

Conclusions

This study show female have higher self-efficacy, self-regulation and academic motivation rather than male. There are several ways to overcome this problems and one of it is teacher must provide guidance and
counseling services to improve and develop self-efficacy, especially towards male students as self-efficacy of male students is lower than female students. In addiction, self-efficacy, self-regulation and academic motivation are very important in students life. The perceived self-efficacy, self-regulation and academic motivation among students in Permata Insan in Islamic Science University of Malaysia was positively correlated with self-efficacy, self-regulation and academic motivation. Therefore, perceived self-efficacy with more social support, less stress, manage self-regulation, better relationship which lead to increase academic motivation in life. Moreover, head administration should encourage students to promote positive relationship to enhance the self-efficacy, self-regulation and academic motivation among students.

Relationship between Teaching Experience with Self-Efficacy and Instructional Strategies Applied among Secondary School Teachers

Pei Syan Woo¹, Zakiah Mohamad Ashari²
¹Master Student, ²Senior Lecturer, School of Education, Universiti Teknologi Malaysia (UTM), Skudai, Johor, Malaysia

Abstract

Within the education system around the world, teaching experience is proven to be one of the important factors in both the teaching and learning processes, which continue to fascinate researchers and educational deliverer. In order to strengthen STEM initiatives which listed in the Malaysia Blueprint 2013-2025, Malaysia places outstanding significance on STEM education. This quantitative study was carried out to identify the relationships between years of teaching experience with self-efficacy and instructional strategies applied among secondary school teachers in implementing STEM education. This study was conducted in 22 secondary schools located in Kemaman, Terengganu. A simple random survey method was used to complete this investigation which involving a total of 217 teachers. They were tested using the Teaching Efficacy Scale (TES) and Minnesota Elective Practice Instructional Strategies Assessment (MEPISA) instrument. The data were analyzed using Statistical Package for Social Science (SPSS) software version 24.0. Pearson correlation was employed to reveal the relationships between the variables in this study. The findings depicted that there was a low but significant positive correlation found between years of teaching experience and personal teaching self-efficacy. Besides, there was no significant correlation between years of teaching experience and general teaching self-efficacy. Furthermore, there was also no significant correlation between years of teaching experience and instructional strategies applied among secondary school teachers in implementing STEM education. To summarize these relationships, an increase in teaching experience can be an indicator of a heightened level of teachers’ personal teaching self-efficacy in the implementation of STEM education.

Keywords: teaching experience, teachers’ self-efficacy, instructional strategies, STEM

Background of Study

Education is crucial to the path of development in human capital and an innovative based economy¹. Malaysian Blueprint 2013-2025 introduces a new educational innovation with the main purpose of preparing all-rounded youth with the skills needed to compete in the job market and economic development. Educator is vital in shaping successfulness in various educational reforms². Thus, the role of teacher as an implementer of innovation should be taken seriously in promoting STEM education³.

The concept of Science, Technology, Engineering and Mathematics (STEM) is about integration of instruction, assessment, and curriculum to improve science education by prioritization of engineering. STEM also mentioned as the professional practice or advance studies in extensive fields of Science, Technology, Engineering, and Mathematics⁴. Due to its integrative approach, STEM is rapidly becoming a new initiative for educational purposes.

Actual teaching experience is believed to be the most influential activity that shapes an individual’s confidence in his or her abilities⁵. Teachers who had more science or math courses in college⁶ or had experience in
implementing similar instructional strategies are better in promoting the inductive and deductive reasoning across disciplines necessary for STEM. Besides, teachers with prior experiences with engineering scored higher on their knowledge of instructional techniques associated with STEM education. Thus, prior experiences by teachers is a plus factor to STEM success.

In educational context, the concept of teacher self-efficacy is referred as teacher’s beliefs regarding his or her ability to plan, set up and conduct events that are essential to achieve educational targets. General teaching efficacy is defined as the teachers’ belief that regarding students’ ability to learn regardless of external determinants, such as their home environment and socioeconomic conditions. Meanwhile, personal teaching efficacy is defined as the teachers’ belief regarding his or her ability to influence student learning.

Instructional strategies are referred as the methods or approaches applied by the teachers in order to hit the basic targets of instruction. Instructional strategies could affect learners’ outcome and let instructors to enhance the diversity of instructional practices. The successfulness of instruction can be accomplished primarily by avoiding the mystical or randomly occurrence of this process. The instructional process ought to be organized, connected and assessed in a deliberate, arranged and orderly manner.

According to previous researches, majority of the science and mathematics teachers lack experience in teaching engineering and STEM integration. Besides, there is a limited number of studies that investigate the teaching experiences necessary for educators to implement integrated instruction. Teacher’s self-efficacy also plays an important role in assisting teachers to screen their teaching experiences as well as interpret their subsequent instructional practices in implementing STEM education. This phenomenon has urged the necessity in studying teaching experience, self-efficacy and instructional strategies applied among secondary school teachers in implementing STEM education.

**Objectives**

The objectives of this study are:

- To identify the relationship between years of teaching experience and self-efficacy (personal teaching self-efficacy and general teaching self-efficacy) among secondary school teachers in implementing STEM education.
- To identify the relationship between years of teaching experience and instructional strategies applied among secondary school teachers in implementing STEM education.

**Methodology**

This study was conducted in 22 secondary schools located in Kemaman, Terengganu. A simple random survey method was used to complete this investigation which involving a total of 217 teachers. The integration of STEM studies in Malaysia was found to be concentrated in the higher education and less attention was paid the primary and secondary school level. The first section was the demographic background which aimed to determine the years of teaching experience. In the second and third section, teachers were tested using the Teaching Efficacy Scale (TES) and Minnesota Effective Practice Instructional Strategies Assessment (MEPISA) instrument. TES developed by Gibson and Dembo was used to determine teachers’ self-efficacy. TES consisted of 16 items with two uncorrelated subscales. Nine items in the personal teaching efficacy subscale were positive items and several items (2, 3, 4, 8, 11, 16) in the general teaching efficacy subscale were negative items. A 6-point Likert scale was used with options ranging from 1=Strongly Disagree to 6=Strongly Agree. MEPISA established by Ford was used to determine the dominant instructional strategies applied in implementing STEM education. MEPISA consisted of 33 items with no subscales. A 5-point Likert scale was used with options ranging from 1=Never to 5=Always. The data were analyzed using Statistical Package for Social Science (SPSS) software version 24.0. Pearson correlation were employed to reveal the relationships between the teaching experience, self-efficacy and instructional strategies applied among secondary school teachers in implementing STEM education. Table 1 shows the relationship of teaching experience with self-efficacy and instructional strategies based on the correlation coefficient analysis.

Findings

Table 2 shows the distribution of respondents according to years of teaching experience. 35.5% (77) of the teachers had 16 years and above teaching experience and followed by 32.7% (71) who had 11 to 15 years of teaching experience. However, only 3.2% (7) of the teachers had 1 to 5 years of teaching experience and the rest had 6 to 10 years of teaching experience.

Pearson correlation analysis was carried out to determine the relationship between teaching experience with self-efficacy (general teaching self-efficacy and personal teaching self-efficacy) and instructional strategies. The findings show that the correlation coefficient (r) between years of teaching experience with general teaching self-efficacy and personal teaching self-efficacy was 0.092 and 0.250 respectively. While, the correlation coefficient (r) between years of teaching experience and instructional strategies was 0.081. According to the Guildford’s Rule of Thumb, there is a positive and low relationship found between years of teaching experience and personal teaching self-efficacy. The positive relationship indicated that an increase in teaching experience would contribute to an increase in personal teaching self-efficacy of the secondary school teachers in implementing STEM education. The finding was statistically significant as the p-value (p=0.000) obtained was lower than alpha at 0.01 level of significance. Meanwhile, years of teaching experience shows negligible relationship with general teaching self-efficacy and instructional strategies. Both results were statistically insignificant (p=0.178, p=0.236).

Discussion

Based on the Pearson correlation analysis, result showed that there was a low but significant positive correlation (r=0.250) between years of teaching experience and personal teaching self-efficacy of secondary school teachers in implementing STEM education. This result was in line with the study carried out by Taimalu and Öim, on examining Estonian teachers’ efficacy beliefs and characteristics that have an impact on teacher efficacy. The authors found that the years of teaching experience was positively related to personal teaching self-efficacy. This showed that the experienced teachers’ belief in their ability to bring about change in students’ learning was stronger compared to less experienced teachers. Besides, a research done by Flores et al., on 162 public school teachers documented that there is a significant relationship between the years of teaching experience and personal teaching self-efficacy. Regarding teaching experience and STEM pedagogy,
more experienced teachers (greater than or equal to 15 years) felt more positively about the potential impact of STEM pedagogy than teachers with less experience (one to five years). Therefore, teachers with greater years of teaching experience showed a higher level of personal teaching self-efficacy in implementing STEM education.

Meanwhile, there was a negligible correlation ($r=0.092$) found between the years of teaching experience and general teaching self-efficacy of secondary school teachers in implementing STEM education. The result was contrary with the research conducted by Taimalu and Ötmü, the authors found that years of teaching experience was negatively related to general teaching self-efficacy. Teachers with more teaching experience feel more feebleness to solve the negative impacts of the students’ family background and other factors outside of the teachers’ control than teachers with less teaching experience. Besides, Taimaluet al. found that more experienced teachers agreed less that home environment encompassed a larger influence on students’ learning than less experienced teachers. It might be due to teachers with greater years of teaching experience feel more confident in their ability to overcome the negative impacts of home environment and promote students’ learning even without family support. However, the result was in line with the study conducted by Lee et al. The authors indicated that general teaching self-efficacy was not related to years of teaching experience. In a study of K–5 teachers, Nadelson et al. stated that the second cohort’s efficacy for teaching STEM education were not correlated with years of teaching experience. Therefore, the result in this study demonstrated that teaching experience does not account for advancement in general teaching self-efficacy within STEM teaching.

Next, there was a negligible correlation ($r=0.092$) found between the years of teaching experience and instructional strategies. Regarding teaching experience and STEM instructional strategies, Adams et al. opined that experiences with STEM learning and teaching conducted under integrated, place-based events affect positively on pre-service teachers’ understanding of place-based techniques, their perceived ability, and projected intent to design and implement place-based STEM learning events. Nevertheless, current investigation in this study contradicted their findings. One reason may be the respondents involved in this study were not pre-service teachers. The results of this study also challenged the research carried out by Lochmiller who deemed that teachers’ prior experience influenced the way that they conducted instruction in math and science subjects. The findings concluded that the instruction of high school science and math teachers was restricted by distinct subject subcultures that derived from their prior teaching experience. However, the result in this study was supported by Ogunkola and Archer-Bradshaw, on examining 55 secondary school science teachers in Barbados. The authors claimed that the reported instructional assessment practices of teachers were not affected by their teaching experience. Thus, the result in this study showed that teaching experience did not play a significant role in predicting the teachers’ willingness to use effective instructional strategies in the implementation of STEM education.

**Conclusion**

Teacher is a crucial factor in affecting students’ achievement and performance within the integration of STEM education. The findings of this study revealed that there was a low but significant positive correlation found between years of teaching experience and personal teaching self-efficacy. Besides, there was no significant correlation between years of teaching experience and general teaching self-efficacy. Furthermore, there was also no significant correlation between years of teaching experience and instructional strategies applied among secondary school teachers in implementing STEM education. To summarize these relationships, an increase in teaching experience can be an indicator of a heightened level of teachers’ personal teaching self-efficacy in teaching STEM education. However, the findings indicated that years of teaching experience did not make significant contribution to teachers’ general teaching self-efficacy and their willingness to apply instructional strategies in implementing STEM education. Therefore, more studies on STEM education need to be highlighted in order to strengthen STEM initiatives which listed in the Malaysia Blueprint 2013-2025. It is recommended that other factors contributing to teachers’ self-efficacy and instructional strategies should be investigated so that teachers are able to implement STEM education more efficiently on students.

Students’ Perceived Learning Environment for Self Regulation

Sook Ling Lim¹, Kee Jiar Yeo²
¹Postgraduate Student, ²Professor, School of Education, Universiti Teknologi Malaysia (UTM), Skudai, Johor, Malaysia

Abstract

The aim of this review was to identify students’ perceptions of self-regulated learning environment. Seven studies (N = 16,493) met inclusion criteria for this review. Five top characteristics of self-regulated learning environment identified in most studies were teachers’ social support, student cohesiveness, equity, task orientation, autonomy support regardless of the variability in terms of participants’ age group, types of learning institution or geographical location. This review provides synthesized information for more effective implementation of self-regulated learning in future.

Keywords: students’ perception, learning environment, self-regulation, student engagement, autonomy support

Introduction

Self-regulated learning (SRL) is a goal-oriented cyclical process which involves three phases. The cycle starts with forethought phase, wherein learners set goals and do planning for a task; It is then followed by performance phase, wherein learners monitor their progress and finally learners reflect on the outcomes. Reflections made will be used to make the necessary adjustments for the next task when cycle repeats. SRL has increasingly become important in education during recent years. One of the reasons is the similarity shared by SRL and the 21st century competencies, which both emphasize on self-directed learning to function effectively in terms of fulfilling goals and social communication.

Apart from that, a number of studies indicated that SRL can benefit children in some ways. For example, SRL may decrease the impulsive behaviours, and SRL was significantly associated with academic achievement. However, SRL is not a common practice in most of the learning institutions owing to limited knowledge among the educators and the restrictive curriculum which hinder the integration of SRL in the existing practice.

The aim of this review was to explore the key features of self-regulated learning environment preferred by students. We also intended to understand how these perceived learning environments may motivate students to become active participants of own learning.

Literature Review

From the perspective of social cognitive theory, SRL was illustrated in a triadic reciprocal causation, where the environmental, behavioural, and personal factors were interdependent and influenced one another. In other words, students’ use of SRL strategies depends not only on the environment factors but also on the perceptions of learners (personal) before deciding their actions (behaviour). According to Bandura, personal factors such as self-efficacy, and social environments exerted a stronger influence over human behaviour as compared to the individuals’ objective properties. For instance, if one perceives the learning environments as conducive, they are more confident and thus more motivated to work towards their goals, which increases the likelihood of success.

Nonetheless, learners and contexts were studied independently in most of the previous research. This approach was primarily based on what researchers or teachers think, with the assumption that students will also interpret in the similar manner, which was inadequate to explore how and why SRL develops and changes over time and across contexts. Similarly, Maehr contended
that self-perception was a critical personal variable in regard to contextual changes. This can be illustrated briefly by considering learners’ perceptions towards self, others, and tasks in the context which eventually affect their subsequent behaviours or actions. Hence, the personal factors contributing to SRL should be investigated specifically in the targeted context for a more insightful and reliable outcome.

**Objective**

The objective of this review was to identify the students’ perceived learning environments for self-regulated learning.

**Methodology**

The PRISMA for Abstracts Checklist was used for reporting this review.

**Participants**

From primary school students to undergraduates were eligible for inclusion.

**Types of Studies**

Only published research articles in English with number of participants ≥ 100 were considered. The participants from various regions of the world such as Asia, Middle-East, Australia and Europe were included to minimise the selection bias and to obtain a better representative of the targeted population.

**Types of Outcome Measures**

Studies were only included if the outcomes were obtained through the standardized questionnaires, which were widely used across multiple disciplines or different cultural contexts.

**Search Strategy**

A total of 1194 studies were obtained from five databases. After the application of conditions and stages of screening, only seven articles were selected for this review. Figure 1 shows the flow of information through the different phases of a systematic review.

---

Figure 1: Flow of Information Through the Different Phases of a Systematic Review
Quality Assessment

Risk of bias was assessed according to the guidelines from the Cochrane Handbook for Systematic Reviews of Interventions. Since there were only seven studies included in this review, there was a high risk of overemphasizing effects. Therefore, each study was assessed based on these domains: a) participants (sample size and the cultural context) b) type of instruments used c) main variables involved in the studies d) data completeness in terms of collection and reporting.

Studies were assessed based on six specific domains, namely sequence generation, allocation concealment, blinding, incomplete outcome data, selective outcome reporting and other issues. Each domain was evaluated of the risk of bias and assigned the judgement accordingly. The types of judgement are ‘Yes’ that indicates low-risk of bias, ‘No’ that indicates high-risk of bias and ‘Unclear’ if there are insufficient data reported in the studies. Two authors evaluated the studies against these criteria independently and inconsistencies aroused during the process were resolved through discussion. Figure 2 shows the summary of risk of bias rating.

Result

Characteristics of Studies

From a total of seven studies, the number of participants in each study ranged from 315 to 8570. Most of the populations were Grade 6-10 students, minority were undergraduates. The selected articles were from a broad range of regions such as Europe, United States, Asia, Australia, and Arabic countries. The instruments used in the included articles were either the original version or adapted from the prior studies. The reliability and validity of each tool were examined through data analysis or pilot study and all the result fell within the acceptable range. The variables in all studies were primarily focused on the students’ perceived learning environment towards self-regulation.

**Synthesis of results**

The first author examined the following data from each study: (a) studies, (b) participants details, (c) types of instruments used, (d) variables examined, (e) findings obtained. The second author independently reviewed each included article and the respective information. Any clarification or disagreements were resolved through discussion.

**Discussion**

The main outcomes of the included studies were synthesized and discussed. Teachers’ social support was the learning environment factor reported in most studies \( (n=6/7) \). Supportive teachers concerned about the well-being of their students. They were responsive to students’ needs, always offer constructive praise, help, encouragement to students. Hence, students obeyed teachers’ orders more readily, which indirectly disengaged students from deviant behaviours\(^5\) and subsequently helped them to regulate the negative behaviours.\(^12\) In line with this, social support from teachers was expected to motivate students in mastering a given learning task or to persevere through challenging tasks.\(^12\)

Four studies \( (n=4/7) \) reported that student cohesiveness played a significant role in learning process through higher motivation, confidence, engagements, and use of self-regulation strategies. To create a cohesive learning environment, teachers must consistently provide opportunities for students to work together or to interact. When they worked in groups, they felt a sense of togetherness and positive peer relationships might be formed, which eventually led to higher efficacy and self-regulation among the students.\(^8\) A good illustration of this was students were motivated when they received help or guidance from their peers, which then drove them to engage in meaningful learning tasks such as the use of self-regulation strategies.

The third constructive learning environment factors was equity as reported in three studies \( (n=3/7) \) which was found to be positively associated with student engagement or self-regulation. Equity in the context of classroom referred to the equal learning opportunities, praise, help or encouragement given to each student regardless of their gender, level of progress, behaviours or any differences. Fair treatment from teachers created a healthy learning atmosphere which encouraged students to express themselves and also to participate in school activities more voluntarily.\(^24\) Likewise, students were more motivated and eager to use self-regulation strategies if they perceived themselves to be treated equally by teachers.\(^13\)

Task orientation was another learning environment variables reported by three studies \( (n=3/7) \). It was not only a good predictor of self-efficacy, but also closely related with motivation and self-regulation. A task-oriented learning environment could be illustrated as one which emphasized on the importance and the exercise of goal setting. In other words, students needed to set clear and relevant goal for each task and also to know well of what to accomplish upon task completion. For meaningful goals, teachers had to monitor their students consistently and provided the constructive feedback when necessary to ensure they focused on and completed the assigned task.\(^13\) This was supported by Middleton & Midgley\(^4\) who reiterated on how crucial it was to ensure the students understand what they learnt and also to complete the tasks assigned.\(^9,8\)

Lastly, two studies \( (n=2/7) \) reported that autonomy support was a contributing environmental factor towards self-regulation. Typically, an autonomy supported learning environment was one which provides decision-making opportunities, where the students could participate in the discussion.\(^7\) As a result, the students were more likely to engage in meaningful learning tasks and thus promoted school identification, which was the sense of belonging and valuing of school.\(^14\) Another research suggested that autonomy support could retain learners’ intrinsic and rather self-determined regulation\(^15\) which affects self-regulation as learners.

**Conclusion**

**Research Implications**

This review synthesized the information on the students’ perceived learning environments towards self-regulation. The results are good predictors to understand how learners think and interpret the characteristics of an effective classroom, which works for them. Hence, perceptions of learners can be taken into consideration in the context to ensure a more realistic and practical way of problem-solving. In addition, the awareness of putting emphasis on the right learning environment variables benefits educators in various ways such as regulating negative behaviours, increasing the school participation,
and boosting the motivation and perseverance in learning among the students.

**Limitations and Future Directions**

For this review, a number of important limitations needed to be considered. First, this current review yielded only seven studies. The small number of studies restricted a thorough evaluation from various perspectives, thus the conclusion drawn may not be appropriate for generalization purpose. Another limitation was in terms of methodology, which all included studies used quantitative measures such as questionnaires or subscales. Such tools are usually presented in a structured format with close-ended questions determined by researchers, which limit the outcomes. Therefore, the results may not cover the probable natural occurring.

In future research, much effort is required for a more accurate prediction of the learning environment variables, which promote self-regulation among students. First, the availability of literature review for this issue was limited but more were emerging during the recent years, this indicated that SRL was a recent but potential topic to explore. Hence, experimental or intervention programmes are very much needed to observe and to understand how self-regulation develops dynamically within or across individuals, over a relative longer period or across contexts. Besides, researchers may consider to include qualitative measures such as interview since it is on the basis of human experiences, thus provide researchers a more realistic idea for future implementation.

Retrieval Based Learning on Student Memory Retention Time: A Meta-Analysis

Noor Azizah Bt Aziz¹, Amirmudin Bin Udin²
¹Postgraduate Student, ²Senior Lecturer, School of Education, Universiti Teknologi Malaysia (UTM), Skudai, Johor, Malaysia

Abstract
This article is mainly about Retrieval Based Learning (RBL) in memory retention. This meta-analysis study has 2 objectives: (a) to address the time usage for memory retention, and (b) to measure the biggest quantitative effect size according to memory retention time through retrieval activities. This study was conducted by calculating the percentage of 69 studies, including research into practice, research article, intervention study, and journal papers. The studies were selected according to the following criteria: experimental studies on retrieval based learning, and retrieval practice at different educational levels. The studies, which were included within this scope, were carried out between the year 2000 and 2018. A few inclusive criteria are explained in more detail in this article. To obtain more precise articles in answering the objectives, the researcher has chosen 10 suitable articles with retention time as independent variable and were done experimentally. The effect size value can generally be viewed as positive to improve students’ achievement in RBL activities. As the current research may benefit educators, it is hoped to be useful for future research as well as teaching and learning practices in various fields.

Keywords: Meta-analysis, Retrieval based learning, Retrieval practice

Introduction

Retrieval Based Learning is a strategy to regain subject content. It is a main process in understanding a certain subject and it involves cognitive process¹,². It also emphasize that retrieval based learning is a natural process in learning as information is coded and retrieved before the assessments are done³. The retrieval process mainly involves cognitive process within human beings. Previous research³ also state that cognitive process is often related to the education field as it involves individual thinking process and the ability in understanding and expanding information. The researcher thinks that retrieval based learning focuses on the methods of remembering information by using a certain signal so the result of learning can be utilized well. This involves strategies that use memory and cognitive theories in learning. Learning using the retrieval strategy is considered as gaining information and knowledge as well as learning mastery by regaining knowledge. Previous research⁴ also has shown that retrieval based learning is able to improve understanding of knowledge.

This strategy has been used worldwide since the 1990s, and research continues to be done by John Gloverpada in the 198⁵. The essence to the RBL principle is the continuation from a research by a psychologist named Abbott, who was responsible at introducing RBL for its ability to improve learning process through his “recall in the learning process” experiment⁶. Abbott is a psychologist who emphasizes on the effects of using RBL in learning for centuries. Learning occurs through tests or assignments that can help improve one’s memory actively more than just merely reading. In 2006, a research on RBL gains attention once again when it is almost forgotten due to its effectiveness at improving students’ understanding which has been proven in several researches. According to Karpicke and Grimaldi, RBL is
able to improve students’ achievement if actively used in teaching and learning\(^6\). Nunes and Karpicke state that RBL has contributed towards teaching and learning activities in classrooms\(^1\). This is supported by other previous studies\(^2\)–\(^9\) in which they believe that regaining information is done through long-term memory.

**Research Questions**

This meta-analysis is based on the research questions below:

Research Question 1: What is the commonly used time frame in memory retention when RBL process takes place?

Research Question 2: What is the biggest quantitative effect size according to memory retention time with retrieval activity?

**Methodology**

**Collection of the Data**

This study utilizes quantitative meta-analysis method\(^10\) to determine the related fields in RBL, the materials used for RBL learning procedure, learning activities in RBL, and time utilization in memory retention when RBL process is carried out based on the percentage. This research also aims to determine the effect size based on the differences between RBL learning activities and students’ achievement. Research papers were collected based on the publishing years starting from 2000 until 2018. There were 208 related articles found either through online or offline search based on title, keyword, and abstract as the main reference. Once the articles were filtered using Mendeley software, the number of articles decreased to 197. To ensure the suitability of the found articles, further filtering was done until there were 69 relevant ones left. Of these, only 10 articles were found to be best suited to the researcher’s study.

**Analysis Inclusion and Exclusion Criteria**

The criteria used for inclusion into meta-analysis study are given below in detail:

a) The research must be conducted between 2000 and 2018.

b) It must be an article published or scientific refereed journal which is written in English and available in full text.

c) It must consider ‘retrieval based learning’ or ‘retrieval practice’ as one of the independent variables.

d) The studies must be designed according to true or quasi-experimental design.

e) Mean and standard deviations of the scores of experimental and control groups must be given in the findings.

f) The sample size in the experimental and control groups must be given.

g) Assessment tools used in studies must have adequate levels of validity and reliability.

The criteria used for exclusion into meta-analysis study are given below in detail:

a) Not available in full text.

b) Not related to our research questions.

c) Outside the time span of our search.

d) Duplicated studies.

e) Does not include ‘case retrieval’, ‘information retrieval’ and ‘retrieval system’.

**Validity**

Data validity level obtained from studied resources in the meta-analysis research is related to the ability of the data collecting tool used. This is to ensure the needed area can be measured\(^10\). This shows that the tool used in this research has high reliability.

**Data Analysis**

At first, this research only analyzes articles from 2000 to 2018, where data were analyzed using the line chart to help researcher studies the trend at producing articles for 20 years. Data were analyzed in percentage form to classify articles based on the country. Next, the researcher classifies data provider in terms of percentage to ensure the articles are qualified from trusted resources. The researcher studies the population in terms of percentage to ensure that the population of focus by the researcher is similar to those in prior studies for a more matured analysis. The following analysis is the memory retention time by previous researchers to ensure that the time is suitable with the memory theory. The final
analysis is measuring the biggest quantitative effect size based on memory retention time with retrieval activity by using the online effect size calculator provided by David B. Wilson, Ph.D., George Mason University, through http://www.campbellcollaboration.org/escalc/html/EffectSizeCalculator-SMD30.php

Results of Research

Research Question 1: What is the commonly used time frame in memory retention when RBL process takes place?

This study has referred to 10 articles classified according to the analysis inclusion criteria. Based on Figure 1, studies on RBL are mainly conducted for 1 week as found in 6 articles, 5 minutes in 5 articles, and 2 weeks in 3 articles.

![Figure 1: Summary of Previous Research on RBL based on Memory Retention Time](image)

Research Question 2: What is the biggest quantitative effect size according to memory retention time with retrieval activity?

This research refers to 10 articles classified according to the criteria on Coding of Data and Variable, in which only articles with RBL activity and memory retention time as variables are analyzed. According to Table 1, the measure of effect size starts from very small to huge.

![Table 1: Measure of Effect Size](image)

Discussion

Research Question 1: What is the commonly used time frame in memory retention when RBL process takes place?

Meta-analysis statistic finding shows that out of 69 experimental researchers, only 10 are related to memory retention time. According to the period, 1 week is the most studied followed by 5 minutes and 2 weeks. The researcher thought that the period chosen in previous studies are suitable to test students’ memory retention. If the period is too short or too long, the testing process might not be definite. This could occur due to forgetting little by little based on the theory of memory.

Research Question 2: What is the biggest quantitative effect size according to memory retention time with retrieval activity?

Meta-analysis statistic finding shows that there are 10 articles that count the effect size value of the experiment conducted in previous researches. The researcher thought that retrieval activity and period do not show the exact benchmark of effect size value. This means that the period is not exactly the best to measure memory and retrieval activity in a conducted experiment. Thus, there is a need for further study to identify effective retrieval activities in students’ memory retention.

Conclusion

In conclusion, the research finding has shown that Retrieval Based Learning is closely related to memory retention, and that it helps to improve students’ cognitive skills in learning. The results support several previous researches although there are some which do not agree with each other. Thus, this field should be discovered more so that an RBL model or clear guidelines with better variables can be produced and practiced in teaching and learning. The research implication was also discussed as
a reminder and to create awareness among researchers, educators and students for a better quality learning to improve students' achievement.

A Systematic Review of Play-Based Intervention in Enhancing Social Skills Children with Autism Spectrum Disorder

Joanna Hie Ping Ting¹, Kee Jiar Yeo²

¹Postgraduate Student, School of Education, Universiti Teknologi Malaysia (UTM), Skudai, Johor, Malaysia, ²Senior Lecturer, School of Education, Universiti Teknologi Malaysia (UTM), Skudai, Johor, Malaysia

Abstract

Children with Autism Spectrum Disorder (ASD) display social skills dysfunction, such as lack of social interaction, communication skills, social engagement, emotion recognition and social play. One of the aspects being emphasized in managing behaviour of ASD and other categories of learning problems is teaching social skills and academic skills. While learning through play to strengthen social skills behaviour has gained its place in normal preschools but it has been neglected for children with disabilities in classroom settings. Hence, a pressing need for more studies to look into play-based intervention, particularly within the school setting, so as to enhance social skills functioning amongst children with ASD. In fact, many studies have exemplified the benefits of play for those diagnosed with ASD. As such, this review combs through evidences that employ play as an intervention for children with ASD in enhancing their social skills. The objectives of this review are: (i) to identify empirical studies that employed play-based interventions in enhancing the social skills amidst children with ASD, and (ii) to identify the type of play approach applied in natural setting. In order to gather published articles for the study, online databases, such as ScienceDirect, ERIC, ProQuest, PsycINFO, PubMed, Springer link, JSTOR, and Google Scholar, were used for data search. Thirty papers were collected and the outcomes suggest that numerous studies have explored schools to investigate a wide range of play strategies in both structured and unstructured approaches based on specified target skills. Furthermore, this study lists the strengths and shortcomings of the reviewed studies, along with several implications that highlight the practice of play as an intervention within the school setting.

Keywords: Play-based intervention, Social skills, Autism Spectrum Disorder, Systematic

Introduction

Healthy social skills development enhances a child’s engagement in social interaction¹. Social skills are critical to successful social, emotional, and cognitive development. As such, effective social skills programming should be an integral component of educational. However, amongst children diagnosed with Autism Spectrum Disorder (ASD), social skills disabilities have been time and again proven as a core deficit. The social skills competence displayed by children with ASD has attracted extensive empirical researches. The studies show that children with ASD display impair in social interaction², communication³, poor emotional coordination during social exchanges⁴, as well as impairment in response to reaction given by others. In addition, they exhibit impairment in expressing their emotions and more likely to be less empathetic⁵. Furthermore, social skills deficits impede one’s ability to establish meaningful social relationships, which often leads to withdrawal and a life of social isolation⁶.

Children can learn social skills to communicate and express their feelings to others through play⁷. For instance, play provides a safe distance from their psychological problems and expresses appropriate interactions with others⁸. As such, play therapy functions as a means of communication with a therapist to interact with their environment. Although social skills deficits are
a central feature of ASD, few children receive adequate intervention either at school or home. In fact, play-based intervention is a well-known technique that can be used to help children diagnosed with autism. Play-based intervention is part of the imitative therapy as children appear to be more natural in a play setting.

Emotional competence is crucial in social competence as emotions are contextually embedded in social interactions, and spontaneously regulate these interactions by exchanging emotions in accordance with the requirements of the situation. Emotional competence is related to social competence. Similarly, Begeer, Koot, Rieffe, Meerum, & Stegge asserted that emotional competence is embedded in both social interaction and emotion recognition, and children communicate through emotion. Emotion and communication become more meaningful when a child grows older. Emotion becomes a primary medium for communication that regulates social relationship. Furthermore, emotion is vital in creating good relationships with others, including healthy emotional exchanges. Children can learn social-emotional skills to communicate and express their feelings to others through play. For instance, play provides a safe distance from their psychological problems and expresses appropriate interactions with others. As such, play therapy functions as a means of communication with a therapist to interact with their environment.

Play enables children in several areas, such as social skills, cognitive, social-emotional, and physical skills. Play is the most developmentally appropriate way for children to learn perspective-taking, social-emotional, and social skills, and to enhance the ability in social cognition.

Objective

Given the evidence for co-occurring impairment social skills in children with ASD and the relationship between play and social skills amidst the children with ASD, this systematic review examined the objectives as follows: (i) to identify empirical studies that employed play-based interventions in enhancing the social skills element among children with ASD, and (ii) to identify the type of play approach applied in natural setting.

Methodology

This study gathered several published articles retrieved from a number of online databases, namely ScienceDirect, Taylor & Francis Online, ERIC, PubMed, Springer link, JSTOR, and Google Scholar. During the process of data search, the following keywords were used: ‘play’, ‘play intervention’, ‘play therapy’, ‘Theraplay’, ‘Child Centred Play Therapy’ (CCPT), and ‘Intergred Play Group’ were paired with ‘social skills’, ‘social competence’, ‘social and emotional’, ‘autism’, and ‘Autism Spectrum Disorder’ (ASD). Studies including participants with other disorders or disabilities, and with interventions implemented for other skills were excluded.

Since this study investigated play intervention to enhance the aspect of social skills development among children with ASD, the articles retrieved from the search databases had been examined manually to identify articles that were related and appropriate for the purpose of this study. As a result, 15 articles seemed to meet the following criteria: (1) empirical studies that employed play-based intervention in enhancing social skills children with ASD; and (2) articles published from year 2000 and onwards to review recent studies, to enlighten the increasing interest, and to probe into the cutting-edge knowledge in the autism educational research field. Among the 15 reviewed articles, 8 studies employed quantitative approach, while 3 studies utilised qualitative approach, and the other 4 studies used mixed method approach to explore the research questions.

Discussion

The systematic review that discussed in this session included intervention, outcome on social skills development, research design, setting, target areas, interventionist, duration and effectiveness of the intervention.

Intervention

Based on the articles gathered, two play interventions appeared dominant, namely, CCPT and Floortime, herein 7 studies looked into CCPT, while the rest employed Floortime, Theraplay, and Responsive teaching curricula, ‘Learn to Play’ and other play approaches.

The studies exhibited that CCPT interventions promoted positive social behaviours, besides enhancing self-concept and emotional regulation among children diagnosed with ASD. Apart from CCPT, Floortime also appears to an effective approach applied by preschool
teachers to increase social interaction, engagement, and socio-emotional functioning. Besides intervention at home, the Floortime approach has also been used across several settings, such as therapy centres and at schools. Integrated Play group (IPG) support children with autism by engaging them in play with peers in social setting. IPG model emphasises conducive and environment to foster enjoyable social interaction and play sessions.

Outcome on Social Skills

The primary objective of all the interventions reported in the selected articles mainly supported social skills development as well as constructs of social and emotional skills. All the studies mentioned their main purpose of implementing the approach of play interventions. Therefore, in general, CCPT intervention was emphasised for social skills, socio-emotional functioning and play skills. Based on the review, most studies seemed to report successful achievement of their targets among children with ASD.

Research design

From the review, most of the studies employed the pre-test and post-test experimental design to compare the difference social skills, social-emotional functioning, social interaction, emotion recognition, engagement, maladaptive behaviour and play skills between experimental and control groups. Meanwhile, some studies carried out single case study that looked in-depth regarding the social skills subject that targeted.

Setting

Since younger children spend much of their time in preschool setting and less time at home, it is appropriate to implement the necessary intervention in preschool setting. In fact, a research has proven that intervention implemented in preschool setting generates overall positive development outcomes. In this review, all the interventions were carried out in preschool setting. The school setting provides an effective atmosphere in terms of group or individual setting for their social and emotional development.

Targeted areas

All the gathered studies focused on social skills through play intervention in school setting. The aspect of social skills refers to social competence such as interaction, engagement, emotion recognition, social awareness, and social cognition. Some studies focused on social emotional, which are also related to social skills constructs as well. Social interaction and engagement are associated to the recognition of social awareness. Meanwhile, play skills such as pretend play, symbolic play and social play are part of the social competence in social skills. Apart from this construct, empathy, self-regulation, and emotional regulation were also embedded in several studies as the constructs that were investigated.

Duration

The duration of therapy was measured by using two variables: number of sessions and length of treatment. The length of treatment was coded as the elapsed time from the first day until the last day of the play therapy treatment. This coding scheme was adopted to detect possible interactions that may exist between the number of sessions and the length of treatment. More than half of the studies (n =11) failed to provide detailed description of either the frequency or the duration of the play intervention. The remaining studies reported that the duration of the intervention ranged from eight weeks to ten weeks and it was delivered once or twice a week. The average duration per session was only 30 minutes.

Effectiveness

All the studies highlighted the significance of improving social-emotional functioning through play intervention; either structured or non-structured play. The studies also showed that children displayed positive improvement in social behaviour, social skills, social interaction, and enhanced relationships with teachers and therapists.

The outcomes of the review indicated that play intervention is indeed a beneficial intervention that helps children to achieve optimal growth and development in social skills, as well as social competence. An increasing amount of evidence supports the effectiveness of play intervention upon children’s social-emotional.

Conclusion

Play-based intervention has a significant role in enhancing the social skills among young children with ASD, especially in preschool setting. Play based intervention has become more widely recognized as a clinically-proven treatment for children with ASD. Nevertheless, play intervention seems to have been
missed out in school setting, perhaps due to lack of knowledge and skills in conducting this approach among the special education teachers. For that reason, more studies should look into school settings that involve teachers in the research process. This knowledge can form a basis to generate an inclusive environment, apart from avoiding the application of clinical trials at school. In order to achieve this goal, more teachers should be trained to be reflective so that they can implement successful strategies without implementing clinical interventions at schools.

e- PBL: An Innovation to Promote Active Learning and Decrease Cognitive Overload among Medical Students

Heethal Jaiprakash1*, Anudeep Singh1*, Anupam Biswas2, Jaiprakash Mohanraj2, Sarmishtha Ghosh1*

1International Medical University, School of Medicine, Bukit Jalil Campus, Kuala Lumpur, Malaysia
(*Ex-MAHSA UNIVERSITY, Faculty of Medicine, Bandar Saujana Putra, Malaysia),
2MAHSA UNIVERSITY, Faculty of Medicine, Bandar Saujana Putra, Malaysia,

Abstract

Background: Problem based learning (PBL) encourages students to develop generic skills and enhances active & deep learning. However, many times logistics and availability of trained facilitators decrease the possibility of having an effective PBL. This study was planned with an aim to investigate the possibility of using technology along with human support to achieve the same, thus testing the usefulness of e-PBL as one of the options replacing conventional PBL. Methodology: Sixty-four year 2 MBBS students were selected to undergo e-PBL using Google forms. On day 1 the trigger was sent to the students, day 3 they were told to send the facts and unfamiliar words with their meaning. On day 4 the guiding questions were posted which triggered students to search for more information. The answers for the guiding questions were sent by the students on the 6th day. On day 8, the students were given a mini test. The process was repeated for the other triggers. Modified essay question test was given to students who took e-PBL and conventional PBL. The study aimed at assessing the knowledge gained between both groups of students and the perception of the students who took e-PBL. Results: On comparison among the two groups, the P value was found to be statistically non-significant for both end block and e-PBL MEQs (P value 0.6 and 0.2). The students felt that e-PBL increased their ability to link basic science knowledge with clinical and applied knowledge (3.46±.910) and helped them to have a systemic understanding on the topic (3.49±0.910) and also promoted their motivation for self-study and improved their information management skills. Conclusion: There was no difference in the knowledge gained among both groups of students. This suggests that e PBL can be a good alternative for the conventional PBL.

Keywords: e-PBL, Cognitive load, Active learning, technology enhanced medical education, e-learning, online learning.

Introduction

Problem-based learning (PBL), as the name implies, is learning that is driven by problems. The process involves three phases, namely a problem analysis, a self-directed learning and a reporting phase.1,2) In the process of conventional PBL the construction of knowledge is a result of collaborative learning while working with peers as well as through individual self-directed learning.3) The training of students to become self-directed, lifelong learners is one of the outcomes of a PBL curriculum.4) PBL has many advantages., it helps in acquiring generic competencies, encourages deep learning and prepares students for adult learning. There are also drawbacks with PBL. PBL process may inhibit a good teacher from sharing his enthusiasm and experience on the topic while this may also lead to students failing to develop an organized frame work to acquire their knowledge. The facilitators may not have the skills to facilitate PBL and also lack of resources like space for a large group cohort5).
PBL might seem to be an interesting self-learning strategy and is accepted widely by medical educators, but these learning sessions might impose a high cognitive load on students who lack experience in clinical reasoning. The principle of cognitive load is based on a theory called as cognitive load theory (CLT). Cognitive Load Theory (CLT) is an instructional theory that describes the occurrence of optimal learning when instructional material is designed in a manner that fits the function of human cognition. The main focus of CLT is to envisage the outcome performance of the learner by taking into account the capacity and restrictions of human cognition while designing instructional material. CLT provides guidelines to present information in a way that encourages activities which optimise intellectual performance. CLT assumes a limited working memory connected to an unlimited long-term memory, hence instructions should be designed such that working memory is capable of processing the instructions and the working memory load is not exceeded.

Introduction of e-PBL as a teaching learning activity is one of the strategies to reduce cognitive overload.

Use of technology has been widespread in teaching and assessment. They have also been introduced in PBL. This has led to a technology based PBL, the e-PBL. Use of technology increases the interest of the students and also reduce cognitive load and therefore promote active learning. This makes the learning student centered. With idea of reducing the cognitive over load among the students and promoting active learning this study was initiated.

Objectives: The objectives of the current study were

- To compare the knowledge gained among students taking e-PBL session (Test Group) and conventional PBL session (Control Group).
- To analyse student’s perception on e-PBL.

Methodology

Study design: This was an experimental study conducted on sixty-four year 2 MBBS students which was the test group and 110 students were the control who took up conventional PBL. The 64 students of the test group were divided into six groups to ensure that their learning is team based and collaborative. The students were selected by random sampling and their participation in the study was voluntary. The study was conducted in the gastrointestinal and nutrition block and the case selected for the study was gastroesophageal reflux disease (GERD).

Procedure: Ethical clearance was obtained from MAHSA University ethics committee. Informed consent was obtained from all the students under the study. Students who signed the informed consent and only year 2 medical students were included in the study and those who did not matched the criteria were excluded.

Google form and PowerPoint were used to conduct the e-PBL. A total of four triggers were used for the case. The students were instructed to work as a team for all the tasks assigned. The steps followed were as follows for each trigger separately:

Day 1- Trigger was sent to the students via power point

Day 3- Facts and difficult terms were identified by the students and sent to the facilitators

Day 4- Guided questions related to the trigger were posted which would stimulate the student’s thinking process and facilitate their learning. They were told to find answers for these questions and send to the facilitators.

Day 6- The answers to the guiding questions were sent by each group after discussion among the group members

Day 8- Online mini test related to the trigger was given through google form to all the students which they needed to answer individually and not as a group.

The same process was followed for the other three triggers. At the end of the study a modified essay question (MEQ) test was given to test and the control group. Their performance was compared. The gastrointestinal and nutrition end block exam (EBX) MEQ scores were also compared between the test and control groups.

A validated questionnaire was distributed to the test group to assess the perception of the students regarding the e-PBL. The questionnaire contained 10 questions and the students were asked to give their opinion by means of a five point Likert scale. The respondents indicated their agreement or disagreement as scores 5, 4, 3, 2 and 1 for options strongly agree, agree, neutral, disagree and strongly disagree respectively. In addition to this the
Indian Journal of Public Health Research & Development, April-June 2019, Vol. 10, No. 4

students were given an option for free comments.

Analysis: The data was analysed using descriptive statistics and reported as mean and standard deviation. The mean scores were compared using t-test. SPSS version 25, 2018 was used to analyse the data. P value of <0.5 was considered significant.

**Results**

A total of 64 students participated in the study and 110 students were the control. The mean age of the students was 21.4±2.2 years.

### Table 1: Comparison between e-PBL MEQ and End block MEQ score between test and control groups

</thead>
<tbody>
<tr>
<td>e-PBL increased my level of knowledge in the particular topic.</td>
<td>3.42±1.002</td>
</tr>
<tr>
<td>Helped me to have a systematic understanding of the topic covered in the e-PBL</td>
<td>3.49±.877</td>
</tr>
<tr>
<td>e-PBL Increased my ability to link basic science knowledge with clinical and applied knowledge</td>
<td>3.46±.910</td>
</tr>
<tr>
<td>I had a better understanding of the topic rather than what I would have in the paper PBL</td>
<td>2.93±1.146</td>
</tr>
<tr>
<td>e-PBL promoted my motivation for self-study</td>
<td>3.22±1.126</td>
</tr>
<tr>
<td>e-PBL improved my skill of managing the gathered information</td>
<td>3.27±1.053</td>
</tr>
<tr>
<td>e-PBL helped me in preparing for my Gastrointestinal and nutrition end block exam</td>
<td>3.24±.986</td>
</tr>
<tr>
<td>The idea of e-PBL is interesting</td>
<td>3.16±1.053</td>
</tr>
<tr>
<td>e-PBL is time consuming and not worth all the effort</td>
<td>2.85±1.034</td>
</tr>
</tbody>
</table>

As shown in table 2 the perception of the students regarding e-PBL was positive. They felt that e-PBL promoted self-study and also helped in increasing their knowledge.

### Discussion

Problem based learning (PBL) was first implemented at McMaster university medical school in the 1960’s where it has revolutionised the field of medical education since then.\(^{11}\) In PBL the learners are empowered to integrate theory and practice, and apply knowledge and skills to develop a viable solution to the problem.\(^{12,13}\) In a study conducted in Malaysia, the preliminary data showed that the PBL session imposed a high intrinsic load and low extraneous load on the students. These results showed that students invested more mental effort processing the intrinsic load than the extraneous load.\(^{14}\) Hence we require a strategy which decreases the cognitive load on the students and hence make learning more effective. Use of technology has become widespread in education more so in medical education. Studies have proved that use of technology increase interest and motivation of students, hence promotes learning.\(^{15,16}\)
In our study we found that there was no difference between e-PBL scores and the end block exam scores between the students taking the e-PBL and those who took the conventional PBL. This shows that there was no difference in the knowledge gained between the groups and e-PBL can be an alternative for the conventional PBL. E-PBL gives the students to learn in the comfort of their home and at their own pace. This reduces their cognitive load and improves long term memory. In the logistics point of view, the resources required for an e-PBL is much lesser than that of a conventional PBL. In a study conducted in turkey they found no major difference in the assessment scores between students who took conventional PBL and e-PBL, which was in concurrence with our study. (17)

The perception of our students regarding e-PBL was positive. The students felt that they could learn at their own pace and comfort of their home. They also felt that the accessibility for resources was better in e-PBL. They felt it was a relaxing way of learning. However, some of the students also felt it was time consuming and it was better to have the facilitators to guide them. The study conducted in turkey on medical students also showed good feedback scores for the perception of e-PBL which was in concurrence with our study. (17) The comments were a mix of positive and negative as in our study. This implies that e-PBL can be a good alternative to conventional PBL as it allows the students to be individualised and at the same time collaborative. Therefore, enhance deep learning and improve long term memory. Information overloads the working memory and hence affects long term memory. Splitting the problems into parts and giving the students space to assimilate at their own pace will help the students improve their long term memory and thus enhance learning and their future academic performance. (18)

Conclusion: There was no difference in the knowledge gained between both the study groups. Most of the students had a positive perception about e-PBL. We need further studies to validate this hypothesis.

Limitation of the study: The sample size was too small to come to a logical conclusion. The study was done on a single cohort of students and in only one block. Further studies with multiple cohorts and more blocks can be conducted to come to a definite conclusion.

Prenatal Testosterone and Sporting Success among Malaysian Rugby Athletes

Zulkhairi Azam¹, Zainal Abidin Zainuddin², Halijah Ibrahim³, Asha Hasnimy Mohd Hashim¹, Mohd. Hafizuddin Baki¹, Mohd. Saizul Hafifi Md. Noor⁵

¹Postgraduate Student, ²Associate Professor, ³Senior Lecturer, School of Education, Universiti Teknologi Malaysia (UTM), Skudai, Johor, Malaysia, ⁴Strength and Conditioning Coach, Malaysia Rugby Sevens National Team, Kedah State Sports Council, Malaysia, ⁵Head Coach, Malaysia Rugby Sevens National Team, Tunku Mahkota Ismail Sports School, Malaysia

Abstract

Most researchers imply that superior performance in sports, masculinity and aggression has been accounted to relate with low 2D:4D. During the past South East Asian (SEA) Games 2017, the Malaysia rugby sevens national team won the gold medal in the final and this has put them as the most dominant rugby team in the region. Thus, the objective of this study was to investigate the 2D:4D status of the team and associate with their recent success and also determine whether right 2D:4D or left 2D:4D has higher prenatal testosterone. The team participations in international tournament achievement records were taken from year 2015 to 2017. The result demonstrated that all subjects (N=12) possessed low 2D:4D (0.93 ± 0.023mm), and this was in alignment with past studies stating low 2D:4D was associated with elite athletes and frequent sporting success in various sports. However, there was no significant difference discovered between right 2D:4D and left 2D:4D, proving that either right 2D:4D nor left 2D:4D of the subjects was more susceptible to prenatal testosterone. It is highly suggested that given with proper periodization and along with other related factors, low 2D:4D athletes can have the potential to perform much better and higher chances of having sporting success.

Keywords: Digit ratio, 2D:4D, Testosterone, Rugby, Sporting success

Introduction

For the past decade, researchers are directing their focus on the human biomarker such as the 2D:4D because of its distinctive capability to offer early forecast or predict the individual’s ability in many aspects. It is evident in many recent studies as lower 2D:4D among men has been reported to correlate with positive impact on their ability to perform not just in football and rugby, but it is also associated with high level of attainment across a number of sports such as sumo and basketball and rowing.

In 2D:4D field of discussion, it is proven by many researchers that athletes with low 2D:4D achieved more success and perform better than high 2D:4D athletes. Regardless of that, not many studies were conducted on finding association of 2D:4D influencing higher chances of achieving sporting success especially in rugby. Moreover, there were also a number of contrasting findings that disagree on the suggestion of 2D:4D to be use as sports talent screening tool as they reported there were weak correlation on 2D:4D on sporting success and performance.

Role of sex hormones in sports

Looking into the possible connection of testosterone towards performance in sports, the role of testosterone in human body must be understand first. Testosterone is known as a male-like hormone, contrast to the oestrogen hormone, which is correlates to femininity.

DOI Number: 10.5958/0976-5506.2019.00923.9
Understanding to that, the likelihood of an individual to be more masculine or feminine, it depends on these secretion of testosterone, oestrogen or both received during the foetal period\textsuperscript{10-12}.

Relating to sports performance, studies by \textsuperscript{13–16} implied that efficient cardiovascular system, good visual spatial ability and higher muscle cell tissues are affected by testosterone and prominently found in low 2D:4D subjects. Those findings approved that low 2D:4D does have an important contribution in achieving sporting success and performances resulting to some degree from the activity of pre-birth sex hormones\textsuperscript{17} towards the development of better physique and physiologically. In addition to the nature of the rugby sevens, high-risk/contact-sport players tend to have higher level of testosterone than low-risk/noncontact-sport players\textsuperscript{1,18}.

Focusing on the elite and non-elite athletes, low 2D:4D also has been negatively correlate in various findings. For example, a study in English football league\textsuperscript{1} reported that most first team players had lower 2D:4D compared to the reserve and youth team players. This suggests that 2D:4D can influence the sports or skill ability of athletes thus it is highly possible to use 2D:4D as an indicator separating them from the non-winner or non-elite athlete. Moreover, testosterone is also responsible for regulating human personality trait as it accounts for masculinity and aggressiveness level shown by an individual\textsuperscript{19,20}. High amount of testosterone received is suggested to play big influence in moulding an individual’s characteristic to be more aggressive and masculine than high 2D:4D individuals.

**Objective**

The main purpose of this research was to explore the 2D:4D status and profile of the Malaysia rugby sevens national team players, and which we hypothetically presumed that those national rugby players possessed lower 2D:4D that can be associate with their rugby achievements. Apart from that, this study also intends to analyse the differences between the right hand 2D:4D and left hand 2D:4D in order to find out which hand has lower 2D:4D (higher testosterone content), as some studies suggested that lower 2D:4D was more prominent in the right hand of the male human\textsuperscript{21}.

**Method**

**Participants**

For the past few years, Malaysia rugby sevens national team has been recognized as one of the top teams among the south east Asian countries. Further recognition came after the much-anticipated South East Asian Games (SEA Games) 2017, the team had been crowned as the rugby sevens men champion after beating Singapore in the final cup with score 22-7 thus winning the ultimate gold medal. This success further separates the Malaysia rugby sevens national team on a higher standard apart from their SEA counterparts.

The participants’ selection method used was the purposive sampling, as they were from the Malaysia rugby sevens national team, which made up of 12 players (N=12). According to the head coach of the team, the selection criteria were very tough and structured; therefore, all of the selected players were counted as the best rugby sevens players in the nation. This distinguish them as the nation’s elite rugby players and in accord with reports from\textsuperscript{2,6,7}, stated that elite players possessed superior physique, overall fitness, higher testosterone content and moreover perform better from the non-elite and non-winner players. The time period for including their achievements were set for two years, from year 2015 to year 2017, taking account into consideration that those selected players have been a mainstay in the team for at least 2 years.

**2D:4D Measurement**

In this study, both hands were included for 2D:4D measurement as neither both hands out predict each other\textsuperscript{21}, as both right 2D:4D and left 2D:4D have the capacity to predict athletic ability. Indirect measurement is implemented by using the scanner machine (Canon CanoScan LiDE 120 with 2400x4800dpi high resolution), as it can eliminate the possibilities of high human error\textsuperscript{22}. To start scanning, hands were put firmly on the scanner in a soft manner with palm facing down the scanner.

After the scanning completed, the hand images were opened in an image viewer software program called as MicroDicom Viewer (version 2.7.9). Both fingers length was measured from the fingertip to the base of finger wrinkle proximal. The result from both fingers were calculated for mean (2D:4D). With a view to guarantee the validity and reliability of the data, the measurement
for each finger was done twice by the same researcher. Measurements ranging above 1.00mm were counted as high 2D:4D and measurements ranging below 1.00mm were counted as low 2D:4D.

**Findings**

Referring to Table 1, the average age of the players was 23±1.54 years old. Meanwhile, for right 2D:4D it was identified lower than left 2D:4D with mean score was 0.92±0.027mm, and mean score for left 2D:4D were 0.93±0.026mm. For overall 2D:4D mean of both hands were recorded as 0.93±0.023mm. This showed that all players possessed low 2D:4D.

Referring to Table 2 below, it described the overall tournaments record achievements for the Malaysia rugby sevens national team over the past two years from year 2015 to 2017. The highest achievement in Asia Rugby Sevens Series 2016 was in Sri Lanka which the team achieved fifth place out of eight competing Asia teams. After the series, the team competed in pre-SEA Sevens and finished in the semi-final for SEA Sevens 2016 and runner up for the SEA Sevens 2017. In the next edition of SEA Games 2017, the team won the gold medal in the final and this suggesting that there was a relationship of sporting success with low 2D:4D.

As for Figure 1 below, the figure was meant to show the overall 2D:4D status of the participants. The highest 2D:4D were found in Player 1 with score 0.97mm in his left 2D:4D. Meanwhile, the lowest 2D:4D were found in Player 7 with score 0.87mm in his right 2D:4D. Overall result from Figure 1 suggested all participants had low 2D:4D in both hands.

![Figure1: 2D:4D Status of Right (R) and Left (L) 2D:4D](image)

**Discussion**

Deriving from the results, it can be established that all of the participants had low 2D:4D from the mean score of 0.93±0.023mm, which this study can suggest that they had high testosterone level. As for the nature of the rugby game that is characterised with aggression, frequent physical contact, speed, and forceful movements, low 2D:4D is strongly proven to be the contributing factor for the players to be able to perform and excel within those characteristics²²⁻²⁵.

None of the participants have high 2D:4D, and this is in alignment with most studies¹⁻²,²⁶⁻²⁷. Those previous studies agreed that elite world class athletes possessed low 2D:4D compared to non-athletes, non-elite athletes, non-winners and suggesting that athletes with much lower 2D:4D than others performed far better and achieve more sporting success. This is furthermore being proven through their recent success for winning the gold medal in SEA Games 2017. In Asia Rugby Sevens Series, their best ever national record was set by securing fifth place out of eight teams at the Asia Rugby Sevens Series 2016 at Sri Lanka, which it is considered as the most challenging competition due to the higher standard of opponents. In addition to that, none of any South East Asia countries were qualified enough to compete in the Asia Rugby Seven Series and Malaysia was the sole team qualified based on merit.
The result also found out that there was no significance difference between right 2D:4D and left 2D:4D. Therefore, the result specifically suggests that both hands 2D:4D of the participants do not determine which hand are more susceptible to prenatal testosterone. Contrasting to past studies, which suggested that the right 2D:4D was prominently found lower than left 2D:4D in male athletes and contained higher testosterone level compared to the lower 2D:4D are more significant on the left hand among female athletes. However, it should be taken into consideration that this study sample was small with only 12 players participated compared to those past studies. Increasing the participants may give different perspectives.

**Conclusion**

In conclusion, this study managed to find out most significant part of this study is it managed to associate low 2D:4D of the Malaysia rugby sevens national team players with previous findings on having greater performance and sporting success. For this reason, this study suggests that low 2D:4D has enormous potential to be as explore as an indicator to associate with high performances and success in sports, focusing in context of aggressive and competitive contact sports as testosterone surge is much higher when in aggressive mode.

On Admission Levels of High Sensitive C-Reactive Protein as A Biomarker in Acute Myocardial Infarction: A Case-Control Study

Hayder Abdul-Amir Maki Al-hindi, Mazin Jaafar Mousa, Thekra Abid Jaber Al-kashwan, Ahmed Sudan, Saja Ahmed Abdul-Razzaq

1University of Babylon/Iraq

Abstract

Atherosclerosis is multi-factorial process, which involves the accumulation of lipid, macrophages and intimal plaques in smooth muscle cell of both large and medium sized arteries. Considerable scientific studies have publicized that inflammation plays a major role in the initiation, progression and destabilization of atheroma. C-reactive protein (CRP) is a non-specific acute phase protein produced by liver in response to injury, infection and inflammation (1). C-reactive protein is an inflammatory marker can be considered as global risk assessment for coronary heart disease (2). The objective of study is to determine the CRP level as risk marker in acute myocardial infarction patients.

This was a hospital based cross-sectional study included 68 acute myocardial infarction (AMI) patients aged 30-89 years besides age and sex matched 50 healthy subjects as control group. Blood samples were obtained from both groups and the levels of high sensitive CRP (hs-CRP) have been measured. The current study is an attempt at better understanding the role of hs-CRP in AMI patients.

The mean ± SD of serum hs-CRP levels of patients and control subjects were 8.2 ± 7.1 and 0.6 ± 0.4 mg/dl consequently. It was founded that 64% of patients have higher values of CRP and only 4% have high values of CRP in controls with P-value < 0.05, which was found to be significant. Dyslipidemia, a conventional risk factor of AMI is also associated in this study.

The study showed that high sensitive-C-reactive protein has higher association with acute myocardial infarction.

Keywords: High Sensitive C; Case-Control Study; Reactive Protein; Biomarker.

Introduction

Atherosclerosis involves the accumulation of lipid, macrophages and intimal plaques in smooth muscle cell in both medium and large sized arteries. Recent evidences suggests that that inflammation plays a chief role in the initiation, evolution and destabilization of atheroma (1) and hence the levels of inflammatory biomarkers offer a method of evaluating cardiovascular risk. C-reactive protein (CRP) is a non-specific acute phase protein produced by hepatocytes in response to inflammation and can be considered as universal biomarker for ischemic heart disease (IHD) risk evaluation (2, 3). National guidelines issued by American Heart Association, basically given to measure the CRP in the prevention of IHD (4). The stability of this protein during long-term frozen blood storage and availability of standardized assays have assisted studies of CRP (5). Hepatic synthesis of CRP de novo starts very rapidly after a single stimulus, serum concentrations rising above 5 mg/l by about 6 hours and peaking around 48 hours (6). As a rebuttal to this point, it might be convincingly argued that the value of CRP in AMI is predictive and independent of troponin and the burden of atherosclerosis (7). The current study is an attempt at better understanding the role of hs-CRP in AMI patients and to see whether it can be used as a risk...
marker for AMI.

**MATERIALS AND METHOD**

**Participants:**

This work had been accomplished in Merjan Teaching Medical City, Babylon. It was a case-control study, included 68 AMI patients while the controls were sex & age matched 50 healthy volunteers.

Inclusion criteria: AMI cases age 20- 90 years and both sexes were involved.

Exclusion criteria: acute infection &/or Inflammation, malignancy, renal failure, being on aspirin or NSAIDS.

The patients been evaluated and diagnosed as AMI by physicians and cardiologists depending on history, clinical examination, ECG, echocardiographic finding and cardiac enzymes. Hospital local ethical committee approved the authorization of the current work, and an oral consent of all subjects had been appropriately obtained.

**Laboratory methods:**

Blood samples were obtained from all subjects and the levels of hs-CRP, have been measured, though triglycerides, total cholesterol, HDL, VLDL & LDL levels were reported from patients records that been accomplished in the hospital laboratory. The levels of hs-CRP were estimated by a high sensitivity immunoturbidometric assay using immunology analyzer - Roche Diagnostics Cobas c 111- (USA).

Levels of hs-CRP of subjects classified according to the American Heart Association into (10):

- Low Risk = <1 mg/L
- Moderate Risk = 1 - 3 mg/L
- High Risk = > 3 mg/L

**Statistical analyses:**

Statistical data were obtained using SPSS version 22 software and been expressed in Mean ± SD. Levels of *P*-value < 0.05 considered as significant while levels < 0.001 as highly significant.

**Results**

A closer look at the demographic data shown in table (1) indicates that the mean age (years) of all subjects was 50.5±13.5 with no significant age differences between the groups. Both hypertension, diabetes mellitus besides smoking where significantly higher in patients group. In addition, the table displays overall male predominance 93 Vis 25 female, likewise no significant variation in sex distribution between the two groups. Furthermore, no significant variation concerning body mass index among patients and controls. The data gathered in this study suggests that 88.2% of patients have higher hs-CRP levels (>3.0 mg/dl) while only 4% of the controls were having high hs-CRP values signifying the prominence and impact of inflammation in IHD (Table-2). The specificity and sensitivity of hs-CRP test were considered in order to assess its validity and it were 96% & 88% respectively. The overall accuracy of the test was 91% that render hs-CRP test simply suitable as screening tool for IHD (table-3). The data reported in table (4) reveals significant dyslipidemia in the levels of total lipid profiles among the groups being higher in AMI cases other than the levels of HDL cholesterol.

Discussion

Coronary artery diseases (CHD) represents the main cause of morbidity and/or death in the industrial world (8). Experimental and laboratory researches have revealed that inflammatory process plays a vital role in the atherosclerosis. The presence of CRP is probably point to ongoing inflammation associated with vascular events in addition to a higher possibility of a plaque becoming unstable (9,10). Elevated hs-CRP is a significant prognostic indicator for early risk stratification in patients with an acute coronary syndrome. Increased hs-CRP level, after acute myocardial infarction and during unstable angina correlated to the risk of recurrent attack (11).

This study is an attempt to address the issue of the role of hs-CRP in CHD. There seems to be no compelling reason to argue that CRP has a considerable influence in pathogenesis and progression of all stages of atherosclerosis (8, 12). In the present study, the mean plasma hs-CRP levels in AMI cases was 8.2 ± 7.1 mg/ L which was higher significantly (p < 0.001) than that of healthy group 0.6 ± 0.4 mg/L. This finding is in agreement with the overwhelming evidences corroborating such associations (8, 9, 22). The results of mean serum levels of hs-CRP in the controls are in in accordance with several other researches all over the world (13, 14, 15). In comparison to the study held by Thakur et al (2011), which also exposed association of hs-CRP with CHD significantly. However, the sample size of later study was two hundred; 150 were CHD cases and fifty were controls. Once more, the diagnosis was also accomplished depending on clinical features besides laboratory findings like exercise test, ECG findings, as well as echocardiographic results (16).

In the current study, the specificity and sensitivity of hs-CRP test (96% & 88% respectively) were considered in order to observe the accuracy and validity of test. Meanwhile the overall accuracy of the hs-CRP test was 91%. These results were nearly comparable to that generated by a current study held in Pakistan this year which included 100 CHD patients plus 50 healthy control subjects (8). The later study revealed that the hs-CRP test is 92% specific and 74% sensitive plus an overall accuracy of 80%

On logical grounds, there is no compelling reason to argue that such high sensitivity, specificity and a respectable accuracy rate render the researcher reach to a conclusion that hs-CRP test simply suitable as screening tool for IHD. Additionally, hs-CRP test are obtainable in several standardized research labs. Furthermore, there is overwhelming evidence corroborating the notion that hs-CRP levels correlated with the severity of CAD (14) meanwhile, baseline CRP concentrations are not subject to time-of-day variation, even after years of storage! (14, 17, 18). Based on these evidences, it can be considered as valuable and applicable measure for screening and diagnosing AMI.

Variations in the levels of plasma lipids often detected in IHD patients indeed contribute to the development of atherosclerosis. Our results revealed that the AMI group had higher values of total cholesterol, triglycerides, LDL and VLDL cholesterol nonetheless reduced levels of HDL cholesterol in comparison to the healthy control. Several cohort researches and trials have exposed same conclusions of the association among changes of lipid profile and an increased risk of CHD (19, 20).

Conclusion

In the current study, it could be claimed that hs-CRP represent a substantial biomarker in causation as well as strong association with ischemic heart disease. Hs-CRP biomarker can be considered as a useful measure for diagnose and screen patients with AMI.

Cholesterol and Triglyceride Indices Are Linked to the Left Ventricle Diastolic Dysfunction: An Echocardiography and Tissue Doppler Study

Suaad Muhssen Ghazi1, Ismail Ibrahim Hussain1, Aalaa Saad Adil1
1College of Medicine/Al-Mustansriyah University, Iraq

Abstract

Echocardiography and tissue Doppler are non-invasive technique that used to detect the subclinical abnormalities of the myocardial function in diabetic patients.

Determination of the lipid indices and the parameters of the left ventricle function by using conventional and tissue Doppler in asymptomatic T2D patients.

This cross-sectional study included 39 healthy subjects (Group I) and 28 patients with type 2 Diabetes (Group II). The measurements of the blood pressure, anthropometric variables and fasting lipid profile were determined. The cardiac function was determined by using conventional and tissue Doppler echocardiography.

Group II expressed significantly high values of anthropometric measurements, and diastolic blood pressure, and a low value of high density lipoprotein. Significantly high values of E/é (medial annulus), E/é (lateral annulus) and É/Á (medial annulus) were observed in Group II compared with Group I. The area of the under the curve of E/A, É/Á (lateral annulus), É/Á (medial annulus) ratios were significantly higher in Group II compared with Group I (0.640 versus 0.385; 0.610 versus 0.259; 0.668 versus 0.396, respectively) when the cholesterol index >1. The area of the under the curve of E/é (lateral annulus) ratio and left ventricular mass were significantly higher in Group II compared with Group I (0.533 versus 0.299; 0.561 versus 0.230, respectively) when the triglyceride index >1.

We conclude that the determinants of the diastolic left ventricle dysfunction which that detected by conventional and/or tissue Doppler in T2D are associated with high cholesterol and triglyceride indices which may serve as discriminator markers.

Keywords: Cholesterol index; Triglyceride index; Echocardiography; Tissue Doppler; type 2 Diabetes

Introduction

Atherosclerosis that resulted from diabetes mellitus is an important cause of cardiovascular events and usually associated with dyslipidemia.1 Echocardiography and tissue Doppler are non-invasive technique that used to detect the subclinical abnormalities of the myocardial function in diabetic patients.2 Echocardiographic phenotype in type-2 diabetes (T2D) showed different patterns that related to the associated risk factors including the gender, obesity and hypertension.3 Preclinical diastolic and systolic dysfunction that detected by conventional and tissue Doppler are observed in T2D, and more commonly found in diabetic patients with other risk factors including hypertension and obesity.4,5 Hypercholesterolemia per se caused diastolic left ventricle dysfunction that did not show improvement with using statins6 whereas the subclinical systolic dysfunction of the left ventricular was observed in hypercholesterolemia and hypertriglyceridemia that associated with T2D7,8 The importance of this study is to clarify the link between the lipids and functional...
changes of the heart in asymptomatic T2D patients. Therefore, the aim of this study is to determine the lipid indices and the parameters of the left ventricle function using conventional and tissue Doppler in asymptomatic T2D patients.

Materials and Method

This study is a cross sectional conducted in the department of physiology, college of medicine at Al-Mustansiriya University in Baghdad-Iraq between October 2016 and June 2017. The patients were recruited from the consultant clinics at the Al-Yarmouk Teaching hospital and refereed to the laboratory and radiological investigations. A consent form was obtained from each patient prior to the admission to the study. The study was conducted according to the ethical guidelines constructed by the Institutional Scientific Committee in which the treatment or using device should not be harmful to the patient and the patient is free to decline from the study or to refuse for study admission. The eligibility of the study was women aged ≥ 35 years. Healthy subjects and T2D were included, and patients were excluded if there is evidence of clinical, laboratory, and radiological findings indicated that the patients had a cardiovascular disease or any complication of diabetes. Type 2 diabetes was defined as either a reported history of this disease or the current prescription of either an oral antidiabetic drug or insulin. Demographic characteristics, blood pressure determination and anthropometric measurements including the calculated body mass index (kg/m$^2$) and waist circumference were recorded. An echocardiogram (conventional and tissue Doppler was performed to all patients. All patients were drawn a fasting venous blood sample at the time of admission into the study for determination of serum glucose and lipid profile including total cholesterol, triglyceride and high density lipoprotein-cholesterol (HDL-c) by enzymatic reaction. Non-high density lipoprotein-cholesterol (Non-HDL-c) was simply calculated by subtraction of HDL-c from the TC. The ratio of TC to the 200 and, the ratio of TG to 160 represented the total cholesterol index (TCI) and triglyceride index (TGI). Lipid index was calculated by subtraction of TGI from TCI and, the positive result indicates excess of cholesterol whereas the negative result indicates excess of TG. The ratio of log TG to HDL-c ≥ 0.5 indicates that patients or subjects are at risk of cardiovascular events.

Statistical analysis

The results were expressed as number, percentage and whenever possible as mean ± SD. The data were analyzed by application of two-tailed, unpaired t test and the difference between percentage test (which indicated when (p) and n(1-p) must both be equal to or greater than 5) and a (p) values of ≤ 0.05 is considered as the lowest limit of significance. The area under the curve of cholesterol and triglyceride indices >1 were calculated for the echocardiography data to discriminate the diabetic patients (Group II) from Group I (healthy subjects. Excel 2007 and SPSS version 20 programs were used in the statistical analysis.

Results

Group II patients showed significant high values of diastolic blood pressure, body mass index, waist circumference and the fasting serum glucose level (Table 1). Fasting serum level of HDL-c was a significantly higher in Group II compared with Group I whereas the other lipid parameters and indices did not significantly differ between Group I and II (Table 2). The mean value of the left ventricle mass index was a significantly higher in Group II patients than corresponding value of the Group I whereas the other echocardiographic parameters of Group II patients did not significantly differ from corresponding values of Group I (Table 3). Group II patients had a significant lower E/A ratio and a significant higher values of E/é (medial annulus), E/é (lateral annulus) and É/Á (medial annulus) compared with corresponding values of Group I (Table 3). Cholesterol index of >1.0 discriminates a significantly area under the curve of E/A ratio, É/Á (lateral annulus), and É/Á (medial annulus) whereas the triglyceride index of >1.0 discriminates a significantly area under the curve of the left ventricle mass index and E/é (lateral annulus) (Table 4).

**Discussion**

The results of this study showed that diabetic women who were free from clinical evidence of cardiovascular disease had a paradoxical changes of the conventional and tissue Doppler echocardiography when compared with age and gender healthy subjects. Group II patients had a significant evidence of the cardio-metabolic risk factors. This observation is in agreement with other studies that T2D patients have significant increase of the body mass index, waist circumference and high blood pressure. The level of serum high density lipoprotein-cholesterol is reduced significantly in Group II patients compared with Group I subjects. It is well known that T2D patients have hypertriglyceridemia, and low serum level of high density lipoprotein-cholesterol. The level of serum HDL-c in Group II patients is in the range of the lower limit of acceptable range, and this explains that the patients were presented without
clinical evidence of the cardiovascular disease.\textsuperscript{[13]} The data of conventional echocardiography did not discriminate significant difference between Group I and II. This observation does not agree the results of Pareek's study\textsuperscript{[14]} which demonstrated a significant high left ventricle mass index in a large sample size of the participants including both genders. The possibility of the gender-based effect could explain the variability in our study. Moreover, abnormalities of the left ventricle is a manifestation of impaired glucose tolerance even in absence of diabetes.\textsuperscript{[15]} A significant low mean E/A ratio was observed among Group II patients compared to the Group I subjects which indicated that there is evidence of diastolic dysfunction which related to the impairment of ventricular relaxation in the presence of normal ejection fraction percentage.\textsuperscript{[16]} This observation is documented by a significant increase of E/é (medial annulus) ratio which is an estimation of the left ventricle filling.\textsuperscript{[16]} These changes in E/é ratio is attributed to multifactors including the level of glucose, the blood pressure level and the medicines that used.\textsuperscript{[17]} The É/Á ratio that determined by tissue Doppler is significantly decreased as with E/A ratio that determined by conventional echocardiography. Jørgensen et al demonstrated that the serum levels of cholesterol and triglyceride serves as biomarkers of left ventricle function.\textsuperscript{[18]} In this study, the cholesterol and triglyceride indices were applied to discriminate the data of echocardiography that indicated the impact of these lipid on the left ventricle function. Cholesterol index > 1 discriminates the diabetic patients from healthy subjects by the evidence of a high value of the area under the curve of E/A, É/Á (lateral annulus) and, E/é (medial annulus) whereas the triglyceride index > 1 impacts the left ventricle mass index, E/é (lateral annulus) and, E/é (medial annulus). Therefore, levels of cholesterol and triglyceride more than cutoff value of upper normal limit should be consider in the interpretation of echocardiography data that indicated the diastolic dysfunction of left ventricle. Arhlade et al reported that dyslipidemia is an important risk factor of inducing a significant left ventricle dysfunction but the authors did not clarify the effect of each abnormal lipid on the left ventricle dysfunction.\textsuperscript{[19]} Small sample size is one of the study limitations. We conclude that the determinants of the diastolic left ventricle dysfunction which that detected by conventional and/or tissue Doppler in T2D are associated with high cholesterol and triglyceride indices which may serve as discriminator markers.

Microbial Contamination Indoor Environment of Hospitals and Health Centers in Al-Diwaniyah Governorate, Iraq

Saba Abdulameer Kadhem1, Hussein R.Mahmood1, Alaa Mohammad Hasson Al-Husseini1

1College of sciences, university of AL-Qadisiyah, Iraq

Abstract

The current scientific study was carried out to detect the air microbial contamination inside the hospital buildings and health centers in AL-Diwaniyah governorate, where included five hospitals (public and private) are Al-Diwaniyah Teaching Hospital, Al-Diwaniyah Teaching Hospital private, Women & Children Hospital, Shifa Hospital and Al Furat Hospital and five health centers were selected randomly (Center of Blood Diseases, Al - Tali’ah Health Center , Specialized Dental Center , Al Furat Health Center and Algeria Health Center). Many fungal and bacterial species that are considered to be hazardous to public health were isolated and identified. (11) pathogenic fungal species such as Aspergillus fumigatus, Aspergillus sp A.ochraceus, Alternaria alternata, Fusarium solani, Foxyssporum, Mucore sp., Rhizopus stolanifer., Penicillum sp., Penicillum, Cladosporium sp and Candida albicans, whereas bacteria included Staphylococcus aureus, Streptococcus. E.coli did not appear all study areas of AL-Diwaniyah governorate. These results give a clear indication of the level of contamination that could lead to a pandemic.

Keyword: Microbial air pollution, Air fungi, Air bacteria, indoor environment.

Introduction

Air is an important constituent of the atmosphere and is susceptible to contamination with many substances, fumes, fungi, bacteria, pollen and micro-organisms. The air is rarely devoid of fungal spores (1), where several thousand species of fungal and bacterial affect humans, animals and plants were diagnosed in the air (2). The presence of high rates of micro-organisms in the internal environment of hospitals is a worrying and growing factor, and is related to many acute diseases, infections and allergies caused by such microorganisms (3). Internal air quality is very important in controlling microbial contamination in hospitals. Problems associated with indoor air quality in the hospital environment are the most common environmental health issues. Hospitalized symptoms differ from one hospital to another, depending on the nature of hospitals and their health systems (4). The most scientific studies on fungal diseases and bacteria indicate that inhalation of fungus or bacteria can cause allergies, infections and poisoning diseases depending on the type of fungus and the duration of exposure. The fungal spores are considered to be one of the most important pathological factors that can be transmitted through the external and internal air to the hospital environment as well as through the visitors, patients and air conditioners (5). Although the most closed hospitals in terms of ventilation outlets have air conditioning systems based on internal air circulation, they are highly likely to have diseases associated with these buildings. Airborne microbes are a major cause of respiratory infection in humans (6). Fungi are an eukaryotic organism that differs in its nutrition, composition, and behavior from all other living organisms. It is characterized by the difference in nutrition and also has the ability to produce various toxins. Microorganisms, such as fungi, can enter the buildings through outside air, heating, ventilation, air conditioning, doors and windows, as well as with building materials and contaminants (7). Air fungi in buildings have become increasingly important as it has harmful effects on health. According to information obtained from samples of fungi, exposure to fungi causes irritation, sensitivity and toxic effects that can cause many human health problems. Air can assist in

DOI Number: 10.5958/0976-5506.2019.00926.4
medical assessment, determine of treatment methods, and assessment of health risks. It also helps to stimulate follow-up of internal air quality measurement to avoid damage.

**Materials and Method**

**Collection of sample**

The research was carried out during November and December (2017-2018) in hospitals and health centers of AL-Diwaniyah governorate with two repeats of the culture media used to isolate fungus and bacteria.

**Preparation of the cultural media used in the study**

Potato Dextrose Agar (PDA) and Sabrouad Dextrose Agar (SDA) were used to isolate fungi, whereas Eosin-Methylene Blue Agar (EMB) medium and Mannitol Salt Agar medium were used to isolate bacteria. The culture media were prepared based on the information on container.

**Isolation of fungi and bacteria**

The dishes containing (PDA-SDA) media with chloramphenicol(250mg/l) were used to isolate fungi, while EMB agar- and Mannitol Salt Agar were used to isolate bacteria by exposure petri dishes to air in hospitals and health centers for 5 minutes at a height of 1.5 m then incubated at 25°C or 7 days for fungi and 37°C for two days for the bacteria and then fungi were identified based on the outer appearance of the colony, such as color and shape of the colony and also depending on the micro-characteristics according to the approved taxonomic bases. Bacteria were diagnosed using diagnostic culture media.

**Results and Discussion**

About (11) fungal species, yeast *Candida albicans* and two species of bacteria were isolated from air inside the buildings of hospitals and health centers of AL-Diwaniyah governorate.

Five hospitals (public and private) and five health centers were selected randomly. Which could give a clear indication of the level of contamination that could lead to a pandemic. Various of fungal species such as *Aspergillus fumigatus, Aspergillus sp. A.ochraceus, Alternaria alternata, Fusarium solani, F. oxysporum, Mucore sp., Rhizopus stolonifer, Penicillium sp, Cladosporium sp* and *Candida albicans* were isolated and identified. While bacteria included two species *Staphylococcus aureus* and *Streptococcus*. The results revealed that the dominance of fungal species on bacteria in spread and air contamination in all study areas. Fungi are considered to be obligate or facultative saprophytic, their nutritional requirements are simple and produce large numbers of reproductive units, most of which cause health and environmental problems. *Staphalococcus* was recorded in all the hospitals and centers under study except the Euphrates Health Center and the Algiers Health Center. The highest incidence was in the blood transfusion center for thalassemia, whereas *Streptococcus* was recorded in all study areas, where the highest appearance was recorded in the hospital AL-Diwaniyah private and no records for *E.coli* (Table 1).

The results illustrated that the following species *Alternaria alternata, Fusarium solani, Penicillium sp* and *Cladosporium herbarum* were isolated from AL-Diwaniyah Teaching Hospital, while *Aspergillus fumigatus, A.ochraceus, Alternaria alternata, Fusarium solani, Mucore sp* and *Penicillium sp* from the Specialized Dental Care Center. AS for the Blood Transfusion Center for Thalassemia Genetic Diseases, *Penicillium sp, Alternaria alternata, Fusarium solani, F. oxysporum* and yeast *Candida albicans* were isolated. In the same way *Penicillium sp, Mucor sp, Alternaria alternata*, and *Fusarium solani* isolated from Al - Tali’ah Health Center. The results revealed isolating the following species *Mucor sp, Alternaria alternata* and *Fusarium solani* from women’s hospital and children in comparison with The Euphrates Health Center, where *Alternaria alternata, Fusarium solania* and *Aspergillus sp* were isolated. *Alternaria alternata, Fusarium solani*, *F.xoxysporium, Cladosporium sp, Penicillium sp* and *Aspergillus ochraceus* from Algeria Health Center. The results from the air inside the building of Shifa Hospital referred to the Isolation of species (*Alternaria alternata, Cladosporium sp*). The following species *Alternaria alternata, Fusarium solani, F.xoxysporium and Cladosporium sp* were recorded in the Euphrates Hospital. A large proportion of hospital infections acquired as a result of contamination and microbial transmission occur through the hands of health-care workers as a major source of microbial contamination (Figure 1).
**Staphylococcus aureus** and **Streptococcus sp** are considered to be opportunistic pathogens. It is rare to infect healthy humans, but they have high virulence when they infect patients with weak defensive mechanisms causing Bacteremia, eye infections, burns, skin infections, ear infections, bone injuries, wounds, joint, central nervous system infections and heart attack inflammation and their resistance to antibiotics. (8) reported that most isolates of **Staphylococcus aureus** have various resistance methods to various antibiotics such as penicillin, oxacillin, tetracyclines, erythromycin, and clindamycin in a study in the Teaching Hospital of Maternity and Pediatrics in Al-Diwaniyah city. The local invasion by pathogenesis is related to the relationship between patient and microbial contamination and it is one of the important causes of the injuries acquired from hospitals because of their presence in the indoor environment of hospitals, especially when the presence of moisture and spread (9). As well as all isolated fungi are related to allergic diseases such as respiratory allergies due to the inhalation of volatile fungal spores in the air (10, 2). The fungal species Cladosporium spp, Aspergillus spp, Pencillum spp and Alternaria sp are One of the most common allergens in Iraq, Iran, Kuwait, Turkey and Saudi Arabia. (11,12,13). The fungal species Alternaria alternate, Fusarium solani, Penicillium notatum and Candida albicans were isolated by (14) in a study aimed at isolating and diagnosing fungi from the indoor environment of the halls and student clubs of AL- Qadisiyah University. The air of slaughterhouses in AL. Diwaniyah city are contaminated with some microorganisms and included the isolation of several species of bacteria including Staphylococcus aureus and other fungal species such as Aspergillus niger, Aspergillus faveus, Mucor sp and Penicillum notatum (15).

Expression of Cyp2c8 Enzyme in Non-Small Cell Lung Cancer with 6A-Hydroxy Paclitaxel Drug by Flow Cytometric Technique

Firas A. Hassan
Department of Chemistry, College of Science, Al-Nahrain University, Baghdad, Iraq

Abstract

Flow cytometry is a way of quantitative elementary cell dissection, a laser or resistance, using in cell sorting, cell counting and biomarker revelation. Cytochrome P450 “CYP” enzymes metabolize carcinogens to inefficient derivatives, however, sometimes the behavior of “CYP” enzymes leads to development of more effective carcinogens. CYP enzymes are also implicated in the activation or inactivation of operators, which are used in the therapy of lung cancer. Paclitaxel drug a high sublime performance in non-small cell lung tumor (H1299) by measured half maximal restrained concentration IC\textsubscript{50} value was 94.48 µg/ml by compared with normal cells IC\textsubscript{50} value was 213.6 µg/ml. Flow cytometric analysis of paclitaxel drug cause cumulation of H1299 cells at G1 phase at 5,10, and 15 µg/ml concentrations. 6α-hydroxy paclitaxel exhibit cell cycle detention across H1299 and maximum concentration at 10 that high influenced on G1 phase accumulation in H1299 cell cycle.

Keywords: Paclitaxel, flow cytometric technique, statistical analyses, cytochrome P450 (CYP2C8).

Introduction

Paclitaxel is a toxic operator that is exceedingly utilized for therapy diverse tumor kinds, like (ovarian, breast and lung tumor). Paclitaxel therapy is often correlating with toxicities like (myelosuppression and neurotoxicity) that display remarkable inter topic variability\cite{[1]}. Intensity of paclitaxel/prompt neurotoxicity is dose-vassal and may be related to its regulation mechanisms \cite{[2]}. Paclitaxel is metabolized by (CYP2C8) to compose 6 α-hydroxy paclitaxel at the (C\textsubscript{6} position) of the “taxane ring” and byCYP3A4 to compose 3-hydroxy paclitaxel at the “phenyl” (C\textsubscript{4} position on) the C\textsubscript{13} side series \cite{[3]}. The cytochrome P450 “CYP” family is a great group of constitutive and inducible haem-including enzymes that stimulate the “mono-oxygenation reaction” utilizing molecular oxygen and equivalent electrons from “NADH via NADH-dependent P450” reductase. CYPs function a central role in the oxidative metabolism of a various extent of xenobiotics \cite{[4]}. Many cytochrome substrates are carcinogenic, whereas other substrates are anticancer drug, subsequently have different potentially remarkable functions in tumor biology \cite{[5]}. Although the liver is the main organ that expresses extreme “CYPs” metabolizing exogenous chemicals, modern development in quantitative and qualitative revelation methods of mRNA and proteins has authorized us to invent that many organs and tissues as well as diverse types of tumor also express distinct CYPs \cite{[6]}.

Materials and Method

In vitro cytotoxic activity of 6 α-hydroxy paclitaxel treatment:

Cytotoxic of non-small cell lung cancer was individual by “MTT” technique, was based on the electric capacity living cells to low the yellow dissolve (tetraezolium corn), to a purple blue unsolvable “formazan” deposit. Residues of viability cell were acquired from 5 independent exam for lung tumor. Cancer cells were plated (1x104cells/well) in 96/ well plates, these were brooded at 37°C, 10%CO2 for 24hours. Next incubation period, agar was extracted and two-folded serial dilution the 6 α-hydroxy paclitaxel
(400, 200, 100, 50, 25, 12.5 µg/ml) were added to the plate. Five times were used for each concentration as well as the normal cells. Agar were accurately extracted and 120µl for DMSO solubility settling was added per each well for 10 minutes, measurement absorb by an “ELISA” reader at a wavelength 570nm.

Human CYP2C8 ELISA kit [7]:

This kit employ Enzyme-linked Immune Sorbent Assay (ELISA) respect on biotin paired antibody sandwich technique to inspection human cytochrome P450 (CYP2C8). CYP2C8 was added to wells that were pre-coated together cytochrome monoclonal antibody and subsequently incubated. After incubation, (anti CYP2C8) an antibody labeled with biotin was added to unite with streptavidin-HRP, whose forms the immune complex. Unrestrained enzymes were isolated next incubation and was irrigation, then substrate A(trypsin buffer) (6mlx1) were added.

Flow cytometric assay procedure [8]:

The cells were clarified by utilizing (density-gradient) centrifugation following the industry directive for use of the separation medium. Cell severance was placed into a labeled (17x100mm/tube). Centrifuge for 5 minute at 300g at room temperature 25C. The supernatant was aspirated, departure approximately 50µl of remaining fluid in the tube to parry disturbing the pellet. One hundred ml of buffer solution was added and disconnect the cells by softly overtaxing at low speed. The concentration was regulated to (1x106 cells/ml) with buffer solution. All the supernatant was flow carefully, then was added 250 µl of solution A (trypsin buffer) and incubated for 10 minute at 25C. Two hundred ml of solution B(trypsin inhibitor and RNase buffer) was added to each tube, then incubated for ten minute at 25C and added 200 µl of cold 8C solution C (PI stain solution). Cell cycle division of nuclear DNA was measurement by flow cytometry (BD Biosciences). The percentage of cells in G1, S, and G2 phases were resolved by Divan software (BD Biosciences).

Statistical analyses:

Two-way “ANOVA” (Duncan) was performed to test whether group variance was considerable (p ≤0.01) or not. It was analyses of differences ” ANOVA” test to compared the parameters group with concentration by post hoc test. Data were expressed as a mean SD deviation and drowned using Graph Pad (Prism version6).

Results and Discussion

Cell viability Measurement:

The cytotoxic influence of the paclitaxel was evaluated towards lung tumor (H1299) by using “MTT” method. The viability rates of H1299-cells treated with 6α-hydroxy paclitaxel were shown in table 1. The results indicated that 24 hrs. after the division of different concentrations of paclitaxel to H1299-cells, viability values were (47.57, 61.23, 80.48, 87.04, 96.95, 97.57%) by compared with normal cells (75.89, 84.22, 92.75, 96.03, 96.88, 93.90%), respectively. The 6α-hydroxy paclitaxel significantly efficiency versus (H1299) of IC50 value (94.48 µg/ml ) than the normal cell with IC50 value (213.6 µg/ml), as shown below in figure 1.

Figure 1: Effect of 6 α-hydroxy paclitaxel on non-small cell lung tumor (H1299), represent of IC50 for lung tumor cell line and normal cell, respectively.
Level of serum cytochrome P450 (CYP2C8):

The result of (CYP2C8) enzyme grade in serum sample of non-small lung cancer was found a significant increment in the mean level of (CYP2C8) that observed in then 6 α-hydroxy paclitaxel at 44.53 ± 7.26(U/L) by compared to the healthy control at 15.24±5.34(U/L), P<0.001. This enzyme (CYP2C8) was selected because it is accountable for the metabolism of more than 50% of the ready pharmaceutical \[^9\]. Inhibitory influence of a offered drug versus demarcation P450 (CYP2C8) enzyme is often described based on certain probe reactions. Data acquired utilizing this path are precious for the characterization of drug interaction prospect and the design of sufficient clinical realizing, also important to inform whether a kinase inhibitor will intervene with the metabolic salvage of the combining operator like paclitaxel drug \[^10\]. The variation of (CYP2C8) action may be initiative alteration in metabolite ratio, and so on simulating the performance and integrity results of paclitaxel based collection therapies, as paclitaxel-induced neurotoxicity has been related to (CYP2C8) efficiency. CYP enzyme in human lung cancer have been studied obviously less than “CYPs” in pulmonary tissue of animals, fundamentally to obstacles in gaining adequate amounts of human tissue \[^11\].

Paclitaxel effect on cell cycle phase distribution of (H1299) cells:

Cell cycle phase distribution of (H1299) cells experiment was conducted in order to assess whether the inhibition of H1299 cell viability by 6 α-hydroxy paclitaxel was a cell cycle arrest related or not. Flow cytometric technique was used to detect the DNA contents after cell staining with (propidium iodide). The distribution of cell cycle was analyzed after treating the cells with paclitaxel at concentrations (5, 10, and 15 µg/ml). Results data in table 1, figure 2, appeared that at G1 phase, the percentage of cells was significantly increased by increasing the concentration of paclitaxel in a (dose-dependent) manner, starting from slight change at 5 µg/ml (48.2±0.561 µg/ml ) to maximum increase at 10 µg/ml (54.79±0.627 µg/ml) as compared with control. The increase in G1 phase was accompanied with no significant differences in S phase at 5 µg/ml and 10 µg/ml, except at 15µg/ml, an apparent decreased G2/M population was observed in a concentration dependent manner after 24 hrs. in comparison to the control. Induction of cell cycle arrest and apoptosis considered as the most important targets for developing anti-tumor drug, as shown below in figure 3.

![Figure 2: The effect of 6α-hydroxy paclitaxel at. (A) Control. (B) 5 µg/ml. (C) 10 µg/ml, and (D) 15 µg/ml, on H1299 cell cycle phase flow cytometry histogram showing in different cell cycle phase S, G1, and G2/M, using different concentrations of 6α-hydroxy paclitaxel.](image-url)
Conclusions

Paclitaxel drug appeared cell cycle arrest towards non-small lung cancer (H1299) by using flow cytometric technique. It’s showed dose-dependent manner, the maximum concentration at 10 µg/ml that more effected G1 phase accumulation in non-small lung cancer, and showed a significant at (P < 0.01) by compared with S and G2 phases about different concentration that used in flow cytometric assay.

The Role of Prophylactic “Window” Hydrocelectomy in Prevention of Postvaricocelectomy Hydroceles

Ehab Jasim Mohammad¹, Waleed Nassar Jaffal², Duraid Taha Abdulkareem²
¹College of Medicine, Ibn Sina University of Medical and Pharmaceutical Sciences, Baghdad, Iraq, ²Medical College, AL-Anbar University, Iraq

Abstract

One of the common complications of varicocele surgical treatment is the post-operative hydrocele (PH). A ‘window’ in tunica vaginalis we describe here as a PH prevention procedure modification.

From January 2010 to January 2015, 300 patients, aged 17-39 year old referred to AL-RAMADI TEACHING HOSPITAL in ANBAR, IRAQ, were involved in a case controlled study. They were referred for Varicocelectomy. The patients were into 2 equal groups each of 150 patients. Group A; underwent Sub-inguinal repair without modification, and group B; underwent Subinguinal repair with Window hydrocelectomy. Patients in both groups were evaluated for 12 months.

The age of patients ranged from 17 to 37 years in group A (mean 28±4.3), 18-39 years in group B (mean 27±5.1), there was no significant difference between the two groups. None of the patients in the Subinguinal repair with Window hydrocelectomy group developed post-operative hydroceles, while 24 (16%) of patients in the Subinguinal repair without modification group developed post-operative hydroceles, (P= 0.005) which is statistically highly significant. Non-significant difference was reported with other parameters between group A and B.

Patient follow up, recurrent varicocele was seen in 5 patients in group A and 3 in group B which is statistically non-significant. The seminal fluid parameters improved in 94 patients in group A and in 96 patients in group B with statistically non-significant difference. Wound infection occurred in 3 patients in group A and 4 patients in group B with no significant difference (p value > 0.05).

Window hydrocelectomy is safe and effective in preventing postvaricocelectomy hydrocele formation.

Keywords: varicocele, varicelectomy, hydrocele, complications, outcome

Introduction

Varicocele has been described as a common surgically correctable cause of male subfertility. This is a disease that develops during puberty when both endocrine and exocrine function of the testicle dramatically increases, along with testicular blood flow. Varicocele is rarely detected in boys less than 10 years of age(1)

A varicocele is reported in 15% of males and in about 35% - 40% of men presenting with abnormal semen parameters(2)

Varicocele is rare prior to puberty; presenting in about 10% of adolescents. Bilateral or unilateral (left side affected in 90%) (3)

Varicocele treatment surgery still common for treating male subfertility despite some limitations(4)

Whether treating a varicocele is effective in increasing pregnancy rates in sub fertile couples is controversial, but the current consensus (including a Cochrane review) is that it is not(5,6) although this remains
a highly controversial question(7)

Varicocele are also treated because they may be the cause of chronic scrotal discomfort or for cosmetic reasons.

In adolescents, varicocele are associated with ipsilateral reduction in testicular growth. The discrepancy in testicular size recovers in most boys after treatment of the varicocele(8)

Hydroceles are serous fluid collections in the space between the visceral and parietal layers of the tunica vaginalis. Hydrocele is the most common complication of varicocelectomy, with rates≤20% following the retroperitoneal approach(9)

‘Window’ formation in tunica vaginalis was conducted to allow fluid drainage to scrotum superficial layers and to subinguinal lymphatic nodes(10)

The use of microsurgical lymphatic-sparing techniques has virtually eliminated this complication(9)

Materials and Method

From January 2010 to January 2015, 300 patients, aged 17-39 year old referred to AL-RAMADI TEACHING HOSPITAL in ANBAR, IRAQ, were involved in a case controlled study. They were referred for Varicocelectomy. The study design was approved by the local ethics committee.

The patients were divided according to the simple random sampling method into 2 equal groups each 150 patient. Group A; underwent Subinguinal repair without modification, and group B; underwent Subinguinal repair with window hydrocelectomy. Patients in both groups were evaluated for 12 months.

All patients with pampiniform plexus veins dilation were ultrasound assessed. Surgery indications based on one year or more of infertility with palpable varicocele, pain, stress pattern of semen and testicular atrophy(11,12)

Patients with subclinical varicocele without pain or infertility, bilateral varicocele, recurrent varicocele, patient with previous Subinguinal or scrotal surgery, hydrocele, bleeding tendency, and infection were excluded.

In all cases Subinguinal repair was performed through a small incision just below the external inguinal ring. All veins are ligated. Lymphatic branches are spared to reduce post-operative hydrocele formation(9)

In group A patients, no modification in prevention of postvaricocelectomy hydroceles formation was followed, but in group B patients, a “window” was cut in the tunica vaginalis. Window operations may adequately treat smaller hydroceles. During this procedure a window of tissue from the tunica vaginalis is excised and the edges are oversewn(9)

In order to evaluate surgical results, all patients were followed up for 12 months.

ANOVA test was used to analyze the statistical differences between group means and McNemar’s test for comparison of. Statistical analysis was performed using (SPSS version 24) software. P value of less than 0.05 was considered statistically significant.

Results

The age of patients ranged from 17 to 37 years in group A (mean 28±4.3), 18-39 years in group B (mean 27±5.1), there was no significant difference between them. There was no significant difference in the indications of surgery and the grades of surgery between the two groups (Table 1).

Discussion

Postvaricocelectomy hydroceles formation is common, with an average incidence of about 7% (4,13).

Hydrocele was diagnosed based on scrotum asymmetry. According to the literature, 4-5mm of fluid around the testis anteriorly and laterally, suggests a hydrocele (14,15).

Different modifications have been tried by many authors in order to decrease the incidence of this complication: Atteya et al used lymphatic vessels hydrodissection (16), methylene blue dye used by Alessio et al for identification and preservation of lymphatic vessels during surgery (17). Lymphatic vessels were spared draining the testis in boys operated by standard Palomo method (18), and microsurgical procedure using the operating microscope was used by (19,20), all of the above modifications resulted in significant decrease in hydrocele formation. Also the laparoscopy magnification may have the benefit (21).

Microsurgical varicocelectomy offers the best outcome (20), but the operating microscope is not available to many urologists so we and other authors tried another modification to decrease the incidence of hydrocele formation (22). Combining Jaboulay’s operation with varicocelectomy was suggested for all patients with varicocele to avoid the occurrence of hydrocele and the need for a second surgery (23).

In present study, none of the patients in the Subinguinal repair with Window hydrocelectomy group developed post-operative hydroceles, while 24 (16%) of patients in the Subinguinal repair without modification group developed post-operative hydroceles, ($P= 0.015$) which is statistically highly significant. So our modification is safe and effective in preventing hydrocele formation, and have no adverse effect on seminal fluid parameters improvement after surgery with comparable results to previous studies.

Long period follow up and out-patient control are necessary for higher detection of post-varicocelectomy hydroceles.

The current modification of varicocelectomy allows delivery of the testis with ligation of the gubernacular and external spermatic veins which may lower the incidence of varicocele recurrence, we noted less number of patients with recurrence although it was statistically non-significant.
Conclusions

Window hydrocelectomy is effective in preventing postvaricocelectomy hydrocele formation and it is safe procedure as it does not affect the outcome of surgery regarding improvement in seminal fluid parameters and does not affect the incidence of other complications.

Analysis of Serum IL-6 and CRP Levels among Autoimmune and Non-Autoimmune Hypothyroid Patients

Sahar H. A. Al-Hindawi
Department of Basic Science, College of Dentistry, University of Baghdad, Baghdad, Iraq

Abstract
Hashimoto Thyroiditis (HT) is the most common autoimmune thyroid disease and the commonest cause of hypothyroidism. C-reactive protein (CRP) is synthesized in hepatocyte in response to autoimmune disorders; strongly induced by IL-6. This study aimed to estimate serum IL-6 and CRP levels in autoimmune and non-autoimmune hypothyroidism. The present study included 60 Iraqi female hypothyroid patients divided to 30 autoimmune and 30 non-autoimmune, with age ranged between 24-50 years and 30 healthy controls with age ranged between 27-52 years. Serum samples were collected from study groups. The levels of thyroid hormones (TSH, T4 and T3) were determined by using automated Chemiluminescence Immunoassay (CLIA) analysis system. Detection the levels of thyroid peroxidase antibody (TPO-Ab), thyroglobulin antibody (Tg-Ab) and Interluekin-6 by enzyme linked immunosorbent assay (ELISA) kits. While latex agglutination slide test used for determination the presence of serum CRP. The current results revealed that serum TSH, TPO-Ab, Tg-Ab, IL-6 levels and CRP positive ratio are increased significantly (P<0.01) in autoimmune hypothyroid group as compared with non-autoimmune hypothyroid group and control group. But there are no significant differences (p˃0.05) between non-autoimmune hypothyroid patient and control in the level of TSH, T4, T3, TPO-Ab, Tg-Ab, IL-6. Only the positive ratio of CRP is elevated significantly than ratio in control. This study showed significant increase (P<0.01) in IL-6 level and CRP positive ratio in autoimmune hypothyroidism, that indicates to the effect of autoimmune thyroid disease on inflammatory markers IL-6 and CRP in the serum; and increase CRP positive ratio in non-autoimmune hypothyroidism suggested the alteration in the levels of inflammatory marker has been independent from etiology of thyroid disease.

Keyword: autoimmune hypothyroidism, non-autoimmune hypothyroidism, IL-6, CRP

Introduction
Hashimoto’s thyroiditis (HT) is one of autoimmune disorders, caused by environmental and genetic factors that may lead to produce antibodies from immune system that attacked thyroid gland (1), due to loss of tolerance to auto-antigens thyroid peroxidase (TPO) and thyroglobulin (Tg). HT is the most common autoimmune thyroid disease and the commonest cause of hypothyroidism (1,2). Hypothyroidism is caused by inadequate supply of or response to, thyroid hormones throughout the body (3).

C-reactive protein- (CRP) is a protein synthesized in the liver and the major protein of plasma (4). The magnitude of inflammation is directly related to the concentration of CRP which is not affected by other serum components; nevertheless, CRP production is under the control of IL-1, IL-6, and TNF-α (5). It is likely to be responsible for the expansion and increase of permeability of the blood vessels of the thyroid gland, which can lead to pathological changes in the structure and function of the thyroid gland (6). CRP, like other acute-phase proteins, is synthesized in hepatocyte in response to microbial infection, tissue injury, and autoimmune disorders; induced by IL-1 and IL-6 (7,8). Interleukin-6 is a pivotal cytokine with diverse physiological functions that include regulation of immune cell proliferation and differentiation (9). The anti-inflammatory action of IL-6 promotes physiological cell function by binding to the
IL-6 also controls homeostatic function such as hypothalamic-pituitary-adrenal axis [12]. Generally, cytokines directly down-regulate several components of the thyroid hormones synthesis pathway at the thyrocyte [13]. This study aimed to estimate IL-6 and CRP levels in autoimmune and non-autoimmune hypothyroidism.

**Materials and Method**

Sixty Iraqi female hypothyroid patients were rounded up from The National Center for Endocrine Disease and Diabetes; their ages ranged between (24-50) years. Patients were divided to two groups, 30 autoimmune hypothyroid and 30 non-autoimmune hypothyroid patients. Beside 30 volunteers female subjects as control, their ages and gender were matched with patients ranged between (27-52) years.

Approximately (4ml) of human blood was collected intravenously from patient and control groups. Certain exception criteria were followed to exclude unsuitable subjects. All patients and control had no complained of other chronic or systemic diseases. Diagnosis of hypothyroidism was based on clinical features and serum thyroid hormones levels (TSH, T4 and T3) by using automated Chemiluminescence Immunoassay (CLIA) analysis system produced by Shenzhen New Industries Biomedical Engineering Co., Ltd (SNIBE). Thyroid antibodies (TPO-Abs and Tg-Abs) were measured by commercially available ELISA kits from (MyBiosorcem, USA). Also, detection of IL-6 serum level was measured by using ELISA kit from (MyBiosorcem, USA). Latex Agglutination Slide Test for Qualitative and Semiquantitative used for determination of C-reactive protein in non-diluted serum by using commercially available kit, The HUMATEX CRP kit from (Human comp., Germany).

Statistical Analysis System- SAS program was used to identify the effect of different factors in study parameters. The variables were described by mean ± standard error (SE) and tested for statistical significance by t-test.

**Results and Discussion**

The results of this study in table-1 showed that serum levels of thyroid stimulating hormone (TSH) are increased significantly (p<0.01) in autoimmune and non-autoimmune groups (10.69± 0.56 and 10.05± 0.47 μIU/ml) respectively, as compared to serum level of control group (5.99 ± 0.25 μIU/ml). On the other hand, mean level of serum thyroxin (T4) and triiodothyronine (T3) in autoimmune patients group (3.48 ± 0.29 and 0.560 ± 0.03 ng/ml) and in non-autoimmune group (3.49± 0.20 and 0.567± 0.02) respectively, are decreased significantly (P<0.01) as compared to T4 and T3 levels in control group (6.12± 0.37 and 0.813± 0.04 ng/ml). There are no significant differences (p>0.05) between hormones (TSH, T4 and T3) levels in autoimmune group (10.69± 0.56, 3.48 ± 0.29 and 0.560 ± 0.03) and non-autoimmune group (10.05 ± 0.47, 3.49 ± 0.20 and 0.567 ± 0.02) consistently (Table 1).

These results confirmed the diagnosis of hypothyroidism which is characterized by elevated TSH and decline T4 and T3 hormone levels as compared with control.

Thyroid antibodies were measured to confirm the presence of autoimmune thyroiditis, as presented in table-2. The serum concentrations in autoimmune group of TPO-Ab and Tg-Ab are (259.61± 19.60 and 333.66 ±57.94 IU/ml) are increased significantly (p<0.01) than concentrations of TPO-Ab and Tg-Ab in non-autoimmune group (38.81± 3.25 and 14.49± 2.92); and in control group (37.72 ± 8.26 and 43.39 ± 8.61) respectively. There are no significant differences (p>0.05) between levels of antibodies in autoimmune and non-autoimmune groups (Table 2).

These results are coincidence with results of Krishan and Randhir (14) and Senthilkumaran et al. (15) explained that hypothyroidism established by decrease in T4 and T3 concentrations, this lead to hyper-secretion of pituitary TSH because of the negative feedback relationship between the different hormones. Furthermore, McCanlies et al. (16) defined HT with hypothyroidism by the presence of high titers of TPO-Ab or Tg-Ab and elevated levels of TSH in the absence of medication. As well, results of Xie et al. revealed that patients with HT have a great deal of clinical status; in general, it is an inconvertible process of evolving from euthyroidism to hypothyroidism and the positive TPO-Ab increases the probability of developing hypothyroidism (17).

These results in figure-1 are point toward the differences of serum CRP in study groups; there are significant increase (P<0.01) in positive ratio of autoimmune hypothyroid patient group (53.3%) than positive ratio of non-autoimmune group (43.3%). Similarly, the positive ratios of autoimmune and non-autoimmune groups (53.3% and 43.3%) respectively, increase significantly (P<0.001) than control group ratio (16.7%). While negative ratios in control group (83.3%) is increase significantly (P<0.01) than ratios in autoimmune and non-autoimmune (46.7% and 56.7%), sequentially. However, the negative percentages are elevated significantly (P<0.05) than positive percentages in non-autoimmune patient group (56.7% and 43.3%), respectively. In autoimmune patient group, the positive ratios are increase non-significantly (P>0.05) than negative ratio (Figure 1).
These results were agree with studies that detected elevated CRP in individuals with hypothyroidism; Tuzcu et al. (18) and Savas et al. (19) recorded that CRP was significantly elevated in hypothyroid patients and there was clear association between hypothyroidism and raised serum CRP. Likewise, Czarnywojtek and colleagues (20) reported that serum CRP concentration was increased in hypothyroidism. While, Pearce et al. reported in their study that serum CRP levels were similar in all types of thyroid disorder, where all types had positive CRP levels and the level in HT patients did not differ significantly from controls (21).

Conversely, Aksoy et al. (22) demonstrated for lacking difference in CRP levels in women with hypothyroidism compared to the control. As well, Sahin et al. did not detect any significant difference in high sensitivity-CRP (hs-CRP) levels among hypothyroid and subclinical hypothyroid with control groups (23).

Increasing in CRP among hypothyroidism might be due to the result of an interaction of IL-6 on TNF-α and IL-1. Additionally the lack of thyroid hormones causes a slower metabolic rate and hence results in with impaired biochemical processes. As a consequence CRP clearance rate may result with elevated serum CRP levels (20). Significant changes in serum inflammatory marker levels in patients with non-autoimmune thyroid dysfunctions strongly suggested that mild systemic inflammation exists in all types of thyroid diseases (24).

The results of table-3 explained for significant increase (p<0.01) in the serum level of IL-6 in autoimmune patients (32.17 ± 4.02 pg/ml) as compared with IL-6 levels in non-autoimmune patients and control groups (16.88 ± 3.79 and 20.42 ± 2.38 pg/ml) correspondingly. While, there are no significant differences (p>0.05) between levels of IL-6 in non-autoimmune patients group and control group.

</tbody>
</table>

* (P<0.05), a: is differ significantly than b in the same column
The result of IL-6 is consistent with result of El-Shenawy et al. (25) indicated for significant increase in the level of IL-6 in Hashimoto patients as compared with control. As well, Marchiori et al. (26) showed that cytokine level is elevated in patients with autoimmune hypothyroid disease and decreased gradually after treatment. While Kammoun-Krichen et al. (27) demonstrated that serum IL-6 decreased significantly in hypothyroid group and increased significantly in hyperthyroidism than control group. Conversely, other previous studies reported by Mikos et al. (28) indicated that there was no significant difference in IL-6 level in hypothyroid patients than control.

Moreover, Rugerri et al. (29) agreed with our results as they stated that different cytokines released by immune cells caused thyroid cell damage and are involved in inflammatory processes, suggested that IL-6 is involved in the development of the disease in the different thyroid function status. However, Taddei et al. described higher serum CRP and IL-6 levels in patients with HT when compared to controls. They explained that the chronic activation of the immune system due to HT can lead to impaired endothelium dependent vasodilatation and IL-6 promotes atherogenesis indirectly by stimulating hepatic production of CRP (30).

In general, the changes in serum cytokine levels in thyroid diseases often provide controversial results but they remain essential for understanding the implication of cytokines in thyroid pathogenesis. In addition, serum cytokine levels may not reflect the intrathyroidal levels of some cytokines which may be low in the periphery, despite high tissue concentrations (27).

This study showed significant increase (P<0.01) in IL-6 level and CRP positive ratio in autoimmune hypothyroidism, that indicates to the effect of autoimmune thyroid disease on inflammatory markers IL-6 and CRP in the serum; and increase CRP positive ratio in non-autoimmune hypothyroidism suggested the alteration in the levels of inflammatory marker has been independent from etiology of thyroid disease.

Assessment of Overweight and Obesity with Life Style among Secondary School Students in Al-Ramadi City

Ban Nadhum AL- Any

Department of community medicine, College of Medicine, University of Anbar, Iraq

Abstract

Overweight and obesity is a major health problem during adolescence which is related to lifestyle and behavioural factors. Assessment of overweight and obesity with life style among secondary school students in Al-Ramadi city.

A cross sectional study was conducted among 200 secondary school students in AL-Ramadi City during the period from March to April 2018.

For body Mass Index (BMI) > 25, the percentage was 40% for male and 20% for female students that mostly between age 17-18 years. More than half of male students had fatty, starchy food while 30% of female students had this type of food (with statically significance). According to habits 50%, 30% of male and female students had soft drinking/day respectively while for power drinking, 33% of male students and only 5% of females students had it daily (with statically significance). 70% of both sexes had tea with sugar for more than 3 times/day. For smoking 42% of male students were smokers while 3% of female students were smokers for less than 10 cigarette/day. 5% of males had euphoria drugs and 2% had alcohol for different times/week. 70% of students had family history of obesity (with statically significance). There was an association between overweight, obesity and diet according to sex (statically significance).

- Total 50% of obese student had normal hormonal assay, others didn’t do it.
- There was no history of medications, and all of them didn’t do any exercise.

There was high percentage of obesity and overweight mostly among male students who had unhealthy food pattern and habits, with lack of any exercise.

Keywords: Body mass index. Sex, Dietary pattern, habits.

Introduction

Obesity is an increasing of weight with fat accumulation while over weight is an increasing of weight for not more than 20% of normal body weight, according to height, physical activity, age and sex which may has a negative effect on health (1) People are considered overweight when the range of body mass index is between (25–30) kg/m² while considered obese when body mass index is more than 30 kg/m². (2) Obesity increases the risk of certain diseases as cardiovascular diseases, type 2 diabetes, disturb of sleep, cancer, depression and joint pain. (3,4) Obesity is mostly caused by combination of excessive food intake, lack of exercise, genetic and family susceptibility(5), physiological and endocrine disorders and some types of medications(6). The obese people with little eat can gain weight because of slow metabolism(7) and have a greater energy expenditure than the normal counterparts, that more energy is required to maintain the increasing of body mass(7,8) Obesity can be prevented by changing of dietary pattern, exercising, social changes, and personal choices(9). Quality of diet can be improved by reducing consumption of energy-dense foods, as food rich in fat and sugars, and increasing intake of food rich in fibre (3).

In Africa and Asia the prevalence of overweight among

adolescents is below 10% while in the Americas and Europe is above 20%.\(^9\) wild word 39% of adolescents were overweight and 13% were obese in 2016\(^{10}\).

**Objectives:** Assessment of overweight and obesity with life style among secondary school students in Al-Ramadi city

**Materials and Method**

A cross-sectional study was conducted among 200 secondary school students for both sexes in AL-Ramadi City during the period from March to April 2018. The questionnaire included several questions as the following: Gender, family history of obesity, history of hormonal disturbance and medications, dietary pattern and habits related to obesity, life style as smoking, exercise, alcohol, drug abuse.

- A tape measure and a weighing scale were used to estimate the height and weight and calculated the BMI for each student according to the formula:

  \[
  BMI = \frac{Weight}{Height^2} (Kg/m^2).
  \]

  BMI ranges as the following: underweight < 18.5 kg/m\(^2\), normal weight:18.5-25, overweight:25-30, obese >30\(^{11}\). WHO cut-off point for overweight is 25 kg/m\(^2\)\(^{12}\).

**Statistical analysis**

The collected data was analyzed by using SPSS ver.16, Chi square test used, P value less than 0.05 was considered as the level of significance.

**Results**

Table (1) showed that 2% of students were 14 years old. For age group between 15-17 years, 55% of males and 32% of females were at this age respectively while for age group between 18-20 years, 43% of males and 65% of females were at this age respectively.

Discussion

The study revealed that 40%, 20% of male and female students had BMI >25, mostly between age of 17-18 years which was agree with a study mentioned that the prevalence of overweight and obesity is increasing among boys (13), a study in America said that the prevalence of BMI >25 among 2nd school students is 31% (14). Consumption of sugar soft drinks may cause childhood obesity, that in a study among children over 12 years the obesity increased 1.6 times for every additional soft drink consumed per day. (15) Eating fast food is very common among young people with 75% of students consuming fast food in a given week (16,17), carbohydrate overfeeding produced 75–85% excess energy being stored as body fat and fat overfeeding produced 90–95% storage of excess energy as body fat (18). When people eat outside the home, they consume more total calories and fat per eating occasion than they do at home. 70% of obese students had family history of obesity that Adolescents and their families eat more fast food than in the past. All students were failed to do exercises that because of spending whole time on using computer, playing games or watching television. 21.5% of children are likely to be overweight when watching four hours and more of television/day, 4.5% of children are likely to be overweight when using a computer one hour or more /day(19).

Conclusion

There was a high percentage of obesity and overweight mostly among male students who had consumption of diet rich with fat, carbohydrate, imbalance habits with lack of exercise.

A Comparison Study among Several Tumor Markers in Serum Samples of Patients with Colon Cancers

Rasha Hasan Jasim
Department of Chemistry, Faculty of Education for Girls, University of Kufa, Iraq

Abstract

During six years ago, 109 patients with malignant colon cancers at metastasis stages (II to IV stages), 112 patients “as a pathological control group”, and 85 healthy individuals were enrolled in the present work. CLEC4E, CEA, CA 19-9, and Serotonin levels were measured in the sera of study individuals using sandwich ELISA technique. Current study demonstrated significant increase in the levels of CLEC4E, CEA, and CA 19-9 in the malignant colorectal cancers comparison to pathological controls as well as healthy individuals. Serotonin levels were seemed to be lower at cancerous patients comparison to healthy controls. CLEC4E may be used as a definitive diagnostic marker for cancers than other nonmalignant diseases, moreover CLEC4E and serotonin can be considered as new diagnostic tools for colon cancer and are highly effective follow-up tools and can be diagnostic and follow-up tools when measured with other resident parameters. Measured parameters (CLEC4E, CEA, CA19-9, and Serotonin) can be effective screening tools when diagnosing tumor infections in the colon.

Keywords: CLEC4E, CEA, CA 19-9, Serotonin, Colorectal.

Introduction

Statistically, Iraq tops the Arab countries and East Asian countries in terms of the number of people with cancer, with 135 cases per 100,000 people. Colorectal cancer is one of the most serious cancers, with the most common cancers and the second leading cause of death due to cancer in the world. Annually, the number of new colon cancer infections is estimated at 1.4 million worldwide and the number of deaths is 694 thousand every year. According to the American Cancer Society, colon cancer is the third leading cause of cancer-related death in the United States, accounting for about 10 percent of all cancer deaths, while it is the fourth leading cause of death in the Middle East, with more than 15,000 infections annually. According to the latest statistics provided by the Iraqi Ministry of Health and Environment for the year 2017, colorectal cancer is among the ten most common cancers in Iraq, while this type of cancer is the fifth most common cancers in the province of Najaf with a number of 356 proven cases.

Colorectal cancer, also called colon cancer, rectal cancer or bowel cancer almost always occurs in the large bowel - cancer of the small bowel is rare. Symptoms of colorectal cancer include blood in your stools, a change in normal bowel habits, a lump that your doctor can feel in your back passage, weight loss, pain in the abdomen or back passage, and anemia.

There are many factors that directly affect the risk of colorectal cancer, alcohol is considered the main cause of these factors, followed by smoking and bad eating habits, which include eating foods that contain high saturated fat, especially fast food. Recent study indicates that laziness and long sitting position increases the risk of developing this type of cancer. Genetics is one of the most influential factors in raising the risk of colorectal cancer, medical data indicates that one out of every 20 colon cancer cases is due to genetic causes, indicating that the disease can be prevented by early detection.

Occurrence and mortality rates have been declining for several decades because of historical changes in risk factors (eg, decreased smoking and red
meat consumption and increased use of aspirin), the introduction and dissemination of screening tests, and improvements in treatment. Treatment of colon cancer depends on where the cancer is in the bowel and how far it has metastases but may include surgery, chemotherapy and radiotherapy\textsuperscript{(11-13)}.

The current work was designed to assess the ability of four chemical parameters to detect colorectal cancer and to compare non-cancerous colon diseases with the levels of these standards in healthy individuals on the one hand, as well as the effectiveness of surgical and non-surgical treatments (chemotherapy or radiation) Follow-up of recorded response throughout the treatment period and beyond.

Both CEA\textsuperscript{(14-17)} and CA19-9\textsuperscript{(18-31)} were studied and evaluated in different cancer diseases, including colon cancer, which were selected in the current work to evaluate their efficiency as a difference between cancerous tumors from non-cancerous as well as study the possibility of using them as tools in follow-up\textsuperscript{(32-35)}.

Serotonin levels have been monitored in many pathological and unsatisfactory cases and have been shown to change levels in many of the cancer cases, including the injuries of a number of parts of the nervous system, but it was not evaluated independently in patients with cancerous colorectal or even non-cancerous\textsuperscript{(36-40)}.

**Materials and Method**

**Patients and Healthy Controls:** During six years ago, 109 patients (47.694 ± 21.325, with the age range 27-75 years) with malignant colon cancers at metastasis stages (II to IV stages), 112 patients (39.528 ± 18.502, with the age range 25-65 years) “as a pathological control group” included 27 patients with benign colorectal tumors and 85 patients with non-tumoral colorectal illness; i.e. irritable bowel syndrome, colon ulcers, and colon infection, and 85 healthy individuals (33.261 ± 19.592, with the age range 22-67 years) were enrolled in the present work. Full data were summarized in Figure 1.

**Figure 1: Distribution of Study Groups According to the Gender**

MCTPs: Malignant Colon Tumor Patients, PCs: Pathological Controls, and HCs: Healthy Controls

The enrolled patients (malignant colorectal cancers individuals and pathological controls) were collected from several public and private hospitals in addition to centers in Al-Najaf Al-Ashraf governorate; involved: Liver and GIT Center in Al-Sadder Medical City, Al-Ameer Privet Hospital, Al-Ghadeer Hospital, Middle Euphrates Cancer Center, and Daily Specialized Najaf Clinic.

Initial diagnosis of colorectal cancer (before chemotherapy) was performed by specialist physicians and through a range of clinical and laboratory tests. The full information about the current study patients was provided through oral interviews with patients and in cooperation with the supervising physicians. According to the questionnaire in the current work
questionnaire prepared in advance based on the opinion of the specialists, including the age, gender, location and history of the patient as well as the number of individuals with colon cancer or any other type of cancers in the family.

Selection of healthy individuals as a control group based on several criteria included: an absence of major medical or surgical illness in the previous 5 years, no hospital admissions, no current GIT medication, and a subjective perception of good health as determined by health questionnaire. More than, control group might at approximate age range with the patients group, with similar food style.

**Serum Samples Collection:** Five milliliters of venous blood samples were collected from the patients and healthy individuals, after fasting period more than eight hours. Samples were allowed to clot at lab temperature, centrifuged at 5000xg for 5 minutes. Sera were collected and stored at -18°C until used.

**Methods:** Sandwich-ELISA technique was applied to estimate levels of the evaluated parameters prepared by Elabscience Company, China.

**Results and Discussion**

The current study included 306 patients in three groups including the first 109 individuals with colorectal cancer according to the diagnosis of the specialist doctors whose serological samples were taken when they were diagnosed with the disease and during the stages of receiving chemotherapy. The second group included 112 patients with non-cancerous colon diseases whose serological samples were approved as a satisfactory control group. The last group included the healthy individuals who were elected to participate in the current study as a control group based on a set of strict criteria set out in the questionnaire prepared by specialists.

Before treatment, **Table 1** demonstrated significant increase in the levels of CLEC4E, CEA, and CA 19-9 in the malignant colorectal cancers comparison to pathological controls as well as healthy individuals, while no significant variation were observed when the pathological and healthy controls were compared together.

MCTPs: Malignant Colon Tumor Patients, PCs: Pathological Controls, and HCs: Healthy Controls

In fact, the current study failed to detect significant variations between the two genders in the group of patients with cancer or non-cancerous colorectal diseases, as well as, when comparing males with females in the control group when measuring the levels of four parameters, but the study created a set of individual observations when comparing gender, included:

1. The highest levels of CLEC4E (0.721 pg/ml) as well as CEA (4.527 ng/ml) were recorded at cancerous male patients at 73 years old in the end stage of colon cancer, while the lowest level of CLEC4E (0.110 pg/ml) was recorded in the case of healthy male at 25 years old, while the lowest levels of CEA was recorded in a 28-year-old woman with Irritable Bowel Syndrome.

2. The highest levels of CA 19-9 (188.552 U/ml) was observed in the sample of cancerous patients at stage IV at 56 years old, on the other hand, the lowest levels of this parameter (24.614 U/ml) was showed at 31 years old healthy female.

3. Serotonin among the studied tumor markers showed close values in the lowest levels of the two sexes in the group with colon cancer, while the highest levels of this hormone were recorded in healthy women group and the highest levels were observed in samples of women between the ages of thirty and forty, more over; the current study illustrated that the lowest levels of this hormone (and nearly to their levels in the colon cancer cases) were found in male patients with Irritable Bowel Syndrome.

4. The study reported an increase in BMI of 38 Kg / m² for more than 60% of women with colon cancer, whereas BMI was only 52% of those with colon cancer. In the pathological control group, 80% of patients with non-cancerous colon disease were seemed to be extremely obese, while exiguity was observed in patients with bleeding ulcers only.

5. Regardless of age and stage of infection, it was observed that male patients were more committed than women to the doctor’s instructions and more in compliance with the orders for treatment, whether surgical or pharmacological.

In order to assess the efficacy of the four tumor markers in detecting colon cancer, the percentage sensitivity of each marker was calculated individually. To increase the efficiency of the initial diagnosis of colorectal cancer which leads to more effective treatment of this type of cancer, the percentage of sensitivity of the markers assessed together, Table 2.

Figure 2 shows a significant reduction in the levels of CLEC4E, CEA, and CA 19-9 after receiving the first dose of chemotherapy followed by a gradual decrease in levels of these markers with progression of doses received, while serotonin levels were elevated sequently with the doses of chemotherapy.

Figure 2: Alteration in The Levels of The Four Evaluated Parameters at Diagnosis and Through The Different Treatment Stages with Chemotherapy

Results of the present study showed statistically significant decrease in the levels of CLEC4E, CEA, and CA 19-9 in the sera of colon cancer patients after treatment compared to their levels at primary diagnosis, while the results indicated a significant increase in levels of serotonin in the samples of patients with cancerous disease after treatment by chemotherapy compared to their corresponding levels at diagnosis, as shown in Table 4.

Abstract

In utero molar, an abnormal fertilized egg is implanted in the womb (uterus). Cells that become placenta grow very rapidly and control the space in which the fetus usually develops. These cells are called trophoblasts. Knowledge of nurses towards hydatidiform mole evaluates and determines the relationship between knowledge of nurses towards hydatidiform mole and demographic characteristics.

Descriptive study was conducted in the Women’s Hospital and Obstetrics teaching hospital in the holy city of Kerbala from 15/02/2016 to 15/10/2016 to achieve objectives of the study were selected sample is the possibility (object-) consisted of (70) nurses working in the Women’s Hospital and Obstetrics teaching hospitals. The study tool consists of two parts, the first part demographic information, the second part assess nurses’ knowledge and includes three sections; Section I: Knowledge nurses toward hydatidiform mole, Section II: Knowledge about the causes of hydatidiform mole, Section III: knowledge about preventive measures.

Results of the study showed that (45) nurses, was down (64.3%) were in the age group (24-30 years), and (45) nurses, by (64.3%) junior nursing graduates, and 38 nurses, by (54.3%) were married, (1-3) was the years of experience (20) nurses, was down (28.5%), and (41) nurses, by (58.5%) did not participate in the training sessions. The results showed that there was anon significant difference in the level of (P <0.05) and that most of the nurses have an average knowledge of the direction of hydatidiform mole, there is no significant correlation between the knowledge of nurses and level of education, age and marital status with the exception of years of experience.

The study recommends the following: activating the role of training and development to improve knowledge and attitudes of nurses, health awareness trend pregnancy, The distribution of brochures, pamphlets for nurses, guidance on obstetrics and midwifery.

Keywords: Hydatidiform Mole, nurse’s knowledge, Hospitals

Introduction

Hydatidiform Mole (HM) is a spectrum of abnormal gestations arising from villous trophoblastic associated with pregnancy (¹). HM has two histological types, including partial hydatidiform mole (PHM) and complete hydatidiform mole (CHM) (²). HM is among gestational trophoblastic disease (GTD) and others include choriocarcinoma and placenta site trophoblastic tumors that arise from villous trophoblast and interstitial trophoblast respectively (¹). In a “complete mole,” no normal fetal tissue forms. In a “partial mole,” incomplete fetal tissues develop alongside molar tissue. These two
conditions are noncancerous (benign) and make up 80 percent of cases. Three malignant forms of gestational trophoblastic disease occur, including invasive molar pregnancy, choriocarcinoma and placental site trophoblastic tumors (3). Most molar pregnancies are noncancerous and confined to the uterus (hydatidiform moles). In this type of mole, the abnormal placental tissue has villi, clusters of tissue swollen with fluid, giving it the appearance of a cluster of grapes. If a fetus begins to develop along with a hydatidiform mole, it typically has many malformations and almost never can be delivered as a living baby (4). A more aggressive tumor associated with molar pregnancies is an invasive mole, also called chorioadenomadestruens. The invasive mole contains many villi, but these may grow into or through the muscle layer of the uterus wall. Rarely, invasive moles can cause bleeding by perforating the uterus through its whole thickness. In 15% of cases, an invasive mole can spread to tissues outside of the uterus (5). Choriocarcinomas can cause persistent bleeding in the weeks or months after delivery, but this happens very rarely. (Most bleeding like this is not caused by a choriocarcinoma). Choriocarcinomas associated with molar pregnancies almost always follow complete moles rather than partial moles (4,5). Some women will have no noticeable symptoms of molar pregnancy, or may recognize them only after they have been diagnosed. This is because most of the symptoms are due to very high levels of the pregnancy hormone hCG (human chorionic gonadotrophin), so they can be very like the usual symptoms of pregnancy or miscarriage (6). HM has several etiological risk factors and the most established are extreme of maternal age and prior molar pregnancy (7-9). For instance, the risk of complete mole increases threefold for women older than forty years and is much higher in patient with previous history of molar pregnancy (10, 11). The experience of hydatidiform mole can be very distressing. Not only have you experienced a miscarriage but also they need to be in continued medical follow-up to have your hCG levels checked (10). The importance of this study come from that nurses need to know about causes, sign and symptoms, complications, reducing, treatment , and to assess and give care for those women.

Materials and Method

Descriptive study was conducted on hydatidiform mole pregnancy data collected started from 15/02/2016 to 15/10/2016 to in order to assessment for nurses’ knowledge toward HM pregnancy. The study was carried out in the women’s hospital and obstetrics in the holy city of Kerbala. Non- probability (purposive) sample of (50) nurses working in Women’s Hospital and Obstetrics teaching hospital the samples have been selected based on the following criteria: Select the nurses have been working in all the hospitals in delivery rooms and have been asking questions about Hydatidiform Mole pregnancy information. The questionnaire was designed and constructed by the investigators to measure the variable underlying the study. A questionnaire was consisted of two parts:-

Part 1: It includes 3 items about demographical information such as (nurse’s age, educational level, and experience years).

Part 2:- It comprised of structured items concerning nurse’s knowledge toward Hydatidiform Mole pregnancy and comprised of (14) items. These item were developed according to (3) levels Liker Scale as (I know - I do not know - Not sure) and the scale was scored as (1) I know, (2) not sure and (3) for I don’t know. Validity of the questionnaire, the content validity of the study instruments questionnaire format was determined initially through a panel of (5)from different related specialties and agencies. Data analysis: The data were analyses through application of the SPSS program and used both the descriptive and inferential statistical approaches.

This table shown that highly significant association with their experience years, and the other items have non-significant.

Discussion

This study focused on the nurses’ knowledge toward Hydatidiform Mole pregnancy. Through the course of the present study (table 1) and (table 2), shows that the study sample age group at (31-40) have more than one third (48%), their level of education at secondary nursing graduate have (42%), and they (50%) half of the study sample have (1-5) years of experience, that’s mean when the nurses at middle age group and have more than 10 years working in the hospitals have more experience and more information about all the disease mostly maternity and children diseases.

Tables (3), (4), and (5) shows that complete Hydatidiform Mole pregnancy is the dangerous one, that deformities occurs in the placenta, fertilized egg in the partial it was have 69, and fertilized egg in the complete Hydatidiform Mole pregnancy was have 46 chromosomes chromosomes tissue have significant association with the study sample age group, while the other items have non-significant, with their level of education shows that Hydatidiform Mole pregnancy types are (complete and partial), red light vaginal bleeding at the first trimester, cyst formed grapes is exist, have a break for 6 months to one year period after Hydatidiform Mole pregnancy, it may turn to a rare type of tumor, it was deformity occurs in the placenta tissue have significant association, while the other items have non-significant, and finally with the study sample years of experience shown that Hydatidiform Mole pregnancy are deformities occurs in the placenta tissue item have significant association with their years of experience, and the other items have non-significant, that mean not all the nurses have specific information about the Hydatidiform Mole pregnancy and that’s agree with the study by Murray & McKinney (12).

Role of MicroRNA-122 in Predicting Chronic Liver Diseases among Iraqi Patients with HCV

Leena Falh Abd Al Reda1, Dawood Salman Dawood1, Akram Ajeel Najeeb2
1Collage of Health & Medical Technology, Baghdad, Iraq, 2Consultant Gastroenterologist, Iraq

Abstract

MicroRNAs is play important roles in liver pathologies, including hepatitis, liver cirrhosis, and liver cancer. miRNA-122 is a liver-specific. This study aimed to determine the expression level of miRNA-122 in the plasma as a diagnostic marker of liver injury and the ratio of HCV genotype in Iraqi patients. A total of 80 participants who divided into; Group I included 35 patients with CHC infection, Group II included 20 patients with (cirrhosis &HCC) and Group III included 25 healthy control. HCV Genotype and miRNA-122 in the plasma were measured using real-time PCR. This study showed that the mean Log fold of miRNA-122 was higher in CHC group as comparison to controls while in the (cirrhosis&HCC) groups was non-significant in compared with controls. Moreover, the most prevalence genotype 4 then 1a. In conclusion measurements of miRNA-122 may be useful in the evaluation of HCV patients.

Keywords: Chronic Hepatitis C virus, Liver cirrhosis, Hepatocellular carcinoma, Genotype and miRNA-122.

Introduction

Hepatitis C virus (HCV) is associated with one of the major health problems in world that ultimate results in the liver cirrhosis and leads to carcinoma of hepatocellular components round the world. More than 185 million people were found to be infected with HCV (1). Hepatitis C is divided into six distinct genotypes throughout the world with multiple subtypes in each genotype class. A genotype is a classification of a virus based on the genetic material in the RNA (Ribonucleic acid) strands of the virus (2). MicroRNAs (miRNAs) are a broad class of small, noncoding endogenous single RNA molecules that function in gene expression through directly binding to the 3' untranslated region (3'UTR) of the target gene mRNA, resulting in mRNA cleavage or translational repression (3). MiRNAs have been implicated in the regulation of a wide range of important biologic processes, such as cellular growth and differentiation, developmental timing, apoptosis, and modulation of host response to viral infection (4). miRNA-122 is one of the miRNAs that is highly expressed in the liver, constituting 70% of the total miRNA pool. miRNA-122 is a target for extensive study due to its association with cholesterol metabolism and Hepatocellular carcinoma (HCC), and its important role in promoting HCV replication (5).

Materials and Method

Subject

This study was carried out on 80 patients who were divided into three groups: Group I: included a total of 35 cases (21 males and 14 females) of chronic hepatitis C patients whose age range was between (15-70) years. Group II: 20 cases (12 males and 8 females) of (LC &HCC) with age range between (28-70) years. Group III: 25 apparently healthy subjects with ages (18-60) years who were negative for HCV and HBV by ELISA. Participants were enrolled from the Gastroenterology and Hepatology Teaching Hospital and Dowaly Private Hospital in Baghdad, who registered during the period from June/2017 to Feb/2018. The clinical diagnosis was based on the decision of physician and testing for anti-HCV was repeated in all recruited anti-HCV-positive patients using a third-generation immunoassay and if this assay gave a positive result, a PCR technique was performed. Patients were selected if they had no other causes of liver disease, autoimmune or metabolic

DOI Number: 10.5958/0976-5506.2019.00933.1
disorders, HCC or co-infection with hepatitis B virus and/or human immunodeficiency virus, liver steatosis, malignancies, and current alcohol abuse.

**Molecular detection of miRNA-122**

Molecular detection of miRNA-122 was carried out according to (TaqMan™ MicroRNA Assay, inventoried, SM, Applied Biosystems, USA).

Detection the genotypes of HCV:

HCV Genotype detection according to (plus Real-TM HCV Real-TM Quant Dx, Sacace).

**Statistical Analysis**

Analysis of data was carried out using the available statistical package of SPSS-25 (Statistical Packages for Social Sciences- version 25). Data were presented in simple measures of frequency, percentage, mean, standard deviation, and range (minimum-maximum values). The significance of difference of different means (quantitative data) were tested using Students-t-test for difference between two independent means or ANOVA test for difference among more than two independent means. The significance of difference of different percentages (qualitative data) were tested using Pearson Chi-square test ($\chi^2$-test) with application of Yate’s correction or Fisher Exact test whenever applicable. Statistical significance was considered whenever the P value was equal or less than 0.05.

**Results**

The demographic data of the 55 patients with chronic liver disease and 25 controls are presented in table 1. There were 21 male (60%) and 14 female patients (40 %) in the CHC group. Their mean age was (39.5) years. There were 12 male (60%) and 8 female (40 %) patients in the (LC&HCC) group. Their mean age was (52.5) years. While in control group there were 13 male (52 %) and 12 female participants (48%) and the mean age was (35.9) years. The p-values of the differences among the ages and genders of these groups were (0.061, 0.798) respectively.

HCV genotype distribution in fifty-five HCV-positive Iraqi patients as illustrated in figure -1, HCV genotype 4 was the predominant genotype with frequency 19(34.5%) followed by genotype 1 included 1a was 17(30.9%) and 1b was 12(21.8%). The lowest frequency was found in Genotype 2 was 4(7.3%) and Genotype 3 was 3(5.5%).

![Figure 1: Illustrated the frequencies of the genotype in HCV-positive Iraqi patients.](image)
In addition, the distribution of HCV genotypes & sub-genotype in studied groups according to gender as shown in table 2. The more frequently observed genotype in males was genotype 4 with proportion 92.3% (12 out 35) in chronic HCV. There was predominance of Genotype 1a in females than in males with proportion in chronic HCV was 80.0% (8 out 35), followed by Genotype 1b was [male 5(62.5%) vs female 3(37.5%)] in chronic HCV group. Genotype 2 and 3 showed the lowest percentage rate in both genders. There was significant difference in genotype according to gender in chronic HCV patient was (P value = 0.014).

Analysis of mean fold change in expression level of miRNA-122 in patients’ plasma in comparison to the healthy control group showed that miRNA-122 displayed significant fold decrease in expression in (LC&HCC) group (2.708±3.922) and significant fold increasing in expression level in chronic HCV group (19.654±23.458) while, in control group was (3.421±4.093). Table (3) showed highly statistically significant differences in the mean values of miRNA-122 in plasma between the studied groups (P value =0.0001) and also observed highly significant fold change in miRNA-122 expression was found between either (CHC vs control) groups or (CHC vs LC&HCC) groups. Moreover, Non-significant fold change in miRNA-122 expression was found between (LC & HCC vs control groups).

Discussion

The sex of population in present study was shown that the highest percentages of the studied groups were males. The p-values of the differences among the ages and genders of these groups were (0.061, 0.798) respectively. These differences were non-significant at P>0.05. The result of this study appeared an agreement with studies done in different Iraqi provinces as AL-Qadisiya and Thi-Qar that observed HCV infections in males was higher than females through epidemiological studies done before (6, 7). The results also agree with Al Zayed, who found that there was non-significant difference demonstrated for gender (8). But our findings contradict from that of Abdul Hasan who found equal sex ratio 1:1 (9). This high frequency of infection with HCV among males may be attributed to socio-community nature of Iraqi people which make men undergone the responsibility of working and eventually are in great contact with the pathogens rather than the women.

Furthermore, the difference between age groups was failed to reach the levels of statistical significance (P=0.05). However, the observation of present study agrees with previous studies that showed peak prevalence of anti HCV Abs were observed among persons more than 30 years to 49 years (10,11). Also, Similar results were reported by Ezzat et al. This is explained by the fact that this group of age has exposed to more accidents,
occupational risks, blood transfusion, surgeries, than younger groups of patients (12). Moreover, El–Garem et al. who found that there was a significant difference between the diseased groups as regards age \((P < 0.001)\) (13). In current study observed that HCV genotype 4 is the predominant genotype followed by 1a and 1b. In a study conducted in the south of Iraq, it was found that 35.0% of the samples typed as genotype 4 while 50.0% of the recruited samples typed as genotype 1(14). Genotype 4 has been linked with increased incidence of cirrhosis and poor response to interferon therapy (15,16). The results of the current study are divergent from most of other studies done, as that HCV genotype 1 was more found in females while HCV genotype 4 more observed in males. The result of this study agreement with Abdul Hasan., who found that genotype 4 was the dominant in HCV infected male while in female genotype 1a was the common one (9). In a study done by Zainab et al who found that HCV subtype 1a distributed in male 16% vs 4% in female, 1b distributed in male 6% vs 4% in female (17). In contrast, to our observation, in Libya, the prevalence of HCV genotype 1 was found to be significantly associated with males while genotype 4 was seen frequently in females (18). miRNAs are being investigated in HCV infection, with the most popular one being miRNA–122, which is the most abundant miRNA in the liver where it has many important biological roles. miRNA–122 was found to interact with HCV–RNA, thus enhancing its replication (19). Data obtained in this study showed that the mean fold changes in expression level of miR-122 significant fold increase in expression level in chronic hepatitis C group and significant fold decrease in expression in (LC&HCC). Our result was in agreement with the several studies conducted by El–Garem et al, who found that analysis of fold changes expression level of miRNA-122 displayed significant fold increase in expression level in chronic hepatitis C group and significant fold decrease in expression in cirrhotic patients in comparison to normal controls (13) and also, Waidmann et al. who reported that sera from patients with HCV contained higher levels of miRNA–122 compared with sera from healthy controls(20). Matching, our results, Bihrer et al who reported that sera from patients with CHC contained higher levels of miRNA -122 than from healthy controls (21). In addition, Trebicka et al explained the low level of MicroRNA-122 in decompensated liver cirrhosis by noting that MicroRNA 122 is present abundantly in hepatocytes with much lower levels in circulation in healthy subjects. With hepatocyte injury miRNA-122 is released in circulation more readily and serum level rise. (22). The current study revealed a significant decrease in circulating miRNA–122 expression level in patients with (LC&HCC) as compared with the control group.

This finding is in agreement with that of El–Garem et al. showed that significant fold decrease was noticed in the expression level of miRNA–122 in cirrhotic patients, in comparison with normal controls (13). Moreover, Ladeiro and Zucman–Rossi had established a significant down expression of miRNA–122 in 28 HCC liver tissues (mixed etiologies other than HCV) in comparison with four healthy liver tissues using qRT–PCR. Differences in miR–122 expression in HCV versus non–HCV HCC likely reflect virus–specific mechanisms contributing to carcinogenesis (23). Köberle and colleagues reported that it was noticed microRNA-122 expression did not differ significantly between patients with HCC and liver cirrhosis (24). Moreover, Ezzat et al. and Enas et al mentioned Patients with HCC showed non-significant higher expression level of miRNA-122 as compared to cases with cirrhosis (12,25).

Albumin Gradient and Sex Selection in Couples with Normal Seminal Fluid Parameters

Sumeya Ghanawy AL-Najjar

College of Medicine, Dhi-Qar University, Iraq

Abstract

Sex selection is an important concern for some couples. One of the relatively more simple and inexpensive methods, which does not need to use toxic chemicals to separate the Y and X sperms, is the albumin gradient method.

The aim of this study is to evaluate the results of sex selection in normozoospermic males by using the albumin gradient method.

The present study conducted on 90 couples with normozoospermic males. After the induction of ovulation and a vaginal sonography, sperm samples were prepared using the albumin gradient method, after which intrauterine insemination (IUI) was conducted. The rate of successful sex selection was then calculated.

Among 90 cases of performed IUI, 30 cases (33%) were successful, among which 3 cases (10%) suffered miscarriages and 27 cases (90%) were associated with a successful pregnancy. In general, the sex selection success rate was higher for the male gender; 19 cases with male and 8 cases with female.

Albumin gradient is an appropriate sex determination method in IUI cycles.

Keywords: Insemination, Sex selection, Albumin gradient

Introduction

Sex selection is the attempt to control the sex of the offspring to achieve a desired sex (1). In the long history of human reproduction, gender selection to seek a child of a preferred sex has persistently attracted parental interest. The desire for gender selection is a reflection of culture, tradition, religion, civilization, education and medical technologies in a given society or community, all of which may influence morality and mentality of the people living there (2).

Two major types of pre-implantation methods can be used for social gender selection. The Ericsson method, The Ericsson method separates male and female sperm by passing them through a column filled with blood protein, human serum albumin. As the sperm enter the human serum albumin, the differences in mass between the X and Y chromosomes manifest as the lighter male sperm push deeper into the protein than the females dragged down by the weight of the extra “leg” of the X sex chromosome (3) and In vitro fertilization (IVF)/preimplantation genetic diagnosis (PGD) technique (4) in which, the embryos of the desired gender are implanted back in the mother’s uterus.

In vitro sperm activation was designed to mimic an in vivo processes for separation spermatozoa from seminal plasma and selection the normal and highly motile spermatozoa (5). Semen processing methods are also designed to enhance sperm function and increase the chances of conception (6).

Swim down technique relies on the natural movement of spermatozoa to serum albumin medium.(12)

The increase in progressive motility as sperm moved down an albumin column has been observed in Y sperm, this useful in sex selection (8). Since Y bearing spermatozoa are smaller in size and have high motility

Corresponding author
Sumeya Ghanawy AL-Najjar
E-mail: dr.sumeya_inf@yahoo.com
they exhibit a greater downward swimming velocity than X chromosome bearing spermatozoa.

Nearly all the couples wanted boys, and in fact all those who became pregnant wanted boys. Hence, only male selection is considered in this paper.

**Materials and Method**

The study was carried out at infertility unit in Nassirya city and outpatient clinic. From February 2014 to July 2017.

This study involved 90 couples, both fertile and infertile couples (secondary infertility) seeking for gender selection, female factor. Female patient with bilateral tubal blockage that diagnosed by HSG (hysterosalpingography) were excluded. Males with normal seminal fluid parameters was involved. Patients that eligible for IVF were not included in this study. Regarding male, SFA was examined according to WHO 2010.

**Seminal Fluid Analysis**

The specimens were placed in an incubator at 37°C for 30 minutes to allow liquefaction. The liquefied semen is then carefully mixed for few seconds, and then the specimen was examined by macroscopic and microscopic examinations. The standard form of (WHO 2010) is used to record the results of seminal fluid analysis (Table 1).

*WHO (1999) (42)

**Ovarian hyperstimulation**

Ovarian hyperstimulation was carried out with Clomiphine citrate (CC). CC was given in a dose of 50-100 mg early from day 2 to the 6th of the menstrual cycle alone or in combination with Gonadotrophins (gonal® 75 IU) in a dose of 75-150 IU/day starting from cycle day 2.

The follow up was done by Vaginal ultra-sound to monitor number and size of the ovarian follicles and the endometrial thickness. When size of the follicles reaches 17-18 mm, supplemented by subcutaneous injection of the ovulatory hormone Ovitrelle hCG 250 µg, 6500 IU to induce ovulation (11,12) then insemination performed by (IUI) catheter after 34-36 hr (13).

**Sperm Preparation by the Ericsson Albumin Method**

The Ericsson method is based on the assumption that Y-sperm swim faster than X-sperm. Sperm are placed in a test tube atop a “column” of increasingly thicker layers of albumin, and allowed to swim down into the solution. After a certain time period has elapsed, only the fastest sperm should have been able to penetrate to the bottom layer. Here is the procedure as described by Dr. Scott Ericsson. (14)
Intrauterine insemination technique

Intrauterine insemination technique (IUI) was performed by a special intrauterine catheter (GYNÉTICS ® Gynétic Medical Products N.V., Rembert Dodoens straat 51, Lommel-Belgium) attached with 2 ml syringe. Insemination volumes ranged from 0.5-1.0 ml of activated sperm sample.

Luteal phase support started from next day after insemination for two weeks by giving the patient progesterone tablets (duphstone ® 10 mg twice daily). Estimation of Beta human chorionic gonadotropins (B-hCG) was carried out on day 14 after IUI for pregnancy confirmation. Findings were confirmed by ultrasonography at later stages. If pregnancy was confirmed, luteal phase support with progesterone was continued till 12 weeks of gestation, while progesterone was withdrawn on a negative test report. The sex of the fetus determined by ultrasound at 16th week.

Results

Ninety couples were involved in this study. From table (2) significant decline (P < 0.05) was observed in the sperm concentration between pre- and post- in vitro sperm activation using albumin gradient.

Significant increment (P < 0.05) was noticed in the sperm motility (%) between pre- and post- activation. The results of progressive sperm motility (%) showed significant increase (P < 0.05) between pre- and post-activation.

Significant increase (P < 0.05) was assessed in the normal sperm morphology (%) between pre- and post-activation. In regard to the result of sperm agglutination (%), significant decline (P < 0.05) was observed in post- in vitro sperm activation. Significant decrement (P < 0.05) was observed in round cells count (HPF) between pre- and post-activation.

* Data are mean ± S.E

Figure (1) show the rate of pregnancy following IUI of 90 women involved in this study. There were thirty out of ninety women become pregnant (33%) and the sixty women did not get pregnant (67%). The statistical analysis found a significant difference (P < 0.05) between them. Three pregnancies end with abortion.
The male babies was nineteen and the percentage of male sex selection was (70%), only eight female babies delivered which give (30%) percentage (figure 2). The statistical analysis found a significant difference ($P < 0.05$).

Discussion

The present study showed that in vitro sperm activation causes significant ($P < 0.05$) reduction in sperm concentration as compared to pre-activation. It has been shown that the swim down technology lead to marked reduction of the available sperm (15).

Also, this study explained a significant reduction ($P < 0.05$) in agglutination (%). Furthermore, post activation resulted in a significant ($P < 0.05$) reduction in the count of round cells and a significant increment ($P < 0.05$) in the percentage of normal sperm morphology, this is because the sperm preparation techniques for ART have been developed to remove the undesired sperm, round cells, debris, and thereby increase the overall sperm quality (16) (17).

The present study proved that there was significant increase ($P < 0.05$) in the percentages of progressive sperm motility. This is regarded as normal response for sperm activity after removal of seminal plasma since it contain dead sperm, leukocytes, epithelial cells, particulate debris and microbial contamination that produce many oxygen radicals that can negatively influence the sperm functions (18). In addition to that seminal plasma contain factors that inhibit induction of capacitation (19), (20), (21).

Furthermore, inclusion of protein source like albumin or human serum albumin in the medium is important for sperm viability and activity (22).

Human Serum Albumin (HSA), a sticky protein solution so that concentrate healthy, motile sperms, filter out abnormal and immotile sperms cells and debris, such as dead sperms cells and bacteria that may impede fertilization and appears to select population of sperms with normal morphology and high motility (23).

The presence of serum appears to facilitate the process of capacitation and/or the acrosome reaction of sperm, which is essential to enable them to fertilize an oocyte in vitro (24), (25). Serum in culture also appears to reduce the incidence of DNA damage in sperm and increase the rate of cleavage in human embryos (26).

Albumin is thought to function by stabilizing cell membranes and so to prevent the leakage of endogenous amino acid (27).

In addition to that, using human serum albumin for sperm preparation will enrich the medium with high amount of adenine monophosphate, which enhance sperm motility by fueling its energy and increase the number of highly active motile sperms (28).

On the other hand, when the separated spermatozoa have been examined for Y and X bearing spermatozoa, results have varied, some claiming success (29), (30), (31) and others denying it (32), (33).

Lighter sperms (Y sperm) in the albumin gradient technique produces much faster cross-human albumin layers than X sperms (HAS) and are deposited in test tubes (34). Researchers believe that the albumin gradient technique is a good method because it does...
not use chemicals to separate sperms and the fetus is not manipulated. On the other hand, many researchers including (35) (34) (36) confirmed the effectiveness of this method, especially in determining the male gender. Meanwhile, other researchers believed that this method was ineffective (35) (37).

The results presented here confirm the result done in Hong Kong for sex selection for boys (38). The results of the present was similar to the results obtained by Al-Dujaily and Al-Dahan (39). And study done in Omid Persian Gulf Infertility Center of Bushehr, Iran (40). These results obtained match the results obtained by Dr. Ericsson method for sex selection (14).

Conclusions

The albumin gradient is an appropriate, affordable sex determination method with few side effects in IUI cycles. This is due to a 33 % chance of pregnancy in infertile women and the probability of success of 70 % in sex determination.

The Effect Insulin Therapy and Metformin on Osteoporosis in Diabetic Post-Menopausal Iraqi Women

Ali B. Roomi¹, Raid M. H. AL-Salih², Saher. A. Ali²
¹College of Health and Medical Technology, University of Al-Ayen, Iraq, ²Chemistry Department, College of Science, University of Thi-Qar, Iraq

Abstract

The aim of this study is to evaluate the effects of insulin therapy and metformin on osteoporosis (OP) in diabetic post-menopausal women. In this study, 200 individuals, aged (50-73) year. Control and patients were divided to four groups, each group containing 50 patients. Group (CG) were healthy post-menopausal, group (OP) were post-menopausal with OP, group (T2D insulin) were post-menopausal with diabetic and treated insulin once daily and group (T2D-metformin) were post-menopausal with diabetic and treated metformin (500 mg) twice daily. The results revealed that fasting blood glucose (F.B.G), hemostatic model assessment-insulin resistance (HOMO-IR), and bone mineral density (BMD) demonstrated a significant different in (T2D-insulin and T2D-metformin) group comparison with (OP) group. Serum insulin demonstrated a significant increase in (T2D-insulin) group comparison with (OP) group, while a significant reduce in (T2D-metformin) group comparison with (OP) group. Whereas, the osteocalcin (OC) and carboxy-terminal telopeptides of type I collagen (CTXI) was a significant reduce in (T2D-insulin and T2D-metformin) group comparison with (OP) group. The final concluded that insulin therapy increases bone turnover biomarkers more than metformin therapy.

Keywords: Bone mineral density, Osteoporosis, Post-menopausal, Insulin therapy, Metformin

Introduction

Osteoporosis (OP) is a highly prevalent disorder affecting 50 million individuals around the world[1]. It is also a typical skeletal disorder describe by low bone mass, which leads to reduced bone strength and an enhanced risk of fractures [2]. Bone loss occurs in post-menopausal OP as a result of an increase in the rate of bone remodeling and an imbalance between the activity of osteoclasts and osteoblasts [3]. T2D and OP are common metabolic disorders that belong to the most important causes of mortality and morbidity in the elderly population. It has become apparent that subjects with T2D are at higher risk of fracture[4], some the evidence suggested that T2D patients present generally normal or increased BMD [5]. Numerous studies in the previous years have identified additional advantages of metformin therapy, such as improving bone quality among the DM population and lowering fracture risk [6]. Insulin signaling regulates both bone resorption by osteoclasts and bone formation by osteoblasts. The clinical studies suggested that a positive association between BMD and insulin in T2D [7]. In other studies, concentrations of insulin showed rise osteoblast proliferation rate, collagen synthesis, glucose uptake, ALP production, and to inhibit osteoclast activity [8]. Interestingly, the relationship between fasting plasma insulin levels and whole-body BMD differed by the degree of IR, is positively correlated with BMD in the lowest of HOMA-IR, and inversely related with BMD as IR improved [9].

Materials and Method

This study has been conducted at Centre of Diabetes and Endocrine and AL-Hussein Teaching Hospital in Thi-Qar government in Iraq. Samples were collected in January 2018- September 2018. The target population of study were 200 post-menopausal. There was treated with oral anti-hyperglycaemic medications (metformin...
therapy) and insulin therapy for 3 years. Estimation of serum insulin, OC and CTXI by ELISA. Serum F.B.G estimated by copper kit (Randox, England).

Calculate HOMO-RI

The concentration of HOMO-IR calculated as follow\[10\].

\[
\text{HOMO-IR} = \frac{\text{Glucose (mmol/L)} \times \text{Insulin (µIU/mL)}}{22.5}
\]

Estimation of BMD

All individuals examined by DEXA (Osteosys Co., Ltd., Korea).

Statistical Analysis

By Statistical Package Social Sciences version 20 software (SPSS v.20).

Results and Discussion

Body Mass Index (BIM)

Table (1) showed a significant reduce for BMI in (OP) group comparison to (CG) group. There was non-significant increase in (T2D-insulin) group comparison with (OP) group. While non-significant decrease in (T2D-metformin) group comparison with (OP) group. So, BMI demonstrated non-significant reduce in (T2D-insulin) group comparison with (CG) group. While a significant decrease in (T2D-metformin) group comparison with (CG) group. Our results are in matched with results of other studies, which have shown that insulin was significantly higher in patients of post-menopausal with T2D compared with control and post-menopausal with OP group \[11\]. Various investigations have discovered endogenous insulin to have an anabolic impact on the bone \[5\], other examination found that exogenous insulin treatment eliminates the effect of endogenous insulin \[15\]. Col et al (2012) \[15\] have also discovered that insulin will inhibit C-peptide secretion which prompts to a negative effect on bone.

Serum Insulin

The table (2) demonstrated a significant increase for fasting serum insulin in (OP) group comparison with (CG) group. So, the insulin demonstrated a significant increase in (T2D-insulin) group comparison with (OP) group, but there was a significant reduce in (T2D-metformin) group comparison with (OP) group. On the other hand, the insulin was a significant increase can observed in (T2D-insulin) group comparison with (CG) group, but there was no significant reduce in (T2D-metformin) group comparison with (CG) group. These results agree with the other studies, which have shown that insulin was significantly higher in patients of post-menopausal with T2D compared with control and post-menopausal with OP group \[14\]. Various investigations have discovered endogenous insulin to have an anabolic impact on the bone \[5\], other examination found that exogenous insulin treatment eliminates the effect of endogenous insulin \[15\]. Col et al (2012) \[15\] have also discovered that insulin will inhibit C-peptide secretion which prompts to a negative effect on bone.

Fasting Blood Glucose (F.B.G)

The table (3) demonstrated a significant increase for F.B.G (OP) group comparison with (CG) group. At the same time, the F.B.G demonstrated non-significant increase in (T2D-insulin) group comparison with (OP) group, but there was a significant increase in (T2D-metformin) group comparison with (OP) group. While, there significant increase can observed between (T2D-insulin and T2D-metformin) groups compared with (CG) group. These results agree with the other studies, which have shown that evaluated the glycemic state of the DM by measuring F.B.G \[16\]. Blood glucose was decreased...
significantly by metformin therapy in the treated patients but it did not reach a normal [17]. Metformin therapy requires other hypoglycemic medications in combination therapy to improve glycemic control and reduce [18]. Hyperglycemia has been found to reduce bone density by decreasing number and osteoblast function, bone mineralization and constraining osteoblast maturation, reducing the response to 1,25 (OH) Vitamin D3, and inducing glycation of different proteins and glycation end products (AGEs) [19, 20]. Accumulation of AGEs can impact the rigidity of the bone but do not appear to impact mineralization [21].

Hemostatic model assessment-insulin resistance (HOMO-IR)

The table (4) showed that HOMO-IR (OP) group was significantly increased in the (CG) group. So, HOMO-IR demonstrated that highly significant in (T2D-insulin and T2D-metformin) groups comparison with (OP) group. While, the highly significant can observed between (T2D-insulin and T2D-metformin) groups compared with (CG) group. This results agree with the others study, which suggested that HOMA-IR were significant increase in patients of post-menopausal women with T2D compared with the controls and group post-menopausal with OP [14]. There is some evidence that HOMA-IR was highly significant in the T2D post-menopausal compared to the control group [22]. The HOMA-IR was highly significant in T2D-metformin group compared with the group CG, this came in line with those of previous research that supports the idea of greater improvement in insulin sensitivity reported in DM treated with metformin therapy [23].

Bone Mineral Density (BMD)

Table (5) showed BMD demonstrated a significant reduce in (OP) group comparison with (CG) group. So, BMD demonstrated the significant increase in (T2D-insulin and T2D-metformin) groups comparison with (OP) group. While, the significant increase can observed between (T2D-insulin and T2D-metformin) groups compared with (CG) group. There are conflicting studies reporting an increase, decrease, or no change in BMD in T2D patients when compared with healthy post-menopausal [23]. These results are partly in agreement with the result of Christensen and Svendsen, 1999 [24] who stated that post-menopausal IDDM had lower BMD than NIDDM. Post-menopausal IDDM have a moderately reduced BMD, while NIDDM patients seem to be moderately protected from post-menopausal bone loss. Nevertheless, our results only support to some degree the hypothesis of general osteopenia in IDDM patients. Post-menopausal women with OP have a significantly lower BMD as compared with healthy post-menopausal [25]. Other study found that exogenous insulin increased BMD [26], by some, whereas others have found no impact on bone [27], and other studies establish that insulin therapy reduced bone loss or improved rate of fracture [28].

Serum Osteocalcin (OC)

The table (6) showed OC value of (OP) group was significantly increased in (CG) group. So, OC demonstrated a significant reduce in (T2D-insulin and T2D-metformin) groups in comparison with (OP) group. While, the significant reduce can observed between (T2D-insulin and T2D-metformin) groups compared with (CG) group. There are conflicting studies on the impact of insulin therapy on bone biomarker (bone formation) reporting an increase, decrease, no change or not report in T2D patients. [6; 29]. While other studies indicated that, the impact of metformin on bone biomarker (bone formation) is neutral or decrease [6]. Serum OC was established to be significantly higher in post-menopausal with OP than that in the healthy post-menopausal. These results are partly in agreement with [30], they found a significant increase in serum OC were obtained in groups of post-menopausal with OP as compared to healthy post-menopausal. Serum OC was significantly lower in post-menopausal NIDDM compared with post-menopausal IDDM and reference values [24].

Serum Carboxyl-Terminal Telopeptide of Type I Collagen (CTXI)

A significant increase for CTXI in (OP) group comparison with (CG) group. So, CTXI value demonstrated a significant reduce in (T2D-insulin and T2D-metformin) groups comparison with (OP) group. While, there a significant increase can observed between (T2D-insulin and T2D-metformin) groups compared with (CG) group. These results are partly in agreement with other studies which in post-menopausal NIDDM markers both of bone formation and bone resorption were significantly lower than in the post-menopausal IDDM (though no-significantly for bone resorption), also lower than reference values from healthy post-menopausal [24].

Effect of Laser Diode and *Camellia Sinensis* Extract on Some Blood Parameters of Male Laboratory Rats Infected with Arthritis

Wafaa Abdulmutalib Naji\(^1\), Alaa J. Mohammed\(^2\), Mohammed Qasim Waheeb\(^1\)

\(^1\)Department of Biology, \(^2\)Department of Physics, College of Science, AL-Muthanna University, AL-Muthanna, Iraq

**Abstract**

The objective of this study is to investigate the effect of Green tea extracts (GTE) and Low Level Laser Therapy (L.L.L.T.) on healing of feet arthritis. Elevated free radical generation in inflamed joints and impaired antioxidant system has been implicated in arthritis. The medicinal effects of tea have a history dating back almost 5000 years. The chemical components of green tea chiefly include polyphenols, caffeine and amino acids. Tea also contains flavonoids, compounds reported to have antioxidant properties having many beneficial effects. Tea flavonoids reduce inflammation, have antimicrobial effects. Laser Therapy is active at both the cellular and systemic levels activating a variety of mechanisms including cartilage regeneration, DNA synthesis, improved microcirculation and an analgesic and anti-inflammatory effect. This study included twenty four adult male rats; the arthritis induced in all animals by using the formaldehyde then was divided into four groups (6 rats each) G1 control group, G2 treated with Low Level Laser Therapy LLLT, G3 treated with GTE and G4 treated with LLLT and GTE in physiology laboratory.

This study investigates possible mechanisms by which laser and GTE protect joints in rat model by the blood parameters studying in Experimentally Infected laboratory Rats with Arthritis.

**Keywords:** LASER; *Camellia sinensis*; Blood; Male Rates.

**Introduction**

Arthritis results in the deterioration of the joint through the process of chronic inflammation. The most common form is degenerative osteoarthritis, Osteoarthritis most commonly affects the hands, feet, spine and the large weight bearing joints such as the hips and knees \(^1\).

Although many medicines are prescribed for the treatment of arthritis, they are known to produce various side effects including gastrointestinal disorders, immunodeficiency and humoral disturbances. So, there is still a need to seek therapeutic agents with lower side effects that can be used for long-term administration \(^2\).

The chemical components of tea leaves include polyphenols (catechins and flavonoides), alkaloids (caffeine, theobromine, theophylline, etc.), volatile oils, polysaccharides, amino acids, lipids, vitamins (e.g., vitamin C), inorganic elements (e.g., aluminium, fluorine and manganese), etc. However, the polyphenols are primarily responsible for the beneficial healthful properties of tea. The flavonoides have antioxidant, anti-inflammatory, antiallergic and anti-microbial effects \(^3\).

Low level lasers are thought to promote healing and reduce pain possibly through the reduction of inflammation. Healing may come about by increased cell proliferation, Treatment of arthritis is very complex, and in the past years, some studies have investigated the

use of low-level laser therapy (LLLT) in treatment of it [4,5].

The aim of study is assessed the effects of L.L.L.T and GTE on the changing of the levels of some blood parameters in the rats with adjuvant-induced arthritis (AIA) as a model for arthritis.

**Materials and Method**

**Animals**

Twenty four male adult white rats, named scientifically as *Rattus norvegicus*, with six to nine month aged and average weight of (350-400g.), were used in this study. They were kept in standard separate cages and had free access to tap water and were fed with standard pellets *ad libitum*. This model was selected because it provides many desired characteristics to fulfill the requirements of this study. All cages were kept in conditioned room 20-22˚C with controlled lightening. The animals left for two week before the experiment for adaptation.

**Extraction Procedure**

The leaves of tea (*Camellia sinensis*) were powdered, then weighted (15 grams) of the powder and dissolved in 100 ml of 70% distilled water using a magnetic stirrer for 24 hours at room temperature (25˚C). The resultant extract solution was filtered using double layers of cotton gauze. The filtered solution was dried at 40˚C, after that we dissolved every 1 gram in 5 ml distilled water to produce the 200 mg/ml of extracting, the dosing began in the treated groups in the treatment days in fact between day and other from fourteenth day to twenty two day (and according to concentration sentences and took the average of animals weight as 300 mg) the amount of the dosing was 1.5 ml for each animal.

**Laser diode**

The laser system used was semiconductor crystal with active medium is Ga Al As (gallium aluminum arsenide).

The laser used was diode 820 nm wave length, a maximum output of 200 mW, density 8 J/cm², pulsing frequency 2.5-20 Hz. Irradiation began in the irradiation groups in the treatment days in fact between day and other from fourteenth day to twenty two day with 1.20 min /session daily. The Irradiation was carried out by 1 cm. from the skin of the paws edema.

**Induction of adjuvant-induced arthritis in rats**

For induction of experimental arthritis, the plantar surface of the left hind paw of rat was injected with 0.1 ml of (HCHO) and with 2 % concentration in the first and third days of experimentation [27]. The changes that have occurred in the foot (after the tenth day postoperation) which is redness, swelling and lameness, as observed there a significant increase (P <0.05) in the thickness of the foot in the fourteenth day (5.78 ± 0.62 mm) comparing with the first (4.01 ± 0.21 mm).

**Blood sampling**

Blood samples were collected under general anesthesia using a mixture of Ketamine hydrochloride (10 mg/Kg) and xylazine (3 mg/ Kg) administered i/m., at regular intervals from the heart after disinfection using 70% alcohol, in first, fourteenth, nineteenth, twenty three and twenty eight days post operation the amount of blood was 3 cc, and blood samples were collected using syringes 3 mL, then used complete blood system to measure Hb and RBC, WBC and platelets counts and used westergrene method for ESR levels and hematocrit centrifugation for PCV measurements.

**Statistical analysis of data**

The minitab statistical program was used to calculate the statistical significance of difference between groups. The difference between groups at the $P \leq 0.05$ levels was considered statistically significant.

**Results**

RBC counts, PLT count, HB levels, PCV value decreasing in the all groups after the inducing of the disease put in the treatment groups returns to the normal values after the treatment and with significant varies between these groups and control group, according to the (fig. 1),(fig. 2),(fig. 3), (fig.4) respectively.

WBC counts and ESR levels increasing in the all groups after the inducing of the disease put in the treatment groups returns to the normal values after the treatment and with significant varies between these groups and control group, according to the (fig.5), (fig.6) respectively.
Figure 1: RBC counts variations among the groups of rats during the experimentation time (inducing and treatment). There are significant variations between G1 & G2 at $P \leq 0.010$, between G1 & G3 at $P \leq 0.015$ and between G1 & G4 at $P \leq 0.014$.

Figure 2: PLT counts variations among the groups of rats during the experimentation time (inducing and treatment). There are significant variations between G1 & G2 at $P \leq 0.041$, between G1 & G3 at $P \leq 0.047$ and between G1 & G4 at $P \leq 0.038$.

Figure 3: HB Levels variations among the groups of rats during the experimentation time (inducing and treatment). There are significant variations between G1 & G2 at $P \leq 0.015$, between G1 & G3 at $P \leq 0.011$ and between G1 & G4 at $P \leq 0.006$.

Figure 4: PCV Levels variations among the groups of rats during the experimentation time (inducing and treatment). There are significant variations between G1 & G2 at $P \leq 0.019$, between G1 & G3 at $P \leq 0.01$ and between G1 & G4 at $P \leq 0.004$.

Figure 5: WBCs counts variations among the groups of rats during the experimentation time (inducing and treatment). There are significant variations between G1 & G2 at $P \leq 0.023$, between G1 & G3 at $P \leq 0.020$ and between G1 & G4 at $P \leq 0.042$.

Figure 6: ESR Levels variations among the groups of rats during the experimentation time (inducing and treatment). There are significant variations between G1 & G2 at $P \leq 0.051$, between G1 & G3 at $P \leq 0.053$ and between G1 & G4 at $P \leq 0.038$.

Discussion

Rheumatoid arthritis (RA) is an autoimmune disease that causes chronic inflammation of the joints and tissue around them with infiltration of macrophages and activated T cells. The pathogenesis of this disease is linked predominantly with the formation of free radicals at the site of inflammation and decreased...
Camellia sinensis. The most thrombocytopenia of the group of experimental in patients with rheumatoid arthritis (RA) due to anemia. 

With what indicated of red blood cell deposition and this result is consistent indicates anemia and a significant increase in the rate hemoglobin, red blood cells and blood mass, which with arthritis may be due to the low percentage of with the findings of the researcher explained anemia 

Reduced numbers of red blood cells in male laboratory rats with arthritis may be due to the increased level of inflammatory cytokines, especially IL-6, IL-1β, TNF-α, which inhibit the formation of progenitors of the pellets, as well as reduce the level of Erythropoietin. This is in line with the reference [9,10], or the decrease in the number of red blood cells may be due to an imbalance in the function of the thyroid gland and its hormones, which results from the effects of toxins generated in the body of the animal after the disease was introduced by formaldehyde, as hormones play a role in directing the metabolic process within the body as well as its indirect role in influencing the production of red blood cells in the bone marrow [11].

The decrease in the concentration of total hemoglobin of male laboratory rats infected with osteoarthritis may be due to the free radicals of ROS that lead to hemoglobin damage and formation of red blood cells. These deposits dissolve red blood cells, and free radicals attack the membranes of the pellets Red blood cells are broken and oxidized by the lipid forming of these membranes, or low levels of Erythropoietin and malnutrition are the main causes of hemoglobin deficiency, which leads to anemia [12]. These reasons were consistent with what the researchers explained [13,14].

The decrease in morbidity in the value of the blood mass is due to the reduction of red blood cells production and is mainly reflected on the value of the blood mass, which leads to a decline. The results of this study with the findings of the researcher [15]. Experimentally with arthritis may be due to the low percentage of hemoglobin, red blood cells and blood mass, which indicates anemia and a significant increase in the rate of red blood cell deposition and this result is consistent with what indicated [16], which explained the rise in ESR in patients with rheumatoid arthritis (RA) due to anemia. 

The significant increase in the number of thrombocytopenia of the group of experimental laboratory rats infected with arthritis may be due to the significant effect of one of the inflammatory cytokines (IL-6) in the immune response and regulation of the acute reaction stages of the infection [17]. There is also a significant effect of blood hemoglobin on blood platelet counts. The lower the hemoglobin level, the higher the platelet counts [18].

The increase in the total number of white blood cells in laboratory rats infected with osteoarthritis may be due to the condition of oxidative stress on animals, which leads to increased secretion of adrenal cortex stimulating hormone (ACTH) secreted from the pituitary gland, which stimulates the secretion of corticosteroids from Adrenal cortex and thus increase the number of white blood cells, which is the effects of the reaction of systemic inflammation within the body, as it involves the production of more white blood cells and monotonous nuclei that have a significant role in influencing the production of red blood cells in the bone marrow.

The antioxidant, anti-inflammatory, and antioncogenic properties of a polyphenolic mixture derived from green tea (Camellia sinensis). The most abundant of the polyphenolic compounds in green tea is epigallocatechin gallate (EGCG), with other catechins such as epicatechin (EC), epigallocatechin (EGC) and epicatechin gallate (ECG) also present [23].

The researcher [21] has been reported that laser photonic energy is absorbed by the mitochondria in the cell in which this energy is converted to chemical kinetic energy and finally leads to more production of ATP. ATP is the source of energy in the cell which is necessary for cell activities such as synthesis of DNA, RNA and proteins that are important in cellular proliferation [7,22].

The antioxidant, anti-inflammatory, and antioncogenic properties of a polyphenolic mixture derived from green tea can ameliorate inflammation in a murine model of inflammatory arthritis.

In studies using human chondrocytes derived from osteoarthritis cartilage, it had showed that EGCG is effective inhibitor of production of as nitric oxide (NO) and PGE2 by transcriptional and translational regulation [25]. Mohamadin and his colleagues found the supplementation of green tea extract (GTE) attenuates cyclosporine A-induced oxidative stress in rats [26]. Thus, there is experimental evidence to support further studies to investigate the anti-oxidative effects of green tea at
the molecular level.

Conclusion

The treating of the arthritis with GTE and L.L.L.T was useful and efficient that the healing was promoted and accelerated because its healing stages were induced by GTE and L.L.L.T.

Abstract

**Background:** Nanotechnology is a new science that has the ability to offer a wide range of uses and improved technologies for biological and biomedical applications. It is considered as the production, categorization, and exploration of materials in the nanometer. This study was aimed to demonstrate the effect of zinc oxide nanoparticles (ZnO NPs) on aerobic and anaerobic bacteria from internal cavity of the dental implants and sulcus of natural teeth in comparison with chlorhexidine 2% and solvent (water 3: 1 ethanol 99.9%).

**Materials and method:** Aerobic and anaerobic bacteria were isolated from sulcus of natural teeth and internal cavity of dental implants after 3 months from implant placement surgery (flapless design) to 6 female with age range 30 to 44 years with a total of sixteen implants. Different concentrations of ZnO-NPs (6, 2, 1, 0.5, 0.25, and 0.1mg/ml) were prepared. In this in vitro study, disk diffusion method was used to demonstrate the antibacterial activity of different concentrations of zinc oxide nanoparticles to isolated bacteria in comparison to 2% (positive control) and solvent (negative control).

**Results:** Aerobic and anaerobic bacterial isolates were sensitive to concentrations (6, 2, 1, 0.5, 0.25, and 0.1mg/ml) of zinc oxide nanoparticles in comparison with CHX and solvent. There was synergistic effect between CHX and 1mg/ml in all agar plates. All concentrations when compared with negative control showed highly significant differences.

**Conclusion:** This study shown that zinc oxide nanoparticles were effective against bacteria isolated from internal cavity of dental implant and sulcus of natural teeth.

**Keywords:** ZnO, Nanoparticles, Aerobic bacteria, Anaerobic bacteria, teeth implant.

Introduction

Dental plaques, also defined as oral biofilms, are defined as “matrix-enclosed bacterial populations adherent to each other and/or to surfaces or interfaces” [1]. The development of dental plaque is started by pellicle that formed on the surfaces of the tooth, initial colonizers of streptococcal species are attached to specific receptors have been provided by these pellicles [2]. During biofilm development, anaerobic changes occur in its environment from aerobic conditions. According to these changes bacterial colonizers of this biofilm also change toward gram negative bacteria while it was previously dominated by Gram-positive species [3]. This bacterial building change is indicative of transformation from health to diseased state of periodontium [4-10].

Prevention of early biofilm formation at the implant hole is important to prevent further bone loss at early stage. Deferent materials had been tested as CHX 1% and 2% concentrations [11]. Nanotechnology is a developing technology including production or application of nano-sized structures or materials [12]. Nanotechnology is considered as the production, categorization and exploration of materials in the nanometer. The materials that are relevant in this technology are those whose structures display new and significantly enhanced biological and physicochemical properties in addition to functionalities as an effect of the nano-scale size [13].

The combination between nanotechnology and biotechnology, for emerging biosynthetic and ecological friendly technology for creation of nanomaterials, is called Bionanotechnology [14].

The material started to be used for different purposes, one of them is antibacterial action from their materials is Zinc oxide nanoparticles (ZnO-NPs). ZnO is described as a strategic, promising, functional and valuable white inorganic material with a wide range of applications. ZnO has a chemical sensing, unique optical, electric conductivity semiconducting, and piezoelectric properties [15-18].

Many mechanisms for the antibacterial actions of ZnO-NPs have been suggested including destruction of the bacterial cell wall and membrane integrity by direct contact with ZnO-NPs [19,20], generation of reactive oxygen species (ROS) like H$_2$O$_2$ [27,28] and release of Zn$^{2+}$ ions that have the ability to damage cell membrane and interact with intracellular organelles [21,22].

ZnO-NPs with smaller size (higher specific surface areas) displayed highest antibacterial activity [23].

This study was aimed to demonstrate the effect of zinc oxide nanoparticles (ZnO NPs) on aerobic and anaerobic bacteria from internal cavity of the dental implants and sulcus of natural teeth in comparison with chlorhexidine 2% and solvent (water 3:1 ethanol 99.9%).

**Materials and Method**

**Characterization and preparation of ZnO-NPs**

Zinc Oxide Nanoparticles (ZnO, 99.8%, 10-30nm) Skyspring USA. absorbance spectra of NPs stock solution were measured by UV-VIS spectrophotometer (Spectro UV-VIS Double beam UVD-3500). In the wavelength range 200nm-800nm

ZnO-NPs powder were identified by the Scanning Electron Microscope SEM (CM 10 Philips) and prepared by:

A. Solvent preparation distill water 3:1 ethanol 99.9% for preparation of ZnO-NPs concentration.

B. Zinc oxide nanoparticles (10-30nm) prepared by adding solvent (3:1, water: ethanol) [32] to make a stock solution.

**Patient selection**

Six females aged 30 to 44 years with a total of sixteen implants, the dental implants placement was part of their overall treatment plan.

**Surgical implant placement**

By using flapless technique only, the gingiva at the site of implant was removed by tissue puncher, the proposed dental implant (Roott®) site was exposed. Conventional drilling procedure was done in sequence until reaching the requested final drill dental implant that was inserted. Before placement of the healing abutment, all implant screw holes were rinsed with about 20ml of sterile saline solution by disposable syringe and dried using surgical suction, thus preventing further contamination.

**Bacterial samples collection and culture method**

After 3 months from implant placement, healing abutment removed and samples were collected by small sterile brush from implant internal hole of the fixture in Heart Infusion Broth (BHI-B) and from sulcus of natural teeth. Antimicrobial activities of the ZnO-NPs were performed against both aerobic and aerobic bacteria. The antibacterial activity was done by well-diffusion method, as follows:

0.1ml of activated aerobic and anaerobic isolates were spread in duplicate on Brain Heart Infusion agar plates and left at room temperature for 10 minutes, then eight wells made.

The wells were filled with ZnO-NPs in different concentrations (6, 2, 1, 0.5, 0.25 and 0.1mg/ml) and one well for chlorhexidine 2% as positive control and the last well for solvent (ethanol water mixture) as negative control.

Plates left in the room temperature for 10 minutes and then incubated aerobically for 24hr at 37°C for aerobic bacteria and for anaerobic bacterial plate, it was placed in gas pack and incubated also for 24hr at 37°C. The different diameters of inhibition zone were measured.

**Results**

**Characteristics of ZnO-NPs UV-VIS absorption spectra**
Figure (1) showed that the absorption spectrum exhibited a sharp absorbance onset at 337nm, which indicated that this absorption peak is considered as a hallmark of ZnO NPs at applied nanoparticles size (<40nm).

Figure (2) showed the SEM image of ZnO nanoparticles. The SEM image was taken at X 94,000 magnification. The size of the particles was around 19.4-34.7nm.

Scanning Electron Microscope (SEM)

Figure (2) showed the SEM image of ZnO nanoparticles. The SEM image was taken at X 94,000 magnification. The size of the particles was around 19.4-34.7nm.

Determination of antibacterial activity of Zinc oxide nanoparticles (agar well-diffusion method)

ZnO-NPs showed an increase in diameter of the inhibition zone as the concentration increased. The 6mg/ml concentration showed larger inhibition zone than chlorhexidine (positive control), while the solvent (negative control) showed no inhibition zone.

When comparing between inhibition zones of bacterial samples for implants and natural teeth for the same concentration and bacterial type, the results were not significantly different in all concentrations and bacterial type, except for the 6mg/ml concentration in aerobic bacteria as it showed significant difference (P= 0.029; Table 1).

For CHX no significant difference was found in the size of inhibition zone of bacterial samples between implants and natural teeth for aerobic and anaerobic bacteria. Also, for solvent (negative control) no inhibition zones for implant and natural teeth for aerobic and anaerobic bacteria were seen (Figure 3).

Figure 3 Anti-bacterial activity for different concentrations of ZnO-NPs with positive control, CHX, and negative control, solvent.

All concentrations (0.25, 0.5, 1, 2 and 6mg/ml) showed highly significant statistical differences between aerobic and anaerobic bacterial isolates for the same site of sampling, either implant or natural teeth, except concentration (0.1mg/ml) as it was significantly deferent (P= 0.26; Table 2).

For CHX concentration, there is no significant difference between aerobic and anaerobic bacteria for the implant and natural Teeth.

**Discussion**

The results of antibacterial assessment by disk diffusion method to study the antibacterial activity (the size of inhibition zone) revealed a great association with concentration against aerobic and anaerobic bacteria (17-19).

Concentration directly affected the diameter of inhibition zone as it enlarged by increasing concentration. These results revealed that ZnO-NPs had strong antibacterial effect as it had the ability to kill or inhibit isolated aerobic and anaerobic bacteria of the internal cavity of dental implant and sulcus of the natural teeth. CHX 2% had greater inhibitory effect than ZnO-NPs as demonstrated by the size of inhibition zone where it was larger with the use of CHX. Synergism area between CHX 2% and ZnO-NPs 1mg/ml in all plates had more antibacterial action against tested bacteria as it had powerful effect (18,23-25).

All these results and findings indicated the strong anti-bacterial effect of ZnO-NPs and its beneficial uses in decreasing growth of bacteria.

**Conclusion**

Zinc oxide nanoparticles in different concentrations have anti-bacterial effects on aerobic and anaerobic bacteria isolated from internal cavity of the implant and the sulcus of natural teeth. The sensitivity of aerobic and anaerobic bacteria to ZnO-NPs increased with increasing of the concentration of ZnO-NPs in comparison with CHX 2% and solvent.

Use of the Naive Bayes Function and the Models of Artificial Neural Networks to Classify Some Cancer Tumors

Shrook A.S. Al-Sabbah¹, Sada Faydh Mohammad¹, Maryam Mahdi Eanad¹
¹Statistics Department, Administration and Economics College, Kerbala University, Iraq

Abstract

This study is concerned with the methods of classification and separation of observations and the use of two methods: of classification Naive Bayes, using the function of Kernel, and models of artificial neural networks using a function to show the step or sample in order to classify three types of cancer tumors (bone, lung, and breast). For a simple random sample of 150 patients, Naive Bayes was the correct classification of data for 67%, while in the method of neural network models, it was 86%. The model of artificial neural networks was found to be the best in classifying views from the Naive Bayes classification. The correct classification of bone cancer is the highest, followed by breast cancer and lung cancer. The relative importance of the variable age was the highest, then sex, and then the period of survival of the patient, and then the profession of the patient, and then the state of exit of the patient.

Keywords: Naive Bayes. Neural Networks. Kernel Function

Introduction

This research is an addition to the studies and research in the study of classification. The methods of the Kernel function are important techniques, which are widely applied to various areas of data analysis because of their flexibility and good performance, and its use in the discriminant analysis depends largely on the appropriate selection of the Package width matrix (H), which reduces the mean integral square error (MISE) and mean of classification error (. And comparing it with the pattern of neural networks which is based on the step function in order to classify three types of cancer tumors (bone, lung, breast) is a repetitive method that makes the error as low as possible through learning or Tearing training to reach to the weights that reduce the error in the classification.

Materials and Method

Objects

Know the parameters of the normal distribution (the mean and the deviation) of each of the three diseases (breast cancer, bone cancer, lung cancer) depending on the Kernel function, as well as knowing the value of the correct classification of data using the Naive Bayes classification.

Using the artificial neural networks model to classify and distinguish between observations and models with qualitative dependent variables.

Practical application of the two methods to compare them.

Theoretical side:

The Kernel Estimator is defined as an estimator based on the weight function which is used in estimating the non-parametric function. It gives weights to the adjacent data points in the estimation procedure.

The Kernel functions are continuous, limited and identical around zero; their real value and their integration are equal to one. They have a similar symmetric probability density function with the symbol \( K(x) \)\(^{1}\).

It is known that the method of these estimates depends mainly on the selection of the bandwidth parameter, which controls the estimation and the selection of the

DOI Number: 10.5958/0976-5506.2019.00938.0
Kernel function. One of the most frequently used functions is the Gaussian (normal) function with mean (0) and the variance (1). The reason is that there are many desirable characteristics, making the choice of bandwidth easier, and these qualities do not exist for other Kernel functions, (Bandwidth) characteristics are non-random, homogeneous, and positive.

The choice of the bandwidth includes the choice of a single parameter that controls the amount of smoothing in a bivariate state. In a multivariate case, the bandwidth matrix controls both the degree and direction of the smoothing, and therefore, its selection is more difficult.

To get a better estimate with one pattern, we use a bandwidth that reduces the Mean Integrated Square Error (MISE).

Results and Discussion

Data Classification

The number of correct classifications and the misclassifications rate or the apparent error rate is calculated by the rating table and Table (1) shows the classification process for two groups:

Table 1: Classification for two groups

<table>
<thead>
<tr>
<th>Actual Group</th>
<th>Number of observation</th>
<th>Predicted Group</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>1</td>
<td>n_1</td>
<td>n_{11} n_{12}</td>
</tr>
<tr>
<td>2</td>
<td>n_2</td>
<td>n_{21} n_{22}</td>
</tr>
</tbody>
</table>

Misclassification Rate = \[
\frac{n_{12}+n_{21}}{n_{11}+n_{12}+n_{21}+n_{22}}\]  

Apparent Correct Classification = \[
\frac{n_{11}+n_{22}}{n_{1}+n_{2}}\]  

And apparent correct classification rate (Misclassification Rate) can be calculated as follows:

MR = 1 - (correct classification rate)  

Based on Table (1), MR is obtained using the previous probabilities (\(\hat{p}\)) and KDE for the two group's \(\hat{f}(.;H_1)\) and \(\hat{f}(.;H_2)\); then the Optimal Classification Rate is to reduce the MR as follows:

\[
\hat{f}_i(.;H_1) > \hat{f}_i(.;H_2)\]  

The other cases classify observation (i) into the second group.

Misclassification rate (MR):

In 1988, Hall and Wand (1988) reported a bivariate experiment that found the best bandwidth directly by using the error rate of classification or the MR standard. The formula is as follows:

\[
\hat{M}R = 1 - n^{-1} \sum_{j=1}^{m} 1 \]  

Cost of bad classification:

There are two types of bad classification costs: true and expected. Let K be a number of classifications.

The true cost of bad classification is the K-matrix of dimensions, where (i, j) refers to the cost of the bad classification to predict the observation in row j if its true character is i. According to the formula:

\[
\text{Mdl. Cost}(I, j) = 1 \text{ if } I \neq j \text{ and } \text{Mdl. Cost}(I, j) = 0 \text{ if } I = j \]
Cost of bad classification:

There are two types of bad classification costs: true and expected. Let K be a number of classifications.

The true cost of bad classification is the K-matrix of dimensions, where (i, j) refers to the cost of the bad classification to predict the observation in row j if its true character is i. According to the formula:

\[ \text{Mdl. Cost}(l, j) = \begin{cases} 1 & \text{if } l \neq j \\ 0 & \text{if } l = j \end{cases} \]

That is: Mdl. Cost (i, j) is the cost of bad classification; in other words, the cost is 0 for the correct classification, and 1 for any incorrect classification. The expected cost of the bad classification is a K vector of dimensions, where element k is the weighted average cost of the bad classification of the classification of observations in row k, weighted by the probability of the subsequent class.

\[ c_k = \sum_{j=1}^{K} \hat{p}(Y = 1 | X_1, \ldots, X_P) \text{cost}_{jk} \]

Naive Bayes classifier:

This method is dependent on the value and its class in the vector, and the class is predicted according to the values of the variables. If X is a vector of random variables, it consists of \( X_1 = x_1, X_2 = x_2, \ldots, X_n = x_n \) and C represents random variable referring to classes, then in the Bayes theory, the expected classification error can be reduced by taking a conditional probabilistic sample for each x, as in the following formula:

\[ p(C = c | X = x) = \frac{p(C = c) \ p(C = c | X = x)}{p(X = x)} \]

Since the denominator is fixed then, it has no effect on the final choice and can be neglected. The formula is:

\[ p(C = c | X = x) \propto p(C = c) \ p(C = c | X = x) \quad (7) \]

\[ p(C = c | X = x) = p(\bigwedge_{i=1}^{n} X_i = x_i | C = c) = \prod_{i=1}^{n} p(X_i = x_i | C = c) \quad (8) \]

By combining formulas (7) and (8), the formula becomes as follows:

\[ p(C = c | X = x) \propto p(C = c) \ \prod_{i=1}^{n} p(X_i = x_i | C = c) \quad (9) \]

The probability of \( \prod_{i=1}^{n} p(X_i = x_i | C = c) \) can be estimated from the frequency of observations with \( C = c \) and frequency of observations with \( X_i = x_i, \) \( X_i \wedge C = c \), according to the law of large numbers; this estimate is constant, \( p(X_i = x_i | C = c) \). Observation is classified by estimating the posterior probability of each class, and then assigning the observation to the class, leading to the greatest probability of the posterior[11].

**Artificial Neural Networks** [12]

Artificial neural networks are modern techniques, and they use simulations in a way that is somewhat similar to the work of the brain in accomplishing a particular task through a massive treatment distributed in parallel and consisting of simple processing units. Nodes (Neuron) have a neurological characteristic. They store scientific knowledge and empirical information to make them immune to the user by controlling the weights.

Artificial Neural Networks (ANN) are similar to the human brain in that they acquire knowledge of training and storage of this knowledge using the forces arrived at FH inside the neurons called weights, and there is also a vital neurotransmitter similarity which gives the opportunity for scientists to rely on biological (ANN) to understand the vital phenomena. The output of each node is then processed by a non-linear function with a threshold known as the Activation function. Figure 1 shows the neural network action plan.

![Figure 1: the neural network action plan](image-url)
Classification of Neural Networks

Artificial neural networks can be used to classify the function by determining the activating function. We will adopt the step function (function threshold) as in the following formula:

\[
f(x) = \begin{cases} 
0 & \text{if } x < 0 \\
1 & \text{if } x \geq 0 
\end{cases}
\]

If output is 0, it means that the observation follows the class or the first set; then if the result (output) is 1, the observation follows the class or the second set \(^{[13]}\).

Education or training \(^{[14]}\)

The teaching of the neural network and training gives them the ability to learn and thus access to output with the least possible error by giving the neural network a set of examples, called the category of training, which weigh weights between the units of these methods, Perception method (Perception). This method modifies weights in a repetitive manner by adding the adjustment limit for the value of the weights of the past of Artificial Neural Network Components \(^{[15][16]}\) where any processing unit is composed (Neuron) of the following basic components (Weighting Coefficients, Summation Function, Transfer function, Output function).

Weighting coefficients:

Artificial neural networks depend on the weight of the element, which expresses the degree of relative importance of the input element.

Summation function:

The first operation of the processing unit is the calculation of the sum of the next balanced input to the unit using the addition function. This function calculates the average weights of all incoming inputs to the processing unit and multiplies each input value in its associated weight and then finds the sum for each multiplication interval as follows:

\[
S_i = \sum_{j=1}^{n} X_i W_{ij} \quad (10)
\]

\(S_i\): The sum of the combination process for each treatment unit \(j\).
\(X_i\): The value of the next input from unit \(i\) and input to unit \(j\).
\(W_{ij}\): The weight that connects the processing unit \(i\) to unit \(j\) in the previous layer.

Transfer Function\(^{[16]}\)

The transformative function depends on the cumulative function, which is the internal stimulant, conversion process is the conversion of the sum of the combination to one of the values that are supposed to be within the desired network outputs.

Applied side:

1 - The function of Naive Bayes:

A simple random sample of 150 patients was taken at the hospital in Marjan Medical City in Babylon province to diagnose cancer among people with breast cancer, bone cancer and lung cancer. And to implement Naive Bayes and the artificial neural networks.

In the composition of the discriminant function, we depend on a number of variables that were collected for each sample observation that includes intermittent and continuous variables. The variables were defined as follows:

<table>
<thead>
<tr>
<th>Y</th>
<th>Type of tumor</th>
</tr>
</thead>
<tbody>
<tr>
<td>(X_1)</td>
<td>sex</td>
</tr>
<tr>
<td>(X_2)</td>
<td>age</td>
</tr>
<tr>
<td>(X_3)</td>
<td>Patient job</td>
</tr>
<tr>
<td>(X_4)</td>
<td>discharged from the hospital status</td>
</tr>
<tr>
<td>(X_5)</td>
<td>Survival time</td>
</tr>
</tbody>
</table>

Using the Matlab program for cancer patient data and preparing the data according to the Gaussian Kernel function for combined observations and each of the three tumors. By applying equation (4) and (5), osteoporosis was spread around one, with an average of \(\mu = 1.4400\) and a deviation \(\sigma = 0.5014\), as well as in lung cancer spread around one, with an average of \(\mu = 1.4200\) and a standard deviation of \(\sigma = 0.4986\). Breast cancer is spread around the two, with an average of 1.9600 and a standard deviation of \(\sigma = 0.1979\). The program classifies the views into the corresponding category with the lowest cost of the expected poor rating. The application of the formula (16) shows that the correct classification of the data was equal to 0.6667 and the loss value was 0.1600.
For the sake of illustration, the density functions of the three cancer tumors were plotted as in Fig. 2:

For the sake of illustration, the density functions of the three cancer tumors were plotted as in Fig. 2:

**Figure 2: Naïve Bayes for classification**

![Kernel density estimate](image)

**Figure 3: Kernel Density Function for cancer diseases**

To calculate the number of data points within each period represented by histories representing replication, the graph is centered in the middle of each period and reflects the high average number of data points in that period. Bandwidth is (0.2707) and determines the width of the Kernel function. displays Density window around each point. It is the “optimal” display which would reduce the mean of the error box if the data uses a Gaussian Kernel Function?

**Figure 4: neural network architecture**

The neural network model is summarized as follows:

**Table 2: neural network model**

<table>
<thead>
<tr>
<th>Model Summary</th>
<th>Cross Entropy Error</th>
<th>Percent Incorrect Predictions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Training</td>
<td>39.522</td>
<td>18.0%</td>
</tr>

</tr>
</tbody>
</table>

a. Error computations are based on the testing sample.

It is clear from Table (2) that the percentage of wrong classification in the training sample was 18%, while the wrong classification in the test sample was 14%, which is close. This indicates that the network has been well trained in the classification of new units. Stopping Rule Used is when the error rate is constant or when the error rate stops increasing, depending on the test ratio, as shown in the table that the network training time is 6 seconds.
### Table 3: Results of classification using neural network

<td>14</td>
</tr>
<tr>
<td></td>
<td>Overall Percent</td>
<td>38.0%</td>
<td>32.0%</td>
<td>30.0%</td>
</tr>
</tbody>
</table>

Dependent Variable: Y

Table (3) shows that the correct classification rate for breast cancer was 83.3% in the training sample, while it was 92.1% in the testing sample. The correct classification of bone cancer was 94.1% in the training sample, while it was 100% in the test sample, the correct classification of lung cancer was 66.7% in the training sample and 70% in the test sample, which is a very good predictor of new vocabulary.

### Table 4: Analysis of the relative importance of independent data

<table>
<thead>
<tr>
<th>Independent Variable Importance</th>
<th>Importance</th>
<th>Normalized Importance</th>
</tr>
</thead>
<tbody>
<tr>
<td>X1 sex</td>
<td>.210</td>
<td>39.3%</td>
</tr>
<tr>
<td>X2 age</td>
<td>.535</td>
<td>100.0%</td>
</tr>
<tr>
<td>X3 Patient job</td>
<td>.075</td>
<td>14.0%</td>
</tr>
<tr>
<td>X4 discharged from the X5 hospital status</td>
<td>.029</td>
<td>5.3%</td>
</tr>
<tr>
<td>X5 Survival time</td>
<td>.152</td>
<td>28.3%</td>
</tr>
</tbody>
</table>

It is clear from Table (4) that the most important variable in the classification using the neural network is the variable (age X2) with a significance rate of 0.535, followed by a variable (sex X1) by significance of 0.21, and then variable (survival of patient X5) 0.152, followed by variable (patient career) X3 with a significance rate of 0.075 and finally variable (case of exit of patient X4) with a significance of 0.029. It is clear that the most important variable in the classification of cancer (breast cancer, bone cancer, lung cancer) while the variable patient exit status is not important in the classification of cancer, with an impact of almost zero.

The last column of the table is the importance of independent variables for the largest relative importance of those variables.

### Conclusions

1 - The model of artificial neural networks was found to be the best in classifying views from the Naive
Bayes classification.

2 - The correct classification of bone cancer is the highest, followed by breast cancer and lung cancer.

3 - The relative importance of the variable age was the highest, then sex, and then the period of survival of the patient, and then the profession of the patient, and then the state of exit of the patient.

Abstract

Background: Erectile dysfunction (ED) is a pervasive problem among men worldwide. The aim of current study was to determine the clinico-epidemiological features of patients with erectile dysfunction and different associated factors. Method: A descriptive cross sectional study was carried out for a period of six months starting on 1st of October 2017 till the end of March 2018. Results: The prevalence of ED was 35% among a patients attending Al-Kadymia Teaching Hospital during the period of the study with mean±SD age of ED patients of 53±10 years, while 52±12 years for non-ED patients. Regarding the degree of ED, 35.34% had mild, 32.76% had mild to moderate, 18.97% had moderate and 12.93% for severe cases of ED. Most cases of study sample from urban area (68.48%) and had primary education, employed and married. Significant association was found between patients with ED and history of diabetes, cardiovascular diseases & diabetes with hypertension, cigarette smoker and alcohol drinker & lipid profile, while non-significant association was found between ED patients and other risk factors. Highest percentage (54.31%) were improved after treatment compared to (45.69%) who did not improve. Higher percentage of ED patients (25%) had duration of ED of 7-9 years, while lower percentage (12.07%) had duration ≥10 years.

Conclusion: The prevalence of ED was 35% in patients attending Al-Kadymia Teaching Hospital during the period of the study. Significant association was found between patients with ED and history of diabetes, cardiovascular diseases & diabetes and hypertension, cigarette smokers, alcohol drinkers & lipid profile abnormality.

Keywords: Erectile dysfunction, Prevalence, Diabetes mellitus, Cardiovascular diseases, Demographic variables.

Introduction

Erectile dysfunction (ED) is a highly prevalent health problem that affects 30 million men in the USA. It is a common worldwide clinical problem with tens of thousands of new cases per year [1]. ED seems to be a very sensitive question and most individuals do not wish to be made aware [2]. ED can result from poor physical or poor psychological health or both. The principal risk factors are diabetes mellitus, heart disease, hypertension and prostatic hypertrophy [3]. The problem of erectile dysfunction is mainly linked to age, as shown in the Massachusetts Male Aging Study, where 52% of the male study population aged 40–70 years had some degree of erectile dysfunction [4]. The causes of ED are multi-fatorial, which include anatomical, vascular, neurological, hormonal and psychological factors [5]. Since it is not a life-threatening condition, many men take it for granted and leave it undiagnosed and untreated [6]. In addition, because of the perception of people that ED is a “taboo” subject, patients tend to ignore it from the aspect of health care [7]. This situation might lead to approximately 322 million men worldwide being affected by ED by 2025 [8]. Findings from other studies have shown that certain environmental
and lifestyle factors, such as smoking, obesity, and limited or an absence of physical exercise, might also be important predictors of erectile dysfunction \(^9\). It is also reported that psychological problems such as depression, performance anxiety, and relationship problems could be complications and risk factors of ED \(^{10}\). The current study was carried out to determine the clinico-epidemiological features of patients with erectile dysfunction and different associated factors.

**Patients and methods**

**Study design**

A descriptive cross sectional study.

**Study setting**

The current study was conducted in Al-KLadymia Teaching Hospital in Baghdad for the period from 1\(^{st}\) of October 2017 till the end of March 2018.

**Study population**

Study population included all patients attending genitourinary clinic in Al-Kadymia Teaching Hospital during the period of the study.

**Data collection**

Data were collected using a well-designed questionnaire form constructed by the researchers. Subjects were interviewed and information was collected on demographic and epidemiologic variables, medical and surgical history, smoking history and laboratory examination for lipid profile for each subject. A systematic random sampling method was used to recruit the subjects into the study. Every 5\(^{th}\) man who attended the clinic on each clinic day. So it was convenient to carry out sampling in systematic way (through regular interval), then checklist for assessment of erectile functionality and evaluation. ‘The check list used is an abridged version of International Index of Erectile function (IIEF) \(^{11}\) made up of five direct questions about sexuality, with five answer options for each question making a total score of 25. Evaluation of erectile function was based on the scoring system with 22-25 taken as not having ED, 17-21 as mild, 12-16 as mild to moderate, 8-11 as moderate and 1-7 as severe’.

**Statistical Analysis**

Analysis of data was carried out using Statistical Packages for Social Sciences; SPSS version 24). Data were presented in simple measures of frequency, percentage, mean and standard deviation. The significance of difference of different percentages (qualitative data) was tested using Pearson Chi-squared test with application of Yate’s correction or Fisher Exact test whenever applicable. Statistical significance was considered whenever the P value was equal or less than 0.05.

**Results**

Significant association was found between ED patients and age groups, while non-significant association was found between demographic variables such as residence, education, employment status & marital status.
Erectile dysfunction is a highly prevalent problem that remains silent and under-treated. Primary care physicians need to begin the evaluation of erectile function in patients who are considered at high risk. A focused history, physical examination and laboratory evaluation are often helpful in identifying risk factors for erectile dysfunction [12]. The prevalence of ED was 35% among patients attending Al-Kadymia Teaching Hospital during the period of the study with mean±SD age of ED patients of 53±10 years, while 52±12 years for non-ED patients. These data were in accordance with previously conducted studies [13,14]. The true prevalence of ED among the general population cannot be extrapolated from this study because the sample is considered as a convenient sample which is subjected to selection bias and does not represent the total ED patients in the community. Although, the percentage of 35% found in this study was lower compared to the findings in previous studies, this is significant in view of the fact that men with ED do not always speak in confidence to other people or readily seek medical advice. The prevalence of erectile dysfunction varies according to certain characteristics such as age, social characteristics, socioeconomic status, and concomitant disease conditions. The relation with age has been recognized in some studies [15]. It is strongly related to age with its prevalence increasing with age [16]. The current study also shed light on this fact which showed higher percentage of ED patients in older age groups. As one gets older, erections may take longer to develop and may not be very firm, this might be due to several reasons including changes in the testicles and age-related decline in male sex hormones have been added for the increasing frequency of ED in older men [17,18]. As a direct consequence of getting older, or as a result of underlying co-morbid conditions or medications, which is more common in older men [19]. Also, it has been found to be more prevalent in patients with associated medical conditions such as diabetes, hypertension, as well as among heavy cigarette smokers and those who consume lots of alcohol [18]. This was approved in the current study in which significant association was found between patients with ED and history of diabetes, cardiovascular diseases & diabetes with hypertension, smoking and alcohol drinkers & lipid profile abnormality. Furthermore, a study reported that diabetic men have a three to four times increased tendency to develop sexual dysfunction compared to the healthy population [19]. There is no single etiology that can explain the occurrence of diabetic impotency [20]. Regarding the degree of ED, 35.34% had mild, 32.76% had mild to moderate, 18.97% had moderate and 12.93% had severe ED. These results were similar to other reported studies [21]. Regarding the outcome, higher percentage (54.31%) were improved after treatment compared to (45.69%) who did not improve. This finding was parallel to other previously conducted studies [21].

Conclusion

We found that the prevalence of ED was 35% in patients attending Al-Kadymia Teaching Hospital during the period of the study. Significant association was found between patients with erectile dysfunction (ED) and history of diabetes, hypertension & diabetes with hypertension, cigarette smokers, alcohol drinkers & lipid profile abnormality.

Abstract

Surface roughness influences the marginal and internal adaptation of the prosthesis. It also can affect the accuracy of scanned data in CAD/CAM techniques.

Purpose - present study compared surface roughness of a stone and a polyurethane die material.

Methodology – An identical aluminum model in form of prepared premolar was made using CNC milling machine. Poly vinylsiloxane impressions were made from the model. Half of the impressions were poured with type IV stone and the other half with the exacto-form resin die material. Surface roughness of each die was measured by profilometer. The data were analyzed with ANOVA and Tukey’s test at 95% level of confidence (p=0.05).

Results – the mean value of surface roughness for stone die material was 1.79529, and for exacto-form was .89414μm. The difference was significant.

Conclusion – the surface of Exacto-form poly urethane dies is less rough in comparison with stone dies.

Key Words - Die materials- Dental models- surface roughness –scanning- Dental Scanners.

Introduction

Fabricating esthetically, mechanically and biologically ideal indirect restorations which survive mechanical and chemical conditions of oral cavity has been the ultimate goal of dental practice⁴. To fulfill this goal, the first step is to make a precise duplicate of oral structures and the relation of abutment and non-abutment teeth to each other. And it is done by taking impression of dental tissues, using impression materials or scanners. In recent years the popularity of data acquisition by scanning has increased because of development, progress and increasing popularity of CAD/CAM techniques for fabricating indirect restorations. The data is used to form the virtual model of the oral structures, and to design the restoration on it. Scanning might be oral cavity impressions or cast models of oral cavity. When casts are scanned, the properties of its material can affect the precision of data acquisition⁷.

For a long time, dental stones types IV and V have been used for making working models in dentistry. They are inexpensive, easy to use, dimensionally accurate and generally compatible with most of impression materials³. Their main disadvantage is low abrasion resistance, low tensile strength for being burnished in full porcelain margins, low detail reproduction in comparison with resins and high brittleness in case of long and thin dies¹. In an attempt to overcome these disadvantages, the resin modified stones, epoxy resins and poly urethane resins were introduced. They have better mechanical properties but high cost, incompatibility with impression
materials and high contraction during setting\textsuperscript{[3]}. For scanning the casts, the model and die materials should be accurately scannable. In 2013 International Organization for Standardization (ISO) No. 6873 revised the requirements for type IV stone to encompass scannable stones. It is desirable these stones to have superior dimensional stability and high reproducibility, have less expansion (0.07\%) and microbubbles. They should not be shiny or need powder for being scanned. Also their surface should be smooth and doesn’t show much roughness. Surface roughness influences the adaptation of the restoration on the abutment and necessitates adjustments to fit it\textsuperscript{[6,7]}. Results of Kim et al study on the Impact of surface roughness of gypsum materials on the adaptation of zirconia cores showed a clear positive linear correlation between surface roughness of different stone types and the precision of fit of zirconia cores ($P<.05$). They reported that dental stones used during the process of converting the working model to a 3D digital model through a CAD program can influence precision of fit of the resulting prosthesis\textsuperscript{[2]}. The present study compares the surface roughness of two die materials. 

**Materials and Method**

**Preparing Master die**

By using CNC milling machine (imesicore/450i, Germany), an aluminum master die was prepared with 10 mm cervical diameter, 6 mm height, 6° total occlusal convergences and 1mm wide rounded shoulder finish line.

**Making Dies**

Fourteen custom made impression trays were used to make two-step poly vinyl siloxane (Panasil, Germany) impressions of the aluminum master die. In order to have similar impression procedure, Small perforated plastic cup (20mm diameter, 20mm height) used as impression trays, were attached to the upper member of an articulator by means of magnetic rings. The master dies were attached to the lower member and centered into the middle of the cup. Light body (type 3. Panasil, Germany) was injected around the surface of the master dies. Heavy body (Putty soft, type 0. panasil, Germany) was placed in the tray and the articulator was closed. After setting of impression material, it was separated from the master dies. Excess impression material was trimmed away with a scalpel (Figure no.1). The impressions were randomly allocated into two groups of 7 each according to the type of used die material. For stone group, type IV stone (Ultra hard Snow Rockdie stone UD/Korea) was mixed as manufacturer’s recommended water/powder ratio ($W/P = 20\text{ml}/100\text{g}$), under 710 mm Hg vacuum for 60 seconds. The stone was vibrated into the impression and allowed to set for one hour at ambient room temperature and humidity before removal from the impression (20corr). Exacto- form model resin die material has two-component. The particles of the components may residue during storage, so each of the components should be stirred completely before mixing with the other in order to get a homogenous mixture. After that component B (resin) was added to A and mixed together thoroughly for 30 seconds, the uniform color mixture was then poured swiftly into the impression. Although the Exacto- form dies were removed after 30 minutes of mixing, they would achieve final hardness after 90 minutes.

If there were any defects like air bubbles or imperfections the replicas were repoured.

**measuring Surface roughness**

Profilometer (TR200) was used to measure surface roughness(fig-1). Each die was tested three times and the mean of readings each die was calculated. The mean and standard deviation values of surface roughness for each group were measured using these calculations, and compared with independent samples test.

**Figure (1): Surface roughness of Die Stone and Exacto-Form resin.**
Results

Test of normality table (Table 1) showed that sig = 0.200 > 0.05 for both Die stone and Exacto-form resin die materials which mean that data are subject to normal distribution, and the graph for each one of them illustrates this (figure 2,3).

Table (1): Normality table showed the significant of Die stone and Exacto-form resin die materials.

<table>

Discussion

This study compared the roughness of two die materials. The results showed that poly urethane had less surface roughness in comparison with type IV stone. The same is reported by Fan et al in their study on different types of die materials[8].

Different factors may influence surface roughness of the of stone casts like surface roughness of the original objects, the kind of the impression material and the particle size of the stone material, filler additives and use of surfactants[2]. In this study the same elastomeric impression material was used for making dies of both groups and the materials were prepared according to manufacturer’s instruction for use.

Kim et al showed the surface roughness of gypsum materials had a significant impact on adaptation of zirconia cores. They concluded that the rougher the cast the more is marginal gap of the core. It means that surface roughness of the die material had negatively influenced the data acquisition[2].

Both dies are fabricated under a corresponding condition and the explanation of this finding probably because of the irregularities and undulating present in the scanned area lead to missing a lot of data during scanning procedure that lead to reflected the incident laser beam away from their focus point in the receptor device or camera that mean more smoothing more data captured during a scanning procedure while less smoothing (high roughness) mean there are a lot of data loss, that produce irregular distorted 3D virtual model, this finding supported with Al-Jubouri and Azari they concluded that the computer cannot be clearly read the image captured by dental scanner that lead to produce irregular distorted model[9]. This results appears to be similar to the results of Kim et al ,when mentioned that, scannable stone exhibits a very smooth surface and a very low surface roughness, resulting in superior scannability[2].

Nowadays, the attentions in CAD/CAM systems in dentistry are increased, this was mainly due to minimizing the process accomplished with manpower and labor-intensive laboratory processes associated with the conventional ways of producing dental restorations and time consuming production procedures, cost effectiveness and quality control in shorter period of time[10-13].

Several scanner devices had been used to collect a 3D data of the geometry of a physical object and converted it into a digital data[14].

In current study, dental laser scanner (3Shap, Denmark) was used to acquired digital data from the standard die in order to produce two types of dies (stone and Exactoform resin die).

Conclusion

The mean values for surface roughness of die stone dies was significantly higher than those of exacto-form resin.

Gene Polymorphism of Interleukin 1β and Oxidative Stress in Gastritis Patients Infected with Helicobacter pylori

Suhayr A. AlQaysi1, Heba M.ALKatawe1, Huda AI-Hasnawy1
1College of Medicine/ University of Babylon, Iraq

Abstract

Background: Gastritis represents a state of inflammation, irritation and erosion of gastric mucosa that occur suddenly (acute) or step by step (chronic). H. pylori is a spiral gram-negative rod bacteria that has the ability to colonize and infect the stomach. The cytokine gene interleukin (IL)-1β has been concerned in influencing the pathology of inflammation induced by H. pylori infection. The aim of current study was to study the role of H. pylori infection and IL-1β in pathogenesis of gastritis as well as to study the impact of C-511T (rs16944) polymorphism in the promoter region of the IL-1β gene. Method: This case control study included 90 subjects (60 patients and 30 controls). The detection of H. pylori in serum was achieved by H. pylori Antibody Rapid test cassette. Parameters that were measured by ELISA technique were human Interleukin IL-1β level, serum Malondialdehyde concentration and serum Glutathione concentration; whereas serum Total Antioxidant capacity (TAC) was measured by spectrophotometer. IL-1β Gene C-511T (rs16944) polymorphism was measured by using Single-Strand Conformation Polymorphism (PCR-SSCP) after amplified by a polymerase chain reaction (PCR) with specific published primers. Results: IL-1β decreased significantly in patients who are positive for H. pylori. However, no significant increment was observed in those negative for H. pylori. Serum MDA increased significantly in gastritis patients when compared with controls. Also, there was significant increase in negative H. pylori. Serum GSH and serum TAO increased significantly in negative H. pylori patients when compared with control groups. TAO increased significantly in positive H. pylori when compared with negative H. pylori patients. Haplotypes pattern that increased significantly in gastritis patients were A and B (1.66% and 3.33%, respectively). Conclusion: In Iraqi population, the gene polymorphisms with D haplotype were associated with chronic gastritis and mainly development of H. pylori-infected individuals. No correlation was found between IL-1β -511 gene polymorphisms in any gastric disease with A,B and C haplotypes. Gastritis with H. pylori infection plays an important role in development of oxidative stress.

Keywords: H. pylori, IL-1β, IL-1β Gene C-511T (rs16944) polymorphism, Malondialdehyde, Glutathione, Total Antioxidant capacity.

Introduction

Gastric diseases confer with diseases touching the stomach. “Inflammation of the abdomen by infection from any cause is called gastritis”[1]. “Gastritis is a condition in which the stomach lining, known as the mucosa, is inflamed”[2]. Common causes of gastritis include infection with Helicobacter pylori (H. pylori) and use of non-steroidal anti-inflammatory drugs and fewer common causes including alcohol, smoking, cocaine, severe illness, autoimmune problems, irradiation therapy and inflammatory bowel diseases[3]. Helicobacter pylori may be a fragile bacterium that has found a perfect place, the protecting secretion layer of the abdomen, the mucous layer that protects the stomach cells from acid also protects H. pylori bacteria. H. pylori infection may cause both acute and chronic gastritis[4]. Epidemiological studies had indicated that inflammation induced by H. pylori infection was regulated by several interleukins (ILs) including the

Corresponding author:

Email: hudashmm@gmail.com
pro-inflammatory cytokine Interleukin 1 beta (IL-1β) \cite{8}. The (IL)-1β gene has been concerned in influencing the pathology of inflammation elicited by H. pylori infection \cite{8}. IL-1β acts as an inhibitor of viscus acid secretion and plays vital roles in initiating and amplifying the inflammatory responses to H. pylori infection, however, finally permitting extension of H. pylori colonization from the viscus bodily cavity to the corpus, resulting in more progression of inflammation\cite{9}. IL-1β (encoded by IL-1B gene) is involved in many cellular activities including inflammatory response and secretion of gastric acid. It has been shown that IL-1B-31C/T and IL-1B-511C/T polymorphisms are closely related to Gastric cancer \cite{25}. H. pylori contributes to the event of biological process ulcers, gastritis, mucosa-associated lymphatic tissue cancer and viscus cancer, prolonged infection causes chronic inflammation, aerophilic stress and polymer harm \cite{8}. Oxidative stress is defined as an imbalance between free radicals and antioxidants in favor of the oxidants, leading to disruption of redox signaling and molecular damage \cite{9}. Gastro-intestinal tract (GIT) could be a key supply of ROS production. Despite the protecting barrier provided by the animal tissue layer, eaten materials and pathogens will cause inflammation by activating the epithelial tissue, polymorphonuclear neutrophils (PMNs), and macrophages to supply inflammatory cytokines and different mediators that contribute more to aeroophilic stress \cite{10}.

Current study was aimed to study the role of H. pylori infection and IL-1β in pathogenesis of gastritis as well as to study the impact of C-511T (rs16944) polymorphism in the promoter region of the IL-1β gene.

**Subject and Method**

This study included 90 subjects divided into three groups; the first group included 30 patients suffered from gastritis with H. pylori infection, the second group included 30 patients suffered from gastritis without H. pylori infection and the third group included 30 subjects apparently healthy as control group. The age of all subjects was ranged between (30-50) years. The study was carried out from out patients collected from GIT and Hepatology center at Mirjan Medical City in Babylon province, Hilla city, Iraq. Patients were diagnosed clinically and the disease was evaluated by physicians. All samples were collected from 1st, October 2017 till 1st, February 2018. The practical part of the study was performed at the laboratory of Biochemistry Department in Faculty of Medicine/ University of Babylon, Iraq.

**Exclusion criteria:** Subjects who suffered from the followings were excluded from the study: Patients who take any non-steroidal anti-inflammatory drugs (NSAIDs), patients with concurrent inflammatory bowel disease, patients with diabetes, cardiovascular diseases (including coronary artery disease, peripheral vascular disease, heart diseases, hypertension and stroke), and malignancy. In addition, patients with rheumatoid arthritis, patient with any other chronic diseases (metabolic and endocrine) as well as pregnant women and smokers.

**Ethical issues**

The objectives and methodology of this study were explained to all participants in the current study to gain their verbal acceptance. In addition, the study was approved by Research Ethics Committees at College of Medicine/ University of Babylon and at Mirjan Medical City, Hilla City, Iraq.

**Blood collection**

A sample of five mL of blood was obtained from every subject by vein puncture and pushed slowly into 2 tubes (2mL into EDTA tube for genetic study and 3mL into plain tube). Blood inplain tube was allowed to clot at 37°C for 10-15 minutes and centrifuged for about 14000rpm for approximately 10-15 minutes then the sera were divided into four parts in labeled Eppindorf tubes and given a serial number together with the patients names then stored at -20°C until analysis for measurement of Human interleukin 1 beta (IL-1β), Glutathione (GSH), Malondialdehyde (MDA) and total anti-oxidant capacity level (T-AOC), while H. pylori antibody was measured directly before storage.

Body Mass Index (BMI) was calculated from the weight (in kg) divided by the square of height (in m): BMI= Weight (kg) / Square Height (m2).

Assay for detection of H. pylori in serum was performed by H. pylori Antibody Rapid test cassette, while serum Total Antioxidant capacity (TAC) was measured by Spectrophotometric technique. On the other hand, human Interleukin 1β level, serum Malondialdehyde concentration and serum Glutathione concentration were estimated using standard enzyme-linked immune-sorbent assay technology (ELISA) kits.
These kits were provided from Elabscience®/USA and the assay performed depending on the manufacture’s instructions.

**Genotyping analysis**

Genomic DNA Mini Kit (Favorgen, Taiwan) provides an efficient method for extraction of genomic DNA from whole blood. Purity of DNA was assessed by nanodrop device and detection by electrophoresis on 2% agarose gel. IL-1’ gene was amplified by a polymerase chain reaction (PCR) with specific published primers. The forward and reverse primers were show in Table (1).

Discussion

There was no significant difference in age between patients and control groups (P-value = 0.55). This age matching helps eliminate differences in parameters that may originate due to the significant variation in age [11]. The value of BMI between patients and control groups was not significantly different (Table 4) and there were no significant difference in interleukin 1β level between gastritis patients and control groups (P-value = 0.64; Table 5). In addition, there was significant decrease in IL-1β level in gastritis patients with H. pylori infection in comparisons with controls.

Current results were not consistent with [12] who indicated an increase in IL-1β in H. pylori infection. The differences may refer to differences in categories of patients groups, stage of disease, type of sample, age of patients, environmental causes and other unknown causes that need further studies. On the other hand, current results demonstrated that there was no significant difference in interleukin 1β between gastritis patients who are positive for H. pylori infection and those who are negative for H. pylori infection groups. Current data were in agreement with previous studies [13,14], but disagreed with [15]. Present findings indicated many significant differences were observed between gastritis patients and controls. Serum MDA increased significantly in gastritis patients when compared with controls. Also, H. pylori-infected individuals had increased blood MDA levels, ROS production and protein carbonyls, oxidatively-damaged DNA and SOD activity in addition to lower vitamin C. Individuals infected with H. pylori are under systemic oxidative stress, higher ROS production in the peripheral blood. However, these individuals were found to be normalized after eradication of H. pylori [16]. Serum GSH and serum TAO increased significantly in patients negative for H. pylori when compared with control groups. TAO increase d significantly in positive H. pylori when compared with negative H. pylori patients. The results of present study included gene polymorphism of IL-1β. In gastritis patients compared with healthy control, Gene polymorphisms were detected using PCR-SSCP technique because it can give indicators about haplotype secondary structure of the amplified segments of the gene. The results of haplotype polymorphism in IL-1β gene showed five patterns of haplotypes labeled (A, B, C, D and E) as shown in Figure (3) and most abundant haplotypes were D and E among patients groups (41.6%, 15%) and in control groups (64.6%, 36.6%), respectively. On the other hand, there were three patterns (A, B and E) Polymorphisms showed highly significant differences between patients and controls; whereas other patterns did not show any significant (P>0.05) variations between studied groups.

Conclusion

In Iraqi population, the gene polymorphisms with D haplotype were associated with chronic gastritis and mainly development of H. pylori--infected individuals. No correlation was found between IL-1β -511 gene polymorphisms in any gastric disease with A,B and C haplotypes. Gastritis with H. pylori infection plays an important role in development of oxidative stress.

Ethical Clearance: The study was approved by the Research Ethics Committee at at College of Medicine/University of Babylon and at Mirjan Medical City, Hilla City, Iraq.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Evaluation of Serum Cytokines IL-12, 17 and 22 Levels in Patients with Brain Tumors

Ahmed M.B. AL-Sherify; Mayada Farhan Darwesh, Musa Nima Mezher
1College of Science, University of Kufa, AL-Najaf, Iraq

Abstract

Background: There are over 120 brain tumor types and they were classified according to World Health Organization. Previously, attempts were made regarding chemosensitivity testing and molecular biomarkers methods were used as techniques during the management of different types of malignant tumors in routine clinical practice, especially in neuropathology. Current study was aimed to evaluate some immune-markers in Iraqi patients by (ELISA) to assess the different levels of IL-12, IL-17 and IL-22 to illustrate ability of tumor in immune-modulatory activity to increase the progression of disease. Also, it was hoped that these markers can be used as indicators for rapid identification of novel brain tumor in patients, directly from their sera samples in vitro as chemo-sensitivity assay. Methodology: Current study involved 68 Iraqi brain tumor patients (30 Glioma; 14Glioblastoma Multi form (GBM), 10 Astrocytomas, 4 Ependymomas and 2 Oligodendrogliomas) 24 Meningiomas, 5 Schwannoma and other 8 different tumor types were investigated for serum level of IL-12, IL-17 and IL-22 by (ELISA) assay. Control samples were also enrolled in the study, including 30 healthy subjects (18 males and 12 females). Results: The present study illustrated that IL-12 mean serum level decreased to (33.9±9.9pg/ml) compared with its level in controls (47.68±3.5pg/ml). Also, there was a higher reduction in its level in Gliomas, Meningioma and Schwannoma (30.55±10.8, 37.6±8.4 and 33.8±8.7pg/ml, respectively). IL-17 serum level was highly significantly increased with a mean level (42.3±9.7pg/ml) as compared with control level (10.46±3.5pg/ml). In Gliomas, its serum level was (67.8±11.8 pg/ml) compared with its level in Meningioma and Schwannoma (33.8±3.4 and 27±7.7pg/ml, respectively). IL-22 showed significant increase (67±20pg/ml) in comparison with control level (22±5pg/ml). In Gliomas its level was (93±3pg/ml) compared with its level in Meningioma, schwannoma (60±2.6 and 77.78±7.4pg/ml, respectively). Conclusions: This study showed that all brain tumor types patients had increased circulating serum levels of IL-17 and IL-22, while decreased of IL-12. These data indicated that brain tumors might have a systemic effect on the immune system. The data also suggested a possible role of some Interleukins in pathogenesis of brain tumor. IL-12, IL-17 and IL-22 may also be a potential biomarkers and/or immunotherapeutic targets in some brain tumor types.

Introduction

Cancer is a generic term that refers to an extremely complex spectrum of diseases in which cells abnormally undergo uncontrolled and sustained chronic proliferation and growth as well as they are able to invade other tissues [1]. In spite of the advances in cancer field during the past decade, treatments are still insufficient and the survival of tumor patients remains at a figure of 14.6 months from the diagnosis for (GBM) (or little more for some other types) due to different factors [2]. There are over 120 brain tumor types and they were classified according to World Health Organization [3].

Previously, attempts were made regarding chemosensitivity testing and molecular biomarkers methods were used as techniques during the management of different types of malignant tumors in routine clinical practice, especially in neuropathology, then they evolved in using varient molecular markers which may highlight the tumor biology [4]. All these attempts remain dismal so far and very few of them have been used in clinical
practice. If these attempts are achieved, they will be very useful in demonstrating the neoplastic changes at a molecular level, facilitate the diagnosis and would be used as prognostic factors for patients’ survival and considered more advanced techniques that may be used instead of anatomical techniques.

Amongst the most promising ones for clinical use are cytokines and angiogenesis factors. Cytokines are low molecular-weight soluble protein messengers that are involved in all aspects of immunity and may be regarded as hormones of the immune system. These molecules can be secreted by various cells and act as signals between cells to regulate the immune responses. They have a variety of functions that facilitate immune effector mechanisms in cancer immunity and their mechanisms may be either growth stimulation or inhibition of pre-malignant or malignant cells by acquired and/or innate immunity.

Current study was aimed to evaluate some immune-markers in Iraqi patients by (ELISA) to assess the different levels of IL-12, IL-17 and IL-22 to illustrate ability of tumor in immune-modulatory activity to increase the progression of disease. Also, it was hoped that these markers can be used as indicators for rapid identification of novel brain tumor in patients, directly from their sera samples as a chemo-sensitivity assay.

Subjects and Method

Subjects: The study was approved by the Research Ethics Committee at Ministry of Health, Iraq. Current study involved 68 patients (60% males and 40% females) with age range of 2-85 years. The study also recruited 30 apparently healthy, cancer-free adults as controls (18 males and 12 females) with age range of 24-44 years.

Specimen Collection: From each participant, 3ml of venous blood were collected pre-surgical operation and dispensed in a plain tube for the collection of serum. Plasma was separated by centrifugation. The serum was distributed into aliquots (0.25ml each) and kept in the freezer (at -20°C) until assessment of cytokines by ELASA assay. As shown in Table (1) most of micro-/macro-environmental factors of patients were presented (state, gender, smoking, family history of malignancy, education, employment, health state (having secondary infection)). Serum levels of cytokines: Levels of IL-12, IL-17 and IL-22 were assessed in the sera by means of Sandwich-ELISA kit as a method, by using ready-used kits and the instructions of manufacturers (Elabscience (ALISA) KIT. USA) were followed. Statistical analysis: Serum levels of cytokines were statistically analyzed using Statistical Package for Social Sciences (SPSS; version 13). Data were presented as Mean±Standard Error (S.E.) and differences between means were assessed by analysis of variance (ANOVA) followed by Duncan’s test. The difference was considered significant when the probability (P) value was ≤0.05.

The results revealed that patients within the age group ≤44 years old had the highest percentage (58%), while the lowest percentage was those within the age group (65-85) years old who represented 10% of the total number of patients (Table 1).

Most of macro-environmental factors were not risk factors and micro-environmental parameters may be considered significant risk factors. Also, tumor location is prevalent among these age groups, similar to the results of. Tumor initiation and progression is a very complex process involving several agents such as immunological, mutations and micro-/ macro-environmental factors. On the other hand, suggested that immune alteration of inflammatory mediators may also be affected in brain tumor. In contrast, reported that viral infections of beta-herpes viruses were the most candidate agents of brain tumors and other risk factors may activate them. However, did not consider that the micro environmental factors as risk factors. Within the tumor environment, all or some of these factors or mediators may be responsible for tumor invasion, angiogenesis, cellular proliferation and suppression of certain immune functions by anyways.

*: These included 14 Glioblastoma Multi form (GBM), 10 Astrocytomas, 4 Ependymomas and 2 Oligodendrogliomas.
The present study illustrated that interleukin-12 serum level was decreased to (33.9±9.9pg/ml) compared with its level in the serum of healthy controls (47.68±3.5pg/ml) (Table 2 and Figure 1).

Also, results of current study showed that there was strong reduction in serum level of IL-12 in Gliomas, Meningioma and Schwannoma (30.55±10.8, 37.6±8.4 and 33.8±8.7pg/ml, respectively, Table 2). In case of IL-17, there was highly significant increase in its serum level (42.3±9.7pg/ml) as compared with controls (10.46±3.5pg/ml). In Gliomas, serum level of IL-17 was (67.8±11.8pg/ml) compared with its levels in Meningioma and Schwannoma (33.8±3.4 and 27±7.7pg/ml, respectively, Table 2).

Regarding IL-22, these was significant in its serum level (67±20pg/ml) in comparison with its level in controls (22±5pg/ml). In Gliomas, serum level of IL-22 was (93±3pg/ml) compared with Meningioma and schwannoma levels (60±2.6 and 77.78±7.4pg/ml, respectively, Table 2). Also, results of current revealed significant variation between glioma patients and those with other brain tumor types.

Figure 1 Serum levels (pg/ml) of IL-12, IL-17 and IL-22 controls and patients with different types of brain types.

The present study highlighted the importance of IL-12, IL-17 and IL-22 in pathogenesis of brain tumor as some cytokines showed significantly increased or decreased serum levels in the patients.

IL-12 is a key pro-inflammatory cytokine in response to infections, then emerged as a potent inducer of antitumor immunity with multiple biologic effects on peripheral blood lymphocytes [15]. Moreover, [16] reported that the level of IL-12 significantly reduced in Meningioma and Glioplastoma patients compared with control group. Furthermore, [17] reported a link between the immune system and brain tumor, and revealed that the T-lymphocyte infiltrations have been observed in the tumor regions of certain Glioma patients. In Iraq, the association between serum levels of cytokines and the development of Glioma and Meningioma was confirmed in Iraqi population. Finally, [18] observed that IL-12 p40 deficiency resulted in earlier appearance of 3-methylcholanthrene (MCA)-induced sarcomas as compared to wild-type mice.

Interleukin-17 is type I transmembrane protein that is produced by activated T cells [19] and is a pleiotropic pro-inflammatory cytokine that promotes T cell priming and enhances endothelial, epithelial and fibroblastic cells to produce numerous pro-inflammatory mediators involving IL-6, IL-1, TNF-α and chemokines [20]. Also, [21] observed elevated levels of IL-17A in bladder cancer patients.

IL22 is a major cytokine member of the IL10 cytokine super family, it is secreted by (Th17) and exhibits potent proinflammatory properties [15]. In contrast, IL22 was observed to have an antiapoptosis effect in lung cancer, acting in an autocrine manner and drive tumor progression via IL22 R1 signaling in large cell lymphoma [21]. Similarly, serum IL-22 levels were significantly higher in patients than in controls and no differences were observed between patients with Meningiomas, Disgerminomas and Macroadenomas of pituitary gland [22]. Also, [23] reported increased levels of IL-22 in high grade tumors.

The low percentage of IL-12 and high percentage of both IL-17 and IL-22 expression by brain tumor cells may be in favor of tumor progression. In agreement with the present results and accordingly, it was considered as an important factor produced by malignant brain tumors involved in the local immunosuppression [24]. Such cytokine has been reported to be secreted by glioma cells [25], and functionally it impairs T cells activity and responsible for the development of immuno-tolerizing Treg cells [26] [15].

Conclusions

This study showed that all brain tumor types patients had increased circulating serum levels of IL-17 and IL-22, while decreased of IL-12. These data indicated that brain tumors might have a systemic effect on the immune system. The data also suggested a possible role of some Interleukins in pathogenesis of brain tumor. IL-12, IL-17 and IL-22 may also be a potential biomarkers and/or
immunotherapeutic targets in some brain tumor types.

**Recommendations**

The IL-12, IL-17 and IL-22 serum levels have to be revisited, with other types of brain tumors, especially if the grading system of tumor is considered. Monitoring the changing in the neoplastic and immune chemokines in patients and developing chemo-sensitivity tests and molecular biomarkers methods which may highlight the tumor biology and facilitate the diagnosis as well as contribute to the prognosis of the tumor by more advanced techniques that may be used instead of the anatomical technique.

**Ethical Clearance:** The study was approved by the Research Ethics Committee at Ministry of Health, Iraq.

**Financial Disclosure:** There is no financial disclosure.

**Conflict of Interest:** None to declare.

Association between Two Different Methods for Determining Facial Types in Iraqi adults

Haider M. A. Ahmed

Department of Orthodontics, College of Dentistry, University of Baghdad, Iraq

Abstract

This study is aimed to determine the association between two different methods for determining the facial types in a sample of Iraqi adults with normal class I dental and skeletal relations.

Eighty dental students (33 males and 47 females) agreed and signed a consent form to participate in this study. Standardized frontal and profile photographs were taken for each student then analyzed using AutoCAD program (2016). Facial types were determined using two different methods, facial index method and facial taper angle method. Association between these two methods was determined by Chi-square test.

Keywords: Iraqi adults; dental students; facial index method; and taper angle method

Introduction

Faces would display some common features, but they differ from each other as they differ from the rest of us\(^{(1)}\). One of the most important objectives of orthodontic treatment is to improve facial appearance and that’s why we should be able to identify good looking faces\(^{(2)}\).

The first method to determine the facial types is determined by calculating the ratio between facial width (interzygomatic distance) and the anterior facial height\(^{(3,10,11)}\).

The second method is to calculate the facial taper angle which is formed by extending the right and the left lines connecting the most lateral points of the orbits and the junction of the upper and lower lips at the corner of the mouth\(^{(9)}\).

In this study, the relation between the two different methods of assessing facial types was tested in a sample of Iraqi adults with normal skeletal and dental relations.

Materials and Method

Sample

Out of 100 examined students from the College of Dentistry, University of Baghdad, only eighty subjects (33 males and 47 females) met the inclusion criteria.

Inclusion criteria

All of the subjects were Iraqi Arab in origin.

The age ranged between 19-23 years.

All of them had normal skeletal, molars, canines and incisors relationships.

All of them had complete permanent dentition regardless the third molars.

None of the subjects had any history of previous oro-facial surgery, orthodontic treatment or craniofacial disorder, such as cleft palate.

History and clinical examination\(^{(12)}\)

Each subject was asked to sit on the dental chair and a case sheet were filled about the name, age, gender and origin. Medical history, the history of facial trauma, dental history and orthodontic treatment. Then they were asked to look forward horizontally in the natural head position for clinical examination (extra-orally and intra-orally) to check their fulfillment of the required sample selection.

Photographic analysis

Frontal and lateral view photograph was taken for each student in a cephalostat based head position using digital camera (Sony Cyber Shot H 50, 9.1Mega pixels, DOI Number: 10.5958/0976-5506.2019.00943.4
The camera was fixed in position and adjusted in height to be at the level of subject ‘eyes with a height adjustable tripod. The distance from the camera to the subject was fixed at a distance of about 1.01m measured from the tripod’s column to the ear rods, the ear rods fit in the external auditory meatus in order to avoid the forward, backward, and tilting of the subject head (Cephalostat based head position). In the frontal view the subject was asked to look at the center of the lens of the camera, while in the profile view the subject were asked to look to a distant mirror which is placed in front of his/her face. To eliminate the problem of shadows on the submental region the subject held a small rectangular reflecting panel positioned horizontally against the chest just under collar bone. The blue background, 0.95 m width and 1.10 m length was made of a piece of cloth; a ruler was placed near the subject face to correct the magnification\(^4, 13\). The Frankfort horizontal plane was parallel to the floor\(^1, 14\).

Every frontal and profile photograph was analyzed using AutoCAD program (2016) to calculate the angular and linear measurements. The angle was measured directly as they were not affected by magnification, while the linear measurements were divided by scale for each picture to overcome the magnification.

Photographic Landmarks, linear and angular Measurements

Photographic Landmarks

Point n (soft tissue nasion): The point in the midline of both the nasal root and the nasofrontal suture, always above the line that connects the two inner canthi identical to bony nasion\(^5\).

Point gnathion (gn): correspond to skeletal gnathion which is the most anterior and inferior point of the soft tissue chin\(^6\).

Point zygoin (zyg), the most prominent point on the cheek area beneath the outer canthus and slightly medial the vertical line passing through it\(^5\).

Point End, Ene, the right and left internal corner of the eye\(^15\).

Point Abd ,Abe, the right and left corner of the mouth\(^15\).

Linear measurements

Interzygomatic distance (izd): it is the transverse distance between soft tissue zygoin on both sides\(^9\).

Anterior facial height (n-gn): it is the vertical distance between soft tissue nasion and gnathion\(^9\).

Facial type (Figure 1) was determined by calculating the ratio between facial width (izd) and anterior facial height (n-gn)\(^3\).

Euryprosopic (IzD/n-gn) the facial index is > 0.93

Mesoprosopic (IzD/n-gn) the facial index is \(\leq0.93\) and \(\geq0.83\)

Leptoprosopic (IzD/n-gn) the facial index is < 0.83

Angular Measurement

Facial taper angel (Figure 2) was formed by extending the right and left lines connecting the most lateral points of the orbits and the junction of the upper and lower lip at the corner of the mouth. The intersection will form an angel that mean value is 45 degree \(\pm 5\) degrees, larger values of this angel indicates wide face, more square faces, whereas lower ones indicates a longer narrower faces\(^9\).
Statistical Analyses

All the data of the sample were subjected to computerized statistical analyses using SPSS version 24 computer program. The statistical analyses included:

Descriptive Statistics (Frequency and percentages).

Inferential Statistics (Chi-square to find out the association between the two methods).

In the statistical evaluation, the following levels of significance are used:

Results

Table 1 show that in facial taper angle method the Euryprosopic facial type has the highest percentage in both genders and the total sample followed by Leptoprosopic facial type while the Mesoprosopic facial type has the least percentage. In females the Leptoprosopic and Mesoprosopic facial types are equal.

In the facial index method the Mesoprosopic facial type has the higher percentage among the sample followed by Euryprosopic facial type while the Leptoprosopic facial type is the least in both genders and the total sample.

There is a high significant association (p-value 0.000) between the two methods of facial type determination.

Table 1. The frequency distributions and percentage of facial types in the two methods and their association in both genders and total sample.

Discussion

Changes that occur due to different treatment mechanics are not the same for each person due to that fact that they differ in morphology and facial type therefore it’s necessary to figure out the individual person by describing his basic facial type to draw up an effective treatment for his malocclusion(16).

Facial type is related to the craniofacial complex growth which is contributed to malocclusion; several varieties may be present in facial form due to age and genders(17, 18).

Farakas and Munro in 1987 and Ramadan in 2001 used indirect method of measuring photographic measurements by using photographic print and ruler that resulted in error since these measurements are made on minimized images of a large objects, in that way any minor error will result in a false result after calculating magnification, while in this study anatomical landmarks were enlarged and calculated the actual size using a
Determination of the facial type using facial index method of calculating the ratio between facial width \((izd)\) and anterior facial height \((n-gn)\)\(^{(3)}\) indicates that Mesoprosopic facial type is the dominate type in both genders and the total sample this may due to the fact that this method utilize linear measurements and since the facial index is the result of dividing the facial width \((izd)\) on the facial height \((n-gn)\) that make the faces Mesoprosopic which is the neutral facial type lies between the Euryprosopic and Leptoprosopic types\(^{(3,10)}\) which agrees with Bishara and Jacobsen in 1995 and Ramadan in 2001\(^{(7,8)}\).

Determination of the facial type using facial taper angle indicates that Euryprosopic facial type is the dominant type since this method depends on angular measurements and the Euryprosopic faces characterized by wider set of eyes\(^{(3,10)}\) that increase the taper angel and resulting in wider faces which disagree with Bishara and Jacobsen in 1995\(^{(7)}\).

Chi square test shows a highly association between the two methods of facial type determination which makes using either way is the same and in my opinion using facial taper angel is the best since it depends on angular measurements not on linear measurements of facial index method.

Assessment of the Knowledge Regarding Risk Factors and Preventive Measures of Chronic Diseases among Students of Southern Technical University in Basrah

Majid A. Maatook¹, Rajaa Ahmed Mahmoud²

¹Health and Medical Technology College, Basrah, Iraq, ²Directorate of Health, Basrah, Iraq

Abstract

Chronic “non-communicable” disease is a term that describes any disturbance in the function of the body structure and metabolism that results in chronic change of the individual’s usual life style. However, despite knowing the great importance of knowing the risk factors of chronic diseases, very little information is known about the awareness level of university students on this issue.

The purpose of this study is to assess students’ knowledge about the risk factors and preventive measures of chronic diseases among students of Southern Technical University in Basrah.

It’s a cross-sectional study involved 350 college students from the Southern Technical University using a questionnaire approved Basrah Health Directorate/Research Unit/Training Department.

Age and sex were the most identified risk factors by the students (94.3% and 89.1% respectively). While the level of education and over-consumption of alcohol were found by the study to be among the least identified factors (24.9% and 21.7% respectively). Furthermore, on studying the knowledge of the study sample on the preventive measures of chronic diseases at the individual level, maintaining healthy weight was most identified preventive measure followed by avoiding smoking and eating health food (66.3%, 64.3% and 60% respectively).

For the overall knowledge of the Southern Technical University students regarding risk factors of chronic diseases, the study found that only one third of the students knows more than 50% of the total risk factors included in the study.

A poor overall knowledge regarding the risk factors of chronic diseases was found among the students of Southern Technical University in Basrah. That’s why a specified educational program is highly recommended by the present study targeting the students of Southern Technical University in Basrah.

Keywords: Chronic Diseases; Risk Factors; Basrah

Introduction

Chronic “non-communicable” disease is a term that describes any disturbance in the function of the body structure and metabolism that results in chronic change of the individual’s usual life style⁹.

According to the World Health Organization, chronic diseases are the causal factor of 60% of the total global deaths (³). A risk factor to a chronic disease on the other hand, is any factor, or exposure that rises the likelihood of causing a long-term sickness or injury (⁴).

Some studies reveals that having a risk factor for a chronic disease, is considered by the individual as a real life threat, and “the greater the perceived threat, the more likely an individual will change his/her behavior”⁹⁶. Nevertheless, being unaware of such a risk factor can impede having an an action to control/prevent it⁹.
Hindering a risk factor of a chronic disease therefore can result in a missed number of cases within the population and consequently might present lately as advanced and complicated cases.

In India, which doesn’t differ much than the other developing countries, youth and students are considered to be “an age of transformation” that are specifically well known to have practice some risky behaviors that increase the possibility of having chronic non communicable diseases.

Therefore targeting this age group of the population with special awareness programs is a mandatory preventive and control strategy that countries should focus on.

Yet, increasing awareness of communities regarding these risk factors plays a bigger role in preventing future complications and consequently decreasing the morbidity and mortality on a wider population level.

However, despite knowing the great importance of awareness activities regarding chronic diseases risk factors, very little information is known about the awareness level of university students on this issue.

**Materials and Method**

Study design and sampling methodology: The study is a cross-sectional one that took place during March-June 2018. 350 college students from the Southern Technical University were included randomly with the assurance of involving both genders in replying the questionnaire questions.

All of the included students were informed about the aim of the study and an informed consent was ensured for agreeing to participate.

A questionnaire was used after approval from Basrah Health Directorate/ Research Unit/Training Department. Questions included were selected in a way that can assess the knowledge of students regarding risk factors for chronic diseases such as stroke, diabetes and hypertension.

Risk factors for chronic diseases were chosen in the questionnaire according to the World Health Report 2010 so that it can capture risk factors according to the following classification:

**Individual related factors:**
- Background risk factors: age, sex, level of education and genetic composition;
- Behavioural risk factors: smoking, unhealthy diet, Excess alcohol drinking and physical inactivity.
- Intermediate risk factors, such as elevated blood lipids, diabetes, high blood pressure and overweight/obesity.

**Population related factors:**
- Social and economic conditions: poverty and unemployment.
- Environment, such as climate or air pollution;
- Cultural: practices, norms and values

Accordingly, the following factors were included in the questionnaire:
- Age
- Sex
- Level of Education
- Genetic causes
- Poverty
- Employment status
- Smoking
- Excess consumption of alcohol
- High blood pressure (or hypertension)
- Physical inactivity
- High cholesterol
- overweight/obesity
- Unhealthy diet
- High blood glucose
- Environmental pollution
- Cultural practices, norms and values

An overall knowledge of the risk factors was measured as how many students knows 50% of the risk factors or more(8 risk factor or more out of the 16 included in the questionnaire).

**Data entry/Analysis:**

For the data entry and analysis of the study, Microsoft Excel 2010 was used.
Results

Figure 1 shows that the study sample were approximately equal between male and females students.

Age and sex were the most identified risk factors by the students (94.3% and 89.1% respectively). While the level of education and over-consumption of alcohol were found by the study to be among the least identified factors (24.9% and 21.7% respectively). (Figure 2).

Table 2: Knowledge of Students about Risk Factors of Chronic Diseases (%)

Among other risk factors of chronic diseases found by the present study (as shown in table 1) are: environmental pollution, overweight/obesity, smoking, unhealthy diet and genetic causes (75.1%, 67.1%, 64.3%, 59.1% and 58% respectively).

Table 2 represents the knowledge of risk factors and its distribution according to gender among the study respondents. It was noted that Sex was the most identified risk factors by the male respondents (71.2%) followed by excess consumption of alcohol (59.2%), while the level of education was identified in 71.1% of the female respondents followed by unhealthy diet (79.1%).

On studying the knowledge of the study sample on the preventive measures of chronic diseases at the individual level, maintaining healthy weight was most identified measure followed by avoiding smoking and eating health food (66.3%, 64.3% and 60% respectively). (Figure 3)

On the other hand, at the community level, the present study found that students knows more about increasing green areas/gardens (62.9%) and implementing mass media campaigns (58.3%). (Figure 4)

On assessing the overall knowledge of the Southern Technical University students regarding risk factors of chronic diseases, the present study found that only one third of the students knows more than 50% of the total risk factors included in the study (Figure 5).
Discussion

Awareness of university students about the risk factors of chronic diseases is a crucial element in expanding this knowledge throughout the whole community as they will form the families they will be part of in the future.

In this present study, poor overall knowledge was found among Southern Technical students in Basrah regarding the risk factors of chronic diseases.

In a cross-sectional study done to assess the knowledge regarding chronic diseases among 634 students aged 17-19 years in Sri Lanka, poor level of knowledge was found specially about unhealthy lifestyle practices and its relation with chronic non communicable diseases(14).

A similar result was also found in other studies. One of these studies was done to assess awareness level of first year medical students in Karnataka, India about the risk factors of Cardio Vascular diseases(15). And also in another study involving students at Arizona State University, USA(16).

The present study confirmed a higher level of knowledge among female students compared to that of male students specially in relation to the unhealthy diet and the level of education as risk factors to chronic diseases.

Better knowledge about the risk factors of chronic diseases (specifically for Diabetes Mellitus) was also found among female in a cross sectional study done in Brazil(17).

A similar result was also found in another descriptive study conducted in Sulaimaniya city – Iraq during 2015, female knowledge was also found to be higher than male regarding risk factors of hypertension disease(18).

On the other hand, a third study aiming to assess the knowledge about diabetes among the males and females in rural population of India, found that both Males and females awareness level was poor with no gender difference observed regarding the knowledge of the disease(19).

In regards to studying the knowledge of the study sample on the preventive measures of chronic diseases at the individual level, maintaining healthy weight in addition to avoiding smoking and eating healthy were found by the present study as the most identified measures. These results can be compared with a cross-sectional study that was conducted in China during 2011, which revealed that eating healthy food was the most identified preventive measure among the study sample followed by decreasing smoking and drinking(20).

Conclusion

A poor overall knowledge regarding the risk factors of chronic diseases was found among the students of Southern Technical University in Basrah. Age and sex were the most identified risk factors, while the level of education and over-consumption of alcohol were found to be among the least identified factors. The students identified maintaining healthy weight, avoiding smoking and eating health food as the main preventive measures for chronic diseases. A specified educational program is highly recommended by the present study targeting the students of Southern Technical University in Basrah.

Histological Evaluation of Dental Pulp Response to Collagen with and without Laser Therapy

Ahmed D. N. Al-Agele, Ban Abdul Ghani Jamil

College of Dentistry, University of Babylon, Iraq

Abstract

New tissue formation in the pulp chamber can be observed after adequate infection control and the formation of a blood clot. Low-power lasers have been successfully used in dental practice, and it is known that wound healing is accelerated by their irradiation. Collagen has a potent hemostatic property and ability to aggregate platelets, that facilitates wound maturation by it is chemotactic for fibroblasts and improves their migration and attachment through its fibrillar structure. This property may enhance cell migration into the space between collagen membrane and the pulp wound.

The study was conducted to evaluate pulp response to direct capping with collagen with and without laser exposure by histological and histomorphometric analysis.

Direct pulp capping procedure was performed on 40 rabbit incisors which were divided into control (10 teeth capped by mineral trioxide aggregate) and experimental groups (10 teeth exposed to laser and sealed by MTA), (10 teeth capped by collagen), (last 10 teeth capped by collagen and exposed to laser) for 1 and 4 weeks periods.

Histological findings showed variable response of pulp tissue to the applied agents throughout the follow up healing periods as compared to control groups where only mineral trioxide aggregate (MTA) was applied to seal off the exposed pulp. Non-significant differences recorded among the studied groups in duration comparison. There was no significant difference between the Collagen group and Coll/Laser groups.

Keywords: Laser Therapy; Histological; Collagen; Dental

Introduction

The dental pulp is enclosed in a rigid environment comprising three mineralized tissues: dentine, enamel and cementum. This strong mechanical support protects the pulp from the microbial rich oral environment. Dental pulp is a richly vascularized and innervated connective tissue of mesodermal origin enclosed by dentin with communications to the periodontal ligament. It occupies the center of each tooth and consists of soft connective tissue. During the initial carious attack, the pulp turn out to be inflamed and gradually, the evolution of the lesion leads to pulp necrosis and infection. New tissue formation in the pulp chamber can be observed after adequate infection control and the formation of a blood clot. Scaffolds with properties of extracellular matrix temporally support structures for cell growth, differentiation, and tissue formation.

It is still unclear whether there are sufficient numbers of resident stem cells within the pulp to achieve effective pulp repair and regeneration. However, the recruitment of MSCs from outside the pulp would appear to provide an efficient mechanism for locally raising stem cell numbers significantly within a short time scale after injury.

Mineral trioxide aggregate is a bioactive silicate cement that has proven to be an effective material for direct pulp capping teeth of dogs and non-human primates, as studies conducted by Ford, and Camilleri have demonstrated. Its small particles size, sealing
ability and marginal adaptation, the alkaline pH once hardened and the slow release of calcium ions are all behind its success. Laser treatment has advantages with respect to control of hemorrhage and sterilization. Laser irradiation of the exposed dental pulp is performed to stop bleeding and sterilize the area around the exposure. Low-level laser light seems to create many positive functions, such as accelerated wound healing, pain relief, regeneration, and immune enhancement through providing the energy that interacts with the cells.

Collagen, vitronectin, fibronectin, and laminin are the main extracellular matrix proteins (ECMP) which forms the natural scaffold. These ECMP have functions ranging from providing cell anchorage, sequestration of growth factors, and signal cells to migrate, differentiate, and proliferate through integrin receptor-mediated signaling pathways.

Collagen that has a potent hemostatic property and the ability to aggregate platelets, that facilitates wound maturation by enhancing initial blood clot and fibrin linkage formation. It is chemotactic for fibroblasts and improves their migration and attachment through its fibrillar structure. This property may enhance cell migration into the space between collagen membrane and the pulp wound. These collagen fibers are able to induce mineral formation and orient hydroxyapatite crystals.

**Materials and Method**

**Materials:** xylazine, ketamine, MTA, Collagen.

**Study Design**

Total samples of 40 rabbit incisors were selected. The collected teeth were divided into groups according to the applied agent for the healing periods (1 and 4 weeks) as follow:

(Control group (C), Laser group (L), Collagen group (Coll), Collagen/Laser group (Coll/L))

**Pulp capping procedure**

Pulp chamber was opened under aseptic conditions. Irrigation of normal saline was then performed until hemostasis achieved, then the cavity dried gently by cotton. Pulp capping was performed by using laser handpiece, tip No. (E4), bioactivation wavelength of (808 nm) was applied to the remaining pulp tissue for 2 seconds. For laser and collagen/laser groups. A tweezers used to add small piece of collagen sponge to fill the coronal pulp space. For collagen, and collagen/laser groups. Then MTA material applied to seal cavity for all studied groups.

**Histomorphometric analysis**

**Predentin thickness analysis**

The distance between the odontoblastic cell layers of the pulp to the border line of the dentin was considered for the measurement of the predentin thickness. A total of nine sites were considered for each specimen.

**Inflammation severity scores.**

The severity of the inflammatory infiltrate and the extension of pulp necrosis were determined using a four-point scoring system at power x40 of magnification based on the following criteria:

1. absence or insignificant presence of inflammatory infiltrate / necrosis.
2. inflammatory infiltrate / necrosis close to the pulp medication, reaching up to one third of the root canal pulp tissue.
3. inflammatory infiltrate / necrosis involving up to two thirds of the root canal pulp tissue.
4. inflammatory infiltrate / necrosis involving more than two thirds of the root canal pulp tissue.

**Statistical Analysis**

Data were analyzed using SPSS (statistical package of social science) software. The following statistical data analysis approaches were used in order to analyze and assess the results of this study:

Graphical presentation by using Line charts.

Inferential data analysis to accept or reject the statistical hypotheses, which included the following:

Analysis of Variance (ANOVA) for equality of means of several independent Groups with least significant difference (LSD and Games-Howell) Methods.

General Linear model (ANOVA) for two or three factors.
Results

Histological findings

One week duration Microphotograph view of control group after one week of pulp capping with MTA material shows pulp canal which appears filled with necrotic pulp and inflammatory cells, and a layer of reparative dentin, (figure 1). View of laser group shows thin layer of predentin deposited by odontoblasts which appear disoriented at some sites, organizing collagen fibers and fibroblasts (figure 2).

Histological examination of tooth section after one week of collagen application shows areas of hemorrhage, necrotic tissue (figure 3). After one week of laser exposure of pulp tissue capped with collagen the histological examination of tooth section shows remodeling fibers of pulp, a calciotraumatic line separates the tubular secondary dentin from the reactionary dentin, (figure 4).

Four weeks duration

Microphotograph view of control group after 4 weeks of pulp capping with MTA material shows conditions of inflammation and disorganization behavior of the pulp tissue, areas of hemorrhage (figure 5). Histological examination of tooth section after 4 weeks of collagen application shows different grades of inflammation and reorganization of pulp tissue with numerous blood vessels (figure 6).

Discussion

Pulp exposure can occur due to caries process, trauma or accidentally in an operative procedure. In response to these stimuli, at the exposure site, a new odontoblast-like cells are recruited and differentiated to synthesize reparative dentin [15]. Clinical studies have demonstrated induction of an early calcific tissue formation with MTA after 1 and 2 weeks, suggesting that mild inflammation of pulp with MTA is due to high alkalinity and is a reversible process [15, 16].

Histological evaluation of pulpal response to collagen particles impregnated in antibiotics revealed moderate to severe inflammatory cells with newly formed blood vessels and disorganized odontoblastic cell layer after 7, 15, and 30 days with dentinal bridge formation in two specimens proved efficacy of collagen as pulp medicament and its regenerative characteristics [12]. Which matches histological findings of present study regarding collagen groups although dentin bridge could not be detected in studied specimens may be due to application of collagen without addition of any medicament.
In addition, the creation of a reparatory bridge was not noticed in any of the tested samples after 6 weeks duration although collagen obviously led to the forming of new blood vessels and increased extravasation of erythrocytes as reported by Marsan [18] who used collagen for direct pulp capping of mongrel dogs incisors. This finding was explained as follows: Some kind of stimulative chemical factors (may be vitamins, amino acids and other nutritive factors) are necessary for the development of the protective reaction of traumatized dental pulp, and mere contact with biocompatible non-stimulative matter is not sufficient. Collagen, although possessing the capacity to initiate in vitro mineralization, does not show that feature in vivo conditions so creation of a dentine bridge was not observed.

**Predentin thickness (PT)**

With laser exposure PT mean counts showed the highest record (11.2mm) group comparison showed a significant difference between control and laser groups in studied durations which may indicate that use of LLLT in pulp capping before sealing the pulp with MTA material may enhance predentin formation, which seems to agree with Matsui [19] who used Alizarin Red S staining to reveal the amount of calcium which was higher in the laser irradiated group than in control group. Regarding the present findings of collagen application on exposed pulp the result revealed that mean values of PT (which in turn would be mineralized forming the new reparative dentin) were higher than control group, and there was significant difference between both groups while disagree with Suzuki [17] who found that: Laser irradiation was effective in arresting hemorrhaging but showed a tendency to delay reparative dentin formation.

**Inflammatory response analysis**

Giro [20] found that on the 7th day, the inflammatory cell response was significantly greater in pulp of teeth received corticosteroid/antibiotic dressing group. Regarding healing periods in the present study the inflammatory response scoring showed highest values after 1 week duration, and there was a significant difference between (C, Coll), and (C, Coll/L) groups while the other groups showed non-significant difference in duration comparison of applied materials. That might indicate that the use of collagen as a pulp capping material may reduce the inflammatory severity of the pulp.

Application of collagen with laser on exposed pulp might not affect the inflammatory reaction as results of group comparison showed a non-significant difference between collagen and collagen /laser groups. In this study, periods of 1 and 4 weeks were chosen to evaluate the effect of capping materials on pulp tissues. A study used different time interval (8 weeks duration) by Aljandan [21] who found this period to be long because a thick layer of reparative dentine had been formed by that time. Accordingly, interval of present study would be recommended as fairly enough for further studies on rabbits, as was noticed fairly proper growth of reparative dentine. Taking into consideration that rabbit incisor teeth are open-rooted and, in healthy animals, grow continuously [22].

**Conclusion**

It appears from the obtained findings of this study that pulp capping with collagen was efficient and combined laser therapy might have additive benefit in enhancing healing process.

Investigation of Fungi Resistant to Disinfectants used in Burn Units at Baquba Teaching Hospital

Abbas M. AL-Ammari
Biology Department, College of Science, Diyala University, Iraq

Abstract
Fungal contamination of hospital environment considered as risk factor for burned patients. Therefore, the objective was to investigate the occurrence, distribution, and diversity of fungi in burn units at Baquba teaching hospital, Iraq.

One hundred eighty specimens environmental and instrumental specimens collected from Burn units at Baquba teaching hospital using transport media swabs. Ninety specimens were collected before sterilization and equal numbers were collected after sterilization. Swaps were cultured onto different culture media, the cultivated plates were incubated at 28ºC for 7-14 days with daily examination and observation.

Before and after sterilization, the percentages of fungal contamination were 63.3% and 40.0%, respectively. Before sterilization, *Aspergillus niger* was identified as the major contaminated species in burn units, with a percentage 19.3%. Whereas after sterilization, *A. niger* and *Penicillium* spp. were identified as the major contaminated species in burn units, with equal percentage 22.2%.

Our results concluded that a high frequency of fungal contamination in the burn units, particularly with *Aspergillus* spp. so these conditions considered a risk factor for burned patients and other persons in the hospital in particular who suffer from deficiency in immune system.

**Keywords:** Burn units, fungi, Before sterilization, after sterilization *Aspergillus* spp.

Introduction
Fungi constitute about 7% of all eukaryotes on the earth [1]. Hospitals introduce an excellent environment for a wide range of opportunistic fungi, therefore contamination of hospital environment by fungi considered as risk factor for causing fungal infection especially in patients with immunosuppression [2]. In hospital environments fungal spores are transmitted through air, air conditioning, patients and visitors [3].

Opportunistic fungi characterized with their ability to attack people who undergo deficiency in immune system due to many reasons like widespread use of antibiotics, chemotherapy, HIV, diabetes and organ transplant [4]. Opportunistic fungi include two forms, fungi which grow in form of multicellular filaments called molds such as *Aspergillus* spp., *Penicillium* spp. *Mucor* spp. and *Rhizopus* spp. whereas fungi grow as unicellular called yeast such as *Candida* spp., *Cryptococcus* spp. and *Malassezia* spp [5].

Disinfectant are used widely in health care settings especially, hospitals. Commercial disinfectants are classified as fungicides and fungistatics. Disinfectants that have low-level activity against fungi should not be used for disinfection of medical instruments that put in contact with the patient and environment. The most common of used disinfectants are alcohol, iodophors, aldehydes, and a chlorine-based agent were assessed at different concentrations. The long term use of disinfectants have confirmed some valuation on the development of fungal resistance, in particular cross-resistance to antibiotics [6].

It is important to note that antifungal activity can be influenced by different factors such as presence of an organic load, dilution, formulation effects, temperature, synergy, and test method \cite{7}. Fungal infections are major causes of high mortality in burn wound injuries. Therefore, the incidence of fungal infections in burn wound patients appear to be a rising threat \cite{8}.

**Materials and Method**

One hundred eighty specimens collected from Burn units at Baquba Teaching Hospital using transport media swabs, the environmental and instrumental specimens including (air loaded of units, Beddings, Carriages, Floors, Spirometer and walls). Ninety specimens were collected before sterilization and equal numbers were collected after sterilization for a period of 5 months. Swabs were streaked onto different culture media include [Sabouraud’s Dextrose agar (SDA), Potato Dextrose agar (PDA) and Czapek agar], the cultivated plates were incubated at 28°C for 7-14 days with daily examination and observation \cite{9}.

Macroscopic features (Morphology and reverse of Colony) and Microscopic features (shape and color of hyphae and conidia) were examined according \cite{10}. Fungal isolates were cultured on slant of SDA and stored in a refrigerator at 4°C. This method was repeated every 3 weeks by activated culture on Sabouraud’s dextrose broth and re-cultured on slant of SDA to be still active for three months.

**Results**

A total of one hundred eighty specimens had been included in this research, consisting of equal proportion before and after sterilization, which was 50% (Table 1).

Discussion

The contamination of hospital environments especially, that settled in the neighborhood of burned patients, may cause complications burn wound infection in particular who suffer from immunodeficiency. In this survey, *A. niger* was the most common isolate from burn units before and after sterilization. This indicates a risk of acquiring fungal infection from the instruments and environment which surrounded burn units. These results agree with [11, 12] who revealed that *A. niger* was the most fungal contaminated of burn units. We found *A. fumigatus* was responsible for 4.6% of infections occurred in burn patients. The mortality rate has been estimated to be as high as 95% and even higher in immunocompromised patients [13].

According to the sites of specimens, this agree with [14] who founded that air was most contaminated. The explanation of these results may be due to the hot weather and humidity in Iraq. In view of the results of this survey, it is recommended that a regular decontamination of burn units especially in thermally injured children and other immunocompromised patients [15]. *Aspergillus* spp. are exist in different environments such as water, soil and decaying foods, so many places could be named as the hospitals reservoirs of *Aspergillus*, places such as, ventilation system, exhausted water pipe system, air exposed to dust from wards under construction [13].

Conclusion

The results of this survey concluded a high frequency of fungal contamination in the burn units, particularly with *Aspergillus* spp. and these conditions should be considered as a risk factor for burned patients and other persons in the hospital in particular who suffer from deficiency in immune system.

Choosing of the Best Estimate of the Parameters of the Multiple Linear Regression Model of Infertility Using the Weighted Least Squares (WLS) and Robust M

Saif Hussein Ali¹, Ahmed Hamza Abood², Shrook.A.S.AL-Sabbah¹

¹Statistics Department, Administration And Economics College, Kerbala University, Iraq.
²Department of Anatomy, Medical College, Kerbela University, Iraq

Abstract

In this research, methods were used to estimate the parameters of the multiple regression model, namely the method of the weighted least squares (WLS) and the robust- M methods, to show the effect of the presence of outliers values in the observation values on the regression model. A simple random sample of 151 infertile individuals are drawn as dependent variable (size of egg), and Independent variables (age, weight, infertility type, LH Hormone, FSH Hormone, PL Hormone) to compare these methods and to determinate the best method of estimation using measures mean square error MSE and Determination Coefficient, and through the program Stata we found that the best method to estimate was robust- M (Turkey’s biweight).

Keywords: robust M, multiple regressions, estimation

Introduction

Statistical methods are based on a set of important assumptions to obtain a precise regression model, and the probability distribution of data is the most important of the assumptions under study, which are often distributed normally. Sometimes, distributed of data take a different pattern and may not be represented by a particular pattern of distributions, this may sometimes be due to the presence of outliers, which leads to imbalance in the assumptions of the least squares and then loses their good properties, for that we must find a method that is not sensitive to the presence of outliers values and gives us efficient estimates.

Aim of Research:

Comparison of M-robust methods with the WLS method to study the effect of outliers values in the multiple linear regression model.

Theoretical Side:

Weighted least squares method (WLS)¹

The least squares method assumes that there is a constant variation in errors, then we will use the weighted least squares method when the error that not constant, i.e. violation of the least squares method assumptions which is Hetrocadastasity, then the model is:

\[ Y = X\beta + U \]

Where U. It is supposed to be multivariate is usually distributed with a medium vector (0) and variance-covariance matrix, note that each weight is inversely proportional to the error variance, and the weighted least squares are estimated.

In the general linear model:

\[
\begin{bmatrix}
\sqrt{W_1}Y_1 \\
\sqrt{W_2}Y_2 \\
\vdots \\
\sqrt{W_n}Y_n
\end{bmatrix} = \begin{bmatrix}
\sqrt{W_1}X_{11} & \ldots & \sqrt{W_1}X_{1k} \\
\sqrt{W_2}X_{21} & \ldots & \sqrt{W_2}X_{2k} \\
\vdots \\
\sqrt{W_n}X_{nk1} & \ldots & \sqrt{W_n}X_{nkk}
\end{bmatrix} \begin{bmatrix}
\beta_1 \\
\beta_2 \\
\vdots \\
\beta_k
\end{bmatrix} + \begin{bmatrix}
\sqrt{W_1}U_1 \\
\sqrt{W_2}U_2 \\
\vdots \\
\sqrt{W_n}U_n
\end{bmatrix}
\]

We will represent as a shortcut:

\[ P^{-1}y = P^{-1}X\hat{\beta} + P^{-1}u \quad (1) \]
In the general linear model above satisfy the least squares method assumptions because:

\[
E(u, \hat{u}_r) = E\left[ (P^{-1}U - (P^{-1}U)^\prime) \right] \\
= E\left[ (P^{-1}U U^\prime P^{-1})^\prime \right] \\
= P^{-1}E(U U^\prime)P^{-1} \\
= \sigma_u^2 P^{-1} \hat{P} \hat{P}^{-1} \\
E(u, \hat{u}_r) = \sigma_u^2 I_n \quad \text{---(2)}
\]

Equation (2) satisfies the assumptions of the Auto-correlation and satisfies the hypothesis of Heterocedastasy, Therefore, the assumptions of the regression model are realized, and will we use the least squares approach to estimate the vector of parameters as following:
$P^{-1}y = P^{-1}X\hat{\beta} + P^{-1}U$

$P^{-1}U = P^{-1}y - P^{-1}X\hat{\beta}$

$(P^{-1}U)(P^{-1}U) = (P^{-1}y - P^{-1}X\hat{\beta})(P^{-1}y - P^{-1}X\hat{\beta})$

$= (\hat{\beta}P^{-1} - X\hat{\beta}P^{-1})(P^{-1}y - P^{-1}X\hat{\beta})$

$(U(P^{-1}U)^{-1}) = \hat{\beta}P^{-1}P^{-1}y - X\hat{\beta}P^{-1}P^{-1}X\beta - \hat{\beta}X\hat{\beta}P^{-1}P^{-1}Y + \hat{\beta}X\hat{\beta}P^{-1}P^{-1}X\beta$

$(UW^{-1}U) = \hat{\beta}W^{-1}P^{-1}P^{-1}y - \hat{\beta}W^{-1}P^{-1}X\beta - X\hat{\beta}W^{-1}X\beta + \hat{\beta}X\hat{\beta}W^{-1}X\beta$

By taking the first partial differential for the vector $(\beta)$ we will get:

$\frac{\partial(UW^{-1}U)}{\partial \beta} = -2XW^{-1}Y + \hat{\beta}W^{-1}X\beta_{WLS} = 0$

$(XW^{-1}Y) = \hat{\beta}W^{-1}X\beta_{WLS}$

$\hat{\beta}_{WLS} = (XW^{-1}X)^{-1}XW^{-1}Y \quad ... (3)$

Equation (3) gives us the best unbiased linear estimate of the parameter $(\beta)$ in the case of Heterocadastasity and is called the method of estimation in the method of Weighted Least Square (WLS), since this method is based on weights mainly.

$\begin{bmatrix}
\hat{\beta}_0 \\
\hat{\beta}_1 \\
\vdots \\
\hat{\beta}_K
\end{bmatrix} = (XW^{-1}X)^{-1}XW^{-1}(X\beta + U)$

$= (XW^{-1}X)^{-1}XW^{-1}X\beta + (XW^{-1}X)^{-1}XW^{-1}U$

As:

$\therefore E(\hat{\beta}_{WLS}) = \beta \quad ... (4)$

And the variance-covariance matrix for the parameters vector is:

$\hat{\beta}_{WLS} - \hat{\beta} = (XW^{-1}X)^{-1}XW^{-1}U$
Var − Cov\(^{\beta_{WLS}}\) = Var − Cov \[
\begin{bmatrix}
\hat{\beta}_0 \\
\hat{\beta}_1 \\
\vdots \\
\hat{\beta}_K
\end{bmatrix}
\] = E \[
\left(\hat{\beta} - \beta \right) \left(\hat{\beta} - \beta \right)'
\]

= E \left\{ \left(\hat{X}W^{-1}X\right)^{-1}\hat{X}W^{-1}U \right\} \left(\hat{X}W^{-1}X\right)^{-1}

= \sigma^2_0 \left(\hat{X}W^{-1}X\right)^{-1}\hat{X}W^{-1}X(X\hat{X}X)^{-1}

\text{var − cov}(\hat{\beta}_{WLS}) = [\sigma^2_0(\hat{X}W^{-1}X)^{-1}] \quad \ldots (5)

The equation above gives us the variance and the co-variation of the parameters parameter (\(\hat{\beta}_{WLS}\)) which contains the parameters of the model studied in case of Heterocadastasy. Where the sample variance (\(S^2_\epsilon\)) can be estimated as follows:

\[
E(S^2_\epsilon) = \frac{E(\hat{\epsilon}\hat{\epsilon}^*)}{n-k-1}
\]

= \frac{(P^{-1}Y - P^{-1}\hat{X}\hat{\beta}) (P^{-1}Y - P^{-1}\hat{X}\hat{\beta})}{n-k-1}

= \frac{\left(\hat{Y}P^{-1} - \hat{\beta}\hat{X}P^{-1}\right) (P^{-1}Y - P^{-1}\hat{X}\hat{\beta})}{n-k-1}

\[
S^2_\epsilon = \frac{\hat{\epsilon}W^{-1}\hat{\epsilon}}{n-k-1} \quad \ldots (6)
\]

\[
\hat{\epsilon}W^{-1}\hat{\epsilon} = \left(\hat{Y} - \hat{\beta}\hat{X}\right) W^{-1} \left(\hat{Y} - \hat{\beta}\hat{X}\right)
\]

= \left(\hat{Y} - \hat{\beta}\hat{X}\right) W^{-1} \left(\hat{Y} - \hat{\beta}\hat{X}\right)

= \hat{Y}W^{-1}Y - \hat{\beta}W^{-1}X\hat{\beta} - \hat{\beta}\hat{X}W^{-1}Y + \hat{\beta}\hat{X}W^{-1}X\hat{\beta}
\[
= \hat{Y}W^{-1}Y - \hat{\beta}\hat{X}W^{-1}Y
\]

\[
S^2_e = \frac{\hat{Y}W^{-1}Y - \hat{\beta}\hat{X}W^{-1}Y}{n-k-1} \quad \ldots (7)
\]

Robust Estimation Methods\textsuperscript{[2]}

The traditional methods of estimating the parameters of the model are inaccurate in the analysis of data when there is a defect in regression assumptions, or presence of outlier's values or the distribution of random error is not normally distributed. The existence of one or more outlier values will lead to effect in LS properties, the robust estimator should then be used for conservation on the properties of parameters when you violate model assumptions, we shall address some of the following robust methods of estimation as following:

The robust-M method\textsuperscript{[4][6][5][3]}

It's one of robust estimation method, the letter M is mean that the maximum Likelihood. The M estimate is:

\[
\hat{\beta} = [\beta_n(x_1, x_2, \ldots, x_n)] = \beta \quad \ldots (8)
\]

By taking expectation:

\[E[\beta_n(x_1, x_2, \ldots, x_n)] = \beta\]

From equation (8):

\[
\hat{\beta} = [\beta_n(x_1, x_2, \ldots, x_n)]
\]

Which is minimum variance unbiased estimation (MUVE), and M-estimator have minimum variance comparing with the others estimates.

\[
\text{var} \left( \hat{\beta} \right) \geq \frac{[\hat{\beta}]^2}{nE[\frac{\partial}{\partial \beta} ln f (x_i; \beta)]^2}
\]

Where \( \hat{\beta} \) another unbiased linear estimator for \( \beta \)

The principle of the M method of estimation is to reduce or minimize the P residual function:
\[ \beta_m = \min_{\beta} P(y_i - \sum_{j=0}^{k} x_{ij}\beta_j) \ldots (9) \]

We must solve:

\[ \min_{\beta} \sum_{i=1}^{n} P(u_i) = \min_{\beta} \sum_{i=1}^{n} P(e_i / \sigma) \]

\[ = \min_{\beta} \sum_{i=1}^{n} P \left( \frac{y_i - \sum_{j=0}^{k} x_{ij}\beta_j}{\sigma} \right) \]

To obtain the (9) equation we put the estimate \( \sigma \) as following: \(^{[7]}\)

\[ \hat{\sigma} = \frac{\text{MAD}}{0.6745} = \frac{\text{median}|e_i - \text{median}(e_i)|}{0.6745} \]

For the function \( \rho \), Tukeys' bissquares, the objective function:

\[ p(u_i) = \begin{cases} 
\frac{u_i^2}{2} - \frac{u_i^4}{2c^4} + \frac{u_i^6}{6c^6}, & |u_i| \leq c \\
\frac{c^2}{6}, & |u_i| > c 
\end{cases} \]

Moreover we are looking for the first partial derivative \( \beta_m \) for \( \beta \)

\[ \sum_{i=1}^{n} x_{ij} \psi \left( \frac{y_i - \sum_{j=0}^{k} x_{ij}\beta_j}{\hat{\sigma}} \right) = 0 \ldots (10) \]

\[ , j = 0, 1, 2, 3, \ldots, k \]

Where:

\[ p' = \psi \], is the first observation for the independent variable \( \sum_{i=1}^{n} x_{i0} = 1 \)

\[ (e_i) = \frac{\psi \left( \frac{y_i - \sum_{j=0}^{k} x_{ij}\beta_j}{\hat{\sigma}} \right)}{\left( \frac{y_i - \sum_{j=0}^{k} x_{ij}\beta_j}{\hat{\sigma}} \right)} \ldots (11) \]

\[ W_i = \begin{cases} 
\left[ 1 - \left( \frac{u_i}{c} \right)^2 \right]^2, & |u_i| \leq c \\
0, & |u_i| > c 
\end{cases} \]

We take \( c = 4.685 \) for odd Tukeys biasquare function, and then the equation (10) became:
\[ \sum_{i=1}^{n} x_{ij}w_i(y_i - \sum_{j=0}^{k} x_{ij}\beta_j) = 0 \quad , j=0,1,...,k \quad \ldots (12) \]

This method assumes that initial estimator \( \beta \) and \( \hat{\sigma}_i \), then:

\[ \sum_{i=1}^{n} x_{ij}w_0(y_i - \sum_{j=0}^{k} x_{ij}\beta_0) = 0 \quad , j=0,1,...,k \quad \ldots (13) \]

The equation (13) may be written as:

\[ X'W_iX\beta = X'W_iY \quad \ldots (14) \]

\( W_i \) is a matrix of rank \( n \times n \) and its weight has the main diameter elements. Equation (13) is known as the WLS and the solution to this equation is given an estimate of \( \beta \), in other words:

\[ \hat{\beta} = (X'W_iX)^{-1}(X'W_iY) \]

Andres function \cite{8}

\[ \psi(u) = \begin{cases} \sin(u/c) & ; |u| < c\pi \\ 0 & ; |u| \geq c\pi \end{cases} \ldots (15) \]

C is take: 2.1 , 1.5 , 1.339

Applied side:

**Fertility:** \cite{9}

Fertility is influenced by age and weight of the women. Generally, women’s reproductive potential decreases as they get older and fatter due to normal, age-related changes in quantity and quality of egg in the ovaries and the eggs tend to get smaller and less (loss of ovarian reserve).

With the beginning of each menstrual cycle, a group of eggs matures regularly inside of fluid-filled spheres called “follicles.” Under the stimulation of pituitary hormones such as follicle-stimulating (FSH) and prolactin (PL). Normally, only one of those follicles will reach maturity and release an egg (ovulate). The process of ovulation occurs under the effect of another pituitary hormone, that is luteinizing hormone (LH) and the remainder of follicles gradually will stop growing and degenerate.

Based on this information, we used robust methods as a statistical method suitable for studying data. Six independent variables (age, weight, infertility, LH, FSH, PL) were found to affect the response variable (egg size) in a simple random sample consisting of (151) people with infertility

**Data descriptive:**

A simple random sample of 151 infertile individuals in Dhi-Qar Governorate of Al Hussein Educational Hospital - Center of Infertility is represented by the following:

The dependent variable (Y) represents the size of the egg.

The first independent variable (X1) represents the age.

The second independent variable (X2) represents the weight.

The third independent variable (X3) represents the infertility type.

The fourth independent variable (X4) represents LH
Hormone.

The fifth independent variable (X5) represents FSH Hormone.

The sixth independent variable (X6) represents the PL Hormone.

[9] Egg size:

The egg size reflects the quality of the eggs and is considered as an indicator to egg reserve in the ovary and has a significant impact on the pregnancy potential of the ladies. Women are less likely to become pregnant and more susceptible to miscarriage if the quality and number of eggs decreases. These changes were observed in women who reach their mid-thirties more than others. Therefore, the age of women is the most accurate test of eggs quality

[10]: Age

A women’s best reproductive years are in their 20s. Fertility gradually drops in the 30s, chiefly after age 35

Weight: [10]

Excess weight affects ovulation as makes it irregular and thus leads to infertility due to the effect of weight on the levels of hormones, specifically progesterone and estrogen, which have a role in the preparation of the uterus to receive, and implantation of fertilized eggs in the lining of the uterus

Type’s infertility

Primary infertility:

It is the infertility that afflicts women since the beginning of their married life and its causes are due to disorders in the endocrine gland i or chromosomal abnormalities

Secondary infertility

Is the infertility that afflicts a woman after giving birth to a child or two children or after an abortion or as a result of complications of childbirth or abortion. All uterine infections can lead to an increase in infertility rate

[11] Luteinizing hormone (LH)

Is a hormone produced by the anterior lobe of the pituitary gland. It triggers ovulation

Is a hormone produced by the anterior lobe of the pituitary gland. It regulates the development, growth, pubertal maturation, and reproductive processes of the body

Prolactin Hormone (PL): [12]

Is a hormone produced by the anterior lobe of the pituitary gland? Elevated levels of prolactin decrease the levels of sex hormones estrogen in women that leads to prevent implantation of fertilizing egg and infertility

WLS:

In this method to estimate and test the parameters of the robust regression model, we used the SPSS statistical program, according to the null hypothesis:

Using the Stata program, the results of estimating the multiple regression model using WLS were presented in Table (2-1) as follows:

Table (1) shows the values of regression coefficients in WLS

<table>
<thead>
<tr>
<th>t</th>
<th>Standard error</th>
<th>regression coefficients (b)</th>
<th>Independent variables</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>
The above table shows the significance of age and weight variables and the PL hormone because the value of P-value is smaller than (0.05). And non-significant type of infertility and hormone LH and FSH hormone, because the probability values associated with each of them amounted to (0.516, 0.897, 0.186), the largest (0.05).

**Tukey’s biweight:**

An important method used to estimate the parameters of the robust regression model, is to test the null hypothesis:

Using the statistical program (stata) where the results of the estimation of the multiple regression models using M (Tukey’s biweight) presented in Table (4-3) as the following:

**Table (2) shows the values of regression coefficients in Tukey’s biweight**

<table>

</table>

Table 2 shows the significance of age, weight, LH, FSH, and PL hormones, because the value of P-value for each is less than 0.05). While the results of the test did not show significant variable infertility type, P-value) was (0.380636) greater than 0.05).

**Andrew’s sine:**

In this way, the statistical program Stata was used to estimate and test the parameters of the robust regression model, noting that the null hypothesis:

Using the Stata program, the results of the estimation of the multiple regression model using the H (Andrews sine) regression method were presented in Table (2-2) as follows:

**Table (3) shows the values of regression coefficients in the M Andrews sine method**

</tr>
</tbody>
</table>
(P-value) is smaller than the mean level of 0.05). While the results of the test did not show significant variables of the type of infertility and LH hormone and FSH hormone, because the value of (P-value) respectively (0.481218, 0.651577, 0.299960), respectively, and that the value of (P-value) each of the largest 0.05).

Table (4) shows the Determination Coefficient and MSE

<table>
<thead>
<tr>
<th>Method</th>
<th>MSE</th>
</tr>
</thead>
<tbody>
<tr>
<td>WLS</td>
<td>1.288</td>
</tr>
<tr>
<td>M (Andrews sin)</td>
<td>0.429</td>
</tr>
<tr>
<td>M Turkey’s bi weight</td>
<td>0.0551</td>
</tr>
</tbody>
</table>

In order to compare the estimation methods, the MSE and the criterion of the determination coefficient. The results were as in the above table, which shows the advantage of the regression method of M (Turkey’s biweight) method because the value of MSE is 0.0551, The determination coefficient is 0.9997 which is the highest value.

Conclusion

Based on the estimation results of the methods which used in the applied side, some of the conclusions were reached:

1. Turkey’s biweight method is preferable to MSE and \( R^2 \).
2. Methods of estimation showed significant effect of age in infertility. These methods also showed a significant weight variable followed by a significant difference of PL effect in response variable (infertility).

Analysis of Toll-Like Receptor-4 Genes Polymorphism and Il-18 in Severe Chronic Periodontitis

Raghad Fadhil1, Nada M.H. AL-Ghaban1, Batool Hassan Al Ghurabi1

1Department of periodontics, College of dentistry, University of Baghdad, Iraq

Abstract

A number of genetic polymorphisms have been associated with risk for periodontal disease in various populations. The genes encoding toll like receptor-4 (TLR-4) may affect susceptibility to and/or severity of periodontitis. Several studies have shown that the levels of interleukin-18 (IL-18) in patients with periodontitis differ from those in healthy subjects. IL-18 is synthesized intracellularly after TLR4 is activated by lipopolysaccharides.

A case control approach used to explore the correlation between polymorphisms in TLR4 and the degree of susceptibility and severity of chronic periodontitis, also exploring the impact of TLR4 polymorphism on circulating cytokines IL-18 in chronic periodontitis patients.

Ninety six Iraqi subjects (69 males and 27 females) their age range (30-50) years were included in study divided in to two groups (patients with severe chronic periodontitis and healthy control) venous blood were collected from each patients for immunologic analysis of IL-18 and genetic analysis of TLR-4.

Analytic statistics for serum IL-18 between chronic periodontitis and control groups showed significant decrease in the medium of IL-18 in chronic periodontitis group compared to control group. Furthermore, two single nucleotide polymorphisms (SNPs) were detected in TLR-4 according to primer design located at rs 4986790 and rs 4986791, with non-significant association of both SNPs with chronic periodontitis patients although both SNP were strongly correlated with the amount of dental plaque.

Genetic polymorphisms in TLR-4 were not associated with the susceptibility of periodontitis in Iraqi patients. However, they might have an association with the clinical parameters and can modify severity of the disease. High frequencies of TLR-4 at rs4986790 in control group suggest that these alleles may confer protective effects against the disease or a low, weak susceptibility to periodontal disease.

Keywords: toll like receptor -4, IL-18, severe chronic periodontitis, gene polymorphisms.

Introduction

Periodontal disease is a chronic inflammation of the teeth-supporting structures, like other common multifactorial diseases, genetic and environmental risk factors affect the development and advancement of periodontal disease (1-3). Genetic host factors may be responsible in determining susceptibility to periodontal disease (4). Toll- like receptors are a family of at least 13 proteins that act as key pathogen- recognition receptors in the innate immune system, reacted to varied microbial products and injury- induced endogenous products (5-7). TLR-2, 3, 4 and 9 are mostly expressed in gingival tissues of periodontitis patients, suggesting that these receptors have a distinct ability to activate and influence downstream cytokine expression; TLR4 distinguish lipopolysaccharide (LPS) from a number of viral and bacterial proteins (8). Interleukin-18 is a pro-inflammatory cytokine and magnify immune responses by inducing other cytokines viz. IL-1β, TNF-α and IL-8 (9). IL-18 is synthesized intracellularly as a biologically passive precursor and demand caspase-1
to cleave it into the active IL-18 molecule. This process could happen after TLR4 is stimulated by bacterial lipopolysaccharides \(^{(10)}\). Moreover, molecular receptors such as TLR-2 and TLR-4 could also be recognized by uric acid to intervene inflammation \(^{(11)}\). Shaheena et al showed that TLR-4, IL-18 and uric acid may have a role in the inflammatory pathology of periodontitis \(^{(12)}\). The aim of the current study used a case control approach to explore the correlation between polymorphisms in TLR4 and the degree of susceptibility to and severity of chronic periodontitis, also to investigate the impact of TLR4 polymorphism on circulating cytokines IL-18 in chronic periodontitis patients.

**Material and Method**

Ninety six Iraqi subjects their age range (30-50) years were included in a case control study divided in to two groups: - **chronic periodontitis group** was included 55 patients with severe generalized chronic periodontitis while **Control Group** was consisted of 41 Iraqi volunteers all showed a clinical healthy periodontium.

Then clinical periodontal parameters (plaque index (PI), gingival index (GI), probing pocket depth (PPD), clinical attachment level (CAL) were recorded for each subject and venous blood collected from the antecubital vein, in 5ml vacutainer glass blood collection tubes. Two ml of venous blood was transferred into tube buffered with sodium citrate 3.2% and kept at -40°C for the genotyping of TLR4 while the other three ml were placed in gel separating tube and centrifuged to separate the serum from the cells for cytokine analysis (IL-18), for 10 min at 3300g. The obtained blood serum was placed into sterile Eppendorf vials and kept at −40°C until being analyzed.

**Immunological analysis:**

For immunological analysis detection of serum IL-18 was done by the use of ELISA kit for serum IL-18 (Myobiosource, France).

**Genotyping of TLR4 and NF-κB1-94 Polymorphisms:**

DNA Extraction was done by the use of QIAamp DSP DNA Blood Mini Kit uses QIAamp technology for purifying genomic DNA. Then, Design of TLR-4 Primers was done and Allele-specific PCR was performed in order to detect SNPs of TLR-4. The following primers (Forward primer TLR-4′-5′-CTTGCGGGTTCTACATCAA-3′, Reverse primer TLR-4 5′ AGTACCTGAAGACTGGAGAG-3′) were employed for detection of rs 4986790 (Asp299Gly) and for rs 4986791 (Thr399Ile).

Furthermore, Polymerase Chain Reaction amplifications were performed with the following temperature program: denatured at 94°C for 4 min followed by 30 cycles of denaturation at 94°C for 30 sec; annealing at 55°C for 45 sec; and extension at 72°C for 60 sec. A final extension incubation of 7 min at 72°C was included, followed by a10 min incubation at 4°C to stop the reactions.

Then the samples were loaded on agarose gel to perform electrophoresis using AgaroPower™. Moreover, PCR product were send for Sanger sequencing using ABI3730XL, automated DNA sequencer in Macrogen Company- Korea (http://dna.macrogen.com/eng). The sequences of these samples were matched with the source sequence and analyzed by using Basic Local Alignment Search Tool Program (BLAST), which is obtainable at the NCBI information site on the following website http://blast.ncbi.nlm.nih.gov/Blast.cgi.

**Results**

Genetic analysis for TLR-4 showed two SNPs in TLR-4 according to primer design as illustrated in figure (1).

Analysis by Hardy-Weinberg equilibrium for study groups were done for the two SNPs. For rs 4986790 the equilibrium was non-significant in chronic periodontitis group while it was significant for control group and highly significant result was obtained in total sample while the results of equilibrium for rs 4986791 were non-significant for both chronic periodontitis, control groups and total samples as shown in table (3).

Regarding, the SNPs number and distribution in both groups were illustrated in table (4) as there was one SNP in chronic periodontitis group for rs 4986790 and 3 SNPs in control group for the same rs with non-significant differences. On the other hand there were 4 SNPs in both chronic periodontitis group and control group at rs 4986791 with non-significant difference between them. Interestingly the effect of TLR-4 SNPs on chronic periodontitis distribution was assessed by counting the odd ratio and it was found (0.208) for rs 4986790 and the odd ratio for rs 4986791 was (0.637).

Moreover, using fisher exact test to find the genotype frequency of both SNPs in TLR-4 showed non-significant difference in their distribution in both groups as described in table (5), the study illustrate the effect of each genotype of TLR-4 SNPs on disease distribution and prevention. It was found that the genotype A-A had a higher odd ratio (4.263) than other genotype to develop disease in rs4986790. While the genotype C-C have (1.378) chance to develop disease in comparison with other genotype located in the rs4986791.

Discussion

Periodontitis is a multifactorial disease and studies of animals and humans encourage the concept that a large number of genetic factors may be related with periodontitis and clearly have a role in periodontal diseases. The current work revealed a significant decrease in the levels of IL-18 in chronic periodontitis group, this result was in agreement with Chitrapriya et al (13-15) and this could be explained by: In health, a predominance of T cells, minimal B cells, a sophisticated network of professional antigen presenting cells (APC) guarding the gingival barrier (16). It has been documented that APCs and epithelial cells are the source of IL-18. APCs are present in larger numbers in clinically healthy and gingivitis when compared to periodontitis lesions.

The result of Hardyweinberg equilibrium for rs 4986790 was non-significant between the observed and expected genotypes in chronic periodontitis group while it was significant for control group and highly significant result was obtained in total sample. Furthermore, non-significant results was found between chronic periodontitis group and control group although,
the preventive fraction for rs 4986790 was high and this agree with (18), this could increase the chance that the rs 4986790 have protective role as it occurred in more frequency in control group than in periodontitis group. This improved by the negative strong correlation with plaque index that was found in the chronic periodontitis group.

The significant negative correlation with plaque index that was found in the chronic periodontitis group. This was explained by; this SNP is responsible for the change in interactions between TLR-4 present on immune cells and LPS affecting the survival rate of periopathogenes in gingival pockets. The TLR4 rs4986790 SNP significantly interacted with P. gingivalis in conferring a decreased risk of periodontitis and may be protective against alveolar bone height loss, a feature of periodontitis (19).

While the results of Hardy-Weinberg equilibrium for rs 4986791 were non-significant for chronic periodontitis and control groups as well as total samples and this in coincidence with (17). In this study, genotype and allele frequencies of the Thr399Ile polymorphisms in both groups of healthy and chronic periodontitis subjects showed no significant difference in TLR-4 rs 4986791 genotype frequencies.

Regarding the correlation of rs4986791 with clinical periodontal parameters, there was significant positive correlation between plaque index and SNP at rs 4986791, suggesting its association with initiation of periodontal disease. Nieto et al in (2014) (20) reported that polymorphisms have been shown to change the ligand-binding site of the receptor. They can modify the inflammatory response and promoting bacterial infections, furthermore, inhibition of components of the innate host defense system results in the lack of chemokines that normally guides leukocytes to the site of bacterial colonization. The local inhibition of these inflammatory mediators results in the lack of sufficient leukocytes to properly control dental plaque growth, proposed to be one of the major factors in the development of periodontitis (21,22). By this explanation we suspect that SNP in TLR-4 in rs4986791 cause inhibition in activity of TLR-4 which is important part of innate immune response and result in dental plaque growth.

In a conclusion of present study, dental plaque is responsible for initiation of periodontitis and its growth aggravated by suppression in the levels cytokine and SNP in TLR-4 at rs 4986791 while plaque growth was inhibited in rs 4986790. Furthermore, genetic polymorphisms in TLR-4 were not associated with the susceptibility of periodontitis in Iraqi patients. However, they might have an association with the clinical parameters and can modify severity of the disease. High frequencies of TLR-4 at rs4986790 in control group suggest that these alleles may confer protective effects against the disease or a low, weak susceptibility to periodontal disease.

Evaluation of Students’ Knowledge, Practice and Attitudes Related to Antibiotics Use and Resistance in the Context of Iraqi Medical Education

Mohammed Abdul-Hassan Jabarah AL-Zobaidy
School of Nursing, University of Al-Qadisiyah, Iraq

Abstract

Inappropriate use of antibacterial drugs leads to emergence of multi-drug resistant bacteria and renders these agents useless. Raising awareness of medical and nursing students is critical for dealing with this progressive problem. Therefore, the aim of this study was to appraise knowledge, practice and attitudes concerning antibiotics use and resistance among medical and nursing students at University of AL-Qadisiyah, Iraq.

A descriptive cross-sectional questionnaire-based study involved 5th-year medical and 4th-year nursing students at University of AL-Qadisiyah in the 2017/2018 academic year. Data were collected using a structured questionnaire and presented as absolute numbers and percentages.

Participants of current study demonstrated reasonable level of knowledge, yet questionable attitudes and practice about antibiotics.

Knowledge about antibiotics has be translated into good attitudes and practice. Further education about prescription skills and control of infection is required.

Keywords: Knowledge, Attitudes, Practice, Antibiotics resistance, Medical, Nursing, Pharmacology, Microbiology.

Introduction

Immune-competent individuals can effectively deal with infections. However, those who are immune-compromised need antimicrobial drugs to defeat invading micro-organisms. Anti-bacterial drugs are either bactericidal or bacteriostatic. Also, they can be prescribed individually or in combination. However, their choice is governed by type of bacteria and their sensitivity to antibiotics, prescriber’s knowledge and practice, and patient’s characteristics (1).

Bacterial resistance to antibiotics is serious health problem worldwide apart from Iraq. It may result from irrational prescription, self-medication and overuse of antibiotics (2).

Interventions that change Knowledge, Practice and Attitudes (KAP) related to antibiotics use and resistance among doctors, dentists, pharmacists and nurses are essential to deal with this problem (3). Also, the best time for these interventions is during undergraduate training, because after graduation it will be difficult to change their beliefs, views and behaviours related to antibiotics (4).

The current undergraduate medical (6-year) and nursing (4-year) programmes at University of AL-Qadisiyah (UoQ) involve delivery of pharmacology and microbiology courses during 3rd year of these programmes. Given the practical differences between the two professions, the depth of pharmacology knowledge delivered for medical students is greater. Moreover, to the author’s best knowledge there is no previous study that had investigated KAP of antibiotics use and resistance among undergraduate students in the context of Iraqi medical education.

Taken together, current study was aimed at evaluating KAP of antibiotics use and resistance among 5th-year medical and 4th-year nursing students at UoQ, Iraq.
Materials and Method

A descriptive cross-sectional questionnaire-based study conducted at Medical and Nursing Schools/University of AL-Qadysia (UoQ), Iraq from December 2017 to February 2018. The target populations were 5th-year medical (104) and 4th-year nursing (118) students.

Ethical approval was obtained from the Ethics Committees in the two schools after addressing ethical implications of the study.

There were no exclusion criteria or incentives to participate in the study. However, active participation was encouraged by prior informing students that their participation is voluntary, anonymous, confidential and will not affect their academic progression. The questionnaires were administered to 96 medical and 100 nursing students by face-to-face interview and agreements of participants to fill in the questionnaires were considered a consent to take part in the study.

Following evaluation of relevant literature and questionnaires employed in comparable studies, a questionnaire was developed and critically appraised by a panel of experts in pharmacology and microbiology. Afterwards, it was piloted by being administered to 10 students from each school to establish its validity. The approved questionnaire covered Demographic characteristics of participants, Knowledge about antibiotics use, side effects and resistance, Attitudes towards use of antibiotics, Practice concerning antibiotics use and resistance, and the possible causes of bacterial resistance to antibiotics.

Data were analysed using descriptive statistics and presented as absolute numbers and percentages.

Results and Discussion

Demographic characteristics of participants

The response rates were good and numbers of female students, from both schools, who completed the questionnaires were higher than their male colleagues which reflects gender differences within each cohort (Table 1). The reported response rates might because that students were informed in advance of the study that their participation is anonymous, voluntary and will not affect their academic progress. However, novelty of study might have adversely influenced students’ responses.

Previous studies had reported similar response rates. However, other studies reported a response rate of up to 100%.

Knowledge about antibiotics use and resistance

In general, participants from nursing school had reasonable level of knowledge concerning antibiotics use and resistance (Table 2) which was comparable to that of medical students. However, the latter were expected to be better owing to the depth and breadth at which microbiology and pharmacology subjects are explored in medical curriculum. Also, medical students learn about antibiotics during their clinical placements while nursing students do not have such opportunity.

* Numbers of medical and nursing students who answered with “True”.

Regarding economic and medical consequences of inappropriate use of antibiotics, nursing students expressed reasonable, but medical students showed better, level of knowledge about these consequences. These different levels of knowledge expressed by our participants might be attributed to their diverse academic abilities, enthusiasm to learn and their practical talents.

Previous studies reported reasonable level of knowledge concerning antibiotics use and resistance among medical students whereas other studies reported average to good level of knowledge among nursing students.

Inadequate knowledge about antibiotics’ indications, adverse effects and bacterial resistance will pave the way for inappropriate prescription, random use of antibiotics with consequent emergence of bacterial resistance.

In traditional medical and nursing programmes there is fragmentation of knowledge and poor application of
basic knowledge for solving patients’ clinical problems (13). Also, it is possible that our participants did not receive sufficient education regarding the variables considered in current study. The latter may include little emphasis on infection control and making inadequate awareness about the problem of antibiotics resistance.

**Causes of bacterial resistance to antibiotics**

Participants from both cohorts showed comparable views regarding these causes (Table 3). “Unrestricted use of antibiotics” was viewed 73.9% of medical students as the most significant cause of this problem whereas 84.1% of nursing students thought that “consumption of antibiotics for treatment of self-limiting infections” is the most significant cause. Also, our participants showed careful and comparable awareness of the other causes of this problems (Tables 3).

The causes of bacterial resistance to antibiotics considered in current study have been strongly acknowledged worldwide as leading causes in the emergence of multi-drug resistant strains of microorganisms (2,6,7,14).

* Numbers of medical and nursing students who answered with “Yes”.

**Attitudes related to antibiotics use and resistance**

Our participants expressed comparable attitudes concerning safe use of antibiotics (Table 4), as >90% of them acknowledged that the problem of antibiotics resistance is a genuine problem in Iraq. Subjects of other studies worldwide stated that antibiotics resistance is an actual problem in their own countries (6-8).

In addition, >85% of participants (Table 4) believed that the most important reason behind emergence of multi-drug resistant bacteria is irrational consumption of antibiotics. Also, 65-67% of them (Table 4) admitted that bacterial resistance to antibiotics emerges as the rate of antibiotics consumption increases. These perceptions were similarly expressed by subjects of other studies worldwide (5-9).

Despite that, 57-61% of our participants thought that residual antibiotics can be re-used (Table 4). In fact, approximately 49-59% of them did by self-medication and for mild self-limiting conditions. Indeed, these figures are higher than the 17.7% and 20% reported by in other studies (5,6), respectively.

Moreover, nearly 33-46% of our participants believed that use of combined antibiotics reduce their adverse effects (Table 4). Physicians who support this idea think that “the more it is, the better it is” (15). However, such mistaken idea can strongly abolish the
efforts to protect the community from multi-drug resistant bacteria. Moreover, socio-cultural factors and feelings of self-confidence (16) might explain the beliefs of our participants.

Table 4: Attitude related to antibiotics use and resistance strongly agree.

Common practice of antibiotics use

Results of current study revealed that 72.5% and 88.9% of medical and nursing participants, respectively, always commenced antibacterial chemotherapy without medical consultation. Also, 31.9% and 38.1% medical and nursing participants, respectively, terminated their antibacterial treatment prematurely. Previous studies revealed that nearly 30% (7) and 64.3% (17) of their participants always started antibacterial chemotherapy without seeking medical consultation. Also, early stopping of antibacterial chemotherapy was practiced by 20% and 60% of participants in studies conducted in Jorden (18) and India (6), respectively. On the other hand, studies conducted by (6) reported that >90% of their participants always sought professional advice before starting antibacterial chemotherapy and they completed their courses of antibiotics.

On the other hand, 26.1% and 31% of medical and nursing students, respectively, stated that Iraqi doctors do prescribe antibacterial agents for treatment of common cold. It is well-stressed in medical education that bacteria are not responsible for common cold, however, such practice may reflect poor adherence to prescription guidelines (14). The latter places another obstacle on the way towards prevention of bacterial resistance to antibiotics.

Moreover, current study showed that 88.9%, 65.1% and 44.4% of nursing students used antibacterial drugs for acute bronchitis, common cold or fever, respectively, while 15.9%, 7.2% and 23.2% of medical students used such drugs for treatment of these conditions, respectively, (Table not shown).

Previous study (7) showed that 42.03% and 57.24% of participants had used antibacterial drugs for common cold and fever, respectively. Similar data were reported by (6), too. However, in another study (5) only 1% of participants had practiced so.

Malpractice regarding antibiotics use by our participants maybe because the traditional medical and nursing programmes do not give them the opportunity to apply their basic knowledge for solving patients’ clinical problems. In addition, traditional assessment methods focus on evaluating factual knowledge with little emphasis on assessment of skills like prescription skills (13).
Participation rates in current study were good despite that its originality in the context of UoQ. However, recruitment of students from early stages of the two programmes could help evaluate the impact of microbiology and pharmacology courses on students’ KAP.

**Conclusions**

Current study revealed that medical and nursing students at UoQ have reasonable level of knowledge about antibiotics use and resistance, however, their relevant attitudes and practices are questionable. Medical and nursing students in the undergraduate level need to be presented with topics related to prescription skills and control of infection.

Seroprevalence of Cytomegalovirus and Toxoplasma gondii in Infected Women in Babylon Province

Safaa A.AL-Isawi¹, Muhamed Ali Al Kabe², Ameer Kadhim Hussein³, Zaytoon A. Al-Khafaji³

¹Al furat AL-Awsat technical University/Institute Babylon technic/Iraq, ²Wasit University - Faculty of Medicine/Iraq, ³University of Babylon - Collage of Medicine/Iraq

Abstract

**Background:** This study was amid to estimate the occurrence of cytomegalovirus and toxoplasmosis infections in pregnant women with history of repeated abortion i.e.; bad obstetric history in Babylon Governorate. In addition to clarify the impact of the age of the women and the place of domicile on the incidence of those agents among the study group. **Methods:** The research involved (559) serum samples were collected from pregnant women with positive cytomegalovirus (CMV) and Toxoplasma gondii, those women were attending Babylon hospital /department of Obstetrics & Gynecology, who were complaining from single or more attacks of abortions. Crummy obstetric history and (50) normal women with previous normal full term deliveries. The study carried out by serological evaluation by VIDAS technique to detected IgG antibody. **Results:** There were no significant differences between means of age by CMV infection Mean ± SD 25.78 ± 6.44, while there were significant differences between means of age by Toxoplasma infection Mean ± SD 27.75 ± 6.07. Positive Cytomegalovirus infection represent about (97.7%) of study sample. Positive Toxoplasmosis represent only (28.6%) of study sample.

**Key word:** CMV, Toxo, Toxoplasma gondii ; Cytomegalovirus ; women; Abortion.

Introduction

Abortion is defined as termination of pregnancy resulting in dismissal of an immature fetus. A fetus of less than twenty weeks pregnancy or a fetus weighting less than 500 gm. is considered an abortus Number of maternal contagions can lead to a single or recurring pregnancy loss, including:

Human Cytomegalovirus (HCMV) infection is the most common cause of congenital malformation in developed countries, its clinical manifestations range from asymptomatic infection to severe fetal damage¹. CMV will lead to intricate pregnancies. It was been reported that the risk of fetal hurt is greater if the primary infection occurs during the first trimester of pregnancy (²). The placenta and the fetus can be infected either by transplacental transmission or by an ascending infection from the vagina (³,⁴).

Toxoplasmosis which is a systemic illness caused by the protozoan Toxoplasma gondii (T.gondii) infection that acquired by pregnant women through ingestion of cysts, undercooked meat or oocyst that may pollute soil, water, and food. Meat (primarily pork and lamb) is an main source of the infection in humans (⁵,⁶).

The infection has a global distribution. About one-third of humanity had been exposed to this parasite, but seroprevalence differs seriously between countries (less than 10% to more than 90%) and population group (⁷).

T.gondii infection in healthy subject is asymptomatic but in immune compromised patients may have grave disease (⁸).

Toxoplasmosis and CMV infection parts many features ,they most important way of transition and most these infection are asymptomatic and the adult who are infection with T.gondii and CMV are usually have self- limited symptom and usually develop an immune response represented by antibody agent , there for determination the IgM and IgG antibody agent is the

**DOI Number:** 10.5958/0976-5506.2019.00949.5
best ways to diagnosis these infection early (9&10). So present study aimed to estimate the incidence of cytomegalovirus and toxoplasmosis infections in pregnancy abortion in females with bad obstetric history.

Materials and Method

The study was conducted since January (2015) till August (2016), A total of (559) sera samples were collected for the detection of the Blood collection and serological tests. Each subject had 5 ml of whole blood collected by venipuncture in plain tubes; Sera were separated and stored in small screw caped vials at -20°C until serological analysis (11) Samples were screened for the presence IgG antibodies against HCMV and T. gondii, by VIDAS technique kit according to the manufactures instruction.

Statistical Analysis

Statistical analysis was carried out using SPSS version 20. Categorical variables were present as frequencies and percentages. Continuous variables were present as (Means ± SD). Independent sample t-test was used to compare potential between two groups. Pearson’s chi square ($X^2$) and Fisher-exact test were used to discover association between categorical variables. A $p$-value of $\leq 0.05$ was considered as significant.

Discussion

Results are show in Table 1 give high significant incidence of C.M.V and Toxoplasmosis infection among aborted women who lived in rural areas than in those lived in urban area this finding is in agreement with other studies (12,13,14) who back reason it to direct contact for pregnant women in rural area with domestic animal on the one hand and consumption for their product directly without sterilization of the other hand, So all of them were in contacted with soil that may be heavily contaminated with oocytes which is sourced from the large number of animal in those area (15). In this study the VIDAS technique was chosen for determined time of infection: a positive IgG result usually indicates
infection at least six months previously. In this study Cytomegalovirus was appeared with rate 97.7% which is disagreement with (16). The seroprevalence of CMV is vary in the worldwide (17). In developed countries the apositivity of HCMV ranges between 30-90% of human population, and the increasing of prevalence is parallel with the age (18). In Iraq, many studies conducted to detect the sero positivity of CMV in aborted women, and the seropositivity of CMV in AL-Anbar province was 6.1% (26), in waste province was 60.2% (13), in Baghdad province was10% (27),15.7% (14), 9.3% (26), and in sulimania province was 9.18% (27). Risk factors for CMV infection was correlated with the socioeconomic status within a community (19, 20). Some studies experiential that the accumulation of cytotoxic T lymphocytes (CD28 effector) in elderly persons provided protection against symptomatic CMV disease. This study found Toxoplasmosis represent only (28.6%) of study sample It’s an agreement with (21,22) which described that the seroprevalence of toxoplasmosis was decreased This decline could be probably related to a decrease in the frequency of transmission of the parasite telluric where contact with soil was the greatest risk factor associated with T. gondii infection Moreover, improved lifestyle including food hygiene can contribute positively to the decline in toxoplasmosis prevalence. The maximum number of positive cases for CMV and T.gondii antibody antibody was related to abortion. This may be due to the fact that primary infection with Cytomegalovirus and Toxoplasma gondii and in pregnant women can lead to adverse outcome, which is initially unapparent or asymptomatic and thus difficult to diagnose on clinical grounds (25). So the parasite remain in latent state and again when the mother become pregnant where her immunity suppressed due to certain physiological changes in the body that occur during pregnancy, the parasite will reactivated and become the cause of her next abortion unless the treatment is received (24, 25), Table 3and 4 show the prevalence of IgG antibodies in our study population increased with age .These results statistically significant (p <0.05) were already observed in 2007 by El Mansouri et al. (2007). Similar observation has been advanced by Berger et al in France who reported that toxoplasmosis infection increases linearly with age (26) This can be explained by the increase of exposure to infection sources throughout life. This finding relatively analogous with (27,28).

**Conclusion:** The present study demonstrates a strong association between the infectious agents Cytomegalovirus (CMV) and the (Toxoplasma gondii) and abortion in women. It is therefore, recommended that all antenatal cases with such Past should be regularly screened for these alternatives (IgM and IgG) antibodies.

A Comparative Study of Histopathological and Immunohistochemical Expression of MCM3 and MMP-2 in Pleomorphic Adenoma of Major and Minor Salivary Glands

Zena A. Husein¹, Ban F. Al - Drobie¹, Bashar H. Abdullah¹

University of Baghdad, IRAQ

Abstract

Pleomorphic adenoma (PA) is the most common salivary gland tumor, it shows remarkable degree of morphological diversity and biological controversy. This study was undertaken to compare the proliferation and invasion potentials between major and minor salivary pleomorphic adenoma using MCM3 and MMP-2 biomarkers respectively with correlation to PA subtypes and components. Thirty two paraffin blocks of PA (15 affecting major SGs and 17 were arising in minor SGs) were included in this study and examined in detail for their histomorphological features. Immunohistochemical expression of MCM3 and MMP-2 of the two groups was analyzed. PA of major SGs showed a significantly higher expression of proliferation marker (MCM3) than PA affecting minor SGs (P = 0.01). Although not significant, higher expression of MMP-2 was found in PAs arising in minor SGs (P = 0.09). Moreover, significant invers correlation was observed between MCM3 protein and plasmacytoid cell type in minor gland cases (P = 0.023).

Keywords: Pleomorphic adenoma . MCM3; MMP-2 . Major salivary glands. Minor salivary glands.

Introduction

Pleomorphic adenomas are the most common SGs tumors. It is a benign neoplasm but some types occasionally have malignant microscopical features or behave in a malignant manner like metastasis. PA is typically a well-circumscribed, encapsulated tumor. However, the capsule may be incomplete or show infiltration by tumor cells. The tumor composed of epithelial and myoepithelial cells arranged in a great variety of morphological patterns, with areas of mesenchymal differentiation. Clinical and histologic differences between major and minor salivary gland PAs have been partially explained by anatomical differences between these sites. However, this study was conducted to compare some aspects of the biological behavior between major and minor salivary glands PAs in relation to their histological patterns through the expression of MCM3 marker of cell proliferation and MMP-2 for local invassivness.

MCMs is a recently accepted proliferating marker, with its expression tightly associated with the cell cycle and cell-cycle initiation and are expressed throughout the whole cell cycle including cells leaving G0 to enter into the early G1 phase, and therefore MCM proteins specifically MCM3 has been proposed as a novel proliferation marker in SGs tumors.

MMP-2 is a member of matrix metalloproteinases; a family of structurally related, zinc containing enzymes. It degrades type IV collagen, which been thought to be key enzyme in tumor progression. MMP-2 overexpression have been reported in a variety of salivary gland tumors. Localization of MMP-2 protein by immunohistochemical method have been reported in tissue sections of PA, nevertheless, PA progression and/ or development difference in major and minor salivary glands is still undetected.

The goal of this study is to gain understanding of the differences in biological behavior between major and minor salivary glands PAs through MCM3 and MMP-2 proteins expression with respect to histological parameters.
Materials and Method

Sequentially accessioned samples of major gland and minor gland PAs were selected from the archives of the oral and maxillofacial pathology Department, College of Dentistry, Baghdad University between the period 1990 and 2016. Slides were reviewed and diagnosis confirmed by two oral pathologist. There were 15 major gland PAs and 17 minor gland PAs that were of quality and size for study inclusion.

The tumors could be classified into stoma-rich, classic and cell-rich types depending on the amount of stroma and the proportion of cellular components. The evaluated microscopic features included the following: (1) tumor capsule (complete, incomplete, absent), (2) tumor cell types (plasmacytoid, spindle, clear, squamous, basaloid, cubic, oncocytoid and mucous cells), (3) epithelial architecture (ductal, trabecular, solid, cystic), (4) stromal component (myxoid, hyaline, chondroid or calcified tissue).

Immunohistochemistry

Five-micrometer tissue sections were deparaffinized and stained by means of a standard immunohistochemically technique using a high-temperature water bath for antigen retrieving. Abcam Expose Mouse and Rabbit HRP/DAB was used which is a biotin free immunoenzymatic antigen detection system. The sections were incubated with the following antibodies: anti-MCM3 (Monoclonal; Abcam; dilution 1:250) and anti-MMP-2 (Polyclonal; Abcam; dilution 1:500). Human tonsil tissue and neurofibroma section were used as positive controls for MCM3 and MMP-2 respectively. A negative control was obtained by not including the primary antibody.

MCM3 and MMP-2 immunoreactivity was semi-quantitatively evaluated in ten microscopic fields at high magnification (X400). The percentage of positive tumor cells out of 1000 tumor cells was considered the labelling index (LI) of each marker.

Statistical Analysis

Data were analyzed using SPSS version 27.0 software (SPSS, Inc., France). For comparison of MCM3 and MMP-2 expression between the study groups, the Mann-Whitney U-test was used. Associations between MCM3, MMP-2 expression and histopathological features were verified by Pearson’s Chi-square or Fisher exact test. Correlation between MCM3, MMP-2 and cellular components was performed, using pearson’s correlation test. 0.05 significance level was set for all statistical tests.

Results

Histological features

In this study, cell-rich, stroma-rich and classic subtypes of PA had an equal frequencies in major gland cases. The majority of minor gland cases (58.8%) were cell-rich and there was no stroma-rich PA. More than half (66.7%) of the major gland cases were partially encapsulated, while partial encapsulation was observed in all of the minor gland PAs (table 1).

Both tumor site showed diverse cells types although plasmacytoid followed by spindle cells were the most frequent types. The distribution of cellular components is presented in Tables 3 and Fig. 1. Stromal element on both major and minor gland PA had a very large variety of subtypes, although the myxoid stroma being the most frequent in both tumor sites. Ductal structures, trabecular and solid architectures, and cystic spaces were also observed and their distribution is presented in Table 2 and Fig. 1.

MCM3 Protein

The examined cases of PA showed diffuse total cell reactivity with different nuclear intensity (Fig.2 ). In the majority of the minor gland PA cases, negative or low expression of MCM3 was observed in the nuclear tumor cells and the labeling index(mean ±SD = 6.4±6.48). Cases affecting major salivary glands were found to have higher MCM3 reactivity and the labeling index (mean ±SD = 35.22±31.52). Significant difference was found between these two groups of tumors (P = 0.01). Among histopathological variables, plasmacytoid cell type correlated inversely with MCM3 expression ( P = 0.023) in minor gland cases only.

MMP-2 Protein

Immunexpression of MMP-2 was detected in both epithelial-myoepithelial and stromal components (Fig.3). Greater number of the minor gland PA cases
had moderate or high expression of MMP-2 observed in the tumor cells cytoplasm and the labeling index (mean±SD= 54±21). In major gland tumor, the MMP-2 reactivity was slightly lower than that in minor salivary gland PA and the labeling index (mean±SD= 47±23). No significant difference was found between these two groups of tumors (P = 0.09).

Discussion

Salivary gland neoplasms display fluctuating clinical behavior and morphological characteristics. Particular interest has been directed to salivary pleomorphic adenoma, due not only to its frequency, but also to its histopathological diversity and biological behavior controversy (18, 19). Histological differences between major and minor salivary glands

PAs have been reported (7, 20), in addition, series of prospective studies suggested that aggressive tumor behavior like recurrence potential and malignant transformation was more likely to be associated with certain histological findings (13, 18). In this retrospective study, we attempted to compare the influence of histological variation of PA on its proliferation and invasion potentials through MCM3 and MMP-2 biomarkers respectively between major and minor glands PAs.

In various studied conducted, the universal agreement is that the PAs of minor salivary glands are often more cellular than their counterparts in the parotid (21, 22). Our samples demonstrated similar findings. All minor glands PAs and 66.7% of major gland cases in our study were partially encapsulated. In the literature, 54-100% rate of occurrence of partial encapsulation in minor glands PA has been described (7, 20, 23), and a relatively high proportion of major glands PAs are encapsulated (3, 7, 24). However, it has been proved that area of capsular deficiency were seen in all cases when tumors were serially sectioned (25).

The epithelial and myoepithelial cells of PA show a remarkable degree of morphological diversity in both tumor sites (25). Plasmacytoid is the most frequent and predominant type followed by spindle cell in both tumor sites. Ellis and Auclair (18) thought that these neoplastic cells appear to be in transformation from one profile to the other, too many, the plasmacytoid cells are highly characteristic of a PA and almost never found in other salivary gland tumors (26). Although some studies reported that trabecular pattern as most frequently encountered followed by ductal pattern (4, 21), however, the ductal epithelial pattern was the most frequent type in both tumor sites in the present study, similar to was reported in (5, 17, 20, 22). In concordance with our findings in both major and minor glands cases, series of studies showed that myxoid followed by chondroided were the most frequently encountered stromal types in PA (27).

Regarding MMP-2, higher but not significant expression of MMP-2 protein was found in minor salivary glands PAs compared to major glands ones, with all but one case of PA in both groups expressed MMP-2. This MMP along with MMP-9 reported to be related to invasive properties and malignant potential of salivary gland tumors (12). Therefore, it is likely that major and minor gland PAs are still comparable in term of local invasion potential as measured by MMP-2 protein due to small sample size, or there is other than MMP-2 contributing to PA local invasiveness.

Conclusion

Although the biological behavior of major and minor gland PAs were comparable in term of local invasiveness, however, major gland PA had higher proliferation propensity than minor glands ones with this proliferative activity suggested to be attributed to plasmacytoid myoepithelial cells.

Conclusion

Compared to PAs of major glands, PAs affecting minor SGs have lower proliferation potential and comparable invasion propensity as measured by MCM3 and MMP-2 respectively. Further, cellular components-in particular plasmacytoid type- has the potential to play a more important role in biological behavior of this tumor.

Study of the Effect of Some Trace Elements (Calcium) and Some in the Biochemical Variables on the Children of Thalassemia Patients in the Province of Maysan/ Iraq

Farah Majbali jabber
College of Pharmacy – University of Maysan/Iraq

Abstract

The study was conducted to measure the concentration of trace elements of calcium and some enzymatic biochemical parameters for a number of people with thalassemia in Masan Governorate. The study included 50 patients between the ages of (1-14) years (13 males and 19 females) from Thalassemia Center and Hematology. (16 males and 14 females) during the period from January 2018 and the end of March 2018. Patients were divided into three age groups (1-4 years), the second group (5-9 years), the third group (10-14 years). The variables were studied based on age, sex, thalassemia type, and genetics. The results showed that most cases of the disease are of the type of Thalassemia major and that the proportion of males is greater than females. In addition, a decrease in the calcium concentration of patients compared to controls. The concentration of calcium for patients (8.9 ± 0.47) compared to control (9.5 ± 0.6).

Keywords: Thalassemia, Calcium status; trace elements; patients; disease.

Introduction

Thalassemia is derived from the Greek word “Thalassa” meaning “the sea” because the condition was first described in populations living near the Mediterranean Sea (1). Thalassemia major And occurs when there is a mutation in both genes beta globulin, but the type of mutation in the legacy of beta more severe result in a severe shortage of the proportion of beta globulin and thus reducing Hb As a result of the breakage of abnormal red blood cells before the end of life (120) days. The patient needs periodic blood transfusion every 3-4 weeks to maintain a high percentage of Hb to grow healthy body (2). Of the age due to the breakage of early red blood cells appear symptoms of severe skin anemia, sometimes yellowing, “delayed growth, poor appetite, recurrence of inflammation (3-4) and with the persistence of anemia, other symptoms such as change in the shape of bones, especially” facial bones And the symptoms and face features become characteristic of this disease, as there is an enlargement of the spleen and liver and delay the child in the growth, but in simple cases in the case of carriers of the disease may occur a small blood to the extent that the disease is clear, “and live naturally and does not need treatment Thalassemia is one of the most common hereditary genetic diseases that break down red blood cells. Children with Thalassemia cannot produce enough hemoglobin because the bone marrow does not produce sufficient red blood cells for the need of their bodies. The red blood cells produced by them are almost free of hemoglobin. There are two types of thalassemia Alpha Thalassemia and Beta Thalassemia If the husband, wife, or both have Thalassemia, this affects the future of their children and the cause of Thalassemia, (5) it is a defect in the gene that is hemoglobin and the person has thalassemia. If he has a defect in one or more of the genes responsible for the manufacture of hemoglobin and acquired by the genetics of a parent, hemoglobin (6) is a red protein rich in iron is found in red blood cells. Hemoglobin is important because it enables red blood cells to transport oxygen from the lungs to all parts of the body. It is known that most blood cells, including red blood cells, are made regularly in the bone marrow. Red is found within the gaps in the large bones in the body. “(7) But because thalassemia disrupts the production of hemoglobin naturally, lead to a decrease in the level of doi: 10.5958/0976-5506.2019.00952.5
hemoglobin and an increase in the rate of breakage of red blood cells \(^8\), and this explains why it leads to anemia, and therefore does not have enough red blood cells to transport oxygen to all parts of the body, Which causes fatigue and tiredness. Most red blood cells, including red blood cells, are regularly made in the bone marrow, “a red spongy substance found within the gaps in the large bones in the body\(^9,10\), But because thalassemia disrupts the production of hemoglobin naturally, lead to a decrease in the level of hemoglobin and an increase in the rate of breakage of red blood cells, and this explains why it leads to anemia, and therefore does not have enough red blood cells to transport oxygen to all parts of the body, Which causes fatigue as well \(^11\)

**Materials and Method**

2-1 Important of the study.

To determine the levels of serum calcium and serum alkaline phosphatase in patients of thalassemia receiving a repeated blood transfusion to compare the levels of serum calcium and alkaline phosphatase in thalassemia patients with age and sex-matched controls.

2-2 Research samples

A special form was designed containing a number of questions. “A random sample of 50 patients with thalassemia was randomly selected to check for hereditary anemia in Masan for the period from January to the end of March 2018. Tests were performed on the patient to measure calcium concentration in thalassemia patients in the blood, and some enzymatic parameters.

2-3 the collection of blood samples

Blood samples were collected from patients diagnosed by thalassemia and hereditary anemia patients in Masan governorate and by (male and female) and age groups (1-14 )years Motion able sample (control group) were withdrawn from healthy people and model 30 Samples were obtained by withdrawing the venous blood volume (5 ml) from the patients by means of a special syringe for use (one syringe), placing the blood directly in the plastic test tube, a free anticoagulant material and then placing the tubes containing a blood centrifuge after installation of the plugs (3000  rpm / min) for a quarter of an hour to remove all existing blood cells and serum transferred to other specific tubes and stored in the refrigerator at 4 ° C - to perform the required analyzes.

2.4 Procedure:

Assay conditions:Wavelength …………… 570 nm (550 – 590)

Cuvette…………………………… 1 cm. light path

Temperature…… 37 C / 15 – 25 C

Adjust the instrument to zero with distilled water.

Pipette into cuvette (use clean disposable pipette tips for its dispensation)

Note *

1- (CALCIUM CAL: Proceed carefully with this product because due to its nature it can be contaminated easily)

2- (Calibration with the aqueous standard may cause a systemic error in automatic procedures. in these cases, it is recommended to use serum calibration).

2 – 5 Method of measuring enzyme GOT

This enzyme was measured using a bioMerieux-France kit and the activity of this enzyme is measured by chromatic methods according to the following reaction equation

\[ \text{Aspartate} + \alpha \text{-Ketoglutarate} \rightarrow \text{Oxaloacetate} + \text{glutamate} \]

The resulting oxaloacetate is measured through chromatography through its interaction with a compound of 4.2 - dinitrophenylhydrazine to form the hydrazone derivative that this derivative is measured at a wavelength of 505nm.
Method of measuring enzyme GPT

The efficacy of this enzyme was measured using a bioMerieux-France kit and the measurement of GPT glutamic pyruvic transaminase was achieved through chromatic methods and through the following reaction:

Alanine + α-Ketoglutarate Pyruvate + Glutamate

Hydrazine - 2, 4 Dinitrophenyl hydrazine to form a derivative of Hydrazine. This compound is measured by optical spectroscopy with a wavelength of 505nm the absorption intensity will be proportional to the activity of this enzyme.

Method of measurement of alkaline phosphatase enzyme

A bioMerieux-France kit measures this enzyme. The basis of this method depended on the activity of this enzyme in the basal center According to the following equation:-

Phenylphosphate → Alkaline Phosphatase → Phenol + Phosphate

The liberated phenol is measured by the presence of the 4-amino-ante pyrene compound and Potassium ferricyanide, the presence of sodium arsenate is to stop the activity of the enzyme and then measured the solution along the wavelength of 510 nm. The amount of absorption is proportional to the amount of phenol released and this depends on the activity of the enzyme.

Statistical Analysis

The results were analyzed using the statistical Spss program in determining the standard deviation and the percentage as will to the other variables. The differences in case of probability p> 0.05 were considered significant differences.

Discussion

The results of the study showed that the total calcium concentration in microg / 100 ml for blood samples of thalassemia patients (50 samples) and for three different age groups and for both sexes was (8.9 ± 0.47) μg / 100 ml was less than the total calcium level in the serum of the healthy group (30 samples), which ranged from (9.5 ± 0.6) μg / 100 ml. The mean differences were (p <0.05) among patients with thalassemia and healthy shown in the following table (1), Table (2) figure (1,2) shows the relationship between age, Sex and thalassemia type. The most common type of infection is Thalassemia and the
most common age group with this disease (1-9 years) the most common age group with all types of beta-thalassemia is (1-4) years. The percentage of males is 62% for males and 38% for females. This is identical to the study of (11): the results also show that the majority of the infected patients are Thalassemia type. This type needs to give the patient special drugs and give him periodic blood, which costs the family many financial burdens, in addition to the psychological problems suffered by the patient the results showed a higher level of male infection than females. This may not mean a genetic link to sex but may reflect the interest of male families more than females, in addition to the reluctance of families to review centers and hospitals when the disease appeared in females, but we cannot neglect the possibility of sex. Table (3) shows that the mother, father or both are infected the highest percentage was the father’s injury 44% and the proportion of the mother’s injury 26%, while the proportion of infected together “is 30% Hypocalcaemia occurring in β-thalassemia major is attributed to hyperparathyroidism mainly. Low parathyroid hormone levels lead to excessive calcium loss in urine, decreased bone remodeling and decreased intestinal absorption of calcium. Hypocalcemia can also occur with massive blood transfusions due to the complex of citrate with serum calcium.(12) The results showed a significant increase in the activity of alkaline phosphatase enzyme for patients (165 ± 17) The activity of the enzyme in the serum of the control ( 81±22 ) and therefore there was a significant difference p <0.05. The reason for this may be because most of the activity of this enzyme comes from bone tissue and since Thalassemia patients suffer from the dissolution of this tissue, this leads to the leakage of this enzyme to the circulatory system and then increase the effectiveness of this enzyme (13). the study of the enzyme Alkaline phosphatase (ALP) in patients with thalassemia, which is one of the genetic blood diseases, which is characterized by a reduction in the proportion of blood within the hemoglobin of red blood cells where the ALP enzyme in the liver and bone marrow and that the bulk of the enzyme base phosphate in the serum comes from these two tissues (Bone marrow and liver) and is secreted in the circulatory system, so the high activity of this enzyme is often due to the conditions of these two tissues or perhaps due to the effects of iron on liver cells as it may break the increase of iron concentrations . Liver cells leading to the transmission of this enzyme and in large quantities to the bloodstream and thus to increase the effectiveness of this enzyme compared with healthy individuals. For GOT, there were significant differences between patients (GOT) and healthy (P <0.05), (GPT) and P <0.05. Both enzymes are spread in many tissues of the human body (14) and that the enzyme GOT more effective than the enzyme GPT (15). The GOT enzyme is abundant in the tissue of the heart-liver and skeletal muscles as well as the kidney while the liver contains large amounts of GPT Other tissues such as kidney- heart skeletal muscles contain abundant amounts of this enzyme. The reasons for the low effectiveness of enzymes from the normal level of healthy may be due to the amounts of iron in the serum of patients, which precipitate in these members, resulting in the breakdown of fat of some cells of these members. It appears that oxidative stress is the main mechanism in the major disease shifts of patients with thalassemia (16). These results indicate a significant consumption of antioxidants under increased iron output of continuous blood transfusions or oxidative stress in thalassemia patients The main purpose of blood transfusion is to eliminate anemia, suppress the formation of ineffective blood cells and inhibit the increased absorption of iron by the gastrointestinal tract (17) (Thus, excess iron will be stored as in the case of hemosiderin and the liver and spleen. (18) That the accumulation of iron amounts is a toxic condition will lead to tissue damage Leading to the formation of ROS molecules such as superoxide ion (Ȯ2)(ȮH), monoxide and hydrogen peroxide that drive oxidation in the thalassemia.

Conclusion
Our conclusion about some changes in some of the biochemical parameters of Thalassemia patients can be attributed to liver and heart diseases as well as renal failure arising from the toxicity of high iron concentration, which is a characteristic of thalassemia.

Evaluation of Bone Metabolism Biomarkers in Hemodialysis Chronic Kidney Disease

Firas Faris Rija1, Zaid Mohmmed Mubarak Almahdawi1, Sura Zahim Hussein2

1Biology Department, College of Sciences, Tikrit University, Iraq, 2Clinical Biochemistry Unit, Salah Aldeen Directorate, Iraq

Abstract

Metabolic bone disease (MBD) is a common complication of chronic kidney disease (CKD) and is a part of a broad spectrum of disorders of mineral metabolism that occur in this clinical setting and result in both skeletal and extraskletal consequences. This study was a cross sectional which conducted in Dialysis Unit in Tikrit Teaching Hospital in Tikrit city. The study started from January 2018 to August 2018 on study population age ranged from (18 – 68) years old The total of 60 subjects were separated to two groups as following: Control: This group consist of 30 healthy individuals (15 females and 15 males), and Hemodialysis (HD) (CKD) patients: This group consist of CKD 30 patients (15 females and 15 males). The results referred to the increased levels of Transforming growth factor- β (TGF-β), Osteoprogestrin (OPG), Sclerostin (SOST), Osteocalcin (OC) and C-reactive protein (CRP) in CKD with HD with highly significant differences (P≤0.01) when compared with control group. The bone metabolism biomarkers are increased in HD CKD patients who complicated to MBD.

Keywords: Metabolic bone disease, chronic kidney disease, Hemodialysis, Transforming growth factor- β.

Introduction

Metabolic bone disease is a common complication of chronic kidney disease (CKD) and is part of a broad spectrum of disorders of mineral metabolism that occur in this clinical setting. Alterations in the control mechanisms for calcium and phosphorus homeostasis occur early in the course of CKD and progress as kidney function decreases (1).

Chronic kidney disease (CKD) refers to the progressive and irreversible decline in renal function and is defined as kidney damage for ≥3 months based on findings of abnormal structure or function or glomerular filtration rate (GFR) 60 > mL/min/1.73 m² for ≥3 months with or without evidence of kidney damage (2,3).

Osteocalcin is a small protein (49 amino acids) with a molecular weight 5.8 kDa synthesized by mature osteoblasts. Serum osteocalcin levels are high in patients with CKD. The increased serum accumulation of osteocalcin in patients with CKD can be related to decreased renal clearance, increased bone metabolism, or a combination of both (4).

Sclerostin (SOST) is a 190-residue with a molecular weight 22.5 kDa secreted glycoprotein (5). Serum SOST levels were significantly correlated with age and were higher in male than female patients with stage III b and IV CKD (6).

Osteoprotegerin (OPG) is expressed as a circulating glycoprotein of 401 amino acids with seven structural domains (7). PTH appears to stimulate RANKL and inhibit OPG secretion, affecting their serum levels in renal failure. In this way the RANKL/OPG cytokine system mediates the effects of PTH and other humoral factors on bone metabolism, thus reflecting their impact on bone composition in several types of renal osteodystrophy (8).

Transforming growth factor (TGF-β) is a Polypeptide initially synthesized as pre-pro-TGF-β, a monomer of a molecular weight of 55kDa and consisting of 390 amino acid residues (9). TGF-β plays a pivotal role in the progression of renal fibrosis, and therapeutic interventions targeting TGF-β have been successful and well tolerated in animal models (10).

C-reactive protein (CRP) is a 206-amino acid member of the short pentraxin family, alongside serum
amyloid P component (SAP). CRP is predominantly synthesized in the liver (11). Elderly Iranians with the metabolic syndrome and high CRP levels had significantly increased risk of CKD (12).

Materials and Method

The study was a cross sectional which conducted in Dialysis Unit in Tikrit Teaching Hospital in Tikrit city. The study started from January 2018 to August 2018 on study population age ranged from (18 – 68) years old. The total of 60 subjects was separated to two groups as following:

Group one:

Control group: This group consists of 30 healthy individuals (15 females and 15 males) with no personal and familial history of any diseases.

Group Two:

Hemodialysis (HD) (CKD) patients: This group consist of CKD 30 patients (15 females and 15 males) with hemodialysis treatment.

ELISA kits were used to evaluate serum TGF – β, Osteocalcin, SOST, OPG and CRP by sunlong company. The statistical analysis was carried out by using statistical program (SPS, 2001) and comparison between groups which were made by using one-way analysis of variance (ANOVA), and tried out the arithmetic means for parameters by using test of Duncan multiple ranges. The level of statistical significance was taken at (P<0.05).

Results

The mean ± SD of TGF-β levels for total, male and female of HD CKD patients (440.1±366.5, 320.6±338.7, 559.5±366.8 pg/ml) and control (118.7±40.9, 128.5±36.4, 108.9±44.1 pg/ml) respectively as shown in table (1) and figure (1), and the mean ± SD of OC levels for total, males and females of HD CKD patients (14.5±15.2, 11.1±9.88, 17.9±16.4) pg/ml and control (4.0±1.9, 3.9±1.8, 4.1±2.1 pg/ml) respectively as shown in table (1) and figure (2), while the mean ± SD of SOST levels for total, males and females of HD CKD patients (157.1±142.2, 95.9±89.77, 218.3±209.3 ng/ml) and control (22.6±5.0, 24.1±4.3, 21.0±5.3 ng/ml) respectively as shown in table (1) and figure (3), but the mean ± SD of OPG levels for total, male and female of HD CKD patients (585.5±380.1, 588.6±387.2, 582.5±387.4 pg/dl) and control (160.7±103.4, 202.8±96.5, 118.6±95.1 pg/dl) respectively as shown in table (1) and figure (4), and the mean ± SD of CRP levels for total, male and female of HD CKD patients (10.9±7.7, 12.2±8.8, 9.68±6.6 mg/l) and control (4.0±0.49, 3.9±0.53, 4.1±0.48 mg/l) respectively as shown in table (1) and figure (5).

DISCUSSION

In the present study, TGF-β increased in HD CKD patients with highly significant differences (P≤0.01) except male with significant differences (P≤0.05) when compared with control group. Our findings of TGF-β at group HD CKD patients is agreed with some studies were performed by (13-16).

The most abundant form of TGF-β superfamily in mammals is TGF-β1. TGF-β has been recognized as a central player in many pathological events related to CKD progression, at the glomerular, tubulointerstitial and vascular levels, whereas TGF-β overexpression causes renal fibrosis (17).

TGF-β production is associated with CKD progression. Circulating TGF-β levels is a reliable biomarker of CKD (18).

In the present study, OPG increased in HD CKD patients with highly significant differences (P≤0.01) when compared with control group, and this result was agreed with (7, 19).

Elevated OPG levels have been interpreted as a failed compensatory mechanism trying to counteract the ongoing calcification process; however, because OPG production and expression are highly regulated by several inflammatory cytokines (20).

Mechanisms underlying OPG increase in CKD might include low-grade inflammation, FGF-23 elevation, and kidney function itself (21).

The level of SOST was increased with highly significant differences (P≤0.01) in HD CKD patients when compared with control group. These results agreed with (22, 23).

Sabbagh et al. suggests that an increase in osteocyte
production is most likely the primary event that leads to
the elevation in serum sclerostin levels observed in CKD
patients (24).

In our findings, OC increased in HD CKD patients,
and this increase was highly significant differences
(P≤0.01) when compared with control group. These
results of CKD agreed with (25, 26).

In patients with impaired renal function plasma
OC levels are markedly elevated due to increased
bone turnover and decreased renal elimination (27). The
imbalance in the process of endothelial damage and
repair, therefore, may contribute to VC via increasing
the number of OC-positive endothelial progenitor cells
(28).

In the present study, CRP levels increased with
highly significant differences (P≤0.01) in HD CKD
patients when compared with control group. The current
results of CRP agreed with (29-31).

Systemic inflammation occurs among patients
with chronic kidney disease (CKD). Along the drop in
glomerular filtration rate (GFR) below 60mL/min/1.73
m², the severity of inflammation increases with the
progression of renal failure (32).

CRP is also supportive in prognostication and in
monitoring treatment in CKD patients, it rose in these
patients because CKD is an inflammatory process and
pro-inflammatory cytokines are responsible for its
increased synthesis (33).

Conclusion

Our findings suggest that the TGF- β, OPG,
SOST, OC and CRP are plays an important role in the
bone turnover of hemodialysis CKD patients. Mineral
metabolism disturbance caused by renal dysfunction is
inherently complicated.

Estimation of TLR-4 and Cytokines Levels (Interleukin-1 Beta, Interleukin-8, and Tumor Necrosis Factor) in Serum and Peritoneal Fluid of Endometriosis Women

Jinan Abdul-abbas Shamkhi, Ahmed Abdul-hassan Abbas, Thuraya Hussam Al-Deen

Al-Kut Hospital for Pediatrics and Obstetrics, Baghdad, Iraq, College of Medicine, Al-Nahrain University, Baghdad, Iraq, Gynecology Department of Al-Emamain Al-Kademian Medical City, Baghdad, Iraq

Abstract

Many women have a delay in diagnosis of endometriosis; an important factor that contributes to the diagnostic delay is the lack of noninvasive methods for detecting the disease. The aim of this study was to evaluate the levels of IL-1β, IL-8, TNF-α, and TLR-4 in serum and peritoneal fluid (PF) of women with endometriosis. The case group comprised of 30 women with endometriosis who newly diagnosed (admitted to the Gynecology Department of Al-Emamain Al-Kademian Medical City, Al-Zahraa teaching hospital and Al-kut hospital of pediatric and obstetric) and 30 control group during the period from November 2016 to November 2017. The four biomarkers were measured by using ELISA. Endometriosis patients had significantly higher serum and PF concentrations of the four biomarkers compared to controls. These results may indicate the potential role of these biomarkers in non-invasive diagnosis of endometriosis.

Key words:- Endometriosis, Interleukin-1 beta, Tumor necrosis factor, TLR-4

Introduction

Endometriosis is an inflammatory disease characterized by the existence of endometrial glands and stroma outside the uterine cavity with significant reduction in quality of life among reproductive-age females (1). Menstrual tissue and endometrium that is refluxed into the peritoneal cavity is usually cleared by immune cell such as macrophages, natural killer (NK) cell, and lymphocytes. For this reason, immune system dysfunction is one likely mechanism for the genesis of endometriosis in the presence of retrograde menstruation (2).

The production of pro-inflammatory cytokines and growth of endometriosis in the pelvic environment can be regulated by the innate immune system (3). Peritoneal fluid contains higher concentration of proinflammatory and angiogenic cytokines presumably produced from immune cells such as macrophage and from the lesion itself, which contribute to the pathogenesis of endometriosis (4). Immune cells use cytokines to coordinate the host response to infection or trauma via autocrine and paracrine signaling. Based on their immune-regulatory role, cytokines are broadly classified as either pro-or anti-inflammatory. Proinflammatory cytokines such as interleukin-1 (IL-1), tumor necrosis factor alpha (TNF-α), interferon gamma (IFN-γ), IL8 and granulocyte-macrophage colony-stimulating factor (GM-CSF) primarily initiate and amplify the inflammatory response to infection or trauma by signaling the recruit of additional immune cells and pro-inflammatory mediators to the site of injury (5). The secreted TNF-α IL-1 IL-1β and IL8 may play an important role in the local and the systemic manifestations of the disease. Because of its importance in other inflammatory processes, it is likely that these cytokines plays a central role in the pathogenesis of endometriosis (6-8).

Toll-like receptor-4, is an essential receptor for bacterial endotoxin or LPS recognition which derived from the outer membrane of Gram-negative bacteria (9).

A reliable single biomarker or panel of biomarkers may help to diagnose endometriosis earlier and reduce unnecessary operation (10). Simple blood tests for prediction and diagnosis of endometriosis have a major impact on women's health (11), because many women have a delay in diagnosis of endometriosis, an important factor that contributes to the diagnostic delay is the lack of noninvasive methods for detecting the disease.

Materials and method

Thirty newly diagnosed endometriotic patients, admitted to the Gynecology Department of Al-Emamain Al-Kademian Medical City, Al-zahraa teaching hospital and Al-kut hospital of pediatric and obstetric were enrolled in this control study during the period from November 2016 to November 2017, their ages range between (18-45) years. Thirty apparently healthy women were selected as control group in the current study their age matched to the study group. The controls were fertile, not pregnant and non-smoker with no current infection (genital or systemic).

A total of 5 ml of venous blood were collected before the operation in gel tubes and about 3 ml of peritoneal fluid were obtained by gynecologist in plain tubes. Peritoneal fluid had been centrifuged at 300 \( \times \) g for 20 min, after which the supernatants removed to new tubes and stored in aliquots at -70°C.

Statistical Analysis

Data were organized in Microsoft office Excel software, 2010. The statistical package for social sciences (SPSS) software (version. 20) was used for all statistical analysis. Data were subjected to normality test (Shapiro-Wilk test) before statistically analyzed. Continuous variables were expressed as mean ± standard deviation (SD) or median and analyzed either by independent t-test for comparison between two groups or analysis of variance (ANOVA) for comparison among more than two groups. Binomial variables were expressed as frequency and percentage and analyzed by Pearson chi-square. A P-value of \( \leq 0.05 \) was considered a statistically significant.

Results

Demographical picture and clinical presentation

The results of this research were based on the analysis of 30 patients with endometriosis, compared with 30 apparently healthy women as controls. The present study showed that 83.33% of endometriosis patients were infertile [primary infertile 12 (40%) and secondary infertile 13(43.33%)]. Table (1) shows the variables between the two groups which including age, phases of menstrual cycle (secretory and proliferative), family history with disease, the fecundity, stages of disease, and symptoms like as abdominopelvic pain and dysmenorrhea.

Discussion

Endometriosis is classified into four stages (I-minimal, II-mild, III-moderate, and IV-severe), the present study found that the stage 1 was found in 17 (56.67%) patients, stage 2 in 9 (30%), stage 3 was found in 3 (10%), while the rest 1 (3.33%), appeared in stage 4. The higher occurrence stages in this study were the minimal and mild (86.67%). AL-Tai et al. (2013) and Ali AM (2016) mentioned that the most stages were the mild and moderate (12,13) while by Daraj HA.(2017) the most stages were moderate and severe stages (14) also with Saber H, et al.(2013) the most stage was the moderate one (15).

These discrepancies in results of different studies with the present study could be related to that most of patients in the present study were recently diagnosed and discovered incidentally or may be to the small size of samples. Delayed diagnosis and treatment have significant consequences, as endometriosis is more advanced in women whose diagnostic laparoscopy is delayed, supporting progression of disease over time (16).

The pain is the highest priority research questions, beginning from mild, moderate to severe pain. In this study, the majority of women with endometriosis had been suffered from chronic pelvic or abdominal pain and this agree with other studies like AL-Tai TH. et
Multiple mechanisms underlie endometriosis-associated pain including nociception, inflammation, and alterations in peripheral and central nervous system pain processing. As also occurring in other chronic conditions, pain in endometriosis is often associated with psychological distress and fatigue, both of which may amplify pain (17).

The second most important chief complaint found by this study was infertility. The present study showed that 83.33% [primary infertile 12 (40%) and secondary infertile 13(43.33%)] of endometriosis patients were infertile, it was agree with study by Daraj HA.(2017) who found that secondary infertility in patients group constitute the largest portion (14). The causes of infertility in women with endometriosis may range from anatomical distortions due to adhesions and fibrosis to endocrine abnormalities and immunological disturbances (18).

Endometriosis likely has a genetic basis and a number of studies have demonstrated an increased risk for developing this disease in first-degree relatives of patients. According to the family history, the current work showed that 4 (13.33%) of patients had positive family history of endometriosis, while 26 (86.67%) showed negative family history, and this percentage is higher than the results obtained by Nouri et al. (2010) and Ali A.M.(2016) (19, 13), who found that 5.9% and 6% respectively had positive family history. Specific genes are differentially expressed in eutopic endometrium of endometriosis patients as compared to those from normal woman controls (20). The results suggest that gene dysregulation may play a role in the pathogenesis of endometriosis. A previous study conducted on twins revealed that the incidence of this disease in monzygotic twins was twice as much as that in dizygotic twins (21).

In the current study there was a statistically significant higher level of IL-1β, IL-8, TNF-α, and TLR-4 in serum of patients as compared to healthy controls. This findings in agreement with local study by Ali, AM.(2016) who showed that mean serum level of TNF-α was elevated in endometriotic patients as compared with healthy group (13), also agree with Egyptian study by Foda AA and Abdelaal IA. (2011) who indicated that serum TNF-α was significantly higher in women with endometriosis when compared with controls (22). Malutan AM et al. (2015) found that women with endometriosis had been significant higher level of IL-1β, IL-6, and TNF-α, compared to healthy controls (11).

Tumor necrosis factor-α may play a central role in the local and systematic manifestations of endometriosis, on the basis of evidence showing that it promotes the growth of endometriotic cells (23). On the other hand, blocking TNF-α appears to inhibit the development of the disease in animal models (24).

In the present study, there was no statistically significant difference in serum and peritoneal fluid level of IL-1β, IL-8, and TNF-α in women with endometriosis among different phases of menstrual cycle (proliferative and secretory), also this study is agree with previous studies by Bedaiwy, MA. et al. (2002) and Othman EE, et al. (2008) which demonstrated that there was none of the measured cytokines showed significant correlation with the cycle phase (25, 26). The finding that these measures were not affected by the phase of the menstrual cycles makes them more convenient to apply as reliable diagnostic tests in clinical practice.

Ethical Clearance: Ethical approval and informed consent were obtained from each participant in this study according to the declaration of Helsinki -ethical agreement, it was obtained from the Institutional Review Board of College of Medicine /AL- Nahrain University.

Application of a Rapid Method for Gram Differentiation of Human Pathogenic and Non-Pathogenic Bacteria without Staining (Short Communication)

Ruua A. Talib1, Abid Ali Abeid Abiess1
1Dept. of Pathological Analysis, College of Al-Mustaqbale University, Iraq

SUMMARY

The Gram-stain reactions of pathogenic and non-pathogenic bacteria isolated from clinical samples were accurately characterized by mixing a concentrated droplet of cells with 3% potassium hydroxide (KOH). Compared to standard Gram-staining procedures, the KOH test was rapid, simple, and completely accurate. Forty-one isolates representing Bacillus, Corynebacterium, Escherichia, Haemophilus, Klebsiella, Neisseria, proteus, Pseudomonas, Salmonella, Shigella, Staphylococcus, and Streptococcus species were tested. Bacteria cell were removed from an agar medium with toothpick placed on a glass slide with drop of 3% KOH with rapid circular agitation. With Gram-negative stains the suspension become viscous as revealed by a mucoid thread that formed when the toothpick was lifted. Gram-positive bacteria dispersed in to the drop and did not have this reaction. One isolate of Corynebacterium caused an increase in drop viscosity, but did not produce a mucoid thread.

This method substitutes stains uses which are expensive and can be done in seconds.

Keywords: Gram stain, KOH test

Introduction

Determination of positive or negative Gram-stain reaction is essential in the identification and classification of human pathogenic bacteria. One problem often encountered when using Gram-staining techniques is that some Gram-positive bacteria will have dark decolorize readily and some Gram-negative bacteria will have dark staining bodies depending on the culture medium and the stage of colony growth (1). Pseudomonas aeruginosa is the second most common bacteria cause of nosocomial infections (2). It is characterized by ability to adapt to diverse environments with low nutrient concentration and over a large temperature range between 4 and 42°C (3). Gregersen (1978) used a method for distinction of Gram-negative from Gram-positive bacteria including Pseudomonas aeruginosa, P. fluorescense, Streptococcus spp. and Bacillus spp. often associated with plants (4). Successful application of KOH test proved to differentiate clinical anaerobic bacteria (5). This paper showed the rapid method for Gram differentiation of human pathogenic and non-pathogenic bacteria by using KOH test.

Materials and Method

Human pathogenic and non-pathogenic bacteria used in these tests were obtained from culture collection of laboratory of Al-Sader Hospital in Al-Najaf (SHN) and from department of pathological analysis techniques of AL-Mustaqbal University college (PAT).

All bacteria were grow at 37°C for 24-48 hr. (depending on growth rate) on different selective medium for staining and KOH characterization.

Staining and KOH tests: Gram staining procedure utilizing ammonium oxalate, crystle violet, Iodine solution, 95% ethyl alcohol as the decolorizing agent and Safranin O as the counter stain were followed as described (6). Two drops of hydroxide were placed on a clean glass slide, culture media with a flat wooden toothpick and placed in to the drop of KOH with rapid, circular agitation. After 5-8sec. the toothpick was alternately raised and lowered just off the slide surface to detect astringing effect. The KOH test considered positive if drop viscosity increased and stringing
occurred within 15 sec.

**Results and Discussion**

The results showed that Gram-negative bacteria always caused an increase in KOH viscosity and formed a mucoid thread when lifted from the slide. Gram-positive bacteria had no reaction in KOH and generally dispersed into the drop (table 1).

The use of KOH test as an effective supplement to Gram staining has been very useful for the rapid and accurate differentiation of a large number of bacteria originally isolated from clinical samples. This method utilizes the rapid disruption of the cell wall of Gram-negative bacteria in alkaline solution releasing deoxyribonucleic acid, which causes the viscous threading. Gram-positive bacteria do not lyse in 3% KOH. However, one isolate of *corynebacterium* gave a slight increase in viscosity after 20 sec. but did not form mucoid thread. This study supports other findings that plant pathogenic and saprophytic bacteria can use this method for Gram differentiation without staining.

Accuracy of Ultrasound in Diagnosis of Carpal Tunnel Syndrome in Correlation with Operative Findings

Laith F. Farman Al hialy
College of Medicine, University of Baghdad, Iraq

Abstract

Carpal tunnel syndrome (CTS) is the most common entrapment neuropathy; it is responsible for significant morbidity and occupational absence. Clinical assessment is used for initial diagnosis and Nerve Conductive studies are currently the principal test used to confirm the diagnosis; Ultrasound (US) can be used as an alternative to NC studies to diagnose CTS. US can assess the anatomy of the median nerve & it’s the only way to detect adhesion during dynamic examination and also identify pathology of the surrounding structures that may compress the nerve. The aim of current study was to identify the accuracy of US in the diagnosis of CTS in correlation with the operative findings.

A prospective study included 65 patients with CTS, all of them examined with superficial ultrasound pre operatively were US findings collected, 52 patient of them operated surgically and operative finding recorded, in this study we considered the operative findings as gold stander for correlation its findings with our ultrasound findings, no similar researches was found, but many researches correlate and compare the ultrasound findings with clinical symptoms, neural conductive study or MRI findings.

Enlargement of the median nerve as it enters the carpal tunnel was frequently detected (41) times among the whole sample patients (65) and from the (52) operated patient (28) times recorded, the ultrasound examination was 87% accuracy with 88% Sensitivity, 85% Specificity with PV= 0.001.

Ultrasound examination is very significant and sensitive in diagnosis of (CTS) could be used confidently in symptomatic patient as fist line examination approach, and it is the only modality that can assess the fixation of median nerve in the carpal tunnel through dynamic technique.

Keywords: carpal tunnel syndrome, ultrasound examination, operative findings

Introduction

Carpal tunnel syndrome (CTS) is the most common entrapment neuropathy; it is responsible for significant morbidity and occupational absence. Clinical assessment is used for initial diagnosis and Nerve Conductive studies are currently the principal test used to confirm the diagnosis; the carpal tunnel is fibro-osseous space between the carpal bones and the flexor retinaculum, or called transverse carpal ligament which extended from scaphoid to pisiform and from hamate to trapezium. It contains the eight flexor digitorum tendons, superficialis and profundus, the flexor pollicus longus and median nerve, the etiology of (CTS ) or encroachment of the median nerve result from decrease in size of tunnel, or increase in the volume of tunnel content , the most recently described common cause of CTS is repetitive stress injury as in computer keyboard operators. US examination of the median nerve in the carpal tunnel is relatively quick test that is extremely acceptable to the patient and can be performed in the outpatient clinic at initial assessment.

Patient forearm should rest comfortably and the wrist is in supination, in the longitudinal imaging plane the median never is demonstrated crossing parallel and superficial to the flexor digitorum tendons

Corresponding author:
Laith F. Farman Al hialy
E-mail: drlaithfadhel@gmail.com
The tunnel contains the flexor digitorum tendons which are hyper echoic, the median nerve has a characteristic appearance which differentiates it from the fibillar hyper echoic tendons, the nerve has hypo echoic with a hyper echoic borders, rounded or oval in the proximal wrist and flattens progressively as it courses through the carpal tunnel, within the tunnel the nerve is in intimate contact with the flexor retinaculum, its size remains constant but its shape is quite variable, by dynamic examination, moving the fingers we differentiate the nerve from tendons.

Flattening of the nerve, especially at the level of the hamate bone, volar bulging of the flexor retinaculum, enlargement of the median nerve as it enters the carpal tunnel, fluid or fat-fibrous layer surrounding the tendons, decreased mobility of the median nerve on flexion and extension of the fingers.

The mean cross sectional area of the median nerve is greater than 10 mm squared at the pisiform bone level, the flattening ratio of the nerve (transverse diameter divided by AP diameter) is greater than 1:1 at the level of the hamate bone.

Surgical treatment of CTS involves division of the flexor retinaculum, either in an open procedure or endoscopically during the operation many findings be observe as: Compression of the median nerve under the ligament, pseudoneuroma (nerve swelling) proximal to the compression, adherent tenosynovitis under surface of flexure retinaculum, fibrous lesion surrounding the nerve or Median nerve scaring.

This study aim to identify the accuracy of US examination in the diagnosis of CTS in correlation with the operative findings

**Materials and Method**

A prospective study was conducted at Specialist surgery teaching hospital and Baghdad teaching hospital in Baghdad medical city, during the period from 20th of December 2014 to the 30th of September 2015.

A total of 65 patients agreed to participate in this study, they referred from the neurosurgery department, orthopaedic department, nerve conductive clinic and outpatient clinic, 58 of them were females and 7 males, 52 of them were operated on, 13 not operated, all of them improved and documented by NCS to have CTS.

All patients were examined, through superficial ultrasound examination approach by using Philips HD 11XE® ultrasound system with linear probe of 7.5 MHz frequency. all of them examined with superficial ultrasound pre operatively were US findings collected, 52 patient of them operated surgically and operative finding recorded, in this study we considered the operative findings as gold standard for correlation its findings with our ultrasound findings, no similar researches was found, but many researches correlate and compare the ultrasound findings with clinical symptoms, neural conductive study or MRI findings, examination done with 2 direction, longitudinal and transverse, and dynamic examination, subjective and objective ultrasound findings elected.

We used the upper normal CS area limit for the median nerve before entering the Carpal tunnel, at the pisiform bone level as (<10 mm²), the transverse to AP diameter ratio of median nerve in cross section image greater than (4:1) to be acceptable as flattening of median nerve, volar bulging of flexor retinaculum is greater than (3.1 nm).

These measurements were proved and published in the diagnostic ultrasound guide of CTS.

In the transverse view we calculated the Cross section area of median nerve in the entrance of tunnel at level of pisiform bone in millimetre square (mm²). Also in the transverse view we measure the AP & transverse diameter of median nerve and the ratio of flattening. Lastly we calculated the flexor retinaculum bulging in (mm) then we transfer the data to computer to find the correlation and results.

**Statistical Analysis:**

Statistical analysis was performed by using the statistical package for social sciences (SPSS) version 17, and the appropriate statistical tests were applied accordingly. X-square was used to test the relation between ultrasound and operative tests. P – Value of less than 0.05 was considered significant.

**Results**

**Age & gender distribution**

The mean age of the patients was 45.9 ± 13 years (range from 19 to 74 years).
The female to male Ratio (9:1) with proximal percentage of 89.2% Female to 10.8% Male.

The results are listed in Tables below:

**Discussion**

Carpal tunnel syndrome (CTS) is the most common entrapment neuropathy, currently many modalities were applied to for diagnosis like US and MRI.
US is now well established as a diagnostic tool in CTS, and can be used as an alternative to NCS for diagnosis of CTS, there are many advantages for US, including that it is readily available, non-invasive, lower cost, higher patient acceptability has a shorter examination time and can be used to assess a number of parameters of the median nerve such as size, morphology, mobility (using dynamic examination in addition, US provide information about anatomical variations of the median nerve and surrounding structures that may be a causative factor in CTS).

The current study included 65 patients ranging between (19 – 74 years old) with mean age being (45.9 years).

From the total 65 patients of both genders, in our study the female were predominant, 58 female, 7 male with ratio 9:1 female to male.

This study assesses the accuracy of US in diagnosis of CTS by specific detective ultrasound findings in correlation to the operative findings.

The accuracy of ultrasound regarding the enlargement of the median nerve as it enters the carpal tunnel that assisted and correlate with the operative finding (pseudoneuroma-median nerve swelling-proximal to the compression) was 87% accuracy with 88% Sensitivity, 85% Specificity with PV= 0.001.

The accuracy of ultrasound examination regarding the flattening of the Median nerve, especially at the level of the hamate bone to the operative finding (compression of the median nerve was observed under the ligament) was 76% accuracy with 76% Sensitivity, 100 % Specificity with PV= 0.017. The accuracy of ultrasound examination regarding (decreased mobility of the median nerve on flexion and extension of the fingers) to the operative finding (adherent tenosynovitis under surface of flexure retinaculum) was 71% accuracy with 38% Sensitivity, 100 % Specificity with PV= 0.005.

We considered and depend on the highest result, regarding accuracy, sensitivity , specificity and the lowest PV, the median nerve enlargement, which was frequently detected (41) times among the whole sample patients (65) and from the (52) operated patient (28) times recoded.

Conclusion

Ultrasound accuracy in diagnosis CTS is very significant, its sensitivity approaching that of NCS with accuracy reaching (87%). There is significant correlation between US findings in CTS and the operative findings. Ultrasound could be used confidently in symptomatic patient with CTS as fist line examination approach. Ultrasound is the only modality that can assess the fixation of median nerve in the carpal tunnel through dynamic technique. US of the median nerve in the carpal tunnel is relatively quick test that is extremely acceptable to the patient and can be performed in the outpatient clinic at initial assessment.

Recommendation

Ultrasound advocated as a screening tool in high-risk populations or symptomatic patient. High-resolution ultrasound systems with high frequencies probes (10-14 MHZ) is needed to gate more accurate diagnoses of CTS. Other ultrasound measurement and parameters such as vascularity of median nerve assess by Doppler study, newer technologies such as elastography and three-dimensional ultrasound prospectively will improve the diagnosis of CTS. Further studies with larger sample size, longer duration and follow up duration are highly suggested.

Comparative Study of Hepcidin and Some Inflammatory Parameters in Pregnant Women at the Three Trimesters

Suha Abdul-Khaliq Al-Jowari

Department of Biology, College of Science, University of Baghdad, Baghdad, Iraq

Abstract

Comparative study of hepcidin and some inflammatory parameters (interleukin-2 and 6, tumor necrosis factor and c-reactive protein) from several Health Centers in Baghdad City was performed. Sixty adult apparently healthy pregnant women (twenty in each trimester) at different periods of gestation and twenty normal non-pregnant women (total eighty) were the subjects of this study. From each subject, 10 ml blood was collected in order to obtain serum. The supernatant of blood samples was used to quantify the serum TIBC level by spectrophotometric methods. Serum levels of hepcidin, iron (Fe), C-reactive protein (CRP), interleukin-2 (IL-2), interleukin-6 (IL-6) and tumor necrosis factor-α (TNF-α) were measured by standard methods using commercially available kits.

The results of the present study show that there was a significant (P<0.05) decrease in hepcidin concentration means at the three trimesters of pregnancy as compared with non-pregnant women. This study also demonstrate that there was a significant (p<0.05) increase in TIBC and transferrin concentrations at the second and third trimesters of pregnancy. On the other hand, these results explain a significant (p<0.05) decrease in iron concentration means at the first and second trimesters as compared with non-pregnant, while there was a significant (p<0.05) increase in IL-2 concentration means at the second and third trimesters of pregnancy. Further, the results of the present study demonstrate that there was a significant (P<0.05) increase in IL-6 concentration and C-reactive protein means at the three trimesters of pregnancy as compared with non-pregnant women. On the other hand, there was no significant difference in TNF-α at the three trimesters of pregnancy as compared with non-pregnant.

It is concluded from the present study that hepcidin and inflammatory markers were reduced as the pregnancy developed, while transferrin and TIBC concentrations were elevated in pregnant women at the three trimester as compared with non-pregnant.

Keywords: Hepcidin, Trimester, Interleukins, Pregnancy, C-Reactive Protein.

Introduction

Hepcidin, a peptide composed of 25 amino acids (Hep-25), is considered to be a regulatory molecule of systemic iron homeostasis [1, 2]. Hepcidin, is synthesized mainly in the liver by hepatocytes [3]. It regulates the metabolism of iron by the inhibition of iron absorption in the duodenum at the level of the intestinal epithelium [1, 3]. It is an antimicrobial small peptide and contributes to host defense by depriving microbes access to iron and through direct antimicrobial activity against microorganisms [4]. The role of hepcidin in the regulation of iron metabolism in pregnancy and its effects on the fetus and consequently on the newborn is not fully understood [1].

Cytokines are the intercellular messengers of the immune system and intimately participate in many aspects of pregnancy. IL6 is a multifunctional cytokine plays important roles in acute and chronic inflammation and autoimmunity [5, 6]. C-reactive protein found in the blood is considered as an acute-phase protein in which its level increase during inflammation, tissue damage, infection and neoplasia [7, 9]. Liver produce CRP in response to inflammatory cytokines such as IL-1, IL-6 & TNF-alpha [7, 9], which are responsible for inflammatory
response and maternal endothelial activation [7]. As rare and few studies concerning the level of hepcidin and these cytokines in pregnant women, this study was designed to compare the levels of hepcidin and some inflammatory marker in pregnant women at the three trimester of pregnancy.

**Materials and Method**

**Subjects**

This prospective, comparative study was performed at Baghdad City from the period between June 2018 to October 2018. Sixty adult apparently health pregnant women (twenty in each trimester) at different periods of gestation and twenty normal non-pregnant women (total eighty) were the subjects of this study. They were selected from several Health Centers in Baghdad City on the basis of their apparent health. All subjects were selected randomly during their antenatal visits [10]. Gestational age was estimated by the last menstrual period and confirmed or corrected by ultrasonography of the crown-rump length (dated in the first trimester) [1]. The age of the subjects ranged between 20 to 35 years. The normal non-pregnant women were chosen of the matching age group to act as controls. The informed consent was obtained from all subjects [10, 11]. Experimentally and control groups with history of diabetes, hypertension, hepatitis and any other acute or chronic illness were excluded from this study [8, 10].

**Blood sample collection**

From each subject 10 ml blood was collected from an antecubital vein with whole glass. In order to obtain serum, the blood was centrifuge at 2500×g at 4°C for 10 min and was stored in small portions at −25°C for subsequent biochemical analysis [1, 10, 11].

**Laboratory Analysis**

The supernatant of blood samples was used to quantify the serum TIBC level by spectrophotometric methods supplied by Biolabo Company, France (KURHADE et al., 1994; Talabani, 2015). Transferrin can be estimated indirectly from the TIBC value by the following equation:

\[
\text{Transferrin (g/dl)} = 0.7 \times \text{TIBC (g/dl)} \quad \text{(Talabani, 2015)}.
\]

Serum levels of hepcidin, iron (Fe) and C-reactive protein (CRP) were measured by standard methods using commercially available kits [1, 8].

Further, immunoassays of interleukin-2 (IL-2), interleukin-6 (IL-6), tumor necrosis factor-α (TNF-α) using commercially available immunoassay kits.

**Statistical Analysis**

Analysis of variance test (ANOVA) was used to analyze the data obtained from the present study. The significance among means were found using Duncan’s test with assistance of SPSS program (version 21) at probability level p< 0.05 (Basher, 2003).

**Results and Discussion**

The results of the present study show that there was a significant (P<0.05) decrease in hepcidin concentration means at the three trimesters of pregnancy as compared with non-pregnant women. The hepcidin means were 93.287 ± 8.393, 74.859 ± 8.488, 55.457 ± 7.936 and 39.061 ± 6.543 ng/ml in non-pregnancy, first, second and third trimesters of pregnancy, respectively. (Figure 1).

![Figure 1: Hepcidin concentration means in non-pregnant and pregnant women at the three trimesters.](image)

This study demonstrate that there was a significant (p<0.05) increase in transferrin concentration at the second and third trimesters of pregnancy, while there was no significant difference in the first trimester as compared with non-pregnant women. The transferrin concentration means were 211.629 ± 4.803, 202.441 ± 3.702, 197.484 ± 3.908 and 193.586 ± 4.059 gm/dl in the third, second and first trimesters as well as non-pregnant women, respectively (Figure 2).
The results in Figure (3) illustrate that there was a significant (p<0.05) increase in the TIBC concentration means at the second and third trimesters of pregnancy, while there was no significant difference at the first trimester as compared with non-pregnant women. The TIBC concentration means were 276.623 ± 5.709, 282.120 ± 5.584, 289.201 ± 5.289 and 302.777 ± 6.331 gm/dl in non-pregnant, first, second and third trimesters, respectively (Figure 3).

On the other hand, the results in Figure (4) explain a significant (p<0.05) decrease in iron concentration means at the first and second trimesters, while there was no significant difference at third trimester as compared with non-pregnant. The iron concentration means were 59.833 ± 7.738, 49.618 ± 4.463, 52.269 ± 4.781 and 55.081 ± 4.808 g/dl in non-pregnant, first, second and third trimesters, respectively.

The results in Figure (5) illustrate that there was a significant (p<0.05) increase in IL-2 concentration means at the second and third trimesters of pregnancy, while there was no significant difference at the first trimester as compared with non-pregnant women. The IL-2 concentration means were 48.996 ± 5.021, 53.048 ± 4.313, 63.193 ± 3.982 and 80.217 ± 4.900 pg/ml in non-pregnant, first, second and third trimesters, respectively.

Further, the results of the present study demonstrate that there was a significant (P<0.05) increase in IL-6 concentration means at the three trimesters of pregnancy as compared with non-pregnant women. The IL-6 concentration means were 15.758 ± 4.309, 22.288 ± 5.163, 32.765 ± 5.274 and 44.228 ± 5.177 ng/ml in non-pregnant, first, second and third trimesters of pregnancy, respectively (Figure 6).
On the other hand, there was no significant difference in TNF-α at the three trimesters of pregnancy as compared with non-pregnant. The iron concentration means were 592.138 ± 54.880, 599.52 ± 53.797, 611.740 ± 52.257 and 628.133 ± 51.091 pg/ml in non-pregnant, first, second and third trimesters, respectively.

There was a significant (P<0.05) increase in CRP concentration means at the three trimesters of pregnancy as compared with non-pregnant women. The CRP means were 1.778 ± 0.283, 2.34 ± 0.378, 3.905 ± 0.555 and 6.527 ± 1.181 mg/L in non-pregnancy, first, second and third trimesters of pregnancy, respectively.

Hepcidin synthesis is reportedly stimulated by elevated plasma iron concentration, infection and/or inflammation, and is suppressed in conditions that demand increased serum iron, such as increased or ineffective erythropoiesis, hypoxia, anemia and also iron deficiency[2]. In pregnant women, it is lower than in non-pregnant healthy women and its level decreases as pregnancy progresses, with the lowest hepcidin levels observed in the third trimester[11; 12]. Increasing need for fetal iron and decreasing maternal iron levels in the third trimester were the probable reasons for the decrease in maternal hepcidin in the third trimester.

Hepcidin negatively regulates intestinal iron absorption, iron recycling by macrophages, iron release from hepatic stores and, during pregnancy, iron transfer in placenta. In turn, hepcidin secretion is regulated by iron stores, oxygenation, and inflammatory signals[2]. The signals that suppress maternal hepcidin during pregnancy are unknown. Pregnancy-specific regulators of hepcidin production may exist, or hepcidin may be suppressed in response to decreasing maternal iron levels during pregnancy.

Total iron binding capacity of the serum rise significantly during pregnancy, against the gradient of dilution, which is an expression of the vastly increased turnover of iron in late pregnancy. TIBC is influenced by subject’s iron and endocrine status and increases during pregnancy to the extent of 15% above non-pregnant level. The transferrin not bound to iron, is readily available resulting in increased TIBC.

C-reactive protein is in the range of gestational age-specific reference value[1]. However, it has been found that a positive correlation between the inflammatory marker C reactive protein (CRP) and serum hepcidin at time of delivery (gestational age 37–42 weeks). The C-reactive protein concentrations were slightly higher than in non-pregnant women.

Interleukin-2 concentrations were found to be lower in early pregnancy in those whose pregnancies continued compared with those that failed. Further, it was revealed a significant association between raised serum IL-2 and TNF-α and first trimester pregnancy loss, strengthen the relation between these agents and fetal rejection[6]. IL-2 concentrations have been found to rise towards the end of a normal pregnancy. This rise was attributed to a decrease in the concentrations of circulating immunosuppressive markers at this time.

**Conclusion**

It is concluded from the present study that hepcidin and inflammatory markers were reduced as the pregnancy developed, while transferrin and TIBC concentrations were elevated in pregnant women at the three trimester as compared with non-pregnant.

Call for Papers / Article Submission

The editor invites scholarly articles that contribute to the development and understanding of all aspects of Public Health and all medical specialities. All manuscripts are double blind peer reviewed. If there is a requirement, medical statistician review statistical content. Invitation to submit paper: A general invitation is extended to authors to submit papers papers for publication in IJPHRD.

The following guidelines should be noted:
- The article must be submitted by e-mail only. Hard copy not needed. Send article as attachment in e-mail.
- The article should be accompanied by a declaration from all authors that it is an original work and has not been sent to any other journal for publication.
- As a policy matter, journal encourages articles regarding new concepts and new information.
- Article should have a Title
- Names of authors
- Your Affiliation (designations with college address)
- Abstract
- Key words
- Introduction or back ground
- Material and Methods
- Findings
- Conclusion
- Acknowledgements
- Interest of conflict
- References in Vancouver style.
- Please quote references in text by superscripting
- Word limit 2500-3000 words, MSWORD Format, single file

All articles should be sent to: editor.ijphrd@gmail.com
CALL FOR SUBSCRIPTIONS

About the Journal
Print-ISSN: 0976-0245  Electronic - ISSN: 0976-5506, Frequency:  Monthly

Indian Journal of Public Health Research & Development is a double blind peer reviewed international Journal. The frequency is half yearly. It deals with all aspects of Public Health including Community Medicine, Public Health, Epidemiology, Occupational Health, Environmental Hazards, Clinical Research, Public Health Laws and covers all medical specialities concerned with research and development for the masses. The journal strongly encourages reports of research carried out within Indian continent and south east Asia.

The journal has been assigned international standards (ISSN) serial number and is indexed with Index Copernicus (Poland). It is also brought to notice that the journal is being covered by many international databases.
