A Study of Experiences of Beneficiaries, Enrollees and Stakeholders of Tamil Nadu Chief Minister’s Comprehensive Health Insurance Scheme (CMCHISTN) : A Qualitative Study

P Shirisha
JRF (Junior Research Fellow), Department of Humanities & Social Sciences, University- IIT Madras

Abstract

Recently many states in India have rolled out publicly financed health insurance schemes owing to the poor public health infrastructure. Tamil Nadu Chief Minister’s health insurance scheme is one such scheme launched in 2012. The qualitative design of the study pulls out some interesting themes vis-à-vis the problems faced by the providers as well as beneficiaries with respect to the scheme, the plight of the enrollees. Eight in-depth interviews were conducted with the insurance enrollees and beneficiaries in The Nilgiris district in the state of Tamil Nadu, India. The findings revealed the hardships faced by the beneficiaries to procure smart card both financial and physical. Four formal interview were conducted to gain insight on provider’s and other government officials perspective which revealed the problem of delayed reimbursements for the procedures performed to the providers and inputs on how the scheme could be improved based on population’s health needs.

Keywords: Tamil Nadu health insurance scheme, publicly financed health insurance, qualitative study, smart card

Introduction

The fierce competition in the commercial health insurance to acquire larger volume, lowered the premiums which made it affordable to the government and benefitted the development of Publicly funded health Insurance scheme at least in short term[1]. Tamil Nadu Chief Minister’s Health Insurance Scheme (CMCHISTN) is a health insurance scheme which was launched in 2012 by the chief minister of Tamil Nadu. The scheme is aimed at providing quality healthcare to families earning less than Rs.72,000 per annum are eligible for this scheme. Under this scheme a coverage of Rs,1 lakh per year is assured for a family of four members,[2]. As per Economic Survey 2015-16 brought out by Ministry of Finance, public expenditure on health (Centre and States) was 1.3% of Gross Domestic Product (GDP) and is amongst the lowest in the world[3]. Out of which enormous amount of government’s money has been invested in the implementation of publicly financed health insurance scheme in the past 7–8 years[4]. For instance a total of INR 370 billion (USD 587 million) tax money has been allocated for RSBY since 2008–09 (Ministry Of Health And Family Welfare & Ministry Of Labor And Finance)[5]. If the budgets of state sponsored schemes are also added, it amounts to significant proportion of public exchequer’s money ibid. While the study was carried scheme already finished three years since the CMCHISTN scheme has been rolled out and therefore it was worth studying the experiences of the target population with the insurance scheme.

Objectives

1. To understand the challenges faced by the beneficiaries in availing the scheme and reasons for non-utilisation.
2. To understand the perspectives of different stakeholders- government officials, beneficiaries, providers about the scheme.

Materials and Method

Study design:

A Qualitative study design was implemented to gain insights into the experience of the stakeholders with scheme during 2015-16. A total of 12 interviews were carried out. Out of which 8 were in depth interviews with the enrollees and beneficiaries. Also, 4 formal interviews were conducted with the liaison officer, and vigilance officer of CMCHISTN for ‘The Nilgiris’ district and medical officers for perspectives from the provider’s side (Gudalur Adivasi hospital). In case of enrollees purposive sampling method was used to identify the beneficiaries.

The beneficiaries who were included in the study have been divided into 2 categories:

Those who have the smart card but didn’t avail it (enrollees).

Those who have the smart card and availed it (beneficiaries).

Different interview guides were prepared for both categories and in depth interviews were conducted with all these participants. The interviews with the beneficiaries lasted about 25-40 minutes on an average. The questions were open ended and were encompassing their experiences with enrolment in the scheme. The interview with the government officials and medical officers were conducted in English. While, with the beneficiaries it was in tamil. Notes were taken immediately in case of medical officer and government officials. Also, interviews with the beneficiaries were recorded and were transcribed later.

Sources of data:

Record of beneficiaries maintained by the CMCHISTN unit in Gudalur Adivasi Hospital. Database of tribal inpatient with sangam number maintained in Gudalur adivasi hospital

Primary source:

Primary data was collected through in depth interview with the enrollees, beneficiaries, other stakeholders and the interviews with medical officers and liaison, vigilance officer of the CMCHISTN unit of the Gudalur Adivasi hospital.

Secondary data source:

The records of surgeries performed on the inpatients maintained by the Gudalur Adivasi hospital.

Key Findings:

Provider’s Perspective:

Non-coverage of basic surgeries in private hospitals:

A list of frequently performed surgeries for tribal patients was tabulated from the database maintained by Gudalur adivasi hospital for year 2013-15 and was compared with the list of surgeries enlisted under the scheme. Basic surgeries such as hernia, varicose vein, appendicectomy, oophorectomy, respiratory infections, caesarean section and post-partum sterilization were covered only if one avails the scheme in government hospitals. For instance hernia with mesh repair and other types are covered but simple hernia isn’t covered. So, the private hospitals will be allured to use mesh even in simple cases of hernia. Only in tribal patients in Gudalur adivasi hospitals, many of these basic surgeries accounted for 246 of total cases that were carried out since inception of the scheme. All these cases couldn’t be covered.

‘Many basic surgeries are covered only when the patient goes to the government hospital... inguinal hernia, hysterectomy until unless because of carcinoma, varicose vein, salpingo oophorectomy are the commonest basic surgeries performed in our hospital. We’ve requested so many times to include them, but there is no response’ –

-Medical Officer, CMCHISTN, GAH

Beneficiaries’ Perspective:

1. Issues With The procurement of Smart Card

1a. Time taken for procuring the smart card (kapidhittum card):

If the enrollees have the necessary documents required to obtain Smart card by the VAO (Village administrative officer), then the card should be issued on the same day when the application for smart card is submitted.

‘If the beneficiary goes to the collectorate with the required document (Village Administration Officer’s certificate and ration card) then they should get the smart card within 10-15 minutes of the request’
– vigilance officer (CMCHISTN, The Nilgiris)

Only in 5 out of 8 cases the beneficiaries suffered prolonged delay in availing the card and in 1 case the beneficiary didn’t get the smart card still. For getting the smart card the beneficiaries have to go to the CMCHISTN unit, collectorate office, . In none of the cases it was issued on the same day. Rest of the cases, beneficiaries had to visit to and fro, only to listen come next time.

In case of one beneficiary the reason quoted for delay was that the documents will go first to Ooty and then Chennai that is why it took 6 months

‘I kept on going to CMCHISTN unit, Ooty 2-3 times every month, they will be out going for lunch or somewhere and I’ll be waiting there throughout the day’

-Beneficiary X (CMCHISTN)

1.b Leave and loss of wages for procuring card:

The beneficiaries had to take leave from work due to which they had to suffer loss of wages.

‘I had to take leave from hospital (to travel to ooty for smart card) due to which the management at hospital would scold me. I used to go there (CMCHISTN unit, ooty) and they would turn me away saying it (smart card) didn’t arrive,

-Beneficiary Y (CMCHISTN)

1.c Differences in modes of procurement of smart card:

There were different ways how the beneficiaries got the smart card. In 3 out of 8 cases the beneficiaries didn’t go to the CMCHISTN unit at ooty to get the smart card but they got it in ration shop and taluk office. One of the enrollees had the old Kalaignar card (smart card issued by the earlier government), which she exchanged in the ration shop and got the amma’s ‘kappidhitthu’ (smart card) immediately. Other beneficiary submitted the application for ‘kappidhitthu’ along with the required documents in the taluk office and got the smart card within a week. All these beneficiaries got their smart card in the same year .i.e. 2012. However, in one case the beneficiary had lot of problem in renewing the old smart card with new smart card. She went to more than three times for surrendering the Kalaignar and to get the new smart card.

‘When I went to CMCHISTN unit, Ooty’ they asked me to come next week, then I talked to her (Liasion officer), she told me to call in the helpline number, the official told me to ask them to put the name in emergency list. When I went to my name was already there in the emergency list but now election work is going on.

-Beneficiary P (CMCHISTN)

‘I asked dr.M To call them because she has some contacts there, but that too didn’t work. I told Mrs.S(liason officer) again she called Mr. X (Project officer) and asked him about the card and he talked to me and said that come tomorrow and collect your card, they were simply withholding my card. Finally I got the card after 2 months’

-Beneficiary Q (CMCHISTN)

In 3 out of 8 cases reference from the doctor at Gudalur adivasi hospital was used, either they will issue a letter or they will call directly that the beneficiaries’ case is an emergency case and the card should be issued immediately. Later during emergency conditions the beneficiary has to run for the card in the mean time. People who are not having any reference have more difficulty in getting the card relatively.

Issues in procuring basic documents:

Beneficiaries faced problem in procuring documents like ration card and income certificate also.

Ration card:

In two cases there was a long delay as much as 6 months and One beneficiary applied twice and got the ration card after 1 and a half years, the reason stated was that the address provided wasn’t correct. The female respondents got their name added in the ration card after marriage and didn’t had much problem.

Income certificate:

For getting income certificate, invariably all the beneficiaries except one case went at least 3-4 months to the taluk office. In one case the beneficiary had also to bribe for getting it

‘I went to Its village administration office, one person will say go to him, other will say the same and so on….it happened for 7 days after which I got the income certificate. The office people asked me for some money for ‘chai” (tea).
Beneficiary M (CMCHISTN)

To approach frequently to the office in location far from the place of residence means leave from work, loss of wages and travel expenses, these added to the agony to the procedure. In some cases the beneficiary had to wait for applying for smart card because of delay in getting income certificate.

'I got the income certificate after 3 months and therefore got late in applying for smart card'

Beneficiary P (CMCHISTN)

The beneficiary who applied online got it within a week. In one case the beneficiary stated that there is an emergency and received the income certificate within 4 days of application though the beneficiary had to go and wait everyday in the office.

Awareness about the scheme:

None of the beneficiaries except one knows about hospitals in their area where they could avail this scheme. Except 3 participants the rest 5 didn’t had any knowledge that the scheme is completely cashless and includes transportation and food costs. Only 2 participants knew the maximum limit of amount of the cover provided under this scheme. Also just 2 participants used the helpline number to enquire about their problems.

Experience of beneficiaries while availing the scheme:

Totally cashless scheme:

All the beneficiaries who availed the scheme and undergone any procedure enlisted under the scheme stated there was no delay or problem in getting admission in the hospital and also there was no procedural negligence. All the beneficiaries have given a positive response about the benefit from the scheme. In some cases the vigilance commissioner met in person to check whether they were charged anything, or for identification of the beneficiaries whether the patient is fake or is actually there. The beneficiaries were positive about the vigilance officer’s response and the scheme overall for hospital admissions.

'The cost (if the scheme wasn’t available) that we would had incurred for radiation, operation and injections, would had been huge’ –

Beneficiary V (CMCHISTN)

The scheme is helpful and important to us that is why I have been struggling and running here and there to get the smart card

Beneficiary Q (CMCHISTN)

All of the beneficiaries had cashless treatment for the procedures ranging from chemotherapy, cholecystectomy to angiogram etc. In one case the money was taken but was reimbursed before discharge

Discussion & Conclusion

Latest round of NSSO (NSSO 71st round) highlights inequity in enrolment under PFHIS with lower quintile enrolled lesser than fifth quintile. The inequity may arise due to hardships faced by the target population, hence they discouraged to take up the scheme. A study demonstrates conclusive proof that RSBY and other state government-based interventions failed to provide financial risk protection. However, Early evidence from studies on PFHI schemes- like RSBY suggests that the catastrophic headcount due to hospitalization was higher for districts which had any kind of insurance rather than those which didn’t had any, also there was marginal decline in the share of medical expenditure, mainly attributed to decline in outpatient expenditure. Another study has shown that there has been significant reduction in OOP expenditure but nevertheless in Catastrophic Health Expenditure (CHE). All the PFHI schemes except RSBY and Yeshasvini cover low-frequency, high-cost tertiary care procedures, this excludes the outpatient expenses and drugs which dominates the CHE. Despite the aim of providing financial security these schemes have delivered less than expected. The target population of the scheme are the poor families (BPL) mostly engaged in unorganized sector whose livelihood depends on daily wages or meagre salaries. As many respondents stated that they travelled to the district office of CMCHISTN for enrolment which was far than their residence, there was constant trade-off trade between losing the wage, or delay in enrolment including unforeseen costs like expenses in travelling. But even if they forego a day’s wage for procuring card, the enrolment on the same day was highly unlikely. In cases where the patient is suffering with debilitating illness/acute episodes of illness it becomes all the more difficult as the member may be the only caretaker of the patient and going to the office and fetching the card may be an arduous task. Also, the awareness about the benefits that the scheme offers is low. The providers grappled with problems like delays in reimbursements and also non-inclusion of few
basic commonly performed surgical procedures out of the list of procedures covered. This is an important point as in cases where the government hospitals are either far away or ill-equipped to perform even basic surgeries, private hospital are the mainstay for the beneficiaries. But some studies found significant reduction in OOP expenses on healthcare due to the PFHIS schemes\textsuperscript{10,11} \textsuperscript{12}. The experience of the study participants are also in congruence of above study findings that there is no out of pocket expenditure and also benefitted those families who could otherwise not afford the expensive inpatient services in private setups.

Abstract

Context: Day by day, sports participation in youth is increasing. Due to increased participation, exercise related injuries are increased. Repeated Exercises causes microtrauma leading to fibrous tissue adhesions which further leads to decreased flexibility ultimately leading to Musculoskeletal dysfunctions.

Aim: To study the effectiveness of Self Myofascial Release, Static Stretching and Neural Tissue Mobilization on Hamstring flexibility in athletes

Methodology: 80 subjects of the age group 18-25 were randomly allocated to receive Self Myofascial Release and Static Stretching (Group A) and Neural Tissue Mobilization (Group B). Group A was given 3 sets of Foam Rolling for 30 to 60 seconds combined with 3 sets of static stretching for 20 to 30 seconds hold. Each subject was assessed for Active Knee Extension and Straight Leg Raise at baseline and immediately post-treatment.

Results: Both the interventions significantly improved AKE and SLR immediately post treatment within the groups whereas the inter group analysis showed significant difference in AKE between Groups but no significant difference was found in SLR.

Conclusion: Self Myofascial Release combined with Static Stretching and Neural Tissue Mobilization both were effective in improving Hamstring Flexibility, but Neural Tissue Mobilization was found to be superior.

Keywords: Hamstring tightness, Athletes, Self Myofascial Release, Static Stretching, Neural Tissue Mobilization

CTRI Reg. No: CTRI/2018/01/011479

Introduction

Sports participation in youth is increasing day by day. As a result of increased participation, exercise related injuries are increasing resulting in pain further deterring individuals from continuing the exercise regimen. Repeated and strenuous exercise causes repeated microtrauma to muscle fibers, leading to formation of fibrous tissue adhesions which further results in tightness, decreased flexibility, and decreased range of motion ultimately leading to musculoskeletal dysfunction.

In spite of hamstring tightness being the primary cause in majority of Musculoskeletal problems, it is often neglected in assessment and people concentrate on secondary dysfunctions such as musculoskeletal and soft
tissue injuries as in patellar tendinopathy, patellofemoral pain and hamstring strain injury.\(^{(4)}\)

Baseline Bubble Inclinometer™ was used because the inclinometer has been demonstrated to possess good to excellent reliability (ICC > .088) in studies examining both hip and shoulder.\(^{(18)}\)

Various tests assess hamstring tightness which include 90-90 Straight leg raise test, Hamstring contracture test, Tripod sign, Straight Leg Raise (SLR).\(^{(5)}\) Hamstring Contracture Test and Tripod Sign are not commonly used as their reliability and validity values are not available whereas for SLR and Active Knee Extension (AKE), the reliability were found to be good (0.861) and excellent (0.953) respectively.\(^{(7)}\)

Literature supports the use of many physiotherapeutic interventions namely, Positional Release Technique (PRT)\(^{(8)}\), Active Release Techniques (ART)\(^{(9)}\), Muscle Energy Techniques (MET)\(^{(10)}\), Stretching and Self Myofascial Release (SMR) and Neural Tissue Mobilization for muscle flexibility.

Studies found SMR and Neural Tissue Mobilization individually to be effective in improving flexibility. But, no studies till date have compared SMR followed by Static Stretching and Neural Tissue Mobilization in management of Hamstring tightness. So the present study aims to examine the superior treatment in the management of Hamstring Tightness.

**Materials and Methodology**

**Study Design**

The study was outcome-assessor blinded, clinical trial.

**Clinical Trials Registration**

The study was registered in Clinical Trials Registry-India with the no. CTRI/2018/01/011479 and the reference no. REF/2017/12/016564.

**Participants**

Eighty subjects (30 men, 50 women) with Hamstring Tightness were taken. Inclusion criteria was patients of the age group 18-25, with hamstring tightness of 20°; who were unable to achieve greater than 160° of knee extension with hip at 90° flexion and also those who were unable to reach 70° hip flexion in a SLR.\(^{(6)}\) Subjects with fractures of lower limb, soft tissue injuries, surgical procedures in previous 12 months and with history of musculoskeletal injuries were excluded. The subjects were randomly allocated into A) SMR and Static Stretching group \((n=40)\), B) Neural Tissue Mobilization group \((n=40)\)

**Interventions**

The subjects in Group A received SMR using foam rollers for hamstrings followed by Static Stretching. The procedure of doing SMR was demonstrated prior to the treatment. The subject lay on the exercise mattress and rolled the tested extremity to and fro from the ischial tuberosity to the back of the knee for 60-90 secs. The hands of the subject were fixed on the floor during the rolling motion. The body shifted back and forth. The subjects were asked to place maximum weight over the tested extremity. After SMR, Static Stretching was passively given by the therapist after the subject lay supine on the exercise mattress and then moved the tibia to terminal position of knee extension to the point where the subject complained of a feeling of discomfort in the posterior thigh. The position was maintained for 20 to 30 seconds and was repeated 4 times.

Group B was given Neural Tissue Mobilization technique. The subject was positioned supine. The extremity to be tested was placed on the therapist shoulder. The subject’s hip was passively flexed by the therapist with knee in extended position to a point where subject complains of a feeling of discomfort in hamstring. At this point, the hip was rotated medially and the foot was dorsiflexed by the therapist and this position was maintained for 6 seconds and the tested extremity was then bought to resting position and the same procedure was performed thrice.

**Outcome measures**

Outcome Assessment was done pre and immediately post treatment.

Active Knee Extension: The subject lay in supine position on the table. The non-examining extremity is secured with a Velcro strap across the middle of the thigh. A stabilization stool is placed on the table to help the subject accurately maintain the hip flexion to 90°. The subject is told to extend the knee and stop at the point where he first felt the stretch sensation at the posterior thigh area. The knee flexion angle is determined
by Baseline Bubble Inclinometer™. Inclinometer is positioned on the mid-point of the anterior surface of tibia, which is determined by using measuring tape to measure the participant’s tibia length from the medial malleolus to the medial tibial condyle. The tested extremity is extended and the angle displayed on the Inclinometer is recorded at the point where the subject verbally reports discomfort.

Straight Leg Raise: The subject lay in supine position on the table. The non-examining extremity is secured with a Velcro strap across the middle of the thigh. The subject is instructed to flex his hip, to the point where he complains of a feeling of discomfort in the posterior thigh. The angle is determined by Baseline Bubble Inclinometer. Inclinometer is positioned on the mid-point of the anterior surface of tibia, which is determined by using measuring tape to measure the participant’s tibia length from the medial malleolus to the medial tibial condyle. The tested hip is flexed and the angle displayed on the Inclinometer is recorded at the point where the subject verbally reports discomfort.

Statistics

Data were analyzed using SPSS version 20.0, Chicago.

Results/ Findings

Descriptive data of outcomes are shown in Table no.1 & 2. The intra group analysis was done using paired- t test. The inter group analysis was done using unpaired- t test.

- **Active Knee Extension (Table no.1):**

  In Group A, the mean ROM score pre intervention was 132.52 which increased to 146.42 post session. The p value by paired-t test was found to be <0.0001 which was extremely significant. In Group B, the mean ROM score pre intervention was 137.32 which increased to 155.9 post session. The p value by paired-t test was found to be <0.0001 which was extremely significant.

- **Straight Leg Raise (Table no.1):**

  In Group A, the mean ROM score pre intervention was 47.95 which increased to 64.17 post session. The p value by paired-t test was found to be <0.0001 which was extremely significant. In Group B, the mean ROM score pre intervention was 47.6 which increased to 68.85 post session. The p value by paired-t test was found to be <0.0001 which was extremely significant.

- **Active Knee Extension (Table no.2):**

  On comparing the pre-interventional values for AKE, the results between the two groups revealed that there was no statistically significant difference of ROM with p value 0.0630. While on comparing the post-session values, the results between the two groups revealed that there was extremely significant difference of ROM scores with p value of 0.0001. Pre-treatment shows that there was no significant difference in the ROM scores of AKE with p= 0.0630, whereas post-treatment shows extremely significant difference in the ROM scores with p=0.0001.

- **Straight Leg Raise (Table no.2):**

  On comparing the pre-interventional values for SLR, the results between the two groups revealed that there was no statistically significant difference of ROM with p value 0.8880. While on comparing the post-session values, the results between the two groups revealed that there wasn’t quite significant difference of ROM scores with p value of 0.0515. Pre-treatment shows that there is no significant difference in the ROM scores of SLR with p= 0.8880, whereas post-treatment shows quite not significant difference in the ROM scores with p=0.0515.

Discussion

Subjects in Group A were given SMR with Foam Rollers and Static Stretching. The mean ROM scores for AKE were increased from 132.52° to 146.42° and for SLR it was increased from 47.95° to 64.17°. In accordance with the results of our study, an increase in sit-and-reach scores was noted from 0.97 inches to 2.46 inches using foam rolling followed by static stretching. The probable reason for improvement in flexibility using foam rollers could be due to decrease in overactive myofascial tissues and application of pressure to the trigger points causing the Golgi Tendon Organs to elicit an inhibitory effect on the muscle, allowing it to become less tense and ultimately leading to increased joint ROM and improved flexibility.\(^{(19)}\)

We gave four sets of 20 to 30secs of foam rolling to hamstring muscle which showed statistically significant improvement in Hamstring Flexibility. Similarly, MacDonald, et al reported increase in ROM and performance measures by using foam roller for minimum of 90secs (three sets of 30secs\(^{(23)}\) or two sets of 1 min)\(^{(20)}\).

Multiple theories are available in our literature. One of the theory explains about the thixotropic property of fascia which states that if rolling friction is applied to the fascia, it generates heat and the fascia becomes more gel like allowing for a greater flexibility.\(^{(21, 20)}\) In contradictory to this, Schleip pointed the fact that the effect will only be present when the heat or pressure is applied.\(^{(22)}\)

Subjects in Group B were given Neural Tissue Mobilization which was also found to be effective in improving ROM by 18°. This could be due to viscoelastic changes in the muscle connective tissue. Shrinivas et al, reported similar results when compared Mulligan’s bent leg raise and Neural Tissue Mobilization. Similar to our study, Neural Tissue Mobilization was given thrice and the position was maintained for 6secs and the results came to be extremely significant with difference of 17° for AKE and 18° for SLR.\(^{(5)}\)

A study by Yun-hyeok-Shin et al showed that Sciatic Nerve Mobilization increases flexibility by 8%.\(^{(17)}\) Sandeep Singh et al, evaluated effects of Neural Tissue Mobilization and PNF Stretching and found both techniques to be equally effective.\(^{(15)}\)

Present study and aforementioned studies differ in respect to the methods of neural mobilization employed, its duration, type of participants involved and outcome measures used but inspite of this the results were positive. This is the reason we implicated Neural Tissue Mobilization in our study.

Between group comparison demonstrated that extremely significant difference existed in improvement scores on AKE \((p=0.0001, t=4.219)\). But statistically significant difference was not seen in scores on SLR \((p=0.0515, t=1.978)\).

Inconclusive results of the SLR may be due to inconsistency of pelvic position, posterior pelvic rotation, hip joint capsule stretch and possible neural stretch. Another possible cause may be the subject’s inability to keep the knee fully extended during SLR which may be because of weakness of hip or trunk flexors.\(^{(25)}\)

Conclusion

Study concluded that SMR with Static Stretching and Neural Tissue Mobilization both were effective in improving Hamstring Flexibility, but Neural Tissue Mobilization was found to be superior in improving Hamstring Flexibility.

Conflicts of Interest: Further studies can focus on strength testing of Hip and Trunk Flexors to maximize the increase in ROM and long term follow up to check the efficacy of the treatment.

Abstract

Background: Osteoarthritis (OA) is a common, chronic, degenerative joint disorder which leads to pain, decrease functional activity and decreases quality of life. The following study was carried out to compare the effect of ground level reverse treadmill walking, incline reverse treadmill walking and short wave diathermy along with conventional exercises in chronic osteoarthritis subjects.

Objectives: To compare the effect of ground level reverse treadmill walking, incline reverse treadmill walking and short wave diathermy along with conventional exercises in chronic osteoarthritis subjects.

Method: The study was conducted at physiotherapy outpatient department of Krishna Hospital and MRC, Karad. Sample size was 60 which were further divided into 3 groups each containing 20 subjects by simple random sampling method. Group A was given Ground level reverse treadmill walking along with SWD and conventional exercises. Group B was given incline reverse treadmill walking along with SWD and conventional exercises while Group C was control group which was given only SWD and conventional exercises.

Result: Paired t-test and ANOVA were used for statistical analysis. In pre intervention, there was no statistically significant difference seen in p values for VAS which was 0.2096 and for SF-36 was 0.6602 but was statistically very significant difference seen in p values for WOMAC that was 15.17. On comparing the post intervention score, the results showed very significant difference for VAS with p value 0.0028 while extremely significant difference was seen with p-value for WOMAC and SF-36 was <0.0001 respectively.

Conclusion: The study concluded that incline reverse treadmill walking along with SWD and conventional exercises was more effective in decreasing the pain, stiffness and improving quality of life in subjects with chronic knee osteoarthritis.

Keywords: Chronic knee OA, Ground level reverse treadmill walking, incline reverse treadmill walking, SWD, VAS, WOMAC, SF-36.

Introduction

Osteoarthritis (OA) is a common, chronic, degenerative joint disorder characterized by joint pain, tenderness, limitation of movements, crepitus, occasional effusion, and variable degrees of local inflammation, without systemic manifestations¹,². Individuals with OA of the weight bearing joints are considered to be less...
active and less fit $^{3,4}$

Osteoarthritis is classified as primary or secondary. The process in which articular degeneration occurs in the absence of an obvious underlying abnormality is known as primary osteoarthritis. Repetitive motion, injury or trauma found in certain occupation often leads to secondary osteoarthritis. It can also result from congenital conditions, and underlying diseases, endocrine diseases, bone dysplasia and calcium crystal deposition disease. $^{5}$ Osteoarthritis (OA) a common disease of aged population and one of the leading causes of disability. Incidence of knee OA is rising by increasing average age of general population. Age, weight, trauma to joint due to repeating movements in particular squatting and kneeling are common risk factors of knee OA. Several factors including cytokines, leptin, and mechanical forces are pathogenic factors of knee OA. In patients with knee pain attribution of pain to knee OA should be considered with caution. Since a proportion of knee OA are asymptomatic and in a number of patients identification of knee OA is not possible due to low sensitivity of radiographic examination. In this review data presented in regard to prevalence, pathogenesis, risk factors. **Key Words:** Knee, Osteoarthritis, Pathogenesis, Prevalence

The major risk factors of knee osteoarthritis are history of diabetes, cancer, or cardiovascular disease and the presence of walking disability. Knee Osteoarthritis is more important not only for its high prevalence rate compared with other types of Osteoarthritis but also for its presentation at earlier age groups particularly in younger age groups of obese women. $^{6}$

Knee OA is not a localized disease of cartilage alone but it also includes chronic disease of the whole joint, including articular cartilage, ligament, meniscus, , and peri-articular muscle that may result from multiple pathophysiological mechanisms which affects millions of patients $^{7}$. The aetiology include various mechanical, biomechanical, and genetic factors. The cardinal symptoms that suggest a diagnosis of OA include: pain, reduced function, stiffness, joint instability, buckling or giving way, reduced movement, deformity, swelling, crepitus $^{8}$

The goals of treatment are Pain relief, improved quality of life, improved mobility, improved walking, and Delayed progression of osteoarthritis $^{9}$

Retro walking has more advantageous effects compared to forward walking. During forward walking knee joint flexes, extends and then flexes in support phase, whereas in retro walking knee initially extends, flexes and then extends in support phase, prior to extending and flexing during swing. Retro walking increases stride rate, decreases stride length and increases support time. $^{10}$

Incline walking on a treadmill increases higher firing rate of hamstrings and quadriceps which helps in increase in knee extension moment, increasing strength in functional range and improving physical function. $^{11}$

Short wave diathermy (SWD) is a modality suggested for the management pain and loss of function due to osteoarthritis. Diathermy uses shortwaves which produce deep heat changes within the tissue including vasodilatation, elevation of pain threshold, increase tissue extensibility and increase enzymatic activity. $^{13,14}$

Exercise helps in decreasing pain, improving strength and Endurance, improving range of motion and connective tissue elasticity as well as exercise decreases functional limitation by Improving walking speed, gait, physical activity and decreasing Depression and anxiety. $^{15}$

There is paucity of literature when it comes to find the comparative effectiveness between ground level reverse treadmill walking as well as incline reverse treadmill walking along with conventional physiotherapy for Chronic OA knee. So there is need to find out newer methods of Physiotherapy treatment approaches which can aid in better outcomes, speedy recovery and reducing rehabilitation time.

**Method**

It was an comparative study in the physiotherapy department of Krishna institute of medical sciences. Ethical permission was obtained from institutional ethical committee, KIMSDU, Karad.60 subjects were equally divided into 3 groups using lottery method and selected according to inclusion and exclusion criteria. Written informed consent form was taken, and the whole study was explained to them. A detailed musculoskeletal evaluation was done. Inclusion criteria: (1)Both male and female participants willing to participate in study aged above 50 years.(2)Morning stiffness lasting <30 min.(3)Crepitus with active motion.(4)Bony tenderness.
(5) No warmth to touch. (6) Patients having knee pain for more than 6 weeks. (7) Subjects with clinical diagnosis and radiographic evidence of OA knee. (8) Kellgren-Lawrence radiographic grade 2 and 3. (9) Subjects who can walk reverse on treadmill without any discomfort.

Exclusion criteria: (1) Grade 3 obese individuals with deformed knees. (2) Systemic arthritis. (3) Soft tissue injuries around the knee joint. (4) Recent surgeries around the knee joint. (5) Elderly subjects with balance deficits. (6) Fixed flexion deformity.

As ground level reverse treadmill walking and incline reverse treadmill walking are not the part of our routine life, so they were given training week day prior to the actual intervention in parallel bars.

Group A - ground level reverse treadmill walking along with SWD and conventional exercises

Group B - incline reverse treadmill walking along with SWD and conventional exercises

Group C - Short wave diathermy and conventional exercises.

Frequency - 27.12 MHz
Wavelength- 11 meters
Positioning method- cross fire method to the knee joint
Intensity of application- as per subjects comfort.
time- 20 minutes/session

Conventional exercises for all three groups include:

- Quadriceps isometric strengthening exercises, High sitting knee extension, Isometric quadriceps with plantar and dorsiflexion, Straight leg raising, Side lying Hip abduction, Prone knee bending, Prone hip extension. All exercises were performed in sets of 10 repetitions with 6 sec hold; 1 set of all exercises once-a-day for 1st week and progressed to 2 sets twice-a-day in 2nd week and 3 sets thrice a day in 3rd week. Treatment session was 15 days.

Pre treatment and post treatment scores were made on the subjects on the first day before intervention and after 15 days of intervention

Discussion

Osteoarthritis (OA) is a common, chronic, degenerative joint disorder characterized by joint pain, tenderness, limitation of movements, crepitus, occasional effusion, and variable degrees of local inflammation, without systemic manifestations.\(^5,6\)

The aim of this study was to evaluate the effect of ground level reverse treadmill walking versus incline reverse treadmill walking as an adjunct to conventional physiotherapy in chronic osteoarthritis subjects.

The baseline treatment of short wave diathermy and exercises was common for all the groups. Continuous short wave diathermy or a pulsed short wave diathermy were specified as treatments for acute knee osteoarthritis by 34.8% and 73.9% of the respondents, respectively, and for chronic OA by 97.8% and 59.4% of the respondents, respectively. In present study pain reduction, improvement in functional status and exercise tolerance may be due to the major physiological effects of CSWD which are related to an induced increase in tissue temperature, which may induce vasodilatation, elevation of pain threshold, reduction in muscle spasm, acceleration of cellular activity, and increased soft tissue extensibility.\(^{16,17,18}\)

60 patients (34 Males and 26 Females), out of which 36 were Right and 24 were Left side affected, diagnosed as Osteoarthritis Knee. The present study contradicts finding the previous literature that females are more affected than males in OA knee, this may be because of smaller sample size, smaller area of sample collection and specific inclusion criterias.

For pain assessment VAS was used. Within group comparison which was done by paired t test in which group A, B and C the P value was <0.0001 which was extremely significant. In group A the pre mean value was 70.95 and post treatment it decreased to 36.7. In group B, the pre mean value was 74.5 in post treatment it was decreased to 33.65 whereas in group C the pre mean value was 67.65 which was decreased to 45.35. Between group comparison was done using non-parametric Anova in which pre WOMAC was 15.17 which was very significant significant where as post treatment WOMAC was <0.0001 which was extremely significant. These findings supports the literature which states various advantages of retro walking including improvement in muscle activation pattern, reduction in adductor moment at the knee during stance phase of gait and augmented stretch of hamstrings muscle group during the stride.\(^{19}\)

For assesement of quality of life SF-36 was used. Within group comparison which was done by paired t test in which group A, B and C the P value was <0.0001 which was extremely significant. In group A the pre mean value was 23.56 and post treatment it increased to 59.23. In group B, the pre mean value was 22.12 in post treatment it was increased to 74.07 whereas in group C the pre mean value was 23.69 which was increased to 44.96. Between group comparison was done using non-parametric Anova in which pre SF-36 was 0.66 which was not significant where as post treatment SF-36 was <0.0001 which was extremely significant. Possible reasoning for above findings can be walking programs have a positive effect on quality of life in elderly individuals with knee OA. The significant improvement in quality of life may be in relation with physical activity, by helping patients to reduce fatigue and recover their self esteem, motivation and mental health.\(^{20,21}\)

In this study an attempt was made to analyze the effect of ground level reverse treadmill walking versus incline reverse treadmill walking as an adjunct to conventional
physiotherapy in chronic knee osteoarthritis subjects in reducing pain, functional disability improving quality of life in OA Knee patients. Although the result shows extremely significant improvement in all three groups (P<0.0001) group B which included incline reverse treadmill walking along with SWD and conventional exercises showed the maximum improvement by reduced mean values of VAS and WOMAC and increased mean value of SF-36 as compared to group A and C. As Incline walking on a treadmill increases higher firing rate of hamstrings and quadriceps which helps in increasing knee extension moment, increasing strength in functional range and improving physical function as compared to ground level reverse treadmill walking and the control group.15

Conclusion

Incline reverse treadmill walking along with SWD conventional exercises was more effective in decreasing the pain, stiffness and improving quality of life in subjects with chronic knee osteoarthritis as compared to ground level reverse treadmill walking and the control group.

Conflicts of Interest: This study can be carried out with more various forms of exercises, various degree of inclination and large sample size can also be taken into consideration.

Ethical Clearance: Ethical clearance was taken from institutional committee of Krishna institute of medical science, deemed University, Karad.

Abstract

The search for an ideal restorative material to replace tooth tissue and the demand for products with adhesive and caries protective properties together with a simple procedure for application have led to the development of restorative materials that combine conventional glass Ionomers and light –cure composite resins. It has been demonstrated that composite resins as well as glass ionomers are susceptible to various modes of chemical degradation in vitro; as a result of which the mechanical properties of various composites have been tested after long term storage in solutions. As some polyacid modified composites (compomers) are now indicated for stress –bearing areas, such as posterior and Class IV restorations, the knowledge of how their strength properties are affected by food simulating liquids is important for predicting their clinical performance. The objective of this study was to investigate the effects of food-simulating liquids on the flexural strength of composite and polyacid-modified composite resins. It was seen that the detrimental effects of aqueous solutions on flexural strength appeared to be greater with polyacid modified composite resins than composite restoratives and the latter had significantly higher flexural strength after conditioning in aqueous solutions.

Keywords: Aqueous solutions, compomers, composite, conventional glass ionomers, flexural strength, food simulating liquids, light-cure composite resins, polyacid-modified composite resins.

Introduction

Extensive research has been conducted for an ideal restorative material to replace the tooth tissue.¹ The restorative material should be such that it has adhesive and caries protective properties along with an easy procedure for application. Composite restorative materials consist of a continuous polymeric or resin matrix in which an inorganic filler is dispersed. This inorganic filler phase significantly enhances the physical properties of the composite.² These materials are used in almost all types and sizes of restorations, are accomplished with minimum loss of tooth structure, little or no discomfort, relatively short operating time and a moderate expense to the patient.³ Thus they are an ideal esthetic material for restoring teeth. Materials have been developed that combine conventional glass ionomers and light cure composite resin. A polyacid modified composite resin (compomer) contains either or both of the essential components of a resin modified glass ionomer cement.

Method

Three composite (Z 250, Alpha dent and Esthet X) and one polyacid modified composite restorative (Dyract) were selected for this study. Flexural strength testing specimens of the restoratives were fabricated according to ISO 4049 specifications (35mm lengthx2mm...
widthx2mm height) in customized steel molds and each increment of this restorative placed in the mould polymerized for 40 seconds. 25 specimens were made for each material. They were randomly divided into five groups of five and conditioned for one week at 37°C.

Group 1-Air (control)

Group 2-Distilled water

Group 3-0.02 M Citric Acid

Group 4-Heptane

Group 5-50% Ethanol water solution

At the end of the conditioning period, the flexural strength of the restoratives was assessed in an Instron Universal Testing Machine at a crosshead speed of 0.05 mm/minute until the specimens fractured. The maximum load exerted on the specimens was recorded and the flexural strength calculated in Megapascals. Using ANOVA and Tukey tests the flexural strength of the materials was statistically tested to study the effect of the food simulating liquids.

Statistics

ANOVA reveals statistically significant differences in flexure strength among groups for conditioning in medium Heptane, air, Citric acid and Ethanol water. Statistically no significant differences were seen among groups for deionized water. Statistically a significant difference is seen between Ceram-X and Alpha Dent composite. Statistically a significant difference is seen between Ceram-X and Esthet-X and Ceram-X and Alpha Dent Composite. Statistically no significant difference is seen between Ceram-X and Esthet-X but the difference between Ceram-X and Alpha Dent and Esthet-X and Alpha Dent is significant. Statistically no significant difference is seen between Alpha Dent and Esthet-X and Esthet-X but the difference between Ceram-X and Alpha Dent is significant. Overall the mean flexure strength for different material was as follows: Alpha Dent>Esthet X>Ceram X

Results

Irrespective of the material used the flexural strength was maximum in the samples aged in Heptane and minimum in samples aged in 50% ethanol water solution. Irrespective of the medium used Alpha Dent showed the maximum flexural strength whereas Ceram X showed the minimum.

There is no significant difference between the three groups for heptane, deionozed water and citric acid. Values are least for 50% ethanol among all the solutions.

Discussion

The food simulating liquids used for conditioning the restoratives in this investigation are among those recommended in the FDA guidelines to be used as food simulators. Heptane simulates butter, fatty meats and vegetable oils. The ethanol-water solution and citric acid simulate beverages, including alcohol, vegetables, fruits, sweets and syrup. Deionised water is included to simulate the wet intraoral environment provided by saliva and water. For all the restoratives evaluated, the highest value of flexural strength was observed after conditioning in heptane as compared to conditioning in other aqueous mediums. Conditioning in heptane also resulted in significantly higher flexural strength values than the control.

The reason is:-

1. Heptane reduces oxygen inhibition during post curing that occurs for the specimens conditioned in air (control). Heptane eliminates leaching out of silica and combined metals in fillers which may occur from conditioning in aqueous solutions.

2. In other aqueous solutions -when the different resin –bonded fillers are immersed in aqueous solutions the resin matrices swell and resulting tensile stresses strain the Si double bonds in the fillers making them more susceptible to stress and corrosion attacks. Complete or partial filler debonding occurs due to stress corrosion at the surface layer of fillers and this degradation of the filler-matrix interface results in decrease in flexural strength and other physical properties.

3. 50% Ethanol Water Solution -for all the restoratives tested conditioning in 50% ethanol-water solution resulted in the lowest flexural strength. The reason for this is that the resin matrices of the various restoratives are based either on BISGMA (Bisphenol A glycidyl methacrylate) or UDMA (Urethane dimethacrylate) which have a solubility parameter of 50%, similar to aqueous solution of ethanol water. The extent of damage depends upon the diffusion rate and molecular weight of the penetrant. The damage mechanism is attributed
to the softening of the polymer matrix by ethanol water solution resulting in partial removal at the surface. This results in “prouding” of the filler particles which serve as areas of stress concentration during flexural strength testing.\textsuperscript{9} Dyract-AP is based on a UDMA resin and the maximum softening of this resin results from exposure to 50% ethanol water solution. This is the reason for a significant statistical difference in control and restoratives conditioned in ethanol-water in case of DyractAP. Lower flexural strength values of compomers may be due to uptake of water which is necessary for activation of acidbase reaction in the polymer matrix.

**Conclusions**

The flexural strength of composites was significantly higher than their polyacid modified counterpart in all the mediums tested. Detrimental effect of aqueous solutions was more with compomers than composite. Compomers should be used in stress bearing areas with caution. The highest flexural strength was obtained when the restoratives were aged in heptanes. The lowest flexural strength was obtained when the restoratives were aged in ethanol-water. Esthet-X was the best material as far as flexure strength was concerned.

A Study of Factors affecting Online Shopping in Chennai

V. Andal¹, G. Mythili²

¹Associate Professor, VISTAS, Pallavaram, Chennai, ²Assistant Professor, Vels Institute of Science, Technology & Advanced Studies, Chennai

Abstract

Online retailing has shown enormous growth in India in recent years. However as compared to the other countries which are leading in online retailing, India is still in its initial stage of development. The purpose of this study was to explore the factors that affect online shopping in Chennai. The sampling method used is Random sampling to select a sample of 80. Percentage analysis, Chi-square test for finding out the association between variables and Correlation Co-efficient for finding out the relationship between the factors affecting online purchase behaviour and consumers’ attitude towards online shopping.

Keywords: Online retailing, Consumers’ attitude, Convenient sampling.

Introduction

Online shopping is a new form of electronic commerce by which consumers can directly buy goods or services from a seller over the internet using the web browser. Consumers find a product of their interest by visiting the website of the retailer directly or by searching among alternative vendors using a shopping search engine which displays the same product’s availability and pricing at different retailers.

An online shop evokes the physical analogy of buying products or services at a regular process are called business-to-consumer (B2C) online shopping. When an online store is being set up to enable businesses to buy from another business, the process is called business-to-business (B2B) online shopping. An online store enables the customer to browse a company’s range of products and services, view images of the products and also they can view information about the product specifications, features and prices. And also they can read the reviews of consumers about the products.

Literature Review

Zuroni Md Jusoh et al.¹ (2012) in their study on “factors influencing consumers’ attitude towards e-commerce purchases through online shopping”, used Convenience sampling to collect 100 responses in Taman Tawasi, Ipoh. Pearson’s correlation revealed that there was a significant relationship between e-commerce experience, product perception, customers’ service and attitude towards online shopping among the respondents. It was found out from the study that there was no significant relationship between consumers’ risk and attitude towards online shopping among the respondents.

Hana Uzun et al.² (2014), made a research on “Factors Affecting Online Shopping Behaviour of Consumers”. Data gathering was carried out by the survey from 200 randomly selected citizens, from which 104 responded. The results of this study revealed that there is a relation between customers’ satisfaction with online service and consumers’intention to buy in the future which generates customer loyalty.

V.P.T Dhevika et al.³ (2014) analysed on “factors influencing online buying behaviour in Thiruchirapalli district”. Convenient sampling method was used and responses were collected from 100 people. Collected data were analyzed using tools like percentage analysis, chi square test, one way ANOVA and ‘t’ test and they revealed that the most important factor influencing online shopping was Security followed by Trust worthy shopping and Website design/ features and the least important factors influencing overall online shopping was bargaining.
Yi Jin Lim et al. (2015) studied on “Factors Influencing Online Shopping Behaviour: The Mediating Role of Purchase Intention”, University students aged between 18 and 34 pursuing their studies in University Malaysia Perlis were selected as the subject of analysis. Totally 662 out of 800 sets of questionnaires distributed turned out to be valid for coding, analyzing and testing the hypothesis. They concluded that subjective norm and perceived usefulness positively influence online purchase intention but subjective norm insignificant influence shopping behaviour in a negative way.

R. Ganapathy (2015) conducted “A study on factors affecting online shopping behavior of consumers in Chennai”. In his study, he found out that convenience, website features, security and time saving were the factors that affected online shopping behaviour of consumers by using exploratory factor analysis. The regression analysis indicated that convenience, security, website features and time saving were positively and significantly influencing the purchasing decision of consumers at one per cent level.

Rajyalakshmi Nittala (2015) studied on “Factors Influencing Online Shopping Behavior of Urban Consumers in India”. Factor analysis and multiple regression analysis were used and identified that perceived risk and price positively influenced online shopping behavior. Results revealed that positive attitude, product risk and financial risk were the factors which affected negatively the online shopping behavior.

Objective of the Study

1. To study the factors influencing online buying behaviour.

2. To identify the association between demographic profile and online buying behaviour.

3. To find out the relationship between the factors affecting online purchase behaviour and consumers’ attitude towards online shopping.

Research Methodology

The Chennai city has been purposively selected for the study. The questionnaires were distributed to 100 people selected by using random sampling technique in Chennai city and 80 questionnaires turned out to be fit for analysis. The data information pertains to the year 2018. Chi-square test & Correlation coefficient were used by the researcher for analysis of primary data.

DATA ANALYSIS AND INTERPRETATION

<table>
<thead>
<tr>
<th>Table - 1: Products purchased online</th>

</tbody>
</table>

Source: Primary Data

The above table shows that the respondents prefer to buy more electronic products through online (42.50%), The next preferred online product is Books (33.80%) and the third in the list is clothing (30%). The next in the preferred shopping by respondents are computer accessories (26.30%), Cosmetics (16.30%) and Real estate (2.50%) are the least preferred online shopping product.

Chi-Square Test:

The Chi-Square test of independence is used to determine if there exists significant association between variables. The chi-square test of independence can be used to examine this association. The null hypothesis for this test is that there is no relationship between the variables. The alternate hypothesis is that there exists a relationship between variables.
Table - 2 : Chi – square between Occupation & Buying Behaviour

** Correlation is significant at the 0.01 level (2-tailed).

Source: Compiled from output of SPSS from primary data

The above table indicates Pearson’s correlation among the product satisfaction and the factors that affect online purchase. There is a high positive correlation between Product satisfaction and quality of the website. The correlation among product satisfaction and 8 factors affecting online purchase such as Online buying behaviour, web presentation, price, convenience, product features, quality of the website, ease of finding
product and payment method were positively significant at 1% level. Hierarchically, product satisfaction has the high positive correlation with quality of the website \((r=0.883, p<.01)\) followed by payment method \((r=0.759, p<.01)\).

Online buying behaviour has the high positive correlation with ease of finding the product \((r=0.660, p<.01)\) followed by price of the product \((r=0.620, p<.01)\). Web presentation has high positive correlation with payment method \((r=0.716, p<.01)\). Price has high correlation with quality of the website \((r=0.680, p<.01)\) followed by convenience \((r=0.335, p<.01)\).

Convenience has high positive correlation with quality of the website \((r=0.649, p<.01)\) followed by payment method \((r=0.598, p<.01)\). Product features has high positive correlation with payment method \((r=0.338, p<.01)\) followed by quality of the website \((r=0.296, p<.01)\). Quality of the website has high positive correlation with ease of finding the product \((r=0.338, p<.01)\).

**Findings**

1. The percentage analysis reveals that the electronic goods are the most preferred product to shop online and Real estate is the least preferred product.

2. The percentage analysis also shows that the most influencing factor that influences online purchase is the ease of finding the product online.

3. The Chi-square test reveals that there is a strong association between occupation and buying behaviour of the respondents.

4. The Chi-square test also reveals that there is no association between income of the respondents and price of the product.

5. There is an association between age of the respondents and quality of the website as shown by the Chi-square test statistic.

6. Chi-square test shows that there is no association between Gender of the respondents and convenience of shopping.

7. Pearson’s Correlation co-efficient shows that the product satisfaction has the high positive correlation with quality of the website. Online buying behaviour has the high positive correlation with ease of finding the product.

**Conclusion**

Online shopping is at a increasing pace. Right from school students to office goers, everyone is aware of online shopping. Especially females do a lot of online shopping than male members. The people look at the quality of the website for shopping and also they look into ease with which the products which they search online are available. Even though there are many positive aspects towards online shopping, still many people are afraid of providing their credit card or debit card information for payment through online and go in for cash on delivery mode. The security system can be improved and awareness can be created among public about the security systems available on online shopping.

Perceived Benefits & Risks of Online Grocery Shopping: 
Role of Cognitive Influences

Sneha Ghai¹, Somya Tripathi²

¹Assistant Professor, Amity Institute of Organic Agriculture, Amity University, Uttar Pradesh, India,  
²Student, Melbourne Business School, University of Melbourne, Victoria, Australia

Abstract

Background: Lifestyle and work life in present scenario demands and sees an increased usage of internet for grocery purchase. This paper discusses the perceived role of benefits and risks of shopping grocery online. It also aims to explore the consumer’s purchase behaviour intention and its influence on attitude-behaviour towards online grocery shopping (OGS). Objectives: To determine the relationship between the perceived values like convenience, past experience / perceived risks of OGS and purchase intention. Secondly to explore how these benefits and risk vary amongst the working and non-working class of the respondents. Method: Descriptive study using a pre-tested and structured questionnaire was carried out on 200 respondents across Delhi-NCR out of which 100 were working and 100 were non-working. Data was analyzed using Descriptive statistics, Correlation Technique and Multivariate Linear Regression analysis. Results: The results showed differences in opinion of consumers which are strongly influenced by convenience, ease of purchase and past experience and economic benefits. Conclusion: Differences were observed amongst working & non-working in perception of barriers associated including inability to physically examine the product, difficulty in returning products and high delivery charge and time and lack of social contact with other shoppers. The paper provides an empirical insight about how the e-retailers and advertisers can cater to the needs of consumers of online grocery within different segments.

Keywords: purchase intention, online grocery shopping (OGS), perceived benefits, perceived risks, correlation and regression

Introduction

Food & Grocery are the basic life requirement and while luxuries like restaurants, vacations, etc. may take a backseat., Groceries do sell irrespective of the economic condition of the country. Facing a fierce competition from mom & pop stores and hyper local options available already, condition of online grocery market is still improving. Although popular, shopping for groceries online is arguably a discontinuous innovation¹. Consumers are influenced by habits and deeply rooted traditional behavior when shopping for groceries². Consumer behavior is determined by intention which, in turn, is influenced by consumer attitude towards OGS³. There are perceived values of online grocery shopping like Convenience, Variety, Quality, etc., and also perceived barriers like inability to examine the product physically, lack of social contact, payment issues etc. Convenience is related to forms of non-monetary costs like stress, effort, time and psychological cost⁴. OGS offers consumers a greater convenience as they can shop anytime from anywhere, thus saving time from trips to physical stores. Variety is an important incentive in terms of product type and brand⁵. Quality has a direct impact on the consumer behavioral intentions towards OGS⁶. Also, individuals prefer to purchase online more as it provides better prices & deals⁷,⁸. Results reveals that previous online shopping experiences influences the consumer attitude towards online shopping and intention to shop online⁹,¹⁰. This fact is supported by a study that consumers’ preference towards an e-grocery store might be positively influenced by easiness to order groceries¹¹. Psychological barriers of consumer resistance were stated to be reasons for low adoption in the case of e-commerce services¹². Other hindering factors are the substitutability of the web environment to personally examining products and lack of feeling the tangible goods¹³,¹⁴,¹⁵. Also, security issues and privacy factors during final payment transactions become much of the concern for the consumers¹⁶,¹⁷. Shopping at stores is
often treated as a chance for spending time with friends/family members and also enjoy the social activities which lacks on an online platform\textsuperscript{[18, 19&20]}. A majority of the consumers hate to pay premium in the form of delivery fee for everyday necessity products like groceries\textsuperscript{[21, 22]}. Consumers face difficulty while trying to return a product they purchased online, especially in the online grocery industry. This is why online stores are perceived to have competitive disadvantages with respect to Is “for return” required after exchange/refund policy? as compared to in-store shopping\textsuperscript{[23]}. Having no guarantee about getting what they ordered is a major barrier\textsuperscript{[23]}. Inconvenient & longer delivery times and methods are major reasons cited by consumers who do not purchase groceries online\textsuperscript{[7&15]}.

Materials and Method
A descriptive study was carried out in Delhi-NCR using quota sampling to see the contrasting difference in the attitude, intention and current behaviour of both working and non-working consumers. Questionnaires were filled by 200 respondents, 100 working and 100 non-working, out of which only 160 were found to be valid for study, 80 working and 80 non-working. The data was analysed by using (SPSS). Regression and correlation analyses was employed to find the significant relationship between the perceived benefits & risks and the purchase intention for grocery online.

Source – Primary data SPSS
Measurement of Attitude towards Online Grocery Purchase

Current vs Previous Online Grocery Purchase:

It’s found that out of 49.4% of working population that has previously purchased groceries online, only 42.2% still do, and out of 46.3% of non-working population that has previously purchased groceries online, only 31.3% of still continue to purchase groceries online. This indicates a drop in online grocery purchase for both working and non-working population, though it’s more in the case of non-working population.

Usual place of grocery purchase:

“Local Kirana” (54.2%) is found to be the most popular place for grocery shopping for the working population, followed by “Supermarkets” (42.2%), and for non-working population indulging in online grocery shopping “Supermarket” (38%) is the most popular place.

Current Online Purchase Frequency:

Results indicate that out of the 42.2% working and 31.3% non-working population currently purchasing grocery online, most people purchase groceries online “Once in a month”, i.e., 16.77% working and 13.77% non-working population, respectively.

In comparison, though percentage of non-working population engaging in online grocery purchase is less, their purchase frequency is higher, with only a very small percentage purchasing grocery online rarely.

Preference for online grocery purchase:

Results indicated that out of 57.830% working population that currently doesn’t purchase grocery online, if given a chance, 12.048% would definitely like to, 38.554% might like to and 7.228% would definitely not like to opt for online grocery purchase.

Also, out of 68.70% non-working population that currently doesn’t purchase grocery online, if given a chance, 15% would definitely like to, 38.7% might like to and 15% would definitely not like to opt for online grocery purchase.

Perceived Value of Online Grocery Purchase:

Perception of Online Grocery Purchase to be beneficial:

Results indicated that 81.3% of the working and 69.1% of the non-working population believe OGS to be beneficial.

Results of both, preference for and perceived benefits of OGS, indicated a highly positive attitude towards online grocery purchase by the working and a moderately positive one by non-working respondents, despite the drop in online grocery purchase as depicted by current behavior. Thus, it’s vital for online retailers to understand the perceived behavioral control by analyzing the factors facilitating and inhibiting the online purchase of groceries for both working and non-working population, respectively.

Reliability:

The reliability and consistency of each item is measured with Cronbach’s alpha and interpreted as satisfactory for all the items as the Cronbach’s Alpha is 0.784.

Hypothesis Testing:

Developed on the basis of literature review, all the hypotheses are tested using the Pearson Correlation with a p-value of less than 0.05. Also, higher the ‘r’ value, stronger the relationship.

H1: Consumer intention to purchase groceries online is influenced by their perception of online grocery purchase as convenient.

A moderately strong positive relationship between consumer Online Grocery Purchase Intention and their perception of OGS as convenient (r=0.466, p=.000) at 0.01 significance level is found as p-value is less than 0.05. Hence, hypotheses (H1) should be accepted.

H2: Consumer intention to purchase groceries online is influenced by their perception that online grocery purchase provides variety.

No significant relationship between consumer Online Grocery Purchase Intention and their perception that Online Grocery Purchase provides variety is found (r=0.145, p=.063) at 0.01 significance level. Hence, hypotheses (H2) should be rejected.

H3: Consumer intention to purchase groceries online is influenced by their perception that online grocery purchase provides quality.
A moderately strong positive relationship between Online Grocery Purchase Intention and their perception that OGS provides quality products \((r=0.369, p=.000)\) at 0.01 significance level is found. Hence, hypotheses (H3) should be accepted.

H4: Consumer intention to purchase groceries online is influenced by their perception of online grocery purchase as economical.

A moderately strong positive relationship between consumer Online Grocery Purchase Intention and their perception that OGS is economical is found \((r=0.369, p=.000)\) at 0.01 significance level. Hence, hypotheses (H4) should be accepted.

H5: Consumer intention to purchase groceries online is influenced by their past experience of online grocery purchase.

A moderately strong positive relationship between consumer Online Grocery Purchase Intention and their past experience of OGS \((r=0.373, p=.000)\) at 0.01 significance level is found. Hence, hypotheses (H5) should be accepted.

H6: Consumer intention to purchase groceries online is influenced by their perception of ease of online grocery purchase.

The results indicate a moderately strong positive relationship between consumer Online Grocery Purchase Intention and their perception that online grocery is easy to purchase \((r=0.453, p=.000)\) at 0.01 significance level. Hence, hypotheses H6 should be accepted.

**Multivariate Linear Regression Analysis:**

**Perceived Values of Online Grocery Purchase:**

Results of regression for motives significantly influencing the online grocery purchase intention as summarized below in Table no. 2 & 3, for the working population indicated that Perceived Convenience and Perceived Ease of Purchase have significant standardized regression coefficients \((p\text{-value }=0.034\text{ and }0.01)\) respectively, although the latter \((\text{Beta}=0.356)\) has greater effect than the former \((\text{Beta}=0.204)\) on intention to purchase grocery online.

Results for the non-working population indicated that Perceived Convenience and Prior Purchase Experience have significant standardized regression coefficients \((p\text{-value }=0.024\text{ and }0.49)\) respectively, although Perceived Convenience \((\text{Beta}=0.284)\) has a larger effect than Prior Purchase Experience \((\text{Beta}=0.219)\) on intention to purchase grocery online.

Dependent Variable: Intention to Purchase Grocery Online

Predictors: (Constant), Perceived Convenience, Perceived Variety, Perceived Quality, Perceived Economy, Perceived Ease of Purchase, Prior Experience.

Source – SPSS Data Results, Compiled by Authors

Perceived Barriers/Risks to Online Grocery Purchase:

Results of regression for barriers to OGS which significantly inhibit the online grocery purchase intention, as summarized below in Table 4& 5, indicated that Inability to Physically Examine the Product and Difficulty in Returning Products have significant standardized regression coefficients (p-value =0.31 and 0.40), and the former (Beta=2.201) has a larger effect than the latter (Beta=1.989) on working population’s intention to purchase grocery online. Meanwhile, for the non-working population, Inability to Physically Examine Product, High Delivery Charge and Time, and Lack of Social Contact with Other Shoppers have significant standardized regression coefficients (p-value =0.003, 0.35 and 0.20), and Lack of Inability to Physically Examine the Product (Beta=0.380) has a larger effect than lack of social contact (Beta=0.256) on Non-Working population’s intention to purchase grocery online.

a) Dependent Variable: Intention to Purchase Grocery Online

b) Predictors: (Constant), Security Issues regarding Online Payment, Lack of social contact with other shoppers, High Product Price, Inability to Physically Examine the Product, High Delivery Charge and Time, Difficulty in returning products, No Guarantee, Unsuitable Delivery Hours, Forgery or Defective Product

Conclusions

The findings of the paper have demonstrated the applicability of Theory of Perceived behavioural Control which is directly influenced by perceived benefits of OGS.

The results have indicated a higher frequency of grocery being purchased by non-working respondents with a greater proportion of them purchasing it ‘2-3 times in a week’. The paper establishes a clear difference in perception of consumers depending upon their working status. The results of correlation analysis confirm that online grocery purchase intention is strongly influenced by factors like Convenience, Ease of Purchase, past experience, economy and quality, implying that Variety doesn’t prove to be important in considering the purchase. Findings of regression analysis reveal that perceived ease of purchase has greater effect than perceived convenience on working population’s intention to purchase grocery online. Whereas in case of non-working population, perceived convenience has a stronger impact than prior purchase experience.

Intriguingly, perceived barriers affecting the working consumers’ adoption of OGS are Inability to Physically Examine and Difficulty in returning products. However, in case of non-working population lack of physical examination, lack of social contact with others and high delivery charge and time are the major barriers of OGS.

Effect of Barefoot Functional Rehabilitation in Flat Foot among Obese Women

Hemali Patel¹, S Anandh²

Abstract

Background: Flat foot is among the commonest problems observed nowadays. There have been researches that prove weight to be an associated factor to flat foot. This study is carried out to find out effects of barefoot functional rehabilitation among obese women.

Objectives: To study the effect of Barefoot functional rehabilitation in flat foot among obese women.
To study the effect of conventional exercise alone in flat foot among obese women.
To compare the effect of barefoot functional rehabilitation along with conventional exercises VS conventional exercises alone in flat foot among obese women.

Method: 40 subjects were selected according to selection criteria. They were divided into 2 groups; barefoot functional rehabilitation group and other conventional group. Outcome measures were navicular drop test and foot function index.

Results: Results revealed that barefoot functional rehabilitation along with intrinsic muscle strengthening was more effective than intrinsic muscle strengthening alone in improving navicular drop score and foot function index in subjects with flat foot.

Conclusion: Barefoot functional rehabilitation exercises help in adapting the foot to different surfaces. These exercises help in strengthening certain smaller muscles of foot located at the bottom which helps in decreasing the navicular drop and foot function scores. Thus reduction in both the scores decreases the flat foot structure.

Keywords: obesity, foot abnormality, foot function index, navicular drop test.

Introduction

The most popular and convenient form of exercises that play an important role in weight management is walking, and foot is the essential component required for walking. The development of foot arch is rapid between 2-6 years of age and mature structurally around 12-13 years of age with slightest alteration in further ages due to weight problems etc. Footwear plays a crucial role in protecting the foot from trauma, however the deformations caused by shoes are considered to be a major contributing factor to forefoot pathology. In normal gait the subtalar joint starts to pronate post initial contact till the metatarsal head touches the ground, and thereafter the subtalar joint starts to supinate and converts the foot into a rigid structure for propulsion in the late stance phase. Repeated excessive loading...
may stretch ligament beyond their limits of elasticity, hence damaging soft tissues and increasing the risk of foot discomfort and subsequent development of foot pathologies. Such changes are observed in individuals that are overweight or obese. This discomfort may be caused due to heavy weight of body which may cause anatomical as well as kinematic changes in the body.

According to WHO, obesity is defined as abnormal or excessive fat accumulation that presents a risk to health. Obesity may be associated with several health problems such as dyslipidemia, hypertension, type 2 diabetes etc. Obesity have been shown to negatively affect foot structure and function both in children and adults. Nowadays flat feet is one of the most common conditions observed in adults. According to a research among physiotherapy students aged between 18-25, 18 years were having 2.5% of bilateral flat foot, 19 years were having 3.75% bilateral flat foot, 22 years were having 3.75% of bilateral flat foot, 24 years were having 1.25% bilateral flat foot. There are two types of flat foot: flexible flat foot and rigid flat foot. A flexible flat foot has an arch that is present in open kinetic chain (non-weight bearing) and lost in closed kinetic chain (weight bearing). A rigid flat foot has loss of the longitudinal arch height in open and closed kinetic chain.

Causes of flat foot might be congenital, adult flexible flat foot, posterior tibial tendon dysfunction, tarsal coalition, peroneal spastic flat foot, iatrogenic, post traumatic arthritis, charcot foot, neuromuscular flat foot. Adult flat foot presents symptomatic conditions with clinical consequences ranging from mild limitations to severe pain causing major life problems.

As feet are our main base of support during weight bearing activities it is stated that increased foot pain could act as a deterrent for obese individuals to participate in physical activity and indirectly perpetuate the obesity cycle.

Barefoot exercises not only exercises which give results physically, but they also are easy and efficacious to perform. Therefore, exercises can be implemented and also increased as per needs of individual. Due to these exercises the weakened structure of foot require considerable time for adjustment to new external stimuli; and hence treatment over weeks is recommended.

These exercises include short foot exercises, toe raise, unilateral and bilateral squats, single leg balance, trampoline single leg standing, balance board single leg standing, balance board exercises, grip exercise and walking on toes. There are intrinsic muscle strengthening exercises which are majorly used and show considerable change in individuals with flat foot but there is lack of awareness of barefoot exercises and its uses. Hence the effect of barefoot exercises can be known.

Thus, this study aims to find out the effect of barefoot exercises on obese women with flat foot.

Method

40 subjects were selected according to inclusion and exclusion criterion.

The Inclusion criteria was as follows:

- Female subjects.
- Age under 18-25 years.
- BMI > overweight or obese class 1, 2 or 3
- Obese adult with flat foot and symptoms of pain.
- Navicular drop: >10mm (On Navicular drop test)
- Subjects willing to participate.

The Exclusion criteria was as follows:

- Any recent surgeries in lower limb.
- Cardiovascular pathology.
- Any neurological problems.
- History of arthritis.
- Foot abnormalities.
- Uncooperative patients.

The subjects were divided into 2 groups by convenient sampling method. One group received barefoot functional rehabilitation exercises (short foot exercises, toe raise, unilateral and bilateral squats, proprioceptive exercise such as single leg balance, trampoline single leg standing, balance board single leg standing, balance board exercises, grip exercises of foot using different types of balls, walking on toes, walking on different surfaces like slippery flooring, rough surface etc) whereas, other group received intrinsic muscle strengthening exercises.

Outcome measures:

1. Navicular drop test:

For checking navicular drop, the subject was first
positioned in standing i.e weight bearing position. Using a small rigid ruler, the height of the navicular bone was measured from the floor to the most prominent part of the navicular tuberosity when in the neutral talar position. Again the height of the navicular bone was measured in relaxed sitting position i.e non weight bearing. The difference in measurement is the navicular drop and drop >10mm will be regarded as flat foot.

2. Foot function index: A Foot Function Index (FFI) was developed to measure the impact of foot pathology on function in terms of pain, activity restriction and disability. FFI consists of 17 questions items divided into 3 components. Each subjects were given FFI questionnaire according to inclusion criteria before starting the treatment. The scores of all 3 components were added which was divided 170 multiplied by 100 and percentage was calculated. This same procedure is carried out post treatment.

Result

1. Age distribution:

Age group of all participants were between 18-25 years. The mean age of the participants in Group A was 22.15 ± 1.725 and in Group B was 21.6± 2.186. There was no significant difference between the mean ages of the participants in both the groups. This was done by using unpaired t test (t_{40}=0.8832, p=0.3827)

Inter group analysis of foot function index score was done by using unpaired ‘t’ test. Post intervention analysis showed extremely significant difference between Group A and Group B (p<0.0001).

Discussion

According to studies, the incidence of flat foot has been reported to be 11.25% among a population of 18-25 years old students. Hence the study aims at finding the effect of barefoot functional rehabilitation in flat foot among obese women. Flat foot develops when there is change in lifestyle, comfortable flooring, less hours of standing work, over protection of the foot etc. criterion have been made for individuals having flat foot. Since, previous studies have set the criteria for flat foot as 1.15cm or more plantar arch index(17) and 10mm or greater navicular drop for flat foot (18-20), the subjects in the following study were selected based on the same criterion. There was extreme significance in the navicular drop and foot function scores in group A i.e the group receiving barefoot exercises like short foot exercises, unilateral and bilateral squats, grip exercises of foot using different types of balls, proprioceptive exercise using balance board, walking on toes, walking on different surfaces like slippery flooring, rough surface etc. These exercises were done without arch support and foot wear. These exercises help in adapting the foot to different surfaces. These exercises help in strengthening certain smaller muscles of foot located at the bottom which helps in decreasing the navicular drop and
foot function scores. Thus reduction in both the scores decreases the flat foot structure. The group B received intrinsic muscle strengthening exercises like ankle toe movement, toe curls and heel raise. It does not take part in the loading and unloading activities of the foot but may affect symptoms of flat foot like pain. The result from the statistical analysis of present study supported alternative hypothesis which stated that there will be beneficial effect to the subjects treated with barefoot functional rehabilitation along with conventional treatment. Hence above result showed that subjects treated with barefoot functional rehabilitation along with conventional treatment showed better navicular drop scores and decrease in foot function index scores with improvement in flat foot. Thus it can be stated from the above study that barefoot functional rehabilitation along with conventional treatment is more efficacious.

**Conclusion**

In conclusion, the present study provided evidence to support the use of Barefoot functional rehabilitation along with intrinsic muscle strengthening approach in improving navicular drop score and foot function index in subjects with flat foot. In addition, results supported that Barefoot functional rehabilitation along with intrinsic muscle strengthening was more effective than intrinsic muscle strengthening alone in improving navicular drop score and foot function index in subjects with flat foot. Thus the alternative hypothesis is proved.

**Conflicts of Interest:** This study can be carried out with more various forms of exercises and large sample size can also be taken into consideration.

Abstract

Background: Menopause is one of the biggest transitions in a women’s life. It leads to many anatomical, physiological as well as psychological changes in the body. Accumulation of fats in abdominal area and weight gain are also some of the major problems faced. Hence this study was carried out to find out the most effective among swiss ball, theraband and floor exercises in decreasing abdominal girth and increasing core strength in post menopausal women.

Objectives:
• To study the effect of core stability exercise using swiss ball on abdominal girth and core strength in post-menopausal women.
• To study the effect of core stability exercise using theraband on abdominal girth and core strength in post-menopausal women.
• To study the effect of core stability exercise using floor exercises on abdominal girth and core strength in post-menopausal women.
• To compare the effect of core stability exercise programme using swiss ball, theraband and floor exercises on abdominal girth and core strength in post-menopausal women.

Method: 60 subjects were divided into 3 groups ie: swiss ball, theraband and floor exercises. Outcome measures were BMI, waist circumference, waist hip ratio, abdominal skin fold thickness and double leg lowering test.

Results: There was statistically extreme significant difference (p<0.0001) seen in the waist hip ratio, abdominal skin fold thickness and core strength in the subjects receiving theraband exercises when compared with the other groups.

Conclusion: These results show theraband exercises as the most effective as it not only provides gravity as a challenge for muscles to work upon but also provides an additional component that is linear variable resistance which was also increased with increase in sets of exercises.

Keywords: menopause, obese, BMI, abdominal fat, double leg lowering test, skin fold thickness.

Introduction

There are two transition periods in a women’s life, both related to menstruation. Firstly, the start of menstruation around 12th year, ie; menarche and other at cessation of menstruation around 50th year, ie; menopause.¹ The post menopause period is the
span of time dating from the final menstrual period, regardless of whether the menopause is spontaneous or iatrogenic.\textsuperscript{2} Menopause is a transition phase from the reproductive to the non reproductive phase in a woman’s life.\textsuperscript{3}

The word menopause (menopausie) was used first time by a French physician de Gardenne.\textsuperscript{4} According to WHO Technical report series menopause is characterised by evidence of decreasing ovarian activity and biologically decreasing fertility and clinically alterations in the menstrual cycle intervals.\textsuperscript{5} According to a study, the mean age of menopause is 46 years in India.\textsuperscript{3} During this stage of women’s life there are possibilities of weight gain, muscle weakness which may lead to falls with advancing age.\textsuperscript{6}

Falls occur due to loss of static as well as dynamic balance. The loss of ability to balance the body may lead to lack of confidence. They may also feel hesitated and demotivated to participate in social gatherings or functions due to low self esteem. Dynamic balance of an elderly is supported by the core stabilizers.\textsuperscript{7}

Core stability is the ability to control the position and motion of the trunk over the pelvis to allow maximum production, transfer and control of force and motion.\textsuperscript{8} However, impairments of core stability are mainly caused by core muscle weakness.\textsuperscript{7}

The muscles around the abdominals and lumbar region such as rectus abdominis, erector spinae, quadratus lumborum, external oblique and gluteus comprise of core muscles.

As an attempt to strengthen these muscles, a programme using swiss ball, theraband and floor exercises are to be introduced. During exercises, knowing the trunk muscle activation levels is important in the prescription and design of exercise programs that aim to increase the training intensity over time.\textsuperscript{9}

Swiss ball exercises are beneficial as they are performed on an unstable surface, the level of muscle activity increases and to stabilise the spine muscle co activation takes place.\textsuperscript{10}

There are also researches that prove resistance exercises with the aid of unstable surfaces such as swiss ball are hypothesized to improve the functional capacity of patients because this workout affects balance and proprioception also.\textsuperscript{11} There are many studies that have proved core muscle recruitment during swiss ball abdominal exercises.\textsuperscript{12} Hence, we can refer as swiss ball as an beneficial object for the subjects. The elastic band manufacturers provide a range of such products of various resistance which can be distinguished by colours.\textsuperscript{13} Each colour signifying a level of resistance which would be offered to the patient by the band. The use of theraband exercises have been effective method of providing resistance and improving muscle strength.\textsuperscript{8}

Floor exercises also help to an extent for strengthening core muscles. Floor exercises for core stability should be trained in a progressive fashion, initially with local muscle recruitment, then moving to core stabilization in a variety of postures and then transitioning into total body dynamic movements.\textsuperscript{14}

According to previous researches, it is proved that post menopausal women show an increase in their abdominal girth along with weakness of abdominal muscles. There have been studies which are conducted to increase their strength and reduce abdominal girth, but this study aims at finding out the best and most effective exercises among swiss ball, theraband and floor exercises in relation to abdominal girth and core strength.

Thus, there should be a proper set of exercises which may help in weight reduction and at the same time may also help in maintaining proper balance. This study may also help in developing a good self imagine and boost their confidence.

**Method**

60 subjects were selected according to inclusion and exclusion criterion. The inclusion criteria was as follows:

- Post – menopausal women willing to participate in study.
- Age group 45 - 55 years
- Body mass index (BMI) 25 - 29.9 kg/m\(^2\) (pre obese) 30 - 34.9 kg/m\(^2\) (obese class 1)
- Waist hip ratio > 0.8 cms\textsuperscript{15}
The exclusion criteria was as follows:

- Subjects who have undergone abdominal surgeries 6 months prior to the study.
- Subjects who have undergone spinal surgeries.
- Subjects with prior experience of swiss ball, theraband and floor exercises.
- Subjects with acute low back ache or systemic conditions.
- Subjects on any other weight reduction plan e.g. medications, massage surgery during the study period.

They were divided into 3 groups A, B, C respectively by simple random sampling method.

(1) Treatment programme

<table>
<thead>
<tr>
<th>GROUPS</th>
<th>(A) SWISS BALL</th>
<th>(B) THERABAND</th>
<th>(C) FLOOR</th>
</tr>
</thead>
</table>
| EXERCISES: | - Back extension  
- Plank exercise  
- Bridging  
- Spine rotation | - Trunk curl up  
- Trunk twist  
- Back extension  
- Side bend | - Arm lifts  
- Back extension  
- Pelvic tilt  
- Prone on hands |

The intensity shall be increased as follows:

- 1st week: 3 sets; 15 repetitions in each set
- 2nd week: 4 sets; 15 repetitions in each set
- 3rd week: 4 sets; 20 repetitions in each set
- 4th week: 4 sets; 20 repetitions in each set
- 5th week: 4 sets; 25 repetitions in each set

2 minutes rest was given after each set of exercise.

OUTCOME MEASURES:

i. Body mass index
ii. Waist circumference
iii. Waist hip ratio
iv. Abdominal skin fold thickness
v. Double leg lowering test

Result

Results were analysed using paired t test and ANOVA test respectively. Intra group comparison of BMI using paired t test.

(2) BMI - Intra Group comparison (within Group) using Paired t test.

<tr>
<td>Inference</td>
<td>Not significant</td>
<td>Extremely Significant</td>
</tr>
</tbody>
</table>

On comparing the pre interventional values, the results between the three groups using ANOVA test revealed (p=0.3586, not significant). While on comparing the post session values, the results between the two groups using ANOVA test revealed (p<0.0001, extremely significant).

**Discussion**

The present study was conducted to find the most effective exercises for post menopausal women in relation to abdominal girth and core strength. Results of this study were focussed on body mass index, waist circumference, waist hip ratio, skin fold thickness using skin fold calliper and core strength using double leg lowering test. The results were analysed using paired t test and ANOVA test.

On comparing the values with paired t test ie; within the three groups, it was understood that the effect of swiss ball on waist circumference was not significant as well as the effect of floor exercises on skin fold thickness and core strength was not quite significant.

On analysing the data with ANOVA test ie; between groups, the results revealed that there was no statistically significant difference in BMI, waist circumference and waist hip ratio. The probable reasons for this negligible change could be because no vigorous physical activity or position modification or any treatment intervention focusing on body weight was given. The other reasons could be the sedentary lifestyle of the subjects. The subjects were not involved in any physical activities other than the designed exercises. They were also not involved in any aerobic exercises.

On comparing the values with paired t test, the results revealed that the effect of theraband on BMI was very significant (p=0.0012). The effect of swiss ball exercises, theraband exercises and floor exercises on waist circumference was extremely significant. The results also revealed to prove the theraband exercises to be the most effective as they showed statistically extreme significant difference in the waist hip ratio, skin fold thickness as well as core strength.

On analysing the data with ANOVA test, there was significant difference observed in the skin fold thickness and extremely significant in core strength. The theraband exercises proved to be more beneficial and maximum improvement was seen in the
theraband group on performing double leg lowering test. This may be due to more comfort in performing the theraband exercises than swiss ball and floor exercises. The swiss ball exercises, theraband and floor exercises all involve gravity as a component. Gravity also plays a role in all the exercises but in the theraband exercises there was an additional factor i.e the resistance which was exhibited by the elastic material of the bands. There was not only constant resistance but also an increase in the resistance was given which proved to be a reason for the essential benefit.

Further reasons for noticeable improvement seen in the subjects using therabands could be as they provide continuous tension on the muscle to be trained. The other factor may be because the elastic resistance that offers a linear variable resistance.10.

The other factors which prove to be a reason for more effect of theraband exercises over swiss ball exercises may be as the swiss ball exercises may exert more difficulty of exercises using an exercise ball that varies for each person and challenge areas of stiffness, inflexibility and may be strength improvement is not better than that of theraband.

Considering the above inferences it can be concluded that theraband exercises prove to be the most beneficial and effective among swiss ball and floor exercises in decreasing abdominal girth and increasing core strength.

**Conclusion**

There are various attempts made by the post – menopausal women to decrease their body fat and increase core muscle strength but from this study it is concluded that theraband exercises were the most effective among swiss ball and floor exercises for decreasing abdominal girth and increasing core strength.

Results revealed that exercises of all the three groups; swiss ball, theraband as well as floor proved to be effective and showed improvement. There was maximum effect seen in theraband exercises followed by swiss ball and then floor exercises.

**Conflicts of Interest:** This study can be carried out with more various forms of exercises and large sample size can also be taken into consideration.

**Ethical Clearance:** Ethical clearance was taken from institutional committee of Krishna Institute of Medical Sciences deemed to be university, Karad.

**Source of Funding:** Source of funding is Krishna Institute of Medical Sciences deemed to be university, Karad.

A Community based Cross Sectional Study to Assess the Association between Indices of Obesity and Hypertension

Arun Varghese, Prakash M Durgawale, Satish V Kakade, Dhirajkumar A Mane, Supriya S Patil

1Assistant Professor, Department of Community Medicine, DMWIMS (Dr Moopen’s Wayanad Institute of Medical Sciences), Wayanad, Kerala., 2Professor & Head, 3Associate Professor cum Statistician, 4Statistician, Directorate of Research, KIMSDU, 5Associate Professor, Dean of Academics,Department of Community Medicine, Krishna Institute of Medical Sciences, Karad, Satara, (Maharashtra) India

Abstract

Background: Hypertension is associated with a reduced quality of life and also an increased risk for various cardiovascular, renal, neurological and multiple systemic complications. Objectives: To determine the prevalence of hypertension and to find out the association between anthropometric indices and hypertension. Material and Method: A cross-sectional survey was conducted in 1509 individuals ≥30 years in the rural population of Kasegaon village, Maharashtra by a house to house survey during December 2015 to May 2016. Blood pressure (BP), Waist Circumference (WC), Waist Hip Ratio (WHR) and Body Mass Index (BMI) were measured according to WHO guidelines. Data was analyzed in SPSS version 20 using chi-square test and odds ratio. Results: The prevalence of hypertension in our study was 10.74%. An increase in BMI, WC, WHR were found as risk factors for hypertension. 6.8% (n=7) were hypertensives among those with underweight, 7.5% (n=75) of the population with a normal BMI were found to be hypertensive, 13.0% (n=42) were hypertensives among the overweight category, and 19.5% (n=16) were hypertensive among the obese category. The prevalence of hypertension among those having normal WC was found to be 7.3% (n=88), 12.7% (n=18) were hypertensive among those with WC in the increased risk category and the 21.4% (n=34) were hypertensive among those who had a substantially increased risk WC. Among those who were in less risk WHR category, the prevalence of hypertension were 7.2% (n=88) and 18.2 % (n=52) individuals were hypertensives among the substantially increased risk WHR category. Conclusion: The importance and need of weight reduction by increasing physical activity, lifestyle modification should be incorporated into the community to control this problem.

Keywords: Hypertension, Body Mass Index, Waist Circumference, Waist Hip Ratio.

Introduction

The wealthy and resource constrained countries are now facing the same health issues the shift of communicable diseases to Non-Communicable Diseases(NCDs) such as cardiovascular disease, cancer, diabetes and chronic lung diseases, as the world’s leading cause of mortality.1

According to the World Health Organization (WHO) estimates in 2015, 17.7 million deaths (accounting for 45% of all NCD deaths; cancer, 8.8 million deaths (22%); chronic respiratory disease, 3.9 million deaths (10%); and diabetes, 1.6 million deaths (4%)(2,3).

One of the key risk factors for cardiovascular disease is Hypertension (HTN) which already affects one billion people worldwide, leading to heart attacks and strokes. Researchers have estimated that raised blood pressure currently kills 9 million people every year. Hypertension is ranked as the third most important risk factor for attributable disease burden

DOI Number: 10.5958/0976-5506.2019.00662.4
in south Asia\(^4,5\). It exerts a substantial public health burden on cardiovascular health status and healthcare systems in India\(^5,6\) and is directly responsible for 57% of all stroke deaths and 24% of all coronary heart disease (CHD) deaths\(^5\). The WHO ranks HTN as one of the most important causes of premature death worldwide \(^5\). But there is no need of this risk to be so high, because hypertension is a preventable disease condition\(^1,4\). And doing so is far less costly, and far safer for patients, than the costlier and complicated interventions (cardiac bypass surgery, dialysis) which may be needed when HTN goes undiagnosed and untreated\(^1\).

Aim: To provide necessary feedback to improve the effective delivery of health care services, with special reference to hypertension in the rural population residing in western Maharashtra.

**Objectives**

- To determine the prevalence of hypertension among adult population above 30 years in the rural field practice area under RHTC, Kasegaon.
- To determine an association, if exists; between anthropometric indices and hypertension among the study subjects.

**Material & Method**

This was a descriptive cross-sectional study of adults aged ≥30 years carried out in Kasegaon village, adopted by the KIMS tertiary care centre, Karad, Western Maharashtra, conducted between December 2015-May 2016. Total population of Kasegaon village is 13581, comprising of 5924 females and 6477 males. There were 2397 households in Kasegaon, divided in 5 wards of the village (2011 census).

Using a prevalence (p) of 10% \(^5\) and absolute precision (L) of 1.6 % with 95% confidence interval, the required sample size was estimated to be 1407, using the formulae \(n=4pq/L^2\). Considering a 10% non response rate we decided to collect 1550 samples, However, after analysis 1509 samples were obtained because 41 samples were non responsive. All adults ≥30 years willing to participate in the study were included, whereas those who were absent even after 3 repeated visits on the same week, pregnant and lactating mothers within 6 months of delivery, non-permanent residents of Kasegaon, non-cooperative subjects, persons with chronic illnesses and secondary HTN were all excluded from the study.

The study was conducted after obtaining institutional ethical clearance and with the permission from the Gram Panchayat of Kasegaon.

After obtaining informed consent, data was collected from each of the 5 wards, by house to house visit, using a pretested, modified and validated structured questionnaire. In each ward, we reached at the approximate centre and from there a main land mark was taken as the starting point and followed a clockwise direction for obtaining the samples. Minimum 282 samples were studied from each ward for attaining the desired sample size of 1550 adults. BP was measured according to WHO guidelines, BMI was measured according to the WHO STEPS protocol \(^7,8\), WC and WHR was measured based on the WHO sex specific cut off points for WHR \(^9,10\). Data was entered in SPSS version 20.0. The association of study variables with status of hypertension was assessed by applying chi-square test. A p value of < 0.05 was considered statistically significant. Odds ratio was calculated to find out the association between hypertension and its risk factors.

**Results**

![Sex wise age distribution of the study population](chart)

Figure 1: Sex wise distribution of the study population

Unpaired-t =1.745, p=0.087

Figure 1 reveals that; among the total 1509 study subjects, 55.5% (n=838) were females and 44.5% (n=671) were males. (Age range of the male and female population were 30-100 years and 30-98 years respectively, Mean age of females and males were 49 yrs and 50 yrs respectively). Unpaired t- test was found to be 1.745 and p-value was insignificant which was 0.087 (p>0.05). No significant difference in the sex-wise distribution of population was observed.

A high prevalence of hypertension was observed among the overweight (13.0%) and obese (19.5%) individuals when compared to those with underweight (6.8%) and 7.5% with a normal BMI. There was a proportionate increase in blood pressure with respect to BMI and was found to be statistically significant (p-value < 0.001). Participants who were overweight were having 17.9 times more chance (OR 1.854; 95% CI 1.242-2.768) and those who were obese were having 1.7 times more chance (OR 2.996; 95% CI 1.653-5.432) of becoming hypertensive when compared to those who were normal.

Figures in parentheses denote row percentages.  
*Chi-square = 33.240, p < 0.001*

The prevalence of hypertension was 7.2% among the normal (less risk) waist hip ratio category compared to 18.2% among the substantially increased risk waist hip ratio category. An increasing trend in the prevalence of hypertension was observed with an increasing waist hip ratio. Chi square value was 43.942 and the p-value was < 0.001. Participants who were having a WHR at substantially increased risk category are having 15.8 times more chance (OR 15.764; 95% CI 11.946-20.8021) of becoming hypertensive when compared to less risk WHR category.

Discussion

The aim of this study was to provide necessary feedback to improve the effective delivery of health care services, with special reference to hypertension in the rural population residing in western Maharashtra. Early diagnosis and treatment of hypertension is necessary to initiate preventive measures and to prevent complications.
In our study there was no significant difference between the age and sex-wise distribution of the study population. Similar findings were observed by Anchala R. et al.(5), Deo M.G. et al.(11) in a study conducted in coastal Maharashtra and Premanandh K. et al. (12) in Goa.

The prevalence of pre hypertension and hypertension has been increasing in India especially in urban areas, but now in to the rural areas also(13). The overall prevalence of hypertension from the study was 10.74% among the study subjects. Similar results were obtained in a meta-analysis review of prevalence, awareness and control of hypertension by Anchala R. et al.(5), but lower than the IDSP phase-1 (Integrated Disease Surveillance Project) survey(13). The prevalence of pre-hypertension was high (60%) in our study. A lower prevalence was observed in the Boloor diabetic study (40.4%) (14). The very famous and common “rule of halves” in the epidemiology of hypertension suggests that among the hypertensives, only about half of hypertensive populations are diagnosed (aware of the condition), half of those diagnosed are treated, and half of those treated are adequately treated (controlled); these estimates may be optimistic in many developing countries(15,16,17) diagnosis, treatment, and control among middle-income countries. We analyzed data from 47 443 adults in all 6 middle-income countries (China, Ghana, India, Mexico, Russia, and South Africa). In our study much less than 50% were aware of their hypertensive status (only 20.37% were aware; 33/162=20.37%), but among those who were aware of their condition, more than 50% were treated (87.88%; 29/33=87.88%) and among the treated ones, more than 50% were adequately treated (75.86%; 22/33=75.86%). Hence, a lot of further research on screening and adherence strategies, as well as quality improvement at healthcare delivery system to ensure titration of medications, which are crucial for improving outcomes is required.

In our study there was a proportionate increase in hypertension with respect to BMI and was found to be statistically significant (p-value < 0.001). Similar results were observed in a study done by Imaad Mohammed Ismail et al(18) Premanandh K. et al.(92), Ajeet S.Bhadoria et al., (19) and Sanjeet Panesar et al(110). This may be because obese individuals have an increase in fatty tissue that increases their vascular resistance and in turn increases the work the heart has to do to pump blood throughout the body. In our study, it was noted that there was a progressive trend of hypertension as the waist circumference moves (increases) to substantially high risk category (21.4% prevalence). It was also seen that as the waist hip increases to the substantially increased risk category (Chi square was 43.942 and p-value was < 0.001), the prevalence of hypertension also intensified. Participants who were having a waist hip ratio (WHR) at substantially increased risk category are having 15.8 times more chance (OR 15.764; 95% CI 11.946-20.8021) of becoming hypertensive when compared to those who were having a waist circumference at a less risk category. Many studies suggest waist circumference (WC), BMI and hip circumference are associated with cardiovascular outcome, independent of traditional risk factors. However, WC appears to be a better predictor for cardiovascular risk than other parameters. Waist–hip ratio is not as useful as other measurements(20).

**Conclusion**

According to this study it was found that one-tenth (10.74%) of the rural adult population of Western Maharashtra are hypertensive. Further research is required to document the impact of family structure, physical activity, smokeless tobacco use, family history, obesity and stress on blood pressure among the study population. There is a need for urgent call for early diagnosis, prevention and control measures for hypertension.

**Recommendations**

Appropriate public health education must be imparted through schools starting from primary education, existing or newer national health and hospital outreach programmes to raise awareness about the role of exercise, weight reduction, healthy diet and lifestyles, addictive and harmful nature of tobacco products and alcohol abuse.

As stress been found to have a significant association towards hypertension, national programmes should include preventive and control measures against stress.

**Limitations:** Being an observational study, causality was not inferred and no follow ups were done.

Attitude Towards Ageing among Older Population

B Jayabharathi1, Nisha Yadav2, Tharageshwari2, Buvana2

1Associate Professor, Department of Obstetrics & Gynaecology Nursing, 2B.sc (N) IV Year Students, SRM College of Nursing, SRM Institute of Science & Technology, Kattankulathur, Kancheepuram District, Tamil Nadu

Abstract

Introduction: Ageing is a life spanning process of growth and development from birth to death. The ageing process occurs in every living species, and also in human beings by greying of hair, wrinkling of skin, hardening of arteries, aches and pains in joints and weakening of eye sight.

Aim: The aim of the study is to assess the attitude towards ageing among older population.

Methodology: Non experimental descriptive research design was adopted to assess the attitude towards aging among older population. The study was conducted at SRM general hospital, Kattankulathur, Kanchipuram district. 100 older people who fulfilled the inclusion criteria were selected by using non probability convenient sampling technique. Structured questionnaire was used to assess the demographic variables of older people. Five point likert scale was used to assess the attitude towards aging among older people.

Results: The findings depicted that, majority 59 (59%) older people had moderately favourable attitude towards ageing, 41 (41%) had favourable attitude and no one had unfavourable attitude towards ageing. The results revealed that there was significant association found between attitude towards aging among older population with occupation, but there was no significant association found between attitude towards aging among older population with other demographic variables such as age, gender, religion, education status, family income, place of residence and presence of any disease conditions.

Conclusion: The perception of the public about the older people can have impact on the elderly in employment, education, and health services, and in the general treatment. Further research is needed to examine public perceptions of older people, and the nature and direction that they take, so that interventions can be developed to ensure that older people can live with better quality of life.

Keywords: Attitude, Ageing, Older population

Introduction

Ageing is a life spanning process of growth and development from birth to death. Old age is an integral part of the whole, bringing fulfillment and self actualization. The ageing process occurs in every living species, and also in human beings by greying of hair, wrinkling of skin, hardening of arteries, aches and pains in joints and weakening of eye sight. The way that older adults adjust to the changes of ageing depends on the individual. For some individuals, adaptation and adjustment are relatively easy, where as for other individuals coping with ageing changes may require the assistance of family, friends and health care professional.

As people age, their health needs tend to become more complex with a general trend towards declining capacity and the increased likelihood of having one
or more chronic diseases. Health services are often designed to cure acute conditions or symptoms and tend to manage health issues in disconnected and fragmented ways that lack coordination across care providers, settings and time. 

A recent Health Service Executive (HSE) (2009) report highlighted that, how people’s attitudes and perceptions can have a significant negative impact on the lives of older people. Ageism and ageist attitudes are not the sole factors contributing to elder abuse but can give rise to a culture which creates a fertile environment in which elder abuse can develop, leading to age discrimination, and devaluing and disempowering older people.

In 1975, Butler used the term ageism to refer to “a process of systematic stereotyping of and discrimination against people because they are old”. More than 35 years after he coined the term, Butler (2005) still considers ageism to be deeply embedded in our society. As the proportion of older adults continues to increase in both the population and the labor force, it becomes increasingly important to understand the determinants of attitudes towards the elderly so that it may be possible to promote more positive attitudes in young adults.

Fraboni, Saltstone, and Hughes (1990) have argued that, the Aging Semantic Differential Scale is limited in that it only measures the cognitive components of ageism. In order to assess more completely the concept of ageism, then Fraboni Scale of Ageism (FSA) (Fraboni et al.) was developed. The FSA comprises items designed to assess both the affective as well as the cognitive component of ageist attitudes. Research using the FSA finds that university students, as well as a community based sample of adults of all ages, hold negative attitudes about the elderly. Compared to women, men are consistently found to have more ageist attitude.

Denver J. Miller, et.al conducted a study to examine physicians’ attitudes toward and knowledge concerning driving in older persons. The questionnaire explored physicians’ practice characteristics, general approach to record keeping, frequency of behavior toward educating, counseling, and reporting patients to authorities when deemed appropriate, and their personal understanding of driving issues and physician responsibilities within the state in which they practice. A response rate of 48% was obtained. There was a lack of consensus among physicians, with a broad range of attitudes and practices dealing with this growing public health concern.

The perception of the public about the older people can have impact on the elderly in employment, education, and health services, and in the general treatment. Further research is needed to examine public perceptions of older people, and the nature and direction that they take, so that interventions can be developed to ensure that older people can live with better quality of life.

The present study aims to assess the attitude towards ageing among older population at SRM General Hospital, Kattankulathur, Kancheepuram dist.

**Methodology**

The study was conducted at SRM general hospital, Kattankulathur, Kanchipuram district. Non experimental-descriptive research design. Was adopted for the study. 100 older population who fulfilled the inclusion criteria were selected by using Non-probability–convenient sampling technique. The inclusion criteria includes a. Older population who were available during the period of study, b. Older population who were in the age group of 60-75 years& c. Older population who could able to understand English and Tamil. The exclusion criteria includes a. Older population who were not willing to participate the in study & b. Older population who were with psychiatric illnesses.

**DEVELOPMENT AND DESCRIPTION OF THE TOOL**

It consists of two Sections

**SECTION A:** Structured questionnaire was used to assess the demographic variables of older population which includes age, gender religion, educational status, occupation, family monthly income, place of residence and presence of any disease condition.

**SECTION B:** 5 point likert scale was used to assess attitude towards ageing among older population. The scale consisted of 20 statements with 10 positive worded and 10 negative worded statements. The respondents were asked to indicate the level of agree or disagree the statement against the column given.

Reliability of The Tool

Reliability of the tool was established by split half method. The coefficient correlation $r = 0.75$ which was high. Hence, the tool was considered reliable and feasible for proceeding with the main study.

Ethical Considerations

The research proposal was approved by research committee of SRM College of nursing, SRM University, Kattankulathur, Kancheepuram district. Permission was obtained from the Dean, SRM College of Nursing and Medical Superintendent, SRM General Hospital. Informed consent was obtained from the study participants, after explaining the nature and duration of the study. Assurance was given to the individual that report will be kept confidential.

The results revealed that there was significant association found between attitude towards aging among older population with occupation and there was no significant association found between attitude towards aging among older population with other demographic variables such as age, gender, religion, education status, family income, place of residence and presence of any disease conditions.

**Discussion**

Ageing is the process of becoming older. In humans, ageing represents the accumulation of changes in a human being over time encompassing physical, psychological and social changes. Although the body and mind go through many natural changes as they age, not all changes are normal. There are many misconceptions about what is a normal part of aging. Older age is also characterized by the emergence of several complex health states that tend to occur only later in life and that do not fall into discrete disease categories. These are commonly called geriatric syndromes. They are often the consequence of multiple underlying factors and include frailty, urinary incontinence, falls, delirium and pressure ulcers.

The present study findings depicted that, majority 59 (59%) older people had moderately favorable attitude towards ageing, 41 (41%) had favorable attitude and no
one had unfavorable attitude towards ageing.

The findings are consistent with the study done by Debra Deasey, et.al(2011) on nurses’ knowledge of ageing and attitudes towards older people on therapeutic interactions in emergency care. Sixteen articles were reviewed, including seven cross-sectional surveys, seven qualitative studies and two mixed-methods studies. Emergency department nurses’ attitudes towards and knowledge about ageing processes may affect therapeutic interactions between nurses and their older patients. Issues such as managerial style, past experiences and the medical model used for health-care delivery were secondary factors shown to influence emergency nurses’ negativity towards their older patients.\(^8\)

The findings are consistent with the study done by Soonrim suh, et.al (2011) on the association between knowledge and attitude about aging and life satisfaction among older Korean. A total of 405 older adults were surveyed using a written questionnaire at six elderly welfare centers in a metropolitan city in South Korea in mid April 2011. The score of knowledge on aging was below the medium level. Attitude about aging was neutral, and life satisfaction was at the medium level. Variables such as female sex, age, economic status, monthly allowance, living with a spouse, self-rated overall health, knowledge and attitude about aging accounted for 33.8% of the total variance in predicting life satisfaction of the older adults. Older age and lower economic status reduced life satisfaction. Being female, having a monthly income of 300,000 Korea Republic Won or more, living with a spouse, and better knowledge and attitude about aging were associated with enhanced life satisfaction.\(^9\)

**Conclusion**

The present study results conclude that, majority of the older population 59% had moderately favorable attitude towards aging. The perception of the public about the older people can have impact on the elderly in employment, education, and health services, and in the general treatment. Further research is needed to examine public perceptions of older people, and the nature and direction that they take, so that interventions can be developed to ensure that older people can live with better quality of life.

Impact of Farm Technology on Rice Production in Madurai District, Tamilnadu

S Thangamayan¹, B Chithirairajan¹, S Sudha¹

¹Assistant Professor, Department of Economics, VELS Institute of Science, Technology and Advanced Studies, Chennai

Abstract

The crucial importance of green revolution is to achieving higher yield of productivity and encouraging crops production in all over the places. The major objective of green revolution was to increase the agricultural production to meet out the ever growing demand for food grains due to never ending process of population expansion. It is grown in almost all the states of India but it is mostly concentrated in the river valleys, deltas, and low lying coastal area of North Eastern and Southern India. The rice producing states are Assam, West Bengal, Bihar, Madhya Pradesh, Orissa, Andhra Pradesh, Tamil Nadu, Kerala, Mysore, Maharashtra, Gujarat, and Uttar Pradesh, Jammu and Kashmir which together contribute over 95 per cent of the country’s rice production. Hence, the present study makes an attempt to analyse the impact of rice production in Madurai district, Tamil Nadu. By and large, the study concluded that small farmers are economically more efficient than large farmers irrespective of varieties of rice cultivation in the study area. This is indicated that apart from efficient allocation of inputs, direct supervision and farm management are crucial determinants of economic efficiency.

Keywords: rice production, economic efficiency, management, green revolution, farm technology.

Introduction and Statement of the Problem

No doubt, agriculture is a major livelihood source and it is a backbone of India. Indian agriculture and allied activities were depressed after the Indo-Pakistan and Indo-China wars in 1960’s. Further, the prices of raw materials, jute products, oil seed products and food stuffs were rose at high level. A serious problem was initiated in agricultural sector due to the shortages of food grain productions and the demand for food production was increased on account of war and prisoners, increased consumption in home country, the supply level is also decreased due to that reduction in the marketable surplus. On the other hand, fear of currency devaluation, and the expectation of increase in price level led to stock maintaining by traders, consumers and the farmers much beyond the normal requirements. It brought out that food scarcity and price raised in India. In view of price increased in agricultural goods benefitted only to landlords and Zamindars. But, the farmers were paid huge amount of interest to the creditors, and the position of agricultural labourers felt down, it brought out that the farmers were decided to suicide or shifted from agricultural sector to industrial sector i.e., the farmers were migrated from rural area to urban area. In view of these drawbacks, the father of green revolution M.S. Swaminathan has introduced the new agricultural strategy programme which was initiated in 1966 in the name of Green Revolution and it was first implemented in Punjab for the purpose of to improving wheat production in India. In Tamil Nadu, most of the farmers were cultivated rice production with the effort of Green Revolution. The major aim of green revolution is to implement the high yielding varieties of seeds, improving irrigation facilities, applying high doses of fertilizers, pesticides, using rotator, cultivator and tractor in agricultural land. The crucial importance of green revolution is to achieving higher yield of productivity and encouraging crops production in all over the places. It is interesting to note that, the agricultural production was rose by the way of adopting farm technology method in green revolution scheme. However, the major objective of green revolution was to increase the agricultural production to meet out the ever growing demand for
food grains due to never ending process of population expansion. For our surprise agricultural production was increased from 55 million tonnes to 225 million tonnes in 20th century. It is very significant to note that one third of the world’s rice area in India i.e. 83 million hectares. It is grown in almost all the states of India but it is mostly concentrated in the river valleys, deltas, and low lying coastal area of North Eastern and Southern India. The rice producing states are Assam, West Bengal, Bihar, Madhya Pradesh, Orissa, Andhra Pradesh, Tamil Nadu, Kerala, Mysore, Maharashtra, Gujarat, Uttar Pradesh, Jammu and Kashmir which together contribute over 95 per cent of the country’s rice production. Of these, West Bengal, Orissa, Andhra Pradesh, Tamil Nadu and Bihar are the major rice producing states. Hence, the present study makes an attempt to analyse the impact of farm technology on rice production in Madurai district, Tamil Nadu.

Review of Literature

Sharma (1964) assumes the level of development of agriculture through means of selected indicators like gross area irrigated, gross sown area, rainfall, cropping intensity. This study also assessed the level of development of each of these indicators, which can reflect broadly the potential level of agricultural development.

Dibakar Naik, Beura D. and Behera M.R. (1999) in their study to examine inter-district growth performance of agriculture and its impact of sustainability of agricultural production and food security in Orissa. For the purpose the growth area, production and productivity of principal grains have been analysed for three periods, viz., 1970-80, 1981-90 and 1990-1999. The Gross Domestic Product (GDP) has growh at the rate of 4.91 per cent growth rate of agricultural gross state domestic product during 1980-89. The growth rate of GSDP is 4.33 per cent during 1990-96.

But the growth of agricultural gross state domestic product reduced to 0.47 per cent during 1990-96 due to poor performance of agriculture in the state. The poor performance of agriculture indicates wide gap between farmers practical and scientific knowledge available in the state.

Khanna S.S and Gupta M.P. (1988) have made in depth study into making the prospects of pulse production brighter in their analysis, “Raising Production of Pulses”. Moreover, the area, production and productivity of pulses have remained almost static during the last thirty years. Therefore, the authors feel that there is a great need for vigorously implementing the pulses development project to keep pace with the growing demand for pulses. They point out the present per capita pulses availability in India is much below the minimum pulse requirement as recommended by world Health Organization.

World Food Problems

World food problems involve complex interactions among food production, population growth, poverty, environmental effects, economic and political systems, and ethics. Producing food at a faster rate than population grows will not solve hunger problems unless the poor have enough land to grow their own food or enough income to buy the food they need. Chronic hunger and catastrophic failure are due to lack of access to food, but not a lack of food, 16th October is declared as the World Food Day. Global food production has increased substantially over the past two decades, but producing food and other agricultural products by conventional means uses more soil, water, plant, animal and energy resources, and causes more pollution and environmental damage, then any other human activity. To feed the 8.5 billion people projected by 2025, we must produce and equitably distribute as much food during the next 20 years as was produced since agriculture began about 10,000 years ago.

Objectives Of The Study

1. To analyse the cost and return structure of rice production under different classes of farmers in selected district.

2. To suggest the various suitable measures to improve rice production in different types of farmers.

Materials and Method

The present study is focused on both primary data and secondary data. The primary data is based on multi-stage random sampling method. The first stage, Madurai district has been selected in Tamil Nadu state. In secondly, two taluks are randomly chosen in selected district viz., Thirumangalam and Usilampatti. In view of these two taluks, six villages are selected in third
stage. In view of this Thirumangalam taluk, Urappanur, Cheekanurani and Vagaikulam villages have been selected. Besides, Pappapatti, Valandhur, and Karumathur villages have been selected in Usilampatti taluk. At fourth stage, 125 farmers are interviewed in selected villages. Among the selection of 125 farmers households, 72 farm households are belongs to small farmers and the remaining 53 farmers are selected to large farmers. In addition to primary data, the secondary data collected from various journals, newspapers and internet. Further, the data collection period is covered from the agricultural year in 2017-18. In order to analyse the compare cost and return structure of rice production, average and percentage analysis have been employed.

Source: Survey data.

Table 1 portrait per acre cost and return structure of rice cultivation in selected region. It is spelt out that, the whole farmers were spent overall amount at Rs 11,973.91. It records that the farmers spent more amount for human labour and chemical fertilizer cost at Rs 4516.21 and Rs 1641.13 respectively. Followed by the farmers spent on bullock labour cost at Rs 1321.15, rent at Rs 1008.15, farm manure at Rs 766.10, pesticide cost at Rs 610.66, interest on working capital at Rs 609.13, seed cost at Rs 531.12 and the cost of irrigation at Rs 361.11. As a result found that the farmers took yield per acre at 2316.41 Kg. Moreover in the form of gross return at Rs 16361.15 and net return at Rs 4387.24 in per acre cultivation of rice production in overall farmers.

As a comparative between the small scale farmers and the large scale farmers, the small farm household respondents are spent more amount for per acre cultivation of rice production at Rs 12200.41 and the large farmers spent only at Rs 12053.28. The result found that the small farmers took huge turnover of per acre rice cultivation at 2466.36 Kg as compared to large farmers at 2241.41 Kg.

Source: Survey data.

Table-2 reveals that the percentage cost of variable inputs (Cost A) to total cost (Cost C) at 89.57 per cent for small farmers, 89.15 per cent for large farmers and 89.49 for overall farmers. In Cost A, human labour cost was found to be high for small, large and overall farmers at 38.16 per cent, 38.61 per cent and 38.46 per cent respectively followed by cost of chemical fertilizers. The small farmers spent 12.69 per cent of their total cost on the utilization of chemical fertilizer while large farms and overall farms spent 12.15 per cent and 12.36 per cent respectively. Next to this the major cost component was cost of bullock labour which constituted 10.15 per cent, 9.96 per cent and 11.54 per cent of the total cost for small, large and overall farmers respectively. Cost of pesticides worked out to 6.21 per cent for the small farmer, while it was 5.86 per cent and 6.21 per cent for large farmers and all farmers respectively. Farm manure constituted 6.99 per cent, 6.29 per cent and 6.61 per cent for small, large and overall farmers respectively. The rent for land was higher for large farmers than in the case of small farmer. It accounted for 6.25 per cent and 6.61 per cent for small farmers and large farmers. Interest as farm assets, depreciation of implements and machinery involved 4.18 per cent of the total cost for small farmer and 4.24 per cent of the total cost for large farmers.

Source: Sample Survey
Table-3 reveals that HYV of rice cultivation is biased in favor of human labour, pesticides and land and it against for bullock labour, fertilizer and capital. This shows the need for intensive use of human labour, pesticides and land rather than fertilizer and other variable inputs in the HYV of rice cultivation. Thus, the cultivation of HYV of rice leads to a considerable using a labour in the study area. The HYV of rice cultivation reduces the problem of unemployment in the agricultural sector, particularly in the study area.

**Suggestions**

1. The farmers in the study area were of the opinion that they could not achieve the maximum yield due to severity of diseases and pest attacks. It is suggested that the farmers should be educated property to apply the pesticides at the prescribed level and this may be done through the agricultural department officer attached to the panchayat unions.

2. Non-availability of credit was the other constraint. It is suggested that financial institutions should revitalize and revamp the existing credit facilities in the study area so that the farmers could get timely credit for undertaking improved cultivation practices.

3. Such measures shall certainly pave the way for the farmer’s greater success.

4. The marketing cost constitutes a major portion of the consumer price. Hence, Government should encourage the farmers to start co-operative societies in the study area in order to develop a direct link between the wholesalers/retailers, processors and exporters to cut down the marketing cost incurred for lengthy channel.

**Conclusion**

Thus, it is concluded from the analysis that small farmers are economically more efficient than large farmers irrespective of varieties of rice cultivation in the study area. This could be due to the better supervision and more efficient farm management favored by the smaller size of operational holdings. This indicated that apart from efficient allocation of inputs, direct supervision and farm management are crucial determinants of economic efficiency.

A System Dynamics Approach to Understand Respiratory Health Risk in Rural Population

Snehlata Tigala¹, Anu Rani Sharma², Kamna Sachdeva³
¹PhD Scholar, ²Assistant Professor, Department of Natural Resources, ³Associate Professor, Department of Energy and Environment, TERI School of Advanced Studies, New Delhi, India

Abstract

Indoor air pollution poses innumerable challenges and risks to the health of the exposed population. A cross-sectional study was conducted to assess the respiratory health of the rural population belonging to different socioeconomic strata. To estimate the extent of respiratory diseases prevalent in the rural population, factors that link exposure to health were identified and significance of each of these confounding factors on the health of the exposed were determined. A system dynamics approach was used to evaluate environment-user-health system based on the interrelationships that exist between different system variables. Higher odds of occurrence of chest illness were found in biomass users along with low-literacy and low-income groups, which limited their capacity to purchase clean fuel. Also, tobacco smokers were also at a higher risk of developing respiratory disease. The estimates generated from the study can be used to suggest and weight indicators responsible for health vulnerability.

Keywords: Biomass Combustion, Respiratory Health, Health Risk, System Dynamics

Introduction

According to WHO, every year globally, approximately 3.5 million deaths result from exposure to biomass burning smoke.¹⁻² Exposure to indoor air pollution due to combustion of traditional biomass fuels is a significant cause of various cardiorespiratory diseases among rural population in developing countries.³⁻⁴ Women are exposed to colossal risk due to use of unclean biomass fuel for the purpose of cooking and heating which, in turn, increases their vulnerability to various respiratory disorders.⁵⁻⁶

Documental evidence of an increase in illnesses and mortality due to elevated levels of ambient and indoor particulate air pollution is available.⁷ Suspended particulate matter varies in size depending on the source and deposits in the respiratory airways differently.⁸⁻⁹ Several factors determine the extent of impact of particulate matter on the human health; among such factors, socioeconomic, epidemiological and environmental are imperative to understand health risks and impacts. The synergistic effect of exposure is surrounded by uncertainties and therefore require precise mechanisms to associate health risks with exposure.

The present study, bridges the gap between exposure (through multiple sources) and health outcome in a heterogeneous population. A system dynamics approach has been used to understand linkages among the health risk determinants. After contemplation, a framework was designed to create an inventory of exposure sources and risk factors associated with the respiratory health of the subject population.

Method

A framework has been designed and established with scientific tools and understanding to assess the influence of differential exposure to air pollution and socioeconomic factors on the health of the rural population of Palanpur village using perception-based
surveys (Figure 1).

**Study Area**

The study has been conducted in Palanpur village, Karauli, Rajasthan (26°33’ N, 77°05’ E) which is in the northern part of western peninsular India. It is a medium sized village with a population of 1947 individuals, of which 876 are females while 1071 are males. The literacy varies greatly among men and women. The work force comprises of 963 individuals. People engaged in main work or employed for more than six months are 85.64%, while 14.54% are marginally employed, earning livelihood for less than six months. Most daily laborers are involved in mining due to proximity to the mining site (2.1 Km from the village).

**Sampling Design**

A primary survey was carried out at two different levels, viz, village and individual; during the pre-monsoon season (Figure 1). The village level survey was a focus group discussion with the representatives of the village including the Sarpanch (village head). This was done to get a glimpse of the conditions prevalent in the village and about any ongoing development. The individual level survey comprised of a structured questionnaire to analyze socio-economic setup and air quality perception. During the air quality assessment survey, questions related to air quality were asked to evaluate people’s perception about the pollution source(s), its contribution and seasonal variation. The socio-economic questionnaire assessed the population characteristics like sex ratio, literacy, occupation, income, cooking and housing characteristics. Simultaneously, personal interviews were carried out to assess the health of the subjects. For health assessment, the British Medical Research Council questionnaire for respiratory symptoms (1986, UK) was used. Further, the identification of diseases is based on the combination of these assorted symptoms. Stratified random sampling was performed on the basis of distinctive fuel type usage (LPG/Biomass) and occupation (Miners/Non-miners) in the sampled population. A total of 291 personal interviews were carried out. In case of an absentee individual, household representative was interviewed as proxy. No medical tests were performed on the sampled population during the course of this study. The study used various statistical tools and techniques to contemplate the relationship between health and socioeconomic variables, thus, to understand the dynamic complexity of the environment-user-health system (Figure 2).

**Results**

**Perception Based Surveys**

The air quality assessment survey revealed that the perception of ambient air quality in the region was poor due to extensive mining activities in the vicinity (aerial distance of the village from mining site is 2.1 Km). The indoor air quality was reported to be deteriorating due to biomass combustion. At household level, firewood/crop residue/dung cakes, etc were burnt on a day-to-day basis, during meal cooking for the household members. The respondents observed that there were both annual and seasonal variations in the air quality as the requirement for heating during winters escalates the use of biomass. Despite the bad influence of poor air quality on the health of the individuals, 89.7% people did not take any precautions to prevent/reduce exposure on everyday basis. Most individuals were oblivious to the pernicious effects of prolonged exposure.

In a typical household, on an average, a woman spent 1.8 hours in a day cooking in the kitchen, 1.6 hours per trip to collect fuel and 1.2 hours per trip to extract water. Moreover, the average distance travelled to collect fuel was around 1.5 km which further added to the drudgery of the women involved in the collection and transportation of heavy loads of fuelwood. The major fuel requirement was fulfilled by collecting tree branches from nearby farms. Seasonally available crop branches was also used as cook fuel for traditional cookstoves.

About 49.5% of the households did not use LPG for cooking purposes; while the rest of the 50.5% households had LPG connections, but had no means to buy refill cylinders. Additionally, under the below poverty line scheme, a few selected households were given LPG connections at subsidised rate. However, after using the provided cylinders, none of the households bought refill cylinders pertaining to budget constraints. Further, the annual income varied greatly within different occupational groups. Annual expenditure on health was constrained due to lower income pertaining to occupational limitation. Expenditure usually increased in households with disabled individuals or members having diseases that required regular medical assistance. A study by Duflo et al. (2008) on similar context elaborates on the vicious cycle called ‘poverty trap’, where, an
individual in poor health has limited opportunities to carry out work and hence, the household remains both in poverty and poor health.\[15\]

The health assessment survey (BMRC) evaluated the respiratory health of the subjects. Symptoms such as cough and phlegm were found to be more prevalent than breathlessness and wheezing. Level of breathlessness varied during different activities like hurrying on ground level or walking up slight hill, walking with similar aged individuals, etc. In some of the reported cases, chest condition was egregious; inhibiting the capacity of the individuals to carry out day-to-day activities. Subsequently, this debilitated state ranged from a week and extended up to three years in some severe cases. Among these, 65.3% had no history of chest illness. Also, tobacco smoking was one of the contributing factors for the presence of chest illness. Almost, one-third of the population smoked tobacco regularly. Cases of Pulmonary Tuberculosis (5.8%) and Bronchial Asthma (3.8%) were also reported.

Relationship between Respiratory Health and Risk Determinants

Our study is based on documented work, where, interpretation of disease is based upon symptom variables. Factor analysis revealed aggregation of different symptoms (cough, phlegm, wheezing and breathlessness) onto different components (1, 2). This stipulates that both the components had different causes, since they resolved separately (Table 1). Findings are indicative of bronchitis and asthma in the exposed population. However, the other underlying causes might lead to exhibition of symptoms similar to COPD subjects. Simultaneously, associations between the occurrence of chest illness and various socio-economic indicators (gender, education, primary occupation, annual income and health expenditure) have been found based on factor analysis (Table 3). Additionally, the odds of occurrence of chest illness in tobacco smokers was 3.4 times greater than that of non-smokers. Similarly, the odds of presence of chest illness in biomass-users was 1.9 times greater than that of LPG users. Binary logistic regression analysis (at CI=95%) showed a statistically significant relationship between tobacco smoking and chest illness (p<0.001); fuel type and chest illness (p<0.01); gender and chest illness (p<0.05) (Table 2).

The application of system dynamics approach in the field of environmental exposure and human health risk is done to understand the dynamic complexity of the environmental-user-health system. It elucidates the causal relation of various indicators and health risk. Figure 2 illustrates the relationship between air quality, social, economic and epidemiologic components. The factors that aggravate the risk to health include exposure sources and ignorance. Further, the impact on health is exacerbated by poor health care facilities, occurrence of chest illness among the exposed, ‘poverty trap’, and other risk factors.

Discussion

The study highlights the health vulnerability of the rural population in the context of the prevailing air quality and socio-economic factors. The impact of poor air quality varied from as minor as a sore throat or cough to as severe as a major chest illness among the subjects. Findings suggest that social stratification also plays an integral role towards the health vulnerability of the population. Susceptibility varied across gender, education and income group. Consequently, an association between education and occupation proved the increased susceptibility in lower literacy group. Occupation is highly dependent on education, which in turn also directs the annual income and expenditure. The lower literacy group was found to be prone due to lower wages and inability to purchase exorbitant clean fuel. The women were additionally exposed to incremental risk due to prolonged exposure to biomass burning smoke in a poorly ventilated kitchen. Subsequently, upper chest respiratory disorders were found to be more prevalent among biomass fuel users.

Investigations through cause-effect interface revealed that respiratory health of individuals is dependent on socio-economic parameters as well as on the air quality. Individually and in totality, these factors modulate the exposure source and its duration.

Conclusion

An approach has been used through guided selection of indicators; to explore and establish a relationship between environmental parameters and respiratory ailments (and convalescence), taking into consideration the socio-economic factors. Normalization and aggregation of these indicators can help to create health vulnerability indices to generate meaningful policies for proletarians. The key challenges to ameliorate
the health status in a heterogeneous population are plausibly education and income. The given framework can be used as a tool to assess health risks based on the stochastic relationship between various socio-economic determinants, environmental parameters and physiological factors to establish inter-linkages.

Effectiveness of Lifestyle Modification for Grade I Hypertensive Individuals

Akshaya Ashok Lade1, Poovishnu Devi Thangavelu2, Vaishali Krishnat Jagtap3

1Intern, Faculty of Physiotherapy, Krishna University, Karad. Maharashtra, India, 2Cardio Respiratory Department, 3Musculoskeletal Department, Faculty of Physiotherapy, KIMSDU, Karad. Maharashtra, India

Abstract

Objective: To determine the effect of lifestyle modification on grade I hypertensive individuals.

Materials and Method: Ethical clearance was obtained from the Institutional Ethical Committee. 40 patients were selected for the study on the basis of inclusion and exclusion criteria. Demographic and baseline assessment were done on the first day. They are randomly allocated into two groups 20 in each group. Group A received conventional physiotherapy and Group B received lifestyle modification and conventional physiotherapy. Post test values were assessed after 3 months. The outcome measures are systolic (SBP), diastolic blood pressure (DBP) and heart rate (HR).

Result: Inter group statistical analysis for systolic blood pressure revealed significant in post intervention for group B (p=0.0372). Diastolic blood pressure was extremely significant for group B (P value<0.0001). Heart rate was very significant for group B (p=0.0008). While Post intervention analysis showed extremely significant difference between Group A and Group B (p<0.0001). Group B treated with lifestyle modification and conventional physiotherapy was extremely significant.

Conclusion: Exercises are effective in lowering the levels of systolic, diastolic blood pressure and heart rate. But exercises along with lifestyle modification is significantly more effective for grade I hypertensive individuals.

Keywords: Lifestyle modification, conventional physiotherapy, grade I hypertension.

Introduction

Hypertension is an elevated blood pressure1. High blood pressure is a risk factor for stroke, congestive heart failure, myocardial infarction, peripheral vascular disease and end stage renal disease2. Grade I hypertension that is systolic/diastolic (140/90mmHg) is measure modifiable risk factor for cardiovascular disease4.

Prevalence of hypertension is in one-quarter of the world population5. In India one-fifth of people have blood pressure >160/95mmHg and almost one-half have blood pressure >140/90mmHg4. In Maharashtra prevalence rate is 7.24%4. Hypertension was observed more in females as compared to male. Because menopause women are more prone to hypertension4. Hypertension awareness is problematic issue, only two-thirds of adults are aware of their hypertension status4.

Risk factors have been implicated in the development of hypertension such as diabetes mellitus, stress, family history, sedentary lifestyle, smoking, high intake of saturated fats and alcohol.

The renin is an enzyme secreted by the juxtaglomerular cell of the kidney and linked with Aldosterone in a negative feedback loop. The end product of the action of renin is peptide angiotensin II and adrenal cortex has an increased sensitivity to angiotensin II. The intake of normal or high sodium content, Aldosterone production will not suppressed, but it will lead to a mild degree of hyperaldosteronism with increased sodium retention, volume expansion and increased in blood pressure4.

Till now physiotherapy management for hypertension is not followed to a great extent. Only
daily walking is prescribed which is not followed by patients, stress is taken as a part of life, reduction of salt and regular intake of medications were not educated properly because of lack of guidelines and motivation among patients. so a structured protocol or adjunct therapy is needed for reduced of hypertension.

Lifestyle modification is recommended by Joint National Committee (JNC) VI TO implement first line treatment for up to 6 months the individuals with grade I hypertension. Lifestyle modification regarded as adjunctive therapy for those individuals taking antihypertensive medication. Lifestyle modification includes physician, nurse, behavior therapist, dietician, and physiotherapist.

Physician assesses the patient. Necessary investigation were done Physician analyses the Investigation reports, prescription of medicine was done and refer the patient to lifestyle modification clinic.

Nurse will educate about the normal values of BP, importance of regular intake of Hypertension to patient. And importance of regular intake of medicine is must in hypertensive individuals.

Behavior therapist will modify the personal habits like smoking, alcoholism, tobacco consumption and other types of addictions gradually and stop it, stress management, family counseling etc.

Dietary approach to stop hypertension (DASH) diet which involves the consumption of fruits, vegetables, low fat dairy products; which includes whole grains, poultry, fish, and nuts and it will increase the levels of potassium, magnesium, calcium, fibre and protein.

Regular physical activity has cardio protective effect. Regular exercise associated with increase in high-density lipoprotein and reduction insulin resistance. Regular exercise which include aerobic exercises and strengthening exercise. In Aerobic exercise includes brisk walk, walking, jogging. And in Strengthening program includes chest press, shoulder press, triceps extension, biceps curls, lower back extension, abdominal crunch/curl up, quadriceps extension or leg press, leg curls (hamstrings).

Lifestyle medication create an recommended lifestyle changes related to range of health benefits, and better outcomes of common chronic disease.

Method

It was experimental study conducted in physiotherapy department of Krishna institute of medical sciences. 40 patients were selected for the study by simple random sampling. Demographic and baseline assessments were done on the first day. The patients were selected according to inclusion and exclusion criteria. Inclusion criteria were as follows: 1. Age limit 40-55 yrs, 2. Blood pressure: 140-159/90-99 mmHg (grade I), 3. Normal kidney functions and hormonal functions, 4. Patients pliable with dieting, 5. Currently taking anti-hypertensive medication, 6. Patient who are compatible to perform exercises on regular basis, 7. Ability to provide informed consent. Exclusion criteria were as follows: 1. Family history of hypertension, 2. Symptomatic cardiovascular problems, 3. Severe headache, blurred vision, chest pain, difficulty in breathing, 4. Practicing any type of weight loss program, 5. Inability to provide informed consent. randomization was done in which Group A received only conventional physiotherapy will include only walking and Group B: Group B received lifestyle modification along with conventional physiotherapy will include physician (will prescribe antihypertensive medication), behavior management (progressive relaxation technique and cognitive behavioral therapy), diet (DASH Diet) plan, exercise regime (aerobic and strengthening exercises) and health education.

Discussion

Hypertension is growing health problem in India with every third to fifth Indian as hypertensive. Prevalence of hypertension continues to increasing so, hypertension is becomes an important public health issue. Approximately 10% deaths occur in India because of high blood pressure.

In study has shown clinically significant changes in systolic blood pressure, diastolic blood pressure and heart rate. These findings suggest that lifestyle modification is effective in reducing in high blood pressure.

Lifestyle modifications includes regular physical exercise, salt restriction, moderation of alcohol consumption, high consumption of vegetables and fruits and low fat (DASH diet), cessation of smoking, stress management. Regular physical exercise is associated with an increase in high-density lipoprotein cholesterol and with reduction in insulin resistance, systemic vascular resistance, plasma noradrenalin, plasma renin activity and body weight. Individual with hypertension need to do exercise regularly it reduces the blood pressure by 4.9mmHg. Single episode of exercise is able to reduce levels of blood pressure.

High dietary salt intake associated with an increased incidence of stroke and cardiovascular diseases. Reducing salt intake approximately (75mmol) per day can lower 4 to 5mmHg systolic blood pressure and 2mmHg of diastolic blood pressure.

Reducing alcohol consumption can reduce systolic blood pressure 3.8mmHg patient with hypertension. Hypertensive individuals can limit their alcohol intake to a maximum two drinks per day for men, one drink per day for women.

Smoking is individual risk factor cardiovascular diseases. It causes immediate increase in blood pressure and heart rate that persist for more than 15 minutes after one cigarette. Smoking cessation is also reducing the complications and high blood pressure. But smoking cessation finds it very difficult by hypertensive individuals. They feel restless because of smoking cessation. In such cases behavioral management plays important role. Some individuals are obese they having difficulty in doing exercises on regular basis. DASH diet is also helpful in reduction of blood pressure. High dose of omega-3 polyunsaturated fatty acid supplement (fish oil) also lower blood pressure.

Group B was more significant as compared to group A, group A was not given diet, behavioral management for alteration in addiction and stress management. Group A individuals had no restrictions salt intake and additions. While group B was given lifestyle modification which included behavioral management, diet, and exercises.

Group A was less effective because it includes only conventional exercises no restriction on diet and behavioral management was not part of their protocol which conventional lack as compared to lifestyle modification.

The limitations of the study: 1. The study can be done in other areas of the country. 2. The study is done in Asian race. 3. The study is limited to a small sample size which makes it difficult to extrapolate the result. 4. This study is limited to age group 40-55 year. 5. This study was limited to shorter duration follow up period.

Suggestion and recommendation of the study: 1. This study should be conducted with large number of people. 2. This study can be done on longer duration with longer follow up period for the assessment of long term benefits.

Conclusion

Exercises are effective in lowering the levels of systolic, diastolic blood pressure and heart rate. But exercises along with life style modification as adjunctive therapy is significantly more effective for grade I hypertensive individuals.

Abstract

In the 1980’s and the 1990’s the importance of leather industry stemmed from the fact that it was the sixth or seventh largest foreign exchange earner of the country. The focus of the government clearly is on generating inclusive growth and the nature of employment provided by the leather sector indeed meets this objective. Major problem faced by the industry is with regard to availability of developed industrial plots at affordable prices. There has been talk about developing exclusive leather industrial parks but unfortunately during the last plan period, not much progress could be made. The XI plan have also provided for the establishment of many leather parks. The leather industry growth has been sustained by the country’s large livestock population, which claims a unique position in the world, “estimated at 425 million cattle, buffaloes, sheep and goat.” (57 per cent made up of buffaloes, 16 per cent of cattle, 20 per cent of goat and 4 per cent of sheep population in the world). Liberal imports of raw materials, leather machines, chemicals and auxiliaries have been the major highlights of the new policy. The leather industry has faced many problems i.e., input of raw materials and environment management practices, water consumption and waste water consumption. But leather industry has shown negative growth rate through the manufacturing sector has recorded the highest positive growth rate after liberalization. This position has urged to the study and analyzes the Indian leather industry.

Keywords: Leather Industry, Growth Performance, Facing Problem

Introduction

The leather industry is one of the oldest traditional industries of our country. The industry has three distinct facts: Flaying of animals, renewal of hides and skins and their preservation and Utilization of other carcass components. Conversion of hides and skins into leather or tanning and Manufacture of foot wear and other leather goods.

In the 1980’s and the 1990’s the importance of leather industry stemmed from the fact that it was the sixth or seventh largest foreign exchange earner of the country. However, this situation has now changed drastically with many service and other industries overtaking the leather sector. The focus of the government clearly is on generating inclusive growth and the nature of employment provided by the leather sector indeed meets this objective. The plan targets the industry’s turnover to grow from the current $ 6 billion to $ 13.2 billion by 2011-12, with exports climbing up from about $ 3 billion to $ 7 billion annually in this period. Till one year back, the rising global trade in leather and leather products coupled with the big spurt in domestic demand, thanks to the burgeoning middle class, were the reasons for this optimism. But with the global meltdown and the consequent slowing down of economic activity in developed countries, the industry has to grapple with the immediate problems of a likely recession in 2009 and possibly some part of 2010.

Leather Parks

Major problem faced by the industry is with regard to availability of developed industrial plots at affordable prices. There has been talk about developing exclusive leather industrial parks but unfortunately during the last plan period, not much progress could be made. The XI plan have also provided for the establishment of many leather parks. Tamil Nadu is planning two footwear parks, one at Irungattukottai and another at Rani pet. All these industrial estates have to be taken up
on a war footing. Two large footwear factories, one at Tada in Andra Pradesh and another at Cheyyar in Tamil Nadu are already in operation. Their success may spur many others to make a beeline for India. Some gentle nudging from Indian industry bodies and commercial attaches may accelerate this process. In some parts of Tamil Nadu, the demand for skilled labour from other emerging industries has shot up resulting in a big jump in wage levels. There is need for vocational training on a large scale so that there will be continuous supply of labour at competitive wage levels.

Growth of Leather Industry in India

The leather industry growth has been sustained by the country’s large livestock population, which claims a unique position in the world, “estimated at 425 million cattle, buffaloes, sheep and goat.” (57 per cent made up of buffaloes, 16 per cent of cattle, 20 per cent of goat and 4 per cent of sheep population in the world). However, in view of the fact that livestock is increasing only at 1.2 per cent rate per annum, the available of in ingenious hides and skins has been almost stagnant. According to CLRT (Chennai), over Rs.3.3 crores worth of ovine skins are lost annually to non-flaying of carcasses. Thus in future the available of raw material is going to be one of the major constraints for the growth of leather sector. “Among the important centers of leather and leather products in India, Kanpur specializes in tanning and finishing of buffaloes and production of harness (safflery) and shoe leathers. In Calcutta, tanning and finishing of cow hides and processing of goatskins is a prime activity. Madras and several districts in Tamil Nadu specialize in finished leathers of various kinds”.2

Recent Trends in Leather Industry in India

The following are the recent changes taken place in leather industry in India:

Production in tiny and cottage sector is rapidly declining due to shift from traditional methods of production to factory – based production.

90 per cent of skins and 50 per cent of hides are obtained from slaughter leading to improvement in the quality on finished leather.

The state of the art technology in the leather product sector is commendable due to liberalization in import policy.

Female worker content in footwear and leather products sector has been increasing.

There has been an improved image for the Indian leather products in the international market.

A market increase for technical manpower and skilled labour to cope with export needs is perceived.

Dependence on imported hides and skins is growing significantly.

There has been increasing awareness of the treatments of effluents.

Development of Leather Product Sector in India

During the significant policy shift in 1991 towards globalization of Indian economy, except the duty drawback, the other export incentives for leather products were withdrawn. However restriction on the exports of finished leathers with 5 per cent duty along with ISI norms was introduced. Liberal imports of raw materials, leather machines, chemicals and auxiliaries have been the major highlights of the new policy. The essence of the current liberal policy signifies restriction of a new item of exports and import. With large raw material reserves, access to low cost labour and management, as well as the encouraging support from the government, the factory sector of the product industry made rapid growth in the production and export of leather products. The governments industrial and trade policies, institutional support, coupled with aggressive entrepreneurship and growing demand for exports have been the other factors contributing to its growth. Apart from tanners setting up product units, leading companies like Wipro, Ponds India, MRF, Hindustan Lever etc., also set up product units with 100 per cent export orientation. Some of them entered into technical and marketing tie-ups with reputed overseas companies setting up of such modern product units opened new avenues to technology, machine operations, skilled and unskilled workers.

Statement of the Problem

In 1991, the major reform process started the initiation of the industrial growth and it was regulated by the states through the industrial licensing system for the establishment of new industries and capacity expansion of old industries. The public sector played a major role in capital formation and the government owned and operated many industries. Domestic industries were
protected through quotas and higher tariffs for more products. The foreign exchange rate was fixed by the administrative decision. The central government has unlimited access to borrowing from the Reserve Bank of India. The above-mentioned system was dismantled and more market friendly economic system was introduced in July 1991.  

The 1991’s liberalization policy provided free access to capital technology and market in order to induce greater industrial efficiency and international competitiveness. The policy seeds to free the Indian industries from excessive government regulations and control so as to allow freedom and flexibility in business decisions and for responding for market forces. The policy initiatives have focused on the basic orientation of industries to benchmark it against the global standards.  

**Objectives of the Study**

1. To analyze the growth of leather industry in India.
2. To analyze the productivity performance of leather industry in India during the study period
3. To discuss the general problems of leather industry in India.

Source: http://www.leatherindia.org
**Result Discussion**

In 1991 major reforms process started in India. The 1991 liberalization policy provided free access of capital technology and market in order to induce greater industrial efficiency and international competitiveness. But leather industry has shown negative growth rate through the manufacturing sector has recorded the highest positive growth rate after liberalization. This position has urged the researcher to study and analyze the Indian leather industry.

**Exports**

India has now become an exporter of finished leathers, footwear’s and a variety of leather goods. India’s share in the world trade of leather is however, hardness about 16 percentage. This share of leather, manufacture in the country’s total exports has generally between 4 percentage and 6 percentage. The leather industry, one of India’s oldest industries has been growing fairly rapidly in recent years. The growth of the industry has been mainly qualitative in that processing of the basic raw materials is being taken to higher and higher stage with in the country itself. The qualitative charges are reflected in the produce pattern at the industry, which has changed from being predominantly weighted in favour of raw hides and skins in the early fifties in finished leather and leather goods oriented pattern at present. The large extent these represent the response of the industry to deliberate government policies rather a process of spontaneous growth. While the industry has been primarily export oriented in the future scope for the growth of market within the country will be freight in view at the likely improvements in the standard of living resulting from economic development.

**Problems of Leather Industry in India**

New tanneries in different parts of the country are mushrooming. This would result in lesser flow of hides and skins to India.

The movement from production of leather products is rather slow.

Trained technical personnel in the industry are not easily available.

The industry is affected by frequent power shortage and power cuts.

Persistent pressure to setup common effluent treatment plants by the government.

**Problems faced by the leather industry in India**

The leather industry has faced many problems i.e., input of raw materials and environment management practices, water consumption and waste water consumption. The government of India took several initiatives, including the banning of exports of raw hides and semi-processed hides and skins and liberalized the import of raw materials for the manufactures is reserved mostly for the small scale sector foreign collaboration is liberally allowed for modernization and value added export production.

**Suggestions**

**To the leather industry**

The industry should enhance its technology thereby increase the efficiency of capital than labour.

The capital should be used efficiently to increase the gross value added through efficient management.

The industry should increase the factor size through increase the capital than number of factories.

**To the government**

The factors that influence the productivity of leather industry vary for India.

Government has to help increase the capital requirements of leather industry in India.

Government has to evolve the supportive policies of the leather industry in terms of production and marketing.

**Conclusion**

Leather industry of India is a capital-intensive industry. Technology advancement happened in leather industry of India, but it was not efficiently utilized. The growth of total factor productivity was mainly because of growth in labour productivity. High level of capital in leather industry was not efficiently utilized particularly after the liberalization even it is in good position during the study period. Efficient utilization of labour and capital were attributed in leather industry after liberalization. The reason for the decreasing trend of productivity was due to steep fall in gross value added in the leather industry particularly after 1995-96. To develop the Indian
leather industry, there is need to be efficiently utilized to increase the gross value added. There is also the need to strengthen. Research and Development to increase the gross value added of Leather industry in India.

Effectiveness of Cabbage Leaves Application on Breast Engorgement: *Narrative Review*

Akanksha Yadav¹, Kavitha Mole PJ², Nageshwar V³
¹M.Sc.Nsg. 2nd Year Student, Department of Obstetric and Gynaecology, ²Professor, M.Sc. Nursing, M.Sc. Psychology PGDCP, Department of Obstetrics and Gynaecological Nursing, ³Assistant Professor, Ph.D., Department of Psychiatric Health Nursing, Teerthaker Mahaveer College of Nursing, TMU, Moradabad, U.P.

Abstract

Introduction: Engorged breast is a condition that influence lactating mothers early in the postpartum period. The discomfort and tenderness because of the engorgement is a major contributing component to the early cessation of breastfeeding. Alternative therapies like chilled cabbage leaves and other natural therapy can be encouraged to the mothers in low cost which can be used easily even at home without direction. All the studies was conducted on postnatal mothers including primi and multiparous in postnatal ward of maternity hospital. Objective: The objectives of the study were to evaluate the effectiveness of chilled cabbage leaves application for relief of breast engorgement among postnatal mothers. Method: A comprehensive systematic search of published literature and journal articles from PubMed, EBSCO to assess the effectiveness of cabbage leaf application on engorged breast among postnatal mothers that are focusing till 2017. Search strategy specific to each database was used. Result: During initial search 7899 titles were retrieved and after screening 8 articles were selected for full text screening. Finally 8 research articles were selected based on the inclusion criteria. Conclusion: The study was concluding that cabbage leaves fomentation is effective in the treatment of pain during breast engorgement.

Keywords: Chilled Cabbage Leaf application, breast engorgement, Pain and severity, Postnatal mothers

Introduction

Engorged breast develop in the mammary glands because of extension and pressure exerted by the synthesis and storage of breast milk. Engorgement usually develop when the breasts switch from colostrum to mature milk.

However, engorgement can also occur later if breastfeeding women miss several nursing and insufficient milk is expressed from the breasts. It can be developed by inadequate breastfeeding or blocked milk ducts. When engorged breasts may swell, throb, and cause pain. Volume of the breast milk is increase because of lymphatic and vascular congestion with interstitial edema during initial two weeks following the birth.

Numerous non-pharmacological therapy are there to reduce breast engorgement, utilization of cabbage is one of them. This is natural ways of reducing breast engorgement. It reduces maternal morbidity and help to enhance lactation. Based on the scientific evidences, application of cabbage is effective for relieving breast engorgement without side effects and use of cabbage leaves increase the breast feeding duration also. It is suggested the use of cabbage leaves for engorgement.

Cabbage contains sulphur which act as an anti irritant and antibiotic agent which in turn draws an extra flows of blood to the area. This dilates the capillaries and acts as a counter irritant, thus relieving the engorgement and inflammation and allowing milk to flow freely.

Aim

The aim of this review to evaluate the effect of cabbage leaf fomentation on breast engorgement.

Objective

To evaluate the effectiveness of chilled cabbage leaves application on pain and discomfort during breast engorgement.
engorgement among postnatal mothers.

Methodology

Search strategy methods-

An electronic search of articles published in various journals has been done. Search was restricted to only English language.

Types of intervention:

Cabbage leaf application, warm compression, chilled gel packs application, cold compression, hot water application.

Types of studies:

True experimental, Quasi experimental.

Type of participants

Postnatal mothers including Primiparous, Multiparity women.

Settings

Postnatal ward of maternity hospital

Outcomes:

This narrative review outcome shown that cabbage leaf application will be effective on breast engorgement

Result

The systematic search was conducted by framing the terms independently and in combination with all and synonyms, also according to the database. Likewise, a manual PubMed search was undertaken using the keywords and search synonyms from already found articles. An addition of 8 articles were found. Initial search retrieved 7899 articles over which 2582 articles were selected manually. 2375 articles were excluded as a result of duplications in two databases. Duplicates were removed and reviewed 207 articles for eligibility. 187 more studies were excluded because of inaccessibility of full text. Hence 8 articles were screened which includes quantitative study.

Discussion

According to Joy J, Kharde SN, 2016, it reveals that the mean pre test score (14.86) of postnatal mother is more than the mean post test score (1.33) and there was a significant difference between pre and post treatment scores (p<0.001) [1]

According to Tawheda Mohamed Khalefa E-ISaidy, Reda Mohamed-Nabil Aboushay, 2016, the study showed that there was a statistically significant difference between pre and post test score of pain and engorgement score for both groups (p<0.001) [2]

According to A-Reum Lim, Ji-Ah Song, Myung-Haeng Hur, et al, 2015, the study suggested that there are significant differences of breast hardness among three groups cabbage compression early breast care group showed significantly lower breast hardness compared with the early breast care and general nursing breast care [3]

According to Amanpreet Kaur, Nidhi Sagar, Mamta, Jasbir Kaur, et al, 2015, the finding of the study concluded that alternative cold and hot compresses had significant change in breast tenderness score had decrease of 5.73 to 1.00 in experimental group, where was cold cabbage leaves application had decrease of 6.30 to 2.70 in experimental group so the alternative hot and cold application are more effective [4]

According to Disha, Avinash Rana, Amarjeet Singh et al, 2015, the study reveals that The effectiveness of cabbage therapy was higher as a mean engorgement score after the application of chilled cabbage leaves was comparatively low that is 1.06±0.24 as compared to the hot compression that is 1.16±0.36. So the difference was not significant (p>0.05). This revealed that both interventions were equally effective. [5]

According to Mrs. Chaithanya Prashanth, 2014, finding showed that there is a significant difference in level of breast engorgement before and after the application of cabbage leaves (p<0.001). [6]

According to Kathryn L. Roberts, 2014, it reveals that significant reduction for the cabbage leaves (t=4.7; p=0.001) and for the gelpacks (t=5.6; p=0.001). The study reveals that significance was not found between post test mean score of cabbage leave and gelpacks (t=0.73; p=0.46). [7]

According to R. Nanthini, G. Bhuvaneshwari, 2013, the study suggested that out of 30 postnatal mothers have curable breast engorgement by giving both cabbage leaf application and hot water application. The overall t value was significant at the level of p<0.001.
This shows that there was significant improvement in both cold cabbage leaf application and hot water application.[8]

Ethical Consideration: This manuscript is ethically considered by the panel of Teerthanker Mahaveer College of Nursing, Teerthanker Mahaveer University after discussing with each and every point of this manuscript.

Summary of Findings

The available literature refines to get 8 quantitative. In this review 4 studies are showing that cabbage leaf is effective on breast engorgement among postnatal mothers and 2 studies shown that cabbage leaves and hot application having positive result on breast engorgement, but 1 study shown that hot application is more affective than the cabbage leaf and 1 study shown that alternative cold and hot compression is more effective as compare to cabbage leaves to reduce breast engorgement.

Future Significance

The study findings has focused new image on implication of the future. It has the suggestion in the regions of nursing administrations, nursing training, nursing organization and nursing research.

Many non pharmacological interventions are used to relieve breast engorgement. This therapy is one of them which help to improve lactation and reduce maternal morbidity.

Nursing students will be illuminated with satisfactory learning on evaluation of breast engorgement and non pharmacological strategy for relieving breast engorgement. Nursing students and public health nurses will be prepared in regard to cabbage leave application procedure on breast engorgement. The medical care taker should place emphasis on disseminating information related to evaluation of breast engorgement and their administration in the postnatal wards of the hospital. Nurses and midwives will be prepared with respect to different non-pharmacological techniques to relieve breast engorgement. This study will initiate the midwives to practice the cabbage leaves application to relieve breast engorgement by conducting in service education programme.

Application of cabbage helps to reduce swelling in moderate to severe engorgement and give the evidence for introducing the intervention in clinical practice. So such intervention is considered as a home remedy for women who is suffering from breast engorgement, as it can be applied without any complication.

Hence making awareness among the postnatal mothers is a way of promoting the utilization of such intervention in hospital and thereby it can reduce certain postnatal complication and improve the health of the mothers and baby.

Limitations

Computerized data bases were limited

Was limited to only in postnatal mothers.

Conclusion

There was a significant reduction in pain and severity of breast engorgement among postnatal mothers after application of chilled cabbage leaves. Thus it has proven to be an effective treatment for pain and severity of breast engorgement. Therefore, this intervention should be promoted as an institutional policy and implemented as a routine care for all postnatal mothers having breast engorgement for reducing pain and severity.

Reliability Estimation and Pilot Testing of Diet Quality Assessment Tool for Indian Children

Ritushri Chamoli¹, Vandana¹, Monika Jain²

¹Research Scholar, ²Professor, Department of Food Science and Nutrition, Banasthali Vidyapith, Rajasthan, India

Abstract

Malnutrition in childhood is one of the reasons for the high child mortality rate which can be due to many reasons including inadequate intake of nutrients required for proper growth and poor diet quality. As no index for assessing diet quality of Indian children was found after reviewing of literature, the study aimed to standardize Diet Quality Assessment Tool for Indian children (DQAT). The study sample included 30 school going children selected randomly from school of Banasthali Vidyapith, Rajasthan. Dietary assessment was done by 24 hour recall method and reliability was evaluated using Crohnbach’s alpha, split half and test retest reliability. The intake of nutrients was in accordance with the recommended dietary allowances (RDA) except for energy and iron in both boys and girls. Reliability was 0.65, 0.85 and 0.59 by split half method, test retest and Crohnbach’s alpha method respectively suggesting low reliability, recommending the need for revision of DQAT items.

Keywords: reliability, diet quality, nutritional status, malnutrition, diet quality index, recommended dietary allowances.

Introduction

The school-age period is nutritionally important because it is the main time to build up body stores of nutrients in preparation for rapid growth during adolescence¹. Good nutrition is necessary to reduce illnesses and enhance cognitive development in school children; hence it is obligatory that these children meet their energy and nutrient requirements²,³. Diet with poor quality and less quantity is one of the reasons behind prevalence of malnutrition in children⁴. The challenge is no longer on consuming sufficient calories to avoid malnutrition, but how to eat adequately for optimal health and disease prevention. This transition has affected the significance of the diet quality concept.

It is believed globally that cardiovascular diseases and certain types of cancer can be prevented by diets that are often rich in fruit and vegetables⁵. Such diets have a positive impact in children on long-term health outcomes from cardiovascular diseases and asthma⁶. Since research has reported that the diet quality in children differs, methods of evaluating diet quality are necessary to monitor health status of children⁷.

Dietary surveys and diet quality indices are, therefore, essential components of nutritional assessment⁸. Dietary Quality Indices or Indicators (DQIs) are devised with an aim to assess the overall diet and help in deciding whether the individual is having healthy diet or not. DQIs are essential tools to assess the standard of the diet for specific populations not solely in terms of nutrient intake however conjointly in terms of food diversity and moderation. “The four ‘original’ diet quality scores are the Healthy Eating Index (HEI), the Diet Quality Index (DQI), the Healthy Diet Indicator (HDI) and the Mediterranean Diet Score (MDS) which have been referred to and validated most extensively⁹.” There is no such tool in India for assessing diet quality of Indian children. Hence, the present study was a pilot attempt.
to develop an index for assessing diet quality of Indian children which reflects the recommendations for Indian children according to national dietary guidelines\textsuperscript{10}.

**Materials and Method**

Study sample comprised of 30 school going children (n = 17 boys; n = 13 girls) who were randomly selected. All data collection was done in months of March and April 2016 only after seeking permission from the parents of the school going children and the concerned school authority.

**Development of the Diet Quality Assessment Tool (DQAT) for Indian children**

Diet quality of 7 to 9 years of age was assessed using HEI\textsuperscript{11}, EKINDEX\textsuperscript{12}, DQI\textsuperscript{13}, MDS\textsuperscript{14} and a self-developed tool. After assessment, all the subjects were classified in the unhealthy category. Not finding any of the tool of diet quality correlating well with nutritional status of children, an effort was made to develop a tool according to dietary guidelines for Indian children.

The index was developed using nineteen components that reflect the dietary guidelines\textsuperscript{10} for Indians. The components included cereals, pulses, meat products, milk and milk products, green leafy vegetables, fruits, sugar, roots and tubers, other vegetables, overall variety, empty calorie foods, frequency of breakfast consumption, frequency of consumption of meal given in lunch box, number of meals in a day, frequency of consumption of least favorite food, consumption of meal from any other place except home during the previous two days, dietary behaviour regarding consumption of advertised foods, consumption of homemade foods, sodium and total energy from fats.

Subjects whose dietary intake was in compliance with the dietary recommendations for Indian children\textsuperscript{10} aged 7-9 years of age were awarded maximum points, while those whose diet was not in compliance were awarded minimum points. The Indian DQAT scoring system focused not only on frequency of consumption of different food groups but also on moderation in intake of foods and nutrients shown to be associated with increased risk of some chronic diseases and dietary behaviour regarding food consumption of school age children. Overall DQAT score was ranging from 0-80.

**Data collection**

To ascertain the dietary quality and dietary quantity of the subjects, Dietary Quality Index for Indian children and 24 hour dietary recall methods were used. The present study was designed according to the guidelines for ethical consideration in human studies as suggested by ICMR\textsuperscript{15} (2017), on the basis of revised Helsinki Declaration (2013). All reasonable steps were taken to maintain subjects confidentiality.

For the 24-hour dietary recalls the investigator collected information on food/beverages consumed in the previous 24 hours, including type, amount, brand name, food preparation method and any additions (e.g. sugar in coffee, ghee to chapatis etc)\textsuperscript{16}. Amount of food consumed by the subjects was converted into nutrients using Indian Nutrition Software – “DietCal – A Tool for Dietary Assessment and Planning” (software version-3.0).

**Reliability and statistical analysis of the DQAT**

Reliability was assessed through test retest reliability, split half method and Cronbach’s alpha. A scale is defined as having good internal consistency if Cronbach’s alpha is 0.5 or greater\textsuperscript{17}. Test retest reliability was conducted at one month interval and correlation coefficient was used for determining it. The data was analyzed by suitable statistical methods using IBM SPSS Statistics - 20.0 and M.S. Excel software. A p<0.05 was considered statistically significant. Reliability and validity statistics was used for DQAT standardization. Range for unhealthy, moderately healthy and healthy was decided with the help of statistically calculated tertiles.

**Results**

The mean age of the study group was 8.07 ± 0.88 years. Mean ages of boys and girls were 8.07 ± 0.88 and 8.13 ± 0.89 years respectively. The DQAT comprises of 19 items divided into three different parts: food intake, dietary behavior and moderation. As DQAT had items related to nutrient intake as well, the food and nutrient intake of subjects was assessed using 24 hour recall.

As assessed by the food behavior part of DQAT, there were 50% school children who were having empty calorie foods 5-10 times per week and 10% were having empty calorie foods more than 10 times per week. Majority of the subjects (86.7%) in the present study
were having breakfast daily. It has been reported in the past that the prevalence of skipping breakfast was 23.5% in children in some areas of Udupi district, India\textsuperscript{18} which is higher than the observation of present study. There were 20% breakfast skippers in another study done on children\textsuperscript{19}. One third subjects were having more than 3 meals per day. Most of the parents (80%) reported that their child finished tiffin daily. Less than half of the subjects reported that they were having their least favorite but healthy food daily. Majority of the subjects reported that they are not attracted to commercially packaged foods by advertisements. One fifth subjects reported that they do not eat everything prepared at home. None of the subjects were consuming all the food groups daily.

In case of food intake, there were only 23% subjects who were consuming pulses as per the requirement (≥2 serving/day). Milk was consumed regularly by more than half of the study group (57%) as per the recommendations (≥5 servings per day) and fruits were also consumed by majority of the subjects (87%) as per the recommendations, i.e., ≥1 serving/day. The percentage of children consuming sugar more than RDI was 75%. There were 23% subjects who were consuming green leafy vegetables as per the recommendations (≥1 serving/day) and cereals were consumed by only half of the sample as per the recommendations (≥6 serving/day). Most of the subjects (67%) were having ≥1 servings of roots and tubers daily which is a recommended intake for Indian children. Only 23% subjects were having other vegetables in their diet as per the RDI. Regarding moderation, there were 17% subjects whose sodium intake was as per the RDA (≤ 2 grams per day) and majority (60%) of the subjects diet were having more energy from fat in their diet than the recommended, i.e., >25% of total energy. It was reported in a study that salt intake in India is high and the mean population intake is also higher than the amount recommended by World Health Organization, i.e., 5 g/day\textsuperscript{20}. Daily mean intake of food groups and nutrients are depicted in table 1 and table 2.

Total scores were calculated for each of the subjects and the mean score obtained for the subjects using DQAT was 62.38 ± 7.45 (median = 63). The scores of school children ranged from 45 to 74. There was no significant difference observed in scores obtained between boys and girls (p = 0.76). The mean scores obtained by boys were 62.8 and girls was 61.9. As it is evident in table 3, one third of the subjects were having healthy diet on the basis of statistically calculated tertiles as these subjects were having lesser empty calorie foods and more fruits and vegetables. Two third of the subjects were having unhealthy and moderately healthy diet respectively because these were the subjects who were consuming more empty calorie foods and lesser fruits, vegetables and milk than the recommended amounts as per the national dietary guidelines.

Reliability of this tool by split half method and test retest reliability was 0.65 and 0.85 respectively as is shown in table 4. Generally value of 0.60, 0.70 and 0.80 are considered acceptable, adequate and good\textsuperscript{21,22}. Cronbach’s alpha for this tool was 0.59. However Cronbach’s alpha after deleting one item of this tool ranged from 0.51 to 0.68. It was suggested by Tuckman that a Cronbach’s alpha of 0.50 or greater can be accepted for attitude assessments\textsuperscript{17}. Reliability of this tool by split half method is less acceptable. But test retest method correlation coefficient is good as is shown in table 3. Correlation coefficient for different items of this tool ranged from 0.50 to 0.91. There are different reports about the acceptable values of alpha, ranging from 0.70 to 0.95\textsuperscript{23,24,25}. A low value of alpha could be due to a lesser number of questions, poor relation between items or heterogeneous constructs. Since the reliability of this tool was not so good it is clear that this index needs to be reviewed before implementation.

Conclusion

To our knowledge this is the first study to develop diet quality index for Indian children. This index has been developed to evaluate the adherence of diets of Indian children to recommended dietary guidelines for Indian children. Crohnbach’s alpha was not consistent with standard value. This could be due to the longevity of the tool. It needs to be modified in order to improve its reliability for future use. Further research needs to be done for making it more reliable and for standardization of new improved tool by addition or deletion of certain components.

Consent forms were signed by parents of the subjects.

Effect of Task Related Exercise on Arm and Hand Function among Patients with Stroke

Deepthi John¹, Kanmani J²

¹M.Sc. Nursing Student, Amrita College of Nursing, Amrita Vishwa Vidyapeetham, Health Sciences Campus, AIMS- Ponekkara P.O, Kochi. ²Professor, Department of Medical Surgical Nursing, Amrita College of Nursing, Amrita Vishwa Vidyapeetham, Health Sciences Campus, AIMS- Ponekkara P.O, Kochi

Abstract

Background: Stroke is a chronic neurologic disorder that often results in severe functional impairments. The functional capacity of the upper extremity is largely affected causing residual impairments in the post stroke patients. Task specific training improves functional outcomes after stroke.

Purpose: The main purpose of the study to compare the arm and hand function before and after task related exercises among experimental and control group of patients with stroke.

Method: A quasi experimental study was conducted on the effect of task related exercises on arm and hand function among patients with stroke in selected wards, AIMS hospital, Kochi. The study was done on 60 subjects, 30 each to experimental and control group scheduling task related exercise for a 2 weeks period for 20 minutes two times a day. Purposive sampling was done and matching of the two groups was done based on pretest scores. A standardized Chedoke Arm and Hand Activity Inventory (CAHAI-7) tool was used for the assessment.

Results: The study results showed that the mean pretest score of arm and hand function in both experimental and control group was 24.07, while mean post test score of control group was 26.33 and of experimental group was 30.93. A significant improvement in the post test scores after providing task related exercises was noted (t=8.34,p=<0.001) A significant association between time of arrival of hospital after the onset of symptoms and arm and hand function was noted (F =8.68,p<0.05).

Conclusion: The study concluded that the task related exercises are effective in improving arm and hand function in post stroke patients.

Keywords: Task related exercise; arm and hand function; post stroke patients.

Introduction

Stroke is defined as an acute onset of neurological dysfunction due to abnormality in cerebral circulation which results in signs and symptoms that correspond to involvement of focal areas of brain. The WHO defined it as a clinical syndrome identified by rapidly developing signs of focal or global disturbance of cerebral functions lasting more than 24 hours or leading to death, with no apparent cause other than the vascular origin.¹

The heterogeneous consequences of stroke cause residual impairment in a number of functions fundamental for everyday activities. Aside from loss of gross motor function, fine motor skills of the stroke victims may be affected after a stroke ².
According to the World Health Organization, 15 million people suffer stroke worldwide each year. Of these, 5 million die and another 5 million are permanently disabled. In India, the prevalence of stroke was estimated as, 18,012,222 and the population estimated used was 1,065,070,607. In Kerala the annual incidence rate of stroke was 180/100,000 population. According to Trivandrum Stroke Registry, the incidence of stroke was 180/100,000 population.4

The global campaign to fight stroke continues to gain attention from stroke communities around the world. World Stroke Day has been observed on October 2009. The overarching “1 in 6” theme of the campaign continued in 2012/2013.6

Galea MP, Rushey K, Gainu JK in a true experimental study in 2001 studied effect of Early Task-Related Training for Upper Limb Function Following Stroke in 60 stroke patients in Spain who underwent a 3-week long program that consisted of 45-minute task-specific, upper limb training showed improvements in measures of motor function, dexterity, and increased use of the more affected upper limbs (p=0.05).7

A true experimental study was conducted by Boyd LA, at Canada over 18 subjects with chronic stroke with task-specific exercise showed significant improvement (SD 5.67, CI: 95%) in hand function at 0.05 significance level.

A randomized control trial was conducted by Blennerhasse J & Dite in Australia over 30 stroke patients to assess the effect of additional task related practice on mobility and upper limb function. The Mobility Group had better loco motor ability than the Upper Limb Group (between-group differences of 116.4 m, 95% CI 31.4 to 201.3 m, Step Test 2.6 repetitions, 95% CI -1.0 to 6.2 repetitions).

Task specific training improves functional outcomes after stroke.10 Studies of task related training showed benefits for functional outcome compared with traditional therapies. The routine traditional exercises alone are not enough in the management of stroke survivors. Nurses are hence exploring means to improve the client functional capacity through the alternatives like task related strengthening exercises.

Method

Research design

A quantitative approach with quasi experimental, pre-test post-test control group design was adopted for the study.

Hypothesis:

H1: There is significant difference in mean scores of the arm and hand function before and after administration of task related exercises.

H2: There is significance difference in the post test arm and hand function scores of the experimental and control group.

H3: There is significant association between arm and hand function and selected demographic variables.

Sample and sample size: All the clients with stroke having arm and hand dysfunction, getting admitted to AIMS, Kochi was considered as the target population. Total of 60 subjects were chosen for the study 30 each to experimental and control group.

Sampling technique: A non probability purposive sampling.

Inclusion criteria

• Age: 30-70 years.

Patients having Chedoke Arm and Hand Activity Inventory score > than 20

Patients with a history of first stroke.

Exclusion criteria:

• Subjects who have impaired cognitive status, psychiatric or perceptual disorders.

Hemodynamically unstable subjects.

Patients with any musculo skeletal disorders of upper limb, any vestibular dysfunction, hearing and visual impairment.

Study variable:

Independent Variable The independent variable is the task related exercises.

Dependent Variable: The dependent variable is arm and hand function among stroke patients.
Data collection instruments:

**Tool I** – It is a semi-Structured questionnaire with two sections. Section A: Socio Demographic data and Section B: Clinical Data that consists of total of 12 test items.

**Tool II** - Chedoke Arm and Hand Activity Inventory (CAHAI-7). It is a standardized performance tool with 7 tests items which are performance based tasks. The activity scale gives scoring from 1 to 7, thus total score of 49, of which total score 1-19 has severe dysfunction, 20 – 39 has moderate and above 39 has mild dysfunction. Tool reliability was assessed using test retest method (0.96) and content validity was 0.86.

Data collection

After taking informed consent a pre test was conducted using CAHAI- 7 tool. 60 Clients with CAHAI-7 score greater than 20 were selected as subjects and 30 each were allocated to experimental and control group. Homogeneity of the two groups was done using their pre test scores. The experimental group was provided task related exercises for 2 weeks and on the 14th day post test was done for the two groups.

Table 1 shows that, 22(73.3 %) in experimental group and 19(19%) in control group had Glasgow Coma Scale (GCS) score of 12. Daily use of medication was reported in 10(33.3%) of experimental and 16(53.3%) of control group. All the 60 samples had ischemic stroke maintaining homogeneity. 15(50.0%) in experimental group and 16(53.3%) in the control group had time of hospitalization within 1-3 hours of symptom onset. Among the subjects 18(60%) of the experimental group and 17 (56.7%) of the control group has right arm affected with stroke thus maintaining homogeneity of the groups.

(F = 3.15, df – (2, 57), p < 0.05) * Significant

Table 4 presents the frequency, mean, standard deviation and F value of comparison of arm and hand function score and time of hospitalization after the onset of symptoms. Since the table value (3.15) was less than calculated F value (8.68), there was significant association between arm and hand function and time of hospitalization after onset of symptoms at 0.05 level of significance.

Discussion

The first objective of the study was to assess the arm and hand function of patients with stroke before and after providing task related exercises. The study results showed that the mean pre test score of both experimental and control group as 24.06, while mean post test score of control group is 26.33 and of experimental group is 30.93. There is an increase in the post test arm and hand function mean scores after administration of task related exercises. Thus the first hypothesis there is significant difference in mean scores of the arm and hand function before and after administration of task related exercises was accepted. Mohammed A K etal, in 2010 at New Delhi studied the effects of Task Related Training and Hand Dominance on Upper Limb Motor Function in 32 subjects with Stroke, divided into 4 groups with 8 subjects each took part in the study with a true experimental design. The study results showed that mean pre test scores of group 1 was 21.40 and post test scores was 26.34.Thus the study findings supports the first objective that there exist a change in arm and hand function scores after administration of task related training.

The second objective of the study was to compare the arm and hand function before and after the intervention. The test results showed that the calculated t value was 35.01 which were higher than the table t value 3.46. Hence, the null hypothesis was rejected stating that there is significant change in the post test scores of arm and function of the experimental group. Blennerhasset & Dite *(2004) conducted a randomized trial on effect of additional task related practice on mobility and upper limb function in Australia over 30 stroke patients. The Mobility Group had better loco motor ability than the Upper Limb Group (between-group differences of 116.4
m, 95% CI 31.4 to 201.3 m, Step Test 2.6 repetitions, 95% CI -1.0 to 6.2 repetitions).

Third objective was to compare the arm and hand function in the experimental and control group after the intervention. In the present study found that the task related exercise was effective on the 14th day of intervention with p significant at 0.001 level of significance. Thus the null hypothesis was rejected. The post test Chedoke Arm and Hand function Inventory score of the experimental group was greater than the control group. Hence, it was concluded that the task related exercises prove significant effect on the arm and hand function of patients with stroke. Harris JE, Eng JJ, Miller WC, Dawson in 2009 conducted a study on, a self-administered Graded Repetitive Arm Supplementary Program (GRASP) to improve arm function during inpatient stroke rehabilitation in Canada. 103 in patients with stroke were randomized to the experimental group (GRASP group, n=53) and in the control group (education protocol, n=50). GRASP was a combination of task related exercises. At the end of the 4-week intervention (approximately 7 weeks post stroke), the GRASP group showed greater improvement in upper limb function Chedoke Arm and Hand Activity Inventory (CAHAI) compared to the control group (mean difference 6.2; 95% CI: 3.4 to 9.0; P<0.001).

The fourth objective for the study was to find the association between arm and hand function and selected demographic variables. There was an association found between arm and hand function and time of hospitalization after symptom onset. The results showed that greater arm and hand function score was noted on early hospitalization after the symptom onset. Giuseppe A et al in 1997 studied Effect of Delay on the Clinical Efficiency of Early Treatment in 189 patients (84 men, 105 women; mean age, 76.5 years) prospectively collected in the Community Teaching Hospital in Bologna, Italy. The mean interval between onset of symptoms and hospital arrival was 680 minutes; 59 patients (31%) arrived within 2 hours and 100 (53%) within 5 hours. The effectiveness of 17%, extrapolated with the aid of the odds ratio of 1.6 of having a favorable outcome (Barthel Index ≥95 at 3 months) in treated versus patients with delayed treatment group.

Limitations

The subjects included in the study were only from the group of moderate arm and hand dysfunction with CAHAI score between 20-39. None of the subjects with hemorrhagic stroke were available during the time of data collection.

Conclusion

The investigators conclude the effectiveness of task related exercise in acute phase of stroke. It was also an indicator towards the concept of early rehabilitation to prevent or minimize complications. The study depicted the need and importance of implementing task related exercise to improve the arm and hand function in patients with stroke.

Self-disclosure and Quality of Relationship amongst Spouses of Combatants at a Forward Fighter Airbase

MPS Marwaha1, M V Singh2, Rajesh Vaidya3, Bhupinder Kaur Anand4, Alok Kumar Chowdhury5, Rajat Kumar Garg6

1Classified Specialist Aviation Medicine, Air Force Centre Medical Establishment, New Delhi, 2 Commandant AMC Centre and College, Lucknow, 3HOD & Professor Department of Community Medicine, Army Medical College, Delhi, 4Professor, Department of Community Medicine, SGT Medical College, Gurugram, 5Associate Professor, Department of Psychology, ADAMAS University, Kolkata, 6Graded Specialist Psychiatry, Air Force Centre Medical Establishment, New Delhi

Abstract

Objective: The aim of the study was to gain knowledge of the quality of relationship and self-disclosure amongst spouses of combatants at a forward airbase.

Method: 30 wives of Serving personnel of a forward base were voluntarily administered quality of relationship scale along with self-disclosure scales. It was done during health camp and meetings organized by the Station Health Authorities. Data were tabulated and analyzed through SPSS-ver.11 for descriptive and correlations purposes.

Results: The mean age of marriage was 22.4 years and 25.9 years for wives and (husbands) respectively. The study sample has 10.4 years of marital life experiences. Wives reported their quality of relationship with their husbands in terms of depth, affection, support and physical intimacy, while they mostly do self and family related disclosures with their husbands.

Conclusion: Conflict coping strategies are tri-pronged namely active, emotional & avoidance. Emotional coping is a major cause of stress overloading in a relationship. In the present study, Conflict avoidance in quality of relationship is positively correlated with Self (p<.01) and Family (p<.05) related disclosures in all issues amongst the couples residing at the fighter base. Conflict avoidance is helpful in alleviating stress overloading, among couples. These results can be useful in dealing in other relationships also.

Keywords- Self-disclosure, quality of relationship, wives

Introduction

Close personal relationships are the very essence of human existence; nearly as fundamental to survival as air and water are the links between people: mother & son, lover & lover, wife and husband1. Relationships are characterized by at least one of the three factors: emotional attachment, need fulfillment, and interdependence2. At the behavioral level, a relationship implies first a series of interaction between two people, involving interchanges over an extended period of time3.

Relationships among spouses are most important aspect of marital life. The present day scenario depicts the quality of relationships as getting worse day-by-day. According to Indian National Crime Records Bureau’s 2009 reports, suicidal attempts of Indian housewives, dowry deaths, domestic violence etc. all are depicting the tale of worsening relationships. Moreover, this strain in relationship escalates stress in normal life.

What are the reasons behind the deteriorating quality of relationship? There are several processes such as emotion, attachment, intimacy, social support, conflict...
and communication that are conducive to development, maintenance, renewing, disruption, and even termination of relationships, if they are not taken care of.

Communication plays a major role in determining the quality of family life. A crucial modality of communication is self-disclosure. It is hard to imagine how a relationship might get started without such self-disclosure. Self-disclosure loosely defined as what individuals verbally reveal about themselves to others (including thoughts, feelings and experiences) that plays a major role in close relationships. Kamarovshy found that self-disclosure seemed to be positively related to marital satisfaction in couples. In a close relationship, conversation is both indexical, as we are more likely to like and disclose to those who disclose to us, in that it conveys the emotional status of the interaction. In short, communication in relationship creates and maintains a relational culture.

In the light of above the researchers had these objectives:

1. To study the quality of relationship of wives with their husbands serving in a forward/ peripheral air base.
2. To study the self-disclosure of wives with their husbands.
3. To study the relationship between quality of relationship and self-disclosure.

Material and Method

Study Population:- Study group constituted 30 wives of Serving residing at a forward Airbase. Their husbands were working at the same base.

Data collection:- Their mean age is 32.8±5.3 years. The mean age of marriage was 22.4 years and 25.9 years respectively for wives and husbands. The study sample has 10.4 years of marital life experiences. Quality of relationship inventory; an abridged version by Alok & Misra was administered to measure the quality of relationship of respondents with their husbands. The inventory has 26 items pertaining to ten dimensions i.e. conflict avoidance, physical intimacy, possessiveness and dominance by CIFA of Werner & Green, 2000; depth, conflict and support by QRI of Pierce, 1994 affection, mutuality and interaction. Obtained reliability was 0.72. Self-disclosure scale by Alok & Misra was used to measure the level of self-disclosure of respondents for different areas of their life. Self-disclosure scale contained 23 items. Obtained reliability of this scale was 0.63.

Data analysis:- Data were tabulated and entered into Excel software package. The entered data was analyzed through the Statistical Package for Social Science (SPSS-ver.11). Descriptive statistics and correlation were done.

Findings

Means for quality of relationships are as follows:

Table 1: Correlation (r) between various dimensions of Quality of Relationship and various components of Self-disclosure

<table>
<thead>
<tr>

<td>Dominance</td>
</tr>
<tr>
<td></td>
<td>Possessive</td>
</tr>
<tr>
<td></td>
<td>Lack of Conflict</td>
</tr>
</tbody>
</table>

**p<.01, *p<.05
The above table (table #1) shows that Conflict Avoidance (CA) of Quality of Relationship is positively correlated (p<0.01) with ‘Self’ related disclosures. It is also positively correlated (p<0.05) with ‘Family’ and ‘stress due to self & family’ related disclosure.

**Discussion**

It is established from the present study that relationship amongst the subject group of couples is ‘in-depth’(3.83±0.27), ‘affectionate’(3.80±0.36) and ‘supportive’(3.73±0.40). Couples have good physical intimacies(3.20±0.57) amongst them. Conflict avoidance(2.95±0.44), maturity(2.90±0.68), interactions(2.85±0.59) were moderately reported and as well as significant dominance(2.87±0.64) was also shown in the study. Study revealed a low value of possessiveness(2.45±0.64) and lack of conflicts(2.00±0.67) were amongst the couples. Suggestive study is of the fact that conflicts are present in the relationships.

Wives have reported that they disclose to their husbands almost every matter related to self(2.86±0.65), family (2.55±1.05) and friends (2.40±1.07) regularly, but sexual matters (2.10±1.67), neighbors (2.10±1.06) and stress due to self & family related (1.91±1.36) disclosures were the least disclosed factors. Higher levels of disclosure intimacy occurred in the high intimacy condition than in the low intimacy condition.

The study also established the fact that conflict avoidance was positively correlated with self and family related disclosures among the couples. These data is giving an inclination for inculcating the habit of self and family related issues among them to avoid conflicts amongst themselves. Self-disclosure of emotions is also a more important predictor of intimacy than self-disclosure of facts and information.

The above results are based on young couples having an average of ten years of marital life experiences. However, research work by Dindia et al is suggestive of the fact that women discloses greater to female and same sex partners than to opposite-sex or male partners.

The present study results may be compared with aged and old couples to get the broader representation of self-disclosure and quality of relationship because, disclosure levels decreases with time-related factors such as age, length of marriage and in particular, the number of children. So these results can be useful in dealing with other relationships also.

**Conclusion**

It is evident from the present study that, Conflict avoidance in quality of relationship is positively correlated with Self (p<.01) and Family (p<.05) related disclosures amongst couples of combatants. It is pertinent to bring out the fact that conflict avoidance is immense to the nature of issues. These results can be extrapolated in dealing with other relationships also. In future these findings need to be validated with the larger sample size.

Experience of Prioritizing in Nursing Care in India: A Qualitative Study

Lata Mandal¹, A Seethalakshmi²

¹Research Scholar; ²Reader & Head of Department, Department of Nursing Foundation, Faculty of Nursing, Sri Ramachandra, Institute of Higher Education and Research, Chennai, India

Abstract

Background: Prioritizing in nursing care is also known as rationing of care or missed care. It implies any aspect of required patient care that is significantly delayed or omitted. The phenomenon is closely related to patient safety and quality of nursing care. This Qualitative study was undertaken with the aim of acquiring a comprehensive understanding of nurses’ experience of Prioritization in nursing care.

Material & Method: Six focus group interviews were conducted among 38 purposively chosen nurses involved in direct patient care in three tertiary care hospitals of East and South India. Data was analysed through thematic content analysis.

Results: Three major themes emerged from the data: (a) Priority of Curative over Carative activities (b) Organizational factors effecting Prioritization (d) Perceived outcomes of Prioritization.

Conclusion: Prioritizing in nursing care follows the curative doctrine of health care by giving importance to the activities related to the patients’ medical needs. Organizational factors like human resource inadequacy and conflict over role responsibilities of nurses were the perceived reasons influencing prioritizing. The findings suggested that the phenomenon is detrimental for the quality of nursing care and patient related outcomes. Further research is recommended to capture the full spectrum of the phenomenon. Nursing leadership needs to acknowledge and create scope for explicit discussion of the issue among nurses and other health care members.

Keywords: Prioritization of care, Rationing of Care, Patient safety, Quality of Nursing Care

Introduction

Prioritized care is known by different names like Missed care and Rationed care.¹ The concept implies “any aspect of required patient care that is omitted or significantly delayed”.² Literature suggests that nurses commonly gave more priority to bio medical aspects of care like administration of medicines and assistance in diagnostic procedures and delay or completely miss individual and interpersonal aspects of care like teaching or personal hygiene.³ Studies done all over the world demonstrated that prioritization of nursing care significantly influenced negative patient outcomes ⁴⁻⁶ and jeopardized the overall quality of nursing care.⁵ Qualitative studies exploring nurses’ experience of rationing patient care have consistently described nurses feeling guilt and ethical dilemma.⁹,¹⁰ The conceptual Model of Missed nursing care attributed organizational characteristics like adequacy of human and material resources, nursing work environment along with nurses’ individual level factors like values, attitude and role responsibilities to influence nurses’ decision of prioritizing certain tasks over others. ²

In India, there is a total lack of literature on Prioritization of nursing care and the concept remains
more or less unacknowledged and sensitive in the health care settings. Therefore, an attempt to quantitatively measure the phenomena without an in depth understanding of the Indian scenario would be unrealistic and insensitive. This Qualitative research was taken up as an initial field study before conceptualising a project on rationing of care. The purpose of the study was to explore nurses’ experience regarding prioritization of nursing care.

**Method**

The study used a Qualitative approach with focus group interviews as the method of data collection.

**Participants:** Thirty eight nurses working in three large tertiary care teaching hospitals in India were chosen by Purposive sampling. Two of these hospitals were located in the southern region and were 800 and 1500 bedded respectively. The third hospital was from the Eastern part of the country and was 750 bedded. The interviews were conducted between July to October 2017. The inclusion criteria were: speaking in English, registered and permanent employee of the hospitals and involved in direct patient care. Nurses working in Intensive care units were excluded from the study. All participants were female nurses between the age of 23 to 44 years with professional experience varying between 2 to 17 years. They were either graduates (n=21) or held a diploma in nursing (n=17).

**Ethical considerations:** Ethical permission was sought from the Institutional Ethical Committee (IEC) of the concerned hospitals. Written and oral Informed consents were obtained from each participant, ensuring confidentiality, anonymity and their rights to refuse or withdraw at any time.

**Data Collection:** A total of six groups were interviewed. (Group A= 7; group B=6; group C=6; group D=7; group E=6; group F=6). Interviews were conducted in places of convenience of the participants and were mostly in the seminar rooms of the respective hospitals. Data saturation was achieved during the sixth focus group.

All interviews were audio recorded by an assistant and lasted between 50 to 70 minutes (Mean=63 minutes). At the onset the members were requested to share their views honestly while maintaining confidentiality and respect towards each others opinions. It was emphasized that the aim was to discuss prioritization in the context of routine patient care and not on occasions of emergencies. The members were presented with imaginary clinical situations based on previous studies and requested to discuss their own experiences similar in nature. Further discussions were guided by open ended questions.

**Data analysis:** A directed content analysis approach was used for identifying themes from the data. The steps followed were: (a) Audio recorded interviews were transcribed word by word leaving wide margins on both sides of the pages. Expressions like laughter and exclamations were written within brackets. (b) A coding scheme was developed by looking into the data from the first two interviews. Key concepts were identified and coding schemes were decided through discussion with the co author. (c) All similar codes and the supporting interview extracts were grouped in themes. The narrative data was reread with the themes in mind to check if they really fitted in the themes. All the categories were then compared to look for similarities and differences between them. (e) The emerging themes were discussed with reference to existing literature.

**Findings**

**Themes**

**Priority of Curative over carative activities**

Content analysis of focus group data brought out that nurses gave more priority to activities pertaining to patient’s cure. In general, participants expressed that they felt obliged to prioritize tasks according to the medical needs prescribed by the treating physician like administering medications, assisting in diagnostic tests and managing the chain of referrals. Rendering personal hygiene care or giving emotional support to a patient and family during a stressful diagnosis were some of the tasks admitted to be frequently missed by the participants. As expressed by two participants: *I think the most important job that I have in the hospital is to give medicines and injections. Patients get admitted for getting diagnosed and cured.*

*All my time goes in attending to the medical needs of the patient& I hardly explain anything before the tests or before discharge. I presume that they will either see Google or ask junior doctors.*

However differences in the perception of the relative importance of care versus cure were observed among
younger and older nurses. As expressed by a participant with more than 10 years of professional experience: Many a times I felt that an extra pillow under the legs, or a back rub to the old patients would have helped. These small little caring gestures are as important as the capsules and injections. But I miss them frequently.

A different view was reflected in the words of a 23 years old nurse: Anybody can care for him; his relatives can give bath, feed him and talk to him for emotional ventilation. I need to focus on his medical needs.

(b) Organizational factors effecting Prioritization

All groups had a great deal of passionate discussion and imputed the organizational work environment as significant in influencing their decision of prioritizing. Participants agreed that inadequacy of nursing resource in proportion to the workload was the predominant factor leading to their decision of prioritization.

The participants also agreed that the confusion and conflict they face regarding their role responsibilities was another important reason for them to miss many basic nursing activities. The perception that they were “too busy with non nursing tasks” was conspicuous in all the focus group discussions.

I don’t think it is my job to search for the patient’s documents when it is the doctor who misplaces them. But I spend precious time in searching.

I do not understand why the physiotherapist is never questioned when a patient is not ambulated after surgery? Is it all my responsibility?

The participants expressed their helplessness and lack of power over these organizational factors which were expressed by repeated use of phrases like “no use”, “just impossible” in their conversation. Limited power to negotiate their roles with other health team members was the dominant perception that led to a feeling of helplessness in regards to prioritization. As a participant said:

It is impossible to give care without getting disturbed by someone asking for something.

These perceived limitations lead to sense of discontentment against their supervisors and the profession in general. It is no use to tell our problems. Our leaders need to be strong and clarify what is to be done and not done by nurses.

(d) Perceived outcomes of rationing

Surprisingly very little discussion was observed regarding the outcomes of prioritizing. Participants discussed the physical effects of this phenomenon in a theoretical level as to what can happen if a particular activity of care was missed. Discussions excluded any particular real life situation of prioritized care leading to actual adverse patient outcomes.

However, discussion was mainly targeted towards the effect of prioritizing on nursing care quality. It was apparent that the decision to do prioritization led to a perceived sense of Fragmentation and Incompleteness of their work. A participant said: I take patient’s blood but seldom tell them the reports. Taking sample and then telling them the report would have been a complete job, isn’t it?

This inability to perceive a completed view of their work paved way for job strain, and dissatisfaction as expressed by two nurses: I feel pulled from all sides, patients, families, supervisors, doctors, other therapists; I never feel that I have completed everything and feel like sitting on the edge.

While giving medicines I do not even look into their eyes, with the fear that if they start talking I will have no time to complete medications. I feel so guilty.

Discussion

The findings of this Qualitative study threw light on nurses’ experience of prioritizing care and revealed that activities directly associated with patients’ cure were given more priority by nurses. It further revealed that nurses regularly rationed carative activities like emotional support, teaching, communication and hygiene care. Various studies showed that nurses rationed similar aspects of care on a regular basis.

Studies have demonstrated that omitting nursing tasks like education, hygiene and comfort care, etc have consequences on patient safety and may lead to nosocomial infection, pressure injuries, post operative complications and less readiness for self care. Thus the findings of this study shed light on the process of nursing that may contribute to poor patient safety.

Provision of emotional support, considered as an
a profession needs to be rooted in the overall ethos of the environmental framework. The study also brought out an interesting observation among the younger generation of nurses who admitted their perception of carative tasks to be unimportant. Thus the findings of this study suggest a shift in the paradigm of the nursing profession from a caring based discipline to a target oriented profession.

**Limitations**

This study was restricted to nurses’ perception of Prioritization of care through focus group interviews and there could have been chances of participants’ failure to talk about issues different from the group norms. Qualitative observation with participatory approach could have elicited a richer and purer form of data.

**Implications**

To the best of our knowledge this is the first study on Prioritization of Nursing care providing evidence to the existence of the phenomena in the Indian scenario.

**Conclusion**

Prioritizing in nursing care follows the doctrine of the existing Curative model of health care. However it is a concern for the overall quality of nursing care and patient outcomes. The phenomenon is interlinked with organizational work environment and includes multitude of stakeholders like patients and other health care providers. Moreover it seems to be causing strain on nurses’ professional experience. Thus nursing leaders in India need to acknowledge the phenomena and create scope for nurses to explicitly articulate and discuss issues related to prioritization. Through discussion with other stakeholders, nurse administrators need to deliberate and redesign nurses’ charter of duties and create a clear demarcated job description to reduce rationing care. Prioritization of nursing care can also be adopted as a real time indicator for assessing quality of care and patient safety of an organisation. Future researches to measure its level and study the full spectrum of prioritization of nursing care in India can be taken up through large multisite studies.

Efficacy of Botulinum Toxin Type A in the Treatment of Post Surgical Parotid Fistula - A Systematic Review

Kunal Gajendragadkar¹, Kalyani Bhaté², Surabhi Magoo¹, Santhoshkumar S.N³, Bhagyashree Jagtap⁴, Kshitija Sonawane⁵

¹MDS (Trainee), ²Professor, ³Professor, ⁴PG (Trainee), ⁵PG (Trainee), Dr. D. Y. Patil Vidyapeeth, Dept. of Oral & Maxillofacial Surgery, Pimpri, ⁶PG (Trainee), MIDSR Dental College and Hospital, Dept. of Oral & Maxillofacial Surgery, Latur

Abstract

Salivary fistula is a troublesome complication of parotid surgery. The treatment of this condition requires weeks before effect becomes evident. Botulinum toxin injection is a newer treatment modality. This systematic review sheds light on the efficacy of Botulinum toxin in treatment of post surgical parotid fistula. Studies comparing botulinum toxin with the other available treatment modalities as well as those studies solely using botulinum toxin are taken into consideration in the review. Electronic data search of Pub Med, Google Scholar, EMBASE, Institutional Library, Email to authors and manual search of various journals. Finally, 9 studies were included in qualitative synthesis with a total of 25 estimates. Botulinum toxin type A injections are effective in reducing the flow of saliva in treatment of post operative parotid fistula, thereby aiding in healing of the fistula. The studies had a varying variety of dose, route of administration and cycles of administration per case, making it difficult to evaluate the efficacy of Botulinium toxin in the treatment of parotid fistula. Further research focusing on streamlining the dose and delivery of the toxin must be conducted in order to establish definitive guidelines.

Keywords: Parotid Fistula, Botulinum toxin, Complications of parotid surgery.

Introduction

The development of an abnormal salivary gland drainage tract is an unfortunate complication occurring post parotid surgery. A persistent transcutaneous flow of saliva is seen in these cases. The literature unveils the post parotidectomy fistula rate to be around 4–14%¹. Sialoceles are known after-effects associated with parotid surgery and piercing injury to the parotid gland. Owing to the close anatomic relation of the buccal mucosa and Stenson’s duct, the trauma to the parotid duct is usually inevitable when operating in this region².

The discharge of saliva might occur both internally and externally, however internal fistulae usually do not require surgical intervention and usually respond well on application of pressure dressing.¹ In cases of external fistulae, the principles of management aim at the return of normal parotid function in both acute and chronic parotid injury¹.

Many authors have also described different methods of treatment, such as repeated percutaneous needle aspiration, pressure dressings, antisialagogue therapy, radiotherapy⁴, botulinum toxin⁴. The surgeries performed include duct repair, diversion of the proximal segment into the oral cavity, ligation of the proximal duct to induce atrophy of the gland, drain placement, and parotidectomy⁵.

Frequently the treatment protocol is to suppress the parotid secretions in order to allow natural healing process¹. Many agents like Hypertonic saline, scopolamine, etc. have been used in the past¹. Some
researchers also advocate the combination of one or more of these agents to achieve faster results.

Recently, botulinum toxin has gained a lot of importance in the world of cosmetics and dermatological procedures. Botulinum toxin type-A is a neurotoxin produced by *Clostridium botulinum* which inhibits the release of presynaptic acetylcholine. Majority of the secretomotor fibers to the parotid gland are cholinergic autonomic parasympathetic. Hence, botulinum toxin injections prove to be effective to reduce the salivary flow. The type-A toxin is a 2-chain polypeptide consisting of a protease enzyme which attacks one of the fusion proteins at a secretomotor or neuromuscular junction thus preventing vesicles from attaching on to the pre-synaptic membrane to release acetylcholine.

The purpose of this review is to evaluate the efficacy of the toxin in the treatment of post-surgical parotid fistula.

**Method**

**Focused Question**: How effective is Botulinum toxin type A in treatment of post-surgical parotid fistula?

**Objective**: To evaluate efficacy of Botulinum toxin type A in treatment of post surgical parotid fistula.

**Search Strategy**: A comprehensive search of literature was undertaken. The inclusion criteria was, date restriction from 2005 till date, language restriction of English and studies providing information on Botulinum toxin type A in treatment of parotid fistula. Abstracts, letters to editors, animal studies and in-vitro studies not describing method of administration of Botulinum toxin type A or its effects in detail were excluded from the study. The keywords searched were Parotid Fistula, Botulinum toxin, Complications of parotid surgery. The electronic search included Pubmed, Google Scholar, EMBASE and institutional library using keywords and their synonyms (Table1). In addition, the bibliography of included studies was hand searched to identify potentially eligible studies that were not captured by electronic search. Email communication to authors of potentially eligible studies was also done to obtain the same. In addition a manual search of Oral & Maxillofacial and ENT(Ear, Nose & throat) surgery related journals was also performed, including Journal Of Army Medical Corps, American Society for Dermatologic Surgery, Journal Of Oral Maxillofacial Surgery, International Journal of Pediatric Otorhinolaryngology, European Archives Of Otorhinolaryngology, American Journal of Otolaryngology, Annals Of Otorhinolaryngology, Oral & Maxillofacial Surgery, Laryngoscope, International Journal of Oral and Maxillofacial Surgery, British Journal of Oral and Maxillofacial Surgery and Journal of Craniomaxillofacial surgery. The reference list of identified studies on the subject were also scanned for potentially related studies.

**Data extraction**: A standard pilot form in excel sheet, for data extraction, was initially used and then all headings not applicable for the review were removed. Data extraction was done for one study and this form was reviewed by an expert and finalized (Table 2).

**Results**

**Study selection**: This systematic review followed guidelines in PRISMA (Preferred Reporting Items for systematic Reviews and Meta-analysis) statement. Two hundred and sixty studies were obtained from information sources. The studies were screened and 236 studies were excluded for not meeting the eligibility criteria. Out of the remaining 24 studies, 15 were removed for being duplicates. Thus, total 9 studies were included in qualitative synthesis with a total of 25 estimates.

**Discussion**

In the 1820’s, Dr. Justinus Kerner started studying a batch of blood sausages which were responsible for the death of many Germans. He however could not isolate any factor and he called it “wurstgift” (German for sausage poison). In the 1890’s seventy years after Kerner’s experiments, Dr. Emile Pierre van Ermengem of Belgium investigated an outbreak of botulism following a funeral dinner which killed three people and paralyzed 23. Dr. Emile connected botulism to a spore-forming bacterium and named *Bacillus botulinus* which was later renamed as *Clostridium botulinum*.

**Study Characteristics**: Nine case reports and case series which satisfied the inclusion criteria were selected for this study. (Marchese-Ragona R et al.,2005; Marchese-Ragona R et al.,2006; Lim Y et al.,2007; Hill S et al.,2007; Hatzis G et al.,2007; Laskawi R et al.,2013; Gok G et al.,2013; Tighe D et al.,2014; Melville J et al.,2016).
Characteristics of trial settings, investigators and methods:

Five studies were case reports, three were case series while one was a technical note, which were conducted in Italy, Korea, New Zealand, USA and England respectively. The settings for the patient treatments were OPD in 4 studies and IPD in 2 studies. In 3 studies, the setting was not mentioned clearly.

Characteristics of Participants:

A total of 25 participants were treated in nine studies. The age of the participants ranged from 39 to 88 years and included both genders and both side parotid glands. The chief complaint of the patients was salivary discharge and parotid fistula following surgery. The reasons for surgery were Mucoepidermoid carcinoma, Squamous cell carcinoma, Warthin’s tumour, Acinic cell carcinoma, parapharyngeal tumour, ulcerated basal cell carcinoma, Cystadenolymphoma, Undefined infiltrative process, Pleomorphic adenoma, Cyst, self-inflicted shotgun wound, Traumatic fracture of the mandibular condyle.

The surgeries performed were left lateral parotidectomy in 4 patients, mass excision in 1 patient, wide local excision in 1 patient, Mohs resection in 1 patient, superficial parotidectomy in 1 patient, partial superficial parotidectomy in 1 patient, reparative surgery in 1 patient, Open reduction and internal fixation of mandibular condyle in 2 patients, ablation and immediate reconstruction in 3 patients.

The approach for the surgeries was endaural approach in 1 patient, extra oral approach in 15 patients, trans-parotidocervical approach in 1 patient, rotating island pedicle flap in 1 patient, Retromandibular trans parotid approach in 2 patients, and for the patients who underwent microvascular reconstruction, Anterolateral thigh free flap in 2 patients, Radial forearm free flap in 1 patient.

Characteristics of interventions:

As per our inclusion criteria studies using Botulinum toxin type A for the treatment of parotid fistula were selected.

The Botox was used in different quantities in different patients ranging from 10 IU to 225 IU per cycle.

The number of cycles of injection required for complete treatment varied from 1 cycle in 15 patients, 2 cycles in 7 patients and 3 cycles in 3 patients.

The site of injection varied from Substance of the parotid gland, Superficial lobe of the parotid and in proximity to the fistulous tract.

Some of the studies used specific method of delivery of the toxin i.e. Ultrasound guided (USG) 22G needles, 27G Teflon coated Electromyography (EMG) needles, Tuberculin syringe, some authors also dissolved the toxin in saline before injection.

Characteristics of the outcome measures:

All studies were evaluated for closure of parotid fistula with Botulinum toxin type A injection. Time required for stoppage of salivary flow ranged from 24 hours to 2 weeks. In 1 patient the salivary flow stopped in 24 hours, in 2 patients it took 48 hours. Seventy-two hours were required for stoppage of salivary flow in 2 patients. It took 2 weeks in 3 patients, 7 days in 1 patient while in 2 patients the time required for stoppage of salivary flow was unclear.

Time required for closure ranged from 1 week to 21 months with the closure seen in 1 week in 1 patient, 3 weeks in 3 patients, 3 patients in 1 month, 2 patients in 2 months, 1 patient in 3 months, 1 patient in 4 months, 2 patients in 5 months, 1 patient in 9 months, 1 patient in 14 months, 1 patient in 18 months and 1 patient in 21 months.

Out of the 25 patients only one patient discontinued the Botox treatment as no closure of fistula was seen.

No patient faced any untoward complication from Botox injection apart from a few complaints of dryness of mouth for a short period of time in few patients.

**Conclusion**

Botulinum toxin therapy is useful in reducing saliva production in patients with post operative parotid fistula\(^{14}\). Though it does not directly help in the healing of parotid fistula, the reduction of the salivary flow indirectly aids in healing of parotid fistula, by decreasing parasympathetic activity of salivary glands.

The decrease of salivary flow occurring shortly after the injection, has been well documented by many authors. Nonetheless, it should not be equated with the end of wound healing. Nevertheless, this is a very important effect since it alleviates the patient’s symptoms and reduces the discomfort associated with saliva draining through the fistula and running down the cheek and neck. Even if fistula closure cannot be achieved, this is still a very positive effect of the Botulinum toxin injection since it eliminates the visible social stigma\(^{14}\). Authors have performed the injections in a wide range of doses and cycles of administration. However, Melville J, et.al have achieved the reduction in salivary flow as well as the closure of the fistula in the shortest duration with minimum dose of the toxin, i.e., 40 IU in 2 cycles achieved stoppage of salivation in 2 weeks and closure of fistula in 3 weeks. So, we recommend this dose and cycle for closure of parotid fistula. The ultimate closure of parotid fistula depends on multiple factors like radiotherapy, size of the reconstruction flap, overall health of the patient as well as age of the patient.

The cost of the product however is higher than traditional methods and this is probably the biggest hurdle in developing countries like India. Moreover sometimes repeated application is needed thereby increasing the expenditure of the treatment.

Botulinum toxin injection is well tolerated, can be given rapidly in outpatient setting and can be repeated as needed. One of the most disturbing side effect of Botulinum toxin injection maybe post injection paralysis of facial nerve\(^{15}\). The use of ultrasound guidance allows avoidance of damage to intra parotid vessels and also the facial nerve. It also allows delivery of the toxin as close to the fistula as possible\(^{13}\).

Analysis of Factors Influencing Medical Tourism in India Chennai and its Impacts

J. Revathi1, S. Jansi Rani2
1Phd Research Scholar; 2Associate Professor, Department of Economics, VISTAS, Chennai

Abstract

Emerging countries like India has abundant opportunity because it built its own health care and offer high quality treatment at low cost, India adopts western medicine and still practicing Indigenous system also, excellent destination for the medical tourist because of exotic beaches, mountains, pilgrimage places, most importantly is get accreditation from NABH, JCI to offer the quality of treatment and use state of art in technology ,skilled professional these attracts the foreign patients to India,especially Tamil Nadu is the hub of medical tourist many reputed hospital and star hotels are available and transportation makes it easier, service provider also offer the health packages and provides information to their need, tourism and medical tourism are labour oriented, generally India have large pool of professionals, paramedical, these things medical tourism became profit earning industry in India.

Keywords: MT- Medical Tourism, JCI-International Joint commission, SMAC(social, mobile, analytic, cloud), Society for International Health Care Accreditation (SOFIHA)

Introduction

Health Care- India is known for heritage of health science, The Surgical skills were clearly mentioned in Ayurveda by Charaka, Jivaka, etc... History of hospitals can be traced back in the Ashoka period(320BC), Unani was introduced in Mughal emperor period (1000-1500AD), Allopathy took diverse popularity before that people relied Indigenous only .The first Allopathy Hospital was built in 1664 at Madras.18

Wellness tourism origins in the period of 4200 BC to recover from illness to take bathing in thermal spring. In Sumaria, medical tourism originated in 1500 BC in Greek to honor of their god to laying stone temple. Currently more than 50 developing countries engaging in medical tourism like nations from Asia, South America, and Africa1

India as consider one among the global leader in medical tourism. It competes with other countries like Thai and Singapore. the application of 7p’s makes India to be in top rank, 2015 statistic said 18% of medical tourist came to India,so effective medical market strategy seeks the International patients to came India, and also India provide diversified medical procedures Ayurveda, yoga, Fertility treatment, etc... The main factor for going for emerging countries are the elective treatment may not available in their home country or too much of cost , and important thing is travelling can rejuvenate mentally and physically gives mixes leisure and relaxation with the treatment, India offers variety of alternate medicine like Ayurveda, Naturopathy Reiki, Homoeopathy etc.. Obviously India became destination for the medical travellers. Apart from this the qualitative and quantitative shifts in patients moves to developing countries,quality of treatment provided for low cost , some of the treatment are cardiovascular, Orthopedics, Fertility. The comparative cost benefits are larger in India [65-90%]. for this achievement they use traditional marketing trend like conventional products, the patients are consider as target audience, state of art in technology. Medical marketing not only attracts the patients but also build the brand of the hospitals2.

Objective of the study

Infrastructure development

Push and Pull factors, influencing medical tourism

Impacts of Technology influence the medical
Accreditation and Branding the factors to promote the medical tourism

Infrastructure development

Chennai is the Capital of Tamil Nadu, largest city in the state, third busiest International airports in India, and second busiest sea port container hub, extensive road network, Infrastructure development Index Chennai gets second place, it is Industrialized as well as metropolitan city, eleventh largest state in India, second largest tourism industry.  

Tamil Nadu known for its health care madras medical college was started at 1835 public health system is best in the country, medical center and research Institute are avail in Tamil Nadu, the major cities of Chennai, Madurai, Vellore, and Coimbatore offers exponential medical collaboration with Japan (Japan International Agency for Cooperation) to make Chennai as smart city, Japan is known for world class infrastructure and transportation system, without making any disturbance of Chennai’s heritage, the development taking place. Japan provides the financial support, Prime Minister Narendra Modi has a plan to build 100 smart cities in the country, Japan also assist to build the smart city, for this improvement going to standardized the drainage system, transportation system, waste management system etc., Japan converted Kyoto a model without any disturbance to its old heritage they convert in to smart city. In infrastructure development on expressway to Chennai to Bangalore, the cost of the project is 20,000 crore, and extend the suburban areas, and also expand the six laying road ways Tamil Nadu get 1 lakh crore for infrastructure project.

Push & Pull factors which the medical tourism

People club travel and medical treatment together, and Whittaker differentiate medical tourism and health tourism. In Medical tourism they came for elective surgeries and health tourism. The rejuvenation procedure like spa message, alternate treatment takes place.

In India the product which they sold under medical tourism are wellness, rehabilitation, treatments, Ayurveda is birth place of India, which is known for natural system for curative purpose, and treatment is the first preference to the patients, the cost of the treatment is high in developed countries like UK, USA these reasons pull the patients to move emerging countries, so the alternate treatment and low cost are make them to take decision, and India is in nascent stage but it has strong potential to grow in future, Medical tourism is a global business.

Primary factors for growing MT in developing countries are, high level uninsured patients in USA, UK lack of private healthcare and long waiting time, In Japan Pressure of ageing population, long stay in hospitals, Dearth of sufficient doctors, and cost effectiveness, Elective surgery, insufficient health care in developing and under developing countries. Secondary factors-Secular shifts [developed and developing countries], working vs. leisure time, Population, Increasing demand of quality, and Individualization. Socio economic factors, Flexi working time, Higher income, More leisure time, Changing value of holidays, Changing life style, Growing political and medical segment, Many medical tourism companies/facilitators, end-end medical tourism providers. Cost Advantage: The price discrimination for the procedure and cost advantages are the important factor to motivate the people to go to the other countries.

The countries like India, Singapore, Philippines, Greece are promoting the medical tourism because medical tourism became huge profit earning Industry in the world, even though India joined very later, but gets popularity very soon because of the reasons are long waiting time, shortage of professionals, lack of support from family side apart from that the cost of the treatment is huge in developed countries, in UK NHS support service cannot provide so obviously they search for the alternate source, as well as cost effective in emerging countries, The highlight of choosing India as the destination place for the treatment is quality of treatment, no language problem, the cost of the open heart surgery is very less compare to US and UK. Medical tourist get packages it include rejuvenation therapies, hotels, site visits post-operative vacations.

Impacts of Technology:

The most important thing in MT is payment security, to health providers and also medical travellers. The Digital payment system is problem solving to both of them. The health care providers need to set all service along with related service providers are integrated, so the transparency helps the economy to flourish.
Technology is not the solution for the health care but it enables to provide quality of health provide by the providers, so Health care adopts the digital technology for this success they create mobile apps to adopt and government also takes steps for the digital technology. Mobile apps enable the private consultation with doctors it offers on line videos. SMA
cenables the uncover drive. It helps the customer to interact in socialmedia, some apps able to measure the body metrics. And save the information’s in cloud platform, from that they analyses, know the consumer preference. And cloud gives way to access the technology and data for the business.

Cloud helps the Health care organization more focused on their core activities; it. This accurate information provides confidence in emergency .it helps to reduce the time, minimizing insurance coverage, etc. the cloud technology is easy to access. Moreover the cloud technology helps to reduce the utilization of resources, and also to improve the patients safety in the hospital, the hospital design should be evidence based [EBD] for this the design should be evaluated by users from different disciplines. EBD suggest the health care support .and the design cover several stages. These are detailed in hospitals in Kolkata. Midmark An Indian company introduced motorized bed ‘Electra’ for patients, it aims to enhance the patients recovery and efficiency of caregiver,and matches the world class standard, and India entering in to global market ,specialty are the cardiac chair are achieved easily.

Collective diagnostic laboratory in India, Neuberg is a Diagnostic laboratory which is located in Bangalore ,and is managed by Dr.G.S.K.Velu the founder, is the very first global pathology ,laboratory consortium, four Nations like India, Srilanka, South Africa, and UAE,are joined together formed this setup .This diagnostics is affordable to people across the globe, Neuberg have three world class reference laboratory, in Bangalore, Ahmadabad, Durban [South Africa], they have advanced technique along with total lab automation and big data analytics tools, and it is supported by world class laboratory system. They had done more than 5000 pathology test and it empowers the Indian health care service.

Wearable help the patient’s activities, now it used to common people also like measure basic health parameter, BP, Heart rate, etc...In India now 30 crore valued wearable are used and it is expected to increase more. A wristwatch acts as a personal emergency response system; GPS helps to cover remote server.

Accreditation and branding the factors to promote the medical tourism

The deciding factors of MT are Accreditation certificate from JCI, Insurance coverage, Hospitals and Doctors must have board certified, and the most important thing is Accreditation. It’s a voluntary process to develop the standard to ensure safe delivery of health service, it was set by the health professional, to maintain the quality, JCI is best known accreditation group in US. JCI inspects the hospitals then only gives the accreditation certificate. SOFIHA aims to provide safe hospital environment to the patients. These factors influence the patients to come India.

Branding is essential to promote high quality, of Indian Hospitals in International Markets, Low cost compare to developed countries, good infrastructure facilities, like proper sanitation, roads, power back up, accommodation, standards in pricing of procedures in Indian hospitals. This enables market leaders to generate trust among the medical tourist health care is more important to build the brand location like city ,region, country to attract the international patients, stakeholders and partners develop a network synergies , hotels and resorts important in pre-post surgeries India has many hospitals and clinics, Some Indian health care providers provide hospitals and their branches at other countries for the patients who has to get the treatment from India can go for follow up treatment and other purpose, so healthcare providers in India has an advantage to compare to their competitors due to high standards treatments and services offered to patients at a very competitive price and provide valuable information to the patients; this helps them to take informed decision in the available medical treatment. Quality assurance, treatment and service descriptions procedures are provide in internet to attract patients. Most of the healthcare service providers generally need the help of facilitators to promote.

Benefits of MT in India

Through medical tourism the growth of commercial value is exponential, majority of employment is generated [60%] helps to up gradation of facilities, helps to gain knowledge due to different problems of patients, and it helps to learn new techniques in complicated diseases, and makes the organization globally competitive and
also makes friendly atmosphere, main things is improve the Business\textsuperscript{10}

India provide unique basket of health care:

India practicing yoga more than 5000 years ago, people from other countries came to India to learn yoga as well as other alternate medicine and India gets high reputation in cultural, medical and spiritual progress apart from this western medicine became very popular. That is the reason India became destination for the medical travellers \textsuperscript{17}. Tamil Nadu is home land of siddha is consider best alternate medicine, people gets awareness about the healing system, to improve the alternate systems like siddha, government also set up a eco-friendly farm house, by the ministry of tourism\textsuperscript{13}

Government participation:

To promote MT, Ministry of Tourism and The Ministry of Health and Family Welfare jointly formed a force to promote the Health Destinations, this helps to know the foreign patients to choose the places and also provide the infrastructure, and health care expertise. The ultimate aim is to develop the domestic and international markets, the very important thing is to streamline the immigration process government provide the medical visitor and introduce the medical visa [M-visa] this is only for specific period to the foreign patients to get the medical treatment in India, moreover Ministry of Tourism to expand its market development [MDA] to get the International joint commission accreditation [JCI] and National Accreditation Board of Hospitals(NABH) \textsuperscript{6}

Ministry of tourism takes initiative steps to position the brand, conduct exhibition for International travel exhibition, fiscal incentives to medical tourism operators, [providers] ‘Indian Ministry of Commerce created the ‘The India Brand Equity Fund ‘to provide support to the exporters. To set an International standard, Enhance the infrastructure in the cities like Bangalore and Hyderabad, Effective market exercise taken in branding the country\textsuperscript{1}

Impacts of Medical Tourism

Medical tourism is considering conventional tourism. Hotels and travels are byproduct. Many hospitals tie up with the hotels and travel through they arrange and pick up- drops, post surgeries they can arrange the site visits. And provide accommodation in hotels near by the hospitals. It is helpful to the person who accompanied with the patients feel comfortable to stay with them. They booked three star and five star hotel for advanced booking, moreover the resorts near by the hospital also tied up with the hospitals post-surgery they go and enjoy the trip and its very much useful to patients who needs follow up treatments and also can go rejuvenation process like spa’s yoga, etc….These are all cascading effect of medical tourism money being spend throughout host country in many areas it generate the employment\textsuperscript{7}

**Conclusion**

Chennai is called Health capital of India. Internet provides all available information about the Destination countries, hospitals, treatment which they provide, star hotels, accommodations, and other facilities, so patients can choose their wish. The reason is quality accredited hospitals, and skilled doctors available in Chennai. So the star hotels and exotic places attracts the foreign patients and our Ingenious system added value to the medical tourism, nowadays people get more awareness about the alternate medicine, so India has large potential to go further in this market all these things made possible through internet, and patients also gets satisfaction from treatment as well as spend their leisure time in destination countries.

Radicular Cyst Associated with a Primary Molar: A Case Report

Rose Maria Joseph, Karuna Y M, Dharnappa Poojary, Ashwin P Rao, Anupama Nayak P

1Post graduate Student, 2Assistant Professor, Department of Paedodontics and Preventive Dentistry, 3Associate Professor, Department of Oral and Maxillofacial Surgery, 4Associate Professor, 5Assistant Professor, Department of Paedodontics and Preventive Dentistry, Manipal College of Dental Sciences, Mangalore, Manipal Academy of Higher Education, Manipal

Abstract

Radicular cysts are among the most commonly occurring cystic lesions of the jaw, but are relatively rare in the primary dentition. This report presents a case of radicular cyst associated with a grossly carious primary molar. The treatment consisted of enucleation of the cystic sac and extraction of the involved primary teeth with preservation of the permanent tooth bud. At one year follow up, patient showed a complete healing, along with the eruption of the permanent successor. However, the erupted tooth had developmental defects.

Key words: Primary molar, radicular cyst, surgical enucleation

Introduction

Occurrence of radicular cysts are relatively rare in the primary dentition1. In the primary dentition their prevalence is only 0.5-3.3% of the total number of radicular cysts seen in both the primary and permanent dentition1,2. In children they are mostly seen associated with mandibular primary molars3.

Radicular cysts arise from epithelial remnants of the periodontal ligament as a result of inflammation and inflammatory cell infiltration due to pulp necrosis. These cysts are commonly found surrounding the apex of the affected tooth2,3. Dental caries is the most frequent etiologic factor suggested for radicular cysts4.

In most cases these cysts are slow growing and asymptomatic unless secondarily infected4. However, they may rarely cause expansion of the cortical plates and delayed eruption, malposition and enamel defects of the developing permanent successors when they are seen in primary dentition1,5. Surgical enucleation of the cyst with extraction of the associated primary teeth and preservation of the permanent tooth bud is the treatment of choice when the cystic lesion is small in size1,6. Marsupialisation for decompression of the lesion is suggested in case of larger cysts4. Rate of reoccurrence is low following adequate treatment4. Present case describes the surgical enucleation of a radicular cyst associated with a primary molar, along with the post treatment outcomes at one year follow up.

Case report

A 7-year-old female patient reported to the Department of Paedodontics and Preventive Dentistry, MCODS, Mangalore with a chief complaint of multiple decayed teeth (Fig. 1a and 1b). No history of pain was reported with any of the decayed teeth. No other intraoral or extraoral abnormalities were evident during clinical examination.

An orthopantamogram (OPG) was advised due to the presence of multiple decayed teeth in all four quadrants. OPG revealed root stumps in relation to mandibular primary right second molar (85), with a unilocular well defined peri-radicular radiolucency of
size 15mm × 10mm extending from the distal aspect of mandibular primary right first molar (84) and tooth bud of mandibular right first premolar (44) to the mesial aspect of permanent mandibular right first molar (46) involving the tooth bud of mandibular right second premolar (45) and deflecting its position (Fig. 2).

Based on the clinical and radiographic findings, a provisional diagnosis of radicular cyst was made in relation to root stumps of 85. Surgical enucleation of the cyst following extraction of 85 was planned under general anesthesia (GA) after consulting with the Department of Oral and Maxillofacial Surgery and after obtaining informed consent from the parent. Following enucleation the cyst specimen was sent for histopathological examination, which revealed the presence of connective tissue capsule with dense collagen bundles and moderate amount of inflammatory cell infiltration. Patient was recalled after one week for suture removal and was then followed up for one year.

Recall visit at 3 months showed complete healing of the surgical wound and erupting 45, which had hypoplastic defects of the crown clinically and abnormal root development radiographically (Fig 3a and 3b). Clinical examination at 1 year follow up showed continued eruption of 45 (Fig 4) and the OPG showed thickening of the root canal walls of 45, while the root form still remained abnormal (Fig 5).

**Discussion**

The comparatively low prevalence of radicular cyst in relation to primary teeth is because pulpal and periapical infections in deciduous teeth tend to drain more readily than those of permanent teeth. Radicular cysts are usually asymptomatic till secondarily infected and are diagnosed during routine radiographs.

The sequelae of an untreated or undiagnosed radicular cyst of a primary tooth could be harmful to the patient’s secondary dentition, due to its anatomical positioning. The sequelae may include delayed eruption, malposition or enamel defects of the permanent successor. In the present case the cystic lesion had caused deflection of the permanent tooth bud as noted in the pre operative radiograph and hypoplastic defects along with abnormal root development involving 45 as noted during the follow up visits.

In a case report by Narsapur et al the radicular cyst had deflected the permanent tooth bud to the base of the mandible because of which it was extracted. Spontaneous realignment of deflected permanent tooth buds following cyst enucleation has also been mentioned in the literature, as observed in the present case. Gupta et al reported malformation of the permanent tooth as the result of a large radicular cyst in the primary molars in maxilla. The authors removed the malformed tooth along with enucleation of the involved cyst. In our case the tooth successfully erupted into the oral cavity inspite of hypoplastic defects and abnormal root development. Abnormal root development was also reported by McDonnell et al wherein the permanent successor had partially erupted as a sequelae to carious primary predecessor owing to the effect of persistent infection.

Most frequently encountered cysts in a mixed dentition are either a radicular cyst associated with a primary molar or a dentigerous cyst in association with an unerupted premolar. According to a study by Manekar et al in most cases of dentigerous cyst the preceeding primary tooth will be vital as opposed to a carious and non-vital primary tooth found in radicular cysts. The bony expansion resulting from the cystic lesion is very limited in case of radicular cysts. Periapical cementoosseous dysplasia (PCOD) or traumatic bone cyst may also be difficult to distinguish radiographically from a radicular cyst. But, like in the case of dentigerous cyst the primary tooth pulp is vital and healthy in these conditions too. In the present case, the cystic lesion was associated with grossly carious and non vital 85 with minimal bony expansion. These observations along with the radiographic examination helped us in making a diagnosis of radicular cyst in relation to 85.

**Fig 1a and 1b. Preoperative occlusal view of maxillary and mandibular teeth respectively**
Conclusion

Radicular cyst of a primary tooth may have damaging sequelae in the form of affecting the underlying developing permanent tooth bud, if it goes undiagnosed and untreated. Thus, early diagnosis and management of such pathologies are of paramount importance.

Abstract

Introduction: Commination of articular surfaces and metaphyseal region, extensive soft tissue injuries, infection and risk of compartment syndrome are the challenging factors in management of Tibial Plateau Fractures. Various modalities like cast, traction, external fixation and open reduction and internal fixation with plating are the available options for treating such complex fractures. In this study we prospectively analysed the functional outcome of fixation of tibial plateau fractures based on Luo et al’s “Three-Column Concept” fracture classification.

Materials and Method: In this study, twenty patients with complex “three-column tibial plateau fracture” were followed up prospectively clinically and radiologically for a duration of 6 months. After an initial conservative management all patients underwent buttress and supporting multiple plate fixation depending on the specific column involvement of proximal tibia. Final outcome assessment was done with IKDC 2000 & Functional and Subjective Knee society score (KSS) based on functional outcome, fracture union, articular congruity and deformities, if any.

Result: 90% (18/20) of patients showed excellent results according to objective and subjective knee society scoring, whereas 10% (2/20) developed complications postoperatively.

Conclusion: The results of this study concluded that multiple plate stabilization of complex “three-column tibial plateau fracture” is an excellent modality of treatment with minimal complication rate, of these otherwise difficult to manage fractures with other traditional methods.

Keywords: Three-Column Tibial Plateau Fracture, Multiple Plate Stabilization.

Introduction

Knee Injuries sustained in high energy trauma is invariably a combination of complex fracture configuration of proximal tibia along with severe soft tissue injuries due to axial loading combined with valgus, varus and rotational stresses.

Proper implant selection and surgical technique plays an important role to maintain joint stability, congruity, and alignment without much soft tissue dissection thereby achieving early mobilization and preventing late degenerative arthritic changes and stiffness. Open reduction and internal fixation with multiple plating is the corner stone in the management of these otherwise difficult to manage three-column fractures.
proximal tibial fractures. With this treatment modality proximal tibial native anatomy is restored with resultant excellent postoperative functional results.

Posterior tibial plateau fracture (PTPF) is a relatively uncommon injury, with an incidence of 28.8%\textsuperscript{4}. Among the available classifications, Schatzker and AO Classification are widely used, however, these classifications restrict themselves to fracture anatomy and do not help much in deciding the approach and predicting the outcomes. Luo’s Classification added a new dimension by describing the posteromedial and posterolateral column and propounded the “three column concept” of articular area\textsuperscript{5}. Occurrence of a posteromedial fragment was observed in nearly one third of the bicondylar tibial plateau fractures evaluated by CT scan by Barei et al\textsuperscript{6}. The morphologic features of this fragment has clinical implications when using currently available laterally applied fixed-angle screw/plate implants to stabilize these injuries\textsuperscript{7}.

Recent surge in exploring these fractures which have posterior tibial condyle fracture through posterior approaches like Direct posterior, Burke’s, Lobenhoffer have enabled surgeons to tackle these difficult fractures more accurately\textsuperscript{8}.

**Material and Method**

In this prospective study 20 skeltally mature patients were followed up who underwent open reduction internal fixation with multiple plate stabilization of complex three column proximal tibial fracture as classified by Luo et al\textsuperscript{(5)}. Patients with pre-existing deformity, all open fractures, polytrauma, pathological fractures, fractures with ipsilateral neuro-vascular deficit, floating knee injuries or those associated with patella fractures, skeletal immaturity and fractures older than 4 weeks were excluded from this study.

Preoperatively, depending on severity of injury patients were managed conservatively in the form of immobilization and elevation of involved limb with skeletal traction or long leg above knee slab till the subsidence of proximal leg swelling and improvement of the skin condition. Once the soft tissues were amenable to surgical intervention, definitive three-column stabilization of the involved fractured proximal tibia was planned.

Luo et al’s “Three-column concept” classification system which divides proximal tibial plateau fractures into lateral, medial and posterior column as seen on axial plain CT scan images and 3-D reconstruction was used as our standard classification for all our patients\textsuperscript{5,9}.

In our study, we exclusively included Luo et al’s three-column fracture types. The column borders are demarcated by four points on the transversal CT-image: point O represents the artificial axis of the 3 columns and is defined as the midpoint between the two tibial spines; point A is found on the anterior tibial tuberosity and, when connected to point O, it divides the lateral and medial column; point B represents the posteromedial ridge of the tibial plateau; point C represents the most anterior border of the fibular head, when connected to point O, divides the lateral and posterior column(figure-1).

A combination of 4.5 mm locking plates, dynamic compression plates (DCPs) and precontoured periarticular locking compression plates were used as a buttress on the compressible side and supporting plates on the tensile side of the three column tibial plateau fracture. Lateral and posteromedial/reversed L shaped approaches to proximal tibia were used.
Post-operatively, Ankle pumps, active quadriceps and toe movements were allowed immediately. Partial weight bearing was initiated at 8 weeks and full weight bearing was allowed at 12 weeks post-operative after clinical and radiological confirmation of bone healing.

All patients were followed up at 2 weeks interval for first 6 weeks and there after at 4 weekly interval for a total 6 months, postoperatively. International Knee Documentation Committee (IKDC 2000) subjective knee evaluation and objective functional Knee Society Score (KSS) were used to assess post-operative knee function in all our cases. At 24 weeks follow up, all patients were subjected to CT scanogram and x ray evaluation to assess for fracture healing, articular congruity, limb alignment and any remanent deformity. Clinically, knee was evaluated for Range of movement, Extensor lag, Flexion deficit, pain scores, knee instabilities and deformities.

Result

In this study 20 patients with three-column proximal tibial fracture according to Luo et al’s “three-column concept”classification were followed up prospectively clinically and radiologically for a duration of 6 months.

As sited in table-1, patients age ranged from 20 to 60 years, with mean age of 41.45±10.46 years. 19(95%) patients were male, while 01(5%) was female. Right limb was involved in 12 patients(60%) whereas left was involved in 8 patients(40%).19 injuries(95%) were due to high energy trauma because of road traffic accidents and 01 (5%) was due to sports injury.

18 patients (90%) were surgically managed by a combination of one 4.5 mm locking or dynamic compression plate (DCP) used as a buttress plate on the compression side and one low profile 1/3rd semitubular plate or precontoured periarticular locking plate used as supporting plate on tension side of the three-column fracture of tibial plateau. In 2 patients (10%) a
combination of two buttress plates and one supporting plate was used for adequate three column proximal tibial fracture stabilization. 18 patients (90%) achieved excellent (80-100), 1 (5%) achieved good (70-79), 1 (5%) achieved fair (60-69) objective knee score and. 18 patients (90%) achieved excellent (80-100), 2 (10%) achieved good (70-79) subjective knee score.

As listed in table-2, Operation time ranged from 90 to 120 minutes with average blood loss of 147+ 37.57 ml. Post operative hospitalisation was an average 9.00+ 2.66 days. Fracture union was achieved in all patients with average union time of 15.85±2.94 weeks. Mean International Knee Documentation Committee (IKDC) score was 68.26+_8.00. Mean range of knee flexion was 115 degrees.

In our study, complications were observed in 2 patients (10%). 1 patient (5%) developed superficial wound infection one week postoperatively which was successfully managed conservatively. 1 patient(5%) complained of hardware irritation on the lateral side, necessitating removal of lateral supporting plate at 12 weeks post-operatively.

Discussion

Comparable with other studies we had high male/female ratio (19:1)\(^3\). This can be attributed to higher number of males involved in high energy trauma than females. The average operation time of 120.50+ 21.34 minutes in this study is on the higher side as compared to other studies where other traditional methods were used\(^7\). Our three-column proximal tibial stabilization technique had a favourable immediate post-operative outcome with average hospitalisation of 9.00+ 2.66 days and average blood loss of 147+ 37.57 ml. Final radiological and functional outcome; average union time of 15.85+ 2.94 weeks, average IKDC score of 68.26+ 8.00 and average ROM of 115 degrees was comparable with similar studies\(^3\).

As is true for any successful fracture management the first prerequisite is a standardised and descriptive classification system of the involved fracture. The Luo et al’s “three-column concept” tibial plateau fracture classification system\(^6\) based on CT scan evaluation\(^9,10,11\) of the proximal tibia has overcome the inherent falacies in management of these fractures especially involving the posterior column\(^11,12\), associated with other common classification system like Schatzker and AO\(^13\).

A well-designed preoperative surgical strategy which would precisely reduce the fracture fragments providing a congruent joint surface along with minimal soft tissue handling holds the key in successful management of these otherwise difficult to treat fractures. A number of treatment modalities with their share of favourable outcomes and complications have been tried such as Simple Skin Traction, Cast Immobilization, External Skeletal Fixation, Minimally Invasive Techniques (LISS system), Arthroscopically Assisted Fixation, Minimal Percutaneous Pinning and Open Reduction and Internal Fixation with available implants\(^1,7,14\).

Conservative treatment of proximal tibial plateau fractures are not favoured anymore because of prolonged

immobilization and poor functional outcome\textsuperscript{19}. Though, Arthroscopically assisted fixation and minimal percutaneous pinning have shown good results but find use only in limited situations like simple split depression and local compression fractures\textsuperscript{19}. Pin tract infection and prolonged course of treatment has made Hybrid fixation system out of reckoning\textsuperscript{20,21}. However, some studies have reported favourable outcome with open lateral plating and medial uniplaner fixator in complex bicondylar fractures \textsuperscript{21}. Minimally invasive techniques (LISS system)\textsuperscript{22} by their inherent property of preserving soft tissues have given good results but because of limited exposure in these techniques the intraarticular congruency is invariably not achieved leading to early osteoarthritic changes.

In the present study a new concept of three-column fracture fixation as proposed by Luo et al was used to fix comminuted tibial plateau fractures with a buttress plate on compressile side and with low profile supporting plate on the tensile side instead of rigid dual plate fixation. A main buttressing plate is placed first to reconstruct the posteromedial ridge followed by an anterolateral supporting plate which is placed to prevent over reduction. In 18 patients (90\%) we could achieve good stabilization of three-column fracture configuration of proximal tibia by using only one buttress plate and one supporting plate. 2 patients (10\%) required an additional supplementary buttress plate to adequately fix the posterolateral column. Similar technique was used by other authors like Wang et al\textsuperscript{23} with comparable functional results. Intraarticular congruency and fracture union so achieved in all our patients with minimal complications suggests the significance and superiority of this treatment modality over other methods.

**Conclusion**

The new “three-column concept” of tibial plateau fracture fixation has revolutionized this otherwise very challenging situation to manage. This new treatment modality based on three-column concept has made it possible to identify precisely the integrity of posterior articular surface or posterior column, the absence of which leads to an incomplete treatment plan as is true with other traditional surgical modalities. This new concept has made it possible to restore alignment and intraarticular congruency in comminuted tibial plateau fracture. This technique thus has grossly reduced high incidence of early osteoarthritis, pain and disability in long run which was rampantly present in other surgical techniques.

Assessment of the Oral Health Status and Erosive Tooth Wear among Employees of a Petrochemical Industry in Mangalore, India

Vaibhav Pravin Thakkar¹, Ashwini Rao², Rajesh G³, Ramya Shenoy³, Mithun Pai B.H³

¹Ex-PG Student, Department of Public Health Dentistry, Manipal College of Dental Sciences, Mangalore, Manipal Academy of Higher Education (MAHE), Manipal, Karnataka, India, ²Professor, ³Associate Professor, Department of Public Health Dentistry, Manipal College of Dental Sciences, Mangalore, Manipal Academy of Higher Education (MAHE), Manipal, Karnataka, India

Abstract

Objective: To assess occupational exposure to acids and its possible impact on oral health of individuals.

Method: A cross sectional descriptive survey was conducted on 597 employees. A calibrated questionnaire was administered, oral health status of the employees was assessed using WHO Oral Health Assessment Proforma and Erosive Tooth Wear was measured using Basic Erosive Wear Examination (BEWE).

Results: 49.9% employees presented with some form of erosive tooth wear. Employees who had more frequent exposure to acid fumes at work showed more dental erosion (Chi-square test, p < 0.05). Also it was observed that the prevalence of dental erosion increased with increase in work experience of the employee (r = 0.392, p < 0.01).

Conclusions: There was a high prevalence of erosive tooth wear among the petrochemical workers and necessary safety precautions and preventive interventions are recommended.

Keywords: dental erosion; occupational health; oral health; basic erosive wear examination

Introduction

Oral health is the standard of health of the oral and related tissues which enables an individual to eat, speak and socialize without active disease, discomfort or embarrassment and which contributes to general well-being.¹ During a lifetime, teeth are exposed to a number of physical and chemical insults resulting in wear and tear of dental tissues owing to abrasion, attrition, abfraction and erosion. All of these factors result in tooth wear either from the simultaneous and/or synergistic action of these processes.² Erosion is chemical wear as a result of extrinsic or intrinsic acids or chelators acting on plaque-free tooth surfaces. The result of continuing acid exposure, however, is not only a clinically visible defect, but also a change in the physical properties of remaining tooth surface.³

Every workplace is really a work environment where there are interactions between people and the chemical and physical demands involved with performing the job.⁴ In many occupations these interactions are the foundation of health problems among workers. Hence maintenance of ‘healthy’ work environment is given importance in society. Industrial hygiene and the term ‘occupational health’ encompasses all principles related to the same.⁵ One of them is to provide a safe ‘occupational environment’ in order to safeguard the health of workers and to step up industrial production. Oral cavity is vulnerable to external agents and some occupational exposures are associated with oral changes in both hard and soft tissues.⁶⁷ Occupational dental erosion is one such dental health problem encountered in
various industries and is caused by exposure to various types of acidic contaminants in workplace.\textsuperscript{4,8,9,10,11} 

Assessment of effect of environmental exposure to acids has received much attention in recent years and has been the subject of numerous articles published in scientific literature in the recent past.\textsuperscript{4,6,7,9,12} Occupational exposure to acids and its consequences on general and oral health has been identified as “a challenge for the 21st century.” \textsuperscript{13} However, there is a definite paucity of literature on the oral health status of workers in petrochemical industry in this part of the country. Therefore, present study was conceptualized to assess oral health status and erosive tooth wear among employees of a petrochemical industry in Mangalore.

**Material and Method**

Cross-sectional descriptive study was conducted among employees of a petrochemical industry in Mangalore. Basic information was obtained using a questionnaire. Oral health status was assessed using WHO Oral Health Assessment proforma\textsuperscript{14} and erosive tooth wear using Basic Erosive Wear Examination\textsuperscript{15} (BEWE) scoring system. Employees were classified as Type-A; who worked in the core area of refinery (continuous exposure) and Type-B who were not exposed continuously to acid mists (intermittent exposure) which included the ones in administrative block and house-keeping staff. A total of 1,500 employees at the petrochemical industry formed sampling frame and simple random sampling technique was employed to select the study subjects.

Based on the pilot study, prevalence of tooth wear in employees was found to be 40%, considering 10% permissible error at 95% confidence interval, total sample size was estimated to be 600.

Male or female participants aged between 18 and 59 years who gave written informed consent form were included in the present study. Only the employees with work experience equal to or more than a year were included.

Subjects with medical conditions such as Gastro Esophageal Reflux Disease (GERD), Anorexia Nervosa, Bulimia, Bronchial Asthma, Diabetes Mellitus, hypertension, Coronary Heart Disease, Sjogren’s syndrome, subjects undergone head and neck irradiation, immuno-compromised individuals and pregnant subjects were not included. Bruxers with a score of 6 or more were excluded.\textsuperscript{16}

Data collection was started after obtaining approval from Institutional Ethics Committee.

Prior to conducting survey, calibration was done to establish intra-examiner reliability.\textsuperscript{17} Kappa value obtained was 0.951 indicating almost total agreement.\textsuperscript{18} Assessment of inter-examiner reliability for recording levels of dental erosion using BEWE Index showed there was almost total agreement (Kappa value = 0.896). Reliability of questionnaire was measured and Cronbach’s alpha value\textsuperscript{19} of 0.85 was obtained indicating good reliability. All the subjects were provided with a patient information sheet and a written informed consent was obtained from them before examination. The data was coded and analyzed using the SPSS version 11.5. The level of statistical significance was kept at $p < 0.05$. Chi square test and binary logistic regression were used for analysis of collected data.

**Results**

600 workers were examined in this cross sectional survey. All employees used protective footwear and helmets but none of them used face masks. Mean age of the study population was $30 \pm 8.6$ years. Standard method was used to investigate bruxism\textsuperscript{16} and only 3 subjects classified as bruxers were excluded from the study making the total study population 597.

60.1% of the employees consumed carbonated soft drinks and 4 employees preferred having bottled soda on occasional basis. 39.2% of the employees preferred non-carbonated drinks for consumption. 24% of the employees were smokers, 42.5% were tobacco chewers and 31% consumed alcohol.

Mean DMFT was $2.86 \pm 3.07$ and number of employees with decayed, missing and filled teeth being 67.3%, 26.5% and 12.7% respectively. Mean number of teeth with decayed, filled and missing component observed in this population were $1.9 \pm 2.14$, $0.6 \pm 1.3$ and $0.3 \pm 1.0$ respectively. Dental caries prevalence in this population was 67.3%. 54 employees (9%) showed presence of anterior tooth trauma and most of them recalled of accidents at the industrial site as the cause of trauma. Periodontal status of employees was recorded using the Community Periodontal Index (CPI). The analysis showed that 66.3% of the employees had
Calculus as the highest score for CPI whereas 87.4% of the employees did not have any loss of periodontal attachment.

Prevalence of erosive tooth wear was higher in Type-B employees (261/484) as compared with those in Type-A (37/113) and it was statistically significant (Chi-square test, p < 0.05). Odds ratio reported was 2.4 (95%CI: 1.5-3.7) There was significant increase in disease rate with increase in work experience. Using bivariate analysis it was found that correlation was statistically significant at p = 0.01 level between these two variables. (r = 0.392)

Depending on the number of years of work experience in the industry, study population was divided as; Group I (n=334) having work experience from 1-4 years and Group II (n=263) with a work experience of more than 4 years. Using Chi square test it was observed that prevalence of dental erosion appeared to be more in group II and it was statistically significant (p < 0.001). The odds ratio reported was 5.4 (95% CI: 3.8 - 7.7)

Discussion

The total numbers of employees examined for this study were 600, three employees were classified as bruxers and excluded. Hence, the final study population consisted of 597 employees.

Only 3% of the population presented with a medical condition. This could be attributed to the healthy worker effect. 20,21
There was no statistically significant difference between employees with erosion and without erosion in the habit of consumption of carbonated beverages \( (p = 0.080) \). On the other hand there was a statistically significant difference between employees with and without erosion when fruit juice consumption and habit of alcohol consumption were considered \( (p<0.05) \). This can confound the results obtained in the present study as consumption of these beverages is associated with development of dental erosion.

Caries prevalence in this population was less than the previously reported values.\(^{33}\) The mean number of decayed teeth \( (1.9 \pm 2.14) \) observed in this population was less than that seen in earlier studies where it was 2.6 and 3.8 reported by Dale et al\(^{14}\) and Petersen et al\(^9\) respectively. The missing and filled component among the employees was less as compared to those observed in previous studies.\(^{33, 34}\)

Most severe condition in 66.3% of population in relation to periodontal health was deposition of calculus on tooth surface. This finding was similar to that reported by Wierzbicka et al.\(^{35}\) Prevalence of periodontal pocket was more in Group II employees and is in agreement with the previous reports.\(^{8, 33, 36, 37, 38}\) 12% of the employees reported to have some loss of attachment. No previous study could be found presenting the loss of attachment in the workers exposed to acid fumes at workplace.

Previous studies\(^{9, 37, 38, 39, 40}\), have reported that exposure to acid fumes was related to loss of tooth surface, leading to loss of teeth and eventually high number of employees were observed to use prosthesis for the same. In the present study, need for dental prosthesis was very less.

High prevalence of dental erosion (Table 1) in this study population is in line with other reported studies where prevalence ranged from 30-60%.\(^{8, 9, 12, 38, 39}\) However, these results are different from study done by Chikte et al\(^{10}\) where 90% of exposed population presented with dental erosion. This high rate of dental erosion was not reported even in the Group II employees. Prevalence of dental erosion was more in the Type-B employees which was consistent with that reported earlier.\(^{10, 12, 38, 39,}\)

At the surface level it was observed that the prevalence of erosive tooth wear was more on facial/buccal surface and second sextant i.e., maxillary anterior segment was the most severely affected one with dental erosion. (Fig.1)

On an average this population lies in the low risk category (mean cumulative BEWE Index score 2.13 \( \pm 2.99 \)) of the risk levels given by Bartlett et al.\(^{15}\) Recommendations for the low risk level are oral hygiene, dietary assessment and advice, routine maintenance and observation and repeat observations at 2-years interval. For employees with higher scores recommendations given by Bartlett et al\(^{15}\) should be followed for maintenance of proper oral hygiene and prevention of progression of lesions.

Further studies should be done with a well-designed case-control methodology with proper matching among cases and controls to determine the effect of exposure to petrochemicals at workplace on oral health. A prospective cohort study can also be recommended in this population. The amount of sulphuric acid present in the air at different sites in the industry has to be measured and safety precautions to be taken accordingly. Along with all the safety measures taken in the industry for prevention of accidents, the employees should be recommended to have proper oral hygiene practices, maintain the health of their oral cavity and lead a socially and economically productive life.

Contribution of Metagenomics Towards Identification of Oral Flora - A Review

Anitha Balaji¹, Krishnan Mahalakshmi², Jagadeesan Aarthi³, Mohan Valiathan¹, Radhakrishnan Mensudar⁴

¹Professor, Department of Periodontics, ²Professor, Department of Microbiology, ³Senior Lecturer, BIHER, Chennai

Abstract

Oral flora has always presented itself in a perplexing way in terms of its biodiversity and niche. Over the years numerous techniques have been used to identify and relate these microbes to oral and systemic diseases. Recently, metagenomics has gained predominance in this field due to its potential in detecting non-cultivable flora. In the previous decade several reports have been published on identification of floral pattern, new flora and relation of such patterns to pathological processes and risk marking. But a consolidated review, linking these to actual pathology is still not published. This review provides an insight into current status of such associations.

Keywords: Metagenomics, oral microbiome, identification,

Introduction

Oral cavity acts an ecological niche to innumerable number of microbes that exist in a symbiotic relationship. Although their presence is not always alarming, understanding their role and identity has enriched our knowledge on prevention, intervention and control of oral diseases. It has also been known for long that certain set of bacteria are prevalent in certain disease conditions, opening the vista to unlock the relation between floral identity, count or pattern with specific diseases. With an extensive microbial flora present in the oral cavity, not all organisms are cultivable and this leads to the need for genetic methods in order to identify them.

In this view, microbial gene sequencing tools have evolved from a large extent from laborious time consuming methodologies to recent real-time detection techniques come. Genome sequencing especially the Next Generation Sequencing (NGS) method has revolutionized the landscape of microbiology and thus the detection of infectious diseases.¹

The past decade has seen a huge surge in research relating oral flora to oral and systemic diseases. Metagenomics is an equitable way of identifying and studying micro-organisms in their habitat, without culturing them. Oral cavity is known to provide two primary surfaces for microbial colonization - the Mucosa (soft tissue) and teeth (hard tissue).³ Thus, the oral microbiome plays an important role in both healthy and diseased conditions. Of the identified flora, most of them are uncultivable bacteria.⁴⁵

Current evidence suggests the need for biofilm formation for the occurrence of oral infection diseases.⁶ Thus, the microbial composition in different clinical scenarios remains hitherto unexplored. The role of traditional microbiological methods is presently unsatisfactory since most of the bacteria are uncultivable. The newer technology to analyze the microbial population include bioinformatic analysis, DNA-based analysis (Meta-genome), RNA level (Meta-transcriptome), protein composition of the oral microbiome (Proteome), and functional activity microbial population (Metabolome).⁷ Currently, metagenomic analysis plays a vital role in evaluating the complex oral microbiome.

The term ‘Metagenomics’ was first coined by Jon Clardy and Robert M. Goodman who first published their data in 1998. It has been defined as the genomic
analysis of micro-organism by direct extraction and cloning of DNA from an assemblage micro-organism. In Greek, ‘Meta means transcendent’ (Combination of separate analyses). Genomics refers to the study of genome. It differs from the traditional genomic segment in many ways. Metagenomics requires greater attention to sampling and assessing the diversity of a sample and extracting the appropriate nucleic acid from the sample is highly challenging.

The first completed sequence of microbial genome was published in 1955. Numerous genome of oral pathogens have been sequenced and the details of these genomes have been reported by various authors. Earlier it had its reports mostly in ecological analysis (Environmental Genomics). Currently, a wider application into medical sciences as clinical metagenomics is being used for detecting and analysing non-cultivable pathogens.

Microbial metagenomics widely involves 2 possible and parallel strategies:

Targeted-strategy known as Deep Amplicon Sequencing (DAS)

Shotgun metagenomics, which is a much broader analysis.

The sequence-driven approach has limited existing knowledge. If the metagenomic gene does resemble the gene deposited in the database little is learned about the gene or its products from its sequence alone. In the function-driven approach most of the genes cannot be expressed easily by a surrogate host. Thus both these approaches are complimentary and should be pursued in parallel.

In dentistry, metagenomics can identify specific metabolic pathways and genes associated with oral diseases, produce large amounts of genomic information regarding oral microbiome, help to elucidate the potential role of oral bacteria in the initiation and establishment of dental biofilm, enable characterization of bacterial flora present in the endodontic system in order to establish their aetiology thus enabling appropriate treatment for specific diseases. In simpler words, metagenomic analysis helps to elucidate the role of specific pathogens in disease progression thus enabling us to identify the pathogenesis of microbial diseases.

Recently, numerous studies have been reported on applications of metagenomics in dentistry. Burczynska et al. 2017 has reported the application of metagenomics in dentistry with a focus on microbial diversity. It is also noted that metagenomic analyses have improved the speed of microbial identification as reported by Lazarevic et al. (2009) and Hasan et al. (2014). This review provides insight into available literature on metagenomics and oral microbial flora and its future perspective.

Microbial prospecting of biodiversity:

The presenting problem of biodiversity is its consequence on treatment plan. The intervention planned has to focus on the offending microbiota rather than non specific antimicrobial therapy. Metagenomics has contributed immensely to the identification of new species in oral flora which has in turn led to the exploration of unforeseen organisms in the oral cavity. This could be a possible breakthrough in our knowledge towards the etiopathogenesis of various oral diseases. Parahitiyawa et al. (2010) has reported more that 700 species as inhabitants of oral cavity.

Dridi et al. (2011) has reported Archaea spp in oral cavity, which is well beyond its natural habitat of extreme environments. Recently, many new serotypes, phylotypes of known species and new species have been identified. Parahitiyawa has reported that 42% of clones isolated from 2 root canals were yet to be phylotyped. Heller et al. (2016) has studied the biodiversity of dental plaque during its formative stages.

Wylie et al. has established the presence of double stranded DNA viruses in healthy adults such as herpesviruses, papillomaviruses, polyomaviruses, adenoviruses, anelloviruses, parvoviruses, and circoviruses. Interestingly, Moon and Lee (2016) have shown interest in the field of personalized microbiome using bioinformatics approach. With metagenomics, we see surprising microbes in unexpected places, staying symbiotically in the niche, without showing apparent pathogenesis. In such a scenario, it is necessary to establish this personal microbial signature, before grading its presence as pathology.

Wang et al. (2016) has explored phage-bacteria interaction in human oral microbiome. They have shown the invasion of phages in non putative bacteria, showing the phage-bacteria interaction in oral cavity.
Ma et al. (2014) have reported the complexity of Human Pappilloma Viruses (HPV) in the healthy individuals, challenging the existing association of HPV in human diseases. They have also identified new types of HPV beyond the known 109 types.

Biogeographical investigations and clinical implications:

Numerous works reported regarding the microbiota or metagenomics of specific niche in the oral cavity has essentially paved way to split oral cavity in to several sub-niche areas for better understanding of pathogenesis. Human microbiome project has substantially helped to identify such species in addition to bioinformatics.

Gingival biogeographic studies have been conducted by various investigators. Comparing subgingival plaques from postmenopausal women, it was observed that out of the 464 species identified, 22.8% had elevated abundance in disease, while only 6.3% had elevated abundance in health according to LaMonte et al. (2018). In cases of chronic periodontitis, subgingival flora has shown a notable contrast. Streptococcus was dominant in all healthy samples, while Prevotella, Porphyromonas, and Treponema dominated in all samples obtained from diseased individuals.

In cases of peri-implantitis, Fusobacterium nucleatum and Prevotella denticola were more prevalent in samples inhabiting the biogeo graphic picture on implant surfaces. But Cortês-Acha et al. (2017) suggested that flora colonizing the exposed dental implants form a distinct microbiome, independent of the patient’s periodontal profile.

Similarly, tongue coating in children with halitosis has been metagenomically analyzed and found to contain different flora. Prevalence of Leptotrichia wadei, Peptostreptococcus stomatis and Prevotella shahii were higher in subjects with halitosis.

Biodiversity and its relevance to oral/systemic diseases

Human oral microbiota is related to oral and systemic diseases in an intricate way. Though the microbial identification is an age old process, new methods have regrouped the previously grouped species, according to functional and molecular basis. This offers better edge when predicting and prognosing the underlying disease conditions.

Certain studies have also seen the variation in flora with respect to different systemic parameters. Human salivary microbiome is known to show circadian variations according to Takayasu et al. While inter individual variations were high, intra individual variations were low. Streptococcus, Gemella and Prevotella showed high association with the circadian oscillation. In vitro incubation abolished the oscillation, strongly associating the host mediated factors in the changes. In addition to oral disease diagnosis and prognosis, Anukam and Agbakoba (2017) have reported the change in oral microbiome with respect to reproductive age and cycle in women.

A recent study has related microbiota to postoperative inflammation in cleft lip and palate patients. Pre-operative samples have showed inflammation-related flora like Tannerella, sp., Porphyromonas sp., Gemella sp., Moraxella sp., Prevotella nigrescens, and Prevotella intermedia. This model of Liu et al. (2016) showed sensitivity and specificity of 76.9% and 86.7% respectively. They suggest that the oral microbiota profile before alveolar bone grafting may be a good technique to include in the arsenal of investigations to predict the risk of post-operative inflammation at grafted sites.

In a recent research, loss of diversity in oral flora has been consistently noted in periodontitis, attributing predictive value to metagenomic sequencing techniques. Typically they have noted a statistically significant correlation between P. gingivalis population and other marker microbes, as the periodontitis progressed. In a review Zarco et al. (2011) indicated a shift in the microbiome during disease progression. Chen et al. (2017) has noted that bacterial community assembly is robust against disturbances such as periodontitis. Patients with periodontitis are said to exhibit higher biodiversity of flora. This is in contrast with Ai et al. (2017), who reported a decrease in biodiversity.

Hence, at this juncture, potential predictive value of metagenomics has to be ascertained. Liu et al., has reported the disease microbiome to be highly enriched in virulence factors and specifically adapted to a parasitic lifestyle that takes advantage of the disrupted host homeostasis. Wang et al. (2013) has shown that there is an upregulation of functional genes and their consequent metabolic pathways like bacterial chemotaxis in
the microbiomes of periodontal disease. This fact was further confirmed by Shiba et al. (2016) in their metatranscriptome analysis of mRNA and rRNA. Shi et al. (2015) has achieved 81% accuracy in finding the clinical states of subgingival plaque from microbiome studies, where they characterized the subgingival microbiome of individual tooth sites before and after treatment using a large-scale metagenomic analysis. Chen et al. (2017) has analysed oral microbial diversity in health and disease and proposed that the analytical data can provide clues for preventing or curing certain oral conditions by adjusting the disturbed microbial compositions in oral disease to healthy level. Oral microbiota has been reported to undergo significant change in the quality and quantity of bacterioides and proteobacteria, in chronic hepatitis B cases, giving characteristic changes in tongue colour. Oral microbiota has also shown significant changes due to acculturation-related variables, such as nativity, age at immigration, time of stay in a country etc.

Though the oral microbiota may not be a causative agent for infectious diseases, their pattern has shown to enhance our capacity to identify the underlying disease process. Metagenomics has been seen an emerging biomarker for cancer prediction, especially, where Mycoplasma salivarium was proposed as a biomarker for oral carcinoma. Also, salivary microbiome is seen as a great tool of screening and diagnosis. Changes in oral metagenomic pattern was seen in long time sailors, where the diversity is reduced five fold in 120 days and oral flora showed pathological changes.

As understandable, Dysbiosis of buccal mucosa is evident in Oral Lichen Planus (OLP). According to He et al. (2015) four abundant bacteria exhibited significantly different prevalence at the genus level as follows - Streptococcus was more abundant in healthy control group, while Fusobacterium, Leptotrichia and Lautropia showed higher abundance in OLP group. They also noted differences between erosive and non-erosive OLP.

**Conclusion**

Current changes in lifestyle trends states that the human is a “super organism” with more than $10^{12}$ individual micro-organisms coexisting within the human body, which together makes up the human microbiome. WHO reports that around 60 to 90% of oral disease mainly includes periodontal disease and dental caries. Metagenomics is in its early stage of its development but in future, it will revolutionize the clinical diagnosis. It will enable to identify new enzymes and antibiotics. Only few studies have been conducted in dental patients. Thus in future, metagenomic techniques will help us to know the role of various oral microbiota composition, its function and also its relation to pathogenesis of oral infectious diseases. Future research utilizing sequence-based and functional metagenomics will provide an insight in understanding the diversity of the oral microbiome, which will eventually make an impact on clinical decision making to manage the pathogenic bacteria.

Abstract

Introduction:- Diabetes is a chronic disease marked by higher level of blood glucose from defects in insulin production, insulin action or both. According to a recent World Health Organization (WHO) report, India, with 32 million diabetic individuals in 2000, currently has the highest incidence of diabetes worldwide; these numbers are predicted to increase to 80 million by the year 2030 and this has given the country the distinction of being the “Diabetic capital” of the world.

Methodology:- The study was carried out in the Department of Community Medicine, Faculty of Medical & Health Sciences, SGT University. A through general examination, weight, height and BP measurement and blood glucose estimation was done. The filling of schedule was done in each household as per the following study tool. So, finally 420 subjects were included in this study.

Result:- The study “A study of prevalence of Diabetes mellitus and its risk factors in the Urban slum population of Gurugram was a community based cross-sectional study in urban slums of Gurgaon. Total 420 adults were selected for this study and were assessed for the prevalence of diabetes mellitus and associated risk factors by using a pre-designed, pre-tested, semi-structured schedule.

Conclusion:- There is an urgent need to implement prevention strategies for diabetes mellitus that are geared towards adoption of healthy lifestyle measures that prevent or delay the onset of type 2 diabetes mellitus.

Keywords:- Diabetes mellitus, blood glucose
hypertension and cardiovascular disorders have become the most serious health concerns in both developed and developing countries. It has been estimated that the largest increase in the number of people with diabetes will occur in the regions comprising the developing countries.

The number of people with diabetes was approximately 366 million in 2011, and by the year 2030 this number has been predicted to increase to 552 million. It is also estimated that approximately 80% of people with diabetes live in the low- and middle-income countries, which are designated as the developing economies in the world. China and India will bear the major burden of diabetes, with an estimated 129.7 and 101.2 million cases, respectively, by 2030. The largest age group currently affected by diabetes is the 40–59 years age group, and by 2030 this is expected to move to the 60–79 years age group.

According to the World Health Report 2005, NCDs already contribute to 52% of the total mortality in India and this is expected to increase to 69% by the year 2030. Therefore, countries such as India are currently facing an epidemiologic transition with a ‘double burden’ of disease. There is a bit of controversy regarding the prevalence of diabetes in India, since most of the available data are derived from a few scattered studies conducted in different parts of the country. Few multicentric studies are available, those published include: the Indian Council of Medical Research (ICMR) study conducted during the 1970s, which reported a prevalence of 12–19% in urban areas and 4–10% in the rural areas of India; the National Urban Diabetes Survey (NUDS), which reported a prevalence of more than 12% among urban Indians; the Prevalence of Diabetes in India Study (PUDIS) that reported a prevalence of 5.9 and 2.7% among urban and rural subjects, respectively; and the WHO-ICMR NCD Risk Factor Surveillance study, which reported greater than 11% prevalence of diabetes among urban Indians.

The Aim of the study entitled “A study of prevalence of Diabetes Mellitus and its risk factors in the Urban slum population of Gurugram” was conducted in urban slums of Gurugram.

Material and Method

Study Area: - The study was carried out in the Department of Community Medicine, Faculty of Medical & Health Sciences, SGT University.

Data collection: - Each selected household was approached and health worker, local community leaders were informed prior to the visit. After obtaining informed consent from the participant, a face to face interview was conducted and information regarding socio demographic profile, personal and family history, marital status and income, utilization of health services, morbidities, physical activity and awareness regarding symptoms of diabetes was obtained.

A through general examination, weight, height and BP measurement and blood glucose estimation was done. The filling of schedule was done in each household as per the following study tool. So, finally 420 subjects were included in this study.

Inclusion criteria:

All the residents (of either sex) of the selected slums aged 20-79 years, who give consent will be included in the study.

Exclusion criteria:

Patients who are not willing to give consent for the study.

Type 1 diabetics and terminally ill patients will be excluded.

Pregnant women will be excluded.

Data Analysis:- All data was collected, coded, tabulated and analysed using Statistical Package for Social Science (SPSS) version 21 for statistical analysis and necessary statistical tests like proportions and chi square tests were applied. A significant p value was considered when p was less than 0.05 and it was considered highly significant when p value was less than or equal 0.01.

Finding

The study “A study of prevalence of Diabetes mellitus and its risk factors in the Urban slum population of Gurugram” was a community based cross-sectional study in urban slums of Gurgaon. Total 420 adults were selected for this study and were assessed for the prevalence of diabetes mellitus and associated risk factors by using a pre-designed, pre-tested, semi-structured schedule.

<td>242 (86.5)</td>
<td>335 (79.8)</td>
</tr>
</tbody>
</table>

Table 3 shows the prevalence of diabetes mellitus among the study participants. Diabetes mellitus was defined as a person having a random plasma glucose ≥200 mg/dl and/or fasting plasma glucose ≥ 126 mg/dl after ≥ 8 hrs of overnight fasting. Individuals were subjected to a random blood sugar (RBS) screening by glucometer (Optium exceed by Abbott Healthcare).

The prevalence of diabetes mellitus was found to be 20.2% in the present study. The prevalence of diabetes mellitus among males was 33.5% which was higher as compared to prevalence among females i.e. 13.5%. Among those who were diagnosed with diabetes mellitus in the present study, about 44.7% were previously diagnosed and were on treatment. The mean blood glucose study participants was 160.10 ± 31.31 years. The mean blood glucose level of those diagnosed with diabetes mellitus was found to be 238.28 ± 29.29 years.

Table 4. Distribution of study participants according to type of diet

<td>231 (55%)</td>
</tr>
</tbody>
</table>

Table 4 shows the distribution of study participants according to the type of diet. About 45% study participants were vegetarians and rest 55% consumed non-vegetarian food. Among the males, majority were vegetarians i.e. 58.5% and among females majority were non-vegetarians i.e. 61.7%
Discussion

The present cross sectional study on prevalence of diabetes mellitus and its risk factors was conducted among adults residing in the urban slum areas of Gurugram. The study aimed at determining the prevalence of diabetes and its associated risk factors. Diabetes was defined as a previously diagnosed or any person having random plasma glucose ≥200 mg/dl and/or fasting plasma glucose ≥ 126 mg/dl after ≥ 8 hrs of overnight fasting. A total of 420 study participants were recruited for the study, out of which 140 were males and rest 280 were females.

The prevalence of diabetes in the present study was found to be 20.2% which is considerably high . In a study by Jahagirdar SS et al\(^{10}\), the prevalence of diabetes is found to be 22% .In another study done by Madaan H et al. on prevalence of Diabetes in rural Sonepat district of Haryana\(^{11}\), 18.43% were found to be having diabetes. Similarly the National Urban Diabetes Survey showed an age-standardised prevalence of 12.1% for diabetes and 14% for IGT in six large metropolitan cities \(^{12}\).A community-based study done in Ahmedabad by Nayak et al.\(^{13}\) reported that prevalence of Type 2 diabetes as 13.8%. Another study done by Korita et al.\(^{14}\), in Ahmedabad, also reported prevalence of diabetes 7.33% in urban area. The Prevalence of Diabetes in India Study (PODIS) reported lower diabetes prevalence of 5.9% and 2.7% in urban and rural areas respectively with an overall prevalence of 4.3% .Many studies in India have reported a greater diabetes prevalence in urban adults as compared with rural adults.\(^{15-16}\) Recent studies have reported urban diabetes prevalence rates of 8–20% and rural diabetes prevalence rates of 5–15%.\(^{15}\)The higher prevalence of diabetes in the present study could be due to the changes in lifestyle, urbanization, and food habits.

Conclusion

This study concludes that, it has been observed that adults residing in the urban areas are exposed to many risk factors for non-communicable diseases especially diabetes mellitus. Following suggestions are recommended for reducing or preventing the emergence of diabetes

There is an urgent need to implement prevention strategies for diabetes mellitus that are geared towards adoption of healthy lifestyle measures that prevent or delay the onset of type 2 diabetes mellitus .There is a need to device tools for use by health provider to identify those who are at high risk of developing DM in order to start preventive and health primitive activities and follow up.

Relationship between Geriatric Oral Health Assessment Index (GOHAI) and Oral Health Status of the Institutionalized Elderly in Mangalore, India

Priyanka Ravi, Ashwini Rao, Gururaghavendran Rajesh, Ramya Shenoy, BH Mithun Pai

1Ex-Postgraduate Student, 2Professor, 3Professor and Head, 4Associate Professor, Public Health Dentistry, Manipal College of Dental Sciences, Manipal Academy of Higher Education, Mangalore, Karnataka, India

Abstract

Background: Oral health of the geriatric population plays a major role in their overall health and quality of life. There is lack of access to dental care among the institutionalized elderly and there is a need to know their felt oral health needs and oral health evaluation of this population.

Method: This was a cross-sectional, descriptive type of survey carried out among the institutionalized elderly in Mangalore. The study population comprised all the elderly aged 60 years and above residing in homes for the elderly. Oral health-related quality of life was assessed using a pretested, self-administered questionnaire, Geriatric Oral Health Assessment Index (GOHAI). Oral examination was conducted in the homes using WHO oral health assessment form. The data were coded, statistical analysis was done using the SPSS version 19.0 and level of significance was kept at p < 0.05.

Findings: A total of 175 individuals participated in this study. Prevalence of dental caries was 44.6% (20.32±10.19), root caries was 40%, 57% had periodontal disease and 96% were complete or partially edentulous respectively. There was a significant association between GOHAI scores and the method of cleaning (p<0.005) and the frequency of changing toothbrush (p<0.005).

Conclusion: This study demonstrates that there is a high burden of oral disease among the elderly. There is an urgent need for an organized geriatric dental care programs as their oral health is neglected.

Keywords: Geriatric Dentistry, Geriatric Assessment, Oral Health, Homes for the aged, Dental Health Survey.

Introduction

The World Health Organization (WHO) has defined health as “a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity”.

Clinical indicators of oral disease such as dental caries or periodontal disease are not entirely suitable to capture the concept of health declared by WHO, particularly the aspects of mental and social wellbeing. This resulted in a demand for health status measures, in addition to clinical measures of disease status, culminating in the development of Oral Health Related Quality of life (OHRQoL) measures that could evaluate the impact of oral conditions on the physical, psychological and social wellbeing of an individual.

OHRQoL is defined as “a multidimensional construct that reflects (among other things) people’s comfort when eating, sleeping, and engaging in social interaction; their self-esteem; and their satisfaction with
The Geriatric Oral Health Assessment Index (GOHAI) is one of the oral health self-perception tools used worldwide among the elderly, which was developed by Atchison and Dolan. It is associated with quality of life, and its results indicate the impact of clinical oral conditions on well-being. GOHAI is composed of 12 questions about three domains of OHRQoL: physical function (feeding, speech and swallowing), pain or discomfort and psychosocial function (appearance, social relationship).

In almost every country, the proportion of people aged over 60 years is growing faster than any other age group, as a result of both longer life expectancy and declining fertility rates. The proportion of the world’s population over 60 years is projected to double from about 11% in 2000 to 22% in 2050. The absolute number of people aged 60 years and over is expected to increase from 605 million to 2 billion over the same period.

As with other health issues, older people have very different oral health needs. They are more likely to take medication that causes dry mouth, leading to tooth decay and infections of the mouth. The results of oral health problems reverberate throughout the body affecting their quality of life. These considerations led to the conception of this study.

Material and Method

The study was a cross sectional, descriptive type of survey carried out among the institutionalized elderly in Mangalore. The study population comprised all the elderly aged 60 years and above residing in homes for the elderly in Mangalore. Inclusion criteria were those participants aged 60 years and above, residents of institutions for the elderly and those who are able to communicate either in English/Kannada. Those unwilling/unable to give written informed consent were excluded from the study. Data collection was carried out over a period of six months from February 2014- July 2014.

Calibration of the examiner was done by examining ten patients who were re-evaluated by two experts. The intra examiner reliability was assessed using Kappa Statistic (0.78). Face to face interview was conducted to obtain demographic data pertaining to age, sex, educational qualification and duration of stay in the home.

Geriatric Oral Health Assessment Index (GOHAI) was used to assess self-reported oral health problems of the institutionalized elderly. The GOHAI is a 12 item questionnaire which consists of 3 domains, the first domain ‘physical functions’ consists of 4 items, the second domain ‘psychosocial functions’ consists of 5 items and the third domain ‘pain or discomfort’ consists of 3 items. It was recorded by asking the participants if they had always, often, sometimes, seldom, or never experienced problems in the previous 3 months. The questionnaire was translated into Kannada by a professional, and then translated back to English by an independent translator. It was pre tested on 10 individuals. There was a good internal consistency of the questionnaire which was measured using Cronbach’s alpha (0.81). Oral health status was assessed using the WHO Oral Health Assessment Form (1997). The data was coded and analyzed using the SPSS version 19.0. The level of statistical significance was kept at $p < 0.05$.

Findings

The present study was conducted among the institutionalized elderly in Mangalore. A total of 175 participants from 5 institutions for elderly participated in this cross sectional survey. The mean age of the study population was 70.38 ± 10.98 years and 87 (49.7%) participants were between the age group of 60-69 years; 40% were male and 60% were female. One participant had a malignant tumor on the buccal mucosa and alveolar ridge, one participant had ulceration (aphthous) on the buccal mucosa, one participant had candidiasis on the dorsal surface of the tongue and four participants had abscess in the gingiva.

The prevalence of dental caries and root caries were 44.6% and 40%, whereas missing teeth and filled teeth were 96% and 2.3% respectively. The mean Decayed, Missing and Filled Teeth (DMFT) was 20.32 ± 10.19. A total of 11.4% participants required one surface filling while 7.4% participants had need for two or more surface fillings. Pulp care was indicated for 6.9% participants while 38.9% participants had teeth indicated for extraction. (Table 1)

Around 43 subjects had Code 2 as the highest score, which indicated that majority (33.6%) of the participants had calculus deposits. Bleeding on probing was the highest score among 7.1% of the participants whereas...
25% and 11.7% had a pocket of 4-5mm and 6mm or more respectively. Loss of attachment of 0-3mm was seen in 46.1%, 4-5mm was seen in 16.4%, 6-8mm was seen in 23.4%, 9-11mm was in 3.2%, 12mm or more was seen in 10.9% respectively. (Table 2)

There were 2 participants with partial denture, 20 were with full or complete denture. About 23% of the participants did not require any prosthesis, but 27% needed full prosthesis in the upper arch. About 87% of elders did not have prosthesis in the lower arch. There was one participant with partial denture and 21 were with full or complete denture. Need for prostheses were higher for maxillary arch as compared to mandibular arch.

A statistically significant difference was found between GOHAI scores and the method of cleaning [F(2)=5.50, p=0.005] and frequency of changing toothbrush [F(3)=6.55, p=0.00] as determined by one way ANOVA. The method of cleaning and frequency of changing tooth brush were significantly associated with GOHAI score (Table 3).

+GOHAI: Geriatric Oral Health Assessment Index.

++ SD: Standard Deviation

**Discussion**

The present study was an attempt to determine the relationship between Geriatric Oral Health Assessment Index (GOHAI) and oral health status of the institutionalized elderly in Mangalore. The study findings demonstrate that the GOHAI scores ranged from 12 to 60, with a mean score of 44.57 with a higher score indicating poor oral health related quality of life. Similar mean scores were also reported by McMillan et al. (51.9) and Gil-Montoya et al. (52.1). Contrasting mean GOHAI scores were reported by Jones et al. (23.9). Locker et al. in their study in Canada reported that 8.4% had a GOHAI score of zero.

Majority of the participants (96%) did not have any abnormal condition which was in contrast to the findings of several other studies which have reported xerostomia, TMJ pain, oral mucosal changes as common findings among institutionalised elderly. Miyazaki et al. in their study among institutionalized elderly in Japan reported that 81% had no unusual symptoms in their TMJ while clicking sound was the most frequent symptom (17%), which is strikingly in contrast with the present study as there were no TMJ problems in this study. Galan et al. in a study among community-dwelling older Canadians reported higher soft tissue anomalies (67%), alveolar bone (41%) and alveolar mucosal (40%) anomalies along with hyperplastic ridges and denture stomatitis in accordance with the present study. In contrast, Da Silva et al. reported that more than half presented an abnormality of the oral mucosa in his study conducted among elderly in Campinas, Southeastern Brazil.

The mean DMFT among elders has been reported in literature by Galan et al. (25.1±5.1), Gil-Montoya et al. (20.2±10.5), Esmeriz et al. (28.5±4.8) respectively, which was in accordance with our mean DMFT (20.32±10.19) values. There was a high prevalence of root caries in the present study (40%), which was also seen in other studies by Locker et al. and Unlüer et al. whereas, Galan et al. (22%), Jones et al. (10%), Simunković et al. (0.17) have reported a lower prevalence of root caries compared to the present study.

Around 11.4% participants required one surface filling while 7.4% participants had need for two or more surface fillings, similar restorative need were reported by Angelillo et al. and Unlüer et al. Few subjects required pulp care (6.9%), while 38.9% participants had teeth indicated for extraction. Galan et al. have reported restorative treatment need for 79% and prosthetics care for 77% of subjects in their study.
Code 2 was the highest score indicating that majority (24.6%) of the participants had calculus deposits with pocket formation. In contrast Galan et al.\textsuperscript{13} in a study among community-dwelling older Canadians reported that 80% had at least one tooth with shallow pockets (code 3) or deep pockets (code 4). Petelin et al.\textsuperscript{21} used CPITN index and appraised most of the participants (81.9%) needed oral hygiene education, more than half (56.7%) needed scaling and root planning and only 21.6% needed periodontal surgical treatment among the elderly living in residential homes in Slovenia. Prosthetic treatment need was more for maxillary arch as compared to mandibular arch.

Interestingly, current study found an association between GOHAI scores and the method of cleaning and frequency of changing toothbrush which may be attributed to the fact that those respondents are more concerned with their oral health. There was negative correlation between decayed teeth, filled teeth, dental caries experience (DMFT) and GOHAI scores, it was not statistically significant. Positive correlation was found to be present between GOHAI and missing teeth, which also did not show any statistical significance.

An inherent limitation of the present study is the cross-sectional design which does not give any insights into the causality. Longitudinal studies on a varied sample can give information about the causal relationship of different factors influencing normative need and self-perceived need.

**Conclusion**

This study demonstrated that GOHAI scores were associated with materials used for cleaning and frequency of changing toothbrush among institutionalized elderly. There is an urgent need for an organised dental care programs for the geriatric patients as they have a very high prevalence of dental caries. The institutionalised elderly are in need of easily accessible and well organised dental care set up. The poor oral health of the participants in this study is can be related to infrequent dental visits as well as insufficient or incorrect oral hygiene practices.

Comparative Study of CMC 0.5% Eye Drops versus Combination of .05% Cyclosporin Ophthalmic Emulsion and 0.5% CMC Eye Drops in Dry Eye Disorders

Prerana Agarwal¹, D.J. Pandey²
¹Assistant Professor, ²Professor, Department of Ophthalmology, Saraswathi Institute of Medical Sciences, Hapur, U.P (India)

Abstract

Background: Dry eye disease is a common disorder provoking changes in tear film and ocular surface. Untreated dry eye could cause ocular infections, corneal ulcer and blindness. Only a few drugs are authorized so far for the treatment of dry eye disease and the possibilities of evolution in this sector are immense. Objectives: Compare efficacy of carboxy methyl cellulose .5% eye drops with combination of 0.5% carboxy methyl cellulose eye drops and .05% cyclosporin ophthalmic emulsion for treatment of dry eyes. Material and Method: 40 patient presenting with dry were selected randomly. They were divided into 2 groups. Group I received CMC.5% eye drops four times a day and group II received .05% Cyclosporin ophthalmic emulsion two times daily and .5% CMC eye drops 4times a day. All patients were evaluated on day 0, 2 weeks, 1 month, 3 month and 6 month for relief in ocular symptoms and diagnostic dry eye tests. Results: The mean age in group I was 39.72 ± 6.85 years and in group II was 40.2 ± 5.28 years. Ocular discomfort, dryness and tearing were seen in all the cases. Comparison of different parameters after six months of treatment between group I and II showed that the comparison of net score in two groups is statistically significant (p < 0.05). Conclusions: There was statistically significant difference between the outcome of two groups. Group 2 patients who used combination of cyclosporin0.05% ophthalmic emulsion two times daily along with CMC 0.5% eye drops 4times a day were better relieved as compared to patients in group 1 who used 0.5% CMC eye drops four times daily for treatment of dry eyes

Keywords: Carboxymethylcellulose, Cyclosporine, Dry eye

Introduction

“Dry eye is a multifactorial disease of the tears and ocular surface that results in symptoms of discomfort, visual disturbance, and tear film instability with potential damage to the ocular surface. It is accompanied by increased osmolarity of the tear film and inflammation of the ocular surface.”¹ Dry eye is one of the most common causes of ocular morbidity in patients presenting to an ophthalmology outpatient department. Approximately one out of seven individuals aged 65–84 years report symptoms of dry eye often or all of the time.² Management of dry eye depends on the cause and severity of the condition. Various strategies have been described for medical management of dry eye; these include, the topical use of lubricants (artificial tear substitutes), topical corticosteroids and anti-inflammatory therapies, cyclosporine ophthalmic emulsion, and the systemic use of antioxidants (e.g., omega-3 fatty acids).¹²

Artificial tears are aqueous solutions containing polymers that determine their viscosity, retention time, and adhesion to the ocular surface. Various polymers currently in use include cellulose derivatives (e.g., hydroxypropyl methylcellulose [HPMC], “carboxymethylcellulose [CMC]), polyvinyl derivatives (e.g., polyvinyl alcohol), chondroitin sulfate, and sodium hyaluronate. In mild-to-moderate cases, they

DOI Number: 10.5958/0976-5506.2019.00681.8
are the mainstay of treatment. Artificial tears act by replenishing the deficient aqueous layer of the tear film and diluting the inflammatory cytokines.\textsuperscript{2,3} Cyclosporine 0.05% emulsion has been approved by the US FDA for its treatment. Given the role of inflammation in dry eye, it makes sense that anti-inflammatory agents have been evaluated in its treatment.\textsuperscript{4}

These are lack of studies regarding this topic in this area so we did this study to see efficacy of these two treatment over each other.

**Material and Method**

A comparative prospective study was carried out at Saraswathi Institute Of Medical Sciences Anwarpur(Hapur). Patients were enrolled from February 2018 to July 2018. 20 patients i.e 40 eyes were included in each group presenting with dry eye in eye OPD. Patients were randomly divided in two groups. Detailed history was taken. Appropriate laboratory work up was done. Group 1 where patients used carboxy methyl cellulose .5% eye drops for treatment of dry eye. Group 2 in which patients used 0.5% carboxy methyl cellulose eye drops along with 0.05% cyclosporin ophthalmic emulsion for treatment of dry eyes. All patients were evaluated on day 0, 2 weeks, 1 month, 3 month and 6 month for relief in ocular symptoms and diagnostic dry eye test were done. Diagnostic dry eye test included SCH—Schirmer’s test, TBUT—tear breakup time, FLU—fluorescein stain, Rose Bengal staining and marginal tear strip test. Each ocular symptom (ocular discomfort, dryness, tearing) and dry eye test were scored from 0 to 3 depending on severity and combined score of all symptoms and test was calculated on each follow up visit for each eye individually of each patient in both groups. Net score was calculated as difference between total score (of all symptoms and test) on day 0 and total score at 6 month follow up. Net score actually gives improvement score after use of drug for 6 months in both groups. Net score is then compared in both groups to find the comparative efficacy of drugs in both groups. Net score in both groups wascompared using unpaired t test This study was approved by institutional ethics committee

**Discussion**

Dry eye is a common complaint among middle-aged and older adults and its prevalence increases progressively with age. Studies from India reported that the prevalence varies between 18.4% and 63%. This was a comparative study conducted on 40 dry eye cases presenting to eye OPD. The mean age in group I was 36.72 ± 6.85 years and group II was 38 ± 5.28 years respectively. Similar study was concluded by Shah S et al. In the present study the male to female ratio was 1:1 with 21 (52.5%) males and 19 (47.5%) females. This was in accordance with Shah S et al. where the ratio was 1:1. On the contrary Female dominance was reported by Behera S et al.

In the present study middle age formed 60% of the study group patients. Similar higher middle age population was seen with Shah S et al, Kamalakshy J et al and Titiyal JS et al study.

Majority of patients reported dramatic symptomatic relief during treatment period. Patients showed improvement in terms of decrease in score values at different follow ups. All patients had relief in foreign body sensation, discomfort, tearing, photophobia, dryness and itching. At the end of study i.e. at 6 months, eyes having score 03 for different symptoms were 0 in both groups, those with moderate score02 for different symptoms were more in group 1 as compared to group 2 and greater percentage of eyes from group 2 had score 0 for different ocular symptoms.

In the present study ocular discomfort, dryness, tearing was seen in all cases. While in Kamalakshy J et al most frequent ocular surface symptom in confirmed cases of dry eye was itching. In another study by Lee AJ et al conducted in Indonesia burning sensation was the most common symptom.
In this study use of topical cyclosporine 0.05% and CMC 0.5% in group II showed significant improvement in all the parameters specially TBUT which was in accordance to other studies like Shah S et al10, Byun YJ et al17. Sall K et al.18 This is explained by the fact that the ocular surface, lacrimal glands and the neuronal feedback loop that make up a single functional unit for the maintenance of ocular surface homeostasis leading to improvement of the ocular surface Sall K et al.19 Sall K et al19 showed significant decrease in sandy or gritty feeling, dryness, itching and blurred vision in patients treated with cyclosporine 0.05%. A study by Cross WD et al22 showed improvement in signs and symptoms of dry eye diseases in patients treated with cyclosporine 2% Study by Sodhi et al23 showed statistically significant improvement in only lacrimation and photophobia in patients treated with cyclosporine 2% while none of the ocular complaints showed significant improvement in patients treated with artificial tear eye drops. In our study results show better relief in all ocular symptoms in group 2. Therefore our study is in accordance with study of Sall K et al 19 Cross WD et al22 but not in accordance with study of Sodhi et al 23. Difference could be because of the fact that all patients enrolled in study by Sodhi et al were of non immune origin and cyclosporine has immunomodulatory role.

Mean net score in group 2 was more than group 1 indicating more improvement in group 2. Difference in net score in both groups was found to be statistically significant. A recent study by Sal KN et al on American patients has also shown improvement in ocular symptoms and tear film tests value with combination of cyclosporine and artificial tear eye drops24.

In our study, none of the patients showed any drug related adverse effects which was consistent Shah S et al10, Kinoshita S et al20 and Small DS et al.21

**Conclusion**

Present study concludes that there is statistically significant difference in response (in terms of improvement in tear film profile tests and ocular symptoms) in patients treated with combination of cyclosporine 0.05% and CMC 0.5% drops as compared to patients treated with 0.5% CMC eye drops only. It also strengthens the fact that topical cyclosporine A 0.05% twice daily plus CMC 0.5% has no adverse effect.

A Survey of Machine Learning Techniques for Cancer Disease Prediction and Diagnosis

M Kiran Kumar1, Divya Udayan J2

1School of Computer Science and Engineering, 2School of Information Technology and Engineering, VIT, Vellore, India

Abstract

Identification of patterns plays a vital role in Disease Diagnosis for detecting the diseases accurately. Machine learning is a subfield of artificial intelligence (AI). This ML techniques are mostly interesting as it is part of a suggesting personalized, predictive medicine to the diseases. Cancer is the one of the second leading cause of death worldwide, in 2018 it is accountable for an estimated 9.7 million deaths. The most common cancers are breast, oral, skin, colon and lung. Cancer death will be reduced if cases are identified and treated early.

In connection with this review a broad survey is conducted for various machine learning algorithms used for prediction and prognosis of different cancer diseases. A number of methods are reviewed, towards various types of cancer diseases, a heavy reliance on “historical” technologies used in machine learning methods. At the end the benefits & limitations & challenges are identified which helps the researches to develop novel methodologies in ML to improve the performance in disease prediction and diagnosis.

Keywords: Machine learning, Medical diagnosis, Classification algorithms, Decision trees, KNN, ANN, SVM

Introduction

Now a Days, artificial intelligence generate more imaginative machine in computer science. Learning system becomes a basic requirement for an imaginative system. Many researchers currently acknowledge that without learning system, machine can’t produce efficient results. Therefore, Machine Learning (ML) is prevailing divisions of artificial intelligence. These are used to analysis data repeatedly to produce most efficient outputs. Currently machine learning offers crucial machine for imaginative data analyzation. Presently medical organizations are very well equipped with completely automatic machines and those machines are producing large amount of data, these data is collected and shared with computer systems or with consultant to take essential phases These techniques are used to analysis the medical data and it cooperates in medical diagnosis for detecting various dedicated diagnostic problems. With machine learning classification algorithms, for specific disease, improve the accuracy, speed, reliability and performance of the investigative on the present system.

ML is capable of present automatic learning methods to extract common patterns from genuine data and produce precise decisions through different learning behavior. In this survey, we tried to explore the issues of present system related to cancer disease prediction.

The rest of this paper is structured as follows. Section 2 presents the overview of research area. Section 3 presents the cancer disease diagnosis and prediction by using various ML algorithms and survey. Finally, Section 4 concludes with some indication for future work.

Machine Learning

Machine learning is the sub field of AI.it uses variety of statistical and optimization techniques to the computer to learn and improve the performance without being explicitly programmed1. Machine Learning Algorithms are commonly they can be divided into categories according to their purpose and the main
categories are the following:

**Supervised learning**

**Unsupervised learning**

**Semi supervised learning**

**Reinforcement learning**

**Evolutionary Learning**

**Deep learning**

Diagnosis of cancer by Using Different Machine Learning Algorithms

In the last two decades, many researchers started investigating on different machine learning algorithms for diagnosing the diseases\(^2,6\). They accepted that machine-learning algorithms provide good prediction for different diseases\(^10\). In this survey paper a detailed diseases diagnoses for various cancers like skin, lung, breast, oral, liver is been provided. Cancer prognosis prediction improves the quality of treatment and increases the patient’s survivability\(^6\).

In cancer prediction there are three predictive objectives:

*Prediction of cancer susceptibility*: predict the chance of developing cancer earlier to the occurrence of the disease.

*Prediction of Cancer Survivability*: predict an outcome like life expectation, advancement after finding of the malignant tumors.

*Cancer Recurrence prediction*: Quality articulation profiles have been utilized to foresee cancer repeat or other clinical results of patients.

This survey focuses on the application of machine learning approaches for predicting the various types of cancer. A standout amongst the most usually happening malignancies is oral cancer. Oral cancer starts in the oral hole which incorporates the whole mouth, lips, the inward coating of the lips and cheeks, the teeth gums, tongue. According to Fang et al\(^3\) Wang et al\(^4\), tobacco consumption will cause the tumor cell to dedifferentiate which makes them become more aggressive A great deal of work has been anticipated as of late in writing for the oral cancer classification and some vital work is assessed in this paper. Yung-nien\(^5\) developed color based tumor segmentation for the automated estimation of oral cancer parameters.

Skin cancer is the most common human malignancy. Every year more than 5.4 million new cases of skin cancer diagnosed in US. Melanoma is the most deadly form of skin cancer, more than 75% of deaths associated with skin cancer\(^7\). Exact identification of growth would help sparing millions of lives. S. Mustafa\(^14\) applied sequential backward selection feature selection to improve Classification accuracy based on 6-9 useful features. Obtained the highest 91.30% by using KNN classifier. Li,Yuexiang\(^35\) developed deep learning frameworks, which are Lesion Indexing Network (LIN) and the Lesion Feature Network (LFN), the proposed LIN obtained highest accuracy 85.7 and AUC 91.2 by considering Lesion Classification. He has taken the ISIC 2017 dataset.

Lung cancer is a dangerous one among all cancer leading deaths, due to last stage exposure and environmental conditions like air pollution, smoking habits\(^9\). A recent papers from Bram van Ginneken et al\(^8\) and other authors discussed using the pre-trained convolutional neural network and genetic algorithm to classify regions from chest CT scan images as nodule or non-nodule Safiyari Proposed eight classification algorithms including RIPPER, Decision Stump, Simple Cart, C4.5, SMO, Logistic Regression, Bayes Net and Random Forest to diagnose lung cancer. They used AdaBoost algorithm to improve the accuracy of three algorithms RIPPER, decision stump, SMO. Rossetto\(^40\) used Convolution Neural Networks using multiple preprocessing methods in order to increase the accuracy which is 97.5%. Chip M.Lynch, proposed supervised learning technique SVM to lung cancer data in the SEER database for estimate patient survival time.

Liver cancer can be genetic or affected by a range of factors that harm the liver, such as viruses and alcohol use and obesity is also related with liver damage\(^9\). However, only few works in machine learning examine liver disorders, although this disease is aggressively growing and becoming one of the most deadly diseases in more countries.

Colorectal cancer (CRC) is one of the third largest cancer in the United States, it is one of the leading causes of cancer deaths. Like other types of cancers, we can reduce the death rate by an early detection. There
are a variety of diagnostic techniques like fecal occult blood test, stool test sigmoidoscopy etc. So many researchers developed an automated diagnostic system which can identify the different types.

There are a variety of openly available datasets from cancer disease expression studies, including leukemia cancer, colon cancer, and lung and breast cancer datasets.

**Evaluation of ML Algorithms**

Limitations of Machine Learning algorithms in cancer disease diagnose and prediction:

The benefits of machine learning transform to innovative decision making and prediction process that improve the way of disease prediction. The limitations of machine learning techniques in disease prediction are listed below:

*Error diagnosis and correction in disease prediction:* One important limitation of machine learning is its vulnerability to errors in prediction. The original problem with this expected fact is that when they do make errors, diagnosing and correcting these are difficult because it produces underlying complexities of the algorithms and associated methods.

*Time constraints in learning and diagnose process:* It is incredible to design immediate accurate predictions for diseases with a machine learning system. It trains with historical data. The larger the data size and longer it is exposed, the better it will execute.

*Problems with verification and validation:* Another limitation of ML in decision making and prediction is the lack knowledge in diversity of data. The ML deals with statistical truths rather than literal truths. When the data is not included in the historical data, it is very difficult methods are suitable in all kind of diseases.

Open Issues / Research Challenges in Cancer disease Prediction and diagnosis

*Lack of attention paid to data size and learner validation.* Basic requirement for the machine learning approach is comprising a sufficient and large data set. Data set is separated into training data sets and test data sets or some logical form of n-fold cross validation for smaller data sets like 5- or 10-fold cross-validation is sufficient to validate most any learning algorithm. But in realistic sense these not enough to validate the efficiency of the method, because the accuracy of the testing is proportional to the amount of data trained.

*Data set quality and feature selection:* Along with data size data set quality and careful feature selection are also influences the effective machine learning approaches. Identification and selection of appropriate feature specific to the disease is very important but unfortunately, the methods in use to certify data quality and integrity are rarely discussed in most relevant papers.

*Availability of datasets:* It is very difficult to get the bench mark datasets for verifying and validating the Diseases particularly cancer disease. The type of features and number of feature are varied from disease to disease in such cases the dataset using for training the ML system be flaw less and accurate then only it is possible to get the accurate results in testing phase.

**Conclusion**

In this survey, we clearly discussed the concepts of machine learning and role of their application in cancer prediction or diagnosis. Different researchers have been proposed different techniques to predict the cancer disorder and focus on the development of predictive models using classification algorithms aiming to predict valid disease outcomes. Remember that there are various methods to design, develop and deploy a machine learning system for cancer disease prediction and diagnose to improve detection, classification, and characterization, among various diseases accurately with minimum time and efforts. The advantages of a ML system depend on how it is designed and developed for a particular disease prediction and detection. Furthermore, the limitations of ML are dependent on the type of technique or method used to define the prediction system for a specific disease.

Attitudinal Parameters Influencing Treatment Seeking Behavior during Child Diarrhea in India

Surya AV\textsuperscript{1}, Sanjeev MA\textsuperscript{2}, Rahul Sharma\textsuperscript{3}

\textsuperscript{1}South Asia CEO, Kantar Public, \textsuperscript{2}Associate Professor – Jaipuria Institute of Management, \textsuperscript{3}Associate Professor, Jaypee Business School

Abstract

Not seeking timely, correct and comprehensive treatment during childhood diarrheal episodes can potentially increase the risk of child morbidity and mortality. Treatment seeking behavior of parents/ primary care givers (P/ PCG) is very critical to reduce such risks among children below 5 years of age. However, P/PCG’s behavior to seek timely, correct and complete treatment, during child diarrhea episodes, is significantly impacted by many factors which include attitudinal parameters and demographic factors like the education and working status of the P/PCG and gender of the child, among others. This study is an attempt to specifically understand the attitudinal parameters in health seeking behavior, among P/PCG of children below 5 years, in case of childhood diarrhea

Keywords: childhood diarrhea, child mortality, child morbidity, health-seeking behaviour, diarrhea care.

Introduction

Diarrhea is one of the major causes of childhood mortality in India. Despite many efforts by the government to provide sufficient preventive care and treatment services, there are various factors that Impair the uptake of appropriate, sufficient and timely treatment services in India during episodes of childhood diarrhea. Acute diarrhea could lead to fluid loss, which can be life-threatening especially in young children. As per UNICEF\textsuperscript{1} statistics, diarrheal diseases account for nearly 1.3 million deaths a year among children in the age group of under-five years and this is more than all deaths due to AIDS, measles and malaria combined (Wardlaw et al)\textsuperscript{2}. Five countries - India, Ethiopia, Nigeria, Pakistan and Afghanistan- contribute to more than 50% of the diarrheal deaths; which otherwise is preventable as well as treatable (UNICEF)\textsuperscript{1}. In India diarrhea accounts for 13% of all deaths of children under 5 years of age killing about 300,000 under 5 children every year, making it the third most common cause of death for this age group (Lakshminarayanan & Jayalakshmy)\textsuperscript{3}. According to them poor sanitation and personal hygiene, lack of clean drinking water, and malnutrition are some of the factors associated with high incidence of diarrhea among children.

Literature Review

The treatment of infectious diseases, like diarrhea, is largely depended on the public healthcare expenditure and infrastructures – as the incidence is higher among the weaker section of the economy (Avachat et al)\textsuperscript{4} however they are easily manageable. Another factor that affects the management of infectious disease is the poor levels of education and hygiene among the poor making them more prone to such infections (Griffiths & Zhou)\textsuperscript{5}. Apart from these; treatment of any disease, including infectious ones, are affected by patient’s health seeking behavior (HSB). Previous studies have investigated factors that influence the HSB during childhood diarrhea. While studying factors affecting decision to seek treatment for children (including diarrhea) in Kerala; (Pillai et al)\textsuperscript{6} found that social, economic, disease related variables & gender of the child influenced whether, when and what kind of treatment was sought for the child. In a study of healthcare seeking in rural district (Patil & Dixit)\textsuperscript{7} found that the mother’s knowledge, the source of information,
family income, cast and social norms influenced HSB during diarrheal episodes. A study (Malhotra & Choy) based on the FHS 2007 found that mother’s age & education, wealth index, health knowledge, low use of public health facilities & child’s gender affected treatment seeking behavior in childhood diarrhea in India. Most of the research aims at ascertaining the behavior as influenced by demographic factors like education, skill, income, gender etcetera. However, treatment seeking is also dependent on other social and behavioural attitudes like what are the outcome expectation of the P/PCG (whether the child will be cured or not), general healthcare attitude (whether healthcare expenditure is considered an expense or investment), social attitudes towards diarrhea (is it a normal part of growing up that need not be accorded too much importance), the understanding of the urgency of the situation (coming from the knowledge about the disease), and the freedom to act in times of need. The current study considers 7 attitudinal parameters for its impact on health seeking behavior, during childhood diarrhea, in 4 rural districts of Uttar Pradesh. A functional definition of the 7 parameters are given below.

Healthcare Attitudes: indicates the P/PCG’s attitude towards children’s health and the need to invest in the same

Outcome Expectations: indicates how the P/PCG’s perceive the result of a medical intervention to be when provided to the patient

Economic Attitude: indicates the P/PCG’s attitude towards spending money on treating sickness in children.

Behavioral Urgency: indicates the urgency shown by the P/PCG’s to act in case of childhood illness like diarrhea.

Social Norms: indicates the tendency to confirm to the existing social norms, without challenging it, regarding treatment of childhood illness in the social setting of the P/PCG’s.

Behavioural Freedom: indicates the relative freedom the P/PCG’s in deciding on seeking medical care for the sick child.

Prevention attitude: indicates importance assigned by the P/PCG’s to preventing instances of diarrhea in children.

All the sentences were measured on a 5-point Liker’s scale of the ‘agreement’ type, using 3 sentences each, and composite scores were calculated for all the 7 factors applying negative scoring whenever appropriate.

Research Objectives

The objectives of this primary research was two-fold

Firstly, the study aims to understand the impact of the attitudinal parameters on ‘whether healthcare intervention was sought’.

Secondly, it ascertains whether the treatment ‘was the treatment sought timely’.

Research Methodology

The study, conducted with 960 P/PCGs in the state of Uttar Pradesh, adopts a cross-sectional design. The geographical scope of the study was restricted to the 4 districts of Uttar Pradesh state that included Jalaun, Hardoi, Barelliy & Rae Bareli. The sampling method used was stratified-multi-sage cluster sampling. Samples have been equally distributed across each of the districts sampled proportionate to the child population (child under 5 years). In each of the districts, the sample has been further distributed across urban and rural areas proportionate to the under 5 child population. Further, primary sampling units (PSU), that included wards and villages, have been selected through PPS (Probability Proportionate to Size) sampling. All households with at least one child affected by diarrhea, in the past fortnight, in each PSU were considered for the sampling frame.

At the sampled household, a detailed interviewer administered questionnaire was used to collect data from the P/PCG of the child. The interview was conducted only after seeking informed consent by the research team. It was ensured that research ethics including respondent confidentiality, right to refusal, voluntary participation, providing complete information about the study and its risks and benefits and ensuring privacy during the interview, were followed.

Analysis & Discussion

The data was analysed using SPSS version 19.0 (© Copyright SPSS Inc. 1989, 2010) and included cross tabulation, chi-square & logistic regression. The results of the various analysis are discussed separately.
Descriptive

The overall prevalence of diarrhea was 19.4% across all surveyed households (Table 1) and similar to a meta-analysis of prevalence rates between 2002 and 2013 (Ganguly et al)\(^9\). Out of 83.9% caregivers who took their children for a treatment to a medical facility; majority approached a government clinic (31.1%).

It can be observed that the proportion of caretakers who have taken the child to the medical facility for treatment during the diarrhea is significantly lower among the non-working parents compared to that of the working parents (64.7% vs 84.6%, \(p<0.05\)).

Logistic Regression: Binary logistic regression was run to understand the impact of 7 independent variables, the attitudinal parameters, on the treatment seeking behavior. The treatment seeking behavior studied were ‘whether the patient sought outside medical treatment or not’ and ‘whether the treatment was sought timely or not’. The interpretations of the two analysis are done separately.

Seeking of medical treatment: The overall model, to understand the influence of the Independent Variables (IVs) on whether the P/PCG would seek medical treatment, indicated a good model fit (chi-square=122.3, Nagalkereke R=0.50, \(p<0.01\)) (table 5). The Hosmer & Lomeshow test also indicated model fit (chi-square=21.69, \(p=0.186\)).

The overall prediction accuracy was 83.2%; with a higher ability to predict patients who would seek treatment (97.3%) than those who would not (10.3%).

An examination of the exponential B/ odds ratio indicated that only 4 of the IVs were significant in predicting the whether the patient would seek medical treatment, in case of diarrhea, and included patient’s outcome expectation, attitude to prevention, behavioral freedom & behavioral urgency (Table 2).

Source: Survey data

The diarrhea prevalence is significantly higher in rural areas (21.8%) compared to the urban areas (13.4%) (\(p<0.05\)) and may be attributed to better awareness and hygiene among the urban households. Incidence of diarrhea is higher among the male children (20.2%) compared to the female children (18.6%) (\(p<0.05\)); which may be attributed to the fact that male children may be having more outdoor activities unsupervised in comparison to the girls.

Seeking treatment from a health facility, and not relying on the self-medication and home-remedies, is the most recommended method for treating childhood diarrhea. There are many households which report reliance on home-remedies across various studies (Carter et al)\(^10\). These households could be doing that for various reasons be it economic, lack of access to proper medical services or because of their beliefs around diarrhea or even lack of understanding of the seriousness of the disease (Nasrin et al)\(^11\). A significant majority of the caretakers took children for treatment in case of diarrhea episode (83.9%). The figures were similar to that reported from other developing countries like Niger (Anne-Laure et al)\(^12\) and Sierra Leone (Theresa et al)\(^13\) Out of 83.9% caregivers who took their children for a treatment to a medical facility; majority approached a government clinic (31.1%).

The diarrhea prevalence is significantly higher in rural areas (21.8%) compared to the urban areas (13.4%) (\(p<0.05\)) and may be attributed to better awareness and hygiene among the urban households. Attitude towards healthcare, economic attitude & social norms had no influence on whether outside treatment was sought or not along with social norms and family attitude. This may be due to the fact that kids are generally afforded higher importance and care in every household such that health investments on kids are considered a necessity and P/PCGs are not averse to spending on their children’s health.

**Seeking of timely treatment:** it is important that timely medical treatment is sought which will reduce cost, morbidity and mortality in child diarrhea. The logistic model to understand the influence of the IVs on whether timely treatment will be sought or not returned statistically significant model fit (chi-square=164.386, Nagalkereke R=0.235, p<0.01). The Hosmer & Lomeshow also indicated model fit (chi-square=15.36, p=0.052). The overall prediction accuracy was 79.3% with higher accuracy in predicting timely treatment sought (94.8%) than late/ untimely treatment (30.9%). The exponential B/ Odds ratio indicated that except for social norms and outcome expectations all other factors had a significant influence on whether timely medical treatment for diarrhea was sought or not (Table 3).

Conclusions

Successful provision of affordable healthcare to citizen should be the primary aim of any government as it has wide economic and social implications. This becomes more important when the disease is easily treatable, preventable and affects the younger populace; such as diarrhea. The current study finds that social norms, regarding treatment of diarrhea, has significantly undergone changes and is no more an influencing factor in treatment seeking during diarrheal episodes among children under 5 years of age. The factors that affect treatment seeking behavior are outcome expectation, behavioural freedom, behavioural urgency, attitude towards health care, economic attitude & attitude towards prevention of the P/PCG. Except in case of attitude towards prevention all others have a positive impact on health seeking behavior. People who have a positive attitude towards prevention may be better aware of the disease condition making them confident of their ability to handle the situation and delaying their responses to medical intervention. From the results we can propose a model to predict the treatment seeking behavior (Figure.1) that needs further empirical investigation. The proposed model does not include other demographic variables (other than economic factor), like gender, income, religion, caste or education of the P/PCG, which also may have influence on the treatment seeking behavior as shown by the earlier studies.

Policy Implications:

Government’s ambition to provide the best medical care, to children affected by diarrhea, is in the right direction and there has seen progressive efforts towards the same. It is clear from the results of the survey that the government should also develop special communication and outreach campaigns that highlight the importance of timely treatment of childhood diarrhea, the negative consequences of not doing (so as to improve behavioural urgency) and the need to prevent such easily preventable diseases (to improve the attitude towards prevention). From the supply point of view government should also consider reviewing the quality, affordability and accessibility of medical services that are available; especially in rural areas. Enlistment of technological advances, like tele-medicine and private medical service providers in a PPP (Public Private Partnership) like set up can be explored to make diarrheal treatment more reachable and affordable.

Limitations and Future Research:

This research primarily depends on the reported data from the parents about their HSB during the diarrheal episodes of the children. In most cases, the interviewers could verify the claims asking for the prescriptions from the caretakers but not in all cases caretakers could provide the prescriptions for various reasons including that they have not preserved them. The study did not control for the presence of health facilities as a sampling variable. This could mean that the access indicators to health facilities or types of health facilities cannot be generalized directly to the universe and should be considered as specific only to the sampled geographies.

Funding: The study was self-funded.

The Impact of Platelet Rich Fibrin on Periodontally Accelerated Osteogenic Orthodontics (PAOO)- A Perio-Ortho Interdisciplinary Case Report

Chatterjee Soham¹, Shetty J. Neetha², M.V Ashith³

¹Post Graduate, Dept. of Periodontology, ²Associate Professor, Dept of Periodontology, ³Reader, Dept of Orthodontics, Manipal College of Dental Sciences, Mangalore, Manipal Academy of Higher Education (MAHE)

Abstract

Background: In the present day scenario as the number of adult patients presenting with severe teeth malocclusions increase, the orthodontic profession constantly debates on ways to accelerate tooth movement and focuses on improving the patient centered outcomes. PAOO, a surgically assisted orthodontic procedure, which combines the use of corticotomy along with bone grafts, has been used to fasten the clinical results. Platelet rich fibrin, (PRF), an autologous platelet concentrate, with its vast release of growth factors plays an important role in enhancing soft tissue outcomes.

Aim: This case report aimed to demonstrate the efficacy of PRF on soft tissue outcomes when used as an adjunct to a variation of PAOO technique and also assess the time duration to achieve complete space closure.

Case description: A 23 year old female patient had presented herself to the outpatient Department of Orthodontics, Manipal College of Dental Sciences, Mangalore, India, with a chief complaint of protruded upper anterior teeth. The patient had been diagnosed with Class 2 division 1 malocclusion, after which therapeutic extraction of upper 1st premolars and lower 2nd premolars were performed. To facilitate lower molar protraction, the patient was referred to the Dept. of Periodontology for PAOO procedure. PAOO procedure was performed along with PRF and the clinical outcomes were assessed at the end of 6 months.

Conclusion: Correction of severe crowding may pose a significant challenge to the orthodontist. A combination of PAOO with PRF has shown beneficial therapeutic outcomes, better patient acceptance and enhanced soft tissue healing. It would be a viable alternative to the invasive orthognathic surgery.

Clinical significance: PAOO when combined with PRF not only results in faster space closure but also the vast growth factors released from PRF not only improve post-operative healing, but also increases the soft tissue thickness.

Keywords: PAOO, PRF, Interdisciplinary

---

Case Report

Background: Periodontal accelerated osteogenic orthodontics (PAOO) entails procedures that include selective alveolar corticotomy, augmentation of alveolar bone by particulate bone grafting and application of orthodontic forces.¹² It is 2-3 times faster and requires 1/4rd to 1/3th the time required for the traditional orthodontic therapy due to the regional acceleratory
phenomenon (RAP).2,3,4 Platelet rich fibrin (PRF) is a blood-derived, autologous, second-generation platelet concentrate which plays an important role in increasing the gingival biotype and enhances the soft tissue healing.5,6 This case report, demonstrates the use of PAOO along with PRF to accelerate the orthodontic teeth movement, enhance the healing and increase the gingival biotype after 6 months.

Case Description

A 23 year old female patient had presented herself to the outpatient Department of Orthodontics, Manipal College of Dental Sciences, Mangalore, India, with a chief complaint of her upper front teeth being forwardly placed. The patient had been diagnosed with Class 2 division 1 malocclusion, for which therapeutic extraction of upper 1st premolars and lower 2nd premolars were performed. (Figure-1a & 1b). To facilitate lower molar protraction, the patient was referred to the Dept. of Periodontology, Manipal College of Dental Sciences, Mangalore, for undergoing the PAOO procedure. Patient underwent a complete haemogram test and an informed consent was obtained prior to the procedure.

The surgical site was anaesthetized with 2% lignocaine hydrochloride with 1:200000 adrenaline (LOX 2% adrenaline). The gingival biotype was measured with an endodontic K file number 15 (with stopper) pre-operatively and a 2mm thickness was recorded (Figure-2). Sulcular incisions were given using the BP blade number 12 extending from the distal aspect of the 1st premolar to the distal aspect of the first molar. After which, a vertical releasing incision using a BP blade number 15 was given distal to the first premolar extending beyond the muco-gingival junction. After which a full-thickness muco-periosteal flap was reflected.

With a micro motor straight hand piece and Tungsten Carbide round bur of diameter 1mm, vertical corticotomy grooves were made under continuous saline irrigation from the 2mm below the crest of the alveolar bone and extending 2-3mm beyond the root apex followed by joining of the labial and lingual grooves only at the edentulous area. The crestal bone was preserved around the adjacent tooth. Cortical perforations were made in between the vertical grooves on the labial as well as lingual aspect of the bone. (Figure-3)

The decorticated bone was filled with DFDBA. (Figure-4) and PRF membrane which was prepared by using 9ml of the patient’s blood and centrifuging it at 3000rpm.9 (Figure-5) Optimal amount of DFDBA was mixed with PRF and placed at the corticotomy sites. (Figure-6a & 6b)

The periodontal flap was approximated using 3/0 non-resorbable silk sutures in a tension free manner. (Figure-7) Periodontal pack was then placed. Capsule Amox 500 mg thrice daily for 5 days was prescribed as an antibiotic and tab Ultracet, 2 tablets daily for 5 days was prescribed as analgesic. The participants were instructed not to brush the operated area for 10 days. Post-operative instructions were given.

The patient was recalled after 10 days for removal of sutures and the patient was reviewed every week for the first month during which the oral hygiene instructions were reinforced.

Protraction force of about 150- 200gms was applied using elastic chains extending from molar to anterior retraction hook. Bimonthly activations were carried out thereafter to avail RAP phenomenon. Periodontal healing was assessed after 6 months. At the end of 6 months complete closure of the 4mm space was clinically observed and the gingival thickness of 3mm was recorded. (Figure-8)
Discussion

Orthodontic treatment in adult patients, have always been a challenge as they do not exhibit any further maxillo-mandibular growth as a result of reduced bone remodelling rate and increased bone mineral density and also there is a tendency to demonstrate increased risk of periodontal disease. Speeding up the treatment by applying increased orthodontic forces may result in increased chances of hyalinization. To overcome these drawbacks various surgical procedures and modifications have been attempted in the previous decades to obtain optimum clinical results.

Periodontally Accelerated Osteogenic Orthodontic procedure (PAOO) has been indicated when faster orthodontic treatment is desired, in moderate to severe crowding cases, Class II malocclusions requiring expansion and/or extractions, mild Class III malocclusions cases and extrusion for open bite and intrusion for deep bite cases. This technique also gained acceptance and popularity as it resulted in increased alveolar bone thickness, decreased treatment time, decreased amount of apical root resorption and enhanced post-treatment orthodontic stability. In this case report, the patient underwent PAOO procedure bilaterally and PRF was placed only on the 4th quadrant during the mesialisation of 46 in the place of previously extracted 45.

Platelet rich fibrin, a healing bio-material, possesses low thrombin concentration thus allowing the migration of endothelial cells and fibroblasts into the healing site.
It also permits a rapid angiogenesis, thus, showing potential for all types of superficial cutaneous and mucous healing. Platelet rich fibrin has also shown considerable results in increasing the gingival thickness. A study by Thamaraiselvan M. et al, comparing coronally Advanced Flap (CAF) with and without PRF in the treatment of gingival recession showed an increase in gingival thickness when PRF was used along with CAF.

In accordance with the above study, our case also demonstrated an increase in gingival thickness of around 1 mm after 6 months, even though it was used along with PAOO. The increase in soft tissue thickness may have been attributed to the several growth factors released by the platelet rich fibrin which may play a role in the proliferation of the gingival and periodontal ligament fibroblasts. Despite various advantages shown by this procedure, this technique had also previously reported few drawbacks such as, increased patient morbidity associated with the procedure due to its invasive nature, post-operative pain, swelling, risk of infection, avascular necrosis, decreased patient acceptance and damage to adjacent vital structures. However in this case report, healing was uneventful with resolution of inflammation and pain within 12 days, which is in accordance with the results of the study conducted by Munoz et al. Also, this case demonstrated a faster space closure within 4 months, compared to the time taken by the conventional procedure and the results are also in accordance with various reports and studies.

**Conclusion**

A combination therapy of PAOO with PRF tends to have a beneficial therapeutic result as the patients present with a reduce post-operative inflammation, decreased pain and reduced risk of infection without interfering with tooth movement or post-orthodontic stability. It also demonstrates an improved orthodontic treatment result along with reduction in various side effects such as root resorption, tooth devitalization and relapse of orthodontic treatment. Despite showing promising results in wound healing and soft tissue augmentation further well-designed and properly controlled studies have to be performed to validate these results.

Abstract

A prospective double blind study was conducted in 200 patients for the duration of one year with the aim to study the role of low molecular weight heparin (LMWH) for deep vein thrombosis (DVT) prophylaxis in hip and knee arthroplasty patients. Routine bilateral limb venography was employed to detect the presence or absence of the thrombus in patients at the time of admission and till 12 weeks post operatively. Thrombi were detected in 40% of the patients of the control group who did not receive any prophylaxis during the post operative follow up period whereas 50% reduction of DVT was noted in patients who received LMWH prophylaxis. In this study highest incidence of DVT was seen in Bipolar hip hemi-arthroplasty (50% reduction ) and those who underwent revision knee replacement surgeries (71.4%). Lower bleeding rate of 3% in this study has been attributed to intrinsic property of LMWH. Thrombi were detected in 30% to 40% of patient form 2nd post op week onwards uptill 4th post op week , making it imperative for extended and outpatient LMWH prophylaxis.

LMWH contains in its chemical structure a unique pentasaccharide that is required for specific binding to Anti thrombin III (AT III). Their ability to catalyze the inhibition of factor Xa by AT III makes them potent antithrombotic agent used for DVT prophylaxis.

Keywords: Deep Vein Thrombosis (DVT), Hip Replacement Arthroplasty (HRA), Knee Replacement Arthroplasty (KRA)

Introduction

With the aging population on rise the total joint Arthroplasty continues to grow. Though, these procedures are life changing interventions but the release of thromboplastins from dissected soft tissue and especially reamed bone, as well as venous stasis both during surgery and during relative post operative immobility, provoke a high rate of thrombo embolism. Several measures reduce the risk of VTE, but there is always a concern about the prolonged recovery, wound failure and infection. Post operative Venous Thrombo Embolism (VTE) includes venous thrombosis (DVT) and pulmonary embolism (PE). It is a serious and life threatening complication which can be prevented to a large extent by a suitable thrombo prophylaxis ¹. To prevent this life threatening situation and the cost burden of this disease, suitable DVT prophylaxis becomes imperative ².

The incidence of imaging confirmed that asymptomatic DVT was known to vary from 42% to 57% after hip arthroplasty and 41% to 85% after knee arthroplasty. The incidence of PE varies from 0.9% to 28% after hip arthroplasty and 1.5% to 10% after knee arthroplasty (3). Clinically significant symptomatic VTE has been reported to be less common ⁴. Of the various pharmacological agents available low molecular weight

DOI Number: 10.5958/0976-5506.2019.00685.5
heparin (LMWH) prepared by physical, chemical, or enzymatic depolymerization of unfractionated heparin (UFH) has remained the cornerstone for thromboprophylaxis against DVT. Among the available LMWHs, enoxaparin and dalteparin are indicated in major orthopedic surgeries. LMWH is as effective as standard heparin or warfarin with added advantage of not requiring monitoring of activated partial thromboplastin time or international normalized ratio.

LMWH has a number of advantages over other pharmacological agents which has led to their rampant use for thromboembolic prophylaxis. However, patient selection for DVT prophylaxis can be a challenging balance between DVT risk and bleeding risk.

**Material and Method**

A prospective double blind study was conducted in total of 200 patients with a follow up duration of 12 weeks from the day of admission. Out of 200 patients, 100 received LMWH prophylaxis and remaining 100 formed control group.

In this study LMWH (Enoxaparin) 30 mg S/C once a day was advised starting from 6 to 8 hours postoperatively and continuing for 2 weeks in TKR and 4 weeks in THR. Patients were followed up by serial venogram for a duration of 12 weeks postoperatively.

LMWH preparations have varying biochemical and pharmacological properties and of the three LMWHs Enoxaparin, dalteparin and tinzaparin approved by food and drug administration (FDA) in USA for VTE prophylaxis, It is enoxaparin and dalteparin which has been approved for use in orthopaedic joint Replacement Surgery.

LMWH vary in mass from 1000 to 10000 daltons prepared by chemical or enzymatic depolymerization of unfractionated heparin. They possess pentasaccharide required for specific binding to anti thrombin III (AT III) causing thrombin inhibition. Later compared with LMWH, unfractionated heparin have proportionally more of anti factor Xa activity compared with its anti-factor II activity, the ratios of two being between 4:1 and 2:1. Pharmacokinetically, LMWH’s have a very high bioavailability, a longer half life than unfractionated heparin and much less inter individual variation in its anti coagulant reponse to a given dose. They produce less bleeding as compared to unfractionated heparin because of its different effects on platelet function and vascular permeability. The anti coagulant response (anti-Xa activity) to a fixed dose of LMWH is highly correlated with patient’s body weight. There is no requirement of laboratory monitoring of the anti coagulant response by measuring anti-X levels or dose adjustment unless pregnancy, morbid obesity or renal failure is present.

Outpatient administration of the patient with or without the assistance of a visiting nurse or family member is both possible. In 30 to 40 percent of patients treated with LMWH, along with a lower hospital re-admission, rate of VTE recurrence substantiates its cost effectiveness.

In these conditions, the Anti-xa levels are measured four hours after subcutaneous injection; the dose of LMWH should be titrated to achieve a level of 0.6 to 1.0 IU/ml if administered once daily.

In this study, routine bilateral venography was used to measure the presence or absence of venous thrombosis. Bilateral venography was first done at the time of admission to rule out any pre-existing venous thrombosis. Thereafter patient was subjected to serial venography on first post-op day, on the day of discharge i.e. the 5th post op day and at the time of suture removal i.e. the 15th post-op day. Thereafter patients were subjected to venography once in two weeks for next 12 weeks.

After 6-8 hours post-operatively, according to the guidelines issued by American Academy of orthopaedic surgeons AAOS 10 by its DVT/PE work group in 2007, LMWH (enoxaparin) was administered 12 hourly in a dose of 30mg subcutaneously. It was continued postoperatively for 2 weeks in TKR patients and 4 weeks in THR patients.

**Observation And Results**

Out of 100 arthroplasty patients who received LMWH, 50 patients (50%) underwent Hip Replacement Arthroplasty (HRA) and 50 patients (50%) underwent Knee Replacement Arthroplasty (KRA). The results and observations in this study are based on the clinical findings and data obtained from the routine venography of both lower limbs during first 12 weeks post operatively.

In the prophylaxis group (n=100), 20% patients detected for DVT (n=20), 30% patients underwent HRA.
(n=6) and 70% patient underwent KRA (n=14). Patient who underwent HRA detected for DVT (n=6), 33.3% (n=2) had undergone revision hip arthroplasty, 50% (n=3) had Bipolar and 16.7% (n=1) primary THR. However no significant difference, in DVT was seen among 11 patients who underwent primary knee replacement or revision knee replacement weather unilateral or bilateral.

3% of the patients of prophylactic group (n=3) developed bleeding complication (combined major and minor bleeding). It was 2.9% in the study by Greets et al (16). No bleeding episode was noted in any patient in the control group.

In both the groups 20% of the thrombi were detected in the non-operated leg. 30-40% of patients developed DVT 2nd post-op week onwards. In patients undergoing Hip Replacement 4% of patients of THR developed detectable thrombus between 2nd and 4th week post-operatively. Similar finding was noted in the study by planes A et al (15).

At 4 weeks post operative the incident of DVT was 8% (n=8) in patients who received prophylaxis and 26% (n=26) in patients of the control group. Of these 8 patients 82.5% (n=7) had undergone THR and only 17.5% (n=1) underwent TKR. 20% to 35% of DVT occurred after the discharge of the patients from the hospital.

In KRA patients detected for DVT (n=14), 71.4% patients (n=9) had undergone revision TKR and remaining 28.6% patients (n=5) underwent primary TKR.

40% patients (n=40) of the control group (n=100) who did not receive DVT prophylaxis revealed thrombi in their lower limb venography, whereas detectable thrombi was seen in only 20% of patients (n=20) who received LMWH prophylaxis. In this study 50% reduction in the incidence of DVT was seen after prophylaxis with LMWH. In the study by Geerts et al (16) 31% reduction in incidence was noted after DVT prophylaxis with LMWH.

**Discussion**

Incidence of postoperative DVT varies extensively in the literature not only by the ethnic differences and characteristic of population, but also by variations in diagnosis modalities such as venography, CT scan or Duplex ultrasonography, presence of symptoms, the location of thrombosis, the post operative monitoring, duration and use of mechanical preventive devices.

The clinical trials performed to date include both double blind and open label designs. If feasible, a double blind design is preferable because it provides a more valid assessment of the relative safety of LMWH (eg bleeding rate ) in comparison with other clinical approaches.

In this study as in after studies like Geerts et al (16), LMWH reduced the incidence of DVT by 50% which is quite significant (P<0.01). LMWH prophylaxis has been advised in all patients undergoing HRA and KRA as this in the most cost effective modality in preventing otherwise fatal VET and PE. LMWH has been found to be more cost effective than more complex prophylaxis with warfarin and unfractionated heparin and other prophylactic pharmacological agents (17). Parameter used for making a comparative analysis of cost effectiveness includes cost of drug, INR monitoring and cost associated with major bleeding. Feasibility of administering LMWH subcutaneously makes it possible for administering it in 30-40% of patients as outpatient therapy, thus making it very cost effective. Its cost effectiveness is further enhanced by lower hospital readmission rate for VTE recurrence as reported in study by Oster G et al (18).

In this study, Bipolar Hip Hemiarthroplasty and Revision knee Replacement surgeries carried a high incidence of DVT 50% and 71.4% respectively. High incidence of DVT in bipolar hip hemiarthroplasty has been explained in part by the fact that it corresponds to the surgery for hip fracture. Hip fracture surgery has shown greater risk for DVT than elective total hip replacement surgery (19,20). As it has been revealed in this study and also in other studies that LMWH is an effective prophylactic agent for all hip surgeries, whether elective or emergency, producing 70-80% of life threatening reduction in incidence of pulmonary embolism (PE) and venous thrombo embolism (VTE).

Lower bleeding rate in this study of 3% which is comparable with results in study by Geerts et al and in study by Hull R D et al (21) is attributed to its intrinsic safety advantage as compared with other pharmacological agents.

In this study and in other studies like Planes A et al (15), 30-40% of patient who had not received prophylaxis...
at all developed DVT around 2\textsuperscript{nd} post operative week and onwards; 26\% of HRA and 4\% of KRA developed DVT after 2 week post operatively. Henceforth, extent of duration of the DVT prophylaxis is of utter importance considering the high incidence of DVT around 2\textsuperscript{nd} post operative week and thereafter in the absence of any prophylaxis.

In this study as also, mentioned in AAOS guidelines \textsuperscript{22,23,24} the DVT risk after knee replacement is 2 week and after THR is 4 to 6 weeks thus there is a need for extended out of hospital prophylaxis in patients undergoing THR.

In this study and in study by Hull RD et al \textsuperscript{21} LMWH was started 6 to 8 hrs postoperatively which was found to be effective and safe. The thrombotic process starts as soon as the arthroplasty begins and so thromboprophylaxis must be started as close to surgery as possible\textsuperscript{19}.

**Conclusion**

The use of LMWH for DVT prophylaxis has gained popularity in past 20 years. They have a bioavailability superior to that of unfractionated heparin and other prophylactic agents and produce less bleeding for equivalent antithrombotic doses. The favourable properties of LMWH allows it to be administered subcutaneously once or twice daily without monitoring or dose adjustment in most patients. This makes it a drug of choice and the most cost effective means for extended out patient prophylaxis for DVT. Due to high incidence of DVT in patients of the control group and 70-80\% reduction in the DVT incidence after LMWH prophylaxis we conclude that LMWH should be used for prophylaxis in all Arthroplasty patients.

Impact of Attention Deficit Disorder on Academic Performance of Children

Santosh B.R¹, Rachana N²

¹Associate Professor, School of Management, Manipal Academy of Higher Education (MAHE) Manipal, Karnataka, India, ²Research Scholar, School of Management, REVA University, Bangalore, Karnataka, India.

Abstract

Occasionally we all struggle to concentrate for a period of time, to sit still, focus on a particular activity, and have mood swings and social problems. At times we go out of control, unable to subdue our impulses. But children suffering from Attention Deficit Disorder (ADD) wrestle with these conditions every day. With the help of appropriate diagnosis and parent / teacher intervention this disorder can be out grown.

Objective: The main objective of this study is to examine the prevalent conditions and indicators of ADD in children of the age group 6-13 years and how ADD factors and traits have an impact on the academics of the students.

Method: Primary data was collected using a questionnaire distributed to parents and teachers. The data collected was analyzed using SPSS and Smart PLS.

Results: The result of the study revealed that boys are generally more affected than girls in number. Further, the result revealed that there is an inverse relationship between ADD and academic performance.

Conclusion: There is no doubt that if ADD symptoms are prevailing for a period of time one has to seek medical professional help. However, just medical attention may not be the solution to overcome ADD, teachers and parents have a significant role to play. Educating parents and teachers can lead to better parenting and teaching methods, which would improve the condition of children.

Keywords: Attention Deficit Disorder, Parents and Teachers Interventions, Academic performance, Preschool children

Introduction

Inattention deficiency is one of the typical mental ailments which develops in children at a very young age and becomes more prominent in middle school. Child with this condition have trouble staying focused on an activity, sitting still, not being able to pay attention or may lose track and not remembering to do things even after being reminded with. Having these symptoms is just the first step, and then these should persist in for a long time of about more than six months to be called as Attention Deficit Disorder (ADD). The child will not be able to complete any tasks on time as they work with very slow pace and it is very difficult for them to learn anything new. This behavior is sometime misunderstood by the parents, teachers and other elders as lack of interest of the child and is lazy to do any activities. Therefore, children will be shouted at rather than being taken care of [1]. It was found that 6 per cent of school aged face childhood learning and behavioral difficulties [2].

ADD is one of the most common disorders predominantly found among children. But there is a great amount of myths and bad assumptions about the disorder. Since many have access to internet, check symptoms on the web and come to an invalid conclusion, and live with
unsuitable treatment. Hence educating people becomes very essential also it’s necessary for them to comprehend what researches, doctors and science in actual tell about the right diagnosis and treatment for the illness. ADD is a very well documented mental disorder and is a highly treatable disease with the help of medications and therapies.

ADD can be broadly classified into:

Predominantly inattentive type of children generally suffer from poor concentration.

Predominantly hyperactive-impulsive type of children will have symptoms like interrupting, taking risks.

Combination type of children will have symptoms like difficulties staying on task and never seeming to slow down.

**Literature Review**

ADD being a mental illness, its co-occurring conditions affect the child mentally, physically and also emotionally. Most of the previous studies on ADD have focused on medical treatment to overcome the ADD syndrome. There is no doubt that if ADD symptoms are prevailing for a period of time one has to seek medical professional help. However, just medical attention may not be the solution to overcome ADD, teachers and parents have a significant role to play. Therefore, in this paper an attempt has been made to understand ADD from teachers & parents point of view and hence the subsequent literature review is narrowed down to parent teacher intervention to manage ADD child.

It is highlighted that teachers have an importance role in identifying behavioral & achievement results of children with inattention deficiency \(^3\). It is evident that teachers are the first ones to notice on the academic difficulties and failures of a child. Teacher factors do affect the behavioral and academics of the children suffering with the illness and prevalent symptoms. The effect and influence of teacher on education and health outcomes of the child and describing the factors that influence teacher’s patience, understanding and acceptability of ADD and their opinions on treatment options for their students is important. The educational research mostly reviewed two main types of compatibility issues which is among the teachers and students i.e., teacher-treatment compatibility and teacher-student compatibility. A child spends a lot of their waking hours in the classrooms, thus teacher’s viewpoint should also be considered when deciding the treatment regimes. Teachers know the illness, but not knowing how exactly to deal with the situation \(^4\). It is suggested that teachers should be more informative about the various types of treatment and therapies beneficial for a child. Teachers who exhibit patience and have knowledge of intervention techniques collaborating well with a positive attitude towards the children will result in student success.

A study on elementary school teachers has examined the impact of knowledge and misperceptions about ADD and it was founded that teacher’s awareness about both superior knowledge and misperceptions was well above chance \(^5\). Majority of the teachers know that the symptoms are not identical means to say that children with ADD do not misbehave out of willingness.

It was found that ADD was not considered as a ‘real’ disease but rather a combination of behaviors which the parents and teachers have become unwilling to tolerate and handle \(^6\). By the inference of this study on children critics claim that the Attention Deficit Disorder is either over diagnosed and as a result receive inappropriate treatment. Also only half the number diagnosed undertakes medicine and therapy. A certain percent of parents consider it to be a medical problem, but are more likely to believe that excess of sugar content in the diet of the child leads to ADD. Though many of the respondents have heard of ADD but could not be able to describe anything about it. This clearly shows the lack of awareness and knowledge about the disorder and how to deal with it.

Studies have revealed that ADD is associated with social difficulties, academic under achievements, mental co morbidities and peer problems \(^7, 8\). Functional deficits emerge into the children with ADD over a period of time but very little is known. It is reported that children with ADD had lower reading, spelling and math scores and low IQ scores when compared to normal children. Girls have been less likely to have been diagnosed than boys.

It’s argued that the peer relationship affect with children suffering from ADD and how ADD initially contributes to the problematic relationships also the reaction of peer’s to such issues and troublesome situation \(^9\). A peer group is both a social and a primary group of people which they prefer talking to. It is noticed
that observational learning fails in children suffering from ADD. Prior studies and research designate children with ADD experience peer rejection. It is well treated by stimulant medication, social skill training and behavioral contingency management. Short term interventions are not enough to help overcome the peer problems, hence typically require long term treatment. Individuals with ADD have found it difficult to organise tasks and materials, facing difficulty estimating time and prioritising their work and have trouble getting started on work. They tend to lose focus and attention while trying to listen or plan and is easily distracted by internal or external factors and forgets what was read and needs to re-read. They have trouble regulating their sleep, quickly loses interest in task, and finds it difficult to complete task on time. They have trouble controlling emotions and find it difficult to manage frustration. They find it hard remembering to remember and the child is not able to recollect recent happening while he is able to remember things of the past. And finally, he also speaks about ADD child finds it hard to control actions, to monitor and modify own actions to fit situation/aims and are too impulsive in what they think, do and say, jumping too quickly to incorrect conclusions [9].

Therefore from the above literature review it’s identified that common symptoms in ADD child is being organized, focus, effort, emotion, memory and impulsive.

**Objectives**

To determine the prevalence of ADD symptoms in children of the age group 6-12 years.

To identify the gender difference in the prevalence of ADD symptoms.

To determine the impact of ADD dimensions on academics.

**Methodology**

To achieve the objectives of the research study, the primary data was collected through structured questionnaire. The survey in confined to primary school children of Bangalore in the age group 6-13 years. In total 300 parents where contacted and out of which 88 parents agreed to participate in the survey. The parents were asked about their child behavior. Same questionnaire was given to both parents and teachers and an average was taken of their responses. Sampling technique used for the study was simple random technique. To test the hypothesis, the researcher adopted a modified version of Brown ADD rating scale questions and the data was analyzed using SPSS and PLS.

Analysis of Results and Discussion

Table 1 provides the mean and standard deviations between variables. In general, and considering all of the dimensions, memory and effort had the highest mean score of the constructs studied. Likewise, from table 2 it is inferred that boys show more symptoms of Attention Deficit Disorder when compared to girls.

From Table 3 reveals the correlation between study variables and academic performance. The result reveal inverse relationship between ADD and academic performance indicating if the ADD increases the academic performance decreases. Other sub constructs of ADD was positively correlated with ADD dimension with p<0.05.

Table 4 presents the findings form Smart PLS, where beta values are the coefficients of regression and t-values are used to decide on the significance. Expectedly, t-value with greater value of regression coefficients is found higher. Following the rule of thumb, t-value greater than two (t>2) is considered as significant, and is used for making decisions on the constructed hypothesis.
Table 4 provided the β value and t-value. The β value for the path ADD and academic performance was negative indicating inverse relations with t-value of 14.134, therefore $H_1$ is supported. The results comply with the earlier findings \[10\]. This implies that there is a significant impact of attention deficit disorder on academics. A child who shows a pattern of ADD symptoms may often fail to pay close attention to details or make careless mistakes in schoolwork, have difficulty following through on instructions and fail to finish schoolwork.

The result from PLS analysis revealed that t-value for the path being unorganized and its impact on attention deficit disorder was 3.901, hence $H_2$ is supported. This result are in tune with earlier findings \[11\]. A child with this symptoms shows a pattern of trouble organizing tasks and activities, loses items needed for tasks or activities, have trouble getting started with work.

The result from PLS analysis revealed that t-value for the path focus and its impact on attention deficit disorder was 5.800, hence $H_3$ is supported. This result are in tune with earlier findings \[12\]. This implies that a child will face hard time sustaining focused attention on a task having trouble to concentrate, easily distracted, appear not to listen even when spoken to directly.

The result from PLS analysis revealed that t-value for the path effort and its impact on attention deficit disorder is 4.231, hence, $H_4$ is accepted. The results are in line with American Psychiatric Association. This implies that the child finds it hard to control actions and is very impulsive.

**Conclusion**

In this paper an attempt is made to understand teacher and parent interventions on children with ADD. Nurturing a child with ADD is a challenging task. An ADD child may make carless mistakes, may have difficulty to follow instructions, trouble to concentrate, may be emotionally week, and can be very impulsive in such scenarios it’s important for both the teacher as well as parent to have patience, tolerance, persistence and personal belief to nurture an ADD child. Both the teacher and the parent must not react negatively to children acting out, because it can lead to children feeling embarrassed and socially isolated. Teachers and parents have daily interactions with the ADD students. They have access to the behavior patterns of the children on daily basis and they can monitor and record the observation this in turn will facilitate a better understanding and create a better awareness of the child’s requirements enhancing interpersonal relation and academic performance.

Dental Educational Environment in Institutions of South East Asia

Ramprasad Vasthare¹, Swagata Saha²

¹Associate Professor, ²Dental Intern, Dept. of Public Health Dentistry, Manipal College of Dental Sciences, Manipal, Manipal Academy of Higher Education, Udupi district, Karnataka, India

Abstract

Background and Objective: To improve the level of satisfaction of the student from the environment of learning is one of the important challenges faced by dental educators today. It has been hypothesized that since the learning styles of students are extremely varied, adopting methods of imparting dental education that suit their style will result in improved learning. The aim of this study is to effectively gain information about the learning style preferences amongst the dental students in the institutions of South East Asia.

Method and Results: A list of dental schools in the region was made from the World Dental School list. An internet based search was done to identify the infrastructural facilities from the website or via email. Scores were allotted for each learning style preference and the results were tabulated and analysed.

Conclusion: If adequate consideration is given to all parameters that affect dental educational environment, dental institutions will have a positive impact and will make dental learning, a more rewarding and pleasant experience.

Keywords: dental students, dental education, curriculum, learning styles

Introduction

South East Asia, a part of Asia consists of 11 countries namely Cambodia, Brunei, East Timor, Laos, Indonesia, Malaysia, Philippines, Myanmar, Singapore, Thailand and Vietnam and 4 territories namely Cocos Islands, Andaman and Nicobar Islands, Christmas Islands, and Hainan. It has a population of 610,000,000 and has around 65 Dental Institutions.

The dental education at undergraduate and post graduate levels is largely specialty oriented and the requirement of the system is apt infrastructure, healthy learning environment and dedicated training from well qualified instructors. It is well known that each student has his or her preferred way of learning and most students take elements of different styles to see what suits them in order to assimilate new information.

It has been hypothesized that since the learning styles of different students can be extremely varied, adaptation of methods of imparting dental education to suit their style will result in improved learning. [1]

A number of studies have been identified the stress sources that come along the different stages of one’s dental career. The key strategy in improving the overall quality of dental school environment is to identify the catalysts responsible for the stressors.[2]

Since not much information was available on the dental educational environment support systems in the countries of South East Asia, an internet based study was planned.
Objectives

The objectives of this internet based study was to:

Assess the existing dental educational environment in the countries of South East Asia.

Assess whether the Dental Educational Environment is supportive of different styles of student learning preferences namely Visual, Read/Write, Aural (Auditory) and Kinaesthetic.

Review of Literature

According to Bertolami [3], one of the major points of exasperation among students with the syllabus is the discrepancy between content to be learnt and the form of delivery of the very same.

Although a sizeable amount of dental students prefer a myriad learning styles, the faculty of dentistry teach extensively via lectures. Lecturing is critically a passive learning method that only encourages note taking in class rooms and in turn rote memorization as a means to accumulate knowledge [3].

Visual: These learners have a preference to use diagrammatic representations and symbolic illustrations like flow charts, graphs, models, hierarchies and arrows to understand the printed information. They may themselves use diagram or a picture to explain a concept to someone else.

Aural: These learners prefer listening rather than taking notes. To help with their understanding, they may say aloud their answers or hear taped discussions about the same.

Read/ Write: The students in this category learn better through printed words and text. They like studying from glossaries, lists, prescribed course books, notes made in lectures and handouts.

Kinaesthetic: Although put as a separate subpart, kinaesthetic learning is a combination of sensory capabilities. Experience and practice result in learning. In this type of practice, the student has to live or feel the experience in order to learn from it. In dentistry, this type of learning is received through clinical instruction or preclinical laboratory simulation.

The objective of instruments like VARK as stated by Fleming is to act like a catalyst for conversation between students and instructors. These methods are easy to understand and use and may help establish self-awareness amongst students in their endeavour to find the best technique to improve understanding.

There are two critical transitional periods in the life of a dental student i.e. freshman year (first year), when they are make the transition from the undergraduate level to professional school, and during the junior year (third year ), when they move from the classroom to clinical environments and start patient care. The students’ perception at these two levels were measured with the Dental Student Learning Environment Survey (DSLES).

Following are the different scales used in DLES:

FLEXIBILITY: It involves the extent of opportunities for students and faculty to change the environment for learning and the control over students. For example: Students are given the option to formulate their curriculum as per their preferences.

STUDENT TO STUDENT INTERACTION: The ability of students to mix socially and academically with students of different years and of the same year. For example, students in a dental school know each other well.

EMOTIONAL CLIMATE: It is about how a student’s experience affects their non-intellectual (affective) perceptions. Student’s anxiety hindering them from reaching up to their full potential is an example.

SUPPORTIVENESS: It talks about the extent the staff supports and encourages the students. For example, the school takes an active interest in the well-being of its students.

MEANINGFUL EXPERIENCE: The degree to which structured learning activities are up to date with the current practice of dentistry. For example if a student feels that the educational experience at dental school is a sense of achievement then it is a meaningful experience.

ORGANISATION: It is about the level of overall cohesion and coherence of learning experiences set within the curriculum. For example, classes progressing
systematically from week to week is a type of organisation.

**BREADTH OF INTEREST:** It explains about the encouragement given by dental schools to its students to conduct extra-curricular activities outside of regular coursework. Faculty promoting student interest in oral health care in a broad social context is an apt example.

There are a number of other “Learning Environment Assessment Instruments” namely:

- Clinical Learning Environment Inventory ( CLEI )
- Clinical Post Conference Environment Survey ( CPCLES )
- Clinical Education Instructional Quality Questionnaire ( CLIN Ed IQ )
- Dundee Ready Educational Environment Measure ( DREEM )
- State Self Esteem Scale. (SSES)
- Curriculum Strengths Weaknesses, Opportunities, and Threats (C-SWOT) survey.

Various innovative concepts have been put forth in dental education some of which are based on Independent study like individual or group research project which may not require a written examination. Other modules include:

- Problem based Learning
- Human Resources Management Course
- Undergraduate Research Opportunities Programme ( UROP )
- Student Exchange Programme
- General Practice Management Course.
- Student Teacher Guardian Schemes
- Faculty Student Partnership Practice model

**Materials and Methods:**

The list of dental schools in each country and territory in South East Asia as available was recorded from the list of World Dental Schools. The internet was used effectively to gain information about the infrastructural facilities in the dental school as per the websites of the school or information via email. If there were more than 5 dental schools in a country, the year of establishment of the dental school and the annual intake of students were used as a criteria to limit the study to the top 5 dental schools from each country. Information regarding the support systems for the students was systematically collected.

Since learning is individualistic and learning style preferences can vary, the learning style preferences were classified as per VARK instrument i.e.

- Visual
- Aural
- Read/Write
- Kinaesthetic

Visual style was checked by the availability and use of 5 features:

- 3 Dimensional Anatomy Software
- Internet sites with videos and demonstrations
- Digital media in teaching
- Instructional videos, movies and the use of television for teaching
- Powerpoint presentations

The Aural (Auditory) style of learning preference was checked via the availability of following 3 features:

- Audio visual tools
- Audiobooks
- Commentaries/ Narratives/ Interviews

The Read/ Write style of learning preference was checked via the availability of following 5 features:

- Self-study and Group study area
- Availability of Reading Rooms
- Availability of a good library facility
- Writing down notes and points regularly in teaching
sessions

Assignments, written tests and written examination practices.

The Kinaesthetic style of learning preference was checked via the availability of following 2 features:

Pre-Clinical simulation laboratories
Models and Gadgets for hands on training

1 point was allotted if a dental school in a given country had a particular feature and 0 point was allotted if the said feature was absent in a dental school of a given country.

When the data was being organised country wise, the dental school with the highest score for each component of the 4 learning style preferences was selected. It was considered as a representation of the availability of a particular style of learning preference in a given country.

An internet based search of the related facilities with respect to VARK instrument available in the top 5 dental schools of each country was done. The data so processed was recorded and interpreted.

Results

Table 1: Depicts the South-East Asian Countries with the corresponding styles of student learning preferences.

</table>

Table 1: The above data shows the score in percentage with respect to the different learning styles in the individual South East Asian countries.

From the data above it can be inferred that Singapore and Thailand have a good combination of the different styles with a score of 12 out of 15. They are followed by Malaysia, Indonesia and Vietnam with a score of 11 out of 15. Cambodia and Laos have the lowest scores in the area which indicates that the dental schools are equipped with limited infrastructure and the students are not exposed to the different learning style preferences.

Singapore, Malaysia and Vietnam have the highest scores in the Visual learning preference while Cambodia has the lowest score.

Coming to Read/write learning preference, Singapore and Thailand have the best infrastructure to support the same while Cambodia has the least.

With respect to Aural learning preference, Laos has limited support system in this category compared to the other countries as it has 1 point short of others.

Thailand and Indonesia has the highest scores in the category of Kinaesthetic which indicates that the dental schools in these countries encourage the use of
simulation laboratories and hands on training on models compared to the other countries in the region.

**Conclusion**

Student preferences should be addressed by dental educators so that the students are taught in learning conducive environments.

Dental education may be split into visual, read/write, aural and kinaesthetic modalities and is best imparted by interchanging amongst all of them. Students should be given the opportunity to observe and assist before they start their clinical years in the dental school to help in a smoother transition to the clinical aspect of dentistry setup and improve their interaction with the patients. Senior students who mentor the juniors provide an important experience for both of them. It could pave the way for a career in academic dentistry. The chance to shadow faculty and better experienced students, after entering the clinical years is an extremely important but underexploited technique for strengthening the clinical acumen of students.

Application of simulation technologies as a substitute for some aspects of teaching procedural steps hold huge promise and if utilized correctly can completely renovate the methodologies of imparting dental education to the future torch bearers of our profession.

Using high resolution videos to impart teaching helps to free the time of the instructor who can then give more personal training to the trainee, though it will never substitute for direct forms of teaching the clinical procedures.

The learning preferences of dental students for instructors who promote visual presentations and encourage note taking during lectures, is duly noted, but there is a small yet notable amount of students who actually prefer learning by listening or indulging in activities. While the majority comprise of aural learners who prefer lectures, a dialogue, discussion or case study further improves on the much needed learning and retention skills.

Active participation or more opportunities to do so in lectures and preclinical demonstrations definitely appeals to the kinaesthetic learner and pushes them to do better and improve their grasp and understanding of the subjects.

Students may or may not undergo a shift in their preference of learning when they change their learning environment from the lecture halls to preclinical laboratories and finally to the dental clinic. Educators need to be made aware of the differences in order to gratify or at least consider the likelihood of bettering the chances for aural and kinaesthetic learners.

Academicians are also supposed to acknowledge that many students prefer self-directed learning, indicating a desire for more instructions in the more incorporative, electronic form of media. They may mistake poor attendance in lectures as an absence of interest in the subject or even worse, as disrespect.

Faculty should be able to control their feelings by actually trying to understand as to why students want to learn in different ways. A simple gesture like asking “How would you like me to teach you?” will lead to a meaningful debate in a healthy manner of new ways to make learning more easy.

The VARK approach makes the dental educational experience both more productive and enjoyable for students and faculty members.

Further focusing on the below adds value:

- Creating problem centred curricula that will help students bridge the preclinical sciences to patient care.
- Using informational technologies to improve “Anytime, Anywhere” accessibility to a knowledge database and stimulate their learning experience.
- Implementing thematically integrated curricula conducted by interdisciplinary teams.
- Incorporating evidence based learning into the student’s curricula and patient care in clinics.

If adequate consideration is given to all parameters that affect dental educational environment, dental institutions will have a positive impact making dental learning, a more rewarding and pleasant experience.

**Limitations of the study:**

Updating of some websites had not been done. Some of the data available was outdated. Some institutions did not respond to the sent email.
Sometimes specific information in relation to some dental schools was not available on the website and after their email response, created bias in judgement. Such information had to be excluded.

Internet data can be suggestive, but cannot replace a personal interaction, stay or personal experience on a one to one basis.

When there were more than 5 dental schools in a given country, the chances of a country showing a higher score was possible due to reasons of representation.

Recommendations:

Dental Institutions should try and provide student learning opportunities that cater to all preferences of student learning styles namely Visual, Aural, Read/Write and Kinaesthetic.

Reorientation of the data available on the institution’s websites highlighting the facilities available, should be aligned with the student learning preference styles, so that the student using the website for information can judge whether a particular institution will suit him or her according to his or her learning preference style.

Understanding Relationship between Internet Addiction and Emotional Intelligence with Reference to Delhi-NCR Region

Verma Priti¹, Arora Nidhi²
¹Assistant Professor, Department of General Management, Sharda University, Greater Noida, ²Director, Dr. Ambedkar Institute of Management Studies, Bangalore, Karnataka

Abstract

Internet has brought a paradigm shift in almost all the vital aspects of life and has become an integral part of our life and society. Although numerous positive aspects of the Internet cannot be ignored; its excessive and pathological use and resulting health hazards have also drawn attention of researchers. The young generation is worst affected by it. The uncontrolled addiction to and obsession with internet leads to various psychological problems and affects mental health which is closely associated with emotional intelligence. Emotional Intelligence helps create a positive work climate, as it is closely linked with the interpersonal relationships, group dynamics and professional, leadership & managerial effectiveness. Thus, negative affect of internet addiction on Emotional Intelligence may be a big Public Health issue. There is, therefore, a dire need to understand the relationship between internet addiction and emotional intelligence. The present research aims at investigation of relationship between internet addiction and emotional intelligence based on a survey conducted on 1200 Students of various colleges in Delhi-NCR region. The study can be helpful in creating awareness and inspiring active research and thinking to find solutions to reduce the damaging effect of internet addiction on emotional intelligence.

Keywords: Internet addiction, Emotional Intelligence, Mental disorder, Relations, performance.

Introduction

Today, internet has brought a paradigm shift in almost all the vital aspects of life; and has become an integral part of our life and society. Although numerous positive aspects of the internet cannot be ignored; and are readily appreciated, its excessive and pathological use has also drawn attention of researchers. The new generation, highly exposed to internet uses, is likely to face the severe danger to different psychosocial problems.

Presently, all over world, a very large percentage of young generation has access to the Internet and they spend a considerable part of their time on online activities.

Corresponding Author:
Dr Priti Verma,
Assistant Professor, Department of General Management, Sharda University, Greater Noida.
Email: priti.verma@sharda.ac.in

After research on young generation’s uncontrolled addiction to and obsession with internet, researchers have concluded that the use of internet can bring negative consequences on the psychological welfare of users. Nima & Nazarin discovered a positive and significant correlation between anxiety level and internet addiction. It is a matter of serious concern, as internet addiction can result in the individual’s isolation from family and society, resulting in mental and behavioral disorders. Certain side effects pointed out by researchers are anxiety, stress and depression. These are related to mental disorder which affects emotional intelligence; which finally affects performance. Thus, this is a grave public health issue and needs to be researched.

Emotional intelligence is related to mental ability and activity and enhances individual and organizational performance by playing a significant role in understanding and maintaining the relationships with people. The well managed emotional intelligence can build an effective working environment anywhere, be it family or
educational institution or workplace. It is an important key to manage oneself as well as one’s relationship with others; and is thus entwined with social skills. Referring to human relations, success depends on recognition and awareness of our emotions, our emotional reactions, our understanding of others’ emotions and our strategic handling of different situations through emotional intelligence. Effective emotional intelligence helps in maintaining the quality of relations between individuals and thereby creating a positive environment.

There is, therefore, a dire need to understand the relationship between internet addiction and emotional intelligence, as emotional intelligence is closely linked with the interpersonal relationships, group dynamics and professional, leadership & managerial effectiveness. Today, with the prevalence of digitalization in every walk of life, where to cope with the aftermaths of the internet addiction has become a grave concern, the study can be helpful in creating awareness and inspiring active research and thinking to find solutions to reduce the damaging effect of internet addiction on emotional intelligence.

Although some researchers have conducted research on the topic and have discovered a positive relationship between internet addiction, emotional intelligence and students at different levels and employees, yet these studies are related to specific geographic regions. The present research aims at investigation of relationship between internet addiction and emotional intelligence among students in Delhi-NCR region.

### Literature Review

Internet addiction also termed as virtual addiction, can be defined as disproportionate and unrestrained preoccupations with Internet use resulting in distress. Internet addiction is the disorder caused by unreasoning and uncontrolled use of internet. It may negatively affect the individual’s mental and emotional health. Douglas et al. define it as a kind of extreme compulsive use that if the person is deprived, he gets too irritable and bad tempered.\(^6\)

Rickert advanced the view that excessive use of the Internet may lead to Internet Addiction Disorder, which includes problems with daily routines, school performance, and family relationships.\(^7\) Internet addiction is defined as an individual’s inability to control his or her use of the internet, which eventually causes psychological, social, school, and/or work difficulties in a person’s life.\(^8\)

Like any other addiction, internet addiction also results in several problems like little sleep, long gap between two meals, and inadequate physical activity. It also disturbs the studies and other aspects of the daily life of an individual.\(^9\) All of these result in a reduction in social communications and an increase in loneliness and depression.

Emotional intelligence comprises knowing one’s emotions, managing emotions, motivating one, recognizing emotions in others, and handling relationships.\(^10\) Emotional intelligence also refers to true understanding of the self-motivation, environment, recognition and controlling of one’s own feeling & those of others.\(^11\)

Emotional intelligence is the ability to know one’s own emotions and of others. It also includes emotion regulation in social situation.

Salovey and Mayer introduced the term emotional intelligence as the way in which an individual processes information about emotion and emotional responses. They identified emotional intelligence as the “ability to monitor one’s own and other’s feelings and emotions, to discriminate among them, and to use this information to guide one’s thinking and action.”\(^12\) It is emotional ability of a person that helps him/her reach self-awareness-based self-control.\(^13\)

The model of emotional intelligence given by Daniel Goleman says that a person’s set of skills powered by the brain dynamics in the background relate to one’s reactions. According to him emotional intelligence can be divided into two groups: the ability to manage ourselves as individuals, and to understand others, which in turn, is responsible for managing our social skills. The emotional part of the brain perceives the world differently than the reasonable part. Some skills like analytical thinking and technical skills are cognitive; some are a sort of blend of cognition and emotion, known as emotional intelligence.\(^14\)

Emotional intelligence consists of four fundamental capabilities: self-awareness, self-management, social awareness, and social skill. Each capability, in turn, is composed of specific sets of competencies.\(^15\)
In Sweden, Engelberg and Sjoberg conducted a study on 41 university students and used MSCEIT to assess internet addiction. They observed that those who scored high on the internet addiction scale performed poorly in emotion-decoding task.\(^{[16]}\)

The people, addicted to internet face not only physical side effects like back pain, neck stress, eye strain, but may also experiences academic, family and social problems.\(^{[17]}\)

Internet addiction may also lead to anxiety, depression and stress. There exists a positive and significant correlation between the level of anxiety and internet addiction.\(^{[18]}\)

Another very important ramification of internet addiction is increasing cut-off of human being from human being in society. Growing internet obsession is resulting in the avoidance of face to face social interactions.\(^{[19]}\)

Thus, Internet addiction affects social interaction and relation as well. It is making people more and more introvert as they are getting more absorbed in the internet and virtual world and are moving away from family and society.\(^{[20]}\) This virtual Social networking can be potentially harmful to the people.

Hasan Khoshakhlagh et.al., studied the relationship of Emotional Intelligence and Mental Disorders with Internet Addiction, in Internet Users University Students. The research was related to students from Isfahan University, Iran. The results showed a correlation between emotional intelligence and mental disorders with internet addiction.\(^{[21]}\)

**Methodology**

**Sample Design**

A sample of 1200 students falling in the age group of 17-24 years was chosen using convenient sampling from Delhi – NCR Region, India.

**Assessment tools**

1. Dr. Kimberly Young’s Internet Addiction Test.

**Results and Discussions**

**Table 1: Correlation between Age, Gender, Education, Family Income Internet Addiction & Emotional Intelligence**

Statement 1: A Study of Relationship between Internet Addiction and Emotional Intelligence of Students.

Null Hypothesis $H_0$: There is no significant relationship between Internet Addiction and Emotional Intelligence of Students.

Alternate Hypothesis $H_1$: There exists significant relationship between Internet Addiction and Emotional Intelligence of Students. It can be observed from Table 4 that the value of $F$ is 1314.459 and $F$ Critical value is 3.845.

$F > F$ Critical, We reject the Null Hypothesis and accept the alternate Hypothesis.

Conclusion

Thus, from the Results, it can be understood that there exists an influence of Internet Addiction on Emotional Intelligence. Therefore, for the well-being of current generation and posterity, and for the overall future growth; it needs attention of the researchers from interdisciplinary as well as multidisciplinary Area. It is essential to take preventive measures to avoid damaging effect of internet on people and society.

Conflict of Interest: Not applicable. This is a literature review and random sampling data analysis-based paper.

Source of Funding: Self.

Ethical Clearance: For this only questionnaire-based data was collected. Questionnaires were willingly filled by the candidates. Out of 1300 Questionnaires, 1200 questionnaires were properly filled.

No other experiment was done on any one. Hence, it does not require Ethical Clearance.

A Study on Occupational Stress of Assistant Professors in Selected Private Universities – Chennai

P. Abinaya¹, S Indupriya²
¹Research Scholar; ²Assistant Professor; Department of Commerce, VISTAS, Pallavaram, Chennai

Abstract

Today’s fastest, highly populated and polluted world, Stress is a common issue which plays a major role in humans life. Each and everybody are facing Stress due to various reasons. It is a mental strain which promotes various disorders. The present study examines the level of stress among Assistant Professor working in Private Universities and providing few suggestions to overcome from it. Sample includes 60 faculties drawn from four Private Universities in Chennai using simple random sampling method. Primary data were collected using a structured questionnaire and were analysed using mean, t-test and chi-square test. The level of stress factors was determined in a sequence. Further, among demographic information of respondents, the results revealed that there is a significant relationship between socio-economic and demographic variables of the respondents Such as Designation, Gender, Age, Marital Status, and Experience with the level of stress factors. The present study also focuses on suggesting some techniques to reduce the level of Stress by following ways like yoga, breathing exercises, meditation, Listening music, reading stories and novels etc.

Keywords: Stress, Stress Management, Psychological problem, Work burden, Techniques

Introduction

Nowadays a stress has become an internal part of jobs in every sector. Everyone lives is engaged with some stress due to internal and external element. External elements like job related stress, family oriented, Behavioural related stress etc. on the other hand internal elements like feel insecurity, inferiority, and ill-health, unrealistic expectation etc. The stress also creates emotional and psychological problem to all kind of people. Emotional signs are anger, anxiety, forgiveness, sleep disruptions, weight fluctuation, changes in eating habit, irritating. Psychological problems are head ache, blood pressure, stomach problems, hypertension, heart attack etc. The positive stress helps improved productivity & force people to focus sharply and the positive stressed people have to know how handle and overcome from the problem. But if the stress is growing negatively is very dangerous because the stress may cause some incurable diseases like cancer, tumour etc.

In every field a person have to come across stress due to life changing, human tendency and environmental changes. This paper focuses on the study about stress among Assistant professors working in private universities in Chennai. Most of them, they considered that this profession is least stress profession. Although the Assistant professor jobs includes more workload due to student colleagues relationship, Resources Availability, Meetings and professional activities, Management involvement, Regulation of government etc. Nowadays the professor career carries huge amount of stress. They have to handle the young generation (student), have to obey the orders and complete the entire work given by management and most importantly they have to update themselves to current scenarios.

Review of Literature

Reddy K. Jayasankara & Mr. Karishmarajamenon (2018) studied on “Academic Stress and its Sources Among University Students” defines the stress is the integrated part of students academic life. In his paper clearly discuss about the cause of stress in different dimensions like personal inadequacy, fear of failure, interpersonal difficulties, teacher pupil relationships etc. The author analysis data in to two categories are 1. Gender wise, 2. Steam wise. The study employed a quantitative research design. To understanding the source from the different spheres will enables professional in the field.
to tailor-maker intervention for students combining the most effective strategies.

Dr. Ravi and R. Kadhirvel (2016) conducted “A Study on Stress Management of School Teachers with Special Reference to Erode District” in his paper clearly study about, how the school teachers are affected due to stress and this paper also reveals some suggestions to overcome the stress by doing yoga, meditation, exercise, listening music, counselling from counsellors etc. The author used only average and percentage analysis to interpret the result. Finally this paper concludes how to manage people at work differently treating them with respect and valuing their contribution.

D. Selliah and S. Fabiyola Kavitha (2015) in their paper to study about “A Study on Stress Management with References of Softorix Technologies” exposed the level of stress among the employees in softorix technologies. It provided the information about measuring of stress level techniques which will helps to reduce the stress and promote a positive lifestyle. The percentage analysis, chi-square and t-test are used to analyzing the data. Finally the paper depicts the following factors had a close relationship with employee stress age, education, gender, workload, human relation, Relationship with peas and colleagues and physical requirement.

Dr. S. S. Jayasri (2014) conducted study on “Occupational Stress Among the Teacher of the Higher Secondary Schools in Madurai District – Tamilnadu” in her paper to determine the Occupational stress level of government and Aided school teachers in different socio culture and economic situation. She used five point scales for measuring the Occupational stress and the used percentage analysis, factor analysis for testing data. This study throws light on the fact that occupational stress is quite a personal matter and that the perception of the situations enables one to cope with it effectively, being aware of the cause of occupational stress and monitoring.

Dr. M. Prabhu, Dr. G. Madhanmohan (2014) conducted “A Study on Stress Among University Students in India” in his paper they analyse and compare the stress levels, anxiety and depression among Tamilian and Non Tamilian students of Pondicherry Central University. The author utilizes the statistical tools was mean, ANOVA, chi-square, correspondence analyse, Cluster Analysis, Correlation, Multiple Regression and suggest the special attention should be paid to them to address their problem and grievances. So that they get some helps to overcome their problems. The teaching faculty must concentrate on addressing anxiety which will automatically reduce stress among the students.

Dr. Lavanyavedagiri Rao (2013) a study about “Management of Stress Among College Students” she conducted exploratory study on how the college student are affected due to stress. Further study involves perceived levels of stress and detecting sources of stress among the college students. The author used only the percentage analysis to examine the data. The majority of the students experienced high level of stress due to financial problems & low energy levels uncertain future and the career opportunities. The women college students are aware of the stressors and do adopt some techniques to cope up and manage the stress. However the technique involves the dependence of the respondents on themselves and are not keen on seeking others help.

According to 3omoniyimary Bankeyabo (2013) studied “Sources of Work Place Stressors Among University Lectures in South West Nigeria”, reveals list out of sources affect the Nigeria Lecturer due to stress. The author used four point scales to analyze the data. He used gender wise details of measuring the level of stress. The findings of the study was stressors remain unattached to the level of perceived stress among university lecture will remain a permanent future. This may be very detrimental not only to the individual lectures but to the nation in general.

Objectives of the study

Primary objectives
- To analyse the overall study of stress among assistant professor in private universities at Chennai City.

Secondary objectives
- To identify the level of stress among Assistant professor working in private universities at Chennai.
- To suggest the ways how to manage the stress.

Research Methodology

This study deals with stress level of assistant professor in private universities at Chennai city (like
VelsUniversity, SRM University, Sathyabham University, and Hindustan University). Above four universities were selected for the present research. In that four university 15 members are selected in each of the department in Management as sample. The relevant primary data are collected from the respondents with help of structured interview schedule. The collected data are classified and tabulated. The data analysis is done with the help of percentage analysis and chi-square method.

Analysis and Results

The following are the additional demographic information’s that the study shows 67 per cent of the professor falls under the female category. In that, there are 37% of the teachers falling under the age group between 30 to 35 years. 48 percentage of the professors earn 20000- 30000 per month. Finally the 83% of the professors are married.

Hypothesis of the study:

• \(H_01\) – There is no association between male and female Asst.Professors with regard of level of stress
• \(H_02\) - There is no association between Experience of Asst.Professors and the Level of stress
• \(H_03\) – There is no association between Income of the Asst.Professors and the Level of stress.

Statistical Analysis – t-test & Chi - Square test:

\(H_01\) : There is no association between male and the female Professors with regard to level of stress.

\(H_02\) - There is no association between Experience and the Level of Stress.

Table 1: Shows Independent sample t- test for male and female with regard of level of stress

Notes: Denotes * the Signification level at 5%

(Notes : Hence LOS 1- Work Burden, LOS 2 - Job Security, LOS 3 - Over Timings, LOS 4 - Promotion Criteria, LOS 5 - Lack of Family Support, LOS 6 - Role Ambiguity)

Inference:

Since \(P\) value is less than 0.05. The Null Hypothesis is rejected at 5% level with regard to Level of Work burden, Over timings and Lack of family support of the professor. Hence there is significance different between male and female professors with regard to the work burden, over timings and lack of family support. Then comparatively the female professors have felt more stress than the male professors due to Lack of family support.

There is significance difference between male and female professors with regard to levels of stress. Since \(p\) value is greater than 0.05. Hence the null hypothesis is accepted at 5 % level with regard to Job security, Promotion criteria, Role ambiguity.

\(H_02\) - There is no association between Experience and the Level of Stress.

Table 2: Shows Chi-Square test of experience with regard of Level of Stress

<table>

<tr>
<td>LOS 6</td>
<td>8.616</td>
<td>.376</td>
</tr>
</tbody>
</table>

Notes: Denotes * the Signification level at 5%
Inference:

Since, p value is less than 0.05 the null hypothesis is rejected at 5% level of significance. Hence concluded there is association between experience and the level of stress on job security, over timings, and promotion criteria. The level of job security and over timings is having better than the promotion criteria.

There is no significance difference between Experiences of the professor with regard to the level of Stress. The p value is greater than 0.05 hence, the null hypothesis accepted at 5% level with regard to job security, over timings and promotion criteria.

\( H_0 \): There is no association between Income and the Level of Stress.

Table 3: Shows Chi-square test of Income with regard of Level of Stress.

</tr>
<tr>
<td>LOS 6</td>
<td>2.596</td>
<td>.957</td>
</tr>
</tbody>
</table>

Notes: Denotes * the Signification level at 5%

Inferences:

Since, the P value is less than 0.05 Null Hypothesis is rejected at 5 % level with regard to level of work burden and over timings of the Asst.Professors. Hence there is significance difference between income of the respondent with regard to the level of over timings and work burden Criteria’s.

There is no significance difference between Income of the professor and the level of stress. Since the p value is greater than 0.05. Hence, the null hypothesis is accepted at 5% level in the case of job security, promotion criteria, lack of family support, role ambiguity.

Limitation of the study:

- This study only covered four Private Universities in Chennai city alone.
- As the study done within the limited period. So the investigator could not select sufficient large sample for the study.
- Lack of interaction due to their busy schedule.
- The university professors were resistant to give correct information.

Scope of study:

In the present situation the work load and Work pressure is too more to all kind of people. Stress is a mental and emotional strain. Stress promotes various disorders. This study is only about the stress sphere of Assistant Professors in private universities at Chennai level. This paper helps them know how to handle the stress with few managing techniques. In this stream, the professors also need some support from the management side. Especially in job security and personal safety etc. The management can understand that “less stress work more” so without stress they render effective and efficient services to the management as well as to the Society.

Findings

- From this study the 83% of the Asst.Professors are married.
- 67 percentage of the respondent in female categories.
- 62% of the Respondent sometimes feels anger at the time of work due to stress.
- From this study show the female professor have more stress comparatively to the male professor. The female Professor has affected stress mainly due to the lack of family support, and work burden. The male professor have seriously affected due to the stress for the reason of job security and over timings.
- There is no significant difference between Experience, Income and level of stress in the case of job security, over timings and promotion criteria.

Suggestions:

From this study we have identify the that due to Management involvement, Heavy work load , family
commitment are the main factors of to increase the level of stress of the Assistant professors. The stress management should provide adequate training programmes and give counselling to the stressed teachers and individually they should follow the coping strategies like breathing, yoga, meditation, etc... That will helps them to improve their Performance achieving the targets in time allotted by management.

Conclusion

In the current scenario, Education plays a most important role in developing individual as well as whole environment (society). In that, a major part will be played by Professors (handling young generation-College Students). Stress at the workplace not only by the work overload and time pressure, but also by lack of rewards and prizes and most importantly, by not providing individuals with the autonomy to do their work as they would like. The management of Universities have to manage people at work differently, treating them respect and valuing their contribution. If they enhance the psychological well-being and health of Professors in the coming future the establishment make more revenue as well as employee retention.

The management have to consider their work stress. The Work burden and handling the students are the main reason for causing Stress. The management can appoint additional members like attenders (clerks and helpers) to reduce their work burden and over timings schedules and provides rewards, awards to motivate them and contribute their services to the society. Every professor should utilize their opportunities and developing to their skills and finishing their target as successfully.

Recommendation System for Breast Cancer Treatment Using K-Means Clustering Algorithm

Somil Jain¹, Manmohan Sharma², Puneet kumar²

¹Lecturer, ²Assistant Professor, Department of Computer Science, Mody University, Lakshmangarh

Abstract

Data Mining is one of the technology that is generally used healthcare industries now a days. As it helps in number of ways to the end users like doctors and patients. Doctors can prescribe medicine on the basis of mined data whereas patients can be categorized on the basis of severity type of disease and get treatment accordingly. In this paper we have designed a health recommendation system based on k-means clustering, using this approach it is easier for the doctors to segregate the breast cancer patients on the basis of their stages. Once the patients are categorized treatment is given to them accordingly.

Keywords: Recommendation system, K-Means, Healthcare.

Introduction

When we talk about the knowledge discovery from the data then data mining plays an important role by applying some intelligent patterns to generate the results. There are several benefits of using data mining techniques like early detection, medical solution availability, possible treatment methods and it also helps in creating new health care policies⁴. Different tools and techniques of data mining helps in discovering and understanding the hidden pattern in a dataset. Generally, there are two types of learning available in the data mining i.e. supervised and unsupervised. Clustering is considered as the unsupervised method. Here the set of data is partitioned into different groups in order to achieve higher similarity⁴ ratio between the objects of the same group. It has a wide application area which includes image processing, pattern recognition, analysis of purchase pattern of the customer. This paper aims to provide a recommendation system for the breast cancer patients with the help of cloud-based clustering using WEKA Tool.

Data Mining in Health Care

In the medical field a small error can be more harmful and costlier too, due to different types of medical errors many people’s losses their lives each year. In order to reduce the ratio of death due to various chronic diseases a smart recommendation is needed which provides the opportunities to reduce the medical errors and enhance the safety of the patients. Data mining techniques are very useful in developing such types of recommendation systems because of their capability of extracting the hidden pattern and relationship between the data.⁴ For storage of data we use cloud computing as cloud provides a very cost-effective solution. As Prediction of the outcome of a disease¹⁰ is very typical now days due to enormous amount of data and there complex structure so by using data mining tools and techniques it can be quite convenient to predict the outcomes on the basis of different variables¹²,¹⁹ of a large dataset. Data mining applications are also helpful for various stakeholders associated with healthcare like hospitals¹¹, clinics, doctors and patients by identifying the best possible treatments and suggestions. Data mining combines the various approaches to group the data which can be useful for the knowledge discovery process, like statistical techniques, machine learning¹³, visualization etc. are some of techniques which uses data mining as there base. If we talk about the models of data mining then they are broadly classified into two categories: Descriptive modeling and Predictive modeling¹²,¹⁴,¹⁹. Healthcare industries needs a system that handles large and continuous increasing volume of patients using IT infrastructure. Using cloud we can form an interconnection between different computers and source of providing information specifically in healthcare industries²¹.
**Descriptive modeling:** These types of models in data mining are generally used for identification of the data patterns with the help of different association rules, clustering techniques.

**Predictive Modeling:** These types of models are generally used for data prediction by performing various types of analysis upon the data which includes classification and regression analysis.

**Related Work:**

Intarajak T, Kang SH\(^1\) according to them breast cancer is one of the most dangerous types of cancers across the whole world, it was also stated that in north America it is the second largest cause of death after the lung cancer. As the data collection is a very important aspect in diagnosing any type of chronic diseases so Stotter A, Bright N, Silcocks PB, Botha JL\(^2\) has suggested an efficient and improved way of data collection by using COX model, they also suggested that age plays an important role in survival prediction. Nyklíček I, Louwman WJ, Van Nierop PW, Wijnands CJ, Coebergh JW, Pop VJ,\(^3\) suggested that depression is also risk factor in breast cancer. Ogbuabor G, Ugwoke F.N.\(^4\) according to the author’s data mining tools and techniques are considered as an efficient way to discover the hidden pattern and to map the relationship between different objects, here the author has compared two clustering techniques namely K-means and DBSCAN for analysis and as per the execution time and accuracy of clustering K-means performs better it was also suggested that clustering techniques are being immensely used in the healthcare field in order to provide better diagnosis and prediction of diseases in a cost effective manner. Balasubramanian T, Umarani R.\(^5\) has used k-means clustering for analyzing the risk factors associated with fluoride contents of water on the human body. Zheng B, Yoon SW, Lam SS.\(^6\) has developed weight based K-means algorithm to identify the leukemia, inflammatory, bacteria or viral infection, HIV infection and pernicious anemia disease in order to check the efficiency of the algorithm and prediction of diseases. Liou DM and Chang WP\(^7\) has pointed that in medical field diagnosis about the disease is very poor, so they have suggested to use machine learning methods for prediction specifically in medical field. Ahmad LG, Eshlaghy AT, Poorebrahimi A, Ebrahimi M, Razavi AR\(^8\) suggested that the use of classifier is very crucial while performing diagnosis in medical science. Belciug S, Salem AB, Gorunescu F, Gorunescu M\(^9\) have compared the performance of k-means clustering algorithm with SOM i.e. Self-Organizing Map and they have implemented a network of clusters based upon real time decision system to detect the recurrence of breast cancer.

**Why Breast Cancer?**

Now a day’s breast cancer is one of the common disease found in women’s and it is one of the main causes of deaths as compared with other cancers\(^1,10,14,16\). In this disease the cells of human body change their characteristics and behave abnormally and the occurrence of this type of cancer is increasing globally and early detection\(^14,15,16\) of this type of disease can reduce the losses of life. It is very difficult to understand the exact cause of the breast cancer; there are some of the factors like age, history, genetic involvement, late pregnancy, depression etc. by which the developing cancer can be assessed\(^3\). Treatment to breast cancer are categorized in two parts mainly Systematic and local. Under local treatments we have surgery and radiation therapy whereas chemotherapy and hormonal therapy are under systematic treatments\(^10\). As the conventional approaches are not suitable in this case so the various machine learning\(^7,8\) and data mining techniques has created a new hope for health care diagnosis and prediction.

**Different Stages of Breast Cancer**

**Stage 1**

This stage describes invasive breast cancer in which cancer cells are breaking through to or they may invade normal surrounding breast tissue. In this cancer has not spread outside the breast and no lymph nodes are involved in it\(^1\).

**Stage 2**

- If the size of cancer cell is not more than 1 inch but it has spread under the arm in lymph node.
- If the size of cancer cell is between 1 to 2 inch and may and may not spread in the lymph node.
- If the size of cancer cell is larger than 2 inches, but has not spread to lymph node under arm

**Stage 3**

The stage 3 has further categorized into two
categories initial stage and advanced stage

At initial stage doctor may find any of these symptoms:

• If the size of cancer cell is less than 2 inches and is starting to spread to other lymph nodes.

• The cancer cell size is greater than 2 inches and has spread to the lymph nodes.

At advanced stage doctor may find any of these symptoms:

• Cancer cell has spread to skin, chest wall, and nearby tissues).

• The cancer cell has spread along the breast bone near lymph nodes inside the chest wall.

Stage 4

This stage describes encroaching breast cancer that has spread to nearby lymph nodes and other organs of the body, such as the lungs, lymph nodes which are distant apart, skin, bones, and liver.\(^1\),\(^17\).

Various types of suggested treatments for breast cancer are Surgery, Chemotherapy, Radiotherapy, and Hormonal Therapy.

Suggested treatment options based upon the different stages\(^18\):

1. For Stage 1 and Stage 2 the following treatment are prescribed.

a) Total mastectomy or lumpectomy with radiation may be needed.

b) Sentinel lymph node biopsy or axillary lymph node biopsy and possible radiation to supraclavicular or at internal mammary lymph node.

c) Hormonal therapy is prescribed only for those patients who have hormone-receptor-positive cancer.

d) Chemotherapy may be given as safe side to reduce the risk of recurrence.

e) Targeted therapy is applicable when the patient is HER-2 positive.

2. Stage 3:

a) Radiated total mastectomy OR chemotherapy to shrink the tumor by following lumpectomy and radiation.

b) Axillary lymph node removal and to give radiation to the supraclavicular or internal mammary lymph node.

c) At this stage doctor recommend Chemotherapy.

d) Hormonal therapy is prescribed only for those patients who have hormone-receptor-positive cancer.

e) Targeted therapy is applicable when the patient is HER-2 positive.

f) At this stage other parts of the body does not require any treatment.

3. Stage 4:

a) Radiation, Surgery or they can be used together depending upon different factors.

b) If the size of lymph node is increasing then treatment to this node is essential.

c) At this stage doctor recommend Chemotherapy.

d) Hormonal therapy is recommended always when the cancer is hormone-receptor-positive.

e) Targeted therapy is used to treat both HER-2 positive and HER-2 negative with BRCA1 and BRCA2 mutation.

f) Radiations can be used to treat various symptoms and comfortless in the other parts of the body.

Methodology

1. To carry out this work using data mining approach we have created a dataset based upon various parameters like tumor size (in cm), lymph node, HER-2, Estrogen-Receptor, Progestron-Receptor.

2. Based upon the above parameters we have created a data set by classifying the different stages of breast cancer as Stage 1, Stage 2, Stage 3, Stage 4.

3. After creation of the data set clustering is performed on the dataset using K-Means Clustering algorithm for recommendation of suggested treatment to the patient.

4. To perform Clustering on the data set Weka Tool of data mining is used.
About the data set

We have studied different datasets related to breast cancer patients available at Wisconsin Breast Cancer Database. From these datasets and symptoms of different breast cancer stages, we categorize breast cancer on the basis of number of different attributes like tumor size, lymph node etc. We collected data for these different attributes from different medical repositories and designed our own data set as shown in figure 1. As we are designing an approach for experimental purpose so the dataset size is not that much large.

K-Means Algorithm:

As the role of data mining is becoming very important now days in health care diagnosis and prediction, so various techniques like clustering, classification, association etc. are used for this purpose. Clustering is a type of unsupervised learning which is used to group the objects of similar type that groups are known as “clusters”.

K-means clustering algorithm is most widely used method in the health care industry due to its simple use and performance in other research fields. In K-Means clustering algorithm clusters are to be pre-specified before deploying the algorithm. It works in two parts in first part centroids are selected randomly which consists a fixed value for K and in the second part allocation of data point is done to their closest Centre.

Steps to perform clustering:

1. Fetch the data from the database
2. Data is to be preprocessed to get appropriate features.
3. Decide the parameters for which clustering is to be done.
4. Apply the relevant clustering algorithm.
5. Visualize the results.

Discussion

Here we have create structured data set with the attributes like tumor size (in cm), lymph node, HER-2,
Estrogen-Receptor, Progesterone-Receptor, on the basis of the values for these attributes we have clustering using k-means algorithm. The advantage of that k-means provides tighter clustering for global data. As shown in figure 3 four clusters are formed on the basis severity level for different stages. Figure 2 shows instances of different clusters and it is clear from the figure that the cluster 0 has more number of severe patients of stage 4. So patients in this cluster require more and quick attention.

**Conclusion and Future Work**

It is clear from the work that k-means clustering performs better when used with most predictive variables. The proposed methodology is expected to help the therapeutic specialists by giving snappy, exact and solid suggestion as in our results the instances show the severity level and number of patients suffering from breast cancer, so on the basis of obtained clusters the recommendation system will assist the medical practitioners to take appropriate decision. Here we have created structured data set but in future we explore prediction for unstructured data set.

Effect of Core Training with and without Yogic Practices on Selected Psychological Variables among College Women Athletes

R. Meera¹, R. Mohanakrishnan², T. Arun Prasanna³

¹Research Scholar, ²HOD, ³Research Scholar, Dept. of Physical Education and Sports Sciences, SRMIST, Kattankulathur

Abstract

The study aims to examine the effect of core strength training with and without yogic practices on sports achievement motivation among college women athletes. To achieve the purpose of the study forty five (N=45) women athletes were selected randomly as subjects from Chennai city, Tamilnadu, India aged between 17 to 25 years. Three groups with fifteen subjects each were selected randomly and named as experimental group - I core strength training group, experimental group - II core strength training with yogic practices and group – III control group. The subjects were tested before and after the twelve weeks of experimentation. The core strength training and the yogic practices were selected as training protocol. The core strength training was given based on stress given in each exercises and sets, and the load was administered between 5 to 10 repetitions in a set with the time labs of 15 to 10 seconds for a set. The training protocol was followed by proper warming up and cooling down regime. The yogic practice was given in the morning time with proper prayer and warming up practice. The load of the yogic practice was increased by the number of yogic practices by 2 to 8 repetitions with 2 to 5 sets. The obtained data from the experimental and control group with the initial and final readings were analyzed statistically with analysis of covariance (ANCOVA) and Scheffe’s post hoc test was applied to examine the difference between groups and testing condition. The level of confidence was fixed 0.05. Result of the experimental group had significant improvement on sports achievement motivation when compared to control group.

Keywords: Core strength training, Yogic practice, Women Athletes, Sports Achievement Motivation, ANCOVA

Introduction

Core strengthening has drifted to excel in the sports medicine world. Its ethics are followed by familiar programs such as Pilates, yoga and Tai Chi for fitness. The motivation for sports achievement has been developed through the wide beneficial effects of the code stabilization thereby avoiding injuries and enhancing the athletic performance.¹ Muscular box with front abdominals, back paraspinals, gluteals, roofed diaphragm, pelvic floor and bottomed girdle musculature form a core.² Twenty nine pairs of muscles inside this box helps in the stabilization of the spine, pelvis and kinetic chain for functional movements They act all the way through the thoracolumbar fascia known as the “nature’s back belt”. Regular progressive stages form a core exercise program. It starts with the re-establishment of the length of normal muscles and the mobility for rectifying the instability of the muscles. The efficiency and perfection of the joint movement depend on the sufficient length of the muscles and sports achievement motivation.³ Many studies show that the individuals with core muscles deprived of sports achievement motivation will show signs of core weakness. Further more studies reveal that the individuals with lower back pain which is chronic can have higher level of fatigability, lower cross section and higher paraspinal muscles with fatty infiltration.⁴

Also core instability leads to musculoskeletal injuries in the high level athletes. Female athletes with core weakness are subjected to injuries in the anterior
cruciate ligament. They find imbalance and inability in compensating trunk perturbation that are unexpected. Hence the exercises for core stability with well built speculative basis prevent varied musculoskeletal conditions thereby treating spinal disorders. Yoga is a form of practices carried out physically and mentally, has its origination in India over three thousand years ago. It aims to provide us with high potential and achieve health and happiness.

Hatha Yoga initiates the body to work at the structural level, by levelling the vertebrae, increasing sports achievement motivation and strengthening the muscles and the connective tissues. The toning and the rejuvenation of the internal organs; the purification of the epidermal, digestive, lymphatic, cardiovascular, and pulmonary systems; the toning and the stability of the nervous and the endocrine systems; and the nourishment and stimulation of the brain cells are executed simultaneously. The concluding products are the high clarity of mental processes, stabilization of emotions and intellectual well being. Hence Yoga exercises help the human body and breath to get closely connected with the mind.

The mobility and flexibility of a person are improved through the postures of yoga by releasing tension and stress. The optimization of the basic yoga principle connecting body and mind is necessary for the restoration of the normal phase of sports achievement motivation. Perfect shape of the body is not sought during asana, rather passion is required. It guides us to love ourselves by cherishing the present life. The stretching of yoga advances a person’s sports achievement motivation. There prevails a mistaken belief that one must be flexible to perform yoga. The muscles groups in the three areas such as hamstring, hip and shoulders are improved through the yogasanas.

Sports achievement motivation or the freedom to move is defined as the capability of a person’s joint to move like a fluid with varied complete motions at a requires speed. It comprises regular range of movements devoid of undue stress towards the musculo tendinous unit. Many other factors related to performance are linked with sports achievement motivation. It directs a wide extent of motions involving joints in the ex-shoulder, hip, and ball and socket. It develops the strength and speed of the muscles with an effect of saving energy. Motor skills require the joints with an adequate level of sports achievement motivation. Hence, it helps in acquiring higher movement economy. Inaccurate movement executions are observed when the sports achievement motivation is insufficient.

An injury caused through shock and forces externally can be protected through sports achievement motivation. Also it is possible only when the injuries are at the optimum level. There are two kinds of sports achievement motivation namely passive and active. The capability of a person to execute wide range of movements with external assistance such as stretching with partner is called Passive sports achievement motivation whereas the capability of a person to perform a large range of motions devoid of any assistance is known as Active sports achievement motivation. In the view of angle with the above studies, the present study explores the effect of core strength training with and without yogic practices on sports achievement motivation among the college athletes.

Statement of the problem

The study aims to examine the effect of core strength training with and without yogic practices on sports achievement motivation among college women athletes.

Methodology

For achieving the aim of the study, forty five (N=45) women athletes were selected randomly as subjects from Chennai city, Tamilnadu, India aged between 17 to 25 years at random. Three groups with fifteen subjects each were selected as experimental group - I core strength training group, experimental group - II core strength training with yogic practices and group - III control group. The subjects were tested before and after the twelve weeks of experimentation. The core strength training and the yogic practices were selected as training protocol. The subjects were trained with core strength based on stress given in each exercises and sets, and the load administered between 5 to 10 repetitions in a set with the time labs of 15 to 10 seconds for a set. The training protocol was given with proper warming up and cooling down regime. The yogic practice was provided in the morning time making the subjects involve in proper prayer and warming up practice. The load of the yogic practice was increased by the number of yogic practices by 2 to 8 repetitions with 2 to 5 sets. The core training protocol were Crunches, Decline Crunch, Cable Crunch, Oblique Crunches, Jackknife Sit-Up, Barbell Side Bend,
Leg lift, Leg lift - Hang Position, Oblique Leg lift and yogic practices protocol were Suryanamaskar, Tadasana, Trikonasana, Paschimottanasana, Chakrasana, Bhujangasana, Nadi Sodhana, Bastrika, and Kapalapathi. The criterion variables were measured using SAMT inventory. The initial and the final readings derived from the experimental and the control group underwent a procedure of statistical analysis using ANCOVA i.e., Analysis of covariance with Scheffe’s post hoc test to evaluate the difference between the groups under different testing conditions. The IBM-SPSS – v21 software was used and the confidence level is maintained at 0.05.

*Significant at 0.05 confident level
The results as in table I - III obtained prior to the training programme were found similar. The results from the post test on the chosen variables of the experimental and the criterion variables were found significant. Also, the adjusted post test paired mean differences through the Scheffe’s post test based on the sports achievement motivation between the groups like isolated core strength training and core strength training with yoga training, isolated core strength training and control training, and core strength training with yoga training and control training are found to be significant with 0.000 p value. Therefore, the results indicated a significant improvement on the sports achievement motivation in the group with isolated core strength training and in the group with isolated core strength training with the yoga training. The control group showed an insignificant performance on the sports achievement motivation. The data is represented graphically in Figure I and II.

![Figure I](image1.png)  
**FIGURE I:** The graphical presentation of data of descriptive statistics on sports achievement motivation

![Figure II](image2.png)  
**FIGURE II:** The graphical presentation of magnitude of improvement from the initial to final means on sports achievement motivation

**Discussion on Findings**

The study resulted that twelve week training with the core and yoga training, and the isolated core training has significant improvement in comparison with the control group. Hence this study is similar to the observations of the previous research. França et al\(^1\) pointed out that the advantages of using core strength training over the usual resistance training gives the clear demonstration of the disability evaluation instruments compared with the pain evaluation instruments. Though the exercises involved in the training for core strength and trunk balance seem to be challenging, they help in reducing disability. In addition, patients are well benefitted with such kind of training than the pain reduction methods.\(^12\) As evaluation instruments produce results that are objective and distinctive, it is suggested to use them in the future studies to examine the impact of core strength training on the patients with low back pain.\(^13\) A ten day session with asana, pranayama, tratakas i.e., gazing with concentration, meditation and devotional practices can improve the finely coordinated movements in a significant way.\(^14\)

Yoga practices have the ability to reduce the level of optical illusion caused by the Muller-lyer lines, increase the critical fusion frequency, neural performance and reduce fatigue and stress level.\(^15\) Various motions through joint systems yoga training are improved through the training on sports achievement motivation and yoga. Athletes involving in warm-ups with stretching exercises show better improvement on their sports achievement motivation.\(^16\) It is obvious that the core strength with yogic training will yield better results compared with the isolated training. The control group showed null improvement on the sports achievement motivation.

**Conclusion**

On the whole, the motivation for sports achievement of the students in both the experimental groups is significantly improved than the control group. Also, the experimental group with the core and yogic training showed better improvement than the experimental group with the isolated core training on the sports achievement motivation.

Abstract

Aim: To evaluate the prevalence, extent and severity of periodontal disease and tooth loss among rural and urban adult population of northern Indian in local areas of Bakshi Ka Talab district.

Methods: A cross-sectional study was conducted among 1200 adults (632 males, 568 females) aged 35-74 years in urban and rural areas of Bakshi Ka Talab district, U.P., India. Data was collected by an interview followed by clinical examination.

Results: Mean number of missing teeth per person was 4.2 ± 7.4. At least one tooth missing was observed among 51.8% of subjects and 5.2% were completely edentulous.

Conclusion: The insights gained illustrate that tooth loss was highly prevalent in this rural Bakshi Ka Talab district population.

Introduction

One of the most important oral health indicators is the ability to retain more number of teeth throughout life. Oral health goals recommended by World Health Organization for the year 2020 has stated that there should be an increase in the number of individuals with functional dentitions (21 or more natural teeth) at ages 35-44 and 65-74 years [¹]. Tooth loss is the result of complex interaction of factors, of which the clinical condition of the tooth like caries, periodontal disease or trauma may only be the triggering factors, rather than the one single reason for loss of teeth. It is said to vary by age, gender, race, education, income and by geographic region [²]. Cultural factors, accessibility and availability of care, cost of care, individual’s attitudes and beliefs about perceived need for dental care and importance of maintaining the dentition interplay in the decisions of whether or when to extract a tooth. It is an outcome of treatment decision as well as disease [³].

Tooth loss impairs the quality of life, often substantially and affects the well being of the person. Missing teeth can interfere with chewing ability, diction, and esthetics. Low self-esteem related to tooth loss can hinder an individual’s ability to socialize, hamper the performance of work and daily activities, and lead to absence from work [⁴]. Hence, preservation of natural dentition should be the ultimate goal of the dental profession.

Information about the frequency of tooth loss and its risk factors in developing countries is sparse, particularly in Brazil and other Latin American countries. A study conducted in 2001 surveyed major metropolitan area
in Brazil and estimated a mean tooth loss of 11.2 teeth, which varied between 5.5 and 20.2 teeth in the 30-39 and 60+ years age groups, respectively \[^5\]. Prevalence of edentulism was 39.5\%, and mean tooth loss was 20.2 (SE=0.6). Older individuals [Odds Ratio (OR)=2.2], women (OR=2.3), white people (OR=5.9), individuals of lower socioeconomic status (OR=5.6) and smokers (OR=3.5) had higher likelihood of being edentulous \[^6\]. Tooth loss accounts for a high frequency among subjects aged over 60 years in Sri Lanka (20.7 ± 10.7) \[^7\]. Low education and low income were moderately [Relative Risks (RR) between 1.6 and 2.0] associated with tooth loss among both women and men in Germany \[^8\].

Relatively very few studies have been conducted to know the risk indicators associated with tooth loss among Indian adults \[^9,10\]. They reported that perceived need and attitudes towards dental care had an important influence on use of care. The older people prompted to have a fatalistic attitude and were least likely to attend the dentist.

**Materials and Method**

**Study design and setting**

A descriptive, cross-sectional study was conducted to evaluate the risk indicators associated with tooth loss in urban and rural adult population of Bakshi Ka Talab district, India, during August to October 2011.

**Sampling design and study population**

A total of 1293 subjects were approached to participate in the study but 93 declined citing a variety of reasons (response rate 92.8\%). Study sample of 1200 adults were recruited by a multistage stratified random sampling procedure.

**Methodology**

Data regarding the subject’s personal details, sociodemographic characteristics, diet, oral hygiene practices (materials used and frequency of cleaning), habits (smoking/ chewing tobacco and alcohol consumption), oral health knowledge, availability and utilization of dental services and self perceived oral health and need for treatment were recorded on a specially designed proforma. On an average 15-20 subjects were interviewed and examined per day. Amongst the sample of 1200 study subjects, 632 were males and 568 were females. Single investigator who was trained and calibrated performed all oral examinations (kappa value=0.90)\[^11-15\].

**Findings**

The study sample comprised of 1200 adults, aged 35 to 74 years with mean age of 50.9 ± 10.78 years. They included 565 (47.1\%) subjects from urban and 635 (52.9\%) subjects from rural areas. Of these, 632 (52.7\%) were males and 568 (47.3\%) were females. Table 1 show that 43\% of subjects (44.2\% urban adults, 41.7\% rural adults) had an intact dentition, with no tooth loss. Complete (5.2\%) and partial (51.8\%) edentulousness was comparatively higher among the rural adults (p=0.05) and males (p=0.007) in particular.

Discussion

Loss of teeth reflects a major public health problem in many countries. The prevalence of tooth loss among the adults of Bakshi Ka Talab district, India was 57%. Mean number of missing teeth (4.2) was higher in comparison with Haitian immigrants (2.64) of New York City [16]. Complete edentulousness was more prevalent among rural adults which is in conformity with few other studies [10,17,18]. Several other studies have shown no association between tooth loss and the place of residence [19,20].

Also, the attitude of the rural people is generally such that they elect to have their symptomatic teeth extracted rather than conserving those [18].

A directly proportional relationship was observed between age and tooth loss, which was lower than that found in National Oral Health Survey of India [9] and also among Saudi Arabian adults [19].

In the present study, females had fewer missing teeth than males. Though similar observation was found in other studies [17,20,21] few studies have shown female predominance [10,19,22] and also no difference in tooth loss [16,23,24]. Females are generally more concerned about their oral health and are more likely to choose preservation of their teeth over extraction. [23,26]

The level of education was found to be associated with tooth loss. In this study, people with higher levels of education had experienced less tooth loss. This result extends the finding of previous researches documenting that lower literacy level is associated with higher number of missing teeth. [10,21,23,24]

Conclusion

The findings of this study provide an insight into the prevalence of tooth loss which was observed to be higher among rural than urban adults in Bakshi Ka Talab district. The associated socio-demographic risk indicators responsible for increased tooth loss included age, males, illiterates and low socio-economic status groups.

Influence of Organizational Justice on Teachers’ Job Attitude – A Review

S Suganya
Assistant Professor, Department of Commerce, Vels Institute of Science, Technology and Advanced Studies, Pallavaram, Chennai

Abstract

Teachers play an indispensable role in the educational sector. Teaching is one of the distinguished and an astonishing activity involving a diversity of skills, perceptions, sensitivity, attitudes and knowledge. A teacher’s growth is reflected in their attitudes, values, belief and philosophy. The most of the teachers have not attained good position in their workplace. Teachers have been facing unfair in the educational institution. Based on this context, plenty of literatures dealing with teachers’ job attitudes based on organizational justice exists in their institution both in India and outside India have been reviewed. The results showed that some researchers have identified the variations in the perception of justice among male and female teachers. Some studies focused on the level of satisfaction in work itself and the researchers also found the various causes of teachers’ job satisfaction. Some researchers have empirically investigated the dimensions of fairness in the organization and the researchers also highlighted that the justice in the distribution and procedure play an essential role in satisfaction of teachers.

Keywords: Teachers, Organizational Justice, Job Attitudes.

Introduction

Teachers play an indispensable role in the educational sector. Teaching is one of the distinguished and an astonishing activity involving a diversity of skills, perceptions, sensitivity, attitudes and knowledge. A teacher’s growth is reflected in their attitudes, values, belief and philosophy. Attitude is an inclination to act in a particular situation either favourably or un favourably. Attitude is the way of individual feels about a place, a thing, an idea or a situation. Teachers’ job attitude is indispensable because it affects their job behaviour. Job attitude is a psychological statement towards one’s job and its environment. Job attitudes can be measured either by observing the action of the teachers in phenomena or asking questions related to a particular situation. The most of the teachers have not attained good position in their workplace. Teachers have been facing unfair in the educational institution.

Literature Review

Prince et al., (2018) have indentified influence of job satisfaction and organizational justice on turnover intention among teachers. The researcher has used convenient sampling method for one hundred and fourteen teachers and structured questionnaire was used. The results showed that under the variables of job satisfaction, only pay contribution showing negative relationship on turnover intention and also the variables of organizational justice, distributive justice and procedural justice showing a significant relationship on turnover intention.

Demir (2016) has investigated the association between acuteness fairness in organization and teachers’ organizational commitment and work satisfaction via meta-analysis. The author has conducted a wide range of literature review to identify the relationship exists between perspicacity of teachers’ justice, work satisfaction and the organizational commitment. The results also revealed that the perception of interactional justice has shown a significant relationship with organizational commitment.

Mina et al., (2015) have examined the association of organizational citizenship behaviour, profession satisfaction, institutional commitment and organizational justice among physical education teachers’. The results showed that there exists a significant rapport among
profession satisfaction, institutional commitment, and organizational justice with institutional citizenship behaviour. Path analysis revealed that satisfaction in the job has directly related to institutional citizenship behaviour but organizational justice and commitment has indirectly associated with institutional citizenship behaviour.

Ufuk and Unsal (2015) have discovered the effects of organizational justice opinion on intention to quit and the mediating role of teachers’ process of organizational identification. The data was collected from 292 public primary and secondary school teachers in Turkey. Organizational recognition fully mediates the predictive effects on the acuteness of distributive justice on turnover intention, and also it partially mediates the predictive effects on perception of interpersonal justice on turnover intention.

Mirza et al., (2015) have investigated the relationship among organizational justice, organizational citizenship behaviour, psychological empowerment and organizational performance among bank employees in Pakistan. The data was collected from 250 bank employees and to test the hypothesis regression analysis was used. The results also exposed that the organizational citizenship behaviour has a mediating effect on employee psychological empowerment and perceived organizational performance.

Alireza (2014) has investigated the job satisfaction of teachers with perceived organizational justice. The data collected from 437 primary and upper school teachers from Sweden. In order to test the hypothesis MANOVA, Correlation and Multiple regression analysis were used. The results also revealed that dimensions of organizational justice have a significant predictor of job satisfaction of teachers. The researcher also found that procedural justice is the significant predictor than distributive and interactional justice.

Cemal (2014) has analyzed the effects of justice in organization, organizational cynicism and organizational commitment among teachers of primary educational institutions. The data was collected from 515 elementary school teachers and the researcher has used correlation analysis to test the hypothesis. The researcher also suggests that organizational justice perception and cynicism are quite significant variables in employees’ exposition of organizational commitment behaviour.

Hassan (2014) has examined the connection between organizational citizenship behaviours and organizational justice with organizational trust. The researcher collected 191 samples from Syrian private banks. The researcher found that there exist positive significant effect on organizational citizenship behaviours. The researcher also found that organizational trust performs as a mediating role in the association among organizational citizenship behaviours and justice in the organization.

Moosa et al., (2014) have analyzed the “relationship between organizational justice and job performance of Payamenoor university employees in Ardabil province”. The results revealed that there exists a significant optimistic relationship between job performance and organizational justice. Showed that there exist between job performance and procedural justice.

Yadigarjon and Aykut (2014) have identified the association between the opinion of organizational justice and the organizational commitment levels of the teachers working in a private educational institution in the city of Konya. The researchers suggested that the development of organizational justice and fairness behaviours of the managers can create positive results for the organizations and to achieve the employee commitment.

Figen et al., (2014) have examined the association between dimensions of institutional justice and trust in school principals in Ankara. The researchers have collected data from 470 teachers of state primary schools. The results demonstrated that there is optimistic liaison exists between the dimensions of justice and trust in school principals. The results also indicated that the sub-dimensions of organizational justice have related with high level.

Bekir and Ahmet (2014) have determined the association between the perception of institutional justice and institutional commitments among teachers in Ankara. The researchers found that there exists a positive association among teachers’ acuteness of institutional justice and institutional commitment behaviours.

Essam and Iman (2014) have identified the effect of perceived institutional justice on Egyptian teachers’ job outcomes. The researchers investigated the direct and indirect impact of institutional justice among teachers. The results found that justice in distribution has a significant liaison with job satisfaction of teachers than procedural justice.

George et al., (2014) have identified the effects
of perceived distributive justice on organizational commitment of teachers in public secondary schools in Kenya. The samples were collected from 334 public secondary school teachers randomly. The results found that distributive justice was shown as a poor predictor for commitment. The researchers suggested that management needs to follow the fair distribution of rewards.

27Ziad et al., (2014) have explored the association between justice in organization and satisfaction of job among physical education teachers in Jordanian. The researchers collected sample from 166 physical education teachers randomly. The results revealed that teachers of physical education departments’ perceived fairness in organization were positively satisfied with the job. The results also revealed that acuteness of interactional justice was the preeminent forecaster of job satisfaction of teachers followed by procedural justice and distributive justice.

1Aliakbar et al., (2013) have investigated the association among organizational justice dimensions, organizational commitment, trust and perceptions of teachers’ self-efficacy of educational supervisors. The researchers collected samples from 361 teachers from Karaj City. Correlation analysis was used to test the hypotheses. The researchers found that casual relationship exists between justice dimension, trust, and Commitment and teachers supervisory role in self-efficacy.

21Mubashar et al., (2013) have identified the rapport among organizational justice with job performance and satisfaction for performance appraisal. The correlation and regression analyses were used to test the hypotheses. The results also revealed that satisfaction towards performance evaluation showed a significant association with employee job performance.

12Khurran et al., (2013) has explored the association between organizational justice with job satisfaction and work performance. The researcher suggested that the management can use suitable strategies for increasing employee’s job satisfaction and the organization should take care of procedural and interactional justice in order to maintain employee more satisfied.

8Fariba et al., (2013) have examined the association between fairness in the organization and organizational commitment among staff in Chahar Mahal. The researchers have collected 150 samples and correlation analysis was used for hypothesis testing. The researchers have found that fairness in the organization has a direct significant association with organizational commitment. The researchers also suggested the managers should take the effort to increase fairness, commitment and satisfaction in a workplace and also to evolve fairness in the distribution of rewards, sponsorship, promotion and appointment process.

15Matthew et al., (2012) have identified the perception of fairness in the organizational and its impact on organizational commitment with mediating role of job satisfaction among police officers. The researchers also revealed that perception of procedural and interactional justice had a circuitous effect on the police officers’ organizational commitment. Lastly, the perception of fairness in the organization showed an indirect effect on satisfaction and organizational commitment.

14Marzieh et al., (2012) have examined the rapport between fairness in organization and organizational citizenship behaviour. The researchers found that there is a significant relationship between perceptions of justice and organizational citizenship behaviour. The results of MANOVA showed that there is no significant difference observed between components of justice based on the demographic profile of the respondents.

13Malik and Basharat (2011) have scrutinized the influence of organizational justice on the institutional commitment to higher education faculty in Pakistan. The researcher has collected data from 463 higher education faculty and regression analysis was used for hypothesis testing. The results revealed that the junior faculty had a positive effect on procedural justice and distributive justice towards institutional commitment.

24Sajjad (2011) has determined the association between organizational justice, emotional empowerment, organizational commitment, work satisfaction and organizational citizenship behaviour. The results also indicated that job satisfaction has significantly persuaded commitment and citizenship behaviour and commitment has direct association with organizational citizenship behaviour.

22Neetu et al., (2011) have identified that the Organizational Justice improves the effectiveness of organizations by the way of increasing work satisfaction and organizational commitment. The author suggested that the exercise of fair treatment and fair procedures are the key antecedent to promote organizational
Mehmet and Hasan (2011) have analyzed the effects of fairness in the organizational on the citizenship behaviour. Regression analysis reveals that there exist a significant association between fairness in the procedures and contribution to organizational development; transactional justice and commitment to the job; and distributive justice and involvement to organizational development, self-improvement, and more committed to their job behaviour.

David (2005) has identified the influence of cooperation and employee identification with procedural and distributive justice. The results discovered that the procedural and distributive justice have a strong influence in employee identification.

Findings of the Review

Studies conducted on teachers’ perception of justice in various institutions like Schools, Engineering colleges, Medical and Nursing Colleges faced unjust management practice. Majority of the studies have brought the association between perception of justice and their attitudes and behaviours in the organizations.

Some researchers have identified the variations in the perception of justice among male and female teachers. Some studies focused on the level of satisfaction in work itself and the researchers also found the various causes of teachers’ job satisfaction. Some researchers have empirically investigated the dimensions of fairness in the organization and the researchers also highlighted that the justice in the distribution and procedure play an essential role in satisfaction of teachers.

Conclusion

The researcher concludes that teachers’ organizational justice influenced teachers’ job attitudes both positively as well as negatively. Unjust practice in the educational institutions makes the teachers negative involvement in their job and less satisfaction but in case of fair justice makes the teacher more involvement in their job as well as showing higher level of job satisfaction.

Prevalence of Panton Valentine Leukocidin (PVL) gene of *Staphylococcus aureus* Isolated from Different Sepsis Cases in Odisha, India

Anima Mohanty1,2, Bibhuti Bhusan Pal2
1School of Biotechnology (KSUT), KIIT University-2, 2Microbiology Divisions, ICMR-Regional Medical Research Centre, Chandrasekharpur, Bhubaneswar, India

Abstract

Panton Valentine Leukocidin (PVL) gene of *Staphylococcus aureus* is a potent cytotoxin that causes infection in skin and soft tissues which further leads to life threatening diseases. In this study we investigated the prevalence of PVL positivity rate in selected *Staphylococcus aureus* positive strains isolated from different sepsis cases from Odisha. The samples were inoculated on MacConkey agar, blood agar and nutrient agar plates and significant colonies were tested biochemically. The pathogens were tested against different antibiotics following CLSI guidelines. Polymerase chain reaction (PCR assay) was performed to detect mecA gene and PVL gene using specific primers. Out of 530 strains 425(80.2%) were methicillin resistant *S. aureus* (MRSA) strains and 105(19.8%) were methicillin sensitive *S. aureus* (MSSA) strains. PCR analysis revealed that 373(70.4%) were PVL positive MRSA and 51(9.6%) were PVL positive MSSA strains. This study showed high prevalence of PVL gene of *Staphylococcus aureus* in community acquired infection. Thus it is highly essential to understand the pattern of infection that will help for the treatment and control of community acquired and hospital acquired sepsis caused by *S. aureus* in this region.

**Keywords:** Sepsis, *Staphylococcus aureus*, MRSA, PVL, Odisha

Introduction

*Staphylococcus aureus* causes diseases ranging from localized skin infection to life threatening septicemia in human beings. It is the most virulent and prevalent microbial pathogens that cause hospital acquired (HA) and community- acquired (CA) infection throughout the world1. Its most remarkable feature is the ability to acquire resistance to antibiotics, one of which results in methicillin resistant *S. aureus* (MRSA) strain. MRSA is commonly recognized as the multi-drug resistant pathogen in the world, its emergence is found in increasing number of infection and often multi-drug resistant pose serious therapeutic problems to clinicians2,3. Various virulence factors present in *S. aureus* enables the microbe to interact with host tissues and defend itself from the immune system, it also persists to cause organ dysfunction4.

Panton Valentine Leukocidin (PVL) gene is a cytotoxin and an important virulent factor of *S. aureus* which was first reported in 1932. This toxin causes serious skin and soft tissue infection and selectively disrupts leukocyte membrane leading to enhanced virulence5,6 PVL toxin is a bipartite toxin comprising of two proteins, Panton Valentine Leukocidin F (*lukF*-PV) and Panton Valentine Leukocidin S (*lukS*-PV).This toxic PVL gene found in MRSA strains causes community acquired infections7. Worldwide the prevalence of PVL positive *S. aureus* varies within different countries as 97% in United states3,10,12.8% in China9, 4% in Turkey11, 30% in Germany12, 1.8% in Ireland13, 11.6% in Singapore14 and 0.9% in Korea15. The prevalence of PVL

DOI Number: 10.5958/0976-5506.2019.00694.6
gene in India was detected in 16% of S. aureus isolates, predominantly in CA-S. aureus (82%) as reported by Eshwara, et al,(2013). PVL positive S. aureus has become global public health burden due to its rapid emergence. This global emergence and spreading of clones combining methicillin resistant and PVL toxin production can be controlled by improved vigilance and effectively manage the PVL related disease.

As per the scanty reports available on the prevalence of PVL gene related to S. aureus so the present study has been envisaged to know the prevalence of Staphylococcus aureus isolated from different sepsis cases from three different hospitals of Odisha.

**Material and Method**

**Study site:** The pus and blood samples of sepsis cases like accidental infection, burn, ulcers, gangrene, abscesses, skin and soft tissue infection (SSTI), surgical infection and septicemia were included. Samples from these cases were collected from the OPD and IPD of Capital Hospital, Bhubaneswar; District Headquarter hospital, Khurda and SCB Medical College and Hospital, Cuttack during March, 2015 to February, 2018. The inform consent were taken from patients/ their attendants before the collection of samples.

**Isolation and identification of S. aureus:** The samples were immediately inoculated on MacConkey agar, blood agar and nutrient agar (Hi Media, Mumbai) plates and incubated for 24hrs at 37°C. Incubation of blood agar plates were done in both aerobic and anaerobic conditions. Significant colonies showing beta hemolysis in blood agar plates were picked for gram’s staining and biochemical tests for confirmation. Identification of S. aureus isolates was done based on colony morphology and biochemical tests like catalase, coagulase test (slide and tube), etc. Pure isolates of S. aureus were further confirmed by manitol salt agar test and chromogenic agar media (Hi Media, Mumbai) which was used for the rapid detection of MRSA strains.

**Antimicrobial susceptibility:** The sensitivity and the resistance patterns of S. aureus strains were tested with antibiotic-impregnated commercial disks (Hi-Media, Mumbai, India) as per disc diffusion method. The antibiotics used were azithromycin (AZM,15µg), ampicillin (A,10µg), ciprofloxacin (CIP,5µg), chloramphenicol (C,30 µg), cefoxitin (CX,30µg), doxycycline (DO,30µg), gentamicin (G,10µg), oxacillin(OX,1µg), ofloxacin(OF,5µg), penicillin(P,10µg), tetracycline (T,30µg) and vancomycin (VA,30 µg).

**Molecular analysis:** The DNA was extracted from the selected S. aureus isolates for detection of virulence-associated genes (mec A and luk-PV gene). Primers used for mec A gene (985bp) was (5’-CGGTAACATTGATCGCAACG) and (3’- TTTGCCAACCTTACCATCG) as described earlier by Stegger, et al., (2012). Primers used for luk-PV gene (433bp) was (5’- ATCATTAGTAAATGTCTGCGATACCA) and (3’- GCATCAASTGTATGGATAGC AAAAGC) as described earlier by Lina, et al.,(1999) PCR mixture (25 μl) contained 5 μl of DNA template after extraction was amplified (PVL gene) for 30 cycles (30sec denaturation at 94°C, 60sec annealing at 57 ºC and 2min elongation at 72°C). The PCR products were visualized in gel documentation under UV trans-illuminator using 2% agarose gel with Ethidium bromide.

**Results**

A total of 530 S. aureus isolates from different clinical cases from Cuttack, Bhubaneswar and Khurda areas. Out of these PVL positive were 425 (80.2%) in MRSA strains and 105(19.8%) in MSSA strains. The mec A gene (985bp) and luk-PV (PVL) gene were detected by simplex PCR method (Fig-1). The mec A gene were detected in 70% of the selected isolates and luk-PV (PVL) gene were detected in 80% of the selected isolates. The majority of the PVL positive isolates were obtained from MRSA SSTI cases 153 (28.8%) and least were from blood infection cases (Table-1).

The maximum PVL positive Staphylococcus aureus infected cases (25.8%) were seen in age group 50-60years male patients. The least PVL positive cases (1.8%) were seen in female age group of 18-30years. (Table-2)

**Antibiogram profile:** The five hundred thirty PVL positive Staphylococcus aureus were resistant to most of the antibiotics as azithromycin, ampicillin, chloramphenicol, cefoxitin ciprofloxacin, doxycycline, gentamicin, oxacillin, ofloxacin, and tetracycline. Eighty percentages of the Staphylococcus aureus isolates were methicillin resistant S. aureus (MRSA) strains which were, resistant to oxacillin as per CLSI guidelines. (Table-3).

MRSA and MSSA- methicillin resistant and sensitive *S. aureus*

(P<0.005 is Significant)

**Discussion**

Panton Valentine leukocidin increases the pathogenicity of *S. aureus* contributing to increase in morbidity and mortality rate. But the role of PVL in enhancing virulence of *S. aureus* and their pathogenicity is debatable as some studies have shown no association of PVL with the virulence of the organism. PVL is commonly used as a marker for differentiation of HA-MRSA and CA-MRSA which are now widespread in hospital settings and responsible for skin infection and other deep tissue infections. Diep et al., (2004) reported the association of PVL gene in skin and soft tissue infections caused by MRSA in San Francisco but the present findings revealed that *S. aureus* strains harbouring *pvl* gene (32.6%) was found in SSTI cases as well as abscesses, ulcers etc especially the community acquired infections and it was also found in MSSA strains.

Kaur et al.,(2012) from South India, have reported overall 62.85 % of PVL prevalence among MRSA and MSSA (MRSA:85.1 % and MSSA: 48.8 %) which indicates a higher prevalence among MRSA. D’Souza et al., (2010) from Mumbai reported prevalence of 64 % PVL positive isolates among MRSA strains. But in our study prevalence of 70.4 % PVL positive isolates among MRSA and 9.6% PVL positive isolates among MSSA
was observed. This variation in prevalence rate may be due to different geographical location and population. The infection rate as observed from our study was more frequent in male population than the female which was similar to the research carried out in a tertiary care hospital from south India. Most of the patients were male patients of age group 50-60 years, this could be justified as their immune system is weak and they are more prone to infection.

Over the past 2 decades, the incidences of both community-acquired and hospital-acquired \textit{S. aureus} infections have increased, while antibiotic treatment is increasingly hampered by the spread of \textit{S. aureus} strains that are resistant to multiple antibiotics, including methicillin. The results of antibiotic susceptibility testing revealed that both PVL negative MRSA and PVL positive MRSA isolates were resistant to most of the antibiotics except vancomycin. Similar results were reported from a south Indian hospital reported by Karthik, et al., (2016)

Global emergence and spread of MRSA remains a serious public health concern and challenge to clinicians and a number of different factors contribute to the pathogenicity and drug resistance of \textit{Staphylococcus aureus}. Research on PVL gene relating to manifestation to pathogenicity of \textit{S. aureus} strains isolated from different septic patients will be helpful for the treatment and management of septic patients in this region so the future study should be carried out involving more hospitals both from tribal and coastal areas of Odisha.

**Conclusion**

The present finding concludes that the more number of PVL positive MRSA strains were more detected in SSTI cases compared to other sepsis cases. The statistical significant PVL negative MRSA were showing higher MDR then PVL positive MRSA strains. As per the present findings the presence of PVL gene can be used as a reliable marker for CA-MRSA and CA-MSSA strains related to sepsis patients in this region.

**Acknowledgment:** We extend our sincere thanks to ICMR New Delhi for funding to carry out the research work. We are also grateful to the chief medical officers and the staffs of Capital Hospital, Bhubaneswar, District Headquarter Hospital, Khurda and SCB Medical College and Hospital, Cuttack for their kind cooperation and help during sample collection.

Does Serum Cotinine affects Lipid Profile?

Vaishali S. Pawar¹, Ajit Sontakke², Satish Kakade³, Jaywant Thorat⁴

³Cum Associate Professor, Department of Community Medicine, ⁴Technician, Department of Biochemistry

Abstract

Introduction: Use of tobacco is causing major health problems including cardiovascular problems. Nicotine in tobacco has been attributed to changes in lipid profile. Cotinine is one of the nicotine metabolite.

Aim: To estimate serum cotinine (CTN) levels and serum lipid parameters in tobacco smokers and smokeless tobacco users and to compare them with tobacco nonusers.

Materials and Method: This cross sectional study was performed in 240 study subjects divided into 4 groups - tobacco smokers (G1), smokeless tobacco users (G2), dual tobacco smokers and smokeless tobacco users (G3), and tobacco nonusers (G4). G2 was divided into G2a, G2b, and G2c. Serum CTN levels were estimated using enzyme linked immunosorbant assay kit. Enzymatic methods with commercial kits were used to estimate serum lipid parameters- total cholesterol, triglycerides (TG) and high density lipid (HDL). Very low density lipid (VLDL) and low density lipid (LDL) were calculated with formula. Chi-square test, unpaired t test and ANOVA were used for statistical analysis.

Results: Total cholesterol, TG, VLDL & LDL were significantly high and HDL was significantly low in tobacco users than tobacco nonusers (P<0.05). LDL is significantly high in tobacco chewers than smokers (P<0.05). A significant association was found between raised mean serum CTN levels and low HDL (P=0.019), also with raised total cholesterol, TG, VLDL and LDL (p<0.001). Total cholesterol, TG and VLDL were significantly increasing with duration and amount of tobacco use.

Conclusion: Tobacco users with longer duration of tobacco use with increased levels of serum cotinine have deranged lipid profile which can be a risk factor for cardiovascular diseases. Not only smoking but tobacco chewing also affects lipid profile.

Keywords: Serum cotinine, lipid profile, tobacco smokers, smokeless tobacco users.

Introduction

Tobacco use has become a major public as well as social health problem all over the world. Tobacco use is an avoidable cause of many diseases like cardiovascular diseases, chronic obstructive pulmonary disease, cancers, oral diseases etc. According to Global Adult Tobacco Survey India 2009-2010, prevalence of smokeless tobacco use (26%) is significantly more than that of smoking (14%).

Corresponding author:
Dr. Vaishali S. Pawar
Assistant Professor, Krishna Institute of Medical Sciences, Karad, Maharashtra, India

Tobacco contains more than 4,200 chemicals. Nicotine is an important alkaloid and major addicting substance in tobacco. Nicotine is regarded as responsible factor for most of the adverse effects of tobacco use. It is evident that nicotine has great impact on blood lipid levels.

Modification in lipid metabolism caused by pharmacological properties of nicotine and other constituents of tobacco leads to dyslipidemia which may act as a disposing factor for cardiovascular diseases (CVD). This eventually leads to increased morbidity and mortality in tobacco users. CVD are multi-factorial. A strong combined interaction exists between hypercholesterolemia, tobacco consumption and other risk factors.
factors in causation of CVD. Tobacco use leads to a high burden of early death and disability in India as compared to other countries.

The possible mechanisms of tobacco use in pathogenesis of CVD are-

Smoking causes endothelial dysfunction and platelet activation leading to a prothrombotic state.

Carbon monoxide induced atherogenesis.

Nicotine increases catecholamine and cortisol secretion that can alter carbohydrate and lipid metabolism.

Near about 70 to 80 % of nicotine is rapidly metabolized to CTN in the liver. CTN has a longer half-life of 18-20 hours and can be reliably estimated in blood, saliva and urine. Blood CTN is regarded as sensitive, direct and best marker for monitoring tobacco exposure in actively exposed individuals.

Presently, there is limited evidence relating smokeless tobacco use and CVD. Also, very few studies have been done in India regarding effect of smoking, smokeless tobacco use, dual use of smokeless tobacco and smoked tobacco on lipid profile. Hence, in this study we estimated serum cotinine as marker of tobacco exposure and serum lipid profile in tobacco smokers and smokeless tobacco users and compared them with tobacco nonusers.

**Material and Method**

**Study design**

This was a cross sectional study, conducted on subjects attending Ophthalmology OPD, Krishna Hospital, Karad, Maharashtra from January 2016 to December 2017.

**Ethics**

Ethical clearance was taken from Institutional Ethics Committee. Informed written consent was taken from every subject.

**Methodology:**

Based on the previous study done by Srivastava et al, sample size was calculated as follows: to obtain mean difference in serum total cholesterol level of 52.76 miligram per decilitre (mg/dl) (200.88± 15.63 mg/dl vs 148.12 ±16.22 mg/dl) among smokeless tobacco users and tobacco nonusers with permissible error 10%, confidence interval 95%, power 80% it come around minimum 10 in each group. Open Epi, version 3, open source calculator was used.

Hence, in each group 60 subjects were included with total 240 subjects in the following four groups.

Group 1(G1) - 60 tobacco smokers

Group 2(G2) - 60 smokeless tobacco users

G2a -20 tobacco chewers

G2b- 20 tobacco mishri users

G2c- 20 dual, tobacco chewers and tobacco mishri users

Group 3(G3) - 60 dual, tobacco smokers and smokeless tobacco users

Group 4(G4) - 60 tobacco nonusers

**Inclusion and Exclusion criteria**

**Inclusion criteria:** age between 35-60 years

Group 1 included smokers (an adult who has smoked 100 cigarettes or bidis in his or her lifetime and who currently smokes)

Group 2 included smokeless tobacco users (smokeless tobacco user was defined as ever using a smokeless tobacco product once within the past 30 days).

Group 3 included dual, tobacco smokers and smokeless tobacco users

Group 4 included subjects who never used tobacco

**Exclusion criteria**

Individuals with associated systemic illness like hypertension, diabetes mellitus, liver, cardiac or renal diseases, pregnancy and history of any other substance abuse (alcohol, drugs).

Subjects taking regular medications which can affect serum lipid profile level.

Subjects were selected by systematic sampling method. According to inclusion & exclusion criteria and four groups, subjects were selected from the patients coming to OPD. According to the group, every third
A proforma was filled for every subject containing demographic data, past history of tobacco use and medical history. Questionnaire was used to collect details of tobacco use.

In tobacco users, amount of tobacco use in grams per day calculated as follows: subjects were asked on an average how many packets of biddies / cigarettes/ chewing tobacco / mishri they used per day. To calculate how much tobacco each subject consumed, tobacco content \(^{12}\) in each tobacco products was multiplied by number of packets consumed per day.

**Biochemical investigation**

After overnight fasting, 10 ml of venous blood sample was collected in plain bulb with aseptic precautions from all the subjects. Blood was processed in Biochemistry laboratory of KIMSU, Karad. Serum was separated by centrifugation. Serum CTN level was measured by cotinine enzyme linked immunosorbant assay kit (Calbiotech). \(^{13}\)

Serum lipid profile was estimated by using analytical kit. Estimation of total cholesterol by CHOD-PAP method, TG by GPO-PAP method, HDL by Phosphotungstic acid method was done using EM360 Transasia automatically. \(^{14}\), LDL, VLDL were calculated by Fried-Wield’s formula. VLDL= TG/5, LDL=Total cholesterol-HDL-VLDL.

The reference range of serum lipid profile was taken as total cholesterol 150-200 mg/dl, TG 50-150 mg/dl, HDL 40-60 mg/dl, LDL 60-130 mg/dl, and VLDL 10-30 mg/dl. Derangement criteria for lipid profile values was taken as total cholesterol >200 mg/dl, TG >150 mg/dl, HDL< 40 mg/dl, LDL >130 mg/dl, and VLDL <30 mg/ dl.

**Statistical analysis**

Chi-square test, unpaired t test and ANOVA have been used. The data analyzed using IBM SPSS Statistics, version 20. P value <0.05 was considered as statistically significant.

**Results**

On comparison of the mean values of serum lipid parameters between the groups, they were found statistically significant (P<0.001). Total cholesterol, TG, VLDL & LDL were significantly high and HDL was significantly low in tobacco users than tobacco nonusers (P<0.05). In tobacco users, Total cholesterol, TG, VLDL & LDL were significantly high in G1, G2a, G2c and G3 than G2b (P<0.05). LDL is significantly high in G2a than G1 (P<0.05). [Table 1]

**Discussion**

When we come across the various types of lipoproteins, it is the level of LDL that is most directly associated with coronary heart disease (CHD). VLDL has been shown to be associated with premature atherosclerosis; HDL is protective against the development of CHD. 

Our study showed that Total cholesterol, TG, VLDL & LDL were significantly high and HDL was significantly low in tobacco users than tobacco nonusers. Similar findings were seen in study by Srivastava et al in smokeless tobacco users. Also similar findings observed by Khurana et al and Rao et al in smokers and tobacco chewers than tobacco nonusers. This could be explained by significantly higher CTN levels in tobacco users compared with tobacco nonusers as found in our previous study.

On the other hand, Siegel et al study of healthy players with smokeless tobacco use demonstrated no significant differences in Total cholesterol, LDL & HDL levels compared with nonusers.

In tobacco users, Total cholesterol, TG, VLDL & LDL were significantly low in tobacco mishri users than other tobacco users. This could be due to low serum CTN level in tobacco mishri users as proved by our previous study. LDL is significantly high in tobacco chewers than smokers. The differences in levels of other lipid parameters in other tobacco users were not statistically significant. Similarly, Khurana et al observed that the differences in levels of lipid parameters in smokers and tobacco chewers were not statistically significant.

Tucker et al observed that cigarette smokers did not differ significantly from users of smokeless tobacco regarding hypercholesterolemia. There was substantial proportion of hypercholesterolemia among smokeless tobacco users. From these findings, it is obvious that the consequences of using smokeless tobacco may reach beyond the oral cavity.

Gadpal et al observed that on comparison between tobacco chewers and smokers, mean TG and mean VLDL level were non-significant. Mean Total cholesterol, LDL & HDL were significantly high in smokers than tobacco chewers.

In tobacco users, a significant association between increased mean serum cotinine levels with deranged lipid profile was observed. Similar findings were present in study by Srivastava et al.

Significant increase in Total cholesterol and TG levels was found with increase in duration of tobacco use. VLDL & LDL were increasing and HDL was decreasing with duration of tobacco use. Similarly Haragopal et al observed significant increase in Total cholesterol and LDL in long term tobacco users compared with non-users and short-term users. This could be explained as due to long term effects of sustained blood nicotine levels.

Derangement of lipid profile was significantly high in subjects using > 5 grams of tobacco per day. Dyslipidemia in the form of increased TG, LDL & VLDL
along with decreased HDL is associated with occurrence of atherosclerotic lesions in vascular endothelium. A large amount of nicotine is absorbed into the blood as smokeless tobacco remains in contact of buccal mucosa for a longer duration also through gastrointestinal tract. Whereas, nicotine absorption is primarily by pulmonary blood vessels during smoking. A number of factors like pH value, nicotine concentration of the product etc. determine the amount of nicotine absorption and speed of transfer across the oral mucosa.

The finding suggests that smoking as well as tobacco chewing affects lipid profile due to increased levels of serum cotinine. Therefore, tobacco users should be counseled regarding health hazards due to tobacco use and encouraged to give up tobacco and adopt healthy lifestyle to reduce the risk of developing health related problems.

Limitations

Being a cross sectional study, we cannot assess the correlation of deranged lipid profile and CVD, so a longitudinal study is needed. Also we did not have exact information on amount of tobacco used per day, which is approximately calculated from number of packets used per day.

Conclusion

Tobacco users with longer duration of tobacco use with increased levels of serum cotinine have deranged lipid profile which can be a risk factor for cardiovascular diseases. Not only smoking but tobacco chewing also affects lipid profile. So emphasis should be given to educate people on ill effects of smokeless tobacco as well.

Betatrophin: It’s Impact on Lipid Profile in Type two Iraqi Obese Diabetic Women

Raghd A.Y. Alkhader¹, Khitam abdul-wahhab Ali¹, Abbas Mahdi Rahmah Al-Kharasani²

¹College of Medicine-Department of Chemistry and Biochemistry, Mustansiriyah University, Baghdad, ²National Diabetes Center– Mustansiriyah University, Baghdad

Abstract

Background: Betatrophin, have been identified as hormone produced in adipose tissue and liver, and involved in regulating of lipid metabolism and glucose homeostasis.

Aim: To evaluate serum betatrophin levels in type 2 obese diabetic women and compare these levels with obese non-diabetic women, and to investigate the relationship between betatrophin levels with fasting blood glucose and lipid profile levels.

Method: The case-control study was included obese women with type 2 diabetic and non-diabetic (n=44 each) of same age and BMI. Serum betatrophin, fasting blood glucose (FBG), total cholesterol, triglycerides and high-density lipoprotein-cholesterol (HDL-C) were measured from all individuals. Low-density lipoprotein-cholesterol (LDL-C) and very-low-density lipoprotein (VLDL-C) were calculated according to the (Friedewald formula).

Results: Serum betatrophin levels were higher (P<0.001) in type-2 obese diabetic women when compared to obese non-diabetic control, and there was a significant positive correlation (r = 0.332, P = 0.028) between serum betatrophin levels and fasting blood sugar levels. According to Receiver Operating Characteristic curve, betatrophin suitable for distinguishing between type-2 obese diabetic women from obese non-diabetic women (AUC = 0.820, p<0.0001).

Conclusion: Betatrophin hormone showed a highly significant elevated level in type-2 obese diabetic women compare to non-diabetic obese women. The findings of this study established betatrophin a good marker, suitable for distinguishing T2DM women from those without this condition.

Keywords: Type 2 diabetes, Betatrophin, Obesity.

Introduction

Type 2 diabetes mellitus (T2DM) is the most prominently growing chronic disease chiefly resulting from an impairment in both insulin secretion, and insulin action. T2DM, encompasses subjects who have insulin resistance (IR) and insulin deficiency. It is the most common, form of diabetes mellitus; it is not only insidious in onset but also asymptomatic.

Obesity can be generally defined as, an excess amount of body fat, it is a major risk factor for T2DM. Importantly, T2DM is strongly linked to obesity in both sexes and all racial/ethnic groups. It has been estimated that about 80% of T2DM subjects are obese; explaining the close association of adiposity, with IR and justifying the term “Diabesity” from diabetes and obesity.

Betatrophin, is a bioactive peptide hormone, generally encoded by Gm6484 gene in mouse liver and fat. Moreover, betatrophin is mainly expressed in the human’s liver and is encoded by C19orf80 gene. Melton et al. (2013) identified a hormone, ANGPTL8, which they called “betatrophin” and highlighted the role of this
hormone as a regulator in proliferation of the pancreatic β cells. Betatrophin also designated as “Hepatocellular Carcinoma-Associated Gene TD26” TD26, RIFL, ANGPTL8, and Lipasin.

Betatrophin was also named angiopoietin-like 8 (ANGPTL8), as it shares a significant sequence-similarity, with the angiopoietin-like (ANGPTL) protein family, specifically angiopoietin-like 3 (ANGPTL3). Betatrophin /ANGPTL8 is a member of ANGPTLs family, that the (ANGPTL1 to ANGPTL7) have a very similar structure that is made up of a carboxy-terminal (fibrinogen-like) domain, connected with an amino-terminal domain (coiled-coil) by a linker region. ANGPTL8, unlike ANGPTLs family, it possesses only the (coiled-coil domain).

Both in-vitro and in-vivo studies, have been suggested that Betatrophin/ANGPTL8 acts to inhibit lipoprotein lipase (LPL). Thus, in the Angptl8 knockout mice, low TG phenotype is probably caused by increasing in the activity of LPL. Lipoprotein lipase is the rate-limiting enzyme, for hydrolysing the core TG presenting in the circulating lipoproteins, liberating FFA that are generally taken up by cardiomyocytes and adipocytes to be either oxidized or stored.

The discovery of betatrophin/ANGPTL8, as a hormone has the capacity to increase the proliferation of β-cell was hailed as, a scientific breakthrough. It was shown that betatrophin/ANGPTL8 has been increased under the IR states to increase the proliferation of β-cell and the production of insulin. Betatrophin (ANGPTL8) was increased in ob/ob (obese) mouse model, and in the db/db (diabetes type II) mice. The ability to induce the proliferation of the pancreatic β-cell was promising in the DM therapy; nevertheless, this result was irreproducible and “could not be confirmed by further studies”, so beta cell proliferation by betatrophin/ANGPTL8 was invalidated.

The aim of the study is to evaluate role of serum betatrophin levels in type 2 obese diabetic women and compare with obese non-diabetic women, as well as to investigate the relationship of betatrophin levels with FBS and lipid profile values.

Subjects, Materials and Method

This case-control study was conducted at College of Medicine, Mustansiriyah University, Baghdad, Iraq in collaboration with the National Diabetes Center during the period from December 2017 to April 2018.

Eighty-eight subjects were included: type 2 obese diabetic Iraqi women as (patients group, n=44) and obese non-diabetic women as (control group, n=44). They were comparable in age and BMI. All T2DM patients were diagnosed by physicians and measurement the fasting blood glucose levels, according to the ADA, and WHO criteria. Obesity is defined as a BMI of 30 kg/m² and above. Patients with type-1 diabetes, gestational diabetes; concurrent renal disease, liver disease or thyroid dysfunction; lactating women, smoker, alcohol drinker; and patients on hypolipidemic drugs, such as statins were excluded from this study.

After an overnight’s fasting, blood were collected from each patient and control subject at time (8.30-10.30 am). The serum was separated and stored at −20°C till further use. Serum of human betatrophin was measured by Enzyme-linked immunosorbent (ELISA) assay. Serum fasting blood glucose (FBG) and Serum total cholesterol, triglycerides, high-density lipoprotein-cholesterol (HDL-C), were measured by KENZA 240TX/ISE Automatic biochemistry analyser. Low-density lipoprotein-cholesterol (LDL-C), and very-low-density lipoprotein (VLDL-C) were calculated according to the (Friedewald formula). Body Mass Index (BMI) was calculated by using the following equation.

\[
BMI = \frac{\text{weight (Kg)}}{\text{square height (m}^2)}
\]

Medical history regarding the age, duration of DM, as well as history of the other illness, were recorded from the patients, and their medical records were reviewed.

Statistical Analysis

The Analysis of data was performed using the available Statistical Packages for Social Sciences version 24. Data were presented in mean±standard deviation (SD). The statistical significance of difference of [quantitative data] were tested by using (Students-t-test) for difference between 2 independent means, or (ANOVA test) for difference in means among more than 2 independent groups. The P value ≤0.05 was considered significant. The Pearson’s correlation was calculated to determine the correlation between 2 quantitative variables, with its t-test for testing significance of the correlation. The Receiver Operating Characteristic (ROC) curve analysis was used for determining the use
of any parameter as a diagnostic or screening tool for disease, and to determine the “cut-off value” which of optimum sensitivity and specificity to diagnose disease.

Results

The clinical and the biochemical characteristics of study subjects, are shown in Table 1. Mean value of serum FBG in type 2 obese diabetic women 173.00±52.24 mg/dL was increased (P<0.0001) compared to mean serum FBS in obese non-diabetic controls (84.30±7.32 mg/dL). Data in Table 1 demonstrated the mean value of serum betatrophin in type 2 obese diabetic women 1167.35±420.42 pg/ml which was higher (P<0.0001) compared with mean serum betatrophin levels in obese non-diabetic women 724.14±278.9 pg/ml.

*Significant difference at (0.05 level)
The Receiver Operating Characteristics (ROC) analysis for serum betatrophin, when used as a test to diagnosis subjects into cases and control groups, showed the area-under-the-curve (AUC) of serum betatrophin was 0.820 (p<0.0001), the optimum cut-off value for serum betatrophin 921.5 pg/ml with sensitivity 77.3 and specificity 79.5 are shown in Figure 1.

Figure 1: Receiver Operating Characteristics analysis for determining the cut-off value of Betatrophin in distinguishing obese T2DM from control women.

The optimum cut-off value for serum betatrophin (921.5) with sensitivity (77.3) and specificity (79.5).

Discussion

Betatrophin, was identified as hormone which produced in adipose tissue and the liver, and involved in regulating both lipid metabolism and glucose homeostasis. Circulating betatrophin/ANGPTL8 levels are altered in different metabolic disorders, even though many of these results are inconsistent.

Betatrophin levels were highly significant elevated in type 2 obese diabetic women in comparison to controls (Table 1). This finding is in agreement with Al-Daghri et al. who found that betatrophin/ ANGPTL8 circulating levels were significantly elevated in T2DM patients in comparison to controls. In addition, they predicted that higher demands for insulin in T2DM condition as a result of IR, can cause an increased in the production of betatrophin/ ANGPTL8.

Previous reports showed that betatrophin levels were decreased; or even unchanged in diabetic patients. Both of these results were inconsistent with the present results, in addition with results obtained by Yamada et al. Espes et al. demonstrate that circulating betatrophin concentrations were significantly elevated in long standing (type-1 DM) subjects when compared to healthy controls. Fu et al. suggested that this conflicting of results was primarily due to the differences between (EIA/ELISA kits) with reactivity to the (N-terminus or C-terminus) of betatrophin/ ANGPTL8 or because of ethnic differences.

Our findings are accoedance with previous reports. Al-Rawashdeh et al. who found that plasma concentrations of betatrophin were elevated in metabolic syndrome (pre/T2DM subjects in comparison to MS-control subjects. In this study, according to type 2 obese diabetic women the results found that there was a positive correlation between mean serum betatrophin levels and fasting blood sugar levels. Fu et al. who predicted a positive correlation between circulating betatrophin level and fasting glucose.

Extensive research on betatrophin has produced evidence that, via a transcription factor referred to as (ChREBP) “Carbohydrate-responsive element-binding protein”, glucose controls the expression of numerous genes, involved in carbohydrate homeostasis. This glucose stimulated transcription factor regulates the gene expression, by binding to specific consensus sequences in the promoter region of gene which called “carbohydrate responsive elements” (ChRE). In this regard, betatrophin / ANGPTL8 was revealed to have a ChREBP binding site (from -398 to -382) in its promoter region. It has additionally been indicated that in hepatoma (HepG2) cells, ChREBP actually binds to the betatrophin/ANGPTL8 promoter. Hence, taking into account these points a positive correlation between FBS with betatrophin/ANGPTL8 in T2DM, is expected.

Regarding serum betatrophin levels, the results showed that no correlation between betatrophin levels and mean value of BMI and age. Several previous reports have indicated that betatrophin circulating levels was increased in the patients suffering from diabetes, but without the positive correlation with mean BMI. The results of the present study were agreed with these results and showed no correlation between betatrophin and mean BMI.
Conclusion

The results regarding this study, support role of betatrophin in type-2 obese diabetic women, and suggesting that betatrophin, was an important hormone for regulation of the glucose level in type-2 DM. This hormone showed a highly significant elevated level in type-2 obese diabetic women compared to non-diabetic obese women. There was a significant positive correlation between serum betatrophin and fasting blood sugar. Assessment of circulating levels of betatrophin could be a useful diagnostic biomarker for distinguishing type-2 diabetic women from those without this condition. Future studies are needed in order to investigate the probabilities of this hormone (betatrophin) which may serve as potential therapeutic target in type-2 DM and obesity.

Interaction Between Tobacco Consumption, BMI and Diabetes

T Manigandan¹, S Kisore Kumar², A Julius³

¹Research Scholar, Professor, ²Asst.Director, R&D, BIHER Professor, Department of Orthodontics,³Professor& Head, Department of Biochemistry, Sree Balaji Dental College and Hospital, BIHER, Chennai.

Abstract

There is a wide consumption of tobacco in various forms, worldwide. It is well implied from many researches that tobacco has many delirious effects on oral as well as general health. Tobacco has a direct effect on oral cavity which varies from stains to malignancies. It is well known that tobacco has many indirect influence on many body parameters like BMI and it also contributes to many systemic morbidities. This reviews details the interaction between tobacco usage and its effect on BMI & Diabetes. It is inferred that proper health education through tobacco cessation counselling not only reduces the ill-effects of smoking in oral health but also contributes in improving general health.

Keywords: Tobacco, BMI, Diabetes

Introduction

Tobacco use is one among the five greatest risk factors for mortality, and also the single most preventable cause of death. In India, tobacco consumption is a major risk factor responsible for oral and oropharyngeal cancer. India has one of the highest rates of oral cancer in the world, partly attributed to the high prevalence of tobacco chewing habits.¹

India is the second largest consumer of tobacco in the world. The prevalence of all types of tobacco use among men has been reported to be high in most parts of the country (generally exceeding 50%). Further, a national level survey on tobacco use in India has reported that 16.2% are current smokers and 20.5% are tobacco chewers. This survey also showed that beedi is the most popular form of tobacco smoking, followed by cigarette smoking similarly, pan with tobacco is the major chewing form of tobacco.²,³

World Health Organization (WHO) estimates in 2004 projected 58.8 million deaths to occur globally, of which 5.4 million are attributed to tobacco use. As of 2002, 70% of the deaths are in developing countries. It is predicted that 1.5–1.9 billion people will be smokers in 2025.⁴,⁵

Body habitus, as described by BMI, is related to skeletal size, muscle mass, and adiposity. As such, it is influenced by diet, other aspects of lifestyle, and other environmental factors. The association between low BMI and smoking is well documented.⁶,⁷ The high prevalence of tobacco use and its association with low BMI raises important questions about its impact on public health in India, a country which has a high prevalence of low BMI among adults.

Various studies have proved as smoking increased, the rate of diabetes increased for both men and women. A dose response relationship seems likely between smoking and incidence of diabetes. The focus of this paper is to provide a more detailed analysis of the relation between different forms of Tobacco use and BMI and Diabetes and discuss the public health implications of these associations.
Tobacco Usage:

Within countries the prevalence of tobacco use is highest amongst people of low educational background and among the poor and marginalized. In several developing countries there have been sharp increases in tobacco use especially among men and as the tobacco industry continues to target youth and women there are also concerns about rising prevalence rates in these groups. The shift in the global pattern of tobacco use is reflected in the changing burden of disease and tobacco deaths. Tobacco use is a major preventable cause of premature death and also a common risk factor to several general chronic diseases and oral diseases. The negative impact relates not only to smoking but use of smokeless tobacco. In addition to smoking tobacco smokeless tobacco is widely used in a number of countries of the world depending on socio-cultural conditions.

Chewing tobacco is known as plug, loose leaf and twist. Pan masala or betel quid consists of tobacco, areca nuts and staked lime wrapped in a betel leaf. They can also contain other sweeteners and flavouring agents. Moist snuff is taken orally while dry snuff is powdered tobacco that is mostly inhaled through the nose. In comparison to smoking habits, the patterns of use of smokeless tobacco are less documented, particularly in developing countries.

Tobacco and BMI:

Body mass index (BMI) can be computed from height and weight using the formula: (Weight in pounds $\times$ 703) $\div$ Height$^2$ (in inches). BMI has been shown to adequately describe levels of body fat as well as measure overall physical health. Previous research has suggested that the reason for the positive association between cigarette use and BMI may be due to poor behavioral habits. In addition, found that smoking was positively associated with physical inactivity.

Numerous studies have confirmed that smokers do have a lower body mass index (BMI) than non-smokers. Nicotine, whether smoked, used orally or as patches is the major appetite-suppressing component of tobacco. Research into the effects of nicotine on the appetite-regulating regions of the hypothalamus further confirms the contribution it makes to reduced appetite and body weight loss. There is also evidence that nicotine’s effect on the metabolism lowers the body weight set point (normal body weight) and this may account for the initial weight gain experienced by some people when they give up smoking. However, there is evidence that cigarettes smoked per day are positively associated with central fat accumulation, particularly in women. Intra-abdominal accumulation of body fat may confer a higher risk of developing diabetes, cardiovascular disease and death, independently of general obesity. There is also some evidence that heavy smokers have greater bodyweight than light or non-smokers, perhaps because heavy smokers also make other unhealthy lifestyle choices.

Tobacco and Diabetes:

Several plausible biological mechanisms have been advanced to explain an association between cigarette smoking and incidence of diabetes, but more research is needed in this area. Some investigators have suggested that cigarette smoking generally increases insulin resistance by altering the distribution of body fat or by exerting a direct toxic on pancreatic tissues. Another mechanism that may be advanced parallels that proposed to explain how physical inactivity and obesity increase risk for diabetes; the transport of glucose into fat and skeletal muscle cells is impaired. In case of smoking, a chemical component of cigarettes may directly alter intracellular glucose transport, or may indirectly alter it through change in serum chemistry, or diminished vascular blood flow. As cigarettes contain 3500 different compounds in the particular phase and 500 gaseous compounds in the volatile phase, precisely elucidating such mechanism may be a formidable task indeed.

Various prospective epidemiological studies of diabetes incidence have included smoking as a possible risk factor. This positive relationship between cigarettes smoked and diabetes incidence has been noted in two prospective studies. In comparison among the men who smoked that much with the non-smokers, the rate of diabetes were four times as high in the Zutphen study.

Discussion

The effects of tobacco use on the incidence of certain diseases, particularly cancers of the aerodigestive tract and urinary bladder are well documented. But there are very few studies who related the effect of tobacco usage on BMI and diabetes. Most of the documented prospective studies have mentioned the low BMI (proxy of nutritional status), suggest a strong need
for further research on as tobacco use may have even more far-reaching public health implications in India than previously thought. There appears to be a strong relationship between smoking habits, lifestyle factors, and BMI and there may also be a relationship between the number of cigarettes smoked per day and BMI, where the BMI of never-smokers and heavy smokers appears similar. If the association is evaluated as causal then tobacco control research and intervention also will benefit other public health goals on improved nutritional status and consequential health benefits. These results have potential to affect the population living in the developing world.

**Conclusion**

The disease in a community can be compared with an iceberg. The floating tip of the iceberg is what the physician sees in the community, that is formed by the clinical cases. The big submerged part of iceberg represents the hidden mass of disease, which is formed by inapparent, pre-symptomatic and undiagnosed cases and carriers in the community. Water line represents the demarcation between apparent and inapparent disease.

This is approached at chair side, where the public health dentists see the harmful effects of tobacco use and they spend more time with the patient than other physicians. They should use this time to counsel the patient by promoting the oral health and healthy lifestyles. This can be achieved through few minutes of focused talk during oral examination and make the patient aware and conscious of the harmful effects of tobacco use. Thus, every interaction of public health dentist with their patients at every visit can lead to a significant change in patient’s attitude and behaviour toward tobacco cessation.

Effective Usage of Exhaled Volatile Organic Compounds in Disease Diagnosis: A Comprehensive Review

G.S. Karthick¹, P.B. Pankajavalli²

¹Research Scholar; ²Assistant Professor, Bharathiar University, Coimbatore, Tamil Nadu, India

Abstract

Aim: The potentiality of exhaled biomarkers like volatile organic compounds [VOC’s] are gaining more importance and assists in accurate diagnosis of diseases. The main aim of this article is to reveal the existing methodologies on evaluating the exhaled VOC’s with respect to the diagnosis of various diseases which includes asthma, chronic obstructive pulmonary disease [COPD], lung cancer, chronic kidney disease [CKD] and acute respiratory distress syndrome [ARDS].

Literature Source: This comprehensive review was conducted based on the literature identified in PubMed, PsycINFO, Medline Plus and other various search results. This article explores the diagnosing of diseases like asthma, COPD, CKD and ARDS via monitoring the VOC’s in exhaled breath.

Findings and Discussions: From the records identified, twenty two studies were found to be eligible for comprehensive review which includes 1,223 healthy subjects and 1,206 patients. The non-invasive techniques used for collecting and analyzing the VOC’s in exhaled breath and its outcomes were mined. This review seamlessly discloses the differences between the healthy subjects and patients with severe disease.

Conclusion: It is found that exhaled breath VOC’s summary of humans are potential enough to correctly diagnose multiple diseases. The findings has recognized various standardization challenges and proof is required before adapting this practice into clinical diagnosis.

Keywords: Exhaled breath, VOC’s, COPD, CKD, ARDS, Asthma, Pulmonary diseases, Biomarkers

Introduction

Health monitoring technologies and diagnostic tools are highly indispensable for assisting physicians in identifying diseases and its stages [¹]. The accurate and earlier detection of diseases supports the timely treatment and exposes the demand for cost effective and non-invasive diagnosis of diseases. Initially, non-invasive method is used for evaluating the airway inflammation and it is convinced by sputum. Various researchers shown the biomarkers in exhaled air for disease prediction [²]. Greek physicians identified that the volatile contaminants in human exhaled breath has evidence to few diseases [³]. Pulmonary diseases has the significance of causing illness in adults and children [⁴]. Lung cancer is the major disease which causes death because it is mostly identified only at the final stage of the disease that restricts to provide response to the treatments [⁵]. Besides, lung diseases like COPD and asthma are strongly draining the life of human and incurs more cost for treatment. Furthermore, CKD is also a life critical disease which can be easily predicted by analyzing the VOC patterns in the exhaled breath [⁶]. Hence, the earlier diagnosis of these diseases are extremely important for extending treatments and controlling the disease severity. The existing medical tools are not sufficient for accomplishing the earlier diagnosis and later through continuous evolvement of techniques, the non-invasive methods has been introduced for analyzing the VOC’s in exhaled breath. In this review article, the role of VOC’s and its potentiality of clinical usage in disease diagnosis is extracted.

Exhaled volatile organic compounds & techniques for analyzing exhaled breath

Most of the pulmonary diseases like asthma, lung cancer, COPD and ARDS are influenced by airway
inflammation and oxidative stress that are highly helpful in disease diagnosis. From the study [7], the invasive techniques like bronchoscopy, radiological patterns and biopsy for analyzing airway inflammation and oxidative stress is expensive and have more complications when it is being used on children. There is a need for non-invasive technique like exhaled breath analysis for analyzing airway inflammation and oxidative stress. The nitric oxide is a helpful biomarker in few pulmonary diseases and it is not well suited for allergic patients [8]. VOC’s can be originated either externally or internally, hence some of the VOC’s are influenced by the environment pollutants. But other VOC’s are originated by the body via patho-physiological processes [9]. The internally formed VOC’s is termed as endogenous which are highly formed by lipid peroxidation [9]. Apart from hydrocarbons. VOC’s like nitrogen, oxygen and sulphur are formed by bacteria and also through patho-physiological processes on body parts [9]. Such VOC’s in expired breath of diseased patients clinically potential enough to predict the pulmonary diseases [9]. The authors in [10,11] identified that VOC’s are highly related to CKD and diabetes mellitus. Most cases of CKD is accompanied with diabetes mellitus and CKD is clinically recognized in patients with high ammonia in exhaled air [38]. The presence of high concentrated isoprene may tend to renal failure [12] and the several aldehydes are found in exhaled breath of CKD patients [13].

Various techniques are existing for collecting, identifying and analyzing the VOC’s in exhaled breath [9]. Gas Chromatography [GC] is a commonly used technique which stores the exhaled breath in bags and VOC’s are analyzed using either gas chromatography mass spectrometry [GC-MS] or gas chromatography flame ionization detection [GC-FID] [9]. E-Nose is another technique in which an array of nano-sensors has been used for analyzing the VOC’s. Furthermore, other techniques like selected ion flow tube mass spectrometry [SIFT-MS], proton transfer reaction mass spectrometry [PTR-MS] and gold nano particles sensors [GNP] [14].

**Method of Literature Search**

The study was conducted by searching the literatures in PubMed, PsyCINFO and Medline Plus using the index terms which includes volatile organic compounds, VOC, VOC’s, exhaled air, human exhaled breath, non-invasive, e-nose, oncologic diseases, chronic obstructive pulmonary disease, COPD, acute respiratory distress syndrome, ARDS, asthma, lung cancer, Gas Chromatography, GC, SIFT-MS, GNP, chronic kidney disease and CKD. In Table 1, the attributes required for examining the validity of study is shown.

Twenty-two studies were identified and included for the analyzes, in which five articles defined the VOC’s in asthma, one in ARDS, four in COPD, eleven in lung cancer and one in CKD. In total, 1206 healthy subjects and 1279 patients were examined which includes 183 asthma patients, 19 ARDS patients, 258 COPD patients, 735 lung cancer patients and 84 CKD patients.

Many studies revealed that analysis of VOC’s provides an accurate results in predicting the asthma disease as shown in the Table 1. In [14, 15, 17], authors found that VOC profile can easily differentiate the asthma patients from healthy subjects. The selected asthmatic study includes 183 asthmatic patients and 145 healthy subjects were differentiated through VOC analysis. In which 157 asthma patients were discriminated from 131 healthy subjects using VOC profiles whereas 26 asthma patients were discriminated from 14 healthy subjects using single VOC compound.

The diagnosing of COPD patients at a final stage may lead to death, so early prediction of COPD can benefit the patients with high level of interventions. Many studies in [11, 21, 23], accurately distinguish the COPD subjects from healthy subjects. COPD can be predicted by analyzing the narrowed VOC profiles [36] and the increased levels of ethane has been recognized in COPD patients [22]. This study includes 258 COPD patients and 122 healthy subjects were differentiated through VOC’s analysis. In which 236 COPD patients were classified from 108 healthy subjects using VOC profiles where 22 COPD patients were discriminated from 14 healthy subjects using single VOC (ethane) compound.

The subjects with LC can be discriminated from the healthy subjects using various grouping of VOC’s by GC-MS technique [27, 28, 29]. From these studies, it is found that common VOC’s for diagnosing the LC may include pentane, butane, propane, propanol, aldehydes and benzene. In the LC identified subjects, many VOC’s
level were raised but the isoprene level is found to be depleted [37]. Among totally included 657 LC patients and 891 healthy subjects, 291 LC patients were distinguished from 577 health subjects by single VOC compound analysis whereas 366 LC patients were separated from 314 healthy subjects by using VOC’s profiles. In [35], the studies successfully found that increased level of pentane and decreased level of isoprene in ARDS reported subjects. The high concentration of ammonia and nitric oxide in the exhaled breath observed in CKD subjects [38].

**Conclusion**

Nowadays the existing tools and techniques are not satisfying the needs of healthcare providers, so there is an elevated interest contributed by the researchers to improve the various disease diagnoses through the non-invasive measurement of exhaled VOC’s. The present research primarily focusing on multiple VOC’s rather than single VOC compound. Likely, this study reported the ability of VOC’s profiles through which diseases like asthma, COPD, ARDS, CKD and lung cancer can be diagnosed and monitored accurately. Conversely, it is binding to resolve the issues like validation and standardization prior to the adoption of VOC’s analysis for clinical practice.

Patients Health Monitoring System Using IOT

Sudha Senthilkumar¹, Brindha.K², Charanya R³, Abishek Kumar⁴

¹Associate Professor, ²Assistant Professor(SG), ³Assistant Professor, ⁴B.Tech (IT) Student,
School of Information Technology and Engineering, Vellore Institute of Technology, Vellore, Tamil Nadu, India

Abstract

The past health survey shows death of few thousand people due to their heavy workload and mental pressure. Death of more patients is unavailability of doctors in critical situation. With the advancement in technology, the proposed system can monitor the patient’s body condition uninterruptedly from anywhere in the world. The researcher is planned to make an inter-net of things for health care system which can monitor health of human being. In emergency situation notification will be send to doctors immediately. It takes the body parameters like Temperature, humidity, and pulse sensor and body movements. Analysis of patients’ body data is done against the normal situation to track abnormal physiological parameters.

Keywords: Temperature, humidity, pulse sensor, body movements.

Introduction

Every year we hear about a new disease whose cure is not invented till now like in 2014 Ebola outbreak happened; in 2016 Avian influenza A (H7N9) virus outbreak. The past report shows few of them eradicated and still some of the disease exists today [1-2]. Its outbreak results in uncountable numbers of patients. It is very hard to maintain regulation of health of each patient. This paper presents a solution to patient monitoring system⁶. The researcher has used sensors to record body as well as surrounding conditions of patients. Each patient is monitored individually with a given set of sensors⁷. Sensors data is sent on cloud website like thingspeak periodically. The sensors read temperature, humidity, heartbeat and body movements. Data is sent on thingspeak website and analysis of data is done to trace abnormal condition of patients. Doctors are called to see the patients without loss of time. Notification is send using prowl and thinghttp integration. Notification is sent to doctors in emergency⁵.

Proposed Scheme

The proposed system consists of Arduino mega as micro-controller unit. The various modules and components are combined are shown in the diagram. Two types of power supplies 3.3V and 5 V passed to the system and few modules are operated in 3.3 V. The digital sensors such as humidity, temperature, etc are linked to Arduino’s digital pin and the sensor which generates the analog signal is linked to analog pin of the Arduino. The Wi-Fi module or the Ethernet Shield (HANRUN) is used in this system for inter-net connectivity⁴.

Figure 1. Proposed System Architecture
The digital / analog data are passed to the Arduino by internet connection and all the monitored data sent to the ThingsSpeak. The ThingsSpeak considered as cloud environment. When all the sensors are connected together, sensors sense data from human body, then send that data to server. After that these data is compare with standards values that are already stored in system. According to that normal and abnormal condition checking is performs. And if abnormalities occurred then it send message immediately to doctors to avoid critical condition. The system is controlled by administrator. It can control entry of new patient’s details and doctors details when it will get data from sensors and is displayed in separate UI page which refresh periodically and save data in database. Time interval is 10 seconds. When abnormalities occur, message is sent to doctor’s mobile within 1 minute.

**HARDWARE MODULE**

**Arduino mega**

![Figure 2: ARDUINO MEGA](image)

It consists of 54 digital pins. Each of pins on the Mega can be used either as an input or output, using various function such as pinMode(), digitalWrite(), and digitalRead() functions. They operated at 5 volts. Each pin can receive or provide a maximum of 40 mA and has an internal pull-up resistor (disconnected by default) of 20-50 kOhms. Some of pins have special features.

- **Serial:** 0 (RX) and 1 (TX); Serial 1: 19 (RX) and 18 (TX); Serial 2: 17 (RX) and 16 (TX); Serial 3: 15 (RX) and 14 (TX). Used to transmit (TX) or receive (RX) and TTL serial data.
- **External Interrupts:** 2 (interrupt 0), 3 (interrupt 1), 18 (interrupt 5), 19 (interrupt 4), 20 (interrupt 3), and 21 (interrupt 2). The above pins can be configured to trigger an interrupt on a low, high or falling edge.
- **PWM:** 2 to 13 and 44 to 46. These pins Provide 8-bit PWM output with the analogWrite() function.
- **SPI:** 50 (MISO), 51 (MOSI), 52 (SCK), 53 (SS). These pins support SPI communication.
- **LED:** 13. There is a built-in LED connected to digital pin 13. When the value of pin is HIGH, the LED is on, when the value of pin is LOW, it is off.
- **I²C:** 20 (SDA) and 21 (SCL). Support I²C (TWI) communication using the wire library (documentation on the Wiring website). Note that these pins

**SENSORS**

**DHT11**

The dht11 (humidity and temp. sensor) read the temperature and humidity of surrounding around patients and send the data back to serial monitor in module testing. It has one data cable to read the surrounding. After reading data from surrounding, it also sends the data to thingspeak using esp wifi module.

**WIFI**

The Nodemcu wifi module take SSID, password to connect to wifi and thingspeak api to connect to the thingspeak server using port 80. It sends the data to thingspeak after every 20 seconds. It uses espwifi header file is required to send and connect.

**ACCELEROMETER**

Accelerometer used adxl335 to read the movement of patients and to record it and send respective data to thingspeak website. It uses three connections each one for x, y, z direction.

**GPS (neo -6s)**

It makes a connection to GPS satellite to read the data and send the data to thingspeak website through wifi module. It consists of one antenna and receivers. It read the longitude and latitude of our system on earth.

**PULSE SENSOR**

It read the heart beat and sends the data to arduino to serial plotter and serial monitor. It has three connections one of them is used to read the heart beat and other two is used to make connection.
Patient Monitoring System Architecture

The patient’s monitoring system is implemented using the following algorithm:

- The data is collected using sensors and send using Arduino. The patients wear the sensor on their body and data is collected. Some sensors are present in the room like DHT sensors to collect room temperature and humidity.

- The sensors data is send through wifi (esp8266 module) which is connected to Internet via router.

- The data is sent to thingspeak server and saved in to remote database.

- The administrator uses the data and analyzes it against normal situation. In case of emergency the doctor gets the message about patient’s situation and his/her ward information’s.

Results

Due to vast changes in the IT domain, the proposed system should be capable of adopting any changes. In this system sensors can be included without affecting other parts of the system and play a vital role in maintenance. The system designed to adopt any further modifications. The result shows the system provide good performance and accuracy. Figure 4, 5, 6 and 7 show the result of temperature, humidity, latitude and longitude.
Indian Journal of Public Health Research & Development, April 2019, Vol. 10, No. 4

Figure 8.c Z-axis

Figure 8.a, 8.b and 8.c Show the result of accelerometer x-axis, y-axis and z-axis direction.

Figure 9 Shows the result of ECG data.

Figure 9 ECG data

Conclusion

The proposed health care system based on internet of things. It stores the person sensitive information in to cloud and they can check their sensitive information at any time. In emergency situation notification will be send to doctors immediately. It takes the body parameters like Temperature, humidity, and pulse sensor and body movements. Analysis of patients’ body data is done against the normal situation to track abnormal physiological parameters. The system result shows that it monitors the patient condition and any change in the normal condition, message alert pass to registered user.

Nanosensors in Blood Glucose Measurement: A Review

G.Kavitha¹, K.Senthil Kumar²
¹Research Scholar, ²Professor, Dept. of Electronics & Communication Engineering, Dr.M.G.R. Educational and Research Institute

Abstract

Diabetes is a fast growing problem nowadays worldwide. Diabetes, not a curable disease needs blood glucose to be measured very often. Blood glucose measurement is by various methods. Glucose sensors help in measuring blood glucose level. Glucose sensors employ various methods in different technologies to measure blood glucose level. Recently nanosensors employs nanotechnology for blood glucose measurement. Nanosensors fabricated by different nanomaterials has high sensitivity because of high surface to volume ratio. This paper discusses the several methods to measure blood glucose with the advantage and disadvantage.

Keywords — nanosensors, blood glucose, methods, advantage, limitation, nanotechnology

Introduction

Diabetes is a leading cause for the death of millions of people in the world. Diabetes damage blood vessels of heart, brain and legs affecting various parts of our body like eyes, feet and kidney. Diabetes increases cardiovascular problems like heart attack, stroke and atherosclerosis.[1]. Diabetes cannot be cured but controlled by blood glucose measurement. Blood glucose measurement takes place with various methods which suggest a suitable technique by its advantage and disadvantage. Glucometer, Continuous glucose monitoring sensors, Glucose sensors with nanotechnology and nanosensors are the methods to evaluate the glucose concentration.

Methods for glucose measurement:

Glucose measurement is commonly by Glucometer. The Glucometer is a low-cost effective method but a painful sampling process which has large fluctuations between sampling time points and not possible to take if a patient is occupied. Continuous glucose monitoring is another method for glucose measurement with the advantage of increased frequency of measurement and limitation of the implanted sensor inside the body for several days.[2] Glucose sensors employ nanotechnology for this process which offers fast response, improved catalytic activity and high surface area.[3]

Nanotechnology glucose sensors have few drawbacks like sensor fouling and decreased sensor lifetime. Nanotechnology has many applications in the field of medicine. Nanotechnology develops nanosensors that help to calculate glucose level. Nanosensors have a variety of rewards namely small size, high surface area/ volume ratios allowing larger signals, better catalysis and more rapid movement of an analyte through sensors, accuracy, lifetime and usability of sensors.

Medium and Biomarker for Glucose measurement:

Glucose measurement can be in blood, urine, saliva, tears and sweat which is an invasive or non-invasive process. Glucose concentration is high in blood when compared to other parameters. Blood Glucose calculation is an invasive method which offers low cost and reliable procedure with the limitation of highly uncomfortable for patients, Infection risk from injured skin.[4]

Urinal glucose concentration is a non-invasive method with an advantage of painless, affordability and disadvantage of low accuracy and low glucose concentration levels. Sweat glucose level is a non-invasive method that provides painless, easy sample collection and cost-effective method. This method has a drawback of low concentration, require high sensitivity and selectivity for better results.[5]
Saliva glucose level is a non-invasive method with simple collection procedure and minimally non-invasive technique. It has the limitation of high calibration time, inaccurate readings, low glucose concentration levels. Tear glucose concentration is a non-invasive method which is highly accessible, cost-effective and has numerous testing methods. This method has a disadvantage of poor correlation with blood glucose level, requires a low detection limit and lack of a suitable power source for testing.

Blood glucose level helps in diagnosis of diabetes which can also be diagnosed by breath as a medium using acetone as a biomarker. This method offers an advantage of easy to use, quick results and painless process with a limitation of many factors in result analysis.

**Literature Survey:**

Algorithm used, advantages and disadvantages of several papers were analysed

1. Wearable contact lens biosensors for Continuous glucose monitoring using Smart phones, “Mohamed Elsherif” [2018] [7]

   A photonic microstructure was printed on glucose-selective hydrogel. Bragg diffraction modulation correlate periodicity constant and glucose concentration. Sensitivity of the sensor was 12µa/mm. The saturation response time was less than 30 min. Glucose concentration is within 0–50 mm. Signal drift due to electrochemical reaction in-stability. Resulting in time lags and sensor replacement every 3–7 days.

   A skin like nanostructured biosensor system (SNBS) is developed to measure glucose level in non-invasive method. Increase the signal-to-noise ratio. Sensitivity is high. Linear sensing range is large. Accuracy is improved. Challenge lies in the fabrication of the multilayer biosensor. Small detection limit.

   Point of care diagnosis method used for continuous glucose monitoring. High sensitivity. Better patient compliance contrary to invasive ones. Biofouling, fibrous encapsulation of the implanted electrode, inflammation, and loss of host vasculature, affect the precision and accuracy of the blood glucose results, lifetime of the sensors-7 days, cost, toxicity, inconvenience and discomfort

   Diabetic nephropathy diagnosed using electrodynamics Monte carlo simulation. High efficiency up to 72%, Signal and the noise are visible. Sensing should occur in few minutes otherwise signal & noise become indistinguishable.

5. Highly efficient non-enzymatic glucose sensor based on CuO modified vertically-grown ZnO, “Rafiq Ahmad” [2017] [11]

   Non-enzymatic glucose sensor using Electrochemical Impedance Spectroscopy. Large surface area. Easy substrate penetrable structure. High sensitivity with excellent reproducibility, repeatability, stability, selectivity, and applicability for glucose detection in human serum samples. Linear range up to 8.45 mm. The low limit of detection (0.40 µm) Short response time (<2 s)

   Sensors based on a membrane containing immobilized glucose Oxidase and catalyse coupled to oxygen electrodes and a telemetry system, integrated as an implant for 180 days. Feasible. Sensor/telemetry system configured without enzymes as a long-term oxygen sensor to asses permeability. Anaesthesia in abdominal tissue sites in a 25-min outpatient procedure by making a superficial incision 4.5 cm long and dividing the subcutaneous adipose tissue to create a pocket 0.5 to 1.0 cm below the skin surface. Sensitivity varied randomly at an average rate of −2.6%/week for all sensors. Sensitivity to glucose is quasi-linear.

   Breath analysis Chemi-resistant type breath sensors are employed. Non-invasive, simple, and low-cost diagnostic method. High Sensitivity and selectivity.
Biomarkers can be generally found in the blood at relatively high concentrations. Requires more analysis time due to the pre-concentration step to increase the detection capability. Multiple volatile organic compounds should be accurately detected and statistically analysed using sensor arrays with high sensitivity and selectivity.

8. Highly sensitive and wearable In2O3 Nanoribbon transistor biosensors with Integrated on-chip gate for glucose Monitoring in body fluids, “Qingzhou Liu” [2017] [14]

Nanowire-based field-effect Transistor (FET) biosensors are used for glucose monitoring. A better electrical performance with gate voltage. A high on–off ratio and good mechanical robustness. Very large detection range spanning at least five orders of magnitude and a detection limit down to 10 nm. Glucose levels in body fluids is lower than in blood. Results can be affected by ambient Temperature changes, mechanical deformation caused by body Motion, and the sample collection procedure.

Microwave non-invasive blood glucose Monitoring system operating at around 1.4 GHz with a sensor head, a portable vector network analyzer, data logger and a PC split-ring resonator. Exceptional accuracy and repeatability. Restrictive in use. Involves the use of portable network analyser. Not Fully wearable/portable.

Saliva nanobiosensor using amperometric measurements and Clarke error grid analysis to measure glucose level. Excellent clinical accuracy. A Time lag between the peak glucose values from blood and saliva. Noninvasive, Reliable, convenient, fast, and continuous salivary glucose Monitoring for personal and point-of-care use. Only healthy individuals included so that there were no extreme high/low glucose values detected. Sensitivity and reliability limited by spectral signal-to-noise level and skin thickness. Difficulty to collect sweat. Low level of accuracy.

11. Ultrathin gold as a sensor platform for biomolecules, “Christoph Nick” [2015] [17]

Enzyme free approach for glucose Detection applying ultrathin gold films using Keithley software. Miniaturization, safety and most important long-term stability of the enzyme and transducer. Valid for single crystalline films with no grain boundary scattering.

12. Non-Enzymatic Graphene-Based Biosensors for Continuous Glucose Monitoring, “Mahmoud A Sakr” [2015] [18]

Cyclic Voltammetry (CV) and the amperometric method for measurement of glucose. Sensor fabrication, X-ray Photo-electron Spectroscopy. Overcomes enzymatic nature; namely, irreversibility, drift, and interference with body fluids, which affect their accuracy, reliability and longevity. Large surface area increases speed, output current. Highest sensitivity increase the porous structure of graphene. Provides fast response and high reversibility. Minor sacrifice in sensitivity and selectivity.

Nanodiamond depositing onto Silicon substrate via a spray method. Nanodiamond consist unique qualities such as biocompatibility, easy functionalized, non-toxic material, strength and chemical inertness. The potential of the spray method can be improved by studying the effect of spray force, the height of spray in future to get an optimum condition for deposition of a nanodiamond.

In-vivo implantable biomedical device- glucose monitoring uses cyclic voltammetries to verify performance control. Long-term stability, selectivity, calibration, miniaturisation and repetition, power in a downscaled and portable device. Silicon structure along with titanium enhance biocompatibility, implanted device provide reliability. Multiple organisations and sources of data. Detect specific type of target.

15. I-V characteristic effects of a fluidic-based memristor For glucose concentration detection, “Nor Shahanim, Mohamad Hadis, and Asrulnizam Abd Manaf” [2014] [21]

Thin film TiO2 fluidic-based memristor sensor using keithley 4200-scs semiconductor characterization
system. The I-V curve produces a small difference for low concentration. Minitab regression analysis indicates memristor resistance has a quadratic relationship with glucose concentration which is not strong.

Comparison of various parameters from the literature survey is graphically plotted.

Sensitivity is the ability of a test to identify the disease which is high in nanomaterials. Sensitivity depends on surface to volume ratio. Surface to volume ratio is contingent upon diameter. Electrical measurement also determine the sensitivity of nanosensor which include resistivity and conductivity. Width of the nanowire calculate the resistivity which improve ohmic characteristics of the device. Ohmic characteristics improves the sensitivity of the nanosensor. The sensitivity of different nanomaterials in glucose measurement compared in Fig:1. Silicon nanomaterial with gold deposition increase current density and sensitivity of 130.4µa/mm

Fig:1 Comparison of the sensitivity of various nanomaterials

Sensitivity and linearity from amperometric I-t curve compared with different nanomaterial. From Fig:2, Linearity gets improved when silicon deposited with gold nanomaterial

Fig:2 Comparison of linearity of various nanomaterials

Limit of detection(LOD) defined as the lowest quantity or concentration of a component detected with a given analytical method. LOD is small in most of the nanomaterials as shown in Fig:3.

Fig:3 Comparison of the detection limit of various nanomaterials

Response time is time taken for a person or system to react to a given stimulus or event. The response time of different methods of glucose measurement compared in Fig:4. Response time is very fast in nanosensors when compared with other methods.

Fig:4 Comparison of the response time of various methods of glucose measurement.

A correlation coefficient is a statistical measure that calculates the strength of the relationship between the relative movement of two variables. The correlation coefficient of various methods of glucose measurement compared in Fig:5
Nanomaterials:
Nanosensors fabricate with various nanomaterials for different applications. Various nanomaterials used in sensor fabrication namely nanotubes, nanowires, nanofibers, nanocomposites, nanorods, nanostructured polymers and different allotropes of carbon as carbon nanotubes, graphene or fullerene. Nanoparticles are 0-D structures with spatial dimensions between 1 to 100 nm. Nanoparticle has good bioassay because of small size. This bioassay property binds the target molecule and enhance the signal. Nanotubes and Nanowires are 1-D nanostructures with characteristics diameter between 1 to 100 nm. Nanowire has current flow close to the surface. This current flow make nanowire to exhibit good sensitivity. Carbon nanotubes has unique feature of electrical and mechanical properties. This feature attain nanotube to show high surface to volume ratio. Nanofibre has good sensitivity only for low concentration level. Nanocomposites are bi-dimensional nanostructure materials of anionic exchange. This nanocomposites have ruggedness and durability. Nanocomposites have better selectivity. Nanostructured surfaces have thickness between 1 to 100 nm. Dimensions above 100 nm are termed 3-D nanostructures.[22]

Sensor fabrication uses various nanopowders. Iron nanopowder increase the enzyme content in blood. The increase in enzyme result in weight gain. Copper nanopowder raise mineral exchange like potassium, sodium, calcium and phosphorus which affect the bone tissues. Carbon Nanotubes are inert and functioned with a probe molecule. Au and Ag nanopowders are mostly used in medicine. ZnO nanoparticles has high surface to volume ratio, wideband gap, good piezoelectric characteristics, chemical stability and biocompatibility. Cost of production of ZnO nanoparticles in mass production is high when compared to Si nanoparticles. Nanodiamond less than 10 nm in diameter used for biomedical applications[23].

Conclusion
Diabetes a fast growing problem needs a level of glucose to be measured very often. Different methods of glucose in various techniques reviewed in this paper. From the literature survey glucose measurement by an invasive technique is a painful process which leads to the non-invasive method. Various nanomaterials compared which suggest Silicon-dioxide deposited with gold has high sensitivity and good linearity. Silicon substrate increase biocompatibility, stabilise operating temperature, increase the sensitivity.

Aggression in Psychiatric Unit: What is the Feeling of Psychiatric Nurses?

Binil V1, Christopher Sudhaker2, Supriya Hegde3, Unnikrishnan B4, Alphonsa Ancheril5

1Assistant Professor-Senior Scale, Department of Psychiatric Nursing, 2Professor of Manipal College of Nursing and Director of Quality, Manipal Academy of Higher Education, Manipal, 3Professor, Department of Psychiatry, Father Muller Medical College, Mangaluru, 4Associate Dean, Kasturba Medical College, Mangaluru, 5Vice Principal, Professor & Head-Department of Psychiatric Nursing, Athena College of Nursing, Mangaluru

Abstract

Background: The client directed aggressive and violent behaviour towards nurses working in psychiatric setting is a universal issue. The nurses spend most of the time with clients, which make them more vulnerable to any form of injuries during the process of managing aggressive clients without having the required knowledge and skill. Around 20-45% of hospitalized clients with psychiatric disorders show violent behaviour. Objective: To identify the feelings of psychiatric nurses on client directed violence with a view to develop an aggression management and violence prevention training programme for nurses working in psychiatric setting. Method: Qualitative approach was used for the study. A focus group discussion was conducted among 30 psychiatric nurses identified by the nurse administrators of the selected hospitals. Convenient sampling technique was adopted for selecting the participants. Thematic analysis was used in this study to identify and analyze important themes. Results: The following themes were derived from the thematic analysis: Fronting vs management of aggressive clients, facilitating vs facilities available for aggression management, traditional vs training, prevention vs management, suggestion vs support from the hospital management, and expectation vs engagement in an aggression management training programme. Conclusion: An aggression management and violence prevention training programme was designed based on the educational interventions derived from the focus group discussion.

Key words: aggression, psychiatric unit, psychiatric nurse, feeling

Introduction

Client related aggression is an enduring problem in psychiatric setting. It is a multidimensional problem with serious concerns. These aggressions are verbal or physical and most of the time towards healthcare providers. Around 20-45% of hospitalized clients with psychiatric disorders show violent behaviour. It has been reported that the prevalence of violence experienced by the mental healthcare providers due to aggressive client behaviour is between 14% and 61%.1

The client directed aggressive and violent behaviour towards nurses working in psychiatric setting is a universal issue. The nurses spend most of the time with clients, which make them more vulnerable to any form of injuries during the process of managing aggressive clients without having the required knowledge and skill.2 Hence, aggression management and violence prevention remains a challenging task for the nurses. Many of the clients whose aggression is due to serious mental illness are secluded or restrained every day.3 Aggressive and violent behaviour is very common among psychiatric inpatients and need to be identified early and managed professionally. Otherwise it can promptly worsen to potentially dangerous behaviour towards clients or healthcare providers.
A survey was conducted in Mysore, India to assess the clients and visitors aggressive behaviour towards 249 staffs working in the psychiatric and medical units. The results showed that 16% of the staffs working in the psychiatric area were exposed to different forms of violent behaviour for more than a month. The study concluded that training in violence management may be a defensive factor to reduce the prevalence of violence.4

An online survey was conducted in the Netherlands to assess the prevalence, nature and consequences of violence against 1534 mental healthcare professionals working in clinical psychiatry. The study findings showed that 67% of the participants experienced physical violence at least once in the last 5 years. The consequences were very severe in some cases which also affected the employer. The study concluded that violence in clinical psychiatry is a severe and substantial problem.5

The aim of conducting a focus group discussion was to develop a need based training programme for nurses to deal with client directed aggression and violence. Survey and other quantitative methods has limitations to go in-depth into the phenomenon the investigator want to elicit. Therefore to design a need based training appropriate to the context and the work culture, a focus group discussion was conducted among psychiatric nurses identified by the nurse administrators.

Method

A qualitative research approach was used for the study. A focus group discussion was conducted among psychiatric nurses working in different hospitals of Udupi and Dakshina Kannada Districts. Six open ended questions were developed and validated by the researcher for the focus group discussion. The researcher attempted to find answers for the following questions from positive deviant nurses working in psychiatric setting.

How do nurses manage the situation when their client get violent in the ward?

What are the facilities or equipment available in their ward to manage the client with aggression and violence?

What is their choice of training?

What are their roles to prevent the client from going in to aggression?

What kind of support do they need from the hospital management to prevent or manage patient aggression?

What are their expectations regarding aggression management training programme?

Selection of the participants: Convenient sampling technique was adopted for selecting 30 psychiatric nurses for the focus group discussion. An informed consent was taken from all the participants prior to the data collection. The participants were informed that confidentiality of the discussion is taken care by the researcher. The focus group discussion took place among psychiatric nurses working in a psychiatric setting. The nurses who are having a minimum of 5 year experience were selected for the qualitative discussion.

Setting of the Focus group discussion: The focus group discussion was conducted in 6 hospitals of Dakshina Kannada and Udupi districts of Karnataka.

Data collection procedure: The participants were called to a room arranged by the hospital authority which was away from other disturbances. The sitting arrangements were done for the comfort of the participants. The investigator developed a rapport with all the participants before conducting the discussion. Each discussion lasted for 40-45 minutes. The language of the discussion was English and it was audiotaped. Confidentiality was maintained throughout the study by giving participant numbers to each group.

A voice recorder was kept on the table to audio record the discussion. The discussion was also noted down by the researcher on the day of the discussion. Each of the focus groups took place at the participant’s place of work. Both the recorded and written material helped in the analysis of the focus group discussion.

Statistics: Thematic analysis was done to analyze the qualitative data.6 The following steps were used to generate the themes; familiarizing ourselves with our data, generating initial codes, searching for themes, reviewing themes, defining and naming themes and producing the report. Verbatim with the emerged theme was given for validation to five experts from the field of qualitative research. The corrections were taken in to consideration. Whenever in doubt or ambiguity, the investigator went back to some of the participants and revalidated the meaning of the verbatim.
Results

The discussion mainly focused on identifying the strengths and opinion of the expert nurses. The following themes were derived from the thematic analysis.

Fronting vs. Management of Aggressive Clients: The majority of the focus groups expressed that aggressive clients cannot be managed alone. They verbalized that physical or chemical restraints are useful for deescalating the clients. Furthermore, they also said that risk assessment is important before managing the clients. However, this is not possible because of various reasons. Therefore, at present it faces the situation as and when it comes, in terms of its management.

Facilitating vs. Facilities available for Aggression Management: The majority of the nurses expressed that, currently, they facilitate aggressive clients and also face dangers to self and to other clients. They feel that they lack many facilities. Though they have physical restraints, these are very nascent. The physical restraints used in most of the settings are not strong to manage a violent client. They also require muscle power like male nurses and securities to control and sedate the violent clients.

Traditional vs. Training: The focus group discussion revealed that at present, aggression management is done traditionally by nurses who are not specialized in psychiatric nursing, without adequate skill in aggression management. Nurses expressed that training on aggression management must include risk assessment, de-escalation, use of proper defense mechanisms, and use of proper restraints (physical/chemical); which will be more beneficial for taking care of the aggressive clients.

Prevention vs. Management: The majority of the nurses revealed that risk assessment and de-escalation skills will help them to prevent violence. Most of the nurses expressed their interest in learning about maintaining a safe and secure environment in their ward.

Suggestion vs. Support from the hospital management: The staff expressed that, though there are policies and procedures about aggression management and violence prevention, implementing variables like staff requirement, skill mix, training and soft limb restraints are not adequate.

Expectation vs. Engagement in an aggression management and violence prevention training programme: Most of the focus groups revealed that, the majority of the staffs are aware about the importance of undergoing a special training to prevent violence in their setting. But, they are not getting the opportunities to develop their competency by attending a special training.

Educational interventions derived from the themes: Risk assessment- tools and techniques, positive positioning while standing in front of a violent client, self-control plan for the nurse to control his or her own anger while dealing with an aggressive client, environmental strategies to prevent and control violence in the hospital setting, code violet response to deal with psychiatric emergency situation, safe breakaways for self-protection, safe use of restraints and communication, and de-escalation techniques. The derived themes are depicted in figure 01.

Discussion

The present study identified the facets of aggression management and violence prevention training for nurses using focus group discussion with psychiatric nurses. Six themes were derived from the thematic analysis and many educational interventions were identified from those themes. Martina et al 2016 expressed that the most useful method for managing aggression are medication therapy and the use of restraints.7 In the present study also nurses expressed these therapies as traditional treatment methods.
Jacobs et al 2012 assessed psychiatric nurse practitioners’ experience of working with acute psychiatric patients. The study revealed that nurses expressed that working with psychiatric patients are unsafe and a burden for them. Most of the nurse practitioners experienced negative emotional reactions and attitudes towards patients and it compromised the quality of patient care. In the present study also positive deviant nurses expressed that they are not very safe around a violent client.

Ingrid et al 2010 conducted a qualitative study among 45 general practitioners working in psychiatric emergency setting. The participants expressed that psychiatric patients’ unpredictable behavior is a threat to their personal safety as there are limited resources to manage unpredictable behavior. General practitioners also shared that present level of security system cannot manage patients with mental illness. Positive deviant nurses from the present study also expressed similar concern.

Tella et al 2016 conducted a focus group discussion among nurses working in psychiatric setting aimed at exploring the violent events and to examine the suggestion to prevent violent incidences. Most of the nurses expressed that their experience helped them to predict violent behaviors from patients. Majority of the nurses suggested to improve the therapeutic communication techniques which may help to prevent violence. The similar suggestions were also came out from the present study.

**Conclusion**

The focus group discussion mainly focused on identifying the strengths of the expert nurses and various practical information came out from the discussion. Six major themes were identified and many educational interventions were derived from the themes. Overall the qualitative discussion helped to design an aggression management and violence prevention training programme for nurses working in psychiatric and emergency setting.

Caries Prevention by Biofilm Control: Newer Frontiers in Management

Sowmya Sridhar¹, Baranya Shrikrishna Suprabha², Arathi Rao³
¹Post Graduate Student, ²Professor and Head, ³Professor, Department of Paedodontics and Preventive Dentistry, Manipal College of Dental Sciences, Mangalore, Manipal Academy of Higher Education, Manipal, India

Abstract

Since the advent of the Ecological plaque hypothesis of caries etiology, concepts in the prevention and control of caries have changed drastically. These contemporary approaches aim at modifying the existing biofilm and neutralize the environmental factors that may predispose to the creation of disease. This review discusses the need for such approaches in the long-term prevention of caries and also provides a bird’s-eye view to the clinician on the various strategies available for the same.

Key words: Dental caries, dental plaque, biofilm, prevention

Introduction

Dental caries is one of the most prevalent chronic diseases affecting people worldwide, although the prevalence and severity varies in different populations¹. The etiology of dental caries is generally agreed to be a complex one complicated by many factors. Overall, it is based on three essential factors: acidogenic/aciduric microorganisms, dietary carbohydrates, and host factors. Since there is no single agent identified, there is no simplistic method of disease prevention².

However, caries is still an “infectious disease”, and develops as a result of an ecological imbalance in the stable oral microbiome, causing the enrichment of some oral pathogens³. The advent of this ecological hypothesis in caries etiology has shifted the focus away from “traditional pathogens” as being solely responsible for disease.

Caries as a biofilm-mediated disease

In plaque, the bacteria function as an organized, and metabolically integrated community, the properties of which are greater than the sum of the component species⁴. Such an ordered way of formation renders stability to the dental plaque, within which microbial homeostasis is seen⁵.

Marsh stated that a considerable environmental change in a biofilm can affect microbial homeostasis and alter the balance among the resident organisms⁶. Disease can therefore be prevented by interfering with environmental processes that break down homeostasis and cause plaque biofilm dysbiosis⁷.

Newer caries-preventive approaches acknowledge that it is necessary to not only correct the environmental factors, but also help maintain a healthy, microbially diverse, resident microbiome⁸. This review aims to provide a brief overview on the newer strategies available in the modification of oral biofilms.

Review method

An electronic search of publications was made using the electronic databases ScienceDirect® and PubMed® through our institutional membership access. The inclusion criterion was abstract or full text articles including Original research, reviews, or systematic reviews. The keywords used for the search were selected listing the following five combinations:
Prevention of biofilm formation through blocking initial attachment: Anti-adhesive strategies

Adhesion of microbial surfaces to host tissue is a critical event in infection and pathogenesis. Cell recognition of microbial surfaces is mediated by carbohydrate-receptor recognition. After a ligand’s recognition of a receptor, initial adhesion is followed by complex colonization leading to the development of elaborate biofilm structure known as the EPS (Extracellular Polymeric Substance) architecture.

Anti-adhesive strategies aim at blocking this attachment at an early stage thereby altering the structural integrity of the biofilm.

Anti-adhesin antibodies

Adhesion of *S. mutans*, is facilitated by a cell surface adhesin named streptococcal antigen I/II which binds the microorganism to the glycoprotein component of the pellicle. In an early animal study, local passive immunization with monoclonal antibodies (Mc Ab) directed against the surface adhesins of *S. mutans* resulted in decreased *S. mutans* colonization in the fissures and smooth surfaces.

Significant retardation of *S. mutans* recolonization was also seen following the application of a synthetic peptide to tooth surfaces pretreated with chlorhexidine gluconate, in a human trial. However, the diversity of adhesins is such that biofilm formation may continue by other routes, even if one route is blocked.

Antimicrobial peptides

Antimicrobial peptides (AMPs) are a heterogeneous group of molecules with a wide range of antimicrobial characteristics, adept at controlling bacterial infections and modifying biofilms because they lyse microbial cells only by interaction with their biomembranes. Therefore, the creation of resistance forms is also very low. Apart from naturally secreted salivary AMPs, laboratory synthesized peptides have also been discussed in caries research.

Selectively Targeted Antimicrobial Peptides

The STAMP (Selectively Targeted Antimicrobial Peptides) approach involves selective delivery of antimicrobial compounds in high concentrations to selected bacteria. An antimicrobial peptide C16G2 targeting *Streptococcus mutans* has been found to be effective in the complete killing of *S. mutans* with minor effect on the other noncariogenic strains of streptococci.

Similarly, an antimicrobial decapeptide named KSL-W, has been found to selectively destabilize the cell membranes of cariogenic bacteria like *S. mutans*, *S. sobrinus*, and *L. acidophilus*. The use of KSL-W as an additive in a chewing gum preparation, and as a bioconjugate with a hydroxyapatite-binding heptapeptide has also been suggested. However these are very expensive and are susceptible to the action of salivary proteases.

Modifying the bacterial interactions

Quorum sensing targets

Quorum sensing (QS) is a bacterial intercellular communication mechanism for controlling gene expression in response to population density for a particular stimulus. Because of these cell-cell interactions, bacteria in a biofilm are able to function as a group against competitors or while adapting to varying physical stresses, cellular differentiation, and species evolution.

Deregulation of a QS system causes structurally disturbed biofilms. A scanning electron microscopy study found the architecture of biofilms formed by defective *S. mutans* strains to be abnormal with reduced biomass. Recently, a compound, 3-Oxo-N, was seen to significantly minimize lactic acid accumulation, even in the presence of fermentable sugars by modifying the quorum sensing pathway. Bacterial growth is not directly influenced by this signaling pathway. Therefore, less virulent strains will still remain in the biofilm and the chances of antibiotic resistant mutants are very low.

Bacteriocins and mutacins

Bacteriocins are peptides that are bactericidal for other bacteria belonging to similar species. Mutacins are bacteriocins produced by *S. mutans*.

A histidine kinase gene, *ciaH*, was discovered in 2004, whose inactivation abolished mutacin production. Surprisingly, the same mutation also diminished competence development, stress tolerance, and acid tolerance.
and sucrose-dependent biofilm formation.

Photodynamic therapy

Antimicrobial photodynamic therapy (aPDT) is based on the concept that a photoactive dye, also known as a photosensitizer, can be preferentially taken up by bacteria and subsequently activated by light of a specific wavelength, to generate singlet oxygen and free radicals that are cytotoxic to the microorganisms.

Many dyes such as toluidine blue O, methylene blue, photofrin, Rose Bengal dye and erythrosine have been tested as photosensitizers with positive results. White light (λ=600-650nm), LED light (λ=610 nm), diode laser (λ=665 nm) with different durations of application (1-5 minutes) have been used. A recent systematic review evaluated the effects of PDT on S. mutans and C. albicans biofilms, using methylene blue as the photosensitizer and concluded that significant results were present, especially with a longer pre-irradiation time of 15 minutes. A remineralization approach in the arrest of root surface caries has also been successfully tried, involving photodynamic treatment and use of casein phosphopeptide-amorphous calcium phosphate.

Designer bacteria

The concept of designer bacteria, for example, S. mutans strains that lack the acid production capacity, has been researched. In 2010, a true “designer bacterium” was synthesized- Mycoplasma mycoides JCVI. These cells only had the designed synthetic DNA sequences. Even though the genetic material had been modified, these cells were still seen to retain the capacity for continuous self-replication. However, the entire concept is yet to gain widespread acceptance for emotional, ethical, or legal reasons.

Probiotics

Probiotics are “live micro-organisms that, when administered in adequate amounts, confer a health benefit on the host”. Probiotic bacteria are believed to have both local anti-caries and systemic effects. The most commonly studied and used probiotics belong to the Lactobacillus and Bifidobacterium bacterial genera. Laboratory studies involving the use of live yoghurts showed antibacterial activity against S. mutans, A. actinomycetemcomitans, P. gingivalis and P. intermedia from multispecies biofilms.

Koll et al isolated oral lactobacilli based on their probiotic properties and concluded that L. plantarum, L. paracasei, L. salivarius and L. rhamnosus, in particular exhibited high antimicrobial activity. However, a recent systematic review concluded that current evidence is not sufficient for recommending probiotics in the control of dental caries, even though promising results are seen.

Natural products

Include polyphenolic compounds isolated from plants, fruits or herbs. The presence of more than one phenol unit per molecule confers the antimicrobial activity to these compounds.

A recent systematic review revealed enhanced antiadhesive and antibiofilm activity by the extracts obtained from plants like Vitis vinifera, Pinus spp., Coffea canephora, Galla chinensis (Black grapes, cranberry, coffee, tea) on multispecies oral biofilms, with Vitis vinifera being the most promising natural antimicrobial.

The antimicrobial efficacy of propolis, a resinous extract from honeycombs, against three common oral pathogens (S. mutans, P. gingivalis, F. nucleatum) and a yeast (C. albicans) has also been documented. Natural products still remain a largely unexplored territory in the field of caries research, considering the efficacy and non-toxic nature of these molecules.

Conclusions

Innovative strategies that can influence the nature of the biofilm are the need of the hour. Further research in the form of randomized controlled trials are required to ascertain the clinical efficacy of these newer strategies and develop a working protocol for their use in routine caries management.

Comparative Efficacy of Three Different Retreatment Rotary Instrument Systems for Removal of Gutta-Percha from Root Canals: A Comparative in Vitro Study

Jasmine Mary Antony¹, Aravind R. Kudva², Harish K Shetty³, Shravan Kini⁴, Sree Gowri⁴

¹Post graduate Student, ²Reader, ³Senior Prof & Head of the Department, ⁴Reader,
Department of Conservative Dentistry and Endodontics, Yenepoya Dental College, Deralakatte

Abstract

Introduction: Failures of endodontic treatment requiring re-treatment contain a tremendous dimension of patients. Complete removal of gutta-percha from root canal walls, reestablishing working length, disinfection and re-obturing the root canal are the main goals of non-surgical retreatment to obtain predictable success.

Aim: The aim of this study is to compare the efficacy of three rotary instrumentation systems that is protaper retreatment system, Mtwo Retreatment Files and Neoendo Retreatment Files for removal of gutta-percha from root canal.

Materials and Method: Thirty freshly extracted, single-rooted human teeth were instrumented with Protaper Gold rotary file system, and each root canal was filled with gutta-percha and AH Plus (Dentsply Detrey, Konstanz, Germany) sealer using lateral compaction. Specimens were divided randomly into three groups of 10 specimens each. The removal of gutta-percha was performed using protaper retreatment files, Mtwo retreatment files, and Neoendo files after 1 week. The amount of root canal filling material remnant was measured using stereomicroscope and computer image analysis program.

Results: In Mtwo on an average gutta percha remaining on root canal wall was 11.9 ± 1.5, in Protaper system it was 6.66 ± 1.56 and in Neoendo system it was 2.08 ± 1.42.

Conclusion: Neoendo is better with least remaining gutta percha compared to Protaper compared to Mtwo Retreatment files.

Keywords: Protaper retreatment files, Root canal retreatment, Mtwo retreatment files, Neoendo retreatment files.

Introduction

Failures of endodontic treatment requiring re-treatment contain a tremendous dimension of patients. Complete removal of gutta-percha from root canal walls, reestablishing working length, disinfection and re-obturing the root canal are the main goals of non-surgical retreatment to obtain predictable success.

The main goal of retreatment is cleaning and shaping of the root canal with removal of old root filling material, and this can be achieved by either hand instruments or rotary instruments. Endodontic retreatment can be done either by nonsurgical retreatment (orthograde) or by apical surgery (retrograde).¹

Several techniques have been proposed to remove filling materials from the root canal system, including the use of endodontic hand files, Nickel-Titanium (niti) rotary instruments, Gates Glidden burs, heat, ultrasonic instruments, laser and use of adjunctive solvents. Conventionally, the removal of gutta-percha using hand files with or without solvent can be a tedious, time-consuming process especially when the root filling material is well compacted.²

DOI Number: 10.5958/0976-5506.2019.00703.4
Various rotary nickel–titanium (Ni–Ti) files and rotary instrumentation systems such as Profile (DENTSPLY Tulsa Dental, OK, USA), Quantec (Sybron Dental Specialties, CA, USA), K3 (Sybron Dental Specialties, CA, USA), and race (FKG Dentaire, Germany) have been introduced for removal of root filling materials and have proved to be more efficient and safer than the traditional hand files.¹

Protaper Ni–Ti rotary system has been upgraded to the Protaper retreatment system which includes shaping, finishing, and retreatment instruments. The three retreatment instruments are designed for removing filling materials from root canals and have various tapers and diameters at tip. D1, D2, and D3 have diameter sizes 30, 25, and 20 with 0.09 taper, 0.08 taper, and 0.07 taper, respectively. Full length of these retreatment files is 16 mm for D1, 18 mm for D2, and 22 mm for D3. These instruments have convex, triangular cross-section and D1 has an active working tip that facilitates its penetration into filling materials.¹

Mtwo Retreatment Files consist of two instruments with active cutting tip: R1 (size 25, 0.05 taper) and R2 size 15, 0.05 taper. They have an S-shaped cross-section as do the files of the basic sequence, but a shorter pitch length to enhance the advancement of the file into the filling material. These instruments are characterized by two cutting edges, which are claimed to cut dentine effectively.³

Neoendo Retreatment Files Consists of three instruments N1 (size 30, 0.09 )taper For Coronal One-third which is 16mm in length and has a blue ring.N2(size 25, 0.08 taper)For Middle One-third which is 18mm in length and has a red ring and N3(size 20, 0.07) For Apical One-third which is 25mm in length and has a yellow ring.

Because the removal of filling material represents a crucial step in retreatment success.⁴ The aim of this study is to compare the efficacy of three rotary instrumentation systems that is Protaper retreatment system ,Mtwo Retreatment Files and Neoendo Retreatment Files for removal of gutta-percha from root canal.

**Materials and Method**

Thirty freshly extracted human single-rooted teeth, each with a single root canal, were selected for this study from the Department of Oral And Maxillofacial Surgery, Yenepoya Dental College.

Access cavities were prepared using high-speed diamond burs with copious water spray. A size 10 K-file was placed in the canal until it was visualized at the apical foramen. The working length was determined by subtracting 1 mm from this measurement.⁵

The root canal was prepared using Protaper Gold rotary file system (DENTSPLY Maillefer) according to the manufacturer’s instructions. The files were operated using an electric motor (X-Smart; Dentsply Maillefer) with a 16:1 reduction hand piece.⁶

RC-Prep (Premier Dental Products, Philadelphia, USA) was used as a lubricant during instrumentation. A glide path was performed using proglider (Dentsply Maillefer; size 16, 0.02 taper) file to the working length. In all the tooth samples, the root canals were instrumented to the working length using the following sequence: SX, S1, S2, F1, and F2. The first three shaping files were used with a brushing action, and the last two finishing files were used with a nonbrushing action until the working length was reached.

During instrumentation, the canals were irrigated with 2 ml 5.25% sodium hypochlorite.⁶ Each instrument was used to prepare three canals and then discarded. Upon completion of instrumentation the canal was flushed with saline as the final irrigant and dried using absorbent paper points.⁷ Obturation was done using AH plus sealer and F2 gutta percha points ( Dentsply Maillefer) using lateral condensation obturation technique. The access of canals was sealed with glass ionomer cement and the specimens were stored at 37°C in 100% humidity for 7 days.⁸

**Retreatment technique**

The teeth were decoronated at the cemento-enamel junction with a diamond disk to leave a root of 15mm in length and specimens were were divided randomly into three groups of 10 specimens each. Two millimeters of obturation material was removed using Gates Glidden drills 1, 2, and 3 from cervical part of all the specimens.¹

Then, 0.05 ml of xylene solvent was introduced into each canal to soften the gutta-percha.

Two or three additional drops of xylene solvent were applied as required to reach the working length. During retreatment, the root canals were constantly irrigated
with 2.5% sodium hypochlorite. Rotary instruments were used in a brushing circumferential motion whilst pressing against the root canal walls to remove gutta-percha. The obturation removal was done using one of the following techniques:

**Group 1: Protaper Group**

Protaper retreatment files were used in crown-down manner in a brushing motion at constant speed of 500 rpm as per manufacturer’s recommendation. D1 (size 30; 9% taper) was used in the coronal third, D2 (size 25; 8% taper) in the middle third, and D3 (size 20; 7% taper) in the apical third as specified by the manufacturer.

**Group 2: Mtwo Group**

Mtwo retreatment files were used in gentle in-and-out technique along with short brushing motion with an air-driven rotary handpiece at constant speed of 300 rpm as per manufacturer’s recommendation. R1 (size 15; 5% taper) was first used to working length and then followed by R2 (size 25; 5% taper) used up to the working length.

**Group 3 Neoendo Group**

Neoendo retreatment files were used in the following sequence using light apical pressure at a constant speed 350 rpm as per manufacturer’s recommendation. Neoendo retreatment file N1- (size 30, 0.09 taper) for coronal one-third, N2- (size 25, 0.08 taper) for middle one-third, and N3- (size 20, 0.07 taper) for apical one-third were used with a crown-down technique.

On withdrawal, the files were cleansed of any obturating material before being reintroduced in the root canal. Each file was discarded after being used in three teeth.

Retreatment was considered complete when no remnants of gutta percha and sealer were observed on instrument surface or in the irrigating solution.

Roots were grooved longitudinally using a diamond disk, preparing grooves parallel to the long axis of buccal and lingual surfaces, and split gently using a chisel into halves. Sections that showed evidence that the groove had penetrated into the root canal space or exhibited an irregular cleavage were discarded, replaced by a new specimen. For practical purposes no attempt was made to differentiate between gutta percha and sealer remnants.

Specimens were observed under stereomicroscope at 8x magnification. Microphotographs were recorded with a digital camera and subsequently analyzed using Digital Image Analyzing Software (Motic Images Plus 2.0ML) and the amount of gutta-percha/sealer on the canal walls was measured in mm. Collected data was analysed by both descriptive and inferential statistical methods.

Descriptive methods such as mean and standard deviation were obtained to summarize the data of parameters in each group. Inferential methods such as ANOVA was performed to find the significant difference across the group and Bonferroni post hoc analysis was performed to find the significant different in pair vise.

**Results**

In Mtwo group on an average gutta percha remaining on root canal wall was $11.9 \pm 1.5$, in Protaper group it was $6.66 \pm 1.56$ and in Neoendo group it was $2.08 \pm 1.42$.

ANOVA test shows that there is significant difference between the systems as $p = 0.000$ 0.001 further post hoc analysis revealed that remaining gutta percha was significantly different between all the groups so we conclude that Neoendo is better with least remaining gutta percha compared to Protaper compared to M2 Retreatment files.

Discussion

Removal of filling material is an important factor in root canal retreatment because it allows chemomechanical reinstrumentation and redisinfection of the root canal system. To date, it has not been proven that complete removal of filling materials will ensure success of root canal retreatment and that remaining material will cause the retreatment to fail. However, removing as much filling material as possible from inadequately prepared and/or filled root canal systems would appear to be essential in order to uncover the remaining necrotic tissues or bacteria that may be responsible for periapical inflammation and persistent disease.¹¹

One of the most difficult to control parameters in this study was the extent of the anatomical variations that are generally present in human teeth. Variations in original root canal morphology greatly influence the changes that occur after root canal preparation and as a logical extension, after retreatment procedures. In order to minimize these variables a standardized length of root canal filling was adhered to and only teeth with straight canals were selected.¹²

In this study, direct visual scoring with the aid of a stereomicroscope, as proposed earlier, was adopted for the evaluation of residual gutta-percha and sealer on the canal walls, as it was considered a simple and efficient assessment method.¹³

Traditionally, chloroform was used as a popular solvent for gutta-percha removal due to its ability to rapidly dissolve gutta-percha. However due to its carcinogenic nature as reported by the International Agency of Research of Cancer, the use of alternative solvents such as xylene, orange oil, halothane, and tetrachloroethylene has been suggested for the removal
of gutta-percha. Among these, xylene has been found to have the best dissolving efficacy.¹

Das et al (2017) conducted a study to compare the relative efficacy of three rotary instrumentation systems (Protaper retreatment files, Mtwo retreatment files, and R-Endo files) for removal of gutta-percha from root canal during endodontic retreatment. Protaper group was found to have less remnant filling material as compared to the other groups in coronal and middle thirds with/without the use of solvent, but a significant difference was observed between Protaper and Mtwo and Mtwo and R-Endo in the nonsolvent groups (P < 0.05). Mtwo group demonstrated less amount of remaining filling material in the nonsolvent group.¹

Studies done by Tasdemir et al. And Bramante et al. demonstrated that, Protaper Universal retreatment files and Mtwo NiTi rotary instrumentation system are faster and more efficient in removal of obturation material than hand files.¹ Rotary NiTi instruments have also been proposed for removal of filling materials from root canal walls and various studies reported their efficacy in cleaning ability and safety.¹⁴

Neoendo retreatment files has a niti metallurgy design featuring parallelogram cross section, positive cutting edge with microgrinding manufacturing technology. There is no literature review regarding Neoendo retreatment file hence study was conducted with available data obtained from manufacturer.

Analysis of the overall means of residual filling material showed significantly less values for Neoendo retreatment files followed by Protaper universal retreatment instruments and Mtwo retreatment instruments.

In earlier retreatment studies, remaining gutta-percha was assessed radiographically or residual gutta-percha were measured using evaluation scales, e.g. Severe, moderate, mild or no-retreatment debris. In the present study, the roots were split longitudinally and the residual filling material was measured linearly. Delineation of the remaining filling material with aid of softwares is more precise than the utilization of scores. This precision is related to image magnification on the computer, providing better quality of images.¹⁵

**Conclusion**

Under the experimental conditions all three rotary systems proved to be helpful and safe devices for gutta-percha removal in orthograde endodontic retreatment. Niti systems such as Neoendo or Protaper performed better than Mtwo retreatment system in terms canal cleanliness. The use of xylene as a solvent helped to reduce working time and to enhance root canal cleanliness. Nevertheless, completely cleaned root canal walls could not be achieved with any of the techniques under investigation.¹⁶

Abstract

In today’s fast-paced world, it is essential to stay abreast of the ever-changing trends in technology. This will help us to leverage technology for the benefit of our patients. The availability of fast internet connectivity, cloud based solutions and smart devices are making it possible to bring it greater speed, efficiency and safety into existing processes and systems.

This clinical paper attempts to highlight the positive transformation of a traditional Orthodontic Department upon adopting the latest technologies in patient management.

The Orthodontic Patient Management System is a comprehensive patient management software that resulted from a collaborative inter-institutional effort to create a fast, responsive and secure patient management system that incorporated our way of functioning. In essence, we tailor made our patient management software. The OPMS takes into consideration all the needs and requirements of a large orthodontic department and digitizes the entire patient flow, from the first appointment until debonding; stores patient records securely and facilitates appointment placement.

Keywords: Electronic patient management, Orthodontic Office.

Introduction

In today’s fast-paced world, it is essential to stay abreast of the ever-changing trends in technology. It is imperative that we leverage technology for the benefit of our patients. The availability of fast internet connectivity, cloud based solutions and smart devices are making it possible to bring it greater speed, efficiency and safety into existing processes and systems. Digital technologies have the potential to improve diagnosis; facilitate patient treatment procedures; and streamline storage, transfer and retrieval.

The prevalence of electronic patient records is higher in developed economies. Over time, such systems are gaining popularity in India as well. Both clinicians and patients stand to benefit from adoption of digital techniques. It is imperative that clinicians view the adoption of digital technology as a synergistic add on to their practice. A study conducted in Canada revealed that 73% of the orthodontists felt that digital technology was helpful in consultation with patients and other specialists.
Digital dentistry may be broadly defined as any dental technology or device that incorporates digital or computer controlled components in contrast to that of mechanical or electrical alone. The adoption of digital patient management system adds to the digital triad that already exists in our clinical settings; namely digital photography, digital radiography and digital models. This will further increase the efficiency of our model of health care delivery.

This clinical paper attempts to highlight the positive transformation of a traditional Orthodontic Department upon adopting the latest technologies in patient management.

The Orthodontic Patient Management System (OPMS) is a comprehensive patient management software that resulted from a collaborative institutional effort to create a fast, responsive and secure patient management system that incorporated our way of functioning. In essence, we tailor made our patient management software. The OPMS takes into consideration all the needs and requirements of a large orthodontic department and digitizes the entire patient flow, from the first appointment until debonding; stores patient records securely and facilitates appointment placement.

The Orthodontic Patient Management System (OPMS)

The OPMS is a unique software. Its uniqueness lies in the fact it was designed by orthodontists who studied the workflow patterns, optimized processes and then created a digital platform to best serve the needs in an orthodontic clinic.

This software implements an access based login system wherein each user has a unique user name and password. The features and the information accessible to the user depends on the type of the user id. At its core, the OPMS has two fixed user profiles, named as the Head of Department (HoD) and the Clerk (Admin) and multiple number of temporary profiles named as instructors/clinicians and post-graduates. The fixed user profiles are unchangeable but the temporary profiles can be created and disabled as required. (Figure 1)

It employs a simple user interface, which is not cluttered and easily accessible. The left hand side of the screen reveals the navigation tabs and the center of the screen displays the data.

Figure 1 – Access controlled login

Figure 2 – User Interface
Each user profile has a bouquet of features and information available that is curated according to their need. It also maintains data privacy by restricting patient information access. The clinicians and postgraduate doctors can view/edit patient profiles personally treated by them and not by others. (Figure 2)

The software provides for electronic recording of patient information in a phased and systematic manner. The data recorded is stored and digitally transmitted to instructors for approval. Computer aided learning (CAL) is a useful addition to the tool kit of an educator. It has been shown in research that Computer aided learning (CAL) is effective to teach students\(^6\). The OPMS aids in teaching and supervision of clinical cases. The user, hence making the system tamper proof, cannot edit data once approved. This makes it extremely valuable for a medico legal standpoint. Orthodontic treatment has a long course and a single treatment happens over multiple visits.

The software enables capture of data at each visit with a provision to approve or reject the data. OPMS also allows users to upload patient images, lateral cephalogram and OPG images and CBCT. The file formats of .JPEG, .PDF and .PPT are supported. Data in the system are stored on three servers, one at site and two off site. This ensures that data integrity is maintained and patient data is not lost in the event of a hardware malfunction.

OPMS also facilitates patient scheduling. The software sends an SMS to the patient once the appointment is set as a reminder. It also informs the patient if the appointment is rescheduled for some reason. This simplifies patient scheduling and improves patient recall and satisfaction. (Figure 3)

![Figure 3: Patient Scheduling](image)

Research is a very important part of all teaching hospitals today and the OPMS can help clinicians in research through its innovative “Reports” section. This is an analytics function, which enables the user to search and retrieve data from case files from a research standpoint.

![Figure 4: Reports and Analytics](image)
Functions of the Orthodontic Patient Management System

1. It facilitates paperless recording of patient information
2. It ensures confidentiality of patient information
3. It enables patient scheduling for efficient working
4. The software augments specialty training by helping the users to learn and track the treatment done in a phased manner.
5. Teaching learning is facilitated through a feedback mechanism
6. Ability to retrieve patient records for research purposes

The salient features of the OPMS software are as follows-

1. OPMS uses two fixed user ids – the admin clerk and the Head of Department.
2. User ids for staff and postgraduates are generated in requisite multiples and deactivated when access is no longer desired.
3. Search feature enables user to locate a patient based on name, father’s name or file number
4. Completely digital patient record file to record information
5. Multiple choice based answers helping the users to quickly complete entering patient details
6. Treatment plan once decided locks and does not allow modification by users
7. Visit details for each appointment are also submitted online with photographs and appropriate records
8. Online assessment of the submitted data by supervising staff and Head of Department
9. Analytics feature enables the software to read and generate smart reports. Users can list out cases based on malocclusion, treatment done etc.
10. Access to information based on the hierarchy of the user
11. Guest ids can be created for allowing read only access to patient archives
12. Ability to schedule appointments for patients
13. Patients receive SMS reminders whereas doctors and supervising staff get notification regarding the upcoming appointments
14. Patient data is securely stored in multiple locations

Advantages

1. Paperless system- environmentally friendly
2. Reduction in manpower (by avoiding need to store and paper retrieve files)
3. Safety of the records- addresses medicolegal considerations
4. Improved our branding and image

Disadvantages

5. Setting up digital infrastructure and high speed internet entails high upfront cost
6. There may be issues with incompatibility among various software

Conclusion

The key challenges in the pathway to doing digital include infrastructure and cost. The setting up of a high-speed network to transfer and store data is a prerequisite. However, over the long term the costs average out and are significantly lower than manual based systems. Institutions should lead the way forward and set up teams with expertise in information technology to develop electronic patient records specific for their individual needs or explore options of purchasing commercially available systems.

Lastly, Going digital is now no longer a choice but a necessity.

Conflict of Interest- Nil

Abstract

In clinical research studies complex end points are most common. Especially in studies on diseased patients undergo therapy, a relapse can occur, or patients can die after relapse or without former relapse (death). Sometimes, endpoints can be reasonably combined in a composite endpoint, as relapse and death combined into disease-free survival (DFS). In this case, standard survival techniques, as Kaplan–Meier estimation of the DFS probability, can be applied. Often, interest focuses on endpoints for which competing risks are present; a competing risks model plays a special case of a multistate model. A more complex multistate model is required when the effects of events occurring in the course of the study on further disease progress. Another endpoint of interest is time to experience multiple episodes; the multistate model used for analysis must be adapted for this event structure. The aim of this report is to explain use and interpretation of both non proportional hazard Cox (non PH) and proportional hazard Cox (PH) type multistate models for the suitability of assessing different covariate effects in situations of multiple endpoints and also different baseline hazard assumptions in a comparison manner for the European Group for Blood and Marrow Transplantation (EBMT) competing risks data.

Keywords: survival analysis, competing risks, multi-state models, R,mstate

Introduction

In survival analysis, we often concentrate on the time to a single event of interest. In practice, there are many clinical examples of where a patient may experience a variety of intermediate events. Standard survival analysis considers the time until some first event only, whereas competing risks models analyse the time until some first event and the event type that occurs at that time. Competing risks also model the endpoint type but it does not model subsequent events such as multiple events. To do this, more complex multistate models are needed and want to investigate covariate effects for each specific transition between states.

Multi-state models are very much constructive tool to answer questions in survival analysis which cannot be answered by classical models. In recent times, multi-state and competing risks models have been considered with high regard in survival analysis. The multistate framework models events as transitions between states and includes competing risks as a special case. The occurrence of a competing risk is modelled as a transition out of an initial state (e.g. no progression) into a competing risk state (e.g. progression). The transition takes place at the time of the first event. The aim of the present article is to explain use and interpretation of Cox-type regression models for competing risks and multistate models for more complex event structures. To overcome this problem, the analysis of multi-state
Models with transition-specific covariates:

The mstate package supports the analysis of typespecific Cox models. Events are of the same ‘type’ or ‘stratum’ if they share a baseline hazard. We consider a model in which ‘type’ is equivalent to transition: each transition has its own baseline hazard. Here, we believe a usual ‘proportional baseline hazards model’. In both models, covariates can have the same effect for all transitions or different effects for different transitions; in the latter case, transition-specific covariates are needed. The model is a transition-specific Cox model (1)

\[ \alpha_{gh}(t) = \alpha_{gh}, 0(t) \exp(\beta^T Z_{gh}) \rightarrow (1) \]

where \( gh \) indicates a transition from state \( g \) to state \( h \), \( \alpha_{gh}, 0(t) \) is the baseline hazard for this transition, \( Z \) is the vector of covariates at baseline and \( Z_{gh} \) is the vector of transition-specific covariates. This model specifies different covariate effects for different transitions, as well as separate baseline transition hazards for each transition. The covariances of the estimated cumulative hazards are being computed in two different ways by means of the Aalen estimator and the Greenwood estimator. For the estimators of the regression coefficients and baseline hazards (1). Assume we have data with independent censoring and the estimation of the cumulative hazard through the Nelson-Aalen estimator \( \hat{A}(t) \) of the cumulative hazard for transition \( g \rightarrow h \) is now given by

\[ \hat{A}(t) = \sum dN_{gh}(t) / Y_g(t) \rightarrow (2) \]

where \( t \) indicates the event times, \( dN_{gh}(ti) \) is the observed number of transitions from state \( g \) to state \( h \) at time \( ti \), and \( Y_g(ti) \) is the number of subjects at risk for a transition from state \( g \) at \( ti \) (Therneau and Lumley 2010).

The transition probability matrix for the elements is as by \( P(s, t) \). It has elements

\[ P_{gh}(s, t) = P(X(t) = h \mid X(s) = g) \rightarrow (3); \]

denoting the transition probability from state \( g \) to state \( h \) in time interval \( (s, t] \). The transition probability matrix is estimated as

\[ \hat{P}(s, t) = \Pi_{u \in (s, t]} (I + \Delta \hat{A}(u)) \rightarrow (4); \]

where \( u \) indicates the event times and the elements of \( A \) are estimated as in(2) and above equation (4) is called the Aalen-Johansen estimator. The covariance of the empirical transition matrix may be estimated by ((Andersen et al. 1993) (2)

\[ \text{cov}(\hat{P}(s, t)) = \int_s^t P(u, t)^T \otimes \hat{P}(u, u -) \text{cov}(d\hat{A}(u)) \hat{P}(u, t) \otimes P(s, u -)^T \rightarrow (5) \]

models, it is applied to non- and semi-parametric (Cox) models. The sources of data have been provided by the EBMT (the European Group for Blood and Marrow Transplantation) with special interest to the modelling of different covariate effects for all transitions or transition-specific and different baseline hazard assumptions.

where \( T \) denotes vector transpose and \( \otimes \) the Kronecker product. This formulation for the covariance matrix of the Greenwood type and enables integrated cumulative hazards to not necessarily be continuous. The advantage of the Greenwood estimator yields exact multinomial standard errors for the transition probabilities when there is no censoring than the Aalen estimator. Consequently the two estimators give more or less equal results in all kind of practical applications. (2) (1). According to Fiocco et al. (3)(4) the reduced rank model which is formulated for transitions. In this model all covariates have the same effect given by the parameter
vector on each transition apart from the proportionality coefficients. We use a model in which each transition has its own baseline hazard and estimates the parameters of a reduced rank model.

**Data**

A more general introduction into competing risks and multi-state models can be found in\(^6\). There are a variety of challenges in estimating transition probabilities in multi-state models, within both non-parametric or semi-parametric and parametric frameworks\(^{6,1,5}\). We consider estimation and prediction for both semi-parametric and non-parametric models including several relevant clinical covariates. We consider the EBMT data; available in R under mstate as ebmt4\(^5\). It is purely survival after a transplant treatment of patients suffering from a blood cancer. The data have been provided by Three intermediate events are included in the model: Recovery (Rec), an Adverse Event (AE) and a combination of the two (AE and Rec). It is to be expected that recovery improves the prognosis and an adverse event deteriorates it. The model is suitable to show the size of these effects, and to capture the influence of their timing and of the covariates on the prognosis. It shows what happens when both the positive and negative event take place, as compared to one or none of them. We consider 2279 patients who were treated between 1985 and 1998. Four prognostic factors are known at baseline for all patients (see Table 1). They are: donor-recipient match (where gender mismatch is defined as female donor, male recipient), prophylaxis (Treatment), year of transplant and age at transplant in years. All these covariates are treated as time-fixed categorical covariates. The distribution of the values of the covariates over the patients in the data set is shown in Table 1.

A multi-state approach is particularly appropriate for these data, since it can help to model both the disease-related and the treatment-related morbidity and mortality. These are modeled here by including the intermediate events recovery and adverse event. Information about the occurrence of these events is used to update the prognosis of the patients. Total cases recovered 1218(53.4%), adverse event 1134(49.8%), both recovered and adverse event 660(29%), relapse 370(16.2%) and death cases 838(36.8%). We consider the following six-state model for leukemia patients after bone marrow transplantation is illustrated in Figure 1.

1. The six-state model has the following factors with six-state
   1. Transplantation
   2. Recovery
   3. Adverse event
   4. Recovery and Adverse event
   5. Relapse
   6. Death

The detailed states have been illustrated as in Figure 1 as follows

State1. Alive and in remission, no recovery or adverse event;

State2. Alive in remission, recovered from the treatment;

State3. Alive in remission, occurrence of the adverse event;

State4. Alive, both recovered and adverse event occurred;

State5. Alive, in relapse (treatment failure);

State6. Dead (treatment failure).
According to the table 2, Starting from state 1, the patient is at risk for transitions 1,...,4. This means that the patient can move to states 2, 3, 5 and 6. At time 22, the patient moves to state 2 (Recovery), from where the patient is at risk for a further transition to state 4, 5 and 6 (i.e., transitions 5, 6 and 7). None of these occur and the patient is censored at time 995. The patient has no rows for transitions 8-12 because the patient has never been at risk for these. The value of time is equal to “Tstop”-“Tstart”; it is of use in ‘clock reset’-models, where the time t refers to the time spent in the current state. The numbers of transitions, both in terms of frequencies and percentages, are given subsequently. This process by showing a selection of the long format data for the first patient, leaving out the values at baseline and the transition-specific counterparts of “match”, “proph” and “agecl”. Because of zero having factors like year1.1 to year1.12 are being omitted.
Results and Discussion

The original covariates are retained to consider models with any mixture of basic and transition-specific covariates. It is considering for both non-parametric and semi-parametric model. The basic quantities of interest are the transition intensities or hazard rates. For the estimation of the cumulative hazard, it is assumed to have data with independent censoring. This Cox model has separate baseline hazards for each of the transitions and no covariates. In principle, the transition intensities could also be estimated separately, but the combined use of long format data and a single stratified “coxph” object makes further calculations easier.

Co-variances of the estimated cumulative hazards may be computed in two different ways: by means of the Aalen estimator or by means of the Greenwood estimator. An advantage of the Greenwood estimator is the fact that it yields exact multinomial standard errors for the transition probabilities when there is no censoring. The two estimators give almost equal results in all practical applications\(^2\)\(^3\). Since there are twelve transitions in the model, its output is not shown here in the interest of space. The head and tail of the cumulative hazards of all transitions along with time (time in years) are presented in table 3A (below.)

The last time point in the list indicates the last time point in the data, either of an event or of a censoring. Both these method mimics each other there is much differences in their estimation. The Figure 2B using Aalen method illustrates of all estimated cumulative hazards in different colours.

Need to calculate the estimated transition probabilities, and optionally the standard errors and/or the co variances of the transition probabilities. The Stacked transition probabilities (an informative ordering of the transition probabilities) are given (Figure2A and 2B) with plotted using Greenwood and Aalen estimator respectively. These figure shows the distance between two adjacent curves represents the probability of being in the corresponding state. The particular order chosen makes it possible to combine the probabilities of recovery and recovery + AE, and of AE and recovery + AE.

Semi-parametric models (A model with transition-specific covariates) show how the prediction of the transition probabilities can be improved by taking covariates at baseline into account. The mstate package supports the analysis of type-specific Cox models. Events are of the same ‘type’ or ‘stratum’ if they share a baseline hazard. In this section, we consider a model in which ‘type’ is equivalent to transition: each transition has its own baseline hazard. The second session of part, we consider a so-called ‘proportional baseline hazards model’. In both models, covariates can have the same effect for all transitions or different effects for different transitions; in the latter case, transition-specific covariates are needed. We refer to this model as the full model.
Table 4: Regression coefficients (and standard errors) for the full model; covariate effects significant at 0.05 and 0.01 levels are indicated with(*).

</table>
The estimated regression coefficients of the covariates and their standard errors for each of the transitions are shown in the Table 4. For each covariate, the estimated effects are positive for some transition hazards and negative for others. The use of transition-specific covariates is very convenient to observe such effects.
Also it enables to make a different kind of predictions for individual patients and is interested in dynamic prediction of 10-year relapse-free survival (RFS) probabilities (Table 5) and we can see how these prediction probabilities change as more information about intermediate events becomes known in the course of time. We want to study how 10-year RFS probabilities change when the patient experiences the adverse event 60 days (0.164 years) post-transplant and is recovered from the treatment 80 days (0.219 years) post-transplant.

Table 5: Dynamic prediction of 10-year relapse-free survival (RFS) probabilities for specific patients

Figure 3: Standard errors for the transition probabilities AE to Relapse and AE to Death (starting time: 100 days), both for the full model and the proportional baseline hazards model.
It shows finally, (Figure 3) the standard errors of the transition probabilities from state 3 (AE) at time 100 days to states 5 (Relapse) and 6 (Death), for the full Cox model (non-PH) and for the proportional baseline hazards model (PH) and also shows that the proportional hazards assumption does not always decrease the standard errors of the predictions in either of categories. The main advantage of proportional baseline hazards models is accurately that we obtain such a measure for the impact of intermediate events on the final outcome.

Conclusion

Multi-state models are a very useful tool to answer a wide range of questions in survival analysis, especially in the competing risks aspects. R offers the user the opportunity to explore different kinds of multi-state models and estimate their parameters of interest on the basis of a regular data set containing the times to event of the events of interest and optionally covariate values. The functions in the package are flexible, which means that they can easily be combined with user-written software in cases when models not covered by mstate are studied. In mstate, we confine with non- and semi-parametric models. In this work, it has been explored the different phases of a multi-state analysis: model building, data preparation, exploration of different covariate effects and baseline assumptions, estimation of hazards, transition probabilities and associated standard errors using ebmt data. In particular, it has been explained how predictions can be rationalized with dynamic prediction, if supplementary information becomes acknowledged. This possibility is an important extra feature of multi-state models compared to classical survival models. Moreover, numerous ways of presenting the outcomes in figures have been revealed with this kind of European Group for Blood and Marrow Transplantation data.

Abstract

Background: Hypertension being the silent killer pose the individuals at risk for adverse health effects and serious complications endangering the life of an individual. Non-adherence to the recommended treatment for hypertension adds to the likelihood of therapeutic failure. Since family play a very important role in the care of elderly, assessment of family support by the health care providers becomes one of the important components of treating elderly on antihypertensives.

Objective: to assess the medication nonadherence among elderly on antihypertensives and to find the influence of family support on medication adherence.

Materials and Method: The total sample for the study included 124 nonadherent elderly hypertensives and were assessed at baseline and followed up at three and six months. During each follow up the participants were assessed for their level of medication adherence and family support. The data were collected using demographic and clinical proforma, MMAS-8 (r=0.83) and family support scale (r=0.92). Ethical clearance was obtained from the Institutional Ethical Committee and Informed consent was obtained from participants.

Results: It was found that the family support does have a significant influence on medication adherence among elderly hypertensives.

Conclusion: Detailed assessment by the health care provider regarding the family support becomes the basis for the management of nonadherent behavior of elderly on antihypertensives.

Keywords: Hypertension, Aged, Medication Adherence, Family

Introduction

Hypertension is increasing rapidly in the Indian populations. As patients are unaware that they have HTN until they develop complications, detection and timely management of hypertension is vital to reduce the incidence of cardiovascular disease. It is estimated that uncontrolled blood pressure increases the risk of ischemic heart disease 3 to 4 fold and the overall cardiovascular risk by 2 to 3 fold. The incidence of stroke increases approximately 3-fold in patients with borderline hypertension and approximately 8-fold in those with definite hypertension. The therapy prescribed for hypertension will control hypertension only if the patient is motivated in the form of having a good family network. The family is the unit of care; it has great importance in effective management of hypertension. The family unit determines therapeutic success or failure including medication adherence. Geriatric being the vulnerable age group demands family support for the individuals on antihypertensives. One of the major issues among these population is medication non-adherence which needs individualized care for overcoming the issue of medication nonadherence.

Materials and Method

The study was carried out among the patients attending the outpatient department of Medicine in
a tertiary care hospital in Karnataka. Nonadherents identified (N=124) were assessed at baseline, three months and six months. During each follow up the participants were assessed for the level of medication adherence and family support. The study aimed to find out the medication nonadherence among elderly on antihypertensives and the influence of family support on medication adherence.

The background information of the participants was collected using the Demographic and Clinical proforma.

Medication adherence was assessed using Morisky Medication Adherence Scale (MMAS-8) (r=0.83) which is a standardised scale authorized to utilize with due norms. MMAS-8 had 8 items focussing on the drug taking behaviour of the individual. The adherence level was categorized as Low adherence (<6), Medium adherence (6-<8) and High adherence (=8). Standardized Kannada version of MMAS-8 was obtained with permission from the original author.

Family support was assessed using the family support scale which consisted of 14 items. Each item had the option as very often -3, fairly often - 2, once in a while -1 and never - 0. The total score ranged between 14-42 and the perceived family support was interpreted as High family support (32-42), Moderate family support (22-31) and Low family support (14-21).

The inclusion criteria for the study were patients of aged 60 years and above with stage I and stage II hypertension with or without comorbidities like Diabetes Mellitus, chronic Ischemic Heart Diseases, dyslipidemias, chronic rheumatism and any other chronic conditions who were able to manage taking medications and were able to read, write, and converse in English/Kannada. Patients with renal failure, acute stroke, acute ischemic heart disease, major psychiatric disorders, dementia or delirium were excluded from the study.

**Results and Discussion**

The majority 85(68.5%) were between the age group of ≥60-70 years, 65 (52.4%) were females, 60(48.4%) were with the educational qualification of > 7th standard - PUC and 53 (42.7%) were currently not employed. Majority 109 (87.9%) were living with their spouse, 68 (54.8%) were having an annual income of INR <12, 000 and 61(49.2%) expressed that their treatment expenses are taken care by their children (Table 1).

Majority 97(78.2%) were on treatment for hypertension for more than a year, 106(85.5%) were having blood pressure under control, 43(34.7%) were overweight and 78 (62.9%) had co-morbidities. Daily an average of 1- 4 medications was taken by 88 (71%) of the patients including the antihypertensives (Table 2).

Out of 124 participants all (100%) were non-adherent to the antihypertensive medications at baseline. Whereas the adherence level improved over a period of time and majority 111(89.5%) and 115(92.7%) were found to be adherent at 3months and 6 months respectively. Subjects in both the low and medium adherence category were considered as non-adherents to anti-hypertensives (Table 3).

This study reported that all the elderly expressed having high family support (Table 4) and the mean scores of family support ranged between 35-39 over a period of six months (Table 5). Since all the participants were non-adherents initially (at baseline assessment), the analysis to find out the influence of family support on medication adherence was performed with the data collected at sixth month (N=124). As there was normal distribution in the data on perceived family support paired ‘t’ test was performed. The findings revealed that the family support has statistically significant influence (t=75.09, p<.001) on the medication adherence behavior of the elderly hypertensives (Table 6).

With regard to the findings of family support, the study conducted at outpatient departments of Ayder Referral Hospital (ARH) and Mekelle General Hospital (MGH) in Ethiopia by Ali, Bekele and Teklay (2014) revealed that presence of family support is significantly related to adherence and Tricia & Robin (2013) found that lack of family support affects individual’s adherence level to the medications. Ofoli, Dankyau, Sule and Lass (2017) showed that family and social support were significant predictors of good medication adherence. All these above findings are contradictory to the present study findings. Study conducted by Osamor (2015) in Idikan community, Ibadan, Nigeria revealed that social support from friends but not from family was significantly associated with good compliance with treatment for hypertension.

Conclusion

As such care of elderly is a challenging issue, the nonadherent behavior of elderly on antihypertensives increases the intensity of the health care concern required towards their management. In helping the elderly to remain adherent to their antihypertensive medications, the mere presence of family member during their visit to the health care facilities will suffice to make elderly remain adherent to their antihypertensive medications. Cooperation of the family is often necessary in fulfilling medical treatment prescribed by a physician.¹⁰,¹¹

Ethical Clearance: The ethical clearance was obtained from the Institutional Ethical Committee (IEC 253/2012) and CTRI registration (CTRI/2017/04/008405) was done. Informed consent was taken from the patients before collecting the data.

Young People with Physical Disability Talking about Depression

Manoj Mathew P¹, Suja M K²
¹PhD Scholar, ²Associate Professor Department of Social Work, Amrita School of Engineering, Coimbatore, Amrita Vishwa Vidyapeetham, India

Abstract

The depression among people with disability is a serious health concern as the depressive symptoms are more in people with disability than general population. The objective of this study is to scrutinize the differences between two controlled groups of physical disability a) with depression, b) to examine associations among social relationships, c) emotional factors and socio-demographic variables, d) pattern of peer group interactions, e) depression rate and finally overall functioning. The survey assessed 50 respondents with a physical disability from both gender categories between the age group of 12 years to 19 years. Both convenient and random sampling methods were applied and all the respondents were sustained with in-depth interviews and discussions. People with physical disabilities have manifested similar demographic profiles and social relationship factors during the study. The result shows from the study that, there is an association between depression and disability. The attained results explicit the overall functioning of people with physical disabilities.

Key words: Young People, Depression, Physical Disability, India

Introduction

Depression is a predominant issue with regards to public health and it affects more than 350 million people in the world. Feeling sad isn’t an uncommon factor for everyone feels blue or disappointed at one or the other phases of their routine. This suggests that not all sadness can be categorized as depression. Persisting of the sorrowful state over a considerable period of time following subsequent evoking of disturbance and confusion in a person can be accounted as depression. Depression influences a man’s thought, behavior, emotions and physical prosperity, social impact, biological and psychological factors have vital role in leading a person towards stressful life. A survey conducted by the World Health Organization (WHO) in 2011 among 17 countries shows that 1 in every 20 individuals are depressed.

The people with disability fail to meet the requirements to lead a normal life since they are having limited ability to move or function. Physical illness and depression are closely bonded i.e.; physical illness can be a major cause of depression. Most of the cross sectional studies showed that the people with disability have depressive symptoms. Depressive symptoms are more affecting in people with disability than normal people. There are many factors influencing the reason for being the people with disability are in depression, including the social attitude, environmental barriers, limited to access health services, barriers in accessing education and jobs, less chance to being social, financial problems, abuse and restrictions from family members/guardians. The people with disability experience high level of depression than general population irrespective of age and gender.

This paper presents a detailed investigation regarding the level of depression in both the adolescent boys and girls with physical disability. Studies of the entire relationship between physical disability, depression and gender are a very limited in our society. Most of the studies available in the literature are from western culture, and it is important to study the depression in young people with disability with regards to gender specific in India. Women with disabilities experience more depressive symptoms than males. However, by the age 13, a dramatic shift occurs calling for twice
the number of girls being depressed and unfortunately this persists unto adulthood. This ratio exists regardless of racial or cultural backgrounds. Young people with disability are the ones unintentionally ignored during the programs, policies and courses for them. Their problems thus aren’t addressed and are neither issued even by the programs designed for them. Hence there is limited knowledge about these 2 groups namely adolescent (those between age group of 10 - 18) and by the United Nations as“ youth” (19- 24) as assorted by the UNICEF, subgroups are also prevalent however considering the shared features among these 2 they are brought together.

It is in the hands of the public and government to provide necessary facility and see to it that even the disabled are empowered15. It is a matter of shame that even now children with disabilities are considered backward in studies and despite years of literacy they are denied of their basic right. The belief is that they need to rightly be stressed out to get literate. They also are under the opinion that they need to undergo a lot of pressure and gallons of embarrassments and moreover should be kept away from public. Even the very act of constructing a fleet of stairs makes it clear that the chances are made tough for the disabled. If such minute factors continue over the years, it will prove to hinder a vast majority of the disabled. Thus the resolutions can be brought about by wavering all the evil thoughts in the minds of the society. The promises need to be delivered in a step by step manner and for this initially all the citizens should be educated. One thing to be kept in mind is that all are equal before the law and therefore even the disabled and to benefit with an encouraging society and a prosperous future eclipsing all their fear of collapses amongst other abled citizens. The purpose of the study is to find the level of depression among young people with disability with regards to gender and find suitable solutions to make them to lead a happy normal life. This paper is organized as follows:

Methodology

Sample and Data collection

A field-based survey has used for data collection with both convenience and random sampling of disabled students. Participants were selected from the three schools in the disabled people with the age group of 12 to 19 years. The face-to-face interaction and discussion are held; the students were informed about the opportunity to participate in the field oriented research, focusing on their attitudes towards disability and their overall functioning through their life experience. Only physically disabled students from the rural area were included in this study.

Measurements

Self-made questionnaire has applied for analysis of the study. It contained four sections: namely a) measure demographics, b) academic experience, c) attitudes towards disability and d) emotional factors. To assess the academic performance and school experience, a total of eight questions were used. Two items focus on academic performance and six items are for both school atmosphere experiences. These items were developed based on group discussion with students. To assess the adolescent’s depression, six items have collected from the Kutcher adolescent depression scale developed in 2006. To assess the attitudes towards the disability based on social life experience, 14 items was used with four-point scale, like; (not at all, only slightly, partly and to a great extend). It is also collected from the group during the discussion time. To assess the emotional factors associated with disability, 12 items were collected with 04 points scoring applied, Like; (Never, Often, Quite often and always). Demographics have included age, gender, education and ethnicity.

Data Analysis

The descriptive examinations of the information were led to analyze the sample features. Using SPSS 16.0, data analysis was included descriptive statistics, simple percentage and chi-square test. Chi- square test will help to test the significant deference among the variables.

Results and Discussion

This section deals with the results obtained for study conducted in depression among adolescent boys and girls having physical disability. This study conducted during the period 2015- 2017 at rural districts of Kerala, India. Initially 127 samples were met; Researcher reduced sample size due to the following factors: 1) Individuals were not willing to deliver their experience honestly, 2) Due to the lack of support to respondents from parents/ caretakers/peer group. Since people in domestic circle were not aware of the relevance of research study. With these context researcher has identified the suitable 50
samples that delivers daily living experience.

**Sample Descriptions**

The demographics of the respondents identified by their age, gender, religion, family annual income and education. Demographics of Respondents obtained in the study are summarized in Table 1. The result shows that, most of the respondents are coming in the age group of 16-17 years. Both male and female respondents were recruited from the schools with 25 numbers from each gender. Majority of the respondents, 44% were coming from the Christian religion. 42% of the respondents were coming from Hindu religion and remaining from Muslim. Respondents are living in the rural areas and they are depending agriculture for their daily bread. That can be seen in their family monthly income, most of the respondents (56%) are from middle class family. Only 18% of them are having monthly income of above Rs.10,000. 26% of them are below middle class family and facing financial security. It also shows the poor financial security and accessibility of services from the Government sector. Majority of the respondents (48%) are doing 10th-11th class of education.

</tr>
<tr>
<td></td>
<td>24 (48%)</td>
<td>26 (52%)</td>
<td>100</td>
<td>50</td>
<td></td>
</tr>
</tbody>
</table>

The Table 2 summarizes the level of depression among male and female in percentage. Majority of the respondents 26 (52%) are probably depressed and 24 (48%) respondents are probably not depressed. But when it comes on the basis of gender, female respondents with physical disability are more depressed (64%), than the male respondents.

**Chi-square test**

A wide sequence of survey suggests that there is a significant relation between gender bias and the subsequent treatment. Table 3 summarizes the Chi-square test obtained for this study. In fact the calculated value which is around 4.326 differs the table value marginally the latter being around 3.841. Thus the concept of null hypothesis is unreliable and alternative hypothesis is preferred. A wide sequence of survey suggests a significant relationship between gender bias and the level of depression.

**Discussion**

Though disabled akin to the abled are able to compass greater heights it is necessary they be provided with possible mental support for they are mostly dependent. To fight all odds and climb the ladder of success they too require tones and tones of support and encouragement. This should inevitably start from their homes. Society too plays a major role in shaping their mindset. The disabled should be aided to waive all the fear of living. Initially measure should be taken to eliminate all the physical, mental, and emotional barriers and equal opportunities should await them in the educational institutions. Education is the whetstone to awareness and therefore society should initially be educated. Partnerships need to be fosters between rehabilitation professionals and community groups so that problems of the disabled adolescents are brought into limelight. All in all, there should be a feeling of confidence instilled in the mindset of the youth to conquer the world.

**Conclusion**

In this paper we have analyzed the depression among people with disability in men and women. Depression being big very common in the modern day world the issues of the victims should be duly considered for them to perform better. The disability and depressive symptoms are related- disability affects their mood, thinking and behavior. People with disability are more affected with depression than general population. Unlike the abled man they will require much of encouragement from the society to shield their anxiety. The socio-cultural attitude towards them also affects their depressive symptoms. An individual with physical inability may have bouts of severe depression and their dreadful thoughts need to put aside for clear idea of the future. As the studies infer the depression rate varies drastically among the females and males and necessary tactics should be taken to avoid the same. The study showed that gender is a key factor that determines the depression in people with disability. The overall studies prove that women with physical disability are more susceptible than men in matters regarding the same proper planning and implementation of the same should avoid any fallies pertaining to disturb their lives. In spite of the methodological limitations of the research study, young women seem by all accounts, to be critical factors for depression among young people with physical disability.
Ethical Issues: This study obtained consent from the young people with physical disability before involving them in this study and inform about the importance of the study.

Bio-Medical Waste Management at an Academic Hospital: Knowledge and Practice of Hospital Staff

Khajan Singh1, Niti Solanki Gahlot1, Amrit Virk2, Mahima Panigrahi1, Narottam Samdarshi1

1Assistant Professor, 2Prof. and Head, Dept of Comm. Med., Adesh Medical College and Hospital (AMCH), Mohri (Dist.Kurukshetra), Haryana

Abstract

Background: Large volumes of wastes are generated by hospitals as a by-product of variety of health services and procedures. These may be infectious or non-infectious. Hospital staff is constantly exposed to these wastes and is at risk of getting fatal diseases as an occupational hazard. It is not only a legal necessity but also a social responsibility to effectively manage bio-medical waste. Objectives -1. To determine the awareness of hospital staff regarding hospital waste management policy and practices (2016). 2. To relate the practices of hospital waste management to the level of knowledge. 3. To suggest possible remedial measures (if required). Material and Method- The present study was a cross- sectional study, carried out in Adesh Medical College and Hospital (AMCH), Mohri (Dist.Kurukshetra). A total of 296 healthcare professionals consented for the interview (56.9% response rate) which included 80 doctors, 94 nurses, 72 lab technicians and 50 sanitary staff working in AMCH, Mohri (Dist.Kurukshetra), who gave informed consent for their willingness to participate in the study. A self- designed questionnaire, inclusive of items related to socio-demographic data, knowledge and practice of bio-medical waste management (as per 2016 bio-medical waste management guidelines) was used for data collection. The data collected was subjected to statistical analysis using descriptive statistical methods. Findings- Majority of healthcare professionals were ‘male’ i.e. 175 (59%). Most of the healthcare professionals were in the age group 30-40 years i.e. 115 (39%). Among the doctors most were postgraduate i.e. 68 (85%). Majority of nurses were graduate i.e. 72 (77%). Most of the lab technicians had a diploma i.e. 51 (71%) and majority of sanitary staff were educated below matric i.e. 43 (86%). As regards length of service, most of the doctors had more than 10 years of experience i.e. 43 (54%), majority of nurses had 3-5 years of experience i.e. 36 (38%). Among the lab technicians most had length of service of 5-10 years i.e. 41(57%) and majority of the sanitary staff had length of service more than 10 years i.e. 29 (57%). Most of the hospital staff had knowledge regarding BMWM. Majority of hospital staff i.e. 274 (93%) practice waste segregation into different categories. Most of them i.e. 256 (87%) practice colour coding of waste and 215 (73%) use bio-hazard symbol for labelling. Only 136 (46%) of hospital staff maintain waste disposal register. Conclusion- Doctors and nurses have good knowledge and practice of BMW but lab technicians and sanitary staff need regular sensitization.

Keywords: Bio-medical waste, hospital staff, knowledge, practice.

Introduction

Hospitals generate large volumes of wastes as a by-product of variety of health services and procedures which may be infectious or non-infectious. Infectious waste tends to be of smaller volume than non-infectious waste, but once mixed the total unsegregated waste is deemed as infectious which poses a major public health hazard. Hospital staff is constantly exposed to these wastes and is at risk of getting fatal diseases as an occupational hazard. It is not only a legal necessity but also a social responsibility to effectively manage bio-medical waste. The most critical problems associated with hospital wastes are the absence of proper waste...
management, lack of awareness about the health hazards from biomedical wastes, insufficient financial and human resources and poor control of waste disposal. \(^{(1)}\)

To protect the community from various adverse affects of the hospital wastes it is necessary not only to have adequate knowledge about the health hazards of hospital waste, but also to practice proper technique and methods of handling the waste and follow safety measures. With this background, this study was conducted with the main objective of assessing knowledge and practices of doctors, nurses, lab technicians and sanitary staff regarding bio-medical waste management. The objectives of this study are-

1. To determine the awareness of hospital staff regarding hospital waste management policy and practices (2016).
2. To relate the practices of hospital waste management to the level of knowledge.
3. To suggest possible remedial measures (if required).

**Material and method**

The present study was a cross- sectional study, carried out in Adesh Medical College and Hospital (AMCH), Mohri (Dist.Kurukshetra). This is a 600 bedded private tertiary care teaching hospital in Haryana (India). The study was carried out over a period of three months from Dec 2017 to Feb 2018.

A total of 296 healthcare professionals consented for the interview (56.9% response rate) which included 80 doctors, 94 nurses, 72 lab technicians and 50 sanitary staff working in AMCH, Mohri (Dist.Kurukshetra), who gave informed consent for their willingness to participate in the study. They were interviewed and observed for bio-medical waste management (BMWM) practices. Data was collected directly from the study subjects through a pre-designed questionnaire.

**Ethical clearance** - Data collection was started after obtaining approval from the Ethics Committee of Adesh Medical College and Hospital.

**Criteria for selection of subjects**- Staff members working in AMCH, Mohri (Dist.Kurukshetra) participated in the study. The study included doctors, nurses, lab technicians and sanitary staff.

A self- designed questionnaire, inclusive of items related to socio-demographic data, knowledge and practice of bio-medical waste management (as per 2016 bio-medical waste management guidelines) was used for data collection. The data collected was subjected to statistical analysis using descriptive statistical methods. Descriptive statistics was used to describe sample characteristics in terms of frequency and percentage.

**Findings**

The results of the study are presented here under the headings of various parameters considered for the study:-

*Total years of service in hospital were considered which were not necessarily in the present institute.

Table 1 shows that majority of healthcare professionals were ‘male’ i.e. 175 (59%) and 121 (41%) were ‘females’. Most of the healthcare professionals were in the age group 30-40 years i.e. 115 (39%) followed by 40-50 years age group i.e. 77 (26%), above 50 years of age were 59 (20%) and least were in 20-30 years age group i.e. 44 (15%). Among the doctors most were postgraduate i.e. 68 (85%) and rest 12 (15%) were graduate (MBBS). Majority of nurses were graduate i.e. 72 (77%). Most of the lab technicians had a diploma i.e. 51 (71%) and majority of sanitary staff were educated below matric i.e. 43 (86%). As regards length of service, most of the doctors had more than 10 years of experience i.e. 43 (54%), majority of nurses had 3-5 years of experience i.e. 36 (38%), followed by 5-10 yrs of experience i.e. 29 (31%). Among the lab technicians most had length of service of 5-10 years i.e. 41(57%) and majority of the sanitary staff had length of service more than 10 years i.e. 29 (57%).

</table>

The results of table 2 revealed that majority of hospital staff had knowledge regarding colour coding of waste containers i.e. 247 (84%), segregation of waste at source i.e. 243 (82%) and transmission of disease through BMW i.e. 243 (82%). Hospital staff that was aware about disinfection of hospital waste before disposal was 235 (79%). Only 159 (54%) were aware about BMWM rules. Most of the hospital staff i.e. 271 (92%) would like to attend a training program on BMWM. Only 101 (34%) hospital staff reported that hospital had provided annual education on waste management for employees.

Table 3. Practice of Bio-Medical Waste Management (BMWM) by hospital staff

<td>51%</td>
<td>54%</td>
<td>36%</td>
</tr>
</tbody>
</table>
Table 3 shows that majority of hospital staff i.e. 274 (93%) practice waste segregation into different categories. Most of them i.e. 256 (87%) practice colour coding of waste and 215 (73%) use bio-hazard symbol for labelling. Only 136 (46%) of hospital staff maintain waste disposal register.

Discussion

The study was conducted on a predesigned and pretested questionnaire and a cross-sectional study design was selected. Knowledge and practice of BMWM among technically qualified personnel was high. Doctors and nurses have updated knowledge of BMWM (2016 guidelines). However, amongst lab technicians and sanitary staff, there is inadequate knowledge about the subject and poor concept of BMW. This was similar to findings from other studies.\(^{(2,3)}\) The findings of Waseem Q showed that doctors have adequate knowledge about the hazards of BMW.\(^{(2)}\) The findings of present study were in agreement with Y Saraf whose study shows good level of knowledge among doctors and nurses as compared to ward boys and sweepers.\(^{(3)}\) Low level of knowledge is mainly attributed to poor training facilities and also to relatively low education level of the sanitary staff.

The result of present study when compared with findings of study done by Pandit N. B showed that most of the doctors were aware about the existence of the law related to BMW. Awareness of doctors regarding transmission of diseases associated with BMW was good but knowledge of lab technicians about it was poor.\(^{(4)}\) Majority of doctors and nurses were practicing as per rules of BMWM which is complementary to the results of S Saini et al.\(^{(5)}\) In contrast, the study results of Dr. Joseph et al. suggested that hospital staff did not color code the wastes. Only 15% of hospital staff used label of bio-hazard symbol and only 9% respondents agreed that they maintain waste disposal register.\(^{(6)}\)

Thus, the results show that healthcare professionals with higher education i.e. doctors and nurses have more knowledge and good practices about BMWM as compared to lab technicians and sanitary staff.

Conclusion and Recommendations

The study concludes that hospital staff with higher education i.e. doctors and nurses have updated knowledge about the BMWM as compared to lab technicians and sanitary staff who were not aware about BMWM. The study revealed that lab technicians though have poor knowledge about bio-medical waste act and rules, but most of them have good practice habits. Thus, we can conclude that doctors and nurses have good knowledge and practice of BMW but lab technicians and sanitary staff need regular sensitization. Following recommendations are proposed-

Orientation programs for the new employees of hospital on BMWM.

Training sessions should not become merely one time activity but should be a continuous process.

Apart from hospital staff, patients and their attendants should also be sensitized regularly regarding potential dangers of BMW. Instructions regarding not to mix the general waste with BMW be boldly displayed on charts in local language.

Stakeholder Perception of Health Technology Assessment in Industrial Setting

Sowmya Sundararajan¹, Sanjay Pattanshetty², Kiran R Aatre³, Manisha Gore⁴, Ravi Raj Singh Chouhan¹

¹Post Graduate Scholar, Department of Public Health Manipal University, ²Associate Professor, Department of Public Health, Manipal University, ³Program Manager – Robert Bosch Engineering and Business Solutions Pvt. Ltd., ⁴Consultant- Symbiosis Center of Health Care, Faculty of Health and Biomedical Sciences, Symbiosis International University

Abstract

Introduction: Health technology assessment (HTA) is a multidisciplinary process to evaluate the social, economic, organizational and ethical issues of a health intervention or health technology. The main purpose of conducting an assessment is to inform a policy decision making. Objectives: 1. To emphasize on the need of HTA in India. 2. To analyze the application of HTA in various health sectors. Methodology: A qualitative study was done by conducting in-depth interviews with the help of a semi-structured questionnaire from various sectors such as academics, health technology industries and government sectors. Results: The study findings prove that the concept of Health Technology Assessment was familiar to all the participants but was not being implemented by all due to lack of expertise pertaining to the field and resources. Hence there is a need to increase the importance of the topic to help in better decision making when it comes to the health sector. Conclusion: India does not have a formal HTA program due to lack of expertise in the subject and resources. If policy makers are linked to HTA, then the population will be benefitted by this. Although, participating in a HTA consultation can be challenging as well as time consuming, it provides a great window of opportunity to create an impact on the delivery of healthcare in the country.

Keywords: decision making, evidence based medicine, health care, informed decision

Introduction

Health technology assessment (HTA) refers to the systematic evaluation of properties, effects, and/or impacts of health technology. It is a multidisciplinary process which recapitulates evidence about medical, social, monetary and ethical concerns associated with the use of a particular health technology in a methodical, clear and unprejudiced manner.¹

In its Resolution on Health Intervention and Technology Assessment in support of Universal Health Coverage (2013), the World Health Organization suggested that in order to improve healthcare in terms of efficiency, affordability, prioritization and management, the member states need to develop a national framework for HTA and integrate it into frameworks involving health systems research, health professionals’ education, health systems development, and universal health coverage. The organization also urged the member states to collaborate with key stakeholders such as health organizations, academic institutes and such in the country to develop a strategic plan to introduce health interventions and technology assessment research and to seek technical support from its member states and international agencies.

In order to achieve the goal of Universal Health Coverage in India, prioritization in healthcare should take place in an evidence-based and affordable manner. In the current health policy scenario in the country, the keystone is the increasing costs of the various interventions in healthcare and diagnosis. The National...
Health Policy of 2017 seeks to ensure the digitization of the healthcare system and also proposes to establish the National Digital Health Authority (NDHA) to assist in regulating, developing, and deploying digital health across the country. To improve the quality of healthcare in the country, one would require having a sufficient working HTA program in place which should be able to focus on the evidence-based decision making in policies of healthcare. To ensure that the population is being benefitted by this program, it has to be linked to the health policy that is already in place.

This research focuses on the perception of HTA by various stakeholders involved in the health technology sector which fits perfectly given the current HTA scenario in the country. Although, participating in a HTA consultation can be challenging as well as time consuming, it provides a great window of opportunity to create an impact on the delivery of healthcare in the country.

Methodology

A qualitative study was conducted in the state of Karnataka, India (Southern part) across various sectors such as academics, health technology industries and government sectors which were selected by snowball sampling. Data collection was done by conducting in-depth interviews with an open-ended questionnaire. The study was approved by the authors institution and informed consent was obtained from participants before interviews. Transcripts were made and analyzed by MS Word and MS Excel respectively. However, since few of the stakeholders did not oblige to audio-recording of the interviews, hand-written notes were taken which could have led to loss of verbatim.

Results

Excerpts from the interviews:

Importance of HTA

All the individuals included in the study explained that HTA is of utmost importance to improve the healthcare sector in the country and that there is a need to improve HTA. They also attributed the importance to their knowledge about HTA. A majority of the respondents who were from technological industries graded their knowledge on HTA to be average to moderate because they did not have experts in the field to assist them in the process. Academicians and government officials were aware of the theoretical aspects of HTA and reasoned it with the lack of experts in the field and lack of awareness on the topic. As quoted by an academican, “Only theoretically people know what it is. I would say the knowledge is minimal. I think some people will know about what it is. But I don’t think they have experience in HTA as such.”

Improving HTA

Stakeholders’ consultations emerged as one of the best ways to improve HTA, although a few were doubtful about the idea since they were unsure about the differences and the misperceptions that could arise among or between the various sectors involved. A key industrialist gave his opinion stating that, “I think by helping to arrange such consultations on HTA, it will help in better decision making processes. It will also help in making the technology affordable and cost efficient.” Stakeholders are important in order to spread the awareness about HTA and implementing the process in all the procedures undertaken while developing a technological product.

HTA Consultations

All the respondents suggested that consultations have to be done at the beginning of the ideation process before designing the technologies by conducting workshops, conferences or consortium to help in better decision making process. They also suggested that creating a partnership with other organizations having service of HTA will also help in better consultation. However, all the participants agreed that inter-sectoral collaborations was the best way in order to include HTA as part of the healthcare sector and to improve it.

Prerequisites in HTA

All the respondents agreed on having expertise knowledge on HTA as the most important requirement for their organisation to be actively involved in HTA processes including manpower, funding, regular training programs, collaborations and networking with other organizations involved in HTA. More than half of the respondents agreed that problem identification was one of the important steps stated that a detailed situation analysis should be done before designing the product. Apart from the government officials who were unable to respond, the other interviewees suggested that the main
target areas were the target population, geographical location, manpower, market value, affordability and acceptability of the product.

**Discussion**

The study findings prove that the concept of Health Technology Assessment was familiar to all the participants but was not being implemented due to lack of expertise pertaining to the field and resources. Hence, there is a need to increase the importance of the topic in order to help in better decision making when it comes to the health sector. All the participants explained the importance of HTA in order to make informed decisions in terms of health so as to help in providing quality healthcare at affordable prices and since the current status of HTA is inadequate, there is a great demand to take measures to improve and promote HTA. A study done by Henshall and Schuller stated that patient value was the core element during the decision making process and that HTA will help towards a progressive health system decision making which would use evidence based study to make decisions.\(^5\)

Participants explained about the different roles played by the stakeholders with respect to HTA. As reported by one of the respondents, “the companies in the healthcare technology sector mainly focus on the profits. Although this is a duty of the company, the efficiency of the product may sometimes result as an obstacle. The employees in the government sector have to ensure that all the people in the country should have access to quality healthcare at affordable prices.” This will be possible only if there is a proper HTA program in place. Although the academicians are not directly involved in the process of HTA, they are responsible in including the topic in the curriculum in order to impart knowledge on the topic.

All the participants agreed that consultations on HTA have to be done at the beginning itself. It must also be done at different junctions such as ideation process, formation of a guideline for assessment, product designing, rapid assessment for pricing and reimbursement, piloting the technology, scientific advice while developing the product and marketing the product. A public policy statement given by Merck suggested that stakeholders must be involved in all parts of the process in order to improve the credibility of the results obtained.\(^6\)

With respect to the procedures, all the participants agreed that the main requirement was the expert knowledge in the field of HTA. They also emphasized on the need for other resources such as manpower and monetary resources in order to further improve the decision making. Majority of the participants suggested that problem identification was to be done at the beginning of the process itself. This will help in preventing loss of time and resources. However a few participants also mentioned that the severity of the problem is also take into consideration. If the problem is small then only a few changes are made. But if the problem seems quite large then the whole product is re-made.

Strategic planning includes the target areas, cost estimation, market potential and communication strategy. Majority of the participants were aware of the strategy, although the government officials were not able to shed light on this topic. The participants agreed that the target population, geographical location, manpower, market value, affordability and acceptability of the product were the major target areas one had to consider before the product was designed. A study conducted by Giovagnoni et al suggested that since HTA is a multidisciplinary process, no aspect should be overlooked; scientific, medical, ethical, social, legal, and economic. It must be carried out in a way that it involves and is consistent with the other health care and technical processes of the health system involved.\(^7\) While discussing about the cost of the technology, it was put forth that the following areas must be considered; cost of raw material, labor charges, time factor and the transportation charges. L. Gula ´csi et al in their study stated that the cost of a particular technology differs from country to country based on the GDP, status of the health care system, demographic factors, health status of the population in question, standard health practices, reimbursement policies of the medications, insurance costs, reimbursement policies of the medications, insurance costs, and direct and indirect costs.\(^8\) Although one of the participant did emphasize that access to health service is the basic right of any individual and that a cost cannot be put on health. On the topic of market potential, it was suggested by the majority of the participants that it must be identified at the beginning of the process itself in order to ensure the efficiency and the increased usability of the product. This can be done by doing surveys in order to identify the main areas. All the participants suggested that the communication strategy must be done by advertising in conferences, workshops and trade shows. It was also put
forth that the use of key opinion leaders such as medical professionals who will help to talk about the product before it hits the market will also help to increase the market for the said technology.

WHO in its Medical Device Technical Series titled Health Technology Assessment of Medical Devices that was authored by Banken et al suggested that after ascertaining individuals who had a capacity to appreciate HTA, the topic could be gradually introduced and making these individuals the ‘focal points’ of HTA. The focal points could either be in a research organization, government organization, university, or other not for profit agencies that are focused on the use of HTA for policy and decision making. The afore mentioned individuals is then referred to as ‘HTA focal points’ who would pose as ambassadors of the information that would draw attention of policy and/or decision makers.9

Conclusion

One of the strengths of Health Technology Assessment is that it can help in the comparison of medical, surgical, and public health initiatives. If the system is developed with concerns given to the Indian healthcare, including the cultural, ethical, and philosophical considerations that are necessary for the local policy making, these equations can become the basis of decision-making on pricing, reimbursement and future investments that can be useful for the Indian healthcare system. As noted by Virgil, ‘Health is the Greatest Wealth’; economic productivity and prosperity depend on a healthy population. Although healthcare expenditure is considered to be an economic burden in our country, this statement explains the need to consider spending on healthcare as an investment for the economic well-being of the population.10 This can then help the Indian policymakers to make informed choices about choosing the most productive use of investments in the health which will in turn help in the general well-being of the country, by employing rigorous methodologies such as Health Technology Assessment.

Analysis of Uterus Involution, Lochea Expenditures and Back Pains on the Post Partum Mother Using Bengkung and Gurita

Sandu Siyoto  
Associate Professor of STIKes Surya Mitra Husada Kediri Indonesia

Abstract

Physical changes experienced by the puerperal mother one of them occurs in the uterus that is the involution of the uterus and expenditure lochea. Discomfort that often arises is a back pain. Many mothers use bengkung or guritas after childbirth culture, and still become the pros and cons for health practitioners.

This research uses quantitative and qualitative research. For a quantitative approach, the researcher uses true experimental design. The type of design used is posttest only control group design. Data were collected using high fundus uteri examination sheets, observation sheets and visual observation sheets. The dependent variables in this study were the incidence of uterine involution, lochea expenditure, and intensity of back pain. Researchers use in-depth interview guidelines to explore factors related to the use of bends. The sampling technique used by the researcher is simple random sampling. The number of samples in this study were 27 respondents.

Based on statistical test Chi square test obtained asymp.sig value (0.527)> α (0.05) hence it is concluded that H1 is rejected which means there is no difference of involution of uterus. Based on statistical test kruskall wallis test known that asymp. Sig. (0.735)> α (0.05) it is concluded that H1 is rejected which means there is no difference of lochea dispensation event. Based on statistical test kruskall wallis test known that asymp. Sig. (0.664)> α (0.05) hence it is concluded that H1 is rejected which means there is no difference of back pain occurrence.

In the postpartum mother, the effects of relaxin hormone cause abdominal muscle tone to loosen, ischemia in the myometrium, the presence of autolysis and the effects of the hormone oxytocin causes a sequence of uterine involution events and physiologic lochea excretion in the puerperium. Physiological changes also cause back pain in the puerperal mother.

Keywords: Uterus Involution, Lochea Expenditure, Back Pain, Bengkung, Gurita

Introduction

Physical and psychological changes in the postpartum can cause various discomfort after childbirth. Physical changes that one of them occurs in the uterus is the involution or the process of return of the uterus to its original size and expenditure lochea or puerperal fluid. Discomfort that often arises one of them is pain in the back. For postpartum care, the community can not be separated from cultural factors, and there are many women who use bengkung or gurita after giving birth. It is still a pros and cons for health practitioners.

Many things can affect the use of mothers using bengkung or gurita during childbirth, in addition to hereditary culture. Other factors is the mother’s perception of the benefits of bengkung or gurita that can make lean, comfortable feeling when wearing bengkung / gurita, the mother felt her body more balanced and mother feel more confident.

This study aims to analyze the differences in the incidence of uterine involution, lochea expenditure and back pain in postpartum mothers using bengkung and gurita, and exploring the reasons for using bengkung and gurita in mothers who work as health workers or health education background.
Method

This research uses quantitative and qualitative research. For a quantitative approach, researchers used true experimental design. The type of design used in this pure experimental study is posttest only control group design. The data were collected using the examination sheet to determine the involution of the uterus, the observation sheet for lochia expenditure and visual observation sheet to determine the intensity of back pain in the puerperal mother. The dependent variables in this study were the incidence of uterine involution, lochia excretion, and the intensity of back pain in the puerperal mother.

Result

Here are the result of the research:

a. Analysis of Differences of Uterine Involution

Table 1: Cross tabulation

<table>

Based on the table note that the value asymp.sig. or the value of significance or probability value of lochea

Discussion

In the postpartum mother, the effect of relaxin hormone causes abdominal muscle tone to loosen, ischemia in the myometrium, the presence of autolysis and the effects of the hormone oxytocin causes a sequence of physiological uterine involution events in the puerperium (Sulistyowati, 2009). Many factors affect the occurrence of uterine involution, including lactation, early mobilization, nutritional intake, parity, pacifist exercise regularity, and the use of abdominal support (Saleha, 2009).

The results of this study are in line with research conducted by Maryni (2012) which states that the use of bend or stagen does not affect the health status of the mother one of them is the involution of the uterus. Because the stagen works passively to disguise a stretchy abdomen after childbirth.

According to the opinion of researchers if the bengkung or stagen used according to the correct procedure then it will not endanger the health condition of postpartum mothers. Even the results of uterine involution output in this study for mothers who use bengkung or mother who use gurita also did not give a worse result when compared with mothers who did not use bengkung or gurita. And based on the results of research and observation for 14 days in mothers who use bengkung and gurita, the researchers did not find any constraints that mean or even can interfere with the health condition of the puerperal mother and her baby.

The researchers assessed uterine involution on day 14 by measuring the height of the uterine fundus. The researchers also performed a high measurement of fundus on the respondents every 2 days for 14 days.
Normally at day 14 the height of the mother’s fundus is not palpable above symphisis. However, in the sample group of puerperal women who took bengkung, there were two respondents who experienced uterine involution faster than it should be on the day-to-8 high fundus uteri mother is not palpable anymore.

With the involution of the uterus, the outer layer of the decidua surrounding the placental site will be necrotic / dead. The dead decidua will come out together with the remaining liquid called lochea.

Based on the research indicates that the higher the parity lochea expenditure faster. This may be due to the volume and condition of the pores of the uterine blood vessels in the larger multipara so that the expenditure of lochea becomes faster than the mother with the lower parity. The results revealed that the parity of the mother affects the duration of lochea expenditure, the higher the parity the faster the process of lochea expenditure (Cunningham, 2007). Based on the research shows that infants given breast milk alone in the intervention group 1 tend to experience normal and fast lochea expenditure, when compared with infants fed only or breastfed and MPASI. Baby’s sucking will stimulate the smooth muscles of the nipple, this stimulation by the nerve is transmitted to the brain, and then the brain orders the posterior pituitary gland to secrete the hormone oxytocin brought to the innocent muscle of the breast (Saleha, 2009). The oxytocin hormone not only affects the smooth muscle of the breast but also the smooth muscle of the uterus so that the uterus contracts. With a good contraction of the uterus, the expenditure of lochea in the mother who breastfed her baby will become more fluent.

Back pain during childbirth is a common thing experienced by every postpartum mother. Changing the point of body weight during pregnancy third trimester, the hormone relaxin during pregnancy and childbirth causes a back pain. In addition, the muscles and the lower backbone and pelvis that must work hard during the puerperium, whereas the muscles are still weak because of the birth process also contributed to the back pain during the puerperium (Judha, 2012).

Based on observations and interviews conducted by researchers during the research process, postpartum who are in the intervention group that uses bengkung and octopus convey that they use the curve other than due to cultural or customary factors, they use bengkung or octopus because it assumes that the curve or octopus is a tool help to overcome discomfort in the body after the process of pregnancy and childbirth. In addition to supporting the sagging belly and sagging, the puerperal mothers also feel curved or octopus can reduce pain in her back.

**Conclusion**

The results of this study indicate that there is no difference in the incidence of uterine involution, lochea excretion and back pain in the puerperal mother who does not use bengkung and gurita, postpartum mothers who use bengkung and postpartum mother who uses gurita. It cause not many factors can influence the incidence of uterine involution, lochea excretion and back pain in the puerperal mother.

An Economic Analysis of Jasmine Cultivation in Madurai District, Tamilnadu

S Thangamayan¹, S N Sugumar², S Chandrachud³

¹Assistant Professor, ²Professor and Head, ³Professor, Department of Economics, VELS Institute of Science, Technology and Advanced Studies (Deemed to be University) Chennai

Abstract

Jasmine is one of the oldest fragrant flowers cultivated by man. The flower is used for various purposes viz., making garlands, bouquet, decorating hair of women, religious offering etc. More than 80 jasmine species are found in India, of which only three species are used for commercial cultivation. Its flowers are used for making garlands, adorning hairs of women, in religious and ceremonial functions, and for producing perfumery oil. Its commercial cultivation is confined to Coimbatore, Madurai, (Tamil Nadu); The dry land of the sample farmers is 89.75 acres, and the total wet land is 145.7 acres, cultivated land is 105.45 acres and the remaining on uncultivated land is 78.25 acres in these 4 Blocks, Thirumangalam has 165.4 acres and Solvanthan has 108.5 acres of landholdings. These two Blocks have more than 60 per cent landholdings of the sample farmers. Owing to great diversity climate and other environmental conditions in different parts of the country, the varieties of jasmine cultivated vary from place to place. The Malli, Pitchi and Mullai varieties are mainly cultivated in Madurai District. The reduction in productivity is the highest Thirumangalam and lowest in Melur.

Keywords: Jasmine, Cultivation, Area Productivity.

Introduction

Jasmine is one of the oldest fragrant flowers cultivated by man. The flower is used for various purposes viz., making garlands, bouquet, decorating hair of women, religious offering etc. It is also used for production of Jasmine concrete which is used in cosmetic and perfumery industries. More than 80 jasmine species are found in India, of which only three species are used for commercial cultivation. They are Jasminum sambac (Gundumalli / Madurai Malli), J. auriculatum (Mullai) and J. grandiflorum (Jathimalli / Pitchi). The first two species are mainly cultivated for selling as fresh flowers whereas the last one is cultivated for concrete extraction. Tamil Nadu is the leading producer of jasmine in the country with an annual production of 77247 from the cultivated area of 9360 ha. The flowers produced in the state are being exported to the neighbouring countries viz., Sri Lanka, Singapore, Malaysia and Middle East countries. The major jasmine producing districts of Tamil Nadu are Dindigul, Salem, Madurai, Tirunelveli, Virudhunagar, Trichy, etc.¹ Since the crop requires lots of manpower for harvesting and other operations, only small farmers are cultivating the crop. It is an ideal crop for small farmers whose land holdings are less than 1 acre.

Jasmine: Production Practices

Jasmine (Jasminum species) is one of the leading traditional flowers of India. Its flowers are used for making garlands, adorning hairs of women, in religious and ceremonial functions, and for producing perfumery oil. Its commercial cultivation is confined to Coimbatore, Madurai, Dindigul, Athoor, Nilakottai, Thirumangalam, Kallupalli and Thiruparankundrum (Tamil Nadu); Bangalore, Ballary, Mysore and Kolar (Karnataka); Pune, Aurangabad and Ahmednagar (Maharashtra); Ahmedabad, Anand and Vadodara (Gujarat); Ambala, Gurgaon and Faridabad (Haryana); Kannauj, Jaunpur and Gazipur (Uttar Pradesh); Delhi; Ludhiana, Jalandhar, Patiala and Amritsar (Punjab); Ranaghat, Kolaghat, Panskura and 24-Parganas (West Bengal); Udaipur, Ajmer, Jaipur and Kota (Rajasthan); Hoja, Jorhat, Alnagarh (Assam). However, largest chunk
of areas under jasmine flower production is in Tamil Nadu and Karnataka. The annual production of flowers is worth more than Rs 120 million. Apart from internal trade, fresh flowers of jasmine are exported to Malaysia, Singapore and Sri Lanka.

**Review of Literature**

Edwin Desai B (1969) in his study examined that the level and pattern of investment in Agriculture, described capital in terms of durables and non durables. The non-durable capital included capital invested on major farm equipments, irrigation structure, cattle sheds and farm buildings. The non-durable capital included working capital spend on seeds fertilizers, farm yard manures, pesticides, irrigation and hired human labour.

Paul Samuelson (1973) reveals that the total cost of production includes fixed can variable cost. The fixed cost comprise of expense made on permanent human and animal labour, depreciation of farm implements and machineries, land revenue, rental value of land and interest on permanent investment other than land. The variable cost covers wage paid to hired human labour, cost of seeds, manures and fertilizers, irrigation charges, betterment levy, and miscellaneous cost such as protection charges, cost of gunny bags and interest on variable costs.

Sowmya Sankar B. (2008) explained that jasmine cultivation is one of the most remunerative farming enterprises in India. He focused on marketing costs, marketing margins and price spread in marketing of jasmine, and the producer share in a consumer rupee in jasmine marketing. He found that, the marketing channel in which farmer sell their produce directly to the consumer and hence is no proper link between jasmine demand and supply in both the markets. He concluded that, involvement of growers in export promotion has been minimal in India. Region specific export facilitation centers could be developed considering the concentrations of production of grapes in Karnataka.

**Statement of the Problem**

Madurai district is one of the Agriculture oriented district of Tamil Nadu. The district is blessed with perennial river namely Vaigai and also their tributaries. Most of the people in this district are practicing traditional method of cultivation of cash and commercial crops. It is left to the farmer to seek financial assistance from external sources such as commercial banks, land development banks, co-operatives and governmental agencies, besides non-institutional bodies. This institutional credit plays a key role in Jasmine cultivation in the field of viticulture and to identify the constraints faced by the farmers in availing the institutional finance.

**Objectives**

1. To analyze the trend in area production and productivity of jasmine cultivation in Madurai District.
2. To study the relationship between farm size and productivity.

**Tools of analysis**

The statistical tools are used to analyses the collected data and to interpret the research.

Linear Growth Rate
Semi _log model

**Analysis of the Study**

Farmers And Landholdings - Landholdings differ from period to period and at different places.

Farmers and Area of Jasmine Cultivated Land

The Study has made an attempt to find out the area of jasmine cultivated land by the sample farmers. The table 2 shows they are of land utilized by the farmers to cultivate Jasmine. It could be understood that almost all the respondents in the study area were variety of jasmine they cultivated. Out of the 120 respondents 52 (43.33 per cent) of Malli, 40 (33.33 per cent) of Pitchi and remaining 28 (23.34 per cent) of Mullai cultivation. It is clear from above table the majority of 43.33 per cent of Malli cultivated in the study area and the second place is 33.33 per cent of Pitchi cultivated in the study area.

Farmers and Yield Per Acre

The large profitability of agriculture increases with the size of holding, profitability being measured by the surplus of output over costs including the imputed value of labour. The table 3 it is shows the yield per acre, that 40 per cent of the farmers have used land of the size of Jasmine cultivation 18.4 per cent of farmers cultivated 0-0.5 acre Jasmine cultivation and 20 per cent of farmers cultivated 1 to 1.5 acres remaining 11.6 per cent cultivated 1.5 to 2 acres and 8.4 per cent and 1.6 per
cent cultivated Jasmine in 2 to 3 acres and above 3 acres respectively.

**Table - 4: Annual yield per acre**

</tbody>
</table>

The table-4 shows that the size of land holdings in Thirumangalam Block 25 acres and average yield per acre 3642.6 kg of Jasmine cultivated. It’s the high yield per acre of this area. Melur area cultivated land 37.60 acres, average yield per acre 3066.3 kg of Jasmine cultivation and Usilampatti area cultivated 40.6 acres average yield per acre 1802 kg of Jasmine. It’s very low level of than the other Blocks and Solavanthan Block farmers cultivated land 18 acres average yield per acre 2500 kgs of jasmine cultivated.

* Significant at 5 per cent level

** Significant at 1 per cent level

Table-5. Reveals that the regression analysis between farm size and productivity. The samples were taken by 60 farmers in 4 Blocks. The regression analysis suggests that an increasing Jasmine cultivated area by 1 acre will reduce the productivity by 1007 kg of Jasmine, in Thirumangalam. However, in Melur if Jasmine cultivated land is by 1 acre, productivity will come down by 162 kg of Jasmine. In the case of Usilampatti has the productivity will be reduced by 225 kg of Jasmine for every acre of land cultivated additional, in Solvanthan productivity will decline by 585 kg of Jasmine for every one acre of land cultivated additionally. In all the four Blocks in inverse relationship between land size and productivity exist. The reduction in productivity is the highest Thirumangalam and lowest in Melure. The regression co-efficient are significant are one per cent level in Thirumangalam, Melur and Solavanthan, only for Usilampatti Block, the regression co-efficient significant at 5 per cent level. Therefore, the declining of productivity area of farm size increases in the statistically significant.

**Table - 6: Average yield per acre**

<table>
<thead>
<tr>
<th>S. No.</th>
<th>Landholdings (in acre)</th>
<th>V1</th>
<th>V2</th>
<th>V3</th>
<th>V4</th>
<th>Overall average per acre</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>Below 1 acre</td>
<td>(10) 3689.9</td>
<td>(8) 3522.1</td>
<td>(8) 2651.1</td>
<td>(10) 3260.5</td>
<td>3304.8</td>
</tr>
<tr>
<td>2.</td>
<td>Above 1 acre</td>
<td>(5) 2878</td>
<td>(7) 3333.8</td>
<td>(7) 2196</td>
<td>(5) 2501.2</td>
<td>2733.5</td>
</tr>
</tbody>
</table>
The table-6 reveals that the classification of landholdings, below 1 acre having farmer’s cultivated average yield per acre is 3304.8 and above 1 acre farmers cultivated average yield per acre is 2733.5. It was lower in the case of below 1 acre so as the farm size increases yield per acre decreases because irrigation facility low and soil condition differs.

Suggestions

Jasmine growers are to be motivated to form growers association at Micro Level and to meet periodically to discuss the issues relating to jasmine cultivation.

It is suggested that in every jasmine growing districts, in each block a grape growers committee consisting of representative from the Agricultural Department of Tamil Nadu Government, the horticultural board and growers may be formed.

Conclusion

Jasmine plays a vital role in offering significant employment opportunities to the rural people. Hence it deserves a planned and continuous attention. The Jasmine cultivators, traders, exporters, government, and the like would go along way in referring to the share of Indian Jasmine in both domestic and foreign markets. The present study has brought into focus the various issues relating to the cultivation aspects of Jasmine. The policy implications suggested, if properly implemented may result in increased revenue for the nation and for the people concerned.

Effect of Mulligan’s Pain Release Phenomenon with Kinesiotaping in Chronic Patellofemoral Osteoarthritis

Nikhil Bhosale¹, Smita B Kanase², Khushboo Bathia²
¹Physiotherapist, Faculty of Physiotherapy, KIMS ’Deemed to be’ University, Karad, Maharashtra, India, ²Assistant Professor, Department of Musculoskeletal Sciences, Krishna College of Physiotherapy, KIMS ‘deemed to be’ University, Karad, Maharashtra, India

Abstract

Objective: To find out effect of Mulligan’s Pain release phenomenon with kinesiotaping in chronic patellofemoral osteoarthritis. Settings and Design: A comparative study was done with a pre and post test study design on 30 subjects at Krishna Institute of Medical sciences Deemed to be university, Physiotherapy OPD, Karad. Method and Materials: 30 subjects fulfilling the inclusion criteria and willing to participate in the study were divided into 2 groups by Simple random sampling. 15 subjects in each group. Each group have undergone the Treatment for 4 weeks; treatment sessions were given every alternate day. Group A-PRP with Kinesiotaping, Group B-Conventional therapy. Both the groups received ultrasound and VMO strengthening in common. Statistical Analysis:- Data analysis was done using paired t test within the groups and unpaired t test between group comparisons. Results: the within group comparison showed extremely significant difference in both the groups (p<0.0001) for V AS and WOMAC. Unpaired t test between groups showed extremely significant difference post-test in V AS and WOMAC (p<0.0001). The comparison of means showed improvement in group A (PRP+ kinesiotaping) as compared to group B (conventional therapy). Conclusion:- Through the study it was concluded that, both group management was effective but PRP with kinesiotaping showed more improvement in pain and improving the functional limitations in subjects with chronic patellofemoral OA.

Keywords: - Chronic Patellofemoral Osteoarthritis, Kinesiotaping, Pain Release Phenomenon (PRP), Conventional Therapy.

Introduction

Osteoarthritis (OA) is the most common form of arthritis, affecting millions of people and is also the leading cause of chronic disability. It commonly occurs in weight bearing joints like the hip and knee and is most commonly seen in the middle age to old age group. In India, the prevalence rate of Osteoarthritis of the Knee is around 22% - 39% and is observed to increase in the coming decade. The patient may describe arthritis as severely excruciating pain, debilitating and in severe stages, incapacitating. The signs and symptoms for osteoarthritis are: Pain, Decreased range of motion, Sounds, Difficult and painful mobilization, Morphological deformities. The pain in chronic patellofemoral pain is aggravated by daily activities of our life like squatting, rising from sitting or stair climbing. Physiotherapy treatment for the chronic patellofemoral osteoarthritis includes electrotherapy and exercise therapy- Supervised strengthening exercises and manual therapy. There is paucity of literature for newer and better techniques for the severe kind of pain state i.e.; the pain of chronic osteoarthritic knee

Kinesiotaping:-
It is a thin stretchy tape applied in various techniques like: I shaped, y shaped and x shaped application.

patellofemoral joint is affected by the malalignment of the extensor mechanism. The KTG, 5-cm wide elastic tapes can be applied on the quadriceps femoris and the gastrocnemius in cases where the patient felt pain when the knee joint is extended. The tapes should be replaced with new ones at each treatment session. Muscle technique of kinesio tape application can be used.

**Pain release phenomenon**

Brian Mulligan has introduced a newer manual technique for managing Chronic pain which is called as Pain Release Phenomenon Techniques (PRPS). In this technique, joint compression, is used for patellofemoral knee joint as the pain provoking stimuli and the stimuli is maintained for 15-20 seconds. If indicated, the pain will reduce in this period.

The aim was to find out the effect of pain release phenomenon with kinesiotaping in chronic patellofemoral osteoarthritis. As of it is a new treatment approach for the sake of bringing out more specific treatment regimes for such conditions.

**Materials and Method**

The Study Protocol Was Presented For Approval Infront Of The Protocol Committee And Institutional Ethical Committee Of KIMSDU Karad. A Comparative study was done using, Pre and post-test design with sample size of 30 subjects. The subjects were divided into 2 groups by Simple random sampling. Each group consisted of 15 subjects. Each subject was screened as per inclusion and exclusion criteria and they were informed about the study and intervention. Before proceeding to intervention a written consent was taken from them. Intervention duration was 4 weeks for each group with alternate day sessions. Treatment for Group A- PRP with Kinesio Taping and Group B-Conventional Therapy Regime. Both the groups have received ultrasound (-mode-continuous, intensity-1W/cm2, duration- 7minutes) and VMO strengthening in common. Baseline assessment was taken using Visual Analogue Scale (VAS), and Functional Disability Index by WOMAC.

**Intervention:**

**Kinesiotaping:** - Kinesiology tape is a thin, stretchy, elastic cotton strip with an acrylic adhesive. In patellofemoral osteoarthritis, the patellofemoral joint is affected by the malalignment of the extensor mechanism. The KTG, 5-cm wide elastic tapes was applied on the quadriceps femoris and the gastrocnemius in cases where the patient felt pain when the knee joint is extended. The tape was replaced with new ones at each treatment session.

The Pain Release Phenomenon Techniques (PRPS):- For knee pain, Pain release phenomenon was given by compressing the patella against the femoral condyles and the knee joint was moved in flexion and extension by maintaining the compression for 15 seconds. PRPS is a manual therapy technique introduced by Brian Mulligan for the chronic pain management.

**Data Analysis**

**Gender:**

Table no 1: Gender distribution

<table>

<td>0.1900</td>
<td>&lt;0.0001</td>
</tr>
<tr>
<td>T VALUE</td>
<td>1.343</td>
<td>4.640</td>
</tr>
</tbody>
</table>

On comparing the pre interventional values, the results between the two groups using unpaired t test revealed that there was no statistically significant difference seen with p values of 0.1900. While on comparing the post session values, the results between the two groups using unpaired t test revealed that there was extremely significant difference seen with p values of <0.0001. Group A improved more than Group B. Pain reduction was more in group A than Group B.

WOMAC Scale

**Table no. 6: Comparison of pre and post WOMAC within groups**

<table>
<thead>
<tr>
<th>GROUP</th>
<th>PRE TEST</th>
<th>POST TEST</th>
<th>P VALUE</th>
<th>T VALUE</th>
</tr>

<td>39.83 ± 7.93</td>
<td>29.09 ± 5.65</td>
<td>&lt;0.0001</td>
<td>8.57</td>
</tr>
</tbody>
</table>

The table also shows the comparison of mean and standard deviation of pre and post values of Group A and Group B. In the Group A, the mean WOMAC score on pre intervention was 36.66 ± 7.91 which was reduced to a mean of 18.59 ± 8.43 post intervention. The P value by Paired t test was found to be <0.0001 which is extremely significant. In Group B, the mean WOMAC score on pre intervention was 39.83 ± 7.93 which was reduced to a mean of 29.09 ± 5.65 post intervention. The P value by Paired t test found to be <0.0001 which is extremely significant. The within group comparison should that WOMAC score improved in both the groups post interventional.

**Table no 7: Comparison of pre-pre and post-post WOMAC between groups**

<table>

<td>4.002</td>
</tr>
</tbody>
</table>

On comparing the pre interventional values, the results between the two groups using unpaired t test revealed that there was no statistically significant difference in pre interventional score for both the groups. While on comparing the post treatment values, the results between the two groups using unpaired t test revealed that there was statistically significant difference with p values of 0.0004. The between group comparison showed that WOMAC score improved in group A as compared to group B.

**Discussion**

Osteoarthritis (OA) is the most common form of arthritis, affecting millions of people and is also the
leading cause of chronic disability.

It commonly occurs in weight bearing joints like the hip and knee and is most commonly seen in the middle age to old age group. In India, the prevalence rate of Osteoarthritis of the Knee is around 22% - 39% and is observed to increase in the coming decade.

Conventional therapy treatment has been in practice since many years now (conventional treatment includes quadriceps strengthening focusing on VMO, ultrasound and isometrics). There is a need for new innovative treatment approaches in order to improve functional status and improve quality of life and functional status of the patients. The present study was conducted with the aim to find out effect of new combination treatment for managing patellofemoral joint osteoarthritis.

PRP technique is a manual therapy technique for chronic pain management in the extremities. In this technique, joint compression, is used as the pain provoking stimuli and the stimuli is maintained for 15-20 seconds. If indicated, the pain will reduce in this period

The combined effect of this treatment approach makes this newer technique more of its own.

The present study shows that pain was reduced in both the groups after 4 weeks of treatment but the decrease in pain was more in group A receiving PRP and Kinesiotaping. The findings of present study is supported by other study by Sana Shahid stating that Pain release phenomenon is an effective technique in reducing pain and improving function of knee in patients with patellofemoral pain.

Also the functional status of the subjects in present study improved in Group A as compared to Group B. As pain is most debilitating factor in patellofemoral osteoarthritis, reduction in pain in subjects of present study has helped in improving the functional score

Kinesiotaping has several effects. Kinesiotape assists and improve the body's natural healing mechanism. It helps to improve fluid circulation, decrease pain, improves muscle strength, helps in joint proprioception. The application of kinesiotape helps in relieving physical and neurological pain. Pain receptors are present under the skin. The lifting action done by application of kinesiotape helps in relieving the pressure over this pain receptors thus reducing pain. The same mechanism has helped the participants in group A receiving kinesiotaping over extensor compartment of knee, thus helping them to decrease pain and improve functional abilities.

**Conclusion**

This study concluded that PRP (pain release phenomenon) with kinesiotaping is effective in reducing pain and improving the functional limitations caused by the chronic pain state in subjects with chronic patellofemoral osteoarthritis.

Childhood Immunization Coverage and Factors Associated with it among Urban Slum Population in a South Indian City

Akshay Salgar¹, Satyajit Pattnaik¹, Samina Ausvi², Dhananjaya Sharma³

¹Associate Professor, ²Assistant Professor, ³Professor & HOD, Community Medicine, Great Eastern Medical School and Hospital, Srikakulam, Andhra Pradesh

Abstract

Background: Immunisation coverage in slums of urban areas was found to be low in comparison to non-slum areas. The present study was undertaken to determine the immunisation coverage among 12-23 months children in the slum of an urban area. Further attempt was also made to determine the factors responsible for complete immunisation among these children.

Materials and method: This cross-sectional study was carried in 30 slums of Srikakulam Municipal area in north east Andhra Pradesh. A 30 X 7 cluster survey method as suggested by WHO was adopted. Data were also collected on the socio demographic details.

Results: Out of 210 children surveyed, 180 (85.7%) were found to be completely immunised. The dropout rate from Pentavalent 1 to Pentavalent 3 was 4.32%. The odds for child receiving complete immunisation were more for girls and increases with mother’s education. Mothers who stay at home are more likely to complete immunisation for their children. Family with more members had a greater odd for complete immunization.

Conclusion: Many socio demographic factors influence the uptake of immunization among children in urban slums. Periodic local survey is needed to identify these factors and take remedial measures to improve immunisation coverage.

Keywords: Immunisation coverage, determinants, urban poor, slum, children

Introduction

Childhood vaccination is essential to prevent many vaccine preventable diseases. In view of this India started the Expanded Programme of Immunization in 1971, which was scaled up to Universal Immunization Programme (UIP) in 1984.¹ Under UIP, vaccine is given against six vaccine preventable diseases (VPDs). The Rapid Survey on Children (RSOC) undertaken by the Ministry of Women and Child Development and UNICEF between November 2013 and May 2014 showed that 65.3% of children (12-23 months) are fully immunised for India as a whole and 72% coverage among those living in urban areas. ² As per National family Health Survey (NFHS)-4, fully immunised children in the age group of 12-23 months in urban area of Andhra Pradesh are only sixty percent.³

The urban data are usually an aggregate of urban slum and non-slum areas that masks the true picture about slum areas. In a study done in Hyderabad, the proportion of fully immunised children of migrant households living in slums (66.5%) was found to be lower than fully immunization status of the whole city (including slum and non-slum) of Hyderabad (71.3%).⁴

Immunisation coverage is also affected by several individual characteristics such as gender of the child, literacy of mother, socio-economic status of the family.

The present study was planned to evaluate the immunization coverage among children aged 12-23 months among slum population in Srikakulam municipal area in the north east region of Andhra Pradesh. Further the study aims to determine the factors which are associated with complete immunization among the slum population of Srikakulam town.

**Materials and Method**

**Study setting and study population**

The cross-sectional study was conducted in the municipal corporation area of Srikakulam city situated in the north eastern part of the state of Andhra Pradesh. Srikakulam city has a population of 1.47 lakhs as per Census 2011. There are 63 slums in the municipal area with a total population of 43,009, which constitutes around 30% of the total population.

**Sampling Procedure**

A 30 by 7 cluster sampling method, as suggested by WHO for estimating coverage evaluation of routine immunization, was adopted. Selection of household was done by following multistage sampling (two stage). In the first stage, 30 slums were selected from 63 slums by probability proportionate to size method. Then in each selected slum, one street was selected randomly. Survey was started from one end of the street and continued till seven children in the age group of 12-23 months were surveyed. If the number fell short, the next street was taken up. In any household, only one eligible child was selected.

The data were collected between 1st September 2018 and 31st October 2018 (Two months). The data collection team consisted of one supervisor and one MSW (Medical social worker). The field investigators were trained for one day before the start of the survey on various aspects of the survey such as immunisation schedule, consent procedure, selection of street and houses and data collection using the survey questionnaire. Information about vaccination was collected from immunisation card. If no card was available, mother’s recall about past vaccination was obtained. Many socio demographic details of the households were also collected like, religion, caste, type of family, type of house, educational and occupational history of mother and father, SES status etc.

**Operational Definitions**

- **Fully immunised**: A child who received one dose of BCG and measles and three doses of pentavalent and OPV.
- **Partially Immunised**: A child who has received at least one vaccine, but not all.
- **Not immunised**: Who has not received any vaccine.

**Ethical Clearance**: Ethical clearance from the Institutional Human Ethics Committee was obtained prior to starting of the study. The survey was conducted after obtaining prior verbal informed consent from the parents.

**Statistical analysis**

Data were fed into an excel worksheet and analysed using Epi Info (version 7.1.5, Centers for Disease Control and Prevention, Atlanta, GA, USA). Binary logistic regression analysis was performed with each of the socio-demographic indicators as independent variables and outcome (fully immunised or not) as dependent variable. Adjusted odds ratio was also calculated taking all socio demographic characteristics as independent variable and immunization status as the dependent variable. The significance of adjusted odds ratio was determined by using Wald test.

**Results**

A total of 210 children (101, 48.1% boys and 109, 51.9% girls) from 30 slums were surveyed.

**Sociodemographic Characteristics**

Most of the children were Hindus (89.5%). Majority (58.1%) children belong to joint family. Regarding the education of the mother only 5.7% were illiterate and most of them (68.1%) have studied up to 12th standard. Similarly, among the father of the children, only 7.6% were illiterate and 61.9% had studied up to 12th standard. Most (91.4%) of the mothers were homemaker while majority (57.6%) of the fathers were wage earners.

**Immunization Coverage Rate**

Table No.1 depicts the coverage of different vaccines. Most of the vaccine had a coverage of more than 95% excluding Hepatitis B at birth (87.6%) and pentavalent and OPV 3 (94.7%). The dropout rate from
Pentavalent 1 to Pentavalent 3 is 4.32%.

Factors associated with complete immunization

Table No.2 presents the various factors which determine the status of complete immunisation among the children. The association were expressed in crude as well as adjusted odds ratio with confidence interval. The statistical significance was determined by p value less than 0.05. The odds for being completely vaccinated were found to be high for female children, but it is not significant. Similarly, the odds for being completely vaccinated were found to be high for children in family with more members. This was statistically found to be significant (p value 0.03). Further, parents who are more educated seem to immunise their children completely. Homemaker mothers’ children are better placed and are more likely to be fully vaccinated in comparison to children whose mother work outside home. Although this was not found to be statistically significant.

**Discussion**

Globally, vaccine preventable diseases (VPD) contribute significantly towards under-five mortality in spite of availability of many vaccines to prevent them. In order to bring down the under-five mortality, immunization programme need to be successful. Vaccination at correct age is the most important to achieve maximum vaccine-induced protection. DLHS-3 data showed that age-inappropriate vaccination as an important weakness in the national immunization programme. Immunization coverage studies help the programme managers to monitor the gaps in implementation of the immunization programme.

The study findings showed that 180 children (85.7%), were completely immunized. These findings were similar to other studies done among urban poor in Delhi (80.8%) and Mumbai (88.07%). But there are many other studies which have reported very low coverage of complete immunization among children living in urban slums. This indicates that immunisation coverage among urban poor people is not uniform across the country. This calls for more periodic local surveys for identification of gaps in the implementation of immunization programme.

The uptake of immunization among residents of urban slums depends on many factors. In this study, the boy to girl complete immunisation coverage ratio was found to be 1.249 which is consistent to findings in a study done in Tamil Nadu but different from the findings in a study done in Delhi. Completion of the childhood immunisation schedule was higher among Hindu households compared to non-Hindu households and this finding is concordant with other previous studies. Religious belief had shown to influence immunization in low-income and middle-income countries.

In our study, children from joint families and family with more members were found to have more complete immunisation. This phenomenon was not reported in any previous studies. One reason could be more people available to take the child for immunisation. Mother’s education was strongly associated with complete immunisation. Those mothers’s with higher education status tends to give their children complete vaccination. This is consistent with other studies done in the past. Mother’s occupation also affected the immunisation status though in a different way. Mother’s who stay at home is more likely to complete their child’s immunisation in comparison to mother who go out to
work.

There is a complete heterogeneity as far as immunisation coverage is concerned among the poor in urban areas.

Limitation

In some children (18%) the vaccination card was not available. The entire questionnaire was filled from mother’s recall which may not be very accurate. Secondly, we only focused on the receiver side factors without collecting any data relating to supplier’s side limitations like supply of vaccine or regularity of outreach session and other issues related to infrastructure and man power.

Conclusion

Our study estimated the proportion of completely immunized children among residents of urban slum in a city. Various socio-demographic factors influencing vaccination among children were explored. Findings from this and similar studies will help the immunisation programme managers to bring about changes in the system to achieve full immunisation coverage among these disadvantaged groups.

Customer Satisfaction on Health Insurance in India – A Study

A. Meenakshi¹, S. Vennilaa Shree²

¹Assistant Professor, Department of Commerce, VELS Institute of Science, Technology & Advanced Studies (VISTAS), Pallavaram, Chennai, ²VELS Institute of Science, Technology & Advanced Studies (VISTAS), Pallavaram, Chennai

Abstract

Good Health confer on a person or groups’ freedom from illness - and the ability to realize one’s potential. Health is therefore best understood as the essential basis for defining a person’s sense of wellbeing. Health insurance is an insurance beside the risk of incurring health expenses among individuals. Health insurance remainder hugely under-developed in India. Only 11% of population is currently covered with Health Insurance. Around 24% of all people hospitalized in India in a single year drop below the poor-quality line due to hospitalization (World Bank, 2002).

An analysis of finance of hospitalization shows that large section of people borrows currency or sells property to pay for hospitalization (World Bank, 2002). Majority of Indians are more susceptible to Major ailment. Marketing of Health insurance policies become principal important to help people to meet out the unpleasant expenses arising out of unexpected ailments. It will be a win-win condition for Public and companies of growing the dissemination of health insurance harvest to its fullest possible.

The benefit of health insurance must be extended to the excluded population too. visibly there is an urgent need to enlarge the health insurance net in India, in such a situation it is essential to understand the consumers how far they are attracted in import health insurance, customers awareness is to be recorded, it is important to limit the out-of-pocket expenses of the consumers, and suggest and bring an awareness to the consumers how health insurance would help in dropping their financial burden during hospitalization.

Keywords: Awareness, Factors, Customer satisfaction, Problems.

Introduction

The strength of any nation is its health. There is experiential data that the health of a people extensively enhances its economic development, and vice versa. India is a second heavily populated country in the world and also a largest democratic state of the world. Since its self-government India has made significant progress in terms of the health indicator and health communications. India’s National Health Policy first formulate in 1983 and revised in 2002 has been to improve the health of the population. Growing demand for modern medical care, brought on by a rapidly, growing population, rising literacy levels, and technological advancement lead to high expectation from the health services. This has shift demand in favor of health care.

History:

The health insurance industry has grown-up considerably mainly due to liberalization of economy and general awareness. According to the World Bank, by 2010 further than 25% of India’s population had access to some form of health insurance. There are standalone health insurers along with government sponsor health insurance provider. pending recently, to improve the alertness and reduce the procrastination for buying health insurance, the General Insurance Corporation of India and the Insurance Regulatory and Development Authority (IRDA) had launch an awareness crusade for all segment of the population.

Health Insurance Schemes

Based on possession, the existing health insurance schemes can be generally separated into categories such as:

Government or state-based systems
Market-based systems (private and voluntary)
Employer-provided insurance

Member organization (NGO or cooperative) based systems

**Review of Literature**

Since 1954, all employees of the central government, some autonomous and semi government organizations, MPS, Judges, freedom fighters and journalists are covered under the central government Health Scheme.

“One another objective of health reform worldwide is to hold healthcare accountable for its resource use and the way healthcare services are delivered. This relates not only to the overall health of individuals and communities but to the quality of the healthcare experience” - (Reinhardt, 1998) (8)

“The providers and facilities in India can be broadly classified by using three dimensions: ownership styles (public, private not-for profit, private for-profit and private informal); systems of medicines (allopathic, homeopathic and traditional); and types of facilities (hospitals, dispensaries and clinics). These dimensions are interdependent and overlapping”. (Bhat,1993) (4).

“These factors include the growth of home incomes, the inadequacy of the public health sector, and the effects of various government policies on the operation of different health care markets” - (Alejandro Herrin, 1997) (7)

“Marketing is an organizational purpose and a set of processes for create, communicating and delivering value to customers and for managing customer relationship in ways that benefits the organization and its stake holders” - (Kotler Philip, 2008) (1)

R. Amsaveni and S. Gomathi (2013) (3) made an attempt to find out Mediclaim policy holder satisfaction, to recognize the reason for preferring Mediclaim policy to safe guard themselves and stay away from future risk, majority of the respondents have taken personal scheme to employees. The major problems faced by the respondents are lack of timely communication and limited list of hospitals covered by the health insurance providers.

**Objectives of the study**

1. To find the awareness level of the respondents towards the health insurance companies and the health insurance policies which was provided by the health Insurers.
2. To find out the factors which influences the respondents in selecting health insurance company and health insurance policies.
3. To analyze the customer’s level of satisfaction towards the services rendered by the health insurance companies and the settlement of claims.
4. To study out the problems faced by the Health Insurance Policy Holders.
5. To provide suggestions based on the results of the study.

**Hypothesis of the Study:**

Null Hypothesis (H₀): The awareness level of the insurance companies is not equally distributed.

Alternate Hypothesis (H₁): The awareness level of the insurance companies is equally distributed.

**Technical Tools applied in the Study:**

The statistical tool applied to perform this study is Chi-Square Analysis.

Calculation of Chi-Square analysis

**Interpretation:**

H 0 – There is no significant difference exist between the age group of respondents with regard to the Responses towards the health insurance is a mist for all individuals

H 1 – There is significant difference exist between the Age group of the respondents with regard to the response towards the health insurance is a must for all individuals.

The Calculated value of X² is compared with the table value of X² for given degrees of freedom at specified level of significance. If the calculated value of X² is greater than the table value, the difference between and observation is considered to be significant. i.e., it could not have arisen due fluctuations of simple sampling on the other hand if the calculated value of X² is less than the table value the difference assumption and observation is not measured significant, i.e., it could have arisen due to fluctuations of sampling.

**Conclusion**

This study enabled the researcher to understand the nuances about the Health Insurance who should take what are the advantages of the same. This study basically showed that the majority of the respondents who visited private hospitals have health Insurance, which might prove beneficial in the long run. This is very useful in identifying the factors and reasons that are important for individuals taking up and Health Insurance.

**Ethical Clearance:** Exempted. Research involving information freely available in the public domain

**Source of Funding:** Self

**Conflict of Interest:** Nil

Transcranial Direct Current Stimulation in Combination with TENS: Effectiveness on Pain and Functional Outcomes in Knee OA Patients – A Study Protocol

Rekha Chaturvedi, Sivachidambaram Kulandaivelan, Manoj Malik, Shabnam Joshi

1 Assistant Professor; Guru Jambheshwar University of Science and Technology Hisar, Haryana

Abstract

The goal of the study is to investigate the effectiveness of combination of Transcranial direct current stimulation (tDCS) and TENS on pain and functional outcomes in patients with knee osteoarthritis. Patients following ACR criteria for knee osteoarthritis, aged more than 45 years will be selected for the study. 80 patients will be selected and will be randomized into following four groups: Active tDCS/active TENS (group 1), Sham tDCS/active TENS (group 2), Active tDCS/sham TENS (group 3), Sham tDCS/sham TENS (group 4). The study will be participant blinded randomized controlled trial. The outcome variables are pain and functional assessment using six minute walk test and self-reported questionnaire KOOS.

Trial Registration: CTRI/2018/02/012027.

Keywords: Combination, Transcranial direct current stimulation, TENS, Pain, Osteoarthritis, Knee.

Background

Knee osteoarthritis (OA) is one of the common cause of musculoskeletal pain and disability. It is estimated that 20% of people aged over 30 years experience knee symptoms in India,1 resulting in substantial pain and physical dysfunction.2 Various therapeutic exercises are recommended for patients of knee osteoarthritis with the prime aim of improving muscular strength, as weakness is common in knee OA. Strength training can conquer the muscle weakness in such patients by improving the muscle mass. However, pain becomes a hurdle in exercising that causes individuals to underperform the exercises. Therefore, strengthening the musculature of lower limb can overcome this problem. Many pharmacologic treatments are available however; there is growing interest in non-pharmacologic intervention targeting the central nervous pain processing system.

Transcranial direct current stimulation (tDCS) is used in chronic pain conditions because of its neuromodulatory effect3-6. The application of TENS in knee OA has been demonstrated to be effective in managing arthritic pain7-12. Thus, by combining the two interventions can generate both the neuromodulatory effect (cortical effect) as well as segmental inhibition in the pain gate13and descending pain suppression via d-opioid mechanisms (spinal and peripheral effect). Various studies have suggested tDCS combined with TENS resulted in greater pain reduction than their isolated application in low-back pain (LBP) by the priming effect14, 15. Therefore, taking in account of these encouraging results, we hypothesize that the combined application of tDCS, TENS and exercise will reduce pain to greater extent and may enhance mechanistic and clinical outcomes in knee OA. Moreover, RCTs from Asian countries, particularly India where knee pain is common1, is still lacking and our protocol is aimed to reduce this knowledge gap.

Objectives:

The primary objective of the study is to find out the effectiveness of combined tDCS and TENS on pain. The secondary objective of the study is to find out the effectiveness this combination on quality of life in patients with knee osteoarthritis.

Hypothesis:

Transcranial stimulation (tDCS) in combination with TENS will reduce pain and bolster the effect of exercise by priming effect thereby improving function.
in knee osteoarthritis patients and may regulate pain by the “top down and bottom up” mechanism.

**Method**

**Target population and sample:**

The subjects will be recruited from public announcements, flyers and referral cases of knee OA from various hospitals. The study will be conducted at 3 centers in XXX. The participants fulfilling the American college of Rheumatology (ACR) criteria for clinical classification for idiopathic knee OA will be recruited for the study.

The sample size was calculated by pilot study on 8 subjects with 80% power at 95% confidence interval of effect size 0.54. Sample size of 16 subjects in each group was calculated. The sample size was increased to 20 subjects expecting 20% dropout rate.

**Inclusion criteria:**

The subjects will be selected on the basis of criteria defined by the ACR Criteria: Presence of knee pain and any three of following: age over 45 years; morning stiffness lasting less than 30 min; crepitus; bony tenderness; bony enlargement; no palpable warmth.

**Exclusion criteria:**

The subjects will be excluded if they have the following: Any knee surgery in the past 6 months; Knee joint replacement or high tibial osteotomy on the affected side; other muscular, joint or neurological conditions affecting the functions of lower limb; unable to walk unaided; currently undertaking any exercise programme for knee OA; contraindications to tDCS (eg, epilepsy).

**Discontinuity criteria:**

The subjects will be discontinued if: They miss 3 consecutive session of exercise even after repeated reminders made through phone call; any moderate to severe adverse events are presented by the subjects that are related to application of therapeutic intervention or exercises; subjects who involves in other medical treatment for knee OA that may interfere with the results; any other health program like weight reduction or aerobic exercises or Pilates or any other fitness training program.

**Research group and study design:**

**Study design:**

Present study is 4-arm parallel group, participant blinded; sham (placebo) controlled randomized trial. After taking the informed consent at the baseline visit the subjects will be assessed by the researcher thoroughly at the baseline visit and will be randomly allocated to one of the four groups by corresponding author through lottery method done by independent person not participating in the study. All the subjects will receive hot packs followed by the interventions and exercise protocol thrice weekly. All the participants will be assessed four times a) at the baseline visit b) week 1(after 5 days of intervention) c) end of 2nd week d) end of 6th week. All the subjects will undergo weekly thrice supervised exercise training for 5 weeks and advised to do exercises taught at home on the days not coming for the treatment. Home exercises and supervised exercise will be taught by experienced physiotherapist (First author). The study participants were allowed to continue their medications if any, throughout their participation in the trial. At the baseline visit, type of medication, dosage and frequency of medication will be recorded. Total duration of study is 6-weeks including 1st week 5 treatment sessions followed by weekly thrice supervised exercise for 5 weeks.

**Research group:**

The study participants selected following the inclusion and exclusion criteria for the study will be randomly assigned to one of the four groups.

Group 1: Active tDCS /Active TENS (n=20)

Group 2: Active tDCS /Sham TENS (n=20)

Group 3: Sham tDCS /Active TENS (n=20)

Group 4: Sham tDCS /Sham TENS (n=20)

**Intervention description:**

**Transcranial direct current stimulation (tDCS):**

A constant current of 2 mA for 20 min once a day for 5 consecutive days will be by a pair of circular sponge electrode saturated with normal saline. The anode will be placed on primary motor cortex (M1, C3 or C4) as per 10/20 International electroencephalogram EEG system) contralateral to the most painful knee and the cathode will be placed on opposite supraorbital region ipsilateral to the affected knee. For sham stimulation same electrode...
placement will be used. The equipment will be turned on for 30 sec, and then turned off. A Customized model, Medicaid, Chandigarh (Mohali), India will be used for transcranial stimulation.

**Transcutaneous electrical nerve stimulation (TENS):** A pair of surface electrodes 5cm × 5 cm, placed on the skin at medial and lateral side of the knee joint fastened by velcro will be used. High frequency TENS at 100 Hz for 20 min duration will be given to the patient for five consecutive days. Only the most painful side will be stimulated. For sham stimulation the same placement of electrode will be used, with stimulator turned on for 30 sec and then turned off. TENS Enraf Nonius, USA will be used for stimulation. Both the stimulators (tDCS and TENS) will be turned on and off simultaneously during each session of treatment.

**Exercises:** The subjects will perform a supervised exercise protocol following the interventions. Each exercise will be done for 3 sets of 10 repetitions with a break of 30 sec in between the sets. The exercise program will progress as mentioned in the prescribed protocol. The study physiotherapist will decide the initial level of exercise depending upon the ability of the subject and the time when to progress the exercise based on the participant’s performance and therapist’s clinical judgment. The subjects will undergo initial 5 sessions of exercise on 5 consecutive days post intervention (1st week). Subjects will undergo thrice a week supervised exercise sessions for next 5 weeks (2nd-6th week) by study therapist. The participants will also be taught home exercises to be performed on days not coming for treatment. The subjects must undergo at least 12 sessions (including 1st week 5 sessions) of supervised exercise session for estimating the desired benefits of the exercise regime.

**Outcomes:** The outcome variables of all the participants will be assessed four times: at the baseline visit, week 1 (post intervention), 2 week and at week 6.

**Pain:** The intensity of pain will be measured by VAS (0-10 cm) by asking pain on walking during previous day, self-assessed pain describing ‘no pain’ (score 0) and ‘extreme pain’ (score 10) will be reported.

**Function:** Six minute walk test is reliable tool in Indian population will be used for functional assessment. Subject was asked to walk on a 20-m corridor for six continuous minutes as per Ateef et al 2016. The distance covered in meter by the participant will be recorded in the assessment form.

**Quality of Life:** It will be assessed through self-reported Knee injury and Osteoarthritis Outcome Score (KOOS) questionnaire containing 42 questions in five subscales namely pain, symptoms, activities of daily living (ADL), sports/recreation and quality of life. Score ranges from 0 to 100 where 100 means maximum problem. KOOS is a reliable assessment tool in Indian knee OA patients.

**Safety:**

For ensuring safety of the participants questions like any symptoms of itching or burning sensation, tingling, any kind of pain at the stimulation site, headache, mood changes, anxiety, nervousness, or any kind of changes in visual perception during or after the treatment or any other potential risk described by Rossi et al 2009 will be asked.

**Ethical aspects:**

The trial will be conducted according to the ICMR (Indian council of medical research) 2017 guidelines which are in accordance with Helsinki declaration 2013 (7th revision). All the participants will sign the informed consent prior to participation in the study.

The trial has been prospectively registered with the Clinical Trail Registry of India number CTRI/2018/02/012027 registered on 21/02/2018. Ethical approval was obtained from Institutional ethical committee vide letter no. PTY/2017/484 dated 9th October 2017. The findings of the study will be shared with the participants in simple language. Confidentiality of the participants will not be breeched at any point of the study. The raw original data will be archived for 5 years by the investigator of the study. Consolidated data without participant’s personal details will be permanently archived in Mendeley data repository.

**Consent to publish:**

A written permission from the participant will be obtained for the data and images to be published.

**Data analysis:**

The data will be analyzed as per principle of intention to treat. To find out the effectiveness of interventions, analysis of pain and functional outcomes
per protocol analysis of variance (ANOVA) will be used. Repeated measure ANOVA will be used to estimate the effectiveness of interventions within the group for all the four groups. Effect size will be calculated.

**Discussion**

The paper is in accordance with the recommendations of SPIRIT guidelines (Standard Protocol: Recommendations for Interventional Testing) in evolution and recording of protocol for the study. Considering OA as a debilitating health problem, requires better management of pain and function thus making the population less disabled. Supervised exercise program shows better results as the treatment is given on one to one basis. In a study on knee osteoarthritis the application of tDCS demonstrates substantial pain reduction and improved mobility performance and the effect of stimulation lasts for 3 weeks. In another study tDCS combined with TENS demonstrates promising results in chronic LBP patients. Present protocol is similar to Luz-Santos et al. and marginally different from it by outcome measures. We believe 6-minute walk test is more functional hence meaningful to patients; would help the therapists to monitor rehabilitation outcome. Considering the results obtained from these studies the effectiveness of tDCS used alone as well as in combination with TENS must be explored for treating musculoskeletal conditions like knee OA. tDCS, either alone or combination, may be a potential intervention for better management of pain and functional activities in knee OA.

**Benefits:**

The subjects will be asked to continue the exercises even after the completion of trial at home to sustain the benefits of exercises. The results of the study if comes out to be effective, the leading treatment will be offered to the people not received the treatment.

**Trial status:**

The study is enrolling participants from April 2018 onwards and estimated to be completed by March 2020.

**Compliance with Ethical Standards:** This article does not contain any studies with human participants performed by any of the authors.

**Funding:** There is no external funding to write this paper.

**Conflict of Interest:** The author of the study declares no conflict of interest.

An Empirical Study on the Impact of Emotional Intelligence on Occupational Performance

Mekhala. R.S¹, Sandhya K¹
¹Assistant Professor, Department of Business Administration, Vels University, Chennai

Abstract
The main aim of this article is to prove that, developing emotional intelligence have a positive effect in occupational performance. The measurement of emotional intelligence and its best application is proved here to maximize occupational productivity. This paper is composed explicitly for HR experts with the goal that they will be better educated and, hence feel increasingly certain about affecting key partners in the usage of EI projects, procedures and mediations.

Objective: EI dimensions have a positive focus on the emotions and have a stronger positive association with Occupational performance.

Findings and suggestions: EI shows a positive correlation with occupational performance and in-turn increases the productivity. If emotional intelligence is developed through proper training, the Occupational productivity can be increased to desired level according to the ability of the employees.

Keywords: Emotional Intelligence, Occupational Performance, HR experts, Training, EI projects

Introduction
Emotional intelligence (EI) seems to be the most uttered word since the publication of the book “Emotional Intelligence by Daniel Goleman¹⁰. Even though the concept of Emotional Intelligence is an old concept, which draws attention in the recent times, its application is designed to increase individual performance and organizational productivity,

The work of David McClelland from Harvard University which pointed out the relevance of emotionally and socially intelligent behavior among managers. The historical roots of emotional intelligence can be traced the studies of Darwin⁵. Many of the recent articles spot out the importance and relevance of this concept of Emotional Intelligence among the work place

This paper creates a scientific and practical pavement between the variables Emotional Intelligence and Occupational productivity and performance. It provides empirical evidence of the bottom-line impact of EI interventions. Based on Gardners⁹ work explains the measure and define the concept of Emotional Intelligence. Salovey and Mayer’s¹⁵ research gave Bar-on’s idea of Emotional Intelligence that opened the door of scientific outcomes on the concept of Emotional Intelligence. Goleman¹⁰ published the book that explains the above mentioned concepts in a wider range and became one of the best seller. The best way to define, measure and apply emotional intelligence seems still as a million dollar question which is not yet solved.

Bharwaney³, analysed that the above three instruments of emotional intelligence and critiqued, the author compares the other available Emotional Intelligence instruments also. The valid instrument should fulfill the representative sample of the local population and compare with demographic variables like age, gender, socio-economic factors and factorial, construct and predictive vailidity. The scales of these three EI measures are listed in Table 1 to provide the

**Objective of the Study:**

EI dimensions have a positive focus on the emotions and have stronger positive associations with Occupational performance.

**Measurement Instruments:**

1. Salovey and Mayer’s Bar-on’s idea of Emotional Intelligence

**Research Design**

Descriptive research design was followed in this research. Obviously, this aims at finding out relationship among variables. The impact of work place bullying on selected demographic, psychological, and situational
and outcome variables are studied in detail.

**Method Of Administration**

A sum of 391 respondents was met individually in their working place or their leisure time, with a request to fill in the questionnaire. They were informed to feel free and give their unbiased, genuine and realistic responses. They were also assured that their responses would be kept in strict confidence and would be used exclusively for research purposes. The researcher has distributed 391 questionnaires among the employees, out of which 365 employees have returned the filled questionnaire, after scrutiny a total of 340 questionnaires were selected from the employees of different departments. Thus the data collection process was completed. The collected responses from the various department employees were scored as per the procedure and were tabulated. Then they were subjected to suitable statistical treatment.

**Analysis And Interpretation**

First stage of analysis concentrates on self and other focused dimensions of Emotional Intelligence and Occupational Productivity. The second part of analysis concentrates on self and other focused dimensions of Emotional Intelligence which is explained in Salovey & Mayer study. The third part analyses the people’s ability to display emotional intelligence ability in a given situation. Elfenbein suggests that the ability that is depicted by people on every situation not only depend on their EI ability but it also on the group stability, motivation, demands for that particular time.

a. Predictors: (Constant), COMPETENCY, SENSITIVITY, MATURITY

b. Dependent Variable: Occupational performance

From Table 1, it is clearly shown there is a significant difference between the dimensions of EI (Competency, Sensitivity, Maturity) and Occupational Performance has a positive relationship. Thus studying the dimensions of emotional intelligence is allowed to test the fluctuations in job performance. Moreover the approach examines the link closer the Emotional intelligence – performance link in job and contributes the extrapolated way of understanding EI in existing work. Zeidner et al. studies proves the same way of explaining EI dimensions and its link towards Occupational Performance

**Table 2: Showing ANOVA Explaining the link between the three dimensions of Emotional Intelligence and Occupational Performance**

</tr>
<tr>
<td>COMPETENCY</td>
<td>-1.253</td>
<td>.040</td>
<td>-.877</td>
<td>.467</td>
</tr>
</tbody>
</table>

. Dependent Variable: Occupational performance
Table 2 explains the how the dimensions of EI (Competency, Sensitivity, Maturity) and Occupational Performance shows distinct relationship with occupational performance respectively. Sensitivity shows significant difference with Occupational performance, which means the ability to sense and manage one’s own emotions is related and managed to occupational performance. The second part, ie, Maturity, the ability to understand other’s emotions and Occupational performance is significantly different (p=.05). So this ability can be regulated and has a relationship with Occupational performance. The third and the main part of the study is the factor of competency, ie, the ability to regulate and manage our own emotions and others emotions according to the situation has a positive and significant relationship with Occupational performance.

These streams of studies reflect and overlap between the cognitive abilities and the nature of EI. Especially the ability of EI varies with personalities and mainly co-varies with a person’s cognitive ability. O’Boyle et.al \(^{17}\) explains in his study that EI can be best measured with ability tests and self reported questionnaires.

This Figure \(\#1\) explains the relative relationship between the concepts of EI and the Occupational performance.

From the above histogram its clear that mean value constant is 9.65 and standard deviation is .996 which is positive and above 90%, which shows a higher correlation with Occupational performance. Petrides \(^{18}\), explains in his study relating job performance and meta analytic data showing the positive correlations between the trait EI and job performance. In his study the self reported measures sowed more incremental validity in predicting job performance over Cognitive abilities.

Dependent Variable: Occupational performance

Explaining the residual statistics in relation to job performance, meta-analytic data showed that ability EI tests display the correlation (r = .977), followed by self-reported trait EI measures (r = 1.766) and self-reported EI measures (r = .049). O’Boyle et al., (2011) suggested that self-reported EI measures showed more incremental validity in predicting job performance. In the present study, EI is conceptualized based on the Four-Branch Model (Mayer & Salovey, 1997). Besides it is showing a stronger correlation with Occupational performance.

The above mentioned analyses with Emotional Intelligence have found a high association with occupational performance. These analyses also reveal that the factor emotional intelligence act as one of the moderators with Occupational performance. Joseph & Newman12 suggest that Emotional Intelligence has a stronger relationship with sales and counseling jobs, which includes high level of interpersonal contact. Davies, Stankov & Robert’s18 in their study focused on the Emotional intelligence conceptualization, which inturn gives a composite of emotional perception and understanding. For instance, if a sales person is attending a short tempered customer, the focus need to be maintained on the customer's emotion at the same time remaining calm. Wong & Law21 empirically distinguished the components that differ in emotional dimensions from people to people.

Normal P-P Plot of Regression Standardized Residual

Figure no: 2 The relative relationship between the dimensions of EI and occupational performance.
The dimensions of emotional intelligence can contribute to Occupational performance. Especially when it is related to occupational performance, it involves various other people to get indulge. For instance, if one wants to mediate a conflict or sell a product only by focusing on their own emotions in order to influence their own mood state. Even the most well known instruments for emotional intelligence does not distinguish between traits that belong to self and others. Mayer & Salovey\textsuperscript{14} scores mainly focus on emotions of others. Petrides\textsuperscript{18} developed The Trait Emotional Intelligence Questionnaire combines the emotions of the self and the ones which is shown by others. Wisker & Poulis\textsuperscript{20} study says that all the four dimensions of emotional intelligence indeed contribute to the job performance among sales persons. Law et. al\textsuperscript{8} research proved the same concept among laboratory assistants. X. Liu, Zhang, & Liu\textsuperscript{13} a recent research shows that employee satisfaction is positively related to leaders emotion.

**General Discussion**

This article highlights the importance of the trait emotional intelligence among the employees in jobs, where they have to integrate with many more other kinds of people. The lack of emotional intelligence is the reason behind the cases handled by divorce lawyers and the problems faced by sales executives. Wong & Law\textsuperscript{21}, Brasseur et al.,\textsuperscript{4} and Liu et al.,\textsuperscript{13} stated in their studies that the Emotional Intelligence dimensions which is described as sensitivity (knowledge about self), maturity (knowledge about others) and competency (knowledge about group) helps in productive performance in job.

Joseph & Newman\textsuperscript{12} analyzed that beneficial effects of Emotional Intelligence in job performance which includes interpersonal relationships. Thus this research contributes to the literature by proving that a difference between self- and other-focused EI is relevant for the prediction of job performance. Another effective outcome of this study is the examination of the effects of combined EI dimensions. Elfenbein\textsuperscript{7} proved that there are very few studies that have actually tested how and whether these dimensions may interact, even though most studies prove that EI is constituted with various components.

**Conclusions**

Thus the simultaneous implementation of Emotional dimensions is been changed with their different effects. This concept must be further explored. This research article contributes to a different dimension for the enactment of the concept of EI. As the findings suggest that there is a positive and influential implication of emotional intelligence in Occupational performance. This proves to be an added eye opener in the list of various similar researches which is been followed. This suggests that the enactment of the dimensions of various situations and validity measured for different variables is specially designed to prove the same.

**Limitations And Implications**

The present study has got certain limitations. First of all the emotional intelligence scale which is used to measure the variable, describes various other variables also, which has a low impact on our study. Since its well validated scale and its been followed as a protocol in various other related studies, the same scale has been used in this research. EI is a socially accepted character, our respondents might have responded more positively and unbiased. The examination of different combination of EI dimensions might have given birth to a new way of outcome in the present research.

Research on emotion contagion has proved to have too much attention to negative emotions of other people that might have negative consequences for employees themselves Bakker, Schaufeli, Sixma, & Bosveld,\textsuperscript{2}. Related to this point, there is an ongoing debate on the “curse of emotion” Antonakis, Ashkanasy, & Dasborough,\textsuperscript{1}; Jordan et al.,\textsuperscript{11} a phenomenon in which leaders’ sensitivity to their followers’ emotions hinders them to provide corrective feedback or to take disciplinary action when necessary. This point proves that dimensions which are focusing on other factors like job performance and employee well being. In this way employees can be well encouraged to focus on EI dimensions more during their work. To raise awareness of the direct effects of the appraisal of others’ emotions, companies could implement specialized training programs in which both self- and other-focused EI are trained e.g., Clarke,\textsuperscript{4}. The self and others to whom EI dimensions are directed seems important for the forecasting of job performance and might impact the prediction of other dimensions. Finally, the examination of the effects of combined EI dimensions on Occupational performance may correspond better to the dynamics of emotional processes. It is our hope that these new approaches may
move the field toward a better understanding of EI.

Measure to Human Ailments – A Holystic Approach

S N Sugumar¹, M P Agathiyar², S Chandrachud³

¹Prof. and H.O.D of Economics, Vels University, Chennai, ²Agasthiyar Clinic, Vadapalani, Chennai, ³Associate Professor, VISTAS, Chennai

Abstract

The modus operandi of the health article is to understand the pros and cons of the human ailments through approaches in allopathy, acupuncture and yoga. The role of health economist and his responsibilities are analyzed both theoretically and empirically in order to attain the recovery of human ailment in natural way. The current study comprises of six chapters. Chapter one briefs the basics of health economics. Chapter two enlists the review of literature. Chapter two envisages the significance of health. Chapter three analyzes the economics of health. The chapter four is continued causes for human ailments. Chapter five enlists the treatment through allopathy, acupuncture and Yoga. The last chapter concludes with suggestion for health economics.

Keywords: Health, Allopathy, Acupuncture, Yoga, Human ailments

Introduction

Health economics deals with the efficiency effectiveness, value and behavior in the production and consumption of health care products and services. Health economists to do the research on the function of health care system, the demand for and the supply of health care products and services and health affecting behaviors such as consuming alcohol, smoking, food habits, life style and the attitude of an individual and the society. Economists in short, analyze the economics of causes and the consequences of human ailments i.e. the cost - benefit analysis of healthy human beings. The current study throws light on the comparative analysis of three different medical approaches for human ailments such as treatment of allopathy, Yoga solution for human ailments and Acupuncture points for human ailment and exposes the thrust area on health economics.

Review of literature

Justin C. Fay¹ In this study, the author has concluded that the recent progress in understanding how adaptive evolution during human history has incurred some cost to the health of modern humans. The examples used have various levels of support for the association between human adaptation and disease. More importantly, they illustrate the variety of mechanisms and types of supporting evidence used to connect current human health with our evolutionary past. Finally, it is important to recognize that only a subset of human diseases has been influenced by our adaptive history. In this regard, understanding the molecular basis of adaptation may provide insight into certain disease mechanisms.

Lu Liang and Peng Gong² In their research article they mentioned that a wide range of disease and climatic terms is not beneficial to synthesis efforts considering the potential statistical bias caused by insufficient cases for a certain disease or climate type, and the difficulties in result interpretation. The broad categories in the database should thus be merged into several concise classes based on their similar functional characteristics.

V. Ramana Dhara, Paul J. Schramm, and George Luber³ According to them, as India’s economy continues to expand, the growing middle class presents a unique situation. While rising out of poverty will improve sanitation levels and living conditions, thus increasing resilience to infectious diseases, it will also lead to higher consumption patterns that can initiate new health problems while leading to more carbon pollution.

Anteneh Belayneh and Negussie F Bussa⁴ They concluded that the binomial test on the depth of ethnomedicinal knowledge between younger and elderly informants showed a significant difference. Many young people were less knowledgeable about the variety and
value of traditional medicinal plants. This showed the level of deterioration of ethnomedicinal knowledge in this prehistoric study area. It is, therefore, necessary to preserve this indigenous knowledge on traditional medicines by proper documentation, identification of plant species, herbal preparation and dosage. In addition, it should be followed with phytochemical and pharmacological analyses in order to give scientific ground to the ethnomedicinal knowledge. Similar type of research has been conducted in the other side of the globe like, Ketema Tolossaa et al\(5\), (2013) and Getnet Chekole,\(6\) (2017) etc.

**Significance of health**

Health is important for any living being whether it is mankind or animal kingdom. Healthy life makes human life more meaningful and productive. The state of health conditions facilitate the people to carry out their efforts and duties smoothly. Physical fitness is indispensible to offset our economic and social obligations. In all our belongings health comes first and health is our first wealth. That is why we ask “how are you” while we meet others.

Accumulation and maintenance of normal health is more important than the accumulation of material wealth because healthy life leads to wealthy life. Like other goods and services health products and services, health education, health awareness play a major role in human development which inturn facilitate social and economic development of a country. Mental and physical fitness jointly explain the overall health condition of an individual. Strong body and strong mind of human being determine the overall productivity of an economy.

**Economics of Human health**

Human health is part and parcel of human development. Expansion of knowledge and perfect health conditions determine the quality of human capital. Investment in people, especially health and education improves the quality of human capital which in turn determine the level of economic development of a country. In fact, inventions, innovations, technological progress and development are the major determinants of economic developments but they are the direct outcome of human capital. The rapid growth and development of an economy depends upon the quality and quantity of human capital, therefore, the health dimensions of human capital is more significant in an economy.

The major economic issues pertaining to human health are employment and income generations. Better the health conditions of the people the greater the level of employment and income generations. Poor human health is indicated by huge medical expenditure, loss of man hours, loss of production, loss of income, loss of happiness, loss of social interactions, feeling dull and fatigue, tiredness and demotivations, indebtedness etc… Therefore, this paper made an attempt to discuss the causes of human ailments and the solutions for the same through the alternative medicines.

**Causes of human ailments**

As per the concepts of alternative medicines, especially homeopathy medicines all human ailments are caused by our thoughts, actions and suppression of thoughts. According to siddha and Ayurveda the imbalance among vatta, pitta and kapha and ultimately the imbalance is caused by human thoughts and actions. Our thoughts make us happy or unhappy, rich or poor, active or dull etc., As per the law of nature everything is mind and everything came out from our own mind. The whole world is a projection made by our own mind. We see outside what we write inside in our mind. Therefore, mind makes a man healthy or unhealthy. As we think so we live. Mind is nothing but the bundle of thoughts.

Thoughts are nothing but the feelings arise in our mind. It is the feeling that is the life. It is the feeling which determines the status of our health. The feeling of love produces love. The feeling of happiness produces happiness. Thus, the human feelings cause human ailments. As per the alternative medicines, especially, acupressure and acupuncture the feeling of fear damages kidney, the feeling of angry damages liver, the feeling of worries and frustration damages stomach, excess joy and anxiety damages heart and lungs. etc.

Our actions especially excess standing damages urinary bladder and kidney (solution rubbing our back for one minute), excess sitting damages stomach and spleen can also cause anemia and digestive disorder (stimulate st.36), excess lying down damages large intestine and lung and there by affects respiration (stimulate Li 4 & Li 11), excess use of eyes and emotional stress damages small intestine and heart (stimulate CV 17), excess physical exertion damages gall bladder and liver which results in cramp (stimulate LV 3).
Allopathy and Indian medicines

Health, in general, is the outcome of combination of many forces such as intrinsic and extrinsic and collective, private and public medical environment and it is ultimately conditioned by socio-economic and cultural aspects of the society. There is a on-going debate, now-a-days, all over the world on allopathic and alternative medicines. It is a question of efficiency of the treatment not just for a sake of argument. In fact, they are not competitive but complimentary to each other. Allopathic treatment may be indispensable for certain ailments similarly alternative medicines are the best for certain ailments. Whatever may be the method of treatment but the cost of treatment and the outcomes are very important. However, the concept of “prevention is better than cure” is more economical and natural way of treatment for any human ailments.

Yoga solutions to Human ailments

Assanas to overcome hyper tension – vajrasana, padmasana, halasana, janusirasasana and pachimotasana

For obesity ---- suryanamaskar, pachimotasana, salabasana, dhanurasana, bhujangasana and vajrasana

To prevent diabetics – suryanamaskar, pachimotasana, salabasana, dhanurasana, bhujangasana, vajrasana, sarvangasana, halasana and Gomukasana

To overcome back ache --- suryanamaskar, pachimotasana, salabasana, dhanurasana, vajrasana and sethubandasana

Conclusion

The concept of prevention is better than cure makes the treatment for any ailment simple, economical and natural. Man can be an independent entity as long as he goes inside and he gets whatever he wants. If he seeks his requirements from outside it will be inadequate and temporarily in nature. Deviation from nature means deviation from happiness. Through alternative medicines especially, acupressure, acupuncture, yoga and meditation man can prevent disease and keep good health. The techniques of alternative medicines will develop the inner abilities and cure human ailments without any drugs. To conclude, the alternative medicines will develop the degree of independence, and
reduce medical expenditures and improve the quality and health status of human capital. The practice of yoga, acupressure and acupuncture make the mankind healthy and wealthy. Thus, this approach not only keep our health intact but also protect the environment by reducing the degree of dependency on unwanted industrial products and save the mankind from the side effects of drugs.

Discussion

There are various medical research article related to human ailments. But still people are in confused state that allopathy is the best medical approach for medical treatment. Unfortunately, people fail to understand our Indian medicines and their reputation. The researcher related to public health, can concentrate in this research gap and try to augment.

Enhancing the Role of Public Health Center as Gatekeeper on the National Health Insurance

Betri Anita¹, Henni Febriawati¹, Desri Suryani², Yandrizal¹, Bintang Agustina, Pratiwi¹, Wulan Angraini¹, Riska Yanuarti¹

¹Faculty of Health Sciences, University of Muhammadiyah Bengkulu, ²Health Polytechnic of Health Ministry Bengkulu, ³Student at Doctoral Program in Public Health Sciences University of Andalas Padang

Abstract

Public health center as a health care facility that organizes public health efforts and the efforts of individual health first rate, with more emphasis on promotive and preventive efforts that can reduce the number of hospital visits and referrals. The aim of the research is how to improve the role of public health centers as gatekeeper at the National health insurance.

The research used a qualitative method with the exploratory design. A case study approach (case study). The findings of qualitative methods in the form of support, obstacles, and challenges. Analysis Unit: ten public health centers. Primary and secondary data collected include healthy visit, the number of non-specialist referrals, and management efforts to improve the role of the public health centers.

The healthy visit percentage of ten public health centers in January - June 2016 was increased. Non-patient referral specialist was 0% from January to May 2015. Increasing of a healthy visit with enhancing visits and activities: Posyandu, Integrated Health Education Center for Non-communicable Disease/IHEC for NCDs (Posbindu PTM), School Health Unit (SHU), the Early Childhood Education (ECD) and Kindergarten, Company, and home visit. Mini workshop was done at Public Health Centers monthly to discuss the achievement of program indicators, the causes and solutions to improve the achievement of the following month, to enhance efforts to prevent disease, improving the quality of care, and provide an explanation to referred patients.

The role of health centers as gatekeeper enhanced public health efforts and the quality of health care of individuals involve stakeholders to empower the community in an effort to improve the early detection, prevention, and control of diseases.

Keywords: The role of public health centers, public health center Management, Stakeholder and Community Empowerment, Preventing and Controlling Diseases.

Introduction

Public health center as a health care facility that organizes first rate public and individual health efforts, with more emphasis on promotive and preventive efforts that can reduce the number of hospital visits and referrals by optimizing Posyandu, Integrated Health Education Center for Non-communicable Disease/IHEC for NCDs (Posbindu PTM), and management of the health center.

Disease prevention and control can be done by empowering the public health sector. Posyandu is one form resourced public health efforts managed and organized from, by and with the community in the implementation of health development, in order to empower communities and provide convenience to the public in obtaining basic health services.

Efforts to improve the ability of the community independently; prevention, disease control in various forms of activities such as neighborhood health center, maternal affection movement, nutrition, clean and healthy living behaviors (PHBs), mosquito nest eradication (PSN), poskesdes and disaster emergencies.
Lifestyle changes require a comprehensive approach and multi-dimensional.

Therefore the program should focus on the risk factors in an integrated comprehensive (promotive preventive, curative-rehabilitative) cover policy dimension, the environment, people’s behavior and the dimensions of health care, by empowering the community with the support of the Cross programs and sectors. The role of public health centers, stakeholders need to be optimized to achieve the goal of improving community participation in early detection, prevention, and control of diseases.

**Material and Method**

The study used a qualitative method approach with the exploratory design. A case study approach (case study). The findings of qualitative methods in the form of support, obstacles, and challenges. Analysis Unit: Four public health centers as health care facilities that organize the first rate of public and individual health efforts, with more emphasis on promotive and preventive efforts, to achieve the degree of public health as high as possible.

Primary and secondary data collected including input, process and evaluated the implementation of the Integrated Health Education Center for Non-communicable Disease/IHEC for NCDs (Posbindu PTM), Pasyandu, and public health center management. The Input covered the role of stakeholders, cadres, and available of facilities and infrastructure. The results of the research are used as a deepening and study the preparation of insurance policies in an effort to service efficiency. The study results in recommendations to increase the role of policy formulation stakeholder set out to promotive, preventive, motivate and incentives officers.

**Results**

A healthy percentage of visits of 11 (ten) PHC during January-June 2016 there was an increasing, Figure 1.

![Figure 1. Healthy visit percentage](image)

January and June each PHC

The hospital visit percentage of 9 (nine) Public Health Center during January - June 2016 were decreased and 2 (two) health centers were increased in Puskesmas G and J because of doing Home Visit to the ambulatory patients, thus increasing hospital visits. Home vision is an effort so that the conditions are controlled so that the patient should not be referred, see Figure 2.

![Figure 2. Hospital visit percentage](image)

The efforts made by the public health center to increase healthy excursions and visits by informants as:

To increase health visit as part of the indicator contact numbers, because of the hospital visit can not be searched or upgraded, then increase visits and activities: Posyandu, Integrated Health Education Center for Non-communicable Disease/IHEC for NCDs (Posbindu PTM), School Health Unit (SHU), the Early Childhood Education (ECD) and kindergarten, Company(10 informants). The Increasing if sick visits were done Home Visit (2 informants).

![Figure 3: Non-Specialistic Referral Percentage](image)

The efforts made by the public health center to not refer the patient so can be treated at the public health center are:

Provide education, explanation to the patients who ask referred to diagnose their illness that can be treated at the health center (10th informants), if there are still forced by reference but not stuffed diagnose disease, so patients are not accepted as a patient referral to an advanced health facility.
Public Health Center management evaluate actively toward the achievement of program indicators by mini workshop every month, all informants said:

*The Public Health Center Have done a mini workshop every month to evaluate the achievement of program and plan the achievement of the activities that will be conducted in the following months (10th informants).*

**Discussion**

Public Health Center (PHC) as the first level health facility has a gatekeeper function on the National Health Insurance. Starting in January 2016 in the city of Bengkulu applied a policy of norm-setting capitation and capitation payments based on the achievement commitment of service at health facilities first-rate, with indicators, among others, include the numbers of contacts (visits sick and healthy), the ratio of referral outpatient cases of non-specialist (RRNS). The efforts made by the health center to reach the indicator by an increase in promotion and preventive activities to increase the number of visits. PHC can be divided into two categories namely: First, the community health service centers ie primary health centers as promotive and preventive service providers with the target groups and communities to maintain and improve health and prevent disease, and; Second, public health centers as primary individual health care center where the role of PHC is defined as a gate keeper or first contact on the formal health care and referral accordance with standard medical services.¹

The Management of Public Health Center in an effort to improve the health, decrease the number of visits sick and referral to hospital, performed the increase in activity promotive and preventive efforts in Posyandu, Integrated Health Education Center for Non-communicable Disease/IHEC for NCDs (Posbindu PTM), School Health Unit (SHU), Early Childhood Education (ECD) and Kindergarten, Company, Increased visits sick do Home Visit to control the disease so that the patient need not be referred. Public health about disease prevention and control at the population level, through an organized effort that includes organizations, public, private and individual. Contribution to public health comes from systems outside the formal health care system, and the potential for cross-sectoral contribution to public health is increasingly recognized worldwide. The government’s role is very important in influencing the health of the population is not limited to the health sector but also by the various sectors outside the health system.²

Mini workshop conducted every month to discuss the PHC program achievement, causes and prevention solutions of high number disease of visits as well as work on improving the quality of care. PHC identify promotive and preventive efforts in the community so that it can be adapted to the needs of the community. Studi Nshimirimana (2016), review of doorman system, redefinition and strengthening of gatekeepers, capacity building, quality assurance, availability and strengthening of patient referral policies, staff motivation and best service practices for patients at community health centers³. Alberta Health (2016) recommends network policies health services assess community health needs by matching programs and community needs, allocating resources to priority areas, and evaluate to ensure the results were in line with objectives.⁴

Prevention is a prominent feature of health care reform that lasted the late 1960s, starting early 1970 in the United States, a strategy has been like a vaccination across the nation, the promotion of lifestyle changes and safety regulations were introduced and become widely accepted as a means to improve public health while reducing health care expenditures.⁵ Efforts to prevent non-communicable diseases have been developed through coaching Integrated Health Education Center for Non-communicable Disease/IHEC for NCDs (Posbindu PTM). Need strong evidence supports explanation lifestyle behaviors negative role in the incidence of chronic illness, and the role of positive lifestyle behaviors on the incidence and effective management⁶. Community involvement tend to be an important contributor to improving the health and service, has made remarkable progress and gained many benefits. Efforts to combine health care with public health disease prevention campaigns can to the success of American health sector⁷.

Study Mourad (2015), Widening the implementation of health information management systems will improve the function, effectiveness, efficiency, and performance of primary health care⁸.

Indonesia faces some challenges for the effective implementation of the Universal Health Coverage (UHC) in order to extend its coverage, especially in dealing with the condition of non-communicable diseases, which are generally chronic in nature, requiring management of patient case carefully from time to time, and the most cost aimed at primary care level⁹. Indonesian Public Health Center condition yet effective treatment of non-communicable diseases, require special efforts to prevent and control non-communicable diseases in order
not to burden the National Health Insurance program. Since the Chinese government was concerned by the low willingness of patients, gatekeeper policy was not done in China. Interestingly, this study showed that high willingness among patients reported to health insurance, to implement gatekeeper. These findings remind the health sector about the need to formulate a strategy to promote the implementation of the gatekeeper policy priorities. The Australian Government is fully responsible for primary health care funds and policies. The main initiative pushes major changes across the system together, these changes will occur ensuring a strong and effective primary health care system, which underlies the national health and hospital network for the future of Australia. The Policy in increasing the role of gatekeeper for first-level health facilities should be planned and executed well so that health care providers and participants can receive it.

**Conclusion**

Public Health Center as a health care facility that organizes first rate public and individual health efforts, with more emphasis on promotive and preventive efforts that can reduce the number of hospital visits and referrals to hospital. Implementation of gatekeeper policy would be beneficial to control health care costs with planned and implemented with a strategy that focuses on service providers and participants.

Involvement of \textit{KRAS} rs61764370 \textit{T}>\textit{G} Gene Variation in Leukemia Patients of Saudi Arabia

Osama Al-Amer\textsuperscript{1}, KF Alsharif\textsuperscript{2}, Rashid Mir\textsuperscript{1}, FM Abu-Duhier\textsuperscript{1}, Abdulraheem Almalki\textsuperscript{2}, Wayil Yassen\textsuperscript{3}

\textsuperscript{1}Department of Medical Laboratory Technology, Prince Fahd Bin Sultan Research Chair, Faculty of Applied Medical Sciences, University of Tabuk, Kingdom of Saudi Arabia, \textsuperscript{2}Departments of Clinical Laboratory Sciences, Faculty of Applied Medical Sciences, Taif University, Kingdom of Saudi Arabia, \textsuperscript{3}Departments of Oncology, King Salman Armed Forces Hospital, Tabuk, Kingdom of Saudi Arabia

Abstract

Background: Recently, a variant allele in the 3'UTR of the \textit{KRAS} gene (rs61764370 \textit{T}>\textit{G}) was shown to be associated with an increased risk for developing multiple cancer types like lung, ovarian and breast cancer. Therefore, we investigated the association of \textit{KRAS} (rs61764370 \textit{T}>\textit{G}) gene variation in leukemia susceptibility in our population.

Methodology: This population-based case–control study was done on 72 clinically confirmed Leukemia patients and 87 matched healthy controls with no history of any type of cancer. The \textit{KRAS} rs61764370\textit{T}>\textit{G} genotyping was detected by using Allele specific PCR.

Results: We observed a statistically significant difference in the frequencies of \textit{KRAS} \textit{TT}, \textit{GT} and \textit{TT} genotypes among patients and healthy controls (\(p=0.0271\)). This study reported significantly higher percentage of \textit{TT} (11\%), \textit{GT} (75\%) and \textit{GG} (14\%) genotypes in patients compared to controls TT (25\%), GT (69\%) and GG (06\%) genotypes while higher percentage of GG (14\%) genotype were reported in patients compared to control GG (6\%) genotypes. Our findings showed that the \textit{KRAS} rs61764370\textit{T}>\textit{G} variant was associated with an increased risk of Leukemia in codominant inheritance model (OR=5.5, 95\%CI=(1.43-21.0); RR=2.20, (1.04-4.64), \(p=0.038\) \textit{TT} vs \textit{GG}). Dominant inheritance model (OR=2.70, 95\% CI=(1.21-6.52); RR=1.45(1.10-1.91), \(p=0.007\) \textit{(TG+GG)} VS \textit{TT} and Recessive inheritance model (OR=2.64, 95\%CI= (0.86-8.13), RR (1.70(0.82-3.54) P=0.025 (GG vs TT+GT) tested. While, the G allele significantly increased the risk of Leukemia (OR= 1.57; 95\% CI= (1.03-2.45); RR 1.22(0.99-1.51) \(p=0.047\) compared to \textit{T} allele.

Conclusion: Our findings indicated that \textit{KRAS} rs61764370 \textit{GG} genotype and \textit{G} allele are associated with an increased susceptibility to leukemia in Saudi Arabian population. It can be used as a predisposing genetic marker for Leukemia. Further studies with larger sample sizes are necessary to confirm our findings.

Keywords: \textit{KRAS} rs61764370, SNP- Single-nucleotide polymorphism, Leukemia, OR-Odds ratio, CI-Confidence interval.

Introduction

In 2015, leukemia was present in 2.3 million people and caused 353,500 deaths.\textsuperscript{(1)} In 2012 it newly developed in 352,000 people.\textsuperscript{(2)} It is the most common type of cancer in children, with three quarters of leukemia cases in children being the acute lymphoblastic type. However, about 90\% of all leukemia’s are diagnosed in adults, with AML and CLL being most common in adults. It occurs more commonly in the developed world.\textsuperscript{(3)} The International Agency for Research on Cancer (IARC) estimated in Saudi Arabia, that the age-standardized incidence rate (ASIR) for leukemia was 3.0 per 100,000 populations in 2008, and the age-standardized mortality

Corresponding author:
Dr Osama Al-Amer, Department of Medical Laboratory Technology, Faculty of Applied Medical Sciences, University of Tabuk, Kingdom of Saudi Arabia.
The registry of King Faisal Specialist Hospital and Research Center (2011) recorded 6216 cases of leukemia admitted to the hospital during the years from 1975 to 2011. In 2008, the Saudi Cancer Registry (SCR) reported that leukemia ranked third in cancer incidence among the male population, and fifth among females. The ASIR of leukemia in Saudi Arabia is slightly low in comparison with other Arabian Gulf countries.

Three different human RAS genes have been identified: KRAS (homologous to the oncogene from the Kirsten rat sarcoma virus), HRAS (homologous to the oncogene from the Harvey rat sarcoma virus), and NRAS (first isolated from a human neuroblastoma). The different RAS genes are highly homologous but functionally distinct; the degree of redundancy remains a topic of investigation. RAS proteins are small GTPases which cycle between inactive guanosine diphosphate (GDP)-bound and active guanosine triphosphate (GTP)-bound forms. RAS proteins are central mediators downstream of growth factor receptor signaling and therefore are critical for cell proliferation, survival, and differentiation. RAS can activate several downstream effectors, including the PI3K-AKT-mTOR pathway, which is involved in cell survival, and the RAS-RAF-MEK-ERK pathway, which is involved in cell proliferation. RAS has been implicated in the pathogenesis of several cancers. Activating mutations within the RAS gene result in constitutive activation of the RAS GTPase, even in the absence of growth factor signaling. The result is a sustained proliferation signal within the cell.

Single nucleotide polymorphisms (SNPs), disrupting miRNAs, or miRNA binding sites have been demonstrated to be individually powerful biomarkers of cancer risk in humans. A gene polymorphism located in the 3′UTR of the KRAS gene (rs61764370 T>G) has been reported to disrupt a let-7 miRNA binding site which induced increased expression of KRAS in vitro and lower let-7 miRNA levels in vivo. In addition to oncogenic nature of KRAS, the KRAS gene (rs61764370 T>G) variant allele has been reported to confer an increased risk for developing non-small cell lung cancer (NSCLC), as well as ovarian cancer, although the results in NSCLC were not replicated, besides the KRAS-variant was shown to be a genetic marker of poor outcome as well in head and neck cancers. The higher frequency of KRAS gene (rs61764370 T>G) variant allele was reported in triple-negative Breast cancer in premenopausal women, Familial breast cancer patients. The KRAS-variant is an inherited, germline variant that has been demonstrated to serve as a genetic marker of increased risk of ovarian cancer. The KRAS-variant is easily tested in a blood or saliva sample; and has been shown to be at a high prevalence in ovarian cancer patients, being present in over 25% of patients with epithelial ovarian cancer, compared with 6% to 10% of the general population.

Limited studies are available from this part of the world therefore this study was aimed to investigate the association of KRAS gene (rs61764370 T>G) gene variations with leukemia susceptibility in Saudi Arabia.

Materials and Method

Sample collection

This population-based case–control study was done on 72 clinically confirmed Leukemia patients and 87 matched healthy controls with no history of any types of cancer and not related to the patients. Patients with any previous history of cancer were excluded from this study. After assessing the clinicopathological findings, a 4ml sample of peripheral blood was collected by venipuncture in EDTA tubes from each patient and healthy control.

DNA extraction

The DNA was extracted by using DNeasy Blood Kit (cat 69506) from Qiagen (Germany) as per the manufactures instructions. The extracted DNA was dissolved in nuclease-free water and stored at 4°C until use. Quality and integrity of DNA were checked by NanoDrop™ (Thermo Scientific, USA).

Genotyping for KRAS rs61764370T>G

The KRAS rs61764370 T>G genotyping was detected by using ARMS-PCR or Allele specific PCR. The ARMS or AS-PCR primers were designed by using Primer3 software as depicted in Table 1.
The ARMS-PCR was performed in a reaction volume of 25μL containing template DNA (50ng), FO -0.3μL, RO -0.3μL, FI-0.2μL, RI -0.2μL of 25pmol of each primers and 10μL from GoTaq® Green Master Mix (cat no M7122) (Promega, USA). The final volume of 25 μL was adjusted by adding nuclease free ddH₂O. Finally 2μl of DNA was added from each patient. The ARMS –PCR was converted to AS-PCR.

**Thermocycling conditions**

The amplification conditions used were at 94°C for 12 minutes followed by 35 cycles of 94°C for 35sec, 62°C for 40 sec, 72°C for 40 sec followed by the final extension at 72°C for 10 minutes. The amplification products were separated by electrophoresis through 2% agarose gel stained with 0.5μg/mL ethidium bromide and visualized on a UV transilluminator. Primers FO and RO flank the exon of the KRAS rs61764370T>G gene, resulting a band of 538bp to act as a control for DNA quality and quantity. Primers Fwt and RO amplify a wild-type allele (G allele), generating a band of 234bp, and primers FO and Rmt generate a band of 385bp from the mutant allele (T allele) as depicted in figure 1.

**Statistical analysis**

Deviations from Hardy-Weinberg disequilibrium (HWD) was calculated by Chi-square (χ²) goodness-of-fit test. Group differences were compared using Student’s two-sample t-test or one-way analysis of variance (ANOVA) for continuous variables and Chi-squared for categorical variables. Differences in the KRAS rs61764370T>G allele and genotype frequencies between groups were evaluated using Chi-square test. The associations between KRAS rs61764370T>G gene and risk of Leukemia were estimated by computing the odds ratios (ORs), risk ratios (RRs) and risk differences (RDs) with 95% confidence intervals (CIs). Allele frequencies among cases as well as controls were evaluated by using the Chi–square Hardy–Weinberg equilibrium test. A p-value < 0.05 was considered significant. All statistical analyses were performed using Graph Pad Prism 6.0 or SPSS 16.0.
Results

Study population:

This population-based case–control study was done on 72 clinically confirmed Leukemia patients and 87 matched healthy controls with no history of any types of cancer and not related to the patients. This research was approved by the Research ethics committee, University of Tabuk and written informed consent was obtained from all the subjects before enrollment.

Genotype distribution of \( \text{KRAS} \) rs61764370 T>G gene variation in Case-control:

The genotype distribution of \( \text{KRAS} \) rs61764370 T>G gene variation in cases and controls is summarized in Table 2. We observed a statistically significant difference in the frequencies of \( \text{KRAS} \) TT, GT and TT genotypes among patients and healthy controls (p=0.0271). This study reported significantly higher percentage of TT (11%) ,GT (75%) and GG (14%) genotypes in patients compared to controls TT (25%) ,GT (69%) and GG (06%) genotypes while higher percentage of GG (14%) genotype were reported in patients compared to control GG (6%) genotypes as depicted in table 2.

Allelic distribution of \( \text{KRAS} \) rs61764370T>G gene variation in Cases-controls:

The frequency of T allele (fT) was found to be higher among healthy controls (0.60) than the leukemia patients (0.48) whereas, the higher frequency of G allele (fG) (0.52) was observed among leukemia patients than the controls (0.40) as depicted in table 2.

Risk of Leukemia patients with \( \text{KRAS} \) rs61764370 T>G gene polymorphism:

A multivariate analysis based on logistic regression like odds ratio, risk ratio and risk difference with 95% confidence intervals were calculated for each group to estimate the association between the \( \text{KRAS} \) rs61764370 T>G variant and risk of Leukemia patients in Saudi patients as depicted in table 3. Our findings showed that the \( \text{KRAS} \) rs61764370 T>G variant was associated with an increased risk of leukemia in codominant inheritance model (OR=5.5, 95%CI= (1.43-21.0); RR=2.20, (1.04-4.64), p=0.038 TT vs GG and in case of dominant inheritance model (OR=2.70, 95% CI= (1.21-6.52); RR=1.45(1.10-1.91),P=0.007 (TG+GG) VS TT and recessive inheritance models (OR=2.64, 95% CI= (0.86-8.13), RR (1.70(0.82-3.54) P=0.025 (GG vs TT+GT) tested. While, the G allele significantly increased the risk of leukemia (OR= 1.57; 95% CI= (1.03-2.45); RR 1.22(0.99-1.51) P=0.047 compared to G allele as depicted table 3.

In this study, we found that KRAS rs61764370 T>G variant is associated with an increased susceptibility of leukemia patients.

**Discussion**

A multivariate analysis based on logistic regression like odds ratio, risk ratio and risk difference with 95% confidence intervals were calculated for each group to estimate the association between the KRAS rs61764370 T>G variant and risk of Leukemia patients in Saudi patients as depicted in table 3.

The results of our study indicated that the KRAS rs61764370 T>G variant was associated with an increased risk of Leukemia in codominant inheritance model (OR=5.5, 95% CI= (1.43-21.0); RR=2.20, (1.04-4.64), p=0.038 TT vs GG and in dominant inheritance model (OR=2.70, 95% CI= (1.21-6.52); RR=1.45(1.10-1.91),P=0.007 (TG+ GG) VS TT and .Also it was reported that the G allele was significantly increased the risk of leukemia with OR= 1.57; 95% CI= (1.03-2.45); RR 1.22(0.99-1.51) P value =0.047 compared to T allele. The current study confirmed the relationship of KRAS gene polymorphisms and the risk of Leukemia in the Saudi Arabian population.

In accordance with one of the study findings, indicated that KRAS rs61764370 polymorphism was associated with the risk of double primary breast and ovarian cancer. Similar results were showed in another study that the KRAS variant is a risk factor for triple negative breast cancer in premenopausal women highlighting its role as a genetic marker. Since the characterization of the KRAS miRNA-related SNP known as KRAS-LCS6 (rs61764370), there have been a number of studies on the relationship of its genotype with risk and prognosis of several cancers, with many such studies directed toward cancer outcome. The rs61764370 SNP is located in the 3'UTR region of the KRAS oncogene, and its derived allele has been associated with an increased expression of KRAS by weakening the microRNA let-7 binding to KRAS mRNA. This variant has been associated with an increased risk of triple-negative breast cancer, non–small cell lung cancer, and ovarian cancer. The GTPase protein encoded by KRAS, and the miRNA let-7 are involved in the regulation of proliferation, differentiation, and apoptosis. In fact, let-7 is a master regulator in the differentiation process of normal hematopoietic stem cells while activating mutations in KRAS are one of the most common events in cancer development.

**Conclusion**

Our findings indicated that KRAS rs61764370 GG genotype and G allele are associated with an increased susceptibility to leukemia in Saudi Arabian population. Furthers studies with larger sample sizes are necessary to confirm our findings.

Prevalence and Risk Factors of Hypertension Stage 1 in Banjar Ethnic, South Kalimantan, Indonesia: Finding from the Indonesia Family Life Survey (IFLS) 5

Ahmad Taufik Azis¹, Syahrizal Syarif²
¹Master of Epidemiology, ²Departement of Epidemiology, School of Public Health, University of Indonesia

Abstract

Objective. Basic Health Research or Riskesdas 2013 showed that the prevalence of hypertension in South Kalimantan was 30.8%, the second highest prevalence and above prevalence in Indonesia (25.8%). The majority of Banjar Ethnic (65%) living in the area of South Kalimantan are also at risk of hypertension.

Method. This is a cross sectional study. Subjects in this study were the age group ≥18 years who were followed by the interview and had complete data. We investigated risk factors of hypertension stage 1. The data is derived from secondary data from the Indonesian Family Life Survey (IFLS) 5.

Result. The prevalence of hypertension stage 1 in Banjar Ethnic is 16.6% among respondent. The dominant risk factors for hypertension stage 1 in the Banjar Ethnic are obesity, PR=2.726 (95%CI:1.913-3.886), age≥45 years PR=2.146 (95%CI:1.482-3.107) dan male PR=1.641 (95%CI:1.149-2.344).

Conclusion. Obesity, age and gender are determinant for hypertension stage 1 in Banjar Ethnic. It is recommended to routinely check blood pressure, especially for people aged ≥45 years and maintain an ideal body weight in people of Banjar Ethnic.

Keywords: Hypertension stage 1, risk factors, Banjar Ethnic

Introduction

Non-communicable diseases are one of the biggest causes of death in the world, and it predict will increase from 38 million deaths in 2012 to 52 million deaths in 2030. In countries with lower middle income, non-communicable diseases are around 48%. Hypertension is one of the non-communicable diseases which become the global concern and have caused 9.4 million deaths and 7% of the world’s disease burden. According to World Health Organization (WHO), in 2014, the prevalence of hypertension in adults aged 18 years and over is around 22%. Research conducted in Southeast Asia shows that the prevalence of hypertension in Malaysia is 43.5%, Myanmar 30.1%, Vietnam 23.7%, and Sri Lanka 23.7%. The prevalence of hypertension in Indonesia in 2007 at the age of ≥40 years was 47.8%6 and in 2015 was 33.4% at the age of ≥18 years and it higher than the prevalence globally7.

Various risk factors have been found to be linked with hypertension, including socio demographics (age, gender, level of education, marital status, residence)4-6,8, various dietary behaviors were also associated with hypertension, including fruit and vegetable intake9 and fast food10. Higher body mass index (BMI) has been found to be positively associated with hypertension11. A Number of studies found that there was an association between physical activity12, smoking behavior13, and hypertension.

Ethnic/race is one of the risk factors of hypertension. Based on a study conducted by Suglia et al., in 2012, the prevalence of hypertension was higher in black women compared to white (16% versus 12%), in Hispanic’s men having a higher prevalence of hypertension compared to white (29% compared to 25%)14. Similarly, research
on ethnic Rob and Dolan in Xianjiang China by Abdukeram stated that there were significant differences in the prevalence of hypertension in these ethnic groups (28.77% and 14.75%).15

The majority of Banjar Ethnic (65%) who is living in the area of South Kalimantan are also at risk of hypertension.16 This can be seen from the results of the Basic Health Research in 2013 showed that the prevalence of hypertension in South Kalimantan was 30.8%, much higher than the national prevalence of 25.8%.17 Based on the data above, researchers were interested in knowing more about the prevalence and risk factors for hypertension in the Banjar Ethnic.

**Method**

**Ethical Consideration**

The IFLS has been approved by ethics review boards of RAND and University of Gadjah Mada in Indonesia. Written informed consent was obtained from all respondents before data collection was carried out.18

**Study Design**

This study uses a cross-sectional design using data from the Indonesian Family Life Survey-5 in 2014.

**Study Population**

The population observed in this study was the respondents of the Banjar Ethnic as many as 1,074 people from IFLS’s data. Inclusion criteria were ≥18 years old, did not take hypertension drugs. Calculation of sample size in this study uses the population data formula to test the hypothesis. Based on these calculations it is known that the largest sample size is 745 respondents. Sampling by means of total population because it meets the minimum sample requirements. The sample size used is 765 respondents.

**Socio-Demographic Characteristics and Risk Factors**

We include demographic information and individual characteristics (age, gender, education level, residence, and marital status), vegetable consumption, fruit consumption, physical activity and obesity as risk factors analyzed in this study.

**Blood Pressure Measurement**

Blood pressure was measured three times by specially trained nurses, using Omron’s self-inflating digital sphygmomanometers while participants were in a sitting position. The average of the three measurements is used for the current analysis. Blood pressure was classified using JNC VII. Hypertension stage 1 was defined as Systolic Blood Pressure (SBP) 140-159 mmHg or Diastolic Blood Pressure (DBP) 90-99 mmHg.19

**Measurement of Body Size**

Body mass index (BMI <25 kg/m2: normal weight; and ≥25.0 kg/m2)20, obesity derived from the height and weight measured during the physical examination. Height measured by the Shorr measurement board and weight was measured using the Seca floor-model scale developed in collaboration with UNICEF. In this study the measurement of body weight and height was carried out by the interviewer or enumerator who was competent in his field and had received previous training.

**Data Analysis**

Descriptive statistics were used to describe the study variables of the study population, Chi Square test to calculate difference in proportion and Cox Regression analyses were used to test significant determinant of hypertension status. Both the 95% confidence intervals and P value were adjusted considering the survey design of the Study. All analyses were conducted with SPSS 20 for Windows.

**Result**

In the present study, 765 samples met the inclusion requirements. The prevalence of hypertension stage 1 in Banjar Ethnic is 16.6% among respondent. The proportion of hypertension stage 1 increases with age. The largest proportion in the age group ≥45 years (28.4%) compared the age group <45 years (13.8%). The proportion of hypertension stage 1, men were higher (19.5%) compared to women (14.0%). In respondents with low education, the proportion of hypertension stage 1 incidence in is 19.2% (table 1).

The proportion of hypertension stage 1, who live in rural areas are more (17.3%) compared to those living in urban areas (15.2%). In respondents with marital status, the proportion of hypertension stage 1 was higher in divorce (25.4%) compared to single (12.0%) and married.
(16.5%). In table 1 it can be also be seen that the proportion respondents with less vegetable and fruit consumption (15.9%), less physical activity (13.8%) suffer from hypertension stage 1. The proportion of hypertension stage 1, obese were higher (28.4%) compared to with non-obese people (11.7%) (Table 1).

Note: Adjusted by education level, residence, marital status, vegetable and fruit consumption, and physical activity.

Based on table 2, it is known the model of risk factors hypertension stage 1 in the Banjar Ethnic. The determinants for hypertension stage 1 in the Banjar Ethnic are Obesity, PR=2.726 (95%CI:1.913-3.886), Age≥45 years PR=2.146 (95%CI:1.482-3.107) dan Male PR=1.641 (95%CI:1.149-2.344).

### Discussion

In this study, the prevalence of hypertension stage 1 was 16.6% from 765 respondents. Based on the research of IFLS 5 in 2014 showed that the prevalence of hypertension stage 1 in Indonesia using the JNC-VII blood pressure category was 15.6%21. According to WHO in 2011, the prevalence of hypertension will continue to rise sharply and is predicted in 2025 about 29% of adults worldwide suffer from hypertension.

The results of this study also showed that obesity has a significant factor of hypertension stage 1 in the Banjar Ethnic. Research conducted by Rohkuswara and Syarif also found that obese respondents (BMI≥25) had a risk of 1.681 times to suffer from hypertension stage 1 compared to those who were not obese22. This finding also similar with research conducted by Jullaman, that the people with BMI were obese (>25-27kg/m²) at a risk of 1.06 times for hypertension stage 1 compared to those belonging to a normal BMI23. According to Messerli and Frisoli (2013) that by doing a weight reduction of about 5.1 kg it can reduce systolic blood pressure (SBP) by 4.4 mmHg. The BMI is recommended using the Body Mass Index (BMI) criteria, which is between 18.5 - 24.9 kg/m²24.

The results of the statistical test showed that age of the respondent the higher the risk of hypertension. Respondents with age ≥ 45 years were higher at risk of developing hypertension stage 1 compared to respondents aged <45 years. This is in line with the research conducted by Rohkuswara in 2017 that the age group 41-50 years had a risk of 5.541 times suffering from hypertension stage 1 compared to those aged 20-30 years22. The research conducted by Jullaman also shows that the higher the age of the respondent the more risk of suffering from hypertension stage 1, namely age 31-43 years PR = 1.7 (95% CI: 1.076-2.711), age 44-53 years, PR = 2.09 (95% CI: 1.773-4.095), age> 53 years, PR = 4.33 (95% CI: 2.902-6.471)23. The high risk of hypertension is similar with increasing age, caused by changes in the structure of large blood vessels, so that the lumen becomes narrow and the walls of blood vessels become stiff, as a result of increased systolic blood pressure25.

The results of this study also showed that male has a significant relationship with the hypertension stage 1 the Banjar Ethnic. Research conducted by Sari showed that men at risk of 1,620 times suffering from hypertension stage 1 compared to women26. More men experience the possibility of hypertension than women, often triggered by unhealthy behavior (smoking and alcohol consumption), depression and low employment status, feeling less comfortable with work and unemployment25. In addition, the level of concern for women in treating and controlling blood pressure is higher than that of men27.

### Conclusion

According to the findings of present study it can be concluded that obesity, age ≥45 years and male are the determinant in hypertension stage 1 in the Banjar Ethnic.
Based on this finding, there is need for recommended to routinely check blood pressure, especially for people aged ≥45 years and maintain an ideal body weight.

**Study Limitation**

The results obtained in the study are likely still influenced by the selection bias when viewed from aspects such as the selection process of the research population, the use of cross-sectional design which is only carried out at one time. The use of cross-sectional design has weaknesses, because there is no clear temporal time relationship, resulting in the aspect of causality becoming blurred, measurement of fruit and vegetable consumption variables, and physical activity is strongly influenced by the memory of the respondent, so that it is vulnerable to bias information.

Abstract

Heart disease is a common disease in the world and lead to the mortality. The aim of this study is to evaluate the diagnostic values of serum biochemical markers such as hs-CRP, LDH and myoglobin in patients with some heart diseases such as (AMI) and (HF). Hs-CRP and myoglobin were estimated by using a sandwich immune detection method, and LDH activity by enzymatic method using semi-automated chemistry analyzer. Our data revealed that serum hs-CRP, LDH, and myoglobin levels showed a high significant differences in patient groups compared with control group, whereas comparison patient groups between them also showed high significant differences except in hs-CRP levels they were indicates no significant values. Also LDH levels showed high significant in both patient groups compared with the levels of hs-CRP and myoglobin. Finally these parameters now play significant role in the diagnosis of disease and our finding suggest that the elevated levels of hs-CRP, LDH and myoglobin are a significant predictor and considered markers for myocardial damage and necrosis.

Keywords: Biochemical Markers, Myocardial Infarction, Heart Failure, hs-CRP, Myoglobin, LDH

Introduction

Cardiovascular disease influences approximately seventy million americans, and each year an estimated eight million patients enter the emergency unit with symptoms of ischemic heart disease (1). HF is the final state of all heart diseases and public health problem especially in geriatric people (2). Many pathologic factors can cause myocardial injury, which is followed by cardiac remodeling and congestive HF (3). AMI is the main cause of morbidity and mortality in world and acute state of necrosis of the myocardium resulting from disproportion between myocardial metabolic demands and the coronary supply of oxygen and nutrients (4-5). Everyday innumerable number of patients report with chest pain, but only ten percent to fifteen percent have MI (6). All patients with AMI can be considered “high risk” and necessary be treated strongly (7). AMI can be diagnosis spontaneously by chest pain, ECG features, and elevation in serum markers (8).

Hs-CRP is the test used for detection of serum CRP concentration at lower levels (9). Increased CRP concentrations in obesity are associated with more severe metabolic derangements, also in CAD higher CRP concentration are participate with adverse vascular outcomes (10). Estimation of inflammation parameters as hs-CRP may provide a new technique for detecting population at high risk of plaque rupture (11). Many researchers suggest that hs-CRP is a useful indicator of cardiovascular risk (12). The high values of hs-CRP are an independent indicator of prognosis in Chronic HF (13). Myoglobin is a kind of protein which is selected intra muscle tissues and it is able on linking oxygen and iron and carrying them through metabolism. It is specifically exist in myocardium and skeletal muscles so that the release of myoglobin in the blood serum predict a muscle damage, hence myoglobin is considered as one of the most sensitive biomarkers for AMI, especially at the primary stages (14). LDH is serological marker for
the estimation of infarct size, serum concentration of LDH is mostly used. It’s catalysis the conversion of pyruvate to lactate. LDH-1 to LDH-2 increase over baseline approximately ten hours following MI, peak at about 24 to 48 hours and maintain at levels in the blood for up to fourteen day after MI.

**Materials and Method**

This study was conducted at AL-Ramadi Teaching Hospital / Iraq, during the period from December 2017 to October 2018. The study included 25 subjects, (5) subjects were normal healthy controls (both sex) and the mean of age between (20-55 years), (20) patients were admitted to the intensive cardiac care unit, and these patients were divided to two groups, patients suffering from AMI (n=10), and patients suffering from HF (n=10) (both sex) and the range of their age between (50-75 years). All patients undergone clinical and laboratory evaluation, and diagnosed clinically according to the combination of chest pain, detailed clinical history, ECG features, and elevated in cardiac markers such as [CK-MB and cardiac troponin T].

The hs-CRP, myoglobin, and LDH levels of these patients with (HF and AMI) were measured after admission and their peak level were recorded. Hs-CRP and myoglobin were estimated by using a sandwich immune detection method supplied from Ichroma company. LDH activity was measured by using enzymatic method using semi-automated chemistry analyzer supplied by Linear Chemicals Company. About (5) ml of venous blood samples were taken after admission, allow it to clot, separated by centrifuge and serum was collected and stored at (–20°C) until analysis biochemical markers.

**Results**

Serum hs-CRP levels were significantly higher in patient groups as compared with control group (HF= mean ± SEM 10.156 ± 0.286, AMI = mean ± SEM 9.291 ± 0.170 versus control group = mean ± SEM 10.75 ± 0.125, p <0.05), and this study showed also significant differences in patients group between them revealed no significant differences (Fig 1) illustrates the hs-CRP levels among different groups in this study.

Figure 1: The mean levels of hs-CRP in patient groups and control group

Our study revealed that the levels of LDH enzyme activity in patients with HF and AMI show a higher significant differences compared with control group (HF= mean ± SEM 507.633 ± 3.253, AMI= mean ± SEM 948.406 ± 7.058 versus control group = mean ± SEM 224.333± 3.274). But when the comparison of patient groups between them, it was observed significant difference in patient with HF compare with AMI as shown in (fig 2).

Figure 2: The mean levels of LDH enzyme activity in patient groups with control group

This study indicate as shown in the (Fig 3) significant increases in myoglobin levels in both patient groups compared with control group (HF= mean ± SEM 111.929 ± 0.930, MI = mean ± SEM 91.492 ± 0.512, versus control group = mean ± SEM 11.051 ± 3.274, p <0.05), and this study showed also significant differences in patients group between them.

Figure 3: The mean levels of myoglobin in serum of patient groups with control group
Having established that the patients of HF had a high levels of all biochemical markers, the effects of HF group on hs-CRP, LDH and myoglobin were evaluated. fig (4) Explained amazing results and showed that LDH enzyme activity was highly significant in patients of HF compare with others biochemical markers (LDH = mean ± SEM 507.633 ± 3.253, in contrast hs-CRP = mean ± SEM 10.156 ± 0.286, and myoglobin = mean ± SEM 111.929 ± 0.930).

![Figure 4: The mean levels of serum hs-CRP, LDH, and myoglobin in Patients with HF](image)

The effect of MI on biochemical markers was demonstrated previously and all had significant differences (Fig. 5) showed the effect of MI upon all markers mentioned above, and revealed that LDH enzyme levels are highly significant compared with hs-CRP and myoglobin (LDH = mean ± SEM 948.406 ± 7.058, versus hs-CRP = mean ± SEM 9.291 ± 0.170, and myoglobin = mean ± SEM 91.492 ± 0.512).

![Figure (5): The mean levels of serum hs-CRP, LDH, and Myoglobin in Patients with MI](image)

Discussion

The biochemical markers have significant role in the diagnosis of diseases (17). However, according to the American heart association recommendations the hs-CRP values less than 1 mg/L are classified as low risk, the values between 1-3 mg/L classified as average risk and over 3 mg/L is classified as high risk for coronary heart disease (18). In this study patients with (HF, MI) have hs-CRP levels more than 3 mg/L and according to statistical analysis our study showed the significant differences in hs-CRP levels in patient groups (HF, MI) compared with control group. Hs-CRP is inflammatory biomarker; It is elevate in the blood and considered risk factor for many clinical disorders such as cardiovascular diseases and other acute systemic inflammation as well as considered a good marker of myocardial damage but it is not sensitive as troponin I in diagnosis (19-20). This study comes in agreement with studies by (Rathore et al 2015; Yin et al 2004) findings more significant values of CRP in patients suffering from AMI compared in control group, and more significantly with the severity of CHF (13). Also the results revealed not significant differences in hs-CRP levels in patients groups between them as shown in (Fig. 1).

Hs-CRP levels indicates poor prognosis and it also increases risk of long term complications and risk of HF, This finding also was in agreement with the study (Chaudhary and Chhotala, 2016) are consistent with the present study found the hs-CRP increased in patients with MI and suggest that Patients with MI who have higher values (>3mg/L) of hs-CRP on admission are very much prone to develop HF in the future and related morbidity and mortality as compared to those with normal or near normal hs-CRP levels on admission (21).

The normal range of serum LDH enzyme activity from 140-290 IU/L compared with this normal variation (15). Our data demonstrated a high significant differences in LDH enzyme activity in patient groups especially in MI group compared with control group (fig. 2). When myocardial cells damaged because insufficient oxygen supplying or nutrients, the membrane of cardiac becomes permeable or may be led rupture, resulting in release of cytosolic enzymes into the circulatory system with concomitant increases of their serum concentrations (5). The outcomes of our research revealed that high significant between patients of MI compared with HF, and this automatically because the LDH activity specific in diagnosis of MI more than HF. In study done by (Karmen et al; 1950) demonstrated that necrotic cardiac myocytes causes the enzyme release and can be detected in the serum and could aid in the diagnosis of MI (17) .The findings of our study was in agreement particularly with the previous study done by (Vyš et al; 2017) they were found that out of 55 patients who actually diagnosed to have AMI, the LDH enzyme was elevated in 36 patients, in 19 patients in spite of having AMI it remained in normal range (20).
Our study findings the myoglobin levels in serum were shown high significant differences in both patient groups (HF, MI) as compared with control group especially HF group which gives strong peak as explain in (fig. 3). Myoglobin released more rapidly into blood than any other cardiac marker (16). This data also found the high significant deferences in patients of HF compare with MI in myoglobin, this may be due to time differences for draw blood samples, drugs and other risk factors associated with HF group that led to this finding. The clinical specificity of myoglobin is poor because its found not only in cardiac cells but also in skeletal muscle cells (17). So its cannot be used as a lone in diagnostic parameters, but in combination with troponins or CKMB (22).

Finally the (Figs 4,5) confirm the results obtained for comparison between the patient groups compared to the control group as well as the comparison between the patient groups with each other which were previously illustrated in Figs. 1, 2 and 3. Also indicate that the activity of LDH enzyme activity was the most influential and most significant in both patient groups (HF and MI) compared with other biochemical markers. This is because the LDH enzyme is the most specialized in the cardiac muscle of other variables, and because its contain on 5 isoenzymes especially the isoenzymes LDH1 and LDH2. The LDH-1 isoenzyme found in the heart muscle and LDH-2 is found predominantly in blood serum. A high LDH-1 to LDH-2 suggest MI (6).

Statistical Analysis

Statistical meaning of variances among means values from control and treated groups applied by specific (ANOVA) test via Graph Pad Prism ® Version 5.0 software or Bonferroni Multiple Comparison test. p<0.05 established as significant.

Conclusion

All biochemical markers levels examined in this study showed the high significant differences in the patient groups (HF and AMI) compared with control group, but when we compare the results of patient groups between them, only hs-CRP levels don’t revealed any significant differences. On the other hand LDH enzyme activity showed high significant levels in both patients group as compared with hs-CRP and myoglobin. Finally these findings suggest that an elevated level of hs-CRP , LDH and myoglobin are a significant predictor and considered the markers of myocardial damage but not as much sensitive and specific as Troponin I and CK-MB . So for the early diagnosis and intervention of AMI these markers are very helpful and can provide additional prognostic information for the risk stratification and treatment in patients with HF and AMI.

Comparative Study between Ultrasound Finding and Retrograde Urethrography to Evaluate Urethral Stricture

Ahmed Turki Obaid
Assistant Professor/ College of Medicine / Babylon University / Consultant Urologist / Urology Department / Hilla Teaching Hospital/ Babylon province / Iraq

Abstract

The urethrogram is implemented in a retrograde style. Sonourethrography is applied chiefly as an escort performance in an assessment of urethral stricture infection by the chief benefit occurring to improved valuation of related spongiofibrosis. The report was aimed to make comparative among ultrasound finding and retrograde urethrography to assess urethral stricture. The test evaluation at showed in the imaging division of Hilla Teaching Hospital in Babylon (Iraq) from Dec, 2017 to Oct, 2018 containing 95 patients. The records were then analyzed by the use of SPSS version 14. The outcomes of RUG, 22 patients (66.7 %) were be ill with local stricture, and 11 (33.3 %) was analyzed for distributed stricture. In Sonourethrography (SUG) imaging, 16 (48.5 %) were analyzed for local stricture, and 17 (51.5 %) was analyzed for distributed stricture. Finally, the outcomes completely realized over ultrasound were frequently apprehensive by the actuality of varied and echogenic masses external the urethra and the irregularities of the internal wall of the urethra.

Keyword: Sonourethrography, Urethrography, urethral stricture

Introduction

The urethrogram was the elderly radiographic examination to evaluating urethral stricture infection, and rests the traditional for analysis and performance. Most frequently, the urethrogram was implemented on a retrograde style. The analysis originates by a scout picture to evaluate skeletal arrangements as justly as an attendance of several solidified urinary territory pathology. Consequently, 25 - 33 mL of water solvable iodine founded on difference average was inserted to the urethra below straight fluoroscopic or radiographic concept, and numerous imageries are acquired. This is recognized as the self-motivated, that it permits for living valuation of the urethra as difference was brought (Choudhary, 2014).

Indecorous locating would position the urethra at an viewpoint relation to the image, and effect in irony of stricture dimension. The penis would been located on extend in command to increase whole valuation of the . A service of saturated lubrication may unclear the picture, persuade edema, and offer debatable advantage of patient relaxation. Contrast would be imagined over the to permit imaging of the urethral proximal for the, in command to guarantee that the complete amount of is imagined (Pavlica P, 2013). The significance of patients locating is established in figure 1

Figure 1 A illustrative RUG

Around the three key topographies of a stricture which are a RUG necessity classify, containing position of the, the dimension of the, and concurrent urethra pathology. The urethra is classically separated into an posterior and frontal section. The frontal urethra was included of the navicularis and penile urethral, and finally bulbar urethral. The later urethra is included of
the, and finally prostatic urethral (Cheng, 2018). The division of standard urethral structure on RUG was shown on figure 2.

**Figure 2 Standard RUG representative**

The caliber of a frontal urethra would been flat and unchanging from the to a penobulbar connection. In fact, the bulbar urethra receipts a slight S formed alteration in sequence, that is naturally relates to the penoscrotal connection. Intermittently, smooth tissue shapes of the may be recognized, supporting in the documentation of these milestone. Preserving give on a penis consents with greatest, that in try to supports in properly classifying stricture dimension of this section (Wu S., 2011).

At the stage of the, a flared in was detected, tracked by a rapid tapered to the stage of the. Frequently pacification of Cowper’s penile may be gotten there, particularly if here is obstacle distal to the initial of these configures in the proximal. In particular cases, to compare between the frontal leaf of the bulbospongious strength (musculus compressor nuda) can be realized in the actual proximal. This was a standard result that would not be incorrect for a criticism (Sun D., 2014).

The opacities as a slim wisp of difference to the stage of the top of the, that may be recognized in the verumontanum performing as a separate filling fault. The standard, capable posterior urethra will be ended at balance of RUG and period like as distension of these urethral section is not shown (Feng C., 2013).

The compassion and sympathy of RUG to the analysis of a have been informed in many researches. Compassions among 73 % and 99 % had been experiential, with sympathy of 70 – 96 %. Classically, picturing is associated to and dimensions as a contrast (Sharma, 2013). Optimistic prognostic values had been described from 55 – 92 %, by negative prognostic rates variable in the 73 – 100 % rate. For Example, is measured to be great in its facility to diagnose stricture, and additional describe its distance, position, and amount with a great grade of precision. Figure 3 proves the correct description of an extended section penile urethral associated with that it was primarily measured as a “*” (Sharma V., 2011). The long section (6 cm) idiopathic was established on figure 4.

**Figure 3 A Penile urethral stricture**

**Figure 4 A Idiopathic bulbar urethral stricture.**

**Ultrasound**

McAninch (1988) were first defined Urethral ultrasound, or in another meaning sonourethrography (SU). SU is applied chiefly as the adjunctive performance in the assessment of infection with the chief benefit creature an improved valuation of related (Latini J.M., 2014). For frontal strictures 4 - 6 cm in dimension, SU has been revealed to has compassion and sympathies of 65 – 99 % and 96 – 97.5 %, with consistent positive and negative prognostic rates of 51 – 85 % and 95 – 97.5 %, separately (Sharma A.K., 2013).

The advantages of SU contain a (3D) anatomic valuation of distance and position. SU was significantly...
extra sympathetic in recognizing urethra as different to the. Additional problems contain operative dependence and a semi aggressive class, and the condition of typical or universal for complete to increase imagining (Andrich D.E., 2012).11

Problem Statement

General, SU rests a valuable assistant for the valuation of urethral stricture infection chiefly related spongiofibrosis, and can assist an extra task as an intraoperative valuation tool. Respecting the huge occurrence of urethral stricture and the requirement of using precise, easy, inexpensive and suitable approaches, the report was aimed to make comparative among ultrasound finding and retrograde urethrography to assess uretheral stricture

Methodology

The test evaluation at showed in the imaging division of Hilla Teaching Hospital in Babylon (Iraq) from Dec, 2017 to Oct, 2018. The vital administrative preparations and received the necessary licenses, all of the sufferers capable for our investigation have been made completely privy to the method, and objectives of this report after which their formal and knowledgeable agreement was received to contribute in our report. Then extra information lick as age, the length of the signs and other scientific backgrounds consisting of trauma, contamination or congenital disorders was recorded. The patients involved the ones supposed of urethral stricture that had resorted to the center to be analyzed through RUG. At the similar time, the sufferers additionally underwent Sonourethrography. To direct use the RUG, a sterilized Foley catheter become driven 3 to 4 centimeter inner their urethra, after which meglumine contrast solid was injected internal their urethra and graphic radiology become occupied within the indirect location in order to analyses stricture, location of the stricture and its period. Sonourethrography become also performed. For this reason, the ends of the syringe without a needle become injected into the urethra to insert regular saline. Once the urethras have been packed with regular saline, the urethral production was pushed for you to block the liquid from smooth out. Then, using the external probe at the ventral surface of the genital up to the perineum place, the entire urethra turned into tested by sonography to decide the actuality or absence of stricture, location of the stricture and its dimension length. Sonourethrography was showed in the sonography unit of Hilla Teaching Hospital in Babylon (Iraq) with use of Voluson 730 pro appliance thru its floor probe by a rate of 5 to 11 MHz. The consequences of each method had been as compared in opposition to each other. RUG strategies were set because the standard for this assessment and the effects of Sonourethrography have been compared with it.

The suitable technique was used for sampler, and all of the patients capable for the investigation submitted the take a look at in order to finish the volume of sample.

Contemplating, the common sonography compassion established at the report of Akano (92 %), the error of the primary kind was set to 0.05, and the precision were set to 0.05 of the investigation sample (containing 95 humans).

The investigation populace covered all of the sufferers suspected of frontal urethra stricture primarily established on the clinical signs and symptoms who were presented from the urology unit for imaging.

The presence standards permissible were simply for male patients only with frontal urethral stricture to be an applicant for imaging to analyses stricture.

The elimination criteria comprised the unfeasibility of carrying out any RUG techniques or Sonourethrography.

The average, mean and standard deviation were present in variables established; whilst frequency and ratio have been decided on to represent qualitative variables. Compassion, specialty, high quality predictive rate and negative prophetic value had been used to decide the analytical rate of Sonourethrography to RUG. The arrangement stage among RUG and Sonourethrography was determined using Kappa check. The records were then analyzed by the use of SPSS version 14.

Results

The current study was showed to make comparative among ultrasound finding and retrograde urethrography to assess urethral stricture where 95 patients were examined. The mean age of the contributors was 45.84 ± 12.5, and they all vary between from 20 to 85 years old as shown in figure 5.

The totals of 33 patients (34.7%) were analyzed with urethra stricture by RUG as shown in figure 5.
The totals of 35 patients (36.8 %) were analyzed with urethra stricture by Sonourethrography (SUG) as shown in figure 6.

Agreeing with the outcomes of RUG, 22 patients (66.7 %) were ill with local stricture, and 11 (33.3 %) was analyzed for distributed stricture. In Sonourethrography (SUG) imaging, 16 (48.5 %) were analyzed for local stricture, and 17 (51.5 %) was analyzed for distributed stricture.

The mean dimension of the urethra calculated in RUG technique was 11.84 ± 7.18 millimeter, and the mean dimension of urethra stricture calculated in Sonourethrography technique was 7.15 ± 6.28 mm. The dimension of the stricture calculated by RUG technique was meaningfully lengthier than the stricture evaluated by Sonourethrography (P = 0.025).

The outcomes completely realized by sonography survived mostly involved with the being of varied and echogenic masses external the urethra and the indiscretions of the internal partition of the urethra. Contemplating the Standard and possession in awareness the RUG as a technique to examine the urethra stricture by a vision of the outcomes of sonography, these were 19 % true positives, 71 % correct negatives, 5 incorrect positives and 4 incorrect negative situations table 1.

Table 1 Data

<table>
<thead>
<tr>
<th>Compassion</th>
<th>86.63 %</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specialty</td>
<td>94.66 %</td>
</tr>
<tr>

</tr>
</tbody>
</table>

Amongst the 5 incorrect positive situations, 3 had dispersed stricture, and 2 were analyzed with local stricture. Amongst the 4 incorrect negative situations in Sonourethrography, 3 had dispersed stricture, and 1
were analyzed from local stricture.

**Discussion**

Complete discovery of urethral strictures is serious and formative for preoperative choices and rebuilding executive. Currently, the retrograde urethrography (RUG), as standard gold technique, is applied for analysis. The present standard is similarly employed for subtle design of urethral strictures infection in the greatest precise method. Sonourethrography (SUG) is additional influential alternate technique for 3D assessment of stricture position and arrangement, and may be a dependable intraoperative appropriate expedient; however, it is joined with selected boundaries.

While there are numerous investigation regarding the original fruitful requests of ultrasonography in examination and analyzing the frontal urethra stricture amongst males and these techniques were totally harmless and bearable and simply reasonable, it had not regularly involved the consideration of the urologists at least in Iraq. The current investigation pursues to make comparative among ultrasound finding and retrograde urethrography to assess urethral stricture. This investigation analyzed 95 patients doubtful of urethra stricture by the mean age of 46, and they all varied between 20 to 85 years old.

Additional to defecating the opposing results of X ray on gonads, sonography may be simply enlarged to the bladder and kidneys and exposes the associated diseases.

Maciajawsi and others in 2016 were observing the unusual methods in the analysis the urethral stricture infection and described that the RUG has 80 to 99 % sensitivity and 81 to 98 % specificity. The researchers were described that too the RUGs have a Positive predictive rate (PPR) in the scope of 55 to 94%, on other hand the negative predictive rate (NPR) range were from 80 to 98 % (Maciajawi, 2015). They informed reported that the SUGs have 71 to 98% sensitivity and 95 to 100% specificity. The study of Peskar in 2008, was observing that the correctness of sonography associated to urethrography in analyzing urethra stricture were 95% (Peskar DB, 2008).

In this study, the compassion and specialty of ultrasound to analyzing strictures were 86% and 94% correspondingly with the assessment of its negative projection being extra than the rate of positive projection.

**Conclusion**

Finally, the outcomes completely realized over ultrasound were frequently apprehensive by the actuality of varied and echogenic masses external the urethra and the irregularities of the internal wall of the urethra. The effects of the present studies showed that the length of the stricture measure through ultrasound is shorter than the length measured through RUG. The compassion and specialty of this approach as associated to RUG in analyzing strictures turned into 86% and 94% correspondingly that are desirable stages retaining in mind its benefits. We may additionally subsequently give you the belief that urethrography is an easy plan, handy and repeatable technique that does not disclose the affected person to the ionizing radiation. To acquire greater accurate outcomes, those findings want to be in comparison to the outcomes of surgeries so that we will exactly choose which approach is more correct.

The Experience of Married Men Who Have Sex with Female Sex Workers (FSW)

Ainun Sajidah¹, Evy Marlinda¹, Agus Rachmadi¹

¹Department of Nursing, Health Polytechnic of Health Ministry Banjarmasin, Indonesia

Abstract

Background: Sexual disharmony has serious effect, such as having sex with sex workers. This study aimed to explore the factors affecting married men who have sex with female sex workers as well as consequences.

Method: This study used a qualitative design with a phenomenological approach and purposive sampling. Total Sample was 13 married men who had sex with female sex workers in Pembatuan Area Landasan Ulin Timur, Banjarbaru. We conducted in-depth interview and FGD (focus group discussion). The result of study was descriptive analysis includes data reduction, data display, conclusion, and verification. The main outcome measures were themes identified as the reason married men had sex with female sex workers and the consequences of their behavior.

Results: Factors that affecting married men had sex with female sex workers was grouped into some categories that were irritable wife, body’s wife is not ideal, wife is menopause or sick, environmental factors (intervene parents-in-laws), new sensations, loneliness because of distance, female sex workers are more communicative and romantic, get a bonus, excessive sex libido, not satisfied with his wife, the effect of alcohol and friends. While the consequences of married men had sex with female sex workers were financial disrupted, sexual transmitted infections, polygamy, better serving from wife, wife’s appearance better than usual, divorce, regret, anxious, and satisfaction.

Discussion: Married couples are expected to live in the same place to fulfill psychological and biological needs can be fulfilled. If they have to live separately, both of them can control themselves and understand the consequences.

Keyword: married men, sexual activity, female sex workers, qualitative study, FGD

Introduction

Sex as harmonious communication does not occur in every couple (¹). Harmonious sex is needed to make partner feel satisfied. Some married couple can express their affection. Recognition of sexual desire could be a positive trigger and induce positive sexual expression (²)

Otherwise, disharmony sex has serious effect, such as having sex with sex workers. Wrong sex behavior among married men was having sex with female sex worker to look for satisfied at prostitution place or tourist area (¹).

High number sexual transmitted diseases among men and women were reported and recorded in the Provincial Health Agency (Dinkes). Data from the Indonesian Ministry of Health (2016) showed that South Kalimantan had 144 people suffering from HIV, 65 people with AIDS in 2010. While in 2012 showed HIV was 34 people, AIDS was 22 people and Sexual

Corresponding author:
Ainun Sajidah
E-mail: ainunsajidah@gmail.com
transmitted diseases were 141 people. In Banjarmasin, the number of sexual transmitted disease increased in 2011 \(^5\). Based on the description, the aims of this study were to explore the experiences and consequences of married men who have sex with female sex workers.

**Method**

We used qualitative design to explore the experience of married men who have sex with female sex workers. The design of this study is qualitative research with a phenomenological approach. We conducted in-depth interview and FGD (focus group discussion) to explore ideas, health behaviors related to the experience of having sex with female sex workers.

Data were collected from married men who had sex with female sex workers at Pembatuan, Landasan Ulin, South Kalimantan from May to July 2018. We used purposive sampling with inclusion criteria were married men who had sex with female sex worker and provide the informed consent. Recruited continued until saturation data was achieved (n= 10).

We conducted forum group discussion and conducted triangulation through in-depth interviews among 3 participants to ensure reliability data. All interviews were transcribed by first author and translated into English. We used thematic analysis; the reason married men had sex with female sex workers and the consequences of their behavior. Analyzed data include data reduction, presentation, conclusions and verification.

**Results**

The results based on Focus Group Discussion method, Theme 1: factor effecting of married men had sex with female sex workers:

**Irritability**

“If I am at house, my wife always cranky, so I look for another woman” (P.1)

“If I am at house, my wife always cranky, and I do not know the problem, perhaps from my children, or from family in Java, and she is angry all the time” (P.2)

“I want to have sex with my wife, but she does not want to do it. Unfortunately, she refused while angry, and it was Ordinary” (P.4)

**Loneliness due to long-distance marriage**

Most of the reasons were the wife is not at house

“"I asked my wife to go home, but she refused it. So I look for another one” (P.3)

“It depends on my workplace”… (P.5)

“My wife in Java Island, so I want to have sex with others in here” (P.6)

“According to me, I feel loneliness” (P.9)

Wife’s body is not ideal

“My wife is thin; I want someone with a fat body (P.1)

Environment (intervene parents-in-laws)

Parents in-laws interfere, and they asked my wife to come back to their house, so it triggers me(P.7)

Variety in sex

“Eemm, I think, I only want to look for new variety in sex” (P.8)

“There is new woman, I think she is Hollywood actress,” (P.1).

“At that moment, there is good film actress, so I try it” (P.5)

Wife is menopause

“I already old as well as my wife, she often refuses to have sex with me” (P.10)

Female sex workers are communicative

“For us, the reason was I feel so comforable with female sex worker, we can share each other’s, and can communicate well” (P.2)

“Being my friend, and sharing” (P.6)

Female sex workers are romantic

“I always look for romantic one, and click with me, I always look for someone who romantic” (P.10)

Getting Bonus or additional income

“I have money… “ (P.4)(P.6)

“I got bonus” (P.1)

Peer influence

“Initial, my friend invited me to join, currently I am addicted” (P.8)

Fight with wife

“I have problems and argue with my wife….” (P.2)

“I always argue and fight with my wife because of the smell of girl perfume” (P.6)

“If my wife knew about my behavior, we will fight each other” (P.4)
“I will argue and fight, if my wife knew” (P3)

Wife is sick
“My wife is sick” (P.6)(P.5)

Theme 2: The consequence due to having sex with female sex workers
Financial disrupted
“Financial problem” (P.5)(P.4)
“Money runs out, cannot give money to the wife” (P.8)

Fight and argue
“It seems like…..I was scolded by my wife” (P.9)
“…throw the cellphone each other’s” (P.3)
“Oooo….there’s no divorce problem… If argue each others are….. usual…not often but sometimes…
sometimes when my wife knew if I have sex with other” (P.1)

“Only get angry” (P.4)

Sexual transmitted diseases
“The effect is...positive and negative are the first effect... disease is certain.....” (P.5)
“If sexual disease, emm I admit it, I’ve suffered before”. (P.8)

Polygamy
“Already found out, she already knew so polygamy” (P.5)

Wife gives better services
“My wife serves me better” (P.5)
“My wife always gives me.....I mean she never refused me to have sex” (P.4)
“Yes....she always agrees, to serve us”…. (P.2)

Wife’s appearance is better than usual
“Perfume…” (P.5)

“Her smile like onion, I already came to my house” (P.5)

Divorce
“Divorce with my wife, she already leaved me and did not live with me” (P.7)

Afraid and anxious
“I worry about HIV....but I use condom” (P.10)

Discussion
Theme 1: Factors affecting married men had sex with female sex workers

Based on the results there were 15 factors of married men had sex with female sex workers, that were 3 participants (23.1%) due to their wives are irritability. The wives often refuse when invited to have sex. It was similar to this reason, there was one participant (7.7%) said his libido is increase but his wife did not serve him. Previous study mentioned that having sex with others because their partner loses his passion for intercourse. One participant (7.7%) said his behavior due to his wife is already menopause. During menopause a woman often experiences complaints in intercourse due to loss of libido. Another reason comes from wife; there was one participant (7.7%) who had sex with female sex workers because the wife’s body is not ideal. Perception of body size related to quality life. The wrong perception of body size as the reason someone is interested in another. There were three participants (23.1%) said that they often quarreled with their wives so they rarely engage in sexual activity. Conflicts with wife is the most common reasons for married men to have sex with female sex workers. There were 2 participants (15.4%) who had sex with the female sex workers because their wives are sick, so the wife could not serve their husband. Physical or psychological disorders can cause sexual dysfunction. There was one participant (7.7%) said because of dissatisfaction in sexual activity with his wife. Feeling satisfied in sexual activity is needed between husband and wife and it relates with quality of marriages.

Other reasons come from female sex workers, there were 2 participants (15.4%) said that they want to look for variety in sex. Variety and sensation in sex is part of human need. There were 5 (28.5%) participants said that female sex workers are more communicative when invited to talk. Otherwise, their wives are lacked communication with them, so it encouraged them to have sex with female sex workers. Personal communication between husband and wife is needed to create harmonious life. There was one participant (7.7%) said because female sex workers is more romantic. One of the psychological reasons for someone having an affair is affection need.

Other reasons were from environments, there were five participants who had sex with female sex workers due to loneliness. They are doing long distance marriage or due to workplace. Need deprivation will encourage people to fulfill this deprivation with everything.
There was one participant (7.7%) said that the reason was because of parents-in-laws who interfered in their household life. Sometimes, the existence of a family could become problem in the household (13). There were 5 participants (38.5%) said they have sex with female sex workers because he got extra income. Socio-economic facilities this behavior, and trigger married men having sex with female sex workers (14).

There was one participant (7.7%) said his behavior because of alcohol influence. People who consume alcohol are more likely to engage in sex with female sex workers (15) (Schenus et al., 2006). There were two participants (15.4%) who had sex with female sex workers due to friend’s invitation. Peer influences make married men tend to use peer norms and ignore social norms (16).

Theme 2: The consequence due to having sex with female sex workers

There were five participants (38.5%) said they had financial problems because they addicted to having sex with female sex workers. There were four participants (31%) said the consequence was quarrel with wife. The biggest disappointment experienced by a wife whose husband had an affair (17). In this study found one participant (7.7%) who said he divorce due to his behavior. Sexual outside can lead to divorce (18).

Two participants (15.4%) said they suffered sexual transmitted disease or syphilis. The result also showed that four participants (31%) said they feel anxious because never use condom when having sex with female sex workers. Female sex workers believe that pill contraception not only protects the risk of pregnancy but also from sexually transmitted disease (19). One participant (7.7%) said that the consequence was polygamy. This finding is similar with previous study (20). Also, three participants (23.1%) said that it brings a positive impact, the wife provided better service to husband. She maintains the relationship and forgives her husband (21). In this study found one participant (7.7%) said that the appearance of the wife better than usual. There were 3 participants (23.1%) said they remembered their wives when having sex with female sex workers. Someone who has sex with female sex workers can get orgasm, but they do not feel satisfied (4). This study has some limitation, we used qualitative study and purposive sampling, so it could not be generalized, but the diversity of socio-economic characteristic respondents were available, such as age, background, living with partner or long distance marriage, and having menopause partner. Better understanding about these factors and consequences can educate married couple to gain harmonious life.

Conclusion

Factors that affecting married men had sex with female sex workers was grouped into some categories that were wife factors, environmental factors (intervene parents-in-laws, long distance marriage), the effect of alcohol and friends, female sex workers factors, married men factors such as not satisfied with his wife,. While the consequences of married men had sex with female sex workers were financial disrupted, sexual transmitted infections, , better serving from wife, divorce, anxious, and sexual satisfaction.

Abstract

Objective: This study was carried out to evaluate the prevalence of HBV, HCV, and HIV among blood donors, and to identify some features of seropositive blood donors in the Main blood bank in Najaf province, Iraq.

Method: This cross-sectional study was carried out among blood donors. Data were collected from the records of the Main blood bank. Screening of all blood donors was done for the detection of hepatitis B surface antigen (HBsAg), hepatitis C virus antibody (anti-HCV), and HIV antibody by ELISA test.

Results: From a total of 35669 blood donors who attended Main blood bank during 2017-2018, 1305 were seropositive. The prevalence of HBV, HCV and HIV infection among blood donors were 3%, 0.5%, and 0.06% respectively. Most of the seropositive donors were HBV positive 1101, (84.3%), 181 (13.9%) were HCV positive, and only 23 (1.8%) were HIV positive. The majority of them were male (98.5%), they lived mostly in urban areas (80.2%). The highest rates of viral hepatitis and HIV occurred in age groups (30-39) and (40-49) years which were 39.3% and 26.7%, respectively. More than one third (38.4%) of seropositive donors of blood group O, and most of them (86.6%) were of an Rh-positive phenotype.

Conclusion: The current study demonstrated serious challenges regarding the HBV, HCV and HIV prevalence in Najaf Province. Results of the present research will be helpful for the better control and management of viral hepatitis and Human immunodeficiency virus among blood donors.

Keywords: Hepatitis B, Hepatitis C, HIV, Prevalence, Blood donors.

Introduction

Viral hepatitis B and C are major health problems, affecting 325 million people worldwide. Hepatitis B and C are chronic infections that may be asymptomatic for years or decades. They are main causes of liver cancer, leading to 1.34 million deaths every year. At least 60% of liver cancer cases are due to late testing and treatment of viral hepatitis B and C. The most important gap to be addressed is low coverage of testing and treatment in order to achieve the global elimination goals by 2030 (1). The World Health Organization (WHO) has stated that viral hepatitis could be eliminated as a public health threat by 2030. Currently, the global burden of HCV is estimated at 71 million people (2,3). Key recommendations in the WHO elimination goals are to reduce new infections by 90% and HCV-related liver mortality by 65% (3).

Liver disease due to hepatitis virus is a major public health concern that affecting millions of people globally (4). A unique group of hepatitis A, B, C, and E viruses are responsible for liver disease. All these viruses are lead to significant morbidity and mortality in developing and developed countries. The clinical manifestation of viral hepatitis varied from subclinical to life-threatening infection (5).
HBV is mainly transmitted by blood transfusions, risky sexual behaviors, tattooing, occupational hazards, unsafe injection practices, and mother-to-child in the perinatal period. HCV is mainly acquired through blood transfusions, use of unsafe injections by drug addicts or in health care centers. Mother to child transmission, and sexual transmission and are infrequent (6).

HBV is one of the most common causes of chronic liver disease which progress to chronic hepatitis. While HCV is the major source of post-transfusion hepatitis, which can result in chronic infections, cirrhosis and hepatocellular carcinoma (7,8).

HIV has killed 39 million people up to now and infected 70 million people, it is one of the worst pandemics in human history. HIV has high risk of transmission through blood transfusion, therefore; according to the instruction of WHO, screening of blood products for viral infections is mandatory. The prevalence of HIV among blood donors differs between regions and countries depending on different criteria such as the prevalence of HIV, public education regarding blood donation, the pre-donation screening, and the selection of donors.

Therefore; this research aimed to determine the prevalence and the possible risk factors for HBV, HCV and HIV among blood donors in Najaf Province, Iraq.

Materials and Method

Study design

This is a retrospective cross-sectional observational study of blood donors who donated blood in the Main blood bank-Najaf, during the period 2017-2018. A total of 35669 blood donors were included in this study. From them, 1305 were found positive for viral hepatitis or HIV. Data were collected from the records of the Main blood bank, including age, sex, residency, blood group, rhesus factor, and date of registry.

All blood donor samples were screened for the presence of HBsAg, total anti-HBc and HIV Antibody by ELISA (BioMérieux, France). For confirmation of diagnosis, positive samples were retested using the PCR.

Statistical analysis

Chi-square test ($\chi^2$-test) was used for testing of significant association between different variables. Statistical significance was considered if p-value equal or less than 0.05.

Results

Out of 35669 blood donors screened for HBV, HCV, and HIV infections, 1305 were seropositive. The prevalence of HBV infection was 3 %, HCV infection was 0.5 %, and HIV infection was 0.06%. Most of the seropositive donors were HBV positive (84.3%), 13.9% were HCV positive, and only 23 were HIV positive (1.8%). The majority of them were male (98.5%), they lived mostly in urban areas (80.2%). The age of the donors ranged from 20 to 69 years. The highest percentage of viral hepatitis found in age groups (30-39) and (40-49) years which were 39.3%, 26.7%, respectively. More than one third (38.4%) of seropositive donors of blood group O, and most of them (86.6%) of Rh-positive phenotype (Table 1).

Analysis of different variables, including gender, age, residence, blood groups, and Rh-phenotype in the association of HBV in comparison with HCV and HIV among seropositive blood donors demonstrated no statistically significant differences (Table 2).

(Table 1): Clinical and demographic features of seropositive blood donors (N=1305).

**Discussion**

Hepatitis B & C Virus infections are a significant global public health concern. Worldwide, the spread HBV and HCV increase at an alarming rate, this lead to a dramatic impact upon some countries such as Iraq. Globally, recent findings demonstrated that approximately 350 million persons are chronically infected with HBV, about 200 million persons are infected with HCV (9) and more than 70 million subjects have been infected with the HIV virus. In Iraq, viral hepatitis in general is an endemic disease, and all types of the known causative viruses are existing with various rates of infection (10).

Previous studies conducted in Iraq reported that the prevalence of HBV among blood donors was ranging from (1.6% - 4%) (11-15), and HCV ranged (0.2% - 0.5%) (11,12,16-19). Which was similar to our study that reported prevalence of HBV and HCV was 3% and 0.5% respectively.

Globally the prevalence of HBV and HCV among blood donors was ranging from (1.4% – 4.2%) and HCV was ranging from (0.3% - 0.57%) (20,21) respectively, which is similar to current results.

This study reported a higher rate of HBV than the HCV infection among seropositive donors, (84.3%,13.9%) respectively, which was similar to other studies conducted in different cities of Iraq (16-19,22-28) and
in other countries such as Iran (28-32). All these studies showed that the HBV infection was more common than the HCV in seropositive blood donor. Therefore, health programs must be available to inform people about the infectious environment of HBV and how it is transmitted. Since hepatitis B is a vaccine-preventable disease, it is important to motivate people, especially high-risk groups for vaccination.

Our study reported that HBV and HCV were higher among men (98.5%) than women (1.5%). This is due to the majority of blood donors were males, which might be attributed to the fact that in Iraqi society, men are more proactive and independently make decisions. This result was agreed with other studies conducted in Iraq (16, 17, 24-27) and also in other countries (32, 33).

The age distribution of seropositive donors was from 20 to above 60 years. The higher percentage in age group (30-39) and (40-49) years. This result is consistent with other researches (16, 22, 25, 30).

The current study found that HBV and HCV seropositive donors were more in urban than in rural. This is in agreement with other studies done in (16, 24, 25). This is could be due to most of the blood donors were from urban areas.

Our findings demonstrated the diversity of the distribution of blood groups and Rh Phenotype between HBV and HCV. Blood group O and Rh+ showed the higher rate of seropositive HBV and HCV. ABO blood groups have shown some association with diverse viruses (34).

Seroprevalence HBV and HCV was instituted highest in donors who have blood group O (39.1%, 33.1%) respectively, and lowest in donors who have blood group AB (10.3%, 10.5%) respectively, however, statistical analysis reported no significant association between different types of viral infection and ABO blood group and Rh+ phenotype. This finding was similar to the results obtained by previous by Al-juboury et al. (16).

HIV prevalence among blood donors in this study was 0.06%. In Iraq, the previous studies revealed no cases of HIV among blood donors (11, 15). The prevalence of HIV among seropositive blood donors was 1.8%, which agree with other studies conducted in Iran (1.6%) (29). HIV positive cases were males of urban residence 23 (100%). This finding was similar to the result of previous study in Sudan (35). This is may be due to men are more likely to acquire infection because they are more prone to risky behaviors.

The age distribution of HIV cases was from 20 to more than 60 years. The highest rate of HIV was within the age group (30-39) years. This could be explained by this age group has a higher sexual activity. Our study recorded higher cases of HIV among O Blood group (43.5%). This may be due to blood group O being a universal donor and so is easily used as a replacement donor.

One of the limitations of our study is non-availability of information about seronegative blood donors, therefore; we couldn’t assess of risk factors that could be associated with seropositive blood donors. Other important data such as risky behaviors like sexual activities, tattoo, and previous blood transfusions were not available in the records of the Main blood bank.

Conclusion

Our result reflects the high rate of hepatitis and HIV infection among blood donors in Main Blood Bank of Najaf. Seropositive blood donors are more likely to be male, urban residence, age group (30–39), (40-49) years, O blood groups, and Rh+ phenotype.

Conflicts of Interest: None of the authors have any conflicts of interest relevant to what is written.

Ethical Clearance: The study was conducted in accordance with the ethical principles that have their origin in the Declaration of Helsinki. The study protocol and the subject information and consent form were reviewed and approved by a local Ethics Committee.

System Analysis of Public Health Surveillance in School-Age Children

Arief Hargono¹, Kurnia Dwi Artanti¹, Fariani Syahrul¹
¹Faculty of Public Health, Universitas Airlangga, Indonesia

Abstract

School-age children are more susceptible to disease transmission. Health efforts to control health problems are public health surveillance. School institutions have the potential to be the place for conducting surveillance for school-age children, considering that the school institution is a strategic place because its existence will facilitate the outreach of health programs to school-age children. The purpose of this study was to analyze the public health surveillance system for the development of public health surveillance in school-age children. This research was operational research with cross-sectional design. Research variables include data types, data sources, data collection methods, data analysis, health information and information dissemination. Development of a surveillance information system model using the System Development Life Cycle approach. The results of data identification were carried out on the types of data and information that could be monitored and collected by School Health Program teachers and students in schools. The data includes symptoms, immunization data, Adverse Events Following Immunization, student absenteeism and healthy behavior and risk factors for non-communicable diseases. The input entity as a data source is the school and the output entity as the recipient of information is the district/city health office and the education office. Information generated from this surveillance is to complete health program data from health services.

Keywords: model, information system, surveillance, school-age children, Indonesia

Introduction

School-age children are an important period in the growth and development of the human body. School-age children are also more susceptible to disease transmission. One health problem that is a priority for school children is an infectious disease that has the potential to become an epidemic, such as measles and diphtheria. Data from the Indonesian Health Profile in 2017 states that measles suspects occur in all provinces in Indonesia and 45% of measles events occur at the age of 5-14 years. Diphtheria incidence at the age of 5-14 years was 46%. Other health problems that have the potential to occur in children are dengue fever, typhoid, diarrhea, pneumonia and tuberculosis in children.

Various efforts were made by the government to control health problems that occurred. These efforts are reflected in health management in the National Health System which is regulated in the Republic of Indonesia Presidential Regulation Number 72 of 2012 concerning the National Health System. One form of implementation of the health effort sub-system for controlling health problems is public health surveillance. Surveillance is a systematic and continuous analysis of diseases and health problems and risk factors for health problems. The function of surveillance activities is to monitor health problems and evaluate ongoing health programs (Thacker, 2000). Through this surveillance activity, it is expected to be able to monitor disease risk factors so that health problems that occur can be identified earlier.

Health efforts are also carried out in schools through the School Health Program (SHP). The purpose of SHP
activities is to early detection of health problems of students and the availability of data and information to assess the health development of students. The SHP activity is a series of activities which include physical examination, laboratory, mental emotional deviation and physical fitness. Data collected in the SHP includes examining general conditions, measuring blood pressure and pulse, nutritional status, teeth and mouth, senses of vision and hearing, laboratory examinations, measuring physical activity and early detection of emotional irregularities.

School institutions are chosen to be the place for conducting public health surveillance for school-age children. School institutions are a strategic place because their existence will make it easier to reach health programs for school-age children. The selection of program implementation in elementary school institutions is expected to reach more children aged 6-15 years to be monitored for their health status.

Public health surveillance is expected to be able to monitor health problems while evaluating ongoing health programs for school-age children. The purpose of this study is to analyze the public health surveillance system for the development of public health surveillance in school-age children.

Method

The research is part of multi-year study for the development of an integrated model of public health surveillance information systems based on community and school. This research is operational research with cross-sectional design. Research variables include data types, data sources, data collection methods, data analysis, health information and information dissemination.

Development of surveillance information system model using the System Development Life Cycle (SDLC) approach. This approach includes system analysis, system design, system implementation, system maintenance and system monitoring and evaluation. The stages of SDLC carried out in this study is system analysis. The system analysis phase identifies the data and information needed for surveillance in school-age children at school.

The study was conducted in Surabaya City, East Java Province. The choice of research location is based on the high prevalence of health problems that occur. East Java Province is the province with the highest number of measles and diphtheria in Indonesia. The research informants came from Surabaya City Health Office and selected institutions for Public Health Center (PHC), Schools and Integrated Service Post for Mother and Child Health (Posyandu). Informants in the Surabaya City Health Office consisted of officers of the Surveillance Program, Maternal and Child Health, SHP, and Community Based Health Unit. Informants from the PHC consisted of surveillance officers, Maternal and Child Health, and the person in charge of data and information in the selected PHC. Informants from the school are teachers responsible for SHP. Informants from the Posyandu included health cadres in the working area of the selected health center.

Data collection is done by in-depth interviews, document studies and Focus Group Discussion (FGD). Document studies are carried out in the recording and reporting format used in activities related to the ongoing surveillance program at the PHC and schools which includes Maternal and Child Health Program, Immunization, Public Health Surveillance, Environmental Health, Non-Communicable Diseases (NCD) and SHP.

The results of in-depth interviews and document studies will be discussed together in the FGD to agree on the appropriate surveillance information system model. Data collected from in-depth interviews, document studies and FGDs were analyzed descriptively using content analysis.

Results

The development of a system model is a system analysis which is the decomposition of a whole system into its components with the aim to identifying expected data and information needs. The results of the identification of data needed by the system presented in Table 1 to Table 6.

Result of data identification is carried out on the types of data and information that can be monitored and collected by teachers and students that involved in SHP in school. The data includes symptom data, immunization, Adverse Events Following Immunization (AEFI), student absenteeism and healthy behavior and risk factors for non-communicable diseases (NCD). School environment data is also collected by this system. The school environment data includes the existence of water sources, the availability of clean water, the existence of larvae and the cleanliness of latrines and school canteens.

Data collected by the system is carried out by students appointed as “little doctors” from SHP activities at school. The data was later confirmed by SHP teachers. Data collected is then processed to produce public health surveillance information for school-age children which includes:

Student health status data
Number of students with symptom
Number of symptom in students based on frequency and duration
Frequency and duration of student absenteeism
Sickness history of student
Trends in the incidence of symptom in students
Immunization status of students
AEFI incidence in students
Description of healthy behavior in students
Description of NCD risk factors in students

Entities involved in this system model include input entities and output entities. The input entity as a data source is the school while the output entity as the recipient of information is the district/city health office and the education office.

**Discussion**

Syndromic surveillance refers to the use of pre-diagnostic health indicators to allow timely detection and investigation of potential infectious disease outbreaks as a supplementary approach to routine public health surveillance, by enabling early identification of clusters of illness before confirmatory data are available. Syndromic surveillance can be carried out by the community, for example health cadres, teachers for surveillance at schools, caregiver at daycare centers. All component community who have involved Syndromic surveillance must be trained. It is like research in Malawi. There are Malawi’s CCM (Community Case Management) program. This program is a promising strategy for increasing coverage of sick child treatment. Although there is much room for improvement, especially in the correct assessment and treatment of suspected pneumonia and the identification and referral of sick children with danger signs. However, HSAs (Health Surveillance Assistants) provided sick child care at levels of quality similar to those provided in first-level health facilities in Malawi, and quality should improve if the Ministry of Health and partners act on the results of this assessment. Other research by training health care to found of suspected tuberculosis base on syndrome surveillance.
School-based surveillance is needed especially in diseases with the highest prevalence at school age. The disease like as Soil Transmitted Helminthiasis\(^4\), Childhood Obesity\(^5\), stunting and thinness\(^6\). School-based surveillance can be done through the School Health Unit Program or through School absenteeism.

School absenteeism is a plausible simple indicator of unusual health evidence within a community especially for age school\(^1\). The indicator such as child-reported fever, reported recent absence from school, absence from school due to illness, or teacher-summarized weekly absenteeism\(^1\).

School absenteeism can detection early warning some outbreaks. Study in China, it can identified the varicella outbreak, mumps outbreak and ILI (Influenza – Like Illness) outbreak\(^7\). Other research identified syndrome surveillance by some symptoms had found, like as Fever (body temperature higher than 37.5°C or self-disclosure of fever), Diarrhea (≥ three defecations per day), Jaundice (yellow coloration of tissues like skin or pore membrane, abnormal yellowing of tissues), Rash (abnormal changes of the skin, including pruritus and pain), Conjunctiva inflammation (reddened, swollen, and/or burning eyes), Parotid gland inflammation (swelling on the rear side of the earlobe, with fever and local ache when opening mouth or chewing) and Vomiting (and associated headache and abdominal pain)\(^8\).

Research trials have been conducted by recording school reporting through student data coming to the School Health Unit and School absenteeism. The most common complaints were colds (38.5%), cough (27.4%) and dizziness (25.8%)\(^9\). Fever is the common sign for School absenteeism. Study in Thailand found that 74% were absence due to sickness with fever\(^10\). Beside that this surveillance can showed that some student with absence due to sickness were significantly (p = 0.01) to have fever during rainy season (81.00%) than during the other seasons (winter = 62.84% and summer = 70.56%)\(^10\).

In addition to other data surveillance syndromes related to potential disease outbreaks such as immunization, healthy behavior, it possible to detect risk factors related symptoms\(^9\). Food insecurity has been shown to be a determinant of school absenteeism and attainment in Ethiopia\(^11\). Study in Indonesia said that Hepatitis A outbreak in high school at Lamongan District can be identified by the risk factors such as contact history with patients, eating habits together in same place, mutual exchange and sharing same eating utensils, the lack of hygiene habit (such as washing hands with soap for students and food handlers), lack of hand washing facilities, bad sanitation, bad food hygiene management, and inadequate clean and hygienic water source\(^12\).

The usefulness of the system would be dependent on motivation of the school director and teachers to collect and assess absenteeism data, and report to health extension workers when increases occur. No thresholds would be assigned to schools, but it would be the responsibility of the school director to determine when absenteeism becomes unusual and to alert the health extension workers\(^1\). School administrator and local teacher should be increasing awareness syndromic surveillance. It is important to could speed up the response time to signal about outbreak\(^7\).

The potential for recording reports carried out in schools can complement the health data, which has not yet been recorded. Electronic recording can make it easy to record, track and analyze system surveillance. The electronic health record is a cost-effective, promising tool for syndromic surveillance\(^5\). This system can be used as cohort recording to monitors symptoms of disease as an early detection of infectious disease and potential outbreaks in school students.

**Conclusion**

Public health surveillance at school-age children conducted in schools is expected to be able to monitor early illness in students. The data includes symptom data, immunization data, AEFI, student absenteeism, healthy behavior and NCD risk factors. The data is strategic for early detection of disease and monitoring health status in students. This surveillance implementation can be carried out by students and teachers who have implemented the School Health Program. Information generated from this surveillance was reported to the health office and the education office to complete health program data from health services.

Dental Health Behavior in Elderly based on Demographic Characteristics

Aulia Feresia Mauline¹, Taufan Bramantoro², Retno Palupi²

¹Graduate Program of Oral and Dental Health, Faculty of Dental Medicine, Universitas Airlangga, ²Department of Dental Public Health, Faculty of Dental Medicine, Universitas Airlangga, Surabaya, Indonesia

Abstract

Elderly oral health is related to behavior maintenance and dental health improvement. Determinants factor of individual behavior are difficult to control because behavior is the result of various internal and external factors, therefore it is important to do a mapping of psychological factors that lead to dental health behavior to see dental health behavioral intentions in the elderly. Objective: To analyze attitudes, subjective norms, perceptions of behavioral control of dental health behavioral intentions in the elderly based on demographic characteristics. Method: This study is cross sectional study with observational analysis. Dental health behavior tendency is measured by interview method using the Theory of Planned Behavior model. Results: attitude (p = 0.000), subjective norms (p = 0.011), and perceptions of behavioral control (p = 0.000) significant towards dental health behavioral intention in the elderly . Conclusion: The more positive attitude towards oral hygiene, the stronger subjective norms and the higher the perceptions of behavioral control, the greater the intention of the elderly to perform optimal oral hygiene behavior.

Keywords: Intentions of dental health behavior, elderly, demographic characteristics, theory of planned behavior.

Introduction

The elderly population in Indonesia the age above 60 years is ranked at 108 from 196 countries around the world.¹ Generally the elderly experience a decrease in cognitive and psychomotor functions, that can affect the reaction and behavior of the elderly to be slower and less agile. Because of the decrease these two functions, the elderly will also experience changes in the psychosocial aspects related to their personality.²

Dental health behavior is a description of knowledge, attitudes, and actions related to the concept of health and oral problems and its prevention efforts. In this concept, the meaning of dental health is teeth and all of tissues in the oral cavity, including gum.³ There are several efforts that can be done in maintaining dental health, including brushing teeth⁴, regular check up to the dentist⁵, and diet⁶. Based on the study conducted by Bahar⁷, the behavior of maintaining dental and oral hygiene in the elderly was almost entirely included in the moderate category (67.74%) and there was a correlation between knowledge, attitudes and behavior towards the oral health.

Determinants factor of individual behavior are difficult to control because behavior is the result of various internal and external factors. From the various behavioral determinants, experts have formulated theories or models in the formation of behavior, one of the most frequently used and flexible models for mapping the causes of health behavior is Ajzen’s Theory of Planned Behavior. This model has a main focus on the individual’s intention to perform certain behaviors, because intention is considered to affect motivational factors that can influence behavior. ⁸ The main principle of the Theory of Planned Behavior is behavioral intention that predicts behavior itself ⁹, where intention is influenced by three determinants, namely attitudes, subjective norms, and perceptions of behavioral
control.\(^\text{10}\)  

**Materials and Method**

This type of study is cross-sectional study with observational analysis and cluster random sampling method. This study was conducted in 5 health centers (Puskesmas) in the Surabaya city in September-October 2018 with 135 subjects. The inclusion criterion of samples are elderly people aged 60-74 years and can communicate well.

The intention of dental health behavior was measured using the Theory of Planned Behavior questionnaire which consisted of 4 determinants namely attitudes, subjective norms, perceptions of behavioral control, and intentions with a total of 20 questions consisting of 5 questions in each determinant. Questions on the questionnaire related to oral hygiene behavior recommended by the American Dental Association (ADA) regarding the frequency of tooth brushing, tooth brushing time, tooth brushing pressure, duration of tooth brushing, tooth brushing methods, the usage of fluoride toothpaste, interdental cleansing, and tongue cleansing.\(^\text{11}\) Each question was scored with a semantic scale 1-6 with an assessment of 1 (disagree) and 6 (agree).

After data collection, the questionnaire was scored and evaluated and then processed using the SPSS version 16.0 program. Data were analyzed by linear regression to see the effect of attitudes, subjective norms, perceptions of behavioral control over dental health behavioral intentions in the elderly.

**Results**

Total respondent in this study was 135 people, consisted of 45 male (33.33%) and 90 female (66.67%). There were 76 people (56.30%) between the age 60-67 years old and 59 people (43.70%) between the age 68-74 years old. Based on Table 1 shows that based on sex, men have a higher mean than female sex in attitude determinants (17.27), subjective norms (14.80), and perceptions of behavioral control (16.07). Based on age group, elderly aged 68-74 years had a higher mean compared to elderly aged 60-67 years in attitude determinants (16.93), subjective norms (14.61), and perceptions of behavioral control (15.66).

Based on the category of dental health behavioral intention, almost half of the elderly respondents (75 elderly) have a moderate category (55.55%), there are 58 elderly people with a bad category (42.97%), and only 2 elderly people in good categories (1.48%).

<td>Perception of behavior control</td>
<td>0.464</td>
<td>0.000</td>
</tr>
</tbody>
</table>

*p < 0.05

Based on table 2 shows that attitudes are significantly influential on intention (p = 0.000) with positive coefficients (0.313) which indicates that the higher the attitude score, the dental health behavioral intention of elderly is getting better. Subjective norms have a significant effect on intention (p = 0.011) with the value of positive coefficients (0.202) which indicates that the higher the score of subjective norms, the dental health behavioral intention of elderly is getting better. Behavioral control perceptions significantly influence intention (0.000) with positive coefficients (0.464) which indicates that the higher the behavioral control perception score, the dental health behavioral intention of elderly is getting better.

Discussion

Based on the results of study conducted on 135 elderly respondents, significant influence was obtained between attitude variables (p = 0.000), subjective norms (p = 0.001), and perceptions of behavioral control (p = 0.000) on dental health behavioral intentions of elderly with positive coefficients value. This is in accordance with the study by 11-14, there is a correlation between attitudes, subjective norms, and perceptions of behavioral control over intention.

The higher of individual’s intention, the more motivated the individual to behave. Intention is influenced by an attitude which is a disposition to respond positively or negatively to a behavior, the more individuals have an evaluation that a behavior will effect positive consequences then the individual will tending to accept the behavior. Subjective norms are functions that are based on normative belief, that is beliefs about agreement or disagreement that come from people or groups that influence individuals such as parents, partners, close friends, teachers. Perception of behavioral control are individual beliefs about the presence or absence of factors that support or prevent an individual to emerge a behavior. 9,11,12,15

Intention is an indication of how hard someone wants to try and how much effort of an individual will make to carry out a behavior. 8 Many factors influence the decision making of the elderly to behave. The decision making is based on an awareness that starts from the intention so that the behavior is formed. 16

Elderly people often ignore their oral hygiene of their teeth and mouth and often complain of their toothache and mobility teeth which can lead to missing tooth. This condition can be prevented by maintaining dental and oral health by regularly brushing teeth and cleaning the gums, regulating dietary patterns by avoiding foods that contain lots of sugar, and conducting regular dental examinations to the dentist. In addition, the elderly also need to be educated about dental and oral health by health workers including promotive, preventive, curative and

Cryoglobulin Responses and Herd Immunity Plots among Periodontitis Patients

Baha, Hamdi Hakim Al-Amiedi1, IMS Shnawa2, Zainb, M. Hameed3

1Ass.Prof., College of Dentistry, University of Babylon, Hilla, Iraq, 2Department of Biotechnology, College of Biotechnology, University of Qasim, Qisim, Babylon, Iraq, 3College of Dentistry, University of Babylon, Hilla, Iraq

Abstract

A Cryoprotein was separated from periodontitis patients sera and characterized as a cryoglobulin. The cryocrit percentages were ranged from 1-8% in patients as compared to 1-3% in controls. The cryoglobulin concentration were ranged from 90-240 mg/L with mean value of 188 mg/L as compared to 1.3-4 mg/L. Immunofixation studies have shown secondary mixed cryoglobulinemia of IgA-IgG-IgM type. The assessment of herd immunity using cryoglobulin as a probe revealed that there are three main fraction as: low, moderate and high responders. The herd immunity plats were normal and skewed respectively.

Keyword: Cryoglobulin, Cryocrit, Herd Immunity, Immunofixation

Background

As a part of an ongoing program for the assessment of secondary mixed cryoglobulinemia [2018 ICD-10 – CM diagnosis code D 89-1] in chronic infection diseases of human beings which covers tuberculosis [1], typhoid [2], Brucella [3], and tonsilitis [4]. The present work was devoted to assess the cryoglobulin responses among chronic periodontitis patients and their possible use as marker for the herd immunity as well as utility in herd immunity plots.

Material and Method

Twenty two dental diseased patients attending the college of dentistry during the period were diagnosed by the specialist dentist as chronic periodontitis [5]. These patient constitute the study group. Blood samples were drone from patient and sera were saved cryocrit study was made as in [7]. single radial immunodiffusion partigens of IgA, IgG, IgM (Behring Co.) in accordance with manufacturer instruction. Protein determinations were made by Beirut method [8]. Rheumatoid factor testing dene as [6] biometric analysis of the results were done as in [9]

Findings

1- Cryoglobulin:

The separated Cryoprotins found as ; Colloid, opaque, Crystallino or gelatinous in textures, Biuret test positive, precipitated at 4C° within 1-5 days, dissolved at 37C. and reprecipitated 4C°.

2- Cryocrit:

The cryocrit percentages were ranged from 1-8% in periodontitis patients as compared to 1-3% in normal subjects. Table1.

3- Cryoglobulin concentration :

The cryoglobulin concentration were ranged from 90-240 mg/L with the mean value of 188.1 mg/L as compared to 1.3-4 mg/L in control, Table2.

4- Immunofixation :

The single radial immunodiffusion studies for the cryoglobulin isotypes have shown that the periodontitis cryoglobulin responses were of secondary mixed types as IgG- IgM-IgA, Tables 3,4. Rheumatoid factor positive cases were of higher cryoglobulin isotype concentration than that of negative cases table 3-4.

5- Cryoglobulin response And Herd plots

When total cryoglobulin concentration were used as marker for herd immunity three fractions were evident as low, moderate and high responds the herd plots was
of skewed type.

**Fig 2: (Herd plot using Cryoglobulin as a probe)**
Fig 4: (Periodontitis herd plot using IgG as a probe)

Fig 5: (Periodontitis herd plot using IgM as a probe)

Discussion

The separated cryoproteins from the patients sera were characterized as cryoglobulins \[7\] and the immunofixation studies were shown that these cryoglobulin responses were of secondary mixed cryoglobulinemia. The cryoglobulin responses profile was of IgM-IgG-IgA type Table 1-4 \[10\]. These findings were supported by similar results for the cryoglobulin association with tonsillitis patients \[4\]. Rheumatoid factors positive case showing higher cryoglobulin isotype concentration than that Rheumatoid factor negative cases \[10\]. The herd immunity were found to be as low, moderate and high responders.

Cryocrit herd plot was of normal distribution curve. Total cryoglobulin, IgM, IgG, and IgA herd plots were of skewed types \[11,12,13\]. Thus, secondary mixed. IgM-IgG-IgA cryoglobulin response were found in association of chronic periodontitis.

Conclusion

Secondary mixed cryoglobulinemia was found associated with periodontitis patients.

Conflict of Interest: We have no conflict of interest with any academician in any institute.

Source of Funding: It is self

Ethical Clearance: The project was formally registered. The clinical sampling was performed by the dentist of research team using noninvasive standard techniques with satisfaction of the study patients and controls.

Effect of Obesity in the Mode of Delivery

Ban Amer Mousa

MBCHB, DO; FIGOB, Department of Gynecology and Obstetrics/ Babylon collage of medicine/ University of Babylon, Hilla Republic of Iraq

Abstract

Introduction: Obesity is the most common health problem in reproductive age women. The obesity is a heterogeneous illness in which multiple factors interact to produce a state of positive energy balance, which leads to the increase in body weight. Objective: To assess the effect of obesity on the mode of delivery and infant birth weight. Material and method: A cross sectional study was conducted in the Department of OBG, Babylon Teaching hospital for Maternity and child complex from the 1st of Jun 2017 to the end of May 2018. Results: mean age of the respondents was (27.2±9.1) years. (40.4%) of the women were primigravida and (59.6%) were multigravida. (46.5%) were with normal vaginal delivery and (53.5%) delivered by cesarean section. 1108 of the infant were delivered with birth weight ≥4 kg and those who mother with morbidly obese were the main group (29.9%). The caesarean section is increased as the BMI was increased (18.6% for normal to 44.7 for morbidly obese). Birth weight ≥4 kg was increased as the BMI was increased. Conclusion: Caesarean section and infant birth weight ≥4 kg were increased as the BMI of the women were increased.

Key words: Obesity, Normal vaginal delivery, body mass index, primigravida, multigravida

Introduction

Obesity is rapidly becoming one of the major health problems in the developed world. Published estimates of obesity among adult women vary from 18 to 25 %.(1) World Health Organization defines obesity, in women not pregnant, depending on the index of body mass. This index is calculated from size and weight (Kg / m2) and is considered a value normal between 18.5 and 24.9. The overweight is defined as a BMI between 25 and 29.9, is considered obesity moderate (class I) between 30 and 34.9, severe (class II) between 35 and 39.9 and morbid (class III) greater than or equal to 40. Obesity can reduce the life expectancy of a person up to 10 years. (2)

It is also known that is associated with certain pathologies such as hypertension, heart disease, diabetes mellitus type 2, thromboembolisms, osteoarthritis, respiratory problems, dyslipidemia, psychosocial problems and certain cancers in addition to having a negative impact on reproductive health and during the gestational period of the woman. (3) The etiopathogenesis of obesity is complex and intervene by many factors that justify it. The progressive acquisition of Western lifestyles favors on the one hand, sedentary lifestyle; and the absence of interest in participating in some type of physical activity and the high number of hours spent sitting at work they are significant factors of obesity. For another side, both the intake and the composition of the diet play an important role in the pathogenesis of said disease. A high diet in fat, the frequent consumption of fast food and a decrease in the frequency between meals can be associated with an increase of weight. So, these bad dietary habits together with sedentary lifestyle are two of the main responsible increase in obesity in the past 20-30 years. (3)

Pregnancy is one of the periods of greater nutritional vulnerability, estimating an incidence of obesity from 6 to 28% in this era. Faced with a health problem in the pregnancy as emergent as this one, the objective set for this review is to determine in what way affects maternal obesity the course of delivery. Obesity is associated with a series of complications in childbirth,
such as pre-eclampsia (4, 5) or caesarean section (5, 6). As well as thrombo-embolism, congenital malformations, fetal macrosomia, maternal, fetal and neonatal death. Also premature births, hemorrhages and problems of postpartum infection are some of the many dangers that a pregnant woman with obesity runs. An excessive weight gain in the pregnant woman can lead to a delivery with complications, so the limits of this increase must be established according to the body mass index (BMI) before pregnancy. (7)

The different studies have described that the perception of motherhood and the birth of a child will be very different according to the course of pregnancy, the type of delivery and prenatal care and education. (8) When labor is long or becomes instrumental, the experience of women can be comparable to the recovery of a disease and can lead to difficulties in their ability to be emotionally linked to the child. (9)

**Weight During Pregnancy**

Pregnancy is a state of modifications Physiological causes of pregnancy and lactation and the intense growth and development of the fetus. Weight gain total currently recommended during pregnancy and according to the BMI before of pregnancy, it is suggested that it be 11 to 19 kg in twin pregnancy. Pregnant women usually win~ 1 to 2 kg in the first trimester. According the new recommended values, the normal weight women should increase ~ 0.4 kg per week in the second and third trimesters of pregnancy. Women with low weight should earn a little more (~ 0.5 kg per week) and overweight women a little less (~ 0.3 kg per week). Obese women should earn ~ 0.2 kg per week.

**Prevention**

It is recognized that prevention of obesity in women of reproductive age is very important for mother health and the health of her offspring. The interventions of weight control, including pharmacological treatment in pregnant women who are obese or overweight have not had enough impact on pregnancy outcomes and childbirth, suggesting that the focus of intervention must be in the periods preconception or postpartum. (10)

**Aim of the study:** To assess the effect of obesity on the mode of delivery and infant birth weight.

**Material and method**

A cross sectional study was conducted in the Department of Obstetrics and gynecology, Babylon Teaching hospital for Maternity and child complex for 2 years duration from the 1st of Jan 2015 to the end of Dec. 2017. All pregnant women on deliveries who agreed to participate were included and BMI of them were measured.

**Results**

13245 deliveries were included in the current study, with mean age of (27.2±9.1) years. 5357 (40.4%) of the women were primigravida and 7888(59.6%) were multigravida. The main group was in overweight in both primigravida and multigravida (table 1).

| Table 1: BMI and mode of delivery according to gravida of the respondents |
|--------------------|---|---|---|
| Variable           | Total | Primigravida | Multigravida |
|                    | No. | % | No. | % | No. | % |
| BMI group          |     |   |     |   |     |   |
| Normal (20-24.9)   | 521 | 3.9 | 284 | 5.3 | 237 | 3.0 |
| Overweight (25-29.9)| 6812| 51.4 | 2674| 49.9| 4138| 52.5|
| Obese (30-34.9)    | 4422| 33.4 | 1853| 34.6| 2569| 32.6|
| Morbidly obese ≥35 | 1490| 11.3 | 546 | 10.2| 944 | 11.9|
| Total              | 13245| 100.0 | 5357| 100.0| 7888| 100.0|
Table 2 shows that 5357 of the women were primigravida, 2488 (46.5%) were with normal vaginal delivery (NVD) and 2869 (53.5%) delivered by cesarean section. 1108 of the infant were delivered with birth weight ≥4 kg and those who mother with morbidly obese were the main group (29.9%).

For those with multigravida it has been found that normal vaginal delivery were decreased as the BMI of the women was increased (81.4% of those with normal BMI with normal vaginal delivery and this decrease to 55.3% for those with morbidly obese). And the cesarean section is increased as the BMI was increased (18.6% for normal to 44.7 for morbidly obese). Birth weight ≥4 kg was increased as the BMI was increased (Table 3).
Discussion

Many previous studies have noted higher rates of labor induction and induction failure in obese women, and therefore, extremely high rates of cesarean delivery. The results of present study support these previous findings. In fact, the rate of cesarean delivery in our study for women undergoing labor induction was (39.4%), which is in agreement to that found in Subramaniam A et al, (18) (2014).

The current study revealed that as the BMI increases from normal, there is increase in the possibility of a caesarian section for both primigravid and multigravida women. This is same that found by Lynch C et al, (1) (2008). For morbidly obese primigravid women, the caesarean section (Cs) delivery rate was 65.0% compared with 51.1% for those of normal weight. The equivalent figures for multigravid women were 44.7% for those who were morbidly obese and 18.6% for those of normal weight.

To our knowledge, this is the first study to have outlined the prevalence of obesity and its effect on the mode of delivery in Iraqi obstetric population. In this study, 51.4% of women were overweight, 33.4% were obese, and 11.3% morbidly obese, resulting in a figure of 84.8% of women being overweight or obese. These figures are actually more than that published rates by McCarthy S et al, study (2002) on obesity within the general Irish population. This prevalence of obesity is higher than that reported internationally. (20, 21)

Conclusion

Caesarean section and infant birth weight ≥4 kg were increased as the BMI of the women were increased.

Post- Traumatic Stress Disorder among Women with Breast Cancer in Iraq: A Preliminary Report

Aqeel S. Mahmood¹, Mushtaq T. Hashim², Eman A. Al-Kaseer³

¹Dept. of Surgery, College of Medicine, Baghdad University, ²Section of Psychiatry, Dept. of Medicine, College of Medicine, Baghdad University, ³Dept. of Community Medicine, College of Medicine, Baghdad University

Abstract

Background: Diagnostic and statistical manual versions IV AND 5 recognized cancer (life threatening disease) a traumatic event. Exposure to trauma (war or violence) might lead to post traumatic stress disorder (PTSD). Publishing on PTSD after ca breast is scarce in Iraq.

Objective: To comment on the prevalence of PTSD among females with ca breast.

Method: A total of 70 women with cancer of breast after surgery was included in the study. Iraqi version Harvard Trauma Questionnaire (HTQ) was used. It is a self-completed questionnaire.

Results: Out of the total, 81.4% were with PTSD. Women showing PTSD were significantly younger (46.5 ± 10.7 year) than those without PTSD (57.5 ± 10.7 year) (p = 0.002). Of those with PTSD, 93.6% were exposed to > 5 traumatic events during escalated violence in Iraq. The association between number of traumatic events and PTSD was significant (p = 0.001).

Conclusion: High prevalence of PTSD among women treated from ca breast. Age and exposure to traumatic events are determinant of PTSD.

Keywords: PTSD, ca breast, Iraq, trauma, violence.

Introduction

Receiving a diagnosis of breast cancer is likely an impact on mental health of patient. Women affected by breast cancer recall moment of their diagnosis and complain of a series of symptoms may appear (hyperarousal, emotional numbness, intrusive thinking with nightmares).

The diagnostic and Statistical Manual of Mental disorder (DSM) version IV recognized the possibility of diagnosis of post-traumatic stress disorder (PSTD) because of life-threatening disease.¹ In DSM -5 cancer considered a traumatic event only when it is sudden and catastrophic.² Publishing documented the prevalence of PTSD among patients with breast cancer.³⁴ PTSD was originally observed in the military context.

In Iraq, several articles documented the high prevalence of PTSD among youth ⁵, children ⁶, and formerly political prisoners ⁷. Publishing on PTSD among women affected by breast cancer is scarce, which was the impetus to carry out this work.

Materials and method

A total of 70 women with cancer of breast after surgery was participated in this study. Their age was 48.6 ± 11.7 years. They were recruited from Baghdad Teaching Hospital for the period 10th July 2014 to 15th June 2017.

Iraqi version of Harvard Trauma questionnaire (HTQ) was used to assess PTSD and exposure to trauma (physical, sexual and psychological) during wars, civil war and widespread violence.
HTQ was used in Iraq.\textsuperscript{5,7} Its reliability and validity were known. PTSD was assessed by adding the score of 45 questions and dividing by the total score of questions. A score of > 2 was considered as PTSD.\textsuperscript{5}

HTQ is a self-completed questionnaire. It was completed by the women with ca breast after surgery. All participant signed a consent after explanation of the aim and nature of the study.

Chi square was used to examine the association between PTSD (dependent variable) and exposure to trauma (independent variable). Student’s test was used to examine the difference in age between women with and without PTSD. P < 0.05 was regarded significant.

Results

Out of the total participants, 57 (81.4\%) women had PTSD.

The age of women with PTSD was 46.5 ± 10.7 years and those without PTSD was 57.5 ± 10.7 years. The difference in age was significant (t = 3.2, d.f. = 68, p = 0.002) (Table 1).

Of those with PTSD, 44 (93.6\%) women were recently exposed to ≥ 5 traumatic events during her life through the escalated violence in Iraq. The association between exposed number traumatic events and PTSD was significant ($\chi^2$ = 14.1, d.f. = 1, p = 0.001).

Discussion

The study revealed a high rate of PTSD (81.4\%) among women with breast cancer. It is much higher than that reported in Baghdad in 2012 (5\% at any time post cancer diagnosis with liberal criteria).\textsuperscript{8} This difference might be attributed to the differences in methodology (diagnosis of PTSD, criteria of PTSD and questionnaire used for diagnosis). The difference also might be explained by different stages of ca breast. The reported figure (5\%) is much lower than that reported in Baghdad.\textsuperscript{5-7} The reported high rates were explained by heavy exposure to traumatic events escalating widespread violence in the last decade.

The observed rate (84.1\%) is much higher than that reported in literature (0%-32.3\%).\textsuperscript{9,10} The prevalence of PTSD in breast cancer patients resulted in wide variation due to different evidence regarding its prevalence with time. Some studies attested higher prevalence of PTSD soon after diagnosis than at end of active treatment. Other outlined an increase in the prevalence at end of treatment.\textsuperscript{8} This study was carried out after surgery.

Methodological heterogeneity which is in turn lead to variability in results might be an explanation for variation in reported figures and the observed one.

Diagnostic and Statistical Manual of Mental disorders (DSM) version 4 recognized that it is possible to get PTSD because of life-threatening disease.\textsuperscript{1} In DSM-5 a medical disease such as cancer is considered a traumatic event only when it is sudden and catastrophic.\textsuperscript{8}

In Iraq, no screening program for ca breast,\textsuperscript{10} and centers in tertiary hospitals depend on self- referring women which in turn ca breast usually presented late. A delay in diagnosis might be due to the bad eroding of health system\textsuperscript{11} wars and widespread violence. Then, diagnosis with ca breast in Iraq is catastrophic which in turn is a traumatic event that is comply with DSM-5. This situation (late presentation of ca breast) might explain the high prevalence of PTSD among women with ca breast in Iraq.

The finding that PTSD was significantly higher among younger patient is in consistent with that of other studies.\textsuperscript{10}

This study showed that PTSD was significant high prevalence (93.6\%) in women exposed to ≥ 5 traumatic events.
events. It is consistent with that of other articles in Iraq.57

Several articles13,14 stressed that the ca breast might play a less role in development of PTSD. It was suggested that the role ca breast among predictors of PTSD (e.g. exposure to war, widespread violence, conflict …etc.) is augmented in development of PTSD. This opinion further provides an explanation for the high prevalence of PTSD among women treated for ca breast.

Conclusion

High prevalence of PTSD among women treated from ca breast. Age and exposure to traumatic events are determinant of PTSD.

Molecular Diagnosis and Phylogenetic Analysis of 5.8s rDNA Gene of Cutaneous Leishmaniasis Species in Holy Karbala/Iraq

Dhamiaa Maki Hamza¹, Laith Hasan Obayes¹, Fadhil Sami Zghair²
¹Dept. of Microbiology/ College of Medicine / Karbala University, Karbala, Iraq, ²Dept. of Medical Laboratory / Babylon technical institute/Al-Furat Al-Awsat Technical University, Hilla, Iraq

Abstract

Objective: To identify Leishmania species in patients with cutaneous leishmaniasis (CL) in the Holy Karbala in Iraq from November 2017 to the end of January 2018.

Method: Among 100 patients were examined by dermatologists for CL at Al-Husseini Hospital with suspected stained slide smears of 92 patients showed positive result for Leishmania., The aspirated material was inoculated in Biphasic Medium which used for maintaining and cultivating Leishmania spp. polymerase chain reaction (PCR) protocols were used to amplify a region of the ribosomal DNA amplicon of Leishmania (5.8s rDNA gene). Sequencing of amplified products was done by Microgen company/USA through using by forward primer for 5.8s rDNA gene in sequencing reactions by Applied Bio system ABI Prism 377 DNA sequencer at Molecular biology department in Korea.

Results: Of 92 positive sample of Leishmania, 20 (21.7%) belonged to females and 72 (78.3%) belonged males. The PCR assays detected Leishmania major in all samples their ages ranged from (10-19 years) 6(6.5%), while ages ranged from (20-29 years) 11(11.9%), and ages ranged from (30-39 years) 17(18.5%) while the age (40-49) 37 (40.2%) and (50-59) 21 (22.8). The occupation in kids 3(3.2%), students 11(11.9%), soldiers 34(36.9%), workers 20 (21.7%), Employees 9 (9.8) and house wives 15(16.3%). Most of the lesions were found on the exposed areas of the body: face 25 (27.2%), hands 44(47.8%), Legs 11(12%), and ears 12(13%)

Conclusion: Cutaneous leishmaniasis with diverse clinical manifestation, is prevalent in karbala city caused by L.major and all of isolates is similar in 5.8s rDNA gene sequence closest with Iranian isolate genetically and distant for chinese isolate.

Keywords: cutaneous leishmaniasis, Leishmania major, Molecular diagnosis, phylogeny, 5.8S rDNA Gene.

Introduction

Leishmaniasis is endemic in many parts of the world and it is found in different part of Iraq (¹). Leishmania tropica and Leishmania major are, respectively, the main causative agents of anthroponotic cutaneous leishmaniasis (ACL) and zoonotic cutaneous leishmaniasis (ZCL) (²).

Definitive diagnosis of species that caused the disease is essential to select the proper and effective treatment of various forms of infection as well as control the disease in a region (³).

Direct smear method for diagnosis the disease is the traditional technique used for patients who infected with Leishmania lesions. The direct smear has less sensitivity compared with PCR molecular techniques on leishmanial diagnosis (⁴,⁵).

Many different PCR targets, including the coding and intergenic noncoding regions of the gp63 gene locus, splice leader mini-exon (SLME), the SSU rRNA gene, the ITS1 region and 5.8s rDNA have been used for the identification of parasites from cultures and for their direct detection in various animal, sand fly, and human tissues (⁶,⁷,⁸).
The aim of this study was to investigate the Molecular diagnosis of the *Leishmania* species that caused cutaneous leishmaniosis in Holy Karbala and study of sequencing of 5.8s rDNA in isolated specimens by multiple sequence alignment analysis and phylogenetic tree analysis to compare between the local isolated species and the global species recorded in NCBI.

### Materials and Method

**Samples Collection**

One hundred patients with lesions clinically suggestive of CL were evaluated in the outpatient dermatology clinic in a teaching hospital in Karbala, Iraq. The laboratory work was performed in the Department of Microbiology, College of Medicine, University of Karbala /Iraq. The study was performed between November 2017 to the end of January 2018.

After a detailed clinical and epidemiologic history had been obtained, The primary isolation was made from patients with cutaneous lesions. The puncture site (lesion) was cleaned with 70% ethanol before sample aspiration. 1 ml syringe containing 0.1-0.2 ml of sterile saline was inserted intradermal into outer border of the lesion. The syringe was rotated and the tissue fluids were gently aspirated into the needle while its withdrawal.

The aspirated material was inoculated in culture tubes containing five ml of NNN medium. All inoculated tubes were incubated at 25º C. All cultures were incubated and examined for 15-30 days before being considered negatives. Patients were positively diagnosed for CL when actively motile promastigotes were seen in culture(9).

**Molecular diagnosis by Nested PCR for 5.8s rDNA gene**

Nested PCR performed *Leishmania* spices in only 50 patients because of the difficult circumstances in Iraq. Specific primers for 5.8s rDNA gene were derived as forward (GCA GCT GGA TCA TTT TCC) and reverse (ATA TGC AGA AGA GAG GAG GC), (10).

The PCR products were analyzed by 5% agarose gel electrophoresis with 8 mL of the reaction mixture, and the bands on an ethidium bromide stained gel were visualized and photographed under UV light with a Polaroid MP4+ system.

**DNA sequencing methods**

DNA sequencing method performed for confirmative detection and Phylogenetic analysis of the local species of *Leishmania* that responsible for Cutaneous leishmaniasis based on 5.8 rDNA by Phylogenetic tree analysis using the program (MEGA 6), while the Test type was UPGMA tree (bp) PCR product of species *L. major* were purified from agarose gel and sequenced by Macrogen company/USA through using forward primer (GCT GTA GGT GAA CCT GCA GCA GCT GGA TCA TT) and reverse primer (GCG GGT AGT CCT GCC AAA CAC TCA GGT CTG). The sequencing Applied by Bio

**Results**

The current study included 92 CL patients which categorized into 72 (78.3%) males and 20 (21.7%) females. Ages ranged from 10-19 years (6.5%), ages ranged from 20-29 years (11.9%), ages ranged from 30-39 years (18.5%), age (40-49) was (40.2%), and (50-59) was (22.8%). The occupation in kids (3.2%), students (11.9%), solders (36.9%), workers (21.7%), Employees (9.8), and house wives (16.3%). Most of the lesions were found on the exposed areas of the body: face (27.2%), hands (47.8%), Legs (12%), and ears (13%).

Sequence analysis of twelve positive samples of *L. major* were performed to confirm the PCR results. The Multiple sequence alignment analysis of 5.8s rDNA of *L. major* was shown in the (Fig. 5,7), while the Phylogenetic relationship tree analysis was constructed based on the twelve local samples of species *L. major* compare between them (Figure 4) and for compare with global species through MEGA 6 program used of the test from type (UPGMA tree) as shown in the (Fig.

Figure (1): Male 30 years old with typical lesion of CL on the upper limb, an ulcerated nodule lesion on the arm, well circumscribed with a necrotic base and indurate margin

Figure (2): A 5 years old child with typical lesion of CL on the face, an ulcerated nodule lesion behind the ear, well circumscribed with a necrotic base and indurate margin.

All samples showed bands, which indicated the genomic DNA on Agarose Gel Electrophoresis

The presence of the 5.8s rDNA gene was identified by 462bp as shown in Figure (3).

Figure (3): Agarose gel show the PCR product results for *L. major* of 5.8s rDNA where M: 1500bp Ladder, Lane [1-20] are 462 bp positive samples.

Figure (6): The comparison between the phylogenetic Tree analyses of twelve local samples [K1-K12] of *L. major* with global *L. major*.
Leishmaniasis is endemic in more than 80 countries. Its overall global prevalence is estimated to be around 12 million cases and this figure increases by 1.5–2 million each year. CL occurs in 82 countries and 1.5 million new cases are recorded every year (11). Migration, travel, and ecological changes contribute to this increase. Host, parasite, and vector characteristics determine the occurrence and course of the disease (12). CL is highly prevalent in our neighboring countries of Turkey, Iran, and Syria and there are massive migratory flows into Iraq from these countries, both controlled and uncontrolled (13). An outbreak has occurred with the current war against ISIS in the north of Iraq and increased the migration from this area to Middle Euphrates Region and the lack of services provided to the displaced and the poor living conditions led to the spread of cutaneous leishmaniasis among the displaced as well as spread the CL among the soldiers returning from the battlefield in the north (14).

In the current study, the frequency of male was higher than of female It could be due to more contact of men with vectors based on the type and time of their work compared with women. Although most age groups were at risk of the disease, but based on obtained results, the prevalence of CL was higher in age group 40 - 49 years old because most of them are soldiers or migrated. The effect of age might be actually influenced by disease endemcity and immune reactions of the host (15).

Traditional techniques (direct examination and culture) commonly used for diagnosing leishmaniasis do not differentiate Leishmania species and their sensitivity is also less than molecular techniques (16). It is possible that infections of Leishmania parasites will be missed due to disparate growth rates of different parasites in blood agar cultures (17). Nested PCR provides a rapid, sensitive, and specific alternative to traditional techniques (18). In the current study, Leishmania promastigotes isolated from patient samples were typed with Nested PCR and DNA sequencing using primers specific for the 5.8s rDNA. The 5.8s rDNA that were similar to those obtained with standard Leishmania strains was chosen as the target for the diagnostic PCR analysis because 5.8 of the ribosomal DNA repeat unit has previously been used to distinguish Old World Leishmania species using Nested and DNA sequencing. The sensitivity of the 5.8s rDNA analysis has been demonstrated and PCR is an efficient technique for the identification of Leishmania species.

In patients with CL, the lesions differ throughout the clinical course of the disease and in response to treatment, depending on the causative agent. In the present study, the Leishmania species isolated from samples was identified as L. major. Leishmania major is the predominant cause of CL in the Iraq.

The Phylogenetic relationship tree analysis according to (Mega 6) program from type (Test UPGMA tree) to compare between the local L. major showed a high similarity between them except the sample k2 which taken from traveler came from china.

The results of Multiple sequence alignment analysis of 5.8s rDNA gene in the PCR product of twelve samples of species L. major (K1-K12) with global strains shows great affinity with Sudan, Iran, USA, Germany and France while there is a different in the sequencing between the local strain and the China strain.

Obtained results highlight the need to find a universally accepted diagnostic tool for Leishmanial typing, that is sensitive and capable of identifying all clinically significant Leishmania species. The risk of transmitting this “flesh-eating” parasite into the Iraqi society is high. Thus, effective prevention methods and appropriate therapy is critical. Prevention can be as simple as using nets treated with insecticide or spraying insecticides to kill sand-fly vectors (19). For the differentiation of Leishmania at the sub-species level, it is recommended to perform multi-locus sequence typing (MLST) method.

Moreover, whole-genome sequencing (WGS) provides a greater potential to identify genetic component of health problems and infectious diseases (20). Accessible international databases for cases of leishmaniasis in the MENA region (Middle East and North Africa) should be created for a better epidemiological assessment of these infectious agents and for tracing their patterns of migration between countries and continents.
Conclusion

Cutaneous leishmaniasis with diverse clinical manifestation, is prevalent in Karbala city caused by *L. major* and all of isolates is similar in 5.8s rDNA gene sequence closest with Iranian isolate genetically and distant for Chinese isolate.

Conflicts of Interest: None of the authors have any conflicts of interest relevant to what is written.

Funding Source: University funding was provided for: data collection, analysis, and interpretation; trial design; patient recruitment. No public funding was received.

Acknowledgment: Authors would like to express their thanks and gratitude to Prof. Alaa H. Al-Charrakh, University of Babylon, for his critical reading of the manuscript.

Ethical Clearance: The study was conducted in accordance with the ethical principles that have their origin in the Declaration of Helsinki. The study protocol and the subject information and consent form were reviewed and approved by a local Ethics Committee.

Abstract

Background: Endocrine epithelial cells, targets of the autoimmune response in thyroid and other organ-specific autoimmune diseases express HLA class II molecules that are presumably involved in the maintenance and regulation of the in-situ autoimmune response. Presents a clear linkage with MHC class II. Moreover, the common auto antigen in either species. A number of studies have shown that either a reduction in the number of T regs or a reduction in the suppressive abilities of the T regs may cause self-reactive T cells to remain and lead to autoimmune disease. Human autoimmune thyroid diseases (AITD), such as Hashimoto’s thyroiditis and Graves’ disease (GD), are characterized by T and B cell infiltration of the thyroid gland and an intense immune response to well-characterized thyroid auto antigens such as thyroglobulin (Tg).

Aim of the study: To identify any role for certain alleles in occurrence of the disease.

Material and Method: Five ml of venous blood samples withdrawn from 30 patients suffering from confirmed thyroiditis disease, 18 patients were females and 12 males in addition to 30 healthy control samples were enrolled in this study all samples were subjected for (ELISA test) (Enzyme Linked Immunosorbent assay) to estimate the TNF-α, and IL-10 Levels by using three ml of blood to extract the serum. Another two ml was used for DNA extraction, and then HLA-Class II genotyping was performed by polymerase chain reaction-sequence specific oligonucleotide probes (PCR-SSO).

Results: HLA-class II genotyping of thyroiditis patients in comparison with healthy control evoked significant differences in some alleles between both groups. Among DR HLA-DRB1 polymorphism determines susceptibility to autoimmune thyroiditis alleles there were some alleles showed higher frequency in patients group; DR*0403 allele showed increase frequency in patients groups with 35% compared with 6.67% in control group, and the P value was 0.020, which is considered as statistically significant. Another DR*701 allele showed increase frequency in healthy groups with 9 cases 30% and the P value was 0.007. A significant elevation in IL-4 levels and a highly significant increase in IL-10 levels was reported in Thyroiditis patients.

Keywords: Thyroiditis, Genotyping, alleles, IL-4, IL-10.

Introduction

Endocrine epithelial cells, targets of the autoimmune response in thyroid and other organ-specific autoimmune diseases, express HLA class II (HLA-II) molecules that are presumably involved in the maintenance and regulation of the in situ autoimmune response. HLA-II molecules autoimmune thyroid diseases have led to studies of their association with human major histocompatibility complex (MHC) class II genes. One such gene implicated in Hashimoto’s thyroiditis (HT) is HLA-DR3, but the association is weak and is contradicted by other reports. HLA-DRB1 polymorphism determines susceptibility to autoimmune thyroiditis and implicates

Corresponding author:
Samir Sabaa;
Department of Microbiology / Collage of Veterinary Medicine – Al-Muthanna University;
email: ssrj1964@yahoo.com
Tg as an important autoantigen. Several studies in Caucasians have implicated both DRB1*0301 (DR3) and DRB1*11011 (DR5). A negative association with DR3 or lack of any DR region association has also been reported. DRBI polymorphism is a determining factor in susceptibility to autoimmune thyroiditis.

Initially the symptoms of HT may not be apparent. As the disease progresses and hypothyroidism becomes more severe, visible symptoms may occur. Common symptoms include intolerance to cold, mild weight gain, fatigue, constipation, dry skin, hair loss, heavy and irregular menses, difficulty concentrating or thinking, joint stiffness and facial swelling. In some cases, mild thyrotoxicosis and sometimes transient elevation of free T3 and T4. Hyperthyroidism, in extreme cases myxedema (dermal and cutaneous edema caused by deposit of large amounts of mucoproteins in the tissues) leading to a coma may occur. An enlarged swelling in the neck or goiter may also be present as a result of either inflammation or hashimotoxicosis and late in the disease a small or atrophic thyroid gland. If a goiter is present it may be unilateral or bilateral and will be diffuse and firm with pyramidal lobe enlargement. Although it is clear that auto antibodies are present in HT, their exact role in the pathogenesis of the disease remains to be unclear whether the auto antibodies present are the trigger or the result of an autoimmune attack. This is due in part to the variable titers of auto antibodies detected in HT patients.

Materials and Method

Blood Samples: Five ml of venous blood were obtained from each subject, from which 2 ml were kept in EDTA tubes for DNA extraction, and the other 3 ml in plane tubes from which serum was obtained and kept at -20°C until use. The patients related to the medical city in Baghdad- orthopedic unit, during the period from February to August 2017, in addition to thirty healthy control group enrolled in this study.

DNA Extraction and Genotyping: DNA was extracted from whole blood using ready kit (KIAGEN/ Germany) according to the manufacturer’s instructions. Sequence-specific oligonucleotide primed PCR (PCR-SSO) method was used for the amplification of HLA-DRBI and HLA-DQ using ready kit (Lipa HLA DRB, Innogenetics. Murex Biotech Limited, Dartford, UK). Molecular typing of HLA alleles was performed using a reverse hybridization Automatic Line probe assay (Auto-Lipa) supplied by the same company, in which typing tests were based on the reverse dot blot hybridization. Positive probes on each strip were recognized by typing table (provided with the kit).

Serum levels of TNF-α, IL-10: Commercial kits were utilized for estimation of serum levels of IL-10, TNF-α, (Demeditec Diagnostic/ Germany) and using automated ELISA apparatus ((Diagnostic Automation Inc, USA) and following the manual protocol supplied with each kit.

Statistical Analysis: The Statistical Package for the Social sciences (SPSS, version 14) was used for statistical analysis. The association between different alleles and the development of RA was calculated through adjusted odd ratio and 95% confidence intervals using Chi-square test. Serum levels of cytokines were quantititative variables, but were non-normally distributed as shown by Shapiro-Wilk test. These variables are better to be analyzed by nonparametric test, and median but not mean was calculated. The Mann-Whitney test was used to further explore the significance of difference in median between each pair of study groups. The P value < 0.05 was considered statistically significant.

Results

Two class II HLA-DR alleles showed a significant increase in frequency; *0403 occur in 7(35.00%) patients and 2 (6.67%) in healthy control group. The significant allele was *0701 q which occur in 9 (30.00%) in healthy group compare to 0 (0.00%) in patients group.

Discussion

An environmental causal factor such as variation in iodine levels or bacterial/viral infection may affect the thyroid causing an inflammatory response and an influx of dendritic cells and macrophages which could be the trigger to activate other immune cells resulting in an autoimmune response. This theory also links to the Selenium therapy mentioned in the discussion of the treatment of HT. A deficiency in the levels of selenium would cause a prolonged and intensified inflammatory response. This may then cause a heightened sensitivity to pathogens resulting in self antigens being recognized as non-self. Dietary intake of iodine, cigarettes, alcohol and some bacterial infection.

This is usually performed by typing each individual patient and each control for the tested marker, but recently, methods for DNA pooling have been developed, which could simplify large-scale association studies. If the allele tested is associated with the disease, it will appear significantly more frequently in patients than in controls. The probability of having the disease in an individual positive for the allele compared with an individual negative for the allele is estimated by the RR.

Conflict of Interest: This research is a personal non-profit work and there is no conflict of interest.

Source of Funding: None.

Ethical Clearance: Ethical clearance was obtained from the Faculty Scientific Committee (1Department of Microbiology /Collage of Veterinary Medicine –Al-Muthanna University) to study the association of certain HLA–II/ DR alleles with incidence of thyroiditis in Iraqi patients.

Factors Associated with Self-Empowerment among Patients with Diabetes Mellitus in South Kalimantan

Endang Sri Purwati Ningsih, Syamsul Firdaus
1Department of Nursing, Health Polytechnic of Health Ministry Banjarmasin, Indonesia

Abstract

Background: Self-empowering among patients with diabetes mellitus is needed to prevent complication. Self-empowering is influenced by individual factors such as gender, experience for caring diabetes mellitus and eating habit; psychological factors such as self-efficacy and coping; and health literacy such as access to health care services and provider interaction. Objective: The aim of this study was to investigate the factors associated with self-empowerment among patients with diabetes mellitus in South Kalimantan. Method: This study was observational study and used cross-sectional design. Data were collected from patients with Diabetes mellitus using cluster random sampling at 3 hospitals in South Kalimantan Province. Total sample was 250 patients and also used self-report questionnaires. We used chi-square test to measure correlation between independent variable and dependent variable and logistic regression was used to investigate the factors relate to self-empowerment among patients with diabetes mellitus, p-value ≤ 0.2 was considered to analyze the variables into logistic regression. Results: According to chi-square test results, there was significant difference existed in the frequency of eating habits, caring experience, provider interaction, and self-empowerment. Furthermore, there was no significant difference between the two groups for gender, self-efficacy, coping strategies, access to health care services and self-empowerment. In addition, logistic regression showed provider interaction (odds ratio [OR], 50.545; 95% confidence interval [CI], 8.671 to 294.651) and eating habit (OR, 5.086; CI, 1.026 to 32.079) increased self-empowerment Conclusion: Provider interaction and eating habit had significant increase on self-empowerment. Keywords: Self-empowerment, Diabetes mellitus, Health literacy, Psychological, Eating habit

Introduction

Diabetes Mellitus (DM) is described as a metabolic disease with characteristics of an increase in blood sugar levels. A person with DM experiences a high risk of developing life-threatening health problems, increasing health costs, decreasing quality of life and increasing mortality (1). The number of people with diabetes mellitus was 415, with 46.5% undiagnosed. In fact, 1 out of 11 adults have diabetes. Furthermore, it is estimated that the number of diabetics worldwide will increase. In Indonesia recorded that 29 million people had impaired glucose tolerance and will increase to 36.8 million in 2040 (2).

Based on the results of data from basic health research (RISKESDAS) (2013) showed that the population with diabetes mellitus in south Kalimantan province was 2,722,366 and only 38,113 were diagnosed with diabetes. The remainder of this population with diabetes never been diagnosed but in the last 1 month, they have symptoms such as frequent hungry, thirsty, and urination in large quantities also weight loss (3).

Patients with diabetes mellitus must have good control life style and self-management, if they have poor management, it will increase the risk of complications and morbidity (4). Complication can be a burden for patients with diabetes mellitus (5). Complications could be prevented through patient-empower. Self-empowering among patients with diabetes mellitus requires active participation from patients, families and the communities (6).
Self-management in chronic disease is needed (7). Self-management could be increased by self-empowering (8). Patient empowerment is a “paradigm shift” from traditional service providers centered on the medical model to patient-centered collaborative care (6). Self-empowering is influenced by individual factors and psychological factor (9). Individual factors such as cognitive and behavior, in addition, psychological factor was related with self-efficacy that was how confident patients to care of their selves (7). Self-empowerment also can be reached through health literacy such as access to health care and interaction of health care provider (10). Self-empowerment is needed for patients with diabetes mellitus to increase their health status (11). So the aim of this study was to investigate the factors associated with self-empowerment among patients with diabetes mellitus in south Kalimantan.

Method

Research Design

All procedure already granted by IRB from Health Polytechnic Banjarmasin number 065/KEPK/2017. This study was observational study and used cross-sectional design. The aim of this study was to analyze factor related to self-empowerment among patients with diabetes mellitus. This study examined whether the relationship between characteristic, there were gender, experience for caring family members with diabetes mellitus, knowledge in term of Diabetes mellitus, and eating behavior; psychological factors there were self-efficacy and coping strategies; health literacy, that were access to health care service and provider interaction that affecting self-empowerment (dependent variable) for patients with diabetes mellitus.

Participants and setting

The setting of this study was 3 hospitals in South Kalimantan province. Data were collected from patients with Diabetes mellitus using cluster random sampling. The inclusion criteria were age 25-65 years old, can communicate, read and write and no hearing loss. Total sample was 250.

Instruments

We used self-report questionnaires to measure all variables.

Socio-demographic respondents

We asked participants in term of age, experience for caring family members with Diabetes Mellitus, and eating behavior. In term of eating habits, we asked about diet pattern, consumption food with coconut milk, sugar, fried food, and consuming fruits and vegetables (12).

Psychological factors

Self-efficacy

We adopt self-efficacy scale Standford University to measure self-efficacy (13). It consisted of 6 items. The cronbach alpha of this questionnaire was 0.857.

Coping strategy

We developed the questionnaire from Stuart and Sundeen (1991) (14). It consisted of 10 items and had good internal consistency with The cronbach alpha was 0.779.

Health literacy

We modified from health literacy questionnaire from Osborne RH (2013) (15). It has 2 domains, Access of health care and provider interaction. It consisted of 9 items and the cronbach alpha of this factor was 0.731. Another factor was provider interaction, it consisted of 6 items The cronbach alpha of this factor was 0.822.

Self-empowerment

We adopted and modified self-empowerment questionnaire from The Diabetes Empowerment Scale-Short Form (DES-SF) (16). The final version of this questionnaire consisted of 7 items. The cronbach alpha of this questionnaire was 0.822.

Data analyses

Data were analyzed with SPSS for windows (p-value of < 0.05 was considered to describe statistically significant difference. Socio-demographic of respondents, psychological factors, and health literacy were used to categorize subjects as low self-empowerment and high self-empowerment and we used chi-square test to measure correlation between independent variable and dependent variable. Logistic Regression was used to investigate the factors relate to self-empowerment among patients with diabetes mellitus, p-value ≤ 0.2 was considered to analyze the variables. We used internal consistency to calculate cronbach alpha. Cronbach alpha > 0.5 was considered
Results

Socio-demographic and self-empowerment

In this study the respondents that complete all of questionnaire were 250 patients that were, 90 men and 160 women. Based on gender most of participants had high self-empowerment, with female higher than male. In addition, there was no significant difference between the two groups for gender and self-empowerment. In term of eating behavior, most of respondents with high self-empowerment had healthy eating behavior. There was significant difference existed in the frequency of eating habits and self-empowerment. Furthermore, there was significant difference between the two groups for caring experience and self-empowerment.

Factors associated with self-empowerment

There was significant positive correlation existed in the two groups for provider interaction. In addition there were no significant correlation existed in the two groups for self-efficacy, coping strategies, and access to health care services. We conducted logistic regression to analyze factors associated with self-empowerment, with variables that had significance level of ≤ 0.2 in the univariate analysis. Provider interaction and eating habit had significant increase in high self-empowerment.

Discussion

The aim of this study was to investigate the factors associated with self-empowerment among patients with diabetes mellitus in South Kalimantan. According to
chi-square test results, eating habits, caring experience, provider interaction was shown to be factors for self-empowerment. In addition, logistic regression showed provider interaction and eating habit increased self-empowerment.

Socio-demographic such as eating habits was one of factors associated with self-empowerment among patients with diabetes mellitus. This finding was consistent with previous study that habits or behavior also cognitive were factors associated with self-empowerment (7). Behavior was reflected good self-management for caring for chronic disease (7) and good self-management will induce good self-empowerment (8). Also caring experience was one of factors associated with self-empowerment. This finding was consistent with previous study that experience will lead to good self-management (7,10) and it relates to self-empowerment (8).

Our study also showed that provider interaction was factors associated with self-empowerment. Provider interaction is a part of health literacy (15). This finding was consistent with previous study that health care providers contribute to patient self-empowerment. Positive interactions between patients and health care providers contribute to increasing confidence. This good interaction ends with the patient’s positive attitude, satisfaction and active involvement in care (19). Health Literacy without self-empowerment will decrease ability to protect health status (20).

Furthermore, our study showed that self-efficacy and coping strategies were no significant difference in self-empowerment among patients with diabetes mellitus. This study was not consistent with previous study (7,10). We assumed that it relates with characteristic of respondents. Our respondents had time variance of suffering diabetes mellitus from less than one year to more than ten years.

Our study had limitation that was we collect the data used cross-sectional design so the results may be generalized carefully but this study help to identify factor related with self-empowerment among patients with diabetes mellitus. Longitudinal study is needed to develop model in term of self-empowerment among patients with diabetes mellitus.

Conclusion

Provider interaction and eating habit had significant increase on high self-empowerment. Further study is needed to motivate patients with diabetes mellitus in term of eating habit also for health care provider to interact with patients to improve self-empowerment.

Irisin, Resistin and 25-Hydroxyvitamin D in Iraqi Obese and Non-Obese Type 2 Diabetic Patients

Gumar O Zamil¹, Halla G Mahmmod², Basil O Saleh³

¹Clinical Biochemistry, Ibn Al-Baladi Children’s and Women’s Hospital, Ministry of Health, Baghdad, Iraq, ²Clinical Biochemistry, Department of Biochemistry, College of Medicine, University of Baghdad, Baghdad, Iraq, ³PhD, Clinical Biochemistry, Department of Biochemistry, College of Medicine, University of Baghdad, Baghdad, Iraq

Abstract

Objective: evaluate the serum levels of irisin, resistin, and vitamin D in a population of Iraqi obese diabetic men and to compare non-obese diabetic men.

Methods: A case-control study, carried out from July 2017 to January 2018, and included 160 men; 80 patients with type 2 diabetes mellitus (DM) and 80 aged- and BMI matched apparently healthy men. The Subjects subdivided according to their BMI into; obese, overweight and normoweight. Investigations included serum measurements of fasting serum glucose (FSG) and lipid profile, 25-Hydroxyvitamin D, resistin, irisin and insulin.

Results: Serum resistin levels and 25-hydroxyvitamin D did not differ significantly among groups of diabetic men and healthy men with respect to their obesity. Serum irisin concentrations were significantly decreased in diabetic obese when compared with that of healthy obese. While, the mean values of serum irisin of diabetic overweight and diabetic normoweight were higher than those of healthy overweight and normoweight, but did not reach the significant level. The results also showed that there was significant positive correlation between serum 25-hydroxyvitamin D levels and irisin concentrations in diabetic obese group (r=0.398, P<0.022).

Conclusion: The present study suggested the significant role of irisin myokine in pathogenesis of diabetes mellitus type 2, while that of resistin and vitamin D need to be evaluated in one more large study. Obesity may have an important effect on blood levels of irisin and vitamin D.

Keywords: Diabetes mellitus, obesity, 25-hydroxyvitamin D, Irisin, resistin

Introduction

Diabetes mellitus (diabetes) is a metabolic disorder with heterogeneous etiologies, which is characterized by chronic hyperglycemia and disturbances of carbohydrate, fat and protein metabolism resulting from defects in insulin secretion, insulin action or both¹. Obesity has been recognized as one of the most important single risk factors in the pathogenesis of type 2 diabetes mellitus. In obese individuals there are marked increases in the secretion of pro-inflammatory adipokines including resistin, IL-6 and TNF-α and decreased production of anti-inflammatory adipokines such as adiponectin², ³. In humans, resistin is mainly secreted by macrophages, which suggests that resistin is linked to inflammation. Obesity and T2DM have been recognized as chronic inflammatory disorders that may be connected to pro-inflammatory cytokines and various adipokines, including resistin⁴. Irisin is a myokine that causes brown coloration of white fat, promotes fat burning and inhibits weight gain. Irisin is associated with glucose/lipid metabolism⁵ and may prevent obesity and onset of diabetes⁶, ⁷.

Vitamin D is not only essential for maintaining bone health, but it also plays a role in several other biochemical mechanisms within the human body. The mechanism of action of the active form of vitamin D is similar to that of other steroid hormones and is mediated by its binding to vitamin D receptor (VDR). VDRs are found in most tissues, not just in those that participate in the classic actions of vitamin D such as bones, intestines and kidneys, and the enzyme responsible for converting 25 (OH)D to 1,25(OH)2D is also expressed in a variety of extra-renal sites, such as endothelial cells, beta cells, and immune cells. The complex biochemical interactions between adipose tissue and vitamin D in vitro raise the question as to whether hypovitaminosis D itself, may contribute to obesity or inhibit weight loss in vivo. Several studies have indicated a relationship between vitamin D status and the risk of diabetes or glucose intolerance. Vitamin D has been proposed to play an important role and to be a risk factor in the development of insulin resistance and the pathogenesis of type 2 DM by affecting either insulin sensitivity or β-cell function, or both. The aim of the present study is to evaluate the serum levels of irisin, resistin, and vitamin D in a population of Iraqi obese diabetic men and to compare the results with those of non-obese diabetic men.

Method

Study design

This case-control study was carried out at Department of Biochemistry, College of Medicine, University of Baghdad, at Al-Imam Ali Hospital and at Research laboratory for the College of Health and Medical Technology/Baghdad, Iraq during the period from July 2017 to January 2018. It consisted of 160 men subjects; 80 men patients with type 2 diabetes mellitus and 80 apparently healthy men age and BMI matched with patients. The patients and controls were also subdivided according to their obesity into different groups: normo-BMI group which consisted of 28 men with BMI range between 18.5 – < 25 kg/m² and aged (40 – 65 years), overweight group consisted of 19 men with BMI range between 25 – < 30 kg/m² and aged (40 – 65 years), and obese group which included of 33 men their BMI was more than 30 kg/m² and aged (40 – 65 years). Formal consent was taken from each men.

Data setting

Blood sample was taken in the fasting state from peripheral vein of each patient and control. The aspirated blood sample allows clotting for 30 minutes, centrifuged at 3000 rpm. The fasting serum glucose and lipid profile parameters were measured in the same day of blood collection by Abbott c4000 automatic biochemical analyzer. The remainder fraction of separated serum was frozen at – 20 °C until the day of estimation of serum insulin levels using enzyme immunoassay kit (Demeditec, Germany), homeostasis model assessment of insulin resistance (HOMA-IR) and (HOMA-B) were derived from fasting glucose and insulin level by using equation, serum irisin levels were determined by using a commercially available human ELISA kit (cat no. MBS2600406, MyBiosource, USA), serum resistin was measured by using a human resistin demeditec elisa kit (Germany), and serum 25(OH)D level was estimated by using a commercially available human 25-hydroxyvitamin D ELISA kit (Human, Germany).

Statistical analysis

Statistical analysis was performed by using SPSS version 24 for window was used for all statistical analysis. Statistical significance was assessed by ANOVA and student t-test. The linear regression test was applied for the correlation between different parameters, and the significance of the p-value was checked using t-test. P-value of less than 0.05 was considered significant.

Discussion

In the present study, the serum 25(OH)D values were lower than the ideal level of 32 ng/mL (80 nmol/L). However, the range of the serum 25(OH)D concentration in the participants was in accordance with that in a number of other studies establishing the prevalence of vitamin D deficiency in T2DM. In our study the controls (normo-BMI, overweight, obese) presented mean vitamin D levels within the lower range of vitamin D insufficiency and averaging (20.31±6.70, 18.78±5.02, 19.1±5.69 ng/mL, respectively). This finding corresponds to concentrations reported for the Central European general population (17-to-33 ng/mL in mean) from cities in similar latitude. For obese patients with diabetes, we revealed a significant positive correlation between irisin and serum 25(OH)D levels (r= 0.398, p=0.022). This finding corresponding with Nasser M Al-Daghri et al. who found a significant increase in circulating irisin at 12 months post-vitamin D intervention. The elevation in circulating irisin was parallel to the increase in vitamin D level. The possible mechanisms of the involvement for 25(OH)D include the following; 1) Vitamin D can reduce IR in peripheral tissues by regulating inflammatory cytokines and inhibiting the expression of PPAR-γ. Besides, it can affect insulin sensitivity by stimulating PPAR-δ and the gene expression of insulin receptor. 2) Another possible mechanism may involve the direct involvements of both irisin and vitamin D in energy metabolism and regulation as well as adipocyte biology through uncoupling proteins.
Resistin is an adipokine that functions as a pro-inflammatory biomarker and a mediator of obesity-related insulin resistance. The pro-inflammatory effects of resistin were attributed to its ability to activate the nuclear factor-κB signaling pathway and subsequently enhance the production of pro-inflammatory cytokines, including TNF-α and IL-6, which impair insulin signaling pathways and result in the development of insulin resistance. In addition, TNF-α and IL-6 have been shown to alter the expression of PPARγ in adipocytes. PPARγ is an anti-inflammatory nuclear protein with insulin sensitizing functions. The current study did not reveal any relationships between 25(OH)D and resistin. These results are consistent with those reported by other scientists.

According to the National Health and Nutrition Examination Survey (NHANES III) reports, physical activity is related to serum 25(OH)D either due to enhanced vitamin D metabolism or increased sun exposure. Wanner et al. reported significantly higher levels of 25(OH)D in those who exercised outdoors than in those who exercised indoors. Moreover, it was reported that exercise training is associated with systemic anti-inflammatory effects, with a reduction in pro-inflammatory markers such as IL-6 and TNF-a in plasma.

**Conclusion**

The present study suggested the significant role of irisin myokine in pathogenesis of diabetes mellitus type 2, while that of resistin and vitamin D need to be evaluated in one more large study. Obesity may have an important effect on blood levels of irisin and vitamin D.

Diagnostic Value of Clinical Assessment in Comparison to Ultrasound in Meniscal Injury

Mahmoud Khudair Yaseen¹, Faiq I. Gorial²
¹Department of Surgery, ²Department of Medicine, College of Medicine, University of Baghdad, Baghdad, Iraq

Abstract

Background: Meniscal injury has significant impact on patients’ quality of life. Reports on comparison of clinical assessment with Ultrasound are limited.

Objective: To assess the diagnostic value of clinical assessment in comparison with ultrasound (US) in meniscal injury.

Patients and Method: This observational cross sectional diagnostic accuracy study involved 50 patients with clinical features of meniscal tears. Ultrasound was done for each patients and read by a single radiologist blinded to the clinical features and diagnostic accuracy was measured.

Results: There was no statistical significant difference between clinical assessment and US. Meniscal injury detected by clinical assessment was 41(82%) patients versus 35(70%) patients detected by US evaluation, \(p=1.00\). Krippendorf alpha 0.023, percent of agreement 64%). Diagnostic performance of clinical assessment of meniscal injury was accuracy 82%, sensitivity 83%, positive predictive value (PPV) 70.73%, negative predictive value (NPV) 33.33%, positive likelihood ratio (LR+) 1.04, negative likelihood ratio (LR-) 0.86%, and diagnostic odds ratio (DOR) 1.21.

Conclusions: Clinical assessment was a reliable and a valid method for diagnosis of meniscal injury compared to US evaluation.

Keywords: Meniscal tears, knee injury, ultrasound, clinical features, clinical assessment

Introduction

Menisci are 2 semilunar wedges between the tibia and the femur in the knee joint. medial meniscus is C shaped and the lateral meniscus is O shaped (1,2). Meniscal injuries are the most common cause of knee injury which is caused mostly by direct knee trauma. When injury occurs, the superficial MCL is the most commonly damaged ligament of the knee, usually induced by valgus stress, and can occasionally be accompanied by a tear in the medial meniscus (3,4). Meniscal tears are seen in young and old patients .The correct diagnosis of meniscus tears is very important to give the accurate in tie treatment .Full history and clinical examination can assist in differentiation of knee pain due to meniscal tears from other causes (5–7) Studies have showed that US is a non-invasive real-time imaging modality and the primary alternative diagnostic tool to MRI for evaluating meniscal injuries (8,9).

Clinical assessment compared to MRI has been reported, however the studies reported the comparison between clinical and ultrasound evaluation to diagnose meniscal tears were limited (10–16) Up to the best of our knowledge there is no study Iraq to compare clinical assessment with US evaluation of meniscal injuries. Accordingly, the aim of this study was to assess the diagnostic value of clinical assessment in comparison with ultrasound (US) in meniscal injury.

DOI Number: 10.5958/0976-5506.2019.00733.2
Patients and Method

Study design

This observational cross sectional diagnostics accuracy study was conducted at Orthopedic and Rheumatology Units at Baghdad Teaching Hospital from August 2013 to August 2014. We compared clinical assessment with US for diagnosis of meniscal injury and assessed the diagnostic accuracy and validity of clinical assessment.

Sample selection

Elligible Patients with age >18 years and had knee pain were included in this study. Exclusion criteria included patients who other comorbid systemic diseases, taking medications like corticosteroids and diuretics or evidence of loose bodies on plain radiographs, or any prior surgery that may cause knee pain.

Data entry and evaluation

Data collection included age, sex, history of trauma, knee pain, tender joint line, positive McMurray’s test, and positive Apply test for meniscal injury performed by an orthopedist. Ultrasound (Netherland, Phillips, HD 11XE, transducer L12-3). A single expert radiologist blinded to the clinical assessment performed the US and read it.

Statistical analysis

Statistical software (SPSS version 23, IBM, USA) was used for analysis. Shapiro- Wilk test was used to assess the normal distribution of continuous variables. Normally distributed continuous variables were presented as mean ± standard deviation (SD) and categorical variables were presented as numbers and percentiles. Sensitivity, specificity, positive predictive, negative predictive values, accuracy, positive likelihood ration, negative likelihood ration, and diagnostic odd ratio were calculated. Fisher exact test was used to measure the difference between 2 categorical variables. P-value < 0.05 was considered statistically significant.

Results

A total of 50 patients involved in this study. Their mean of age was 35.44 ± 12.09 years. Of those, most of the patients were males [36 (72%)].

Clinically Meniscal tear was detected in 41 (82%) patients and was absent in 9 (18%) patients. While US was positive for meniscal tears in 35 (70 %) patients and was negative in 15 (30%) patients. There was no statistical significant difference between clinical assessment and US evaluation (p=1.00), percent of agreement was 64% and krippendorf alpha =0.023 as shown in figure 1. the clinical assessment was a reliable measure for diagnosis of meniscal injury.

Figure1: Comparison between clinical assessment with Ultrasound evaluation of meniscal injury.

Table 1 shows validity parameters of clinical assessment of meniscal injury. It revealed that Clinical assessment was a valid measure to diagnose meniscal injury with diagnostic Odd raio=1.21 and very good accuracy of 82%, sensitivity was 83%, and establish the diagnosis with confidence ( PPV=70.73%), specificity 20 %, positive likelihood ratio (LR)=1.04, and negative LR 0.86, NPV 33.33, specificity=20%

Discussion

This observational diagnostic accuracy cross-sectional study assessed the diagnostic value of clinical assessment compared with ultrasound (US) in meniscal injury. It showed no significant difference between clinical assessment and US evaluation of meniscal injuries. In addition, clinical assessment of meniscal injuries had good percent of agreement with US evaluation with high diagnostic accuracy, PPV, and sensitivity, but low specificity and NPV. The results were valid and reliable. The current findings are clinically important for early diagnosis and treatment of meniscal tears.

Up to our knowledge, the current study is the first study that compared clinical assessment with US evaluation for diagnosis of meniscal tears. However, several studies compared Clinical assessment with MRI or arthroscopy or US with MRI and arthroscopy. Yan et al (17) identified the sensitivity and specificity of clinical tests and elements of patients’ history with a high predictive value, and assessed the combined diagnostic accuracy of sensitivity and specificity of clinical tests and elements of patients’ history with MRI. They concluded that Giving way, locking and McMurray’s test are independent clinical diagnostic factors for the diagnosis of meniscal tears. MRI has higher accuracy, sensitivity and NPV for the diagnosis of meniscal tears than giving way, locking and McMurray’s test. The combination of giving way, locking, McMurray’s test and MRI for confirmation is typical for a meniscal lesion diagnosis. Based on these findings, MRI should be used in a standard manner to detect meniscal tears found during arthroscopy.

Konan et al (18), studied the role of physical diagnostic tests in screening for meniscal tears and to validate the diagnostic accuracy of the Thessaly test and found that Physical tests may not always be diagnostic of meniscal tears. MRI and arthroscopy may be essential in dubious clinical presentations and especially where more than one pathology is suspected. Our study showed that the Thessaly test in isolation was not useful for the detection of meniscal tears but it helps to increase diagnostic certainty when combined with other standard tests.

Goossen’s et al (19) evaluated the diagnostic accuracy of the Thessaly test compared with an arthroscopic examination in patients with suspected meniscal tears and found that Thessaly test alone or combined with the McMurray test is useful for determining the presence or absence of meniscal tears. Mahdy et al (20) determined the clinical usefulness of ultrasonography for diagnosis of meniscal pathology in patients with acute knee pain and compare its diagnostic accuracy to MRI in a clinical setting.

Gorial and Yaseen (10) evaluated the validity of clinical assessment in comparison to magnetic resonance imaging in diagnosis of medial meniscal tear in a sample of Iraqi patients and demonstrated that clinical assessment is a valid, easy, and simple tool in diagnosis of medial meniscal injury in Iraqi patients with high sensitivity, high diagnostic accuracy, and very high positive predictive value.

This study has some limitations: first, the small sample size of the patients involved in the study. Second, because patients were selected from a tertiary center where the cases are referred with a previous clinical suspicion of meniscal tear is expected so selection bias may be present. However, these limitations can be solved by a larger sample multicenter study.

Despite of these limitations, the clinical assessment is a simple cheap and rapid method for diagnosis of meniscal tears and up to our knowledge this study is the first study that compared clinical assessment with ultrasound for diagnosis of meniscal tears in which validity parameters and reliability were measured.

In conclusion, clinical assessment of meniscal injury was a valid and reliable measure to diagnose meniscal tears compared with US with high accuracy. This may help in early detection of meniscal tears and subsequent appropriate treatment and good prognosis.

Conflict of Interest: The authors declare that there is no conflict of interests between them.

Source of Funding: The source of funding was by authors.

Ethical Clearance: Ethical approval was obtained from the Ethics Committee of University of Baghdad, College of Medicine, Medical Department and Informed consent was obtained from each participant included in this study.

Legal Protection of Midwives Based on Professional Justice in Midwifery Practices

Fitriani Nur Damayanti¹, Absori Absori², Kelik Wardiono²
¹Lecturer at University of Muhammadiyah Semarang, ²Lecturers at University of Muhammadiyah Surakarta, Kedungmundu Raya Street No.18 Semarang, Central Java, Indonesia

Abstract

Introduction: The authority of a midwife is limited in carrying out health service practices. Midwives in childbirth assistance may only handle physiological labor without complications, and there are some regions that have determined that childbirth must be handled at the Community Health Centers (puskesmas) with the midwife of Community Health Centers (puskesmas). In Semarang City, there are only 7 public health centers with the PONED Community Health Center (Basic Essential Obstetrics Service) which is the place of birth delivery. This is not comparable with the number of births each year totaling 26,337 people. In addition, for family planning services and immunization services, midwives are only allowed to deal with government health care facilities and in carrying out government duties.

Material and Method: Sampling was done by non-probability sampling technique with snowball technique. The sample used was Respondents determined by snowball sampling technique of a number of respondents 17 people.

Findings: Indicators of professional justice consisted of equal rights and opportunities. Equity rights were obtained which met as much as 25%. And that didn’t meet as much as 75%. The same opportunity was obtained which met as much as 40%. And that didn’t meet as much as 60%. From the results of an interview with the Head of the Indonesian Midwives Association (IBI) Semarang City, it was stated that professional justice in midwifery regulations did not yet exist, because midwifery regulations were still being fought for in the midwifery law. In addition, the results of interviews with the Health Department of Semarang City on professional justice in midwifery regulations stated that there were no equal rights in midwifery regulations.

Conclusion: Legal protection of midwives based on professional justice in midwifery practices based on professional justice must fulfill the conditions reflected in the values of justice, namely having equal opportunities and equal rights. The step to realize professional justice is by understanding that legal protection for midwives is not merely a positive norm in legislation but must be understood that social behavior in interaction is legal terminology that does not only fulfill legal certainty requirements but also benefits and justice as law.

Keywords: Legal Protection, Midwives, Professional Justice.
there is only one Community Health Center and that is not yet a PONED Community Health Center. So far, independent practice midwives are considered as one of the causes in the high maternal mortality rate and infant mortality rate.

Midwives are demanded for higher education, but in reality, midwifery professional education, midwifery education, midwifery master’s education are only available at certain institutions. It is difficult to get the education establishment permit. Even though the number of midwives in Indonesia in 2016 was 448,783 and not all were able to continue their education with the difficulty of institutions that had further education. This is very ironic with midwives as the spearhead in maternal and child health services.

The injustice in the risk of maternal mortality has been inseparable from the increasing issue surrounding most health policy debates. Even so, a law is needed for legal protection of health workers. The political product of midwives does not yet have a specific law regulating midwifery. The regulation is only still a regulation of the health minister who has not yet had consistency between the competence and authority of the midwife to realize the professionalism of professional justice-based midwives.

Material and Method

Sampling was done by means of non-probability sampling technique with snowball technique. The samples used were respondents determined by snowball sampling technique of a number of respondents 17 people consisting of the Head of the Indonesian Midwives Association (IBI) Semarang City, the Health Department of Semarang City, and the Independent Practice Midwives. The data analysis technique used was the analysis of qualitative data.

Findings

A. Professional Justice

1. Equality of Rights

Table 1

<p>| The Data on Equality of Rights |

<td>4</td>
</tr>
<tr>
<td>Not fulfilled</td>
<td>11</td>
</tr>
<tr>
<td>Total</td>
<td>15</td>
</tr>
</tbody>
</table>

From the data on the frequency distribution of respondents’ answers to the equality of rights in the independent practice of midwives, it was found that stated equal rights fulfilled as much as 25%. And those who did not fulfill the midwife’s independent practice were 75%. From the results of interviews with the Head of the Indonesian Midwives Association (IBI) in Semarang City and with the Health Department of Semarang City, on equality of rights in midwifery regulations stated that there were no equal rights in midwifery regulations.

Equality of rights in the health profession is part of human rights. This is contained in the charter of Medina (Piagam Madinah) which is a constitution that was formulated by the Prophet Muhammad which contained human rights. Some of the human rights provisions include: Recognition of the right to life, the right to freedom, equality rights, justice rights. In Law No. 39 of 1999 concerning Human Rights, arrangements regarding human rights are determined based on the United Nations Declaration of Human Rights, United Nations Convention on the Elimination of All Forms of Discrimination against Women, United Nations Convention on the Rights of the Child, and various other international instruments governing human rights.

Human rights to health are recognized in international devices. The Universal Declaration of Human Rights (UDHR), article 5 paragraph 1 states that every human being has sufficient standard of living, for the health of himself and his family, there is no single profession more important than other professions, there is no superior profession and inferior profession.

However, at present, the pressure on midwives is very strong, because of the fewer professional midwives who practice midwifery services. Midwives struggle and mobilize to maintain and strengthen professions that can make an important contribution in the quality of
midwifery services for women and children. Apart from obstacles, midwives continue to try to maintain and strengthen the profession. They sought support for the passing of the midwifery law. An important role needs to be done by midwife professional organizations, whose central axis is the work of keeping midwives engaged and active in professional matters. Organizations are more effective because they become more organized the better, the more likely the action is for their professionals.

In Law Number 36 of 2009 concerning Health in article 4 paragraph 1 states that everyone has the right to health. In Law No. 36 of 2014 concerning Health Workers in article 57 states that health workers in carrying out the right practice obtaining legal protection as long as carrying out duties in accordance with professional standards.

Minister of Health Regulation Number 28 of 2017 concerning Permission and Implementation of Midwife Practices in article 29 states that in implementing midwifery practices, midwives have the rights obtaining legal protection as long as carrying out its services in accordance with professional standards.

2. Equal Opportunities

Table. 2: Frequency Distribution of Respondents’ Answers Regarding the Indicator of Justice about Equal Opportunities in the Independent Practice of Midwives

Source: Primary data processed in 2018

From the data on the frequency distribution of respondents’ answers about the same opportunity in the independent practice of midwives, it was found that in an independent practice the midwife stated that the same opportunity fulfilled as much as 40%. And those who did not fulfill the midwife’s independent practice were 60%. From the results of interviews with the Head of the Indonesian Midwives Association (IBI) in Semarang City and with the Health Department of Semarang City, it was stated that the value of justice in midwifery regulations did not yet exist, because midwifery regulations were still being fought for in the midwifery law.

The same opportunity is someone who has the same opportunity of one individual with the others. Please note that the same opportunity as one whole. That is, the value of an opportunity depends on the specifications of other opportunities and must be considered in preparing the constitution and legislation in general.

In the development of health personnel, it essentially has equal opportunities and focuses on career development, namely a continuous process that consists mainly of career planning. In the Regulation of the Minister of Health No. 28 of 2017 article 18 concerning authority, the authority of midwives is very limited. It is supposed to be a professional midwife between the competence and authority of midwives arranged in harmony.

According to Hart, being fair and unfair is a form of moral criticism that is more specific than good or bad, it is clear that logically it could be claimed law either because it is fair, or bad because it is unfair, actually it cannot be like that. Law is seen as unfair if the burden of distribution and the benefits of both are discriminated against among people by referring to any characteristics, including the dominant profession ego.

B. Legal Protection of Midwives Based on Professional Justice

Health is needed for human welfare, providing intrinsic value for comfort and satisfaction. Justice refers to the idea of creating an egalitarian culture or institution, respecting human rights, and recognizing the dignity of every human being. Human rights guarantee the most basic rights of all rights possessed by humans solely directed to the interests of the man himself in a narrow sense and by recognizing and respecting the dignity of humanity.

The emphasis for Rawls is that justice for this equality does not merely distribute primary values fairly, but also how this principle of justice is positioned for cooperation in a well-ordered society. The point is that Rawls accommodates the principle of equality as a basic value of justice. Also accepting inequality.
Professional values of justice not only belong to law enforcers but in carrying out their professionalism, midwives also have a value of justice. Midwives must uphold morals and legal principles, client molarity and integrity. The principles of justice state that every person has the right to carry out all aspects of his life to the fullest. The injustice of midwives will have a negative impact on women, babies, and families. This gap is not in accordance with the principle of justice. Injustice in midwives often occurs. It must close the health gap where all health workers can build consensus and where individuals accept personal responsibility. However, at present, there are always values of injustice in midwives. In justice there are two indicators of achieving the value of justice, namely equal rights and equal opportunities.

In midwifery services, the midwife’s independent practice must also fulfill the patient’s rights. This is a legal relationship between midwives and patients called a therapeutic agreement. The relationship between the patient and midwife is a business engagement (inspannings verbintenia) that is where in carrying out their duties the midwife strives to cure or restore the patient’s health.

In a relation arising from an agreement, the fulfillment or violation of the points of the agreement can result in a violation of the therapeutic agreement. This right arises from the party being promised a loss in the form of costs that have actually been incurred, losses incurred and expected profits (wintsderving) that were not received due to the breach of the promise. It is necessary to establish education criteria in accordance with the competence and authority of midwives in midwifery services. In order to avoid midwife discrepancies between authority, competence, regulation and midwife education. Midwife education professionals will provide quality services for the community. The regulation of midwives is currently not in accordance with the regulations that exist in nursing and medicine.

Legal protection of midwives based on professional justice in midwifery practice based on professional justice must fulfill the conditions reflected in the values of justice, namely having equal opportunities and equal rights. Everyone has equal opportunities for the broadest basic freedoms, as broad as the same freedom for everyone. Legal protection with professional justice can be realized through harmonious cooperation between the ministries of health, professional organizations, legislators, and related institutions or agencies in synergy by prioritizing the values of justice and respecting the right to professional equality by ignoring sectoral ego interests as a profession. One step to realizing it is by understanding that legal protection for midwives is not merely a positive norm in legislation but must be understood that social behavior in interaction is legal terminology that does not only fulfill legal certainty requirements but also benefits and justice as law.

**Conclusion**

Indicators of professional justice consisted of equal rights and equal opportunities. Equity rights were obtained which met as much as 25%. And that didn’t meet as much as 75%. The same opportunity was obtained which met as much as 40%. And that didn’t meet as much as 60%. Legal protection of midwives based on professional justice in midwifery practice based on professional justice must fulfill the conditions reflected in the values of justice, namely having equal opportunities and equal rights. The step to realizing professional justice was by understanding that legal protection for midwives was not merely a positive norm in legislation but must be understood that social behavior in interaction was a legal terminology that did not only fulfill legal certainty requirements but also benefits and justice as law.

Study of Biochemical Criteria of Blood for Thalassemia Patients

Hanan Jassim Hammod¹, Zainab Kareem Al-Kazazz¹, Hassan A Farman²

¹Department of Babylon Technical, Al-Furat Al-Awsat Technical University, Iraq,
²College of Health and Medical Technical – Al-Kufa, Al-Furat Al-Awsat Technical University, Iraq

Abstract

This study was conducted for a samples of thalassemia patients who included males and females as well as healthy people as compared. We were measured liver enzymes(ALK, GOT, GPT), blood parameters such as $\text{WBC}_5$ count, $\text{RBC}_5$ count, hemoglobin deposition rate Erythrocyte Sedimentation Rate (ESR), hematocrit or packed red cell volume (PCV) and Quantity of iron.

The results displayed that there were a significantly difference increase in the values of iron and liver enzymes (ALK, GOT, GPT) among thalassemia patients and control under the level of probability (0.05) for males and females, and There was as well a significantly difference increase and decrease in blood parameters for (WBC, RBC, Hb, PCV) and did not showed significantly difference between patients and control in the ESR. When comparing the results between male and female patients with thalassemia, the results appeared that there is a significantly difference increase between them and that Thalassemia directly affects males more than females, especially in the liver enzymes, but iron has recorded a clear reduction in males compared to females and did not record blood standards any significant difference Between males and females despite the higher value of white blood cells in males compared to females.

Keywords: thalassemia, GOT, GPT, PCV, Hb.

Introduction

Thalassemia is a usual inherited sickness in the world and causes serious problems for the Mediterranean region in public health.¹ Thalassemia is a hereditary condition described through insufficient production of hemoglobin and can be divided of the genes affected to alpha and beta attributed to the protein chains that make up the proper hemoglobin.² Thalassemia is common in the Mediterranean, the Indian subcontinent, northern Africa, Eastern Europe and many parts of the world.³ One of the major clinical signs of thalassemia is that it suffers from red blood cell hypertrophy with the formation of myeloid blood with gallstones.⁴ In the first year of the life of patients with thalassemia, they have severe sepsis and need permanent blood transfusions. However, excess iron overload and organ damage should be removed due to repeated transfers.⁵ Iron overload in patients who do not need blood transfusions is that gastrointestinal abortions, especially the liver, absorb excess iron.⁶ Diseases such as hypothyroidism, diabetes or gonadal dysfunction were not observed in patients with central thalassemia despite iron overload.⁷ Therapists of thalassemia patients have become increasingly incremental loading of iron from major complications.⁸ The calculation of the amount of liver enzymes that increase due to the toxic effect of iron directly and because of the liver disease on liver cells, which is the most obvious way to identify liver damage.⁹ Acute thalassemia patients suffer from erythroid activity in blood-forming areas, causing lymph nodes, liver and spleen, and in some patients, tumors outside the intestines.¹⁰ Studies have shown that there is an increase in the level of liver enzymes and decreased hemoglobin in patients with thalassemia.¹¹ This study was conducted to measure the liver enzymes (ALK, GOT, GPT) and the level of iron addition packed cell volume (PCV) to the number of erythrocytes and leukocytes in the blood of thalassemia patients.

Ingredients and Procedures

The study was accomplished on a sample of 165
people, including 105 people with Thalassemia, including 62 males and 43 females. The control sample included 60 healthy people distributed equally between males and females. The samples were taken from patients from (Babylon Hospital for Childbirth and Children). Some of the blood values such as (ALK, GOT, GPT, Iron) and some blood parameters (WBC<sub>S</sub>, RBC<sub>S</sub>, Hb, PCV, ESR) were included in the thalassemia center.

Statistical Analysis The results were analyzed by using the (SPSS). Analysis of variance by ANOVA table as well as excretion mean and standard deviation depending on basic statistic method.

**Result**

The products of the study displayed that thalassemia has a direct effect on some of the blood chemistry and some blood parameters of both sexes.

There was a significantly difference increase between patients with thalassemia and control (male and female) in liver enzymes (Table 1)

Results displayed that thalassemia had a significant effect on the level of iron in the blood where the concentration of iron was significantly higher in illness with thalassemia compared with controller as in Figure(1) in both males and females. When comparing the concentration of iron between males and females, the results displayed that the iron level was greater in male illness than female illness as in Figure(1)
Discussion

The products of the study showed that there was a significantly difference increase below the level under 
(P≤0.05) raised in the level of liver enzymes GOT and GPT in patients compared to controller and this results
is agreed with the researchers of Asif M et al, 2014 (11), Bayejid H et.al, 2015 (12) and Patel et.al, 2018 (13) they
found an increase in liver enzymes in the illness with beta thalassemia when comparison to controller. Liver
enzymes are a sign of liver safety, which is high in thalassemia patients. It can be achieved that higher levels
of liver enzymes may be by reason of livers damage, produced by iron excess in illness many transfusions,
The increase in the amount of iron due to frequent blood transfusions leads to increased serum fractions and this
increase the feritin to an increase in liver enzymes may be due to more than that (11).

Thalassemia patients suffering from tissue damage are a major cause of blood transfusions and also suffer
from secondary iron overload (14). In patients with acute thalassemia, iron accumulates about 2-5 g per year, in
this way, and is stored by increasing iron loading as well as increasing the iron absorption of Gastro intestinal
track (15). This is consistent with our study, The products of the study displayed that there was a significantly
difference increase in iron level among thalassemia and control patients. There was a significantly difference
between males and females with iron level. The increase in iron overload and delayed growth was evident in
thalassemia patients in a study conducted in Sri Lanka Karunaratna et al 2017 (16). Thalassemia is a disease of
the blood that causes a large annihilation of RBCs, which lead to anemia (17). The results showed that a Drop
the level in Hb, PCV among thalassemia patients and control and significant difference (p≤0.05) of them(in
male and female) table(2). This is agreed with research in the Mosul city, where it was found that the level of
Hb and PCV less in patients than control (Sharaf et.al,2006) (18) and Moayad (19). In another study in Nepal,
the researchers found a reduction in the level Hb and PCV of thalassemia patients (20). In our study we found an
increase in the number of white blood cells in patients with thalassemia compared to control with a population
of 7.384 ±0.821 and 9.570 ±0.988 for males and females, respectively, while red blood cells were low
in comparison with control of 1.88 ±0.08 for males and 1.865 ±0.80 for females this is consistent with a study
conducted in Babil also noted a rise in the number of
white blood cells with a decrease in red blood cells Al-Marzok and Maaroof 2017(21) in another study in Cairo university (22) where found the mean and SD for WBCs were 8.8 ±2.3 , but the other indices in form of RBCs were away from our study the values were 2.6±0.78. This is close to the results we have obtained.

Conclusions

We concluded that liver enzymes are increased in thalassemia illness, such as WBCs and iron, while Hb, PCV and RBCs are lower in patients, and male patients are more affected by the disease than females, while ESR is not affected in patients comparative with healthy people.

Acknowledgment: We thanked and appreciated all patients who agreed to take blood samples from them and helped us conduct our research.

Ethical Clearance: A formal permission taken from responsible of thalassemia Center in Maternity and Children’s Hospital in Babylon, Iraq.

Performance Analysis of Indonesian Public Hospitals:
A Panel Data Method

Jon Hendri Nurdan¹, Sjafrizal², Hefrizal Handra², Hardisman Dasman³

¹Student of Doctoral Program of Public Health Sciences, Faculty of Medicine, ²Department of Economic Studies, Faculty of Economics, ³Department of Community Medicine and Public Health, Faculty of Medicine, Andalas University, Padang, Indonesia

Abstract

Balanced Score Card approach to health sector organizations measures performance based on financial and non-financial aspects which are divided into four perspectives, namely customer perspective, business and internal process perspectives, learning and growth perspectives, and financial perspective. The study uses a quantitative approach with panel data regression analysis. Panel data is used to analyze the hospital performance with balanced scorecard approach in Indonesian public hospitals, based on patient satisfaction, service quality, human resources competencies and cost efficiency. Data analysis used the cross section data of 14 public hospitals in Indonesia and the time series data from 2015 to 2017 so that there are longitudinal data as many as 42 data. Based on the results of panel data regression analysis concluded that significantly patient satisfaction, service quality, human resources competencies and cost efficiency affect the hospital performance and they are the critical success factors of hospital performance with balanced scorecard approach in Indonesian Public Hospital.

Keywords: Health Sector Organization, Balanced Scorecard, Hospital Performance

Introduction

Kaplan in 2001 states that balanced scorecard approach could be used in health sector organizations and non-profit organizations with the modification of balanced scorecard according to the characteristics of the organization itself. Modifications to balanced scorecard are very necessary because organizational characteristics in the private sector and public sector are different where the private sector prioritizes financial perspectives.¹,²

Balanced scorecard approach has been used in many health service sectors, both profit and non-profit, including: a) Hospitals; b) Health Service System; c) University Hospital / Department of Health; d) Long-term Services; e) Center for Mental Health; f) Pharmacy Services; g) Health Insurance Company.³

Hospitals as public service institutions must to implement a performance management that is oriented to patient satisfaction. Indonesia public hospitals must be able to create superior performance or performance excellence, as well as hospitals as providers of health services through the provision of services in accordance with service standards. One of the strategies carried out by hospital managers in increasing patient satisfaction is service quality.⁴

The central public hospitals as one of the government agencies must be able to provide accountability to the government and the community as service users. Therefore there needs to be a performance measurement that covers all aspects. Balanced scorecard is the right choice for measuring performance from both financial and non-financial aspects.⁴

Balanced Scorecard approach to public sector organizations measures performance based on financial and non-financial aspects which are divided into four perspectives, namely customer perspective, business
and internal process perspectives, learning and growth perspectives, and financial perspective. Financial perspective looks at performance from the point of view of profitability in achieving financial targets, so it is based on sales growth, return on investment, operating income, cash flow, and cost efficiency. Customer perspective is based on patient satisfaction, customer profitability, customer retention, and market share. Business and internal process perspectives identify critical factors in the organization's internal processes by focusing on developing new processes that are customer needs. Service efficiency, service effectiveness and service quality are things that must be developed and improved to achieve the goals of increasing value for customers and stakeholders. learning and growth perspective measures factors related to technology, development of human resources, systems and procedures, and other factors that need to be updated. (4)

Research conducted by Aurora seeks to implement balanced scorecard for use in public sector organizations. The results of the study indicate that performance measurement using balanced scorecard is better than using traditional performance measurements. Balanced scorecard is deemed appropriate to be used as a tool to measure public sector performance because it not only emphasizes the quantitative-financial aspects, but also considers the qualitative and non-financial aspects. This is in line with the objectives of the public sector which places profits not only as a key performance measure, but services that tend to be qualitative and non-financial. (4)

The Mackay Memorial Hospital in Taiwan shows that balanced scorecard approach is useful in order to sharpen its competitive advantage. It helps to take a more strategic approach that would differentiate services and attract more business. Balanced scorecard approach also improve collaboration and communication between all levels of key stakeholders and staff. (5)

Hogland Hospital in Swedia also uses balanced scorecard as a tool to measure financial control and service quality improvement, along with human resources developments. At first, balanced scorecard was used as a two-year trial but continued because of the success of the trial. (6)

This study aims to analyze the hospital performance with balanced scorecard approach in Indonesian public hospitals, based on patient satisfaction, service quality, human resources competencies and cost efficiency.

Method

This study uses a quantitative approach with panel data regression analysis to determine factors that affect hospital performance with balanced scorecard approach in Indonesia public hospital. Data analysis used the cross section data of 14 public hospitals in Indonesia and the time series data from 2015 to 2017 so that there are longitudinal data as many as 42 data.

Data used for analysis is secondary data in the form of government agency performance accountability report, annual report, business strategy plan, and budget business plan from 2015 to 2017 at Indonesian Public Hospital. The following are described in the stages of this research.

Results

Panel data regression analysis in this study is used to analyze several variables that affect the hospital performance based on four perspectives of balanced scorecard, which is based on previous theory and the results of previous studies. The independent variables used in panel data regression analysis in this research were patient satisfaction, service quality, human resources competencies and cost efficiency during 2015 to 2017.

Hospital performance variable is proxied from the percentage of hospital performance achievement figures based on indicator of public service agency. Patient satisfaction is proxied from the ratio of community satisfaction index assessment results divided by the maximum scale of the community satisfaction index value. Service quality are proxied from the ratio of each indicator of service timeliness, namely outpatient waiting time, emergency response time, length of stay, waiting time for radiology services, waiting time for laboratory service, waiting time before surgery, and speed of prescription services for finished drugs. Human resources competencies is proxied from the ratio of the number of hospital human resources divided by the number of human resources according to the hospital’s minimum service standard. Cost efficiency is proxied from the ratio of PNPB income divided by operating costs. Data used in this study are time series data for three periods (2015-2017) and cross section data as many as 14 RSUP. So that the longitudinal data is 42 data.
One of the requirements in panel data regression analysis is that data must be met with normal elements. Data that is not met by normality, usually due to data that has extreme values or outliers or is also commonly used in terms of outliers. The purpose of this normality test is as a tool to see whether the standardized residual values on the model are normal or not. To find out, it can be seen with most of the standardized residual values approaching the mean.

Normality test in this study was carried out by using the graph method and histogram with Jarque-Bera test. Dependent variable is the average value of hospital performance depicted in the graph as the vertical axis. The horizontal axis shows standardized residual values. To see whether the distribution of data found to be normal or not is seen from the value of Jarque-Bera and its probability value. Data is not normally distributed if the statistical test results obtained p-value <0.05. Whereas, if the statistical test results obtained p-value > 0.05 then data is normally distributed. Based on the statistical test results, Jarque-Bera value is 0.625919 and p-value is 0.731280 (> 0.05), it can be concluded that data is normally distributed and panel data regression analysis can or is feasible.

Regression equations can be estimated using three models, namely Common Effect Model (CEM), Fixed Effect Model (FEM), and Random Effect Model (REM). Common effect model and fixed effect model are estimated using panel least squares method, while random effect model is estimated using GLS method. Of the three models, one of the more appropriate models will be chosen to be used in analyzing the factors that influence the hospital performance using balanced scorecard approach in Indonesian public hospitals. Which approach estimation model will be used in analyzing the factors that influence the hospital performance with balanced scorecard approach in Indonesian public hospitals depending on the results of model selection. The selection of this model is done by testing the model using Chow test, Hausman test, and Lagrange Multiplier (LM) test.

</tbody>
</table>

Redundant fixed effect test/chow test shows that the probability of cross-section chi-square is 0.0003 (<0.05), it can be concluded that the most appropriate model used between common effect and fixed effect is fixed effect.

Correlated random effect test/hausman test shows that the probability of cross-section random is 0.3478 (>0.05), it can be concluded that the most appropriate model used between fixed effect and random effect is random effect.

Omitted random effect test/lagrange multiplier test shows that the probability of cross-section breusch-pagan is 0.0017 (>0.05), it can be concluded that the most appropriate model used between common effect and random effect is random effect. Based on chow test and hausman test, it can be concluded that the most appropriate model used for panel data regression analysis in this study is random effect model.

Model that has been prior to analysis is conducted prior classical assumptions underlying panel data regression model in order to obtain a model that is efficient, visible and consistent. With the Random Effect model selected, it is not relevant to do the Classic Assumption test. This is because the Random Effect model uses the estimated Generalized Least Square (GLS) method. GLS technique can overcome
the time series autocorrelation and correlation between observations (cross section). GLS method produces an estimator to fulfill the Best Linear Unbiased Estimation (BLUE) characteristic which is a treatment method to overcome violations of heteroscedasticity assumptions and autocorrelation.

Goodness of fit test in this study consisted of three tests. There are F-statistic, t-statistic and coefficient of determination. F-statistic test was conducted to determine whether the independent variables in the overall significantly affect the dependent variable.

Based on Table 1, the probability of F-statistic is 0.0001 (<0.05). It can be concluded that the regression model is used to explain the effect worthy of patient satisfaction, service quality, human resources competencies and cost efficiency of the hospital performance. t-statistic test was done to see how far the influence of independent variables individually explain the variations of dependent variable. Table 5 shows that patient satisfaction (p=0.0486), service quality (p=0.0437), human resources competencies (p=0.0049), and cost efficiency (p=0.0278) significantly affect the hospital performance.

Coefficient of determination test was conducted to measure that the independent variables in the regression model was able to explain the dependent variable. Table 1 shows that the value of R^2 is 0.698968, it means patient satisfaction, service quality, human resources competencies and cost efficiency has an influence on the proportion of hospital performance by 69.90%. Indeed, 1.57% is influenced by other variables that are not in the regression model.

The regression equation (1) indicates that HP is the hospital performance, PS is patient satisfaction, SQ is service quality, HRC is human resources competencies and CE is cost efficiency.\( \beta_0 \) is the regression coefficient constants, \( \beta_1 \) is the regression coefficient of patient satisfaction, \( \beta_2 \) is the regression coefficient of service quality, \( \beta_3 \) is the regression coefficient of human resources competencies and \( \beta_4 \) is the regression coefficient of cost efficiency. \( t_0 \) is the t-statistic constants, \( t_1 \) is the t-statistic of patient satisfaction, \( t_2 \) is the t-statistic of service quality, \( t_3 \) is the t-statistic of human resources competencies and \( t_4 \) is the t-statistic of cost efficiency.

\[
HP = \beta_0 + \beta_1 \times PS + \beta_2 \times SQ + \beta_3 \times HRC + \beta_4 \times CE
\]

(1)

\[
HP = 0.153505 + 0.119777 \times PS + 0.013752 \times SQ + 0.045950 \times HRC + 0.110867 \times CE
\]

(2)

The regression equation (2) means that for any increase in patient satisfaction indicator by 1 if the other variable is assumed to remain, the hospital performance will increase by 0.119777. Any increase in service quality indicator by 1 if the other variable is assumed to remain, the hospital performance will increase by 0.013752. Any increase in human resources competencies indicator by 1 if the other variable is assumed to remain, the hospital performance will increase by 0.045950. Any increase in cost efficiency indicator by 1 if the other variable is assumed to remain, the hospital performance will increase by 0.110867.

Discussion

Ramon-Jeremino et al. shows that the balanced scorecard would allow a proper monitoring and tracking system for the main healthcare indicators. This contributes to a better control in comparison with standards that are associated with adequate quality assistance. It is necessary to adapt the balanced scorecard to the specific characteristics of the clinical field, redefining both perspectives and indicators.(7)

Chang and Wu examined the implementation of the Balanced Scorecard in hospital cases in Taiwan. In order to improve its competitive position, hospitals began implementing the Balanced Scorecard in 2001. This was the first hospital to implement the Balanced Scorecard in the health system in Taiwan and one of the few successful implementations. The hospital is a pioneer in implementing the Balanced Scorecard.
for health organizations in Taiwan. Furthermore, the implementation of the Balanced Scorecard in hospitals is for all entities, not just for certain departments. The implementation of the Balanced Scorecard is initiated and evaluated through four sequential phases, which take a complete eight years. By identifying the determinants of success, it can overcome some serious challenges and difficult conditions faced by the Balanced Scorecard that will be implemented. (5)

Edward et al. began examining trends from 29 key performance indicators over a period of 5 years (2004-2008). The findings show that the Balanced Scorecard was successfully used to increase the capacity of the health and service systems through the performance of benchmarking over a 5-year research period. The most important thing is that the use of the Balanced Scorecard helps to show the effects of investment, facilitates policy changes, and culture-based decision making in the primary health care system in Afghanistan. Furthermore, the researchers reminded that the continued success of the Balanced Scorecard in Afghanistan will greatly depend on the ability to accommodate all changes in existing health system policies. (8)

Edward et al. also stated that significantly there was an increase in the domain of patient and community satisfaction with services with p <0,0001. There was also a significant increase in the service quality domain from 2004-2008 with p <0,0001. The availability of drugs, equipment, clinical guidelines, laboratory use, and knowledge of service providers and training shows a significant increase since 2004. (9)

According to Bitner argues that perceived service quality is the result of a comparison of performance and received by consumers from service providers. (9) Oliver and Burke state that overall service quality is determined by the suitability of desires that result from a comparison of wants and performance perceived by consumers. Quality services will create satisfaction for service users who can ultimately provide benefits, including harmonious relationships between service providers and customers, providing a solid basis for repurchase, and creating customer loyalty. (10)

Conclusion

Patient satisfaction, service quality, human resources competencies and cost efficiency affect the hospital performance significantly and they are the critical success factors of hospital performance with balanced scorecard approach in Indonesian Public Hospital.

Evaluation of Platelet Rich Fibrin Effect in the Bone Density after Teeth Extraction by Cone Beam Computed Tomography

Kamal Saheb Mezal¹, Sahar Shakir Al-Adili², Ali S. Al-Haddad²
¹Ministry of Health, Karbala Hospital, Karbala, Iraq, ²College of Dentistry, University of Baghdad, Baghdad, Iraq

Abstract

Background: Platelet Rich Fibrin (PRF) favors the development of microvascularization and is able to guide epithelial cell migration to its surface. This material acts as a biodegradable scaffold that consists of an autologous leukocyte-platelet-rich fibrin matrix composed of a tetramolecular structure, with cytokines, platelets, cytokines and stem cells within it. This work hypothesis is that the platelet rich fibrin increase the bone density after teeth extraction.

Objective: Examine the role of platelet rich fibrin in healing of extraction socket.

Method: 36 participants with an age range from 20-52 years old. The participants divided into two groups, the study group was treated with PRF in the socket after teeth extraction while the control group conducted without PRF. Both groups had simple non-traumatic teeth extraction. The preparation of the PRF include 5 ml of blood centrifuged at 3000 rpm for 10 min, then gently sutured the socket after putting the PRF clot to minimize the suturing effect on the healing process. After 4 months, the new-bone density formed in the socket was measured by Cone beam computed tomography (CBCT).

Result: Maximum and mean density was significantly higher in the study group compared to control, the bone density in upper jaw was significantly higher in study group compared to control, the bone density in upper jaw was significantly higher in study group compared to control.

Conclusion: Platelet Rich Fibrin show better healing effect and increase in bone density compared to standard of care

Keywords: platelet rich fibrin, CBCT, done density, teeth extraction, jaw

Introduction

Maxillofacial reconstruction, oral implants, regenerative procedure etc. are highly dependent on successful regeneration and healing and one of great challenges faced in clinical research in development of bioactive surgical additive regulating inflammation and increasing healing. Bone regenerative techniques including graft material, protein and barrier membrane are used to improve the bone quality. Healing in tissue is mediated by of signaling proteins. Understanding of this process at microcellular level is still not complete, but it is proven fact that platelets do play an important role in wound healing. In order to limit the inevitable alveolar ridge resorption many different bone substitutes have been proposed for ridge preservation, but their placement functions as a double-edged sword; it is effective in limiting ridge resorption, but it delays healing in the socket.

Due to increasing patients demands for timely and esthetic treatment there is a need for new therapeutic protocols that accelerate the healing of post-extraction sockets while minimizing the duration of the treatment. Platelet rich fibrin had shown promising role in bone regeneration in the socket after tooth extraction.
Autologous platelet preparations have shown promising results in bone regeneration in the post-extraction socket\(^6\). Autologous platelet has newly attracted the interest of medical research because of its simplicity of provide as well as promising effect from its medical application\(^7\). Platelet rich fibrin was developed originally in France by Choukroun et al. in 2000, it is considered as a second-generation of platelet concentrate, which characterized as a new step of the therapeutic idea of platelet gel that aims to collect platelets, leukocytes and the released cytokines in a fibrin clot. Platelet rich fibrin is widely used to accelerate hard and soft tissue healing. The PRF preparation is a simple protocol made by centrifugation of natural blood without any additives\(^8\). The hypothesis of this study is based on the ability of local application of PRF to increase the bone density and accelerated bone healing.\(^9\)

**Method**

**Study design**

The study included 36 participants with an age range from 20-52 years old. The participants divided into two groups, the study group was treated with PRF in the socket after teeth extraction while the control group conducted without PRF. Both groups had simple non-traumatic teeth extraction. The study carried out from 1st of January 2017 to end of December 2017.

**PRF preparation**

The preparation of the PRF include 5 ml of blood centrifuged at 3000 rpm for 10 min, then gently sutured the socket after putting the PRF clot to minimize the suturing effect on the healing process. After 4 months, the new-bone density formed in the socket was measured by Cone beam computed tomography (CBCT).

**Data collection**

The following data was collected from each patients: age, gender, and bone density

**Statistical analysis**

Anderson darling test was done to assess if continuous variables follow normal distribution, and data presented using their mean and standard deviation used, Discrete variables presented using there number and percentage, chi square test used to analyze the discrete variable. Two samples t test used to analyze the differences in means between two groups (if both follow normal distribution with no significant outlier), Mann Whitney U test used to analyze the differences between two groups (if they do not follow normal distribution). SPSS 22.0.0 (Chicago, IL), Prism version 8.00 for Windows (GraphPad Software, La Jolla California USA), software package used to make the statistical analysis, p value considered when appropriate to be significant if less than 0.05

**Results**

There was no significant difference in age, gender of the participants, as illustrated in table 1.

Discussion

Nowadays the dentist facing challenge in how accelerate the bone regeneration in the alveolar ridge preservation after teeth extraction. Since years numerous allografts, alloplastic or xenografts are used for this purpose. They include bone substitution such as hydroxyl apatite, freeze dried bone grafts demineralized bone grafts, bio active glass etc. These bio active materials have good osteoconductive and osteoinductive properties, but unpredictable result several a time and the risk of disease transmission, led to explore of the materials which can produce predictable regeneration or can improve the properties of these bioactive graft materials.

The results of the current study indicated that there was high bone density formed in the socket of study group as compared to the control after 4 month by CBCT because the Maximum density was significantly higher in the study group (1,076.1±446.6) compared to control (779.2±238.6), also Mean density was significantly higher in study group (295.9±218.6) compared to control (185.6±181.7) this lead to biological effect of PRF as sole graft. This was in agreement to the results obtained in previous studies conducted by shrivastava et al. 2018 that state on there was early osseous bone regeneration in the PRF groups at a given points of time in mandibular as well as in maxillary in both sexes.

Many clinical studies suggest that the mixture the growth factors contained PRF and PRP with bone graft may be suitable to enhance bone density.

The biological properties of PRF contain several growth factors (BDGF, TGF-beta, EGF, VEGF, IGF-1, beta-FGF, and HGF) obtained with a simple centrifugation procedure, to stimulate several biological functions such as chemotaxis, angiogenesis, proliferation, differentiation, modulation, thereby presenting a possible therapeutic device for a more rapid and effective regeneration of hard and soft tissue.

Study limitation

Only one reading in the bone density post extraction socket needed further reading at different intervals, assessment the bone density by CBCT only, small sample size, and the reason of teeth extraction only dental caries, tooth fracture, orthodontic treatment.

Conclusion

Platelet Rich Fibrin show better healing effect and increase in bone density compared to standard of care

Conflict of Interest: None

Ethical Clearance: Informed written consent was obtained from all the participants in the study, and the study and all its procedure were done in accordance with the Helsinki Declaration of 1975, as revised in 2000. The study was approved by College of dentistry, University of Baghdad.

Abstract

The future-ready strategy has been proposed in the literature and has been widely used in management practice as a useful tool to help the effective implementation of an organization’s strategy. This article examines some of the most relevant strategies, in the specific context of the Iraqi private healthcare organizations, and how can use to improve the healthcare performance. The study instrument was the questionnaire, the main conclusion indicates the positive effect of future-ready strategy development on healthcare performance.

Keywords: Environmental Scanning, Strategic Thinking, Strategic Decision Making, Strategic Planning, Evaluating.

Introduction

From time immemorial, Iraqi private hospital has been offering good and unique services amid the presence of the public hospitals which poses competitive pressure to this private hospital. According to (Hilfi et al., 2013)¹, they stated that the health systems in Iraq are undergoing a lot of transformations which requires hospitals and especially private hospitals to conform to these requirements which entail: demographics, emerging diseases, the high costs of healthcare and the overall rise in the operating costs in terms of hiring experienced doctors and nurses². This, therefore, shows that in order to operate without any problems, there is a need for a private hospital to adopt a strategy so that it can save its costs of operations and quality³, due to this external pressure, it is, therefore, necessary to challenge other hospitals using various ways and one being the use of strategy⁴.

The current number of physician staff and the distribution of healthcare services in the country are no longer at its optimum¹. The nature of services offered at different healthcare facilities have also been reported to be not standardized⁵. The facilities in the country are not networked and the country’s referral systems are still wanting⁶. Recent studies have shown that primary health care in the country lack quality it deserves, with personnel lacking adequate training in quality improvement⁶. Most healthcare authorities in the country indicate that the quality of healthcare could still need improved. The good conditions that currently characterize comprehensive health care force the system with a strategic focus to maintain and improve these conditions so that Iraq can access health indicators similar to those of developed countries⁷. In this regard, the Iraqi government is working hard to achieve improved health performance in the country, and the private health sector has found a great foothold to provide health service.

Accordingly, the purpose of this study is to highlight future strategies that can be developed and implemented in order to improve the health sector in Iraq. The paper seeks to investigate specific measures to be taken by the government to promote not only primary health care but also other levels of care in the country and the use of private hospitals and clinics and improve their performance.

Literature Review

Future Ready Strategy

(Cowley & Domb, 2012)⁸, states that strategy is

Corresponding author:
Safa Tayeh Muhemmed
E-mail: tayehsafaa@gmail.com,
hashimf.dabbas@uokufa.edu.iq
a method, a way or plan to achieve the desired goal, solution to a problem or what the firm desires with ease. To be relevant in the healthcare industry, Iraqi hospitals, therefore, had to come up with strategy so as to sustain itself in this industry. Although there are many factors that hinder the provision of the health care services, the idea of using a strategy to maneuver this problem is a great move for the private hospital. Moreover, the private hospital should come up with different strategies so that they don’t over-rely on the common strategies that other hospitals they compete with, are engaging the same strategies.

Future Ready Strategy includes:

Environmental Scanning (ES)

Environmental scanning is the acquisition and use of information about events, trends, and relationships in an organization’s external environment, the knowledge of which would assist management in planning the organization’s future course of action. The planning of healthcare requires information from internal and external sources to enable make the appropriate decision. it is critical and hence what is promoted should be within the needs of the locals and attainment of the outcome needed.

Strategic Thinking (ST)

Strategic thinking is a reflective process that determines the intention and strategic profile of what an organization wants to become. Its objective is to seek the ability to anticipate events, visualize a destination and build it, and reach the future that is considered most convenient for a person, society, company or nation. It is responsible for determining the future prospects of a company while establishing the basis on which all planning decisions will be made.

Strategic Decision Making (SD)

When talking about strategy in companies, it refers to choosing and making decisions, to compete and to be sustainable over time. Thus, the capacity for strategy is assimilated to think with strategy, to reflect in an orderly manner in search of preventing bad decisions for the viability of the future of the organization. This capacity for decision making allows having clarity about the objectives.

Strategic Planning (SP)

Strategic planning is an organizational or institutional administration activity that is used to set priorities, focus energy and resources, strengthen operations, employees and other stakeholders toward common goals, established agreements to generate intended outcomes or results. The planning also encompasses assessing and adjusting the organization’s direction in response to a changing environment.

Evaluating (EV)

Evaluate the result of the decisions and actions is not a confrontational action, it is an allied process that contributes to increasing the possibility of success of the organization. Evaluating involves comparing what have planned against the actual results obtained; For this reason, in order to evaluate correctly, it is necessary to plan correctly and follow up frequently on the objectives set and the strategies defined.

Accordingly, Figure 1 shows the dimensions.

Figure: Future Ready Strategy Dimensions

Source: (Conway, 2016)

Healthcare Performance (HP)

Performance is an important factor for the quality of any organization. It is especially important for the health sector, As it is required to provide quality health services to the society, because providing health service to society is one of the biggest challenges faced by health sector management. Healthcare performance is featured on the management style adopted by the hospitals, and the number of platforms developed or modified for the patients.
Material And Method

Sampling

The target population of the research consists of the customer of the private hospitals and clinics in Iraq. It is difficult to identify the actual number of private clinics and hospitals, because there is no very accurate statistic, therefore the sample was selected randomly and we have got 319. Sampling design which the process is undertaken to come up with the sample to be investigated was therefore necessary. The response rate is 87% and it considered highly adequate for analysis because it was above 70% which is recommended as adequate by Mugenda(2008). Cronbach alpha was used in this study to determine the reliability of the measures and its exceed 0.70.

Research Hypothesis

After review of the literature, the conceptual framework was formulated in Figure 2 to discuss the hypotheses as follows:

H1: The future ready strategy has a positive relationship on healthcare performance.

H2: The future ready strategy has a significant positive effect on healthcare performance.

Factor Analysis

In order to identify the components of the variables, the confirmatory factor analysis is performed. As it shown in Table 1 the confirmatory factor analysis exceed 0.5 and refer to that the items relating to each factors of future ready strategy and healthcare performance.

Hypotheses Testing

Hypothesis 1

From Table 2 it can be noticed that the correlation between the two variables (FS, HP) is strong and positive (r=0.648), and the significance of this correlation revealed through T test. The calculated T value is 15.530 and accepted at (P<0.05), this result means there are a correlation between (FS,HP) which support H1 Hypothesis.

Regarding to the sub hypothesis it is appeared positive relationship between ES,HP (r1=0.518), The (T=10.771) is accepted at (P<0.05), this result support H11 Hypothesis. While the relation between ST,HP refer to positive relationship with (r2=0.541) and significant with (T=11.445) and (P<0.05) this result support H12 Hypothesis. Regarding to the H13 hypothesis it is appeared positive relationship between SD,HP (r3=0.566), (T=12.222) is accepted at (P<0.05), this result support H13 Hypothesis. While the relation between SP,HP refer to positive relationship with
(r=0.630) and significant with (T=14.462) and (P<0.05) this result support H14 Hypothesis. Finally the relation between EV,HP also refer to positive relationship with (r=0.669), (T=16.018) is accepted at (P<0.05), this result support H15 Hypothesis.

Hypothesis 2

According to the result of Table3, observed that the regression analysis indicates that the constant effect is (B0=1.348), and the value of the regression coefficient (B1=0.574) means that there is an effect of (0.574), and the value of the coefficient of determination was (R2=0.420) that means the model explains (42%) of the variance of independent variable. The model is significant depending on the value of F test at level (P<0.05) and this result supports H2 hypothesis.

Regarding to the sub hypothesis it is appeared positive effect between ES,HP. The value of the constant effect (B0=1.514), the regression coefficient (B1=0.464), the model explains (26.8%) from the variance of HP, and the model was significant (P<0.05), which is accepted. This result supports H21 hypothesis. In accordance with the results, it was observed that there is a positive effect of ST on HP, the regression analysis indicates that the constant effect value is (B0=1.728), and the regression coefficient (B1=0.428), the model interprets (29.2%) from the variance of HP. The model is significant depending on the value of the F test and the significance value (P<0.05). This result supports H22 hypothesis. Also, The results show a positive effect of SD on HP, the value of the constant effect (B0=1.792), the regression coefficient (B1=0.420), the model explains (32%) from the variance of HP, and the model was significant (P<0.05). This result supports H23 hypothesis. In accordance with the results, it was observed a positive effect of SP on HP, the regression analysis indicates that the constant effect value is (B0=1.646), and the regression coefficient (B1=0.481), the model interprets (39.8%) from the variance of HP. The model is significant depending on the value of the F test and the significance value at the level of (P<0.05). This result supports H24 hypothesis. Also, The results show a positive effect of EV on HP, the value of the constant effect (B0=1.457), the regression coefficient (B1=0.550), the model explains (44.7%) from the variance of HP, and the model was significant (P<0.05). This result supports H25 hypothesis.

</tbody>
</table>
According to the multivariate regression it is appeared form Table 4 there are three significant relations with the dimensions (SD, SP, EV), which has (B3=0.180, B4=0.213, B5=0.419), with two not significant relations with the dimensions (ES, ST), which indicates that with multiple regression ES and ST will have no significant effect on HP.

Discussion

Iraq has undergone decades of war and unwavering sanctions from the United Nations. For example, Power failure grids as a result of the Gulf War in the 1990s and a decade of sanctions were among the side effects on the hospitals and water; sanitary installations on which it depends on sufficient electricity supply. Additionally, Long power interruptions that are still common can be extremely damaging, especially during the hot summer months. The hindering factors to the adequate growth of private hospitals are inadequate facilities such as electricity, peace and stability among the residents. After decades of war tension and fear of the unknown lacks behind the minds of many people dwelling in Iraq. For instance, the fighting against terrorism has a big effect on the health sector, the facility needs enough resources to be functional. Therefore, failure of the government to restore the national grid on time is a challenge amid the rising number of medical service demand. These conditions have affected the provision of logistical and financial capabilities; Therefore, the private healthcare sector has emerged as a competitive alternative, requiring effective strategic tools. Many studies ensure that it is beyond doubt that there is indeed a need to bridge the knowledge gaps by examining the relation between future ready strategy and the performance. Basic medicines have often been unavailable in various hospitals in the country. As a result, the mortality rate, more also the infant mortality rate has more than doubled. Unless some drastic measures are undertaken to improve the situation in the country, Iraq’s health care sector is likely to worsen even further. More focus should be placed on how to provide essential facilities like basic sanitation, essential drugs and immunization services. The country should also focus on improving the general level of satisfaction among healthcare customers.

Conclusions

As discussed above, it can be seen that the five strategies have a positive effect on the dependent variable healthcare performance and therefore hospital management should at all means try to make good use of these future ready strategies. It is appeared that hospitals and clinics should use future ready strategies to increase their performance. About 60% of these strategies were found to be competing favorably which clearly shows that the three strategies are prudent issues as far as performance concerned.

Incidence of Rota Virus as a Causative Pathogen in Iraqi Children Infected by Diarrhea

Samir S. Raheem¹, Mohammed M.M. Alomari¹, Nawar J.H. Al-Salih¹
¹Collage of Veterinary Medicine, University of Al-Muthanna, Iraq

Abstract
Rotavirus infection is common, particularly during the cooler months, among infants and children 1 to 24 months of age. Older children and adults can also be affected, but attack rates are usually much lower. Outbreaks among elderly, institutionalized patients have also been recognized. Rotaviruses appear to localize primarily in the duodenum and proximal jejunum, causing destruction of villous epithelial cells with blunting (shortening) of villi and variable, usually mild, infiltrates of mononuclear and a few polymorphonuclear inflammatory cells within the villi. In developing areas of the world, diarrhea is a significant cause of death in infants. It is estimated that young children in developing countries experience 1.5 billion episodes of diarrhea and 4 million associated deaths each year. Approximately 15% of children in developing nations die of diarrhea before 3 years of age, in United States 20-35 million episodes of diarrhea occur in every year, resulting in 2.1 to 3.7 million physician visits. In addition, an average of 220,000 children younger than 5 years of age with diarrhea are hospitalized and approximately 125 deaths are occurring each year, (Hospitalized and outpatient care for pediatric diarrhea result in direct costs of more than $2 billion per year with additional indirect costs to families. Aim of the study to evaluate the role of the Rota virus as a causative pathogen in Iraqi children less than two years of age suffered from diarrhea. A stool samples from 360 children suffered from diarrhea with less than 5 years of age were subjected for detection of Rota virus, using an antigen reagent ((a suspension of polystyrene latex particles of uniform size coated with immunoglobulin directed specifically against rotavirus antigen obtained from the simian rotavirus strain SA-11)). Samples were collected during the period from December 2017 to march 2018 from out and inpatients related to Al-Mansour teaching hospital in Baghdad. A 15 case out of 360 represent 4.16% diarrheal infected children majority below 6 months of age were founded to be positive for Rota virus test, all cases reported in September and October. Rota virus represents a considerable and significant pathogen in diarrheal infected children in Iraq and results in a morbidity and mortality in addition to financial loss.

Keywords: Rota virus, diarrhea, children

Introduction
Rotavirus is a double-stranded RNA, 65-75 nm, naked, double-shelled capsid. Usually incomplete, 5 serotypes important to humans, Duodenum, jejunum, Mechanism of immunity Local intestinal IgA, Epidemic or sporadic, Seasonality Usually winter, primarily affected Infants, children <2 years old, Method of transmission Fecal–oral, Incubation period 2-3(days), The human intestinal rotaviruses were first found in 1973 by electron microscopic examination of duodenal biopsy specimens from infants with diarrhea. Since then, they have been found worldwide and are believed to account for 40% to 60% of cases of acute gastroenteritis occurring during the cooler months in infants and children less than 2 years of age¹. Worldwide, at least 500,000 childhood deaths annually are attributed to rotavirus infections; whereas such deaths in the United States are rather infrequent, the annual morbidity rate has been nonetheless considerable in recent years. Recent introduction of vaccines for routine use may reduce their impact in the future. These viruses have been detected in intestinal contents and in tissues from the upper gastrointestinal tract².

In Iraq according to the information obtained from the biological statistics department in “Iraqi Ministry of Health”, the numbers of mortality of children under
“5” years of age suffering from diarrhea was as the following:

In 2001 the total number was 715340 children and the mortality number was 149 cases.

In 2003 the number was 303217 children and the mortality number was 144 cases.

In 2004 the total number was 897441 and the mortality number was 411 cases.

The mortality numbers without stable curve, in 1998 the number was 464, in 1999 was 456 whereas in 2000 the number was 244 cases.

The usual clinical syndrome is characterized by various combination of nausea, vomiting, abdominal cramps, and diarrhea, fever and dehydration also may be present, occasionally, systemic manifestation occur including bacteremia and immune-mediated extra intestinal manifestations of enteric infections, diarrhea and malnutrition related with, contribute in the past decades in children mortality in the Uruguay which reach to (120) for each (1000) newborn².

The causative agents of diarrhea include bacteria, virus, and parasites, E. coli considered as significant etiology of diarrhea in children in addition to Rota virus which cause 40% of diarrheal cases in children under ‘2’ two years of age, many children under school age infected by diarrhea caused by Shigella sonni and parasites³. Diarrhea still as a major cause of life threatening infections in addition that it’s the second ranking to respiratory system infections in mortality cases in poor countries.

**Material and method**

**Kits:**

1 - Agglutinating antisera for rotavirus. Rapid qualitative test for the direct detection of rotavirus group antigen in feces by agglutination of latex particles on slide. Manufactured by (Biokit – Spain).

**Serologic test for Rotavirus:**

Principle of Rotavirus test according to manufacturer (Biokit Spain):

The antigen reagent is a suspension of polystyrene latex particles of uniform size coated with immunoglobulins directed specifically against rotavirus antigen obtained from the simian rotavirus strain SA-11. Latex particles allow visual observation of the antigen – antibody reaction. When placed in contact with a sample containing rotavirus antigen. The uniform appearance of the latex suspension will convert to a clear agglutination. This change occurs because rotavirus antigen contained in the feces reacts with the specific immunoglobulins coated onto the latex particles, forming a web between them.

**Reagents:**

1 - Antigen reagent: Suspension of polystyrene latex particles coated with rabbit anti-rotavirus immunoglobulins in buffer. 2 -Control reagent: Suspension of polystyrens latex particles coated with non-immune rabbit immunoglobulins in buffer.

Positive control: Suspension of inactivated simian rotavirus antigen (SA-11).

Diluent.

**Procedure of rotavirus test:**

**A – Test performed in feces:**

A centrifuge tube was labeled for each sample to be tested. ~a 2ml of diluent was dispensed into each tube. 0.2g (0.2ml) of fecal specimen was added to each tube. Each tube was vortexed to obtain a homogenous suspension. All tubes stood for (5-10) minutes at room temperature. Then centrifugation of each tube for (10 min.) at 1000 G and Proceeding with assay using supernatant.

**B - Test performed from swab:**

A centrifuge tube was labeled for each sample to be tested. 2 ml of diluents was dispensed in each tube. The swab was immersed in the diluent, rolling it against the walls of the tubes to insure adequate dispersion of sample. Wringing the swab out above the liquid level by rolling it against the walls of the tube until all liquid has been expressed from swab, each tube vortexes to obtain a homogenous suspension. Then tubes were stand (5-10) min. room temperature, centrifuged for 10 min. at 1000 G. Proceeding with assay using supernatant.

Then allowed the reagent to reach room temperature. The reagents were shacked well to disperse and suspend the latex particles in the buffer solution. 5 0 µl of each supernatant was placed onto one section of the slide, and 50 µl onto another adjacent section. Adding
one drop of antigen reagent next to the sample in the first slide section and one drop of control reagent next to the sample in the second section. Using a separate stirrer, mix contents of both sections and spread over the entire surface of the slide section. Rotating the slide for 2 minutes manually or on a rotary shaker set at 60-80 r.p.m. observing for agglutination.

**Results**

Out of 360 cases of tested stool samples a fifteen 4.16% positive cases for Rota virus was detected as shown in the table below

**Table (1): Number and percentage of rotavirus positive patients.**

The present study revealed male 60% exposure to infection higher than female 40%

**Discussion**

A large number of studies have shown the important role of rotavirus as a cause of diarrhea in children in developed in addition to the developing countries 4, 5, 6, 7, 8, 9 and 10. Most of the cases occur in children less than 5 years of age as in table (2) that’s may be due to low tite of antibodies in their body to viral antigens. In addition to the age distribution of rotavirus infection, many studies have indicated a higher ratio of infected males table (3) to infected females 8, 11, 12, 13. This pathogen infects not only children but also adults14, and rotavirus infection may occur repeatedly in humans from birth to old age15. In the present study, a clear seasonal pattern in rotavirus diarrhea was seen peaked during the winter months, from September to December. There is wide range of diversity in the opinion between exerts and scientists about how to face the rotavirus diarrheal infection; some of them recommend to use vaccination as a priority to control the epidemiology others suggest to use the traditional management by replacement of the fluids and electrolytes in addition to emphasis on the hygiene and sanitation and hand washing in addition to the most important factor which is the breastfeeding.

Bladder Injury as a Complication of Cesarean Deliveries And Peripartum Hysterectomy

Naghm K. Tayeh¹, Nada Kadhum Kareem², Hayder Adnan Fawzi³

¹Department of Gynecology and Obstetrics, Fatima Al-Zahraa Administrative hospital, Baghdad, Iraq, ²Department of Gynecology and Obstetrics, Al-Mahaweel General Hospital, Babylon, Iraq, ³Baghdad Medical City, Baghdad Teaching Hospital, Clinical Pharmacy Department, Baghdad, Iraq

Abstract

Objective: review the incidence of iatrogenic bladder injuries (IBI) in obstetrical procedures and to identify the risk factors for these injuries.

Materials and Method: a retrospective research involve all patients that had cesarean deliveries (CS) and peripartum hysterectomies at Fatima Al-Zahraa Administrative hospital, from the 1st of January 2015 till the 30th of September 2018.

Results: A total of 35,212 CS performed during the study period, 68(0.19%) CS and peripartum hysterectomies were complicated by bladder injury of them 41% were type 1, 53% were type 2, and 6% were type 3 complications. Adhesions documented in 73%, while 12% had placenta accreta and 15% had ruptured uterus. Elective CS performed in 47% of the cases. Most cases of IBI occurred during reflection of bladder flap 56% and are mainly in type 1 and type 2 while 30% occurred during delivering the baby. All cases of type 3 (6%) occurred during opening the peritoneum.

Conclusion: bladder injury is a rare complication of cesarean delivery and peripartum hysterectomy but knowledge of the obstetrical, surgical and anatomical factors that can predispose to injury is the key to prevention.

Keywords: cesarean delivery, iatrogenic, bladder injury, adhesion, complication

Introduction

Cesarean section is the most frequently performed obstetrical surgery in the world and their number are increasing every year. The reduced rate of morbidity and mortality to the mother during cesarean section are noticeable over the last century but there is a growing number of urological complications during cesarean sections due to anatomical proximity of urinary tract and genital tract predispose them to iatrogenic trauma during obstetric surgery. Bladder injury has been reported to occur 0.27% in primary cesarean deliveries and 0.43%-0.81% in repeated cesarean deliveries. During repeated cesarean deliveries two surgical challenges are often encountered; that the bladder is densely adherent to lower uterine segment, and might have healed in position much higher on the uterus, thereby blocking access to lower uterine segment.

During emergency lower segment cesarean section for placental abruption or fetal distress bladder injury might occur because of visualization and dissection of each surgical procedure less than optimal. In cesarean deliveries of protracted second stage, the vagina rather than the lower uterine segment might be incised because of difficult identifying the interface between uterus and vagina resulting in an increased risk of bladder injury. Placenta accreta may penetrate posterior bladder wall causing injury to the bladder. When uterus ruptures, shearing force transmitted to the bladder there by cause bladder injury.

Iatrogenic bladder injury associated with significant short and long term morbidity and potential complications include prolonged operative time, urinary tract infection, prolonged indwelling catheterization time and although very rare, visicouterine and vasicovaginal...
fistula. The best management of this pathology is prevention of several predisposing conditions, it had been identified and surgeon should be aware of these risk factors of bladder injury immediate recognition and repair yields better results.

Method

This study represented a single institutional experience of iatrogenic bladder injury during cesarean deliveries and peripartum hysterectomy at the department of obstetrics and gynecology at Fatima Al-Zahraa administrative hospital from the 1st January 2015 till the 30th of September 2018, during the study period the total number of cesarean deliveries was 35,212. Sixty eight of those patients developed bladder injuries and were enrolled in this study. All patients had detailed history taken and clinical examination performed. Iatrogenic bladder injury is identified as full thickness accidental incision of bladder wall which need immediate repair.

Information collected about age, parity, previous pelvic surgeries, the stage of labor, timing of delivery (elective, urgent, or emergent) and concurrent uterine rupture or placental accreta. Timing of delivery was defined as elective if the surgery was scheduled or urgent if surgery needed to be performed in timely manner, or emergent if delivery was immediate emergency. Operative information collected about the presence of adhesions; through retrospective review we researched the site, size, etiologic characteristics, and time of injury.

According to the complexity of injuries it was categorized the patients into three types:

Type 1: simple tear in the dome or anterior wall of the bladder.

Type 2: dome injury complicated by vertical extension either in lateral or posterior bladder wall.

Type 3: those with incision of both anterior and posterior walls of the bladder through which the baby had been delivered.

In all cases with IBI, the senior obstetrician consulted a duty urologist who would thoroughly assess the extent of bladder injury, look for associated ureteric injuries intra-operatively. The bladder defects are sutured in two layers with absorbable sutures and the integrity checked by distending the bladder. Wound drainage is mandatory, Foley catheter is kept for (7-28) days according to the case. Cases with major bladder repair were followed up by the concerned urologists and fully revealed at our center. During follow up, patients underwent ultrasonography, retrograde pylogram or voiding cystogram to assess their urinary tract before declaring cured. No cases with associated ureteric injuries or complicated by fistula.

Statistical analysis was carried was using chi square analysis for discrete variables, the 95%CI of the prevalence was calculated using the formula:

\[ p \text{ (1 - p) } \times \frac{z}{\sqrt{n}} \]

In which \( p \) = prevalence of the disease, \( q = 1 - p \), \( z \) is normal score distribution, \( \alpha = 95\% \), \( n \) = total sample size.

GraphPad Prism version 8.0.0 for Windows, GraphPad Software, San Diego, California USA, software package used to make the statistical analysis, p value considered when appropriate to be significant if less than 0.05.

Results

Bladder injury is a rare complication of cesarean deliveries, in the current study there were 35,212 cesarean deliveries of them 68 cases had IBI, and the rate of injury was 1.93 per 1,000 CS (95%CI: 1.89 – 1.98 per 1,000). The age range from 19-43 years old for women with IBI with mean age 30 years.

Results according to the type and complexity of the bladder injury as following:

Type 1: 28 cases (41%) had simple tear to the dome or anterior wall of the bladder

Type 2: 36 cases (53%) had dome injury complicated by vertical extension either in lateral or posterior bladder wall

Type 3: 4 cases (6%) had incision of both anterior and posterior walls of the bladder through which the baby had been delivered.

Discussion

In this study 35,212 CS were carried out in the center; accidental cystotomy however occurred in 68 cases (0.19%) which is corresponding with the reported incidence that ranged between 0.27% to 0.81% of cesarean deliveries. In the current series, the most common type of bladder injury was type 2 where the injury affect the dome and extended to the posterior or lateral wall followed by type 1 and then type 3. According to the size, in 23% of cases the size of the injury were <2 cm which could be repaired by the obstetrician and may be sutured by single layer, while 14 cases (20%) are of type
2 where the injuries extended posteriorly or laterally so the urologist were involved in repair.9.

The most common cause of IBI was dense bladder adhesion, during repeated cesarean deliveries. In the existing study adhesion was the most common cause of IBI and was responsible for 73% of the cases, and all cases of type three bladder injury caused by adhesion. The pathogenesis of adhesion is a complex process in which fibrin, coagulation factors, and inflammatory cells repairing the peritoneum so preventing the risk factors for development of adhesion includes: infections, excessive tissues manipulations, increased blood loss during surgery, adhesiolysis, and tissue ischemia.2,5. Thus the best approach is prevention of injury by careful sharp dissection and limitation of blunt dissections.2.

A cesarean hysterectomies performed for severe bleeding from Placenta accreta were associated with IBI in 12% of the cases, and all the cases were type 2 so in these instances, an expert multi-professional team is essential to minimalize neonatal and maternal morbidity and mortality throughout planning elective operations.5,8. When the uterus is ruptured, shearing force may be transmitted to the bladder causing direct injury, in our results it occurred in 15% of the cases and there were all in type 1 and type 2.10.

IBI occurred more with elective cesarean sections (35%) of cases due to the fact that elective cesarean delivery were carried for patients of at least one cesarean or in older patients. followed by emergent CS and all cases of type 3 IBI (6%) occurred with emergent CS during opening the peritoneum, which reflect the stressful nature of the operation so despite the emergency situation, the surgeon should be aware of the risk of IBI, and proceed in controlled manner to limit the chance of bladder injury.2. The timing of cesarean delivery during either the first verses second stage of labor also has impact, the risk of damage to the urinary bladder and the extend of this injury is increased in the second stage compared to the first stage due to the fact that the pressure of fetal presenting part changes the local blood supply to the bladder wall rendering it more vulnerable to injury, also it is difficult to distinguish the edge of the lower uterine segment and the bladder.2,8.9.

Time of bladder injury occur during reflection of bladder peritoneum in 56% while 30% during delivery of the baby the station of fetal presenting part deeper or equal to +1 hinders its extraction, promotes damage to the lower uterine segment which often coexist with damage to the bladder. All cases of type 3 bladder injury occur during opening peritoneum.6,8.

One of the most distress injuries that can occur during surgery to an individual is bladder injury which can have serious implications going forward if not identified in timely fashion. It is important to understand that most bladder injuries are preventable, identifiable and treatable. Such an injury is recognizable complication of hysterectomy or cesarean section procedures; however, if an immediate repair is carried out the potential fistula issue can be avoided. There was no evidence of consecutive complications of bladder dysfunction in our patients. In this study we do skipped several limitations including that bladder injury may be grossly underreported in the medical reports we were not relied on the medical coding to identify bladder injury moreover medical reports reviews also bring out inherited bias in reporting on risk factors. It is important that we study and understand the complications associated with cesarean deliveries and particularly with repeated cesarean delivery. We believe that our data have important implications for counseling patients regarding elective cesarean deliveries, thus women planning large families should consider the risk of repeated cesarean delivery.5

Conclusion

Bladder injury is a rare complication of cesarean delivery and peripartum hysterectomy but knowledge of the obstetrical, surgical and anatomical factors that can predispose to injury is the key to prevention.7

Conflict of Interest: None

Ethical Clearance: Informed written consent was obtained from all the participants in the study, and the study and all its procedure were done in accordance with the Helsinki Declaration of 1975, as revised in 2000. The study was approved by Gynecology & Obstetric department of Fatima Al-Zahraa Administrative hospital.

Abstract

The research has contained several axes and it has been emphasized on the axis of measurement of spatial cognition in the research sample and its connection with to the level of performance of the skill of front repel blow of the badminton whereas a test was constructed to measure the cognitive skill of each member of the sample , also the researcher used Luay Al-Bakri’s test to measure the level of skill performance of the front-end blow. After the tests were completed, the statistical results were extracted which showed that there is a significant correlation between the level of spatial cognition and the level of skillful performance of badminton players.

Keywords: Spatial perception, skill.

Introduction

It is possible to consider the badminton game as a sporting event spread all over the world for the ease of its requirements in terms of space, tools and practiced from all age groups as amateur and professional anyone can play the game and even enjoy it without having a little background about this game,¹ Special skill performance and a wide range of abilities and skills, especially mental ones, because the mind occupies a large place because of the small play space and speed of performance and maneuver that may be faced by the opponent, which requires the player to interact mentally and employ all skills associated with creativity.

The consciousness is one of the important issues dealt with in the psychology of study and research as it is the fundamental pillar of human life in practice, mental, and is the basis for the process of knowledge and is shared with all other mental processes of perception, imagination and thinking, providing it with the necessary and necessary information is the main pillar in the success of any human effort, whether theoretical or practical effort applied science,² and the cognitive has a number of the varieties and forms the most important the spatial perception which means sense of the repel of objects, any length and width and the height and depth and its position left, right and we use so many connotations that enable us to understand the spatial aspects arrangements of things in the outside world and thus helps us visual perception.³ The level of skillful performance of most sports activities in general and badminton in particular is closely related to the use of possible mental processes associated with the same skill.

The study aims to:

Recognition of the relationship between spatial cognition and the level of skill performance of the skill (front repel blow) through:

1- Identifying the level of spatial cognition in the research sample.

2. Measuring the level of skill performance.

The advantage of the study:

Knowledge of the contribution rate and the variable correlation (spatial perception) at the level of skill performance and include tests to measure spatial perception and level of skillful performance.

The scientific achievement:

Here Manifested the importance of research in accessing the database of the sample through knowing the relationship of spatial cognition to the level of skillful of badminton players and the inclusion of measures that measure the ability of spatial cognition and the level of performance of the skill (front repel blow) in this field. It
could be considered also one of few also a few attempts to study these aspects in the field of sports and especially badminton.

The practical part:

The Field research procedures:

The researchers have used the descriptive method in the correlative relationships style to suitability and the nature of the research. The researchers chose the sample from the study community in a random stratified manner represented by students of the third grade of college of Physical Education and Sports Sciences / Al-Qadisiyah University with 150 students and 30 students were selected as a sample divided equally on (15) for both gender.

Tests and Metrics:

1- The spatial perception test.

2 - Test the level of the performance skillful of the forward repel blow of badminton.

First: The spatial perception test:

The researcher divided the badminton field from the tested side to (5) vertical rows and (5) horizontally to form transparent squares with a length of 1.5 meters and a width of 1.20 meters in amount (25) square. In order to show the level of difficulty in the test, the researcher neglected the first five squares close to the network to become (20) square and at the start of the test assistant to throw the transmitter to the laboratory and during the maintenance between the laboratory and the assistant, The arbitrator orders (stop) The tested immediately closes its eyes and raises its head to the top and asks for the column number (1-5), the horizontal row number of (1-5) and the square number of (1-20) according to the base and count (5) score for each correct answer and deduct its score whenever the answer moves away by one number from the correct answer and three attempts are given to each examiner then collected and divided into.

Second: Test the level of performance of the blow to the front:

The researcher made a reference to the examined player’s place and divide the stadium into four zones for falling the badminton starting from the area (3) points and at a distance of (50) cm after the back line of the square and then the area of (5) points which is the area between the back line of the square and the beginning of the remote doubles transmitter line at a distance (76) cm followed by the area of (4) points and the occurrence after the remote pairing line at a distance of (70) cm followed by the area of (2) point between the area of (4) points which is located after the remote doubles transmission line and by distance of (70) cm followed by the area of (2) points which sited between the area of the (4) points and ends in the imaginary line down the rope and when sending the badminton to the tested by the assistant, the tested blows the badminton to forward repel blow and send it over the network and rope, the points are calculated where it falls in any place of the four regions, no points are given if the badminton falls off the field or under the rope, 12 attempts are given and counted the best (10) tries to the maximum limit of the attempts (50) points.

The scientific foundations of the tests:

The researchers designed and constructed a test that could measure spatial cognition in the research sample, the researchers keen to test in the badminton court and during the performance of the frontal shocks to match the research requirements for which the test was set up. In order to ensure that the test is suitable for use and according to scientific foundations, the researchers extracted the empirical basis for the test (honesty, consistency and objectivity) by conducting an exploratory experiment on a sample from the outside of the research sample and from the same community to learn about the pros and cons of the tests that the researcher may encounter during work in order to obtain a good measure of honesty and consistency.

The researchers also used a test (Loay Bakri) to measure skill blow forward for badminton.

Validity: One of the most important characteristics of the standard of the scale agreed by specialists in the measurement of psychological integrity and reliability, depending on the accuracy of data or grades obtained from the psychological standards.

The researchers used a questionnaire for referees with experience and specialization in the fields of psychology, tests, measurement and badminton. The number (10) to take their views in terms of validity of the test to measure the skill of spatial perception and modify what they see fit. The test was approved by the
current status of all ten experts. as shown in table (1).

Table (1) shows the validity of the tests

Stability: The fixity stability means that if the same subjects are re-tested under the same conditions and variables, it gives the same conditions and variables, and it gives the same results or may be close (8). To extract the stability of the test, the researchers used the test and retest method on a survey sample consisting of (10) tested of both gender, 5 males and 5 females, under the same conditions and timing. The first test of spatial cognition took place on 17/12/2018, (24/12/2018). The test of the forward blow was performed on (18/12/2018) and the test was repeated on (25/12/2018). The coefficient of statistical stability was calculated by extracting the simple correlation coefficient Pearson and the correlation was high between the two tests, Stability is also high, as shown in the following table:

Table (2) shows the coefficient of correlation of test stability

</tbody>
</table>

Main experience: After the confirmation of the validity of the tests and solid scientific foundations .The researchers conducted the main experiment on a sample of (30) tested of both gender and 15 males and 15 females. The spatial cognition test was conducted on the sample on 2/1/2019, 3/1/2019). After the results were unpacked and statistically computed, the results were significant by the effect of the spatial cognition skill on the forward repel blow.

The statistical means:

The statistical program was used spss.

Results and discussion

After the researchers emptied the results of the main tests and processed statistically and for the purpose of evaluating the performance of the skills of spatial perception and frontal repel blow od badminton which has been analyzed data using the statistical bag (spss) (9), and the results have been shown to a significant correlation between the skill spatial perception and level The performance of the front-end trampoline skill, Table (3) and (4) show this.

It has been shown that the mean of the sample is located in the central region the sample is of average level, the researchers attributed this to the fact that the sample are students of the Faculty of Physical Education and sports sciences and not players clubs or teams. In order to achieve the third goal of the research the researchers have extracted the results of a multiple correlation between the (cognitive and performance) of the variable input ratio questionnaire with the performance level, the results show that there is a correlation between the spatial variable and the performance level, as in Table (6).

The researchers attribute that correlation to the fact that the badminton game is individual and fast-acting needed a great mental abilities to achieve better performance and down to the achievement of those processes are the skill of spatial cognition where it requires, the skillful player must always be aware of his existential position within the arena and distance and proximity to the network so that he can maneuver and deceive the opponent and counter rapid and multi-directional opponent strikes and diversification, in the exercise of the skill forms they will have the ability to recognize the stimuli.
Table (6) shows the percentage of contribution of variables

Since the percentage of the contribution has been shown to the researchers, they have shown the predictive value of the variables and the proportion of their correlation with the level of performance,\(^{10}\) as in Table (6) where through this equation we can know the proportion of performance of students or players and labs by entering the laboratory data test spatial perception to show us what the result His skill level with the frontal impact of the plane feather according to the predictive equation.\(^{11}\)

**Conclusions**

That of spatial perception percentage of the contribution of the correlation between the level of skill performance for badminton players in general and for the skill of blow forward in particular being a particularly important mental skill with quick individual games we can predict the level of skill performance for players through their cognitive level.

The researchers recommend the trainers and teachers to pay attention to the development of the skill of spatial recognition of badminton players through training to train the skill of spatial awareness and enhance the trainees, which reflected positively on the level of skill performance of players.

Echocardiographic Stigmata in the First Attack of Acute Rheumatic Fever as a Major Criterion for the Diagnosis of Rheumatic Carditis in Misan, Iraq

Khalid Obaid Mohsin¹, Hussein Fadhil Musa Aljawadi², Esraa Abd Al-Muhsen Ali²

¹Head of Internal Medicine Department, College of Medicine, Misan University, Misan, Iraq, ²Assistant Professor, Pediatrics Department, College of Medicine, Misan University, Misan, Iraq

Abstract

Background: Doppler Echocardiography facility is usually available in the most areas of the world and its routine use in the initial diagnosis of rheumatic heart disease may promote early detection, much earlier that clinical examination does.

Objectives: To evaluate the utility of Doppler Echocardiography for the diagnosis of carditis in patients whom clinical examination did not indicate any evidence of carditis.

To describe the spectrum of cardiac abnormalities in patients with primary episode acute rheumatic fever.

Patients and Method: A cross sectional and prospective study conducted during a period of five years in Misan province (South East Iraq). Referred patients for an echocardiographic evaluation in Al-Sader Teaching Hospital with diagnosis of acute rheumatic fever as first attack were selected. All patients were examined clinically then subjected to Doppler Echocardiographic evaluation in the first 48-72 hours of acute phase and 2 weeks later.

Results: A total of 36 patients with median age of 13±4.69 years and male predominance were presented with diagnosis of primary attack of acute rheumatic fever. The majority were presented with migratory polyarthritis (80.6%) and clinical carditis (44.4%). Clinical carditis was found in 16/36 patients while the remaining (20 patients) had no clinical carditis. On the other hand, Doppler Echocardiography confirmed the diagnosis of carditis in additional 10 cases without clinical carditis.

About almost all patients with acute rheumatic carditis (25/26) had mitral valve /aortic valve thickness >4mm. Valvular regurgitations were constituted the major manifestation; mitral regurgitation was found in the majority (21/26 patients) followed by aortic and tricuspid regurgitation.

Conclusion: Doppler Echocardiography is more sensitive than a clinical assessment in the detection of carditis in patients with an initial attack of acute rheumatic fever. It is a useful method in identifying the subclinical mitral and aortic valvular disease when carditis cannot be detected clinically. Therefore, it is reasonable and valuable to support the addition of echocardiographic stigmata of rheumatic carditis to the current diagnostic criteria as an isolated major criterion by itself for the validation of rheumatic carditis with subclinical carditis.

Keywords: Rheumatic fever, carditis, echocardiography, Misan, Iraq.

Introduction

Acute rheumatic fever (ARF) is a common serious public health problem in the developing countries (¹). Despite the decline in its incidence in Europe and
North America with the tremendous progress made in cardiology, ARF is still forming a major healthcare concern for the vast majority of the populations in the world including children, adolescent, and young adults (1, 2, 3, 4).

Rheumatic heart disease (RHD), the sequel of ARF, is a very common cause of cardiovascular morbidity and mortality, as well as, the predominant indication for cardiac surgery in the developing countries (1, 5).

At 2001, World Health Organization (WHO) reported that a clinical examination is still the basis of the diagnosis of ARF and carditis, and the role of an echocardiographic study is considered supportive. However, an Echocardiography/Doppler examination should be used if the facilities are available (5).

In addition, the WHO reported that an involvement of echocardiography to detect valvular regurgitation and confirm the diagnosis of subclinical rheumatic carditis is still controversial (5).

Moreover, different studies showed that the inclusion of imaging study of echocardiography into Jones criteria cannot be justified unless long term results of prospective studies are available to emphasize the importance of detecting subclinical rheumatic carditis in treatment and prognosis (6, 7).

Nowadays, Doppler Echocardiography facility is usually available in the most areas of the world and its routine use in the initial diagnosis of RHD may promote early detection, much earlier that clinical examination does (8). Echocardiography has been proven to be more specific and sensitive than auscultation. It can detect early evidence of valvular involvement, can confirm the presence of valvular regurgitation, and can exclude the non-rheumatic etiologies of valvular involvement (9, 10).

Consequently, in 2012, the World Heart Federation echocardiographic criteria for RHD have been developed. Three groups are identified on the basis of assessment by 2-Dimensional, continuous-wave, and color-Doppler echocardiography: definite RHD, borderline RHD, and normal. Additionally, even the morphological features of RHD, as well as, the criteria for pathological aortic and mitral regurgitations are also defined (11).

Lately, in 2015, the American Heart Association released recommendation for using echocardiography with Doppler in ARF; one of these recommendations is to assess for the presence of carditis in the absence of auscultatory findings, especially in moderate to high risk groups and whenever RHD is a possible diagnosis (12).

For these reasons, this study had arised to evaluate the utility of Doppler Echocardiography for the diagnosis of carditis in patients whom clinical examination did not indicate any evidence of carditis and to describe the spectrum of cardiac abnormalities in patients with primary episode ARF.

**Patients and Method**

A cross sectional and prospective study conducted during a period of five years from September 2010 to September 2015 in Misan province (South East Iraq).

Reflected patients for an echocardiographic evaluation in Al-Sader Teaching Hospital with diagnosis of ARF as initial attack were selected. Diagnosis of ARF in these cases was according to the revised Jones criteria (12, 13).

Total sample size was 40 patients with first episode of acute rheumatic fever, but only 36 patients came for follow-up evaluations. So the final sample size was 36 cases; male were 22 cases and female were 14 cases. Age was ranging from 6-22 years.

Initially, all patients were examined clinically at the referral time. So patients were classified into 2 groups:

- 16 cases with clinical carditis.
- 20 cases without clinical carditis.

Then all patients were subjected to Two-Dimensional Echocardiography and Doppler Color Flow (2D Echo Doppler) evaluation in the first 48-72 hours of acute phase and 2 weeks later. All patients were examined by the same specialist doctor to exclude personal variation.

Echocardiographic imaging was performed with GE machine, model vivid, version E9 following the recommendation and guidelines of using echocardiography with Doppler in ARF (11, 12).

**Exclusion criteria:** Previous history of ARF or recurrent attacks of ARF, known case of chronic RHD, and echocardiographic stigmata of chronic valvular disease (such as restricted excursion or doming of valve leaflets or significant mitral or aortic stenosis). In addition, any case rejected to be involved in this study...
or did not complete the follow-up evaluations was excluded.

The study protocol was reviewed; ethical approval and official permission were obtained from Ministry of Higher Education, College of Medicine in Misan, Misan directorate of health and Al-Sader Teaching Hospital to carry out this study. An informed written consent was obtained from each patient or from their parents.

The analysis of data was carried out using Microsoft Excel and was presented in form of tables of numbers and percentages.

Results

A total of 36 patients with median age of 13±4.69 years and male predominance were presented with diagnosis of initial attack of ARF according to revised Jones criteria. The majority were presented with migratory polyarthritis (80.6%) and clinical carditis (44.4%) as shown in Table 1.

Clinical carditis was found in 16 patients with a first attack of ARF while the remaining (20 patients) had no clinical carditis. On the other hand, 2D Echo Doppler confirmed the diagnosis of carditis in additional 10 cases without clinical carditis as shown in Table 2.

About almost all patients with acute rheumatic carditis (25/26) had mitral valve /aortic valve thickness >4mm. Valvular regurgitations were constituted the major manifestation; mitral regurgitation was found in the majority (21/26 patients) followed by aortic and tricuspid regurgitation. In addition, acute heart failure was present in 2/26 patients and the same number was seen with pericardial effusion as shown in Table 3.

Discussion

The recent guidelines of Australian and New Zealand on ARF have been accepted an echocardiographic subclinical carditis as a major criterion. So, all patients with suspected or definite diagnosis of ARF should undergo an echocardiography to detect the evidence of carditis.

In the current study; the frequency of primary episode ARF occurrence during 5 years was 36 (plus 4 cases were excluded) which was much less than the
frequency of Turkey study in which 118 cases were diagnosed during the period of 3 years only (2). This frequency of occurrence would not reflect the exact rate in Misan because some patients may be already referred to other centers.

Additionally, the present study showed that migratory polyarthritis (80.6%) was the commonest manifestation of the first attack ARF while a clinical carditis (44.4%) was the second presenting features. These rates were higher than Turkey (2).

A clinical carditis was diagnosed in less than half of cases (16/36 cases), which was slightly less than Caldas et al study who reported about 50% of cases had a clinical carditis (15). This may be related to a personal variation in the clinical skills of auscultation.

On the other hand, this study revealed that rheumatic carditis was more frequently diagnosed by 2D Echo Doppler than clinical examination, especially in sub-clinical carditis. These results were consistent with different studies (16, 17). A study by Marijon et al in Cambodia and Mozambique revealed that echocardiography can detect up to ten times the number of carditis in ARF in comparison to a clinical examination alone (18).

These findings suggest that carditis was missed by a clinical examination. Also, it was reported that the clinical skill of auscultation by the training physicians may be not the optimum one, especially, in areas where ARF is declining (19).

In addition, the precise diagnosis of both clinical and subclinical carditis by using 2D Echo Doppler has been documented and it is more accurate than clinical auscultation, and if integrated in the Jones criteria, it can prevent both over- and under-diagnosis of valvular pathology in ARF patients (20).

Diffuse thickening > 4 mm and valvulitis of the mitral valve leaflets was a universal feature in acute rheumatic carditis (25/26 cases). Therefore, any carditis without valvulitis or valvular thickening is unlikely to be rheumatic in origin (21).

In rheumatic carditis cases; there was 2/26 cases of acute heart failure, both of them were associated with valvular regurgitation. Obviously, echocardiography is more sensitive for diagnoses of valvular regurgitation with increasing rate in detecting mitral, aortic, and tricuspid regurgitation.

In spite of all these findings, till now, there is a fear from increase the chance of over diagnosing carditis in large proportion of ARF patients (5). The over interpretation of valvular regurgitation (physiological or trivial) may lead to misdiagnosis of an iatrogenic valvular disease (22). This was attributed to a higher sensitivity of 2D Echo Doppler in detecting the abnormal blood flow and valvular regurgitations (9, 10). On the other hand, the use of 2D Echo Doppler can decrease the over diagnosis of the functional murmur as a valvular heart disease (9, 10).

So, an accurate interpretation, as well as, the technical expertise with 2D Echo Doppler with following the World Heart Federation echocardiographic criteria are essential to reach a correct diagnosis and to avoid the over diagnosis in RHD patients (6, 11).

The current study clearly revealed a significant incremental diagnostic utility of 2D Echo Doppler in the first attack of ARF especially in subclinical carditis and can eliminate the over diagnosis of rheumatic carditis depending solely on cardiac auscultatory findings, hence, better diagnosis, treatment, and prophylaxis (23, 24).

Conclusion

The imaging study of Two-Dimensional Echocardiography and Doppler Color Flow is more sensitive than a clinical assessment in the detection of carditis in patients with an initial attack of acute rheumatic fever. It is a useful method in identifying the subclinical mitral and aortic valvular disease when carditis cannot be detected clinically. Therefore, it is reasonable and valuable to support the addition of echocardiographic stigmata of rheumatic carditis to the current diagnostic criteria as an isolated major criterion by itself for the validation of rheumatic carditis with subclinical carditis.

A Comparative Study of Different Types of Warm-up Effect on Postural Stability and Isokinetic Strength

Mohammad Ahsan
Assistant Professor, Department Physical Therapy, College of Applied Medical Sciences, Imam Abdulrahman Bin Faisal University, Dammam, Kingdom of Saudi Arabia

Abstract

To investigate which warm-up method is more effective on the postural stability and isokinetic strength, we conducted this study. Forty-five participants were recruited, all participants divided into three groups. Active warm-up consisted 12-minute jog on self-regulated treadmill followed by five push-ups, pull-ups, five-meter single leg hop to and from with alternate leg, five half and full squats, Passive warm-up consisted moist heat heating device, Combined warm-up involved active warm-up and passive warm-up exercises. The dynamic stability was tested by stabilometer. Test was done with open and closed eyes, with two stability level i.e. hard & easy. The isokinetic dynamometer was used to measure muscle performance. The test was done with 3 repetitions of concentric/concentric at low speed of 60/60/sec, followed by high speed of 180/180/sec. Data were analyzed and findings revealed that combined warm-up is effective as active and passive warm-up for postural stability and isokinetic strength with significance differences.

Keywords: Isokinetic Strength, Postural Stability, Warm-Up.

Introduction

Warm-up is commonly known as preparatory practice that aimed to improve the subsequent performance. It’s often prescribed with general cardiovascular warm-up of 10-20 minutes and stretching followed by a specific warm-up for the specific sports. Prior to any activity, coaches believed that warm-up foster better performance as well as reduce the degree of musculoskeletal injuries. Warm-up improves sports performance in many way by increase body temperature reduce muscle stiffness, increase muscle contraction speed, maximize the muscular-potential, increase heart-rate, increases blood-flow, better utilization of oxygen, greater economy of movement due to decreased muscle resistance, increase concentration and neuro-muscular signals for desired performance outcome in a competition.

There are few researches revealed that there are significant differences in sprint performance or agility and jump performance. The advantages of warm-up before the competition and sports activities remain universally accepted. Some of the investigations used more suitable protocols, either for specific or general warm-up. These researchers found that there are no deteriorations in performance due to warm-up. This might be because of following realistic warm-up protocol, or alternatively because of dynamic warm-up removing or reducing unfavorable effect. Generally, there are two types of warm-up Active and passive.

The active warm-up helps to reduce muscle stiffness through breakdown stable bound between myosin and actin filaments. Active warm-up improve performance in speed, endurance in swimming and accuracy in basketball foul-shooting, peak torque on a cycle ergometer, 55m runtime. Voluntary resistance methods of stimulating post-activation potentiation (e.g. loaded squat exercises) can enhance countermovement jump’s height and short- sprint performance. There were some improvements in vertical-jump performance with general warm-up, static stretching, and proprioceptive neuromuscular facilitation (PNF) performed by female participants. Neiva et al. found that swimmers were significantly 1.5% faster with warm-up while comparing with no warm-up.

Passive warm-up enhances blood flow into major muscle group and prevents energy expenditure. Numerous researchers such as and so on studied
the performance of untrained, moderate trained and trained male athletes with several warm-ups protocol and results showed that there were significant improvements in sprint time, average speed, peak velocity, peak torque at exercise, in comparison to without warm-up. Holmstrom and Aalborg27 also suggest that a small number of warm-ups might be effective for increasing and maintaining range of motion and muscle endurance for untrained male workers. Increase in the muscle performance reduces sports injuries and improve athletic performance28. There is a significant improvement in motor skills from balance training resulting in enhancing the rate of force development29.

Although active, passive and combined warm-up protocols are often prescribed before any sports activity; considerable studies have been accomplished on these concerns to determine effects of different protocols on performance. Some research has significant effect whereas others have non-significant effect. Due to unanimity concerning the effect of warm-up upon sports performance might be lack of heterogeneity to different exercise protocols. To investigate which warm-up (active, passive and combined) method is more effective on the isokinetic strength and postural stability we conduct this study.

Method

Participants:

Forty-five participants were recruited for this study, all participants divided into three groups (15 participants in each group). All players were injury-free and volunteered to participate in this study. The age: 28.6±5.6 years, height: 165.8±5.4cm. of participants. All participants were informed prior regarding objective, protocol, and risk associated with experimental procedures, they provide their consent for this study.

Warm-up methods:

Active Warm-up: Active warm-up (AWU) included different exercises as intervention. AWU started with 12-minute jog on self-regulated treadmill followed by five push-ups, pull-ups, five-meter single leg hop to and from with alternate leg, five half and full squats.

Passive Warm-up: Passive warm-up (PWU) consist moist heat heating device that included eight Chattanooga original hydro-collator moist heat hot packs (Standard-size 10” x 12”) as an intervention. PWU started to leg and hip muscles (Gluteus, Hamstrings, Quadriceps, Gastrocnemius, and soleus) for 20-minutes duration. During application, participants lay down in prone position.

Combined Warm-up (CWU): it involved both warm-up exercises. The only difference is that 6-minute jog followed by five push-ups, pull-ups, five-meter single leg hop to and from with alternate leg and hydro-collator moist heat hot packs were applied over the leg and hip muscles for 12 minutes duration.

Postural Stability Test:

The postural stability was measured by stabilometer (Techno-Body Machine). For the unipedal test, each participant stands with dominant leg on the platform with his hands on his waist. Each test took 30 seconds. Each test was done with open and closed eyes, with two stability level hard and easy. Instructions were followed according to user manual for standardized testing procedure.

Muscles Strength Measurement:

Isokinetic dynamometer (BIODEX) was used to measure muscle performance. The range of motion was set as 0 degree and 100 degrees away from the body and toward body respectively. Weight of leg was measured by fixing on 90 degrees of flexion. Participant performed five repetitions of CON/CON at low speed of 60/60/sec, followed by a high speed of 180/180/sec. One minute rest was given between velocities.

Statistical analysis:

The collected data were statistically analyzed by using SPSS v-20. Descriptive statistic and one-way analysis of variance (ANOVA) with LSD post-hoc were computed to explore significant difference of active, passive and combined warm-up on the postural stability and isokinetic strength. Level of significance was set at 0.05.

*Significant at 0.05 level

The above table revealed that calculated value of F=10.449, 8.107, and 6.487 for postural stability at open-eyes and closed-eyes with easy-level, and hard level respectively showed significant differences in between different types of warm-up. Whereas the calculated value of F=1.636 for open eyes at hard level showed insignificant difference. Thus, LSD has been calculated to determine existence of significant mean difference between warm-ups. LSD showed that combine v/s active and combine v/s passive have a significant difference with open and close-eyes at easy level, whereas combine v/s active also have significant difference with closed-eyes at hard-level. Further, Active v/s passive warm-up showed no significant difference at any level for postural stability.

*Significant at 0.05 level

The above table revealed that the calculated value of F=7.011, 4.109, and 8.736 for isokinetic strength quadriceps-60°/sec, hamstring-60°/sec and quadriceps-180°/sec respectively, showed significant differences for different types of warm-up. Whereas, calculated value of F=0.034 for hamstring 180°/sec showed insignificant difference. Thus, LSD has been calculated to determine the existence of significant mean difference between warm-ups. LSD showed that combine v/s passive and active v/s passive warm-up have significant differences with Quadriceps-60°/sec, Hamstring-60°/sec, Quadriceps-180°/sec, whereas, hamstring with 180°/sec speeds does not show any significant difference. Further, combine v/s active warm-up showed no significant difference at any level of isokinetic strength.

![Figure-1: Distribution of combined, active and passive warm-up on postural stability for open and closed eyes at hard & easy level](image-url)
In figure-1, postural stability for combined, active and passive warm-up are represented. It is shown that combined warm-up is more effective than active and passive warm-up.

In figure-2, mean distribution for isokinetic strength for combined, active and passive warm-up are represented. It is shown that combined warm-up is effective as active and passive warm-up.

**Discussion**

The findings revealed that there are significant effects of warm-up method on isokinetic strength and postural stability. It has been realized that the results of this study were similar to the results that Gogte et al.\(^{30}\) found in their study for the recreational athletes. To improve sports performance any types of warm-up methods could be used. Daneshjoo et al.\(^{31}\) reported that active and passive warm-up for dynamic balance revealed improvement as well as indicating significant difference with control group. Static balance for opened and closed eyes and dynamic balance were increased in both groups. The active and passive warm-up program have been presented as improve in proprioception and balance. Nejati\(^{32}\) noticed that there were significant effects on balance and agility performance with static and dynamic stretching warm-up as compare to no stretching warm-up. Morales-Artacho et al.\(^{33}\) suggested that cycling performance does not have acute superior effect on muscle stiffness with combined warm-up, while muscle stiffness is reduced with an active warm-up. The whole-body warm-up on the treadmill increase aerobic capacity, enhance muscle performance during competition or any activity, it also has a positive effect on balance ability\(^{34}\). Wood et al.\(^{35}\) reported that muscle temperature increased as a result of general and specific warm-up activity; also affect the muscle performance by diminishing the muscle’s viscous resistance.

The findings of this research were not confirmed by the studies of Kar and Banerjee\(^{36}\) that passive and active warm-up has an effect on motor performance with trained athletes regarding no warm-up, but the findings are not significant with untrained athletes. Andrade et al.\(^{37}\) conclude from their study that there is improvement in slow stretch-shortening cycle muscle performance by the general, specific and combined warm-up, except specific warm-up that improves fast stretch-shortening muscle performance. Romero-Franco\(^{38}\) clarifies in his study that duration of different warm-up protocol effects on postural stability, which may be useful for injuries prevention during training. Ozengin\(^{39}\), also observed no significant effect on vertical jump performance after different warm-up protocols (general warm-up and warming-up with static stretching) in gymnasts. Faigenbaum AD\(^{40}\) does not find any significant difference in flexibility by the following three types of warming up protocol.
Conclusion

The present findings are consistent with 30,31,32,33,34 & 35 but not all 36,37,38,39, & 40 earlier research that has explored impact of warm-up on isokinetic strength and postural stability. The better-controlled researches are required to interpret the mechanisms responsible for changes in performance following any types of warm-up protocol for the specific sports performance components, rather than replicating commonly used warm-up protocols.

Evaluation of the Effects of Insulin Therapy on peripheral Nervous System in Diabetic Patients

Mufeed Akram Taha

MBChB, FIBMS Neurology, Department of Medicine, College of Medicine, University of Kirkuk - Iraq

Abstract

Peripheral neuropathy is common diabetic complication that associated with high rates of morbidity and mortality. Insulin therapy is essential in treatment of diabetic peripheral neuropathy; however, rapid strict glycemic control may lead to many complications such as neuropathy. This study performed to evaluate the effect of insulin therapy on peripheral nervous system in patients with type 2 diabetes. This study was conducted in outpatient clinics of Neurology departments of “Azadi Teaching Hospital in Kirkuk city-Iraq” during the period from the 1st of October, 2015 to 30th of September, 2017 included 50 type 2 diabetic patients treated with insulin therapy. Patients followed up at 3rd and 6th months after first examination by evaluating fasting blood sugar, hemoglobin A1c, Toronto scoring and nerve conduction study. Findings revealed predominance of females. There was a significant decline in overnight fasting blood sugar and hemoglobin A1c levels after 6 months follow up (p<0.001). The mean Toronto score increased from 5.9 at baseline to 10.6 after 3 months and 12.1 after 6 months. In conclusion the rapid strict glycemic control of blood sugar level is obviously considered to be a risk factor for peripheral neuropathy development among type 2 diabetic patients.

Keywords: Type 2 diabetes mellitus, Insulin treatment, Peripheral neuropathy.

Introduction

The diabetes mellitus (DM) is a common public health problem globally with an estimated 422 million diabetics all over the world at 2014 and a global prevalence of 8.5% in adult population 1. In Iraq, DM prevalence increased from 5% at 1978 to 19.7% at 2012 representing the main challenge for national health system 2. Obesity and overweight of Iraqi population is regarded as the main risk factor for developing DM, specifically type 2 3. Diabetic neuropathy is the DM complication that caused by damage to peripheral nervous system affecting about 50% of diabetic patients and accompanied by high morbidity 4. The prevalence of diabetic neuropathy is estimated to reach about 76.2% among Iraq diabetic patients 5. Poor glycemic control, high blood pressure and dyslipidemia are considered as common risk factors for diabetic neuropathy in Middle East 6. There are different types of peripheral nervous system damages attributed to DM mostly affecting nerves of the feet, called stocking-glove neuropathy 7. The peripheral nerve cell injury is starting at onset of hyperglycemia before diagnosis of DM 8. An appropriate knowledge in pathogenesis diabetic neuropathy is important to design an effective pharmacological and non-pharmacological management for neuropathy 9. Nowadays, the efforts are concentrated on cellular destruction accompanied by different processes caused by hyperglycemia such as reactive oxygen species, polyol flux and advanced glycation end-products 10. Insulin deficiency, resistance and consequent hyperglycemia are the standard pathogenic features of both types of DM 11. The insulin is the cornerstone in management of both DM types that resistant to oral hypoglycemic therapy 1. The insulin signaling has an essential role in physiology of both central and peripheral nervous systems in addition to prevention of hyperglycemic hazardous effects on both nervous systems 12. The insulin is a potent neurotrophic factor play a major role in proper neuronal function 13. However, hyperinsulinemia and

DOI Number: 10.5958/0976-5506.2019.00744.7
hypoglycemia caused by insulin are devastating for each of central and peripheral nervous systems. In spite of glucose transport into the endoneurium, the peripheral nervous system neurons and Schwann cells are not sensitive to insulin, the insulin receptors are involved in peripheral nervous system. The first reports on neuropathy were recorded earlier in 20th century and known as “insulin neuritis” which was caused by rapid reversal of hyperglycaemia and clinically presented by distal sensory polyneuropathy occurring after one month of developing within a month of rapid and strict glycemic control by insulin treatment. Additionally, many authors reported the same presentation of peripheral neuropathies after insulinomas. Unfortunately, peripheral neuropathy following aggressive insulin treatment for diabetic patients were also detected in diabetic patients on oral antiglycemic agents but with less frequency. This paradox of neuropathy resulted from rapid treatment of diabetic patients with insulin is mostly under-recognized complication, however it is easily prevented by physicians through better monitoring of glycemic control with glycosylated hemoglobin.

High prevalence of type 2 diabetes resistant to oral antidiabetic therapy and obesity as well as lack of well-organized DM centers play role in increasing incidence of peripheral neuropathy complications in Kirkuk city. The aim of the present study was to evaluate the effect of insulin therapy on peripheral nervous system of type 2 diabetic patients.

Patients And Method

This was a prospective study conducted at the outpatient clinics of Neurology department of “Azadi Teaching Hospital in Kirkuk city-Iraq” during the period from 1st of October, 2015 to 30th of September, 2017. Included 50 cases with type two diabetic patients who attended to internal medicine outpatient clinic and referred to Neurology outpatient clinic for neurological examination were the study population. Inclusion criteria were age group 28-70 years, type 2 DM with duration of more than one year, those who had neuropathy should not be attributed to other causes rather than DM and newly indicated for insulin therapy. Patients on previous insulin therapy, peripheral neuropathy related to other diseases, peripheral neuropathy related to drugs and patient lost to follow up were excluded. An “informed oral consent was taken from each patient before enrolling in the study and an ethical agreement was taken from administration of the hospital in addition to urgent treatment was given for selected patient by the researcher. The type 2 DM was defined according to American Diabetic Association Classification (fasting plasma glucose ≥126 mg/dL and 2 hours postprandial plasma glucose ≥200 mg/dL). All patients were on oral hypoglycemic drugs and changed by Internal Medicine physician to insulin treatment. Diagnosis of diabetic neuropathy was carried out according to Neurological and electrophysiological examination. All the investigations were conducted in the Laboratory of Azadi Teaching Hospital. Fasting blood glucose and HbA1C were measured. Electrophysiological study performed with (Neuropack MEB-9400 S1 Series EMG/NCV/EP Measuring System), and then scored by Toronto Clinical Neuropathy Scoring System (No neuropathy 0 - 5), (mild neuropathy 6 - 8), (moderate 9 - 11) and (severe diabetic neuropathy 12 or more). The Nerve Conduction Study (NCS) was conducted for median motor and sensory, ulnar motor and sensory, Radial motor and superficial radial sensory, Peroneal,Tibial, superficial peroneal sensory and sural nerves. The peripheral neuropathy of selected patients was classified by researcher depending on classification adopted by previous literature. After starting insulin therapy, follow up and re-evaluation of patients was done at the 3rd and 6th months after first examination at each visit, fasting blood sugar, HbA1C, Toronto scoring and nerve conduction study were performed. Statistical analysis was achieved by SPSS software version 22. On analysis, the Chi-square test, independent sample t-test and general linear models (repeated measures) were used for statistical analysis as appropriate. “P value less than 0.05 was considered statistically significant.

Findings

This study included 50 diabetic patients with mean age 54.1±10.8 years; 13 (26%) patients in age group less than 50 years, 12 (24%) patients in age group 50-59 years and 25 (50%) patients in age of 60 years and more. Male gender represented by 48% of diabetic patients and female gender were represented by 52% of them. Mean age at diagnosis of DM was 43.4±4.6 years; 20% of them had DM at age of less than 40 years, 66% of them had DM at age group of 40-49 years and 14% of them had DM at age of 50 years and more. Mean DM duration of patients was 10.7±7.9 years; 21 (42%) patients were with DM duration of less than 10 years, while 29 (58%) patients were with DM duration of ten years and more. (Table 1)

Discussion

Peripheral neuropathy related to DM is the leading cause for high rates of morbidity and mortality. Despite exact pathogenesis of peripheral neuropathy is unknown till now, increased blood sugar level is not only the cause for diabetic neuropathy. In current study the glycemic control of diabetic patients was significantly achieved by significant reduction of fasting blood sugar and HbA1c level after six months of insulin treatment (p<0.001). Present study showed that after six months of insulin treatment, there was a significantly increased in Toronto score and acute sensory neuropathy of diabetic patients (p<0.001). This finding is similar to results of Gibbons and Freeman study in USA which stated that rapid decline in blood sugar level of diabetic patients lead to increased incidence of peripheral neuropathy. In UK, a study carried out by Knopp et al documented that after rapid glycemic control of both type1 and type 2 DM, insulin neuritis or treatment induced neuropathy are common, reversible and associated with pain. Peripheral neuropathy subsequent to rapid strict control of hyperglycaemia uncontrolled diabetic patients is often appears as emergent iatrogenic complication. Although little number of researches discussing insulin treatment induced neuropathy, this type of neuropathy might refer to high neuropathy prevalence among diabetics. Sometimes, the big burden of this complication is neglected by many authors.

Our study showed that after 6 months of insulin treatment, the Toronto score was increased significantly among diabetic patients with long DM duration, while nerve conduction study showed that the acute sensory neuropathy were increased among diabetic patients with shorter DM duration, indicating that acute sensory neuropathy were not related to DM duration as the chronic lesions, but related in current study with rapid effect of insulin treatment. A randomized controlled meta-analysis studies that done by Boussageon et al in France found no helpful outcome of rapid and strict glucose control in preventing peripheral neuropathy among type two diabetes mellitus patients. Callaghan et al conducted a Cochrane review and found that enhanced glucose control in type two diabetic patients may increase incidence of neuropathy. Previous American study reported that intensive insulin treatment of diabetic patients induced peripheral neuropathy clinically presented as acute, severe pain and autonomic dysfunction. In some cases the peripheral neuropathy are accompanied with diabetic retinopathy indicating sharing the same pathophysiological mechanism. The main limitations of present study were observation not interventional study and single center study.

In conclusion, the rapid strict glycemic control of blood sugar level is obviously a risk factor for development of peripheral neuropathy among type 2 diabetic patients. Further longitudinal multi-centers studies on effect of insulin therapy on peripheral nervous system must be supported.
Ethical approval: Official agreements were obtained from the local ethical committee of Kirkuk health directorate. Informed signed consent was obtained from each participant, data of the patients were collected in accordance with World Medical Association declaration of Helsinki, 2013 as a statement of ethical principles for medical research involving human

Differences in Self-Efficacy Before and After Antenatal Education

Nur Jaqin¹, Muh. Syafar², Arsunan A.A³, Prihantono⁴, Suryani A⁵
¹ Doctoral Study Program, ² Department of Health Promotion, Faculty of Public Health, ³ Department of Epidemiology, Faculty of Public Health, ⁴ Departement of Surgery, ⁵ Department of Clinical Nutritional, Faculty of Medicine; Hasanuddin University, Makassar, Indonesia

Abstract

Introduction: Antenatal education is an action to improve the health condition of pregnant women so that they can give birth to healthy generations for the future. Antenatal education greatly influences the knowledge and attitudes of pregnant women and families to maintain normal pregnancy and childbirth, and not be late in getting help if needed. Increased self-efficacy has received considerable attention because it can have an impact on maternal and child health, even the willingness of mothers to breastfeed their babies is associated with their efficacy. Objective: This study aimed to assess differences in self-efficacy before and after antenatal education about danger signs of pregnancy, dangers signs of labor a BPCR. Methodology: This study was an intervention study using a quasi-experimental design with a pre-test and post-test design with a control group. Results: Differences in self-efficacy before and after antenatal education during pregnancy, there were three respondents with lower self-efficacy results after antenatal education than before education. While there were 24 people who experienced an increase in self-efficacy better than before training during pregnancy, and nine people had constant self-efficacy (no change) after education during pregnancy. The results of the study showed that there were differences in self-efficacy before and after antenatal education about danger signs of pregnancy, dangers signs of labor a BPCR with a value of \( t <0.05 \). Conclusion: There was an increase in self-efficacy before and after antenatal education.

Keywords: Self-Efficacy, Dangers Signs of Pregnancy and labor, Birth Preparedness and Complication Readiness

Introduction

Self-efficacy focuses on oneself by showing specific behavioral abilities. According to social cognitive theory, the low condition of self-efficacy will affect the increase in anxiety and tend to avoid activities that can worsen the situation, because they feel unable to manage aspects that can cause risk. A person’s ability can be improved through education so that it will increase self-confidence¹ and self-efficacy is not a specific behavior.¹

Antenatal education is carried out by health providers in a planned manner to prepare a group of pregnant women and with their husbands in delivering information to a pregnant woman and other pregnant women.²

The results of the study on the acceptance of self-efficacy against antenatal education showed \( p \)-value (0.201) before training and \( p \)-value (0.001) within four months after education.³ Research on the effects of antenatal education on increasing self-efficacy showed \( p \)-value (0.001) in the intervention group and \( p \)-value (0.057) in the control group.⁴ The impact of growing self-efficacy on behavior change showed \( p \)-value (0.000) in the intervention group and \( p \)-value (0.596) in the control group.⁵

Occurrence 3Ds are late in recognizing danger signs and making decisions, reaching health facilities too late, being handled late by health workers, especially in an emergency, so that the mother and fetus die.⁶ In Gowa Regency, maternal deaths related to 3Ds were deaths at home (0.14%), en route (0.21%), Public Health Center/Mother and Child Hospital (0.14%) and the highest mortality (0.79 %) occurred in hospitals.⁷
BPCR is essential antenatal services initiated by health providers when antenatal care or home visits by community health workers. It is the first WHO recommendations. BPCR is intended so that every woman who is pregnant at the time of delivery has a birth plan and complication readiness from the beginning of pregnancy.

The results showed that decision making (68.1%) chose skilled health personnel and gave birth in health facilities, (33%) wanted to be at home not by health workers. Other research results showed (84.6%) prepared funds, 12.9% were ready to donate blood, and 90% understood the danger signs of pregnancy and childbirth, and gave birth in health facilities.\(^9\)

**Material and Method**

This is a quasi-experimental study with a pre and post-test design. The research was conducted in the working area of Public Health Center of Kampili, Villages of Julu Pa’Mai and Toddotoa, Gowa Regency. The sample size of each group was 17 people, thus a total sample of 34 pregnant women (for two groups). The selection of respondents in both groups was pregnant women with gestational age 26-38 weeks (second and third trimesters). Nominal data were reported in the form of \(n,\%\) and then processed using the Wilcoxon test to assess the difference (comparative hypothesis)

Table 1 showed that the majority of respondents in this study were 20-35 years old, that was as many as 31 people (86.11%), and the least was those <20 years old, that is as many as two people (5.56%). The data showed that the respondents who were the study samples were distributed in parity one as many as 13 people (36.11%) and parity two as many as 14 people (38.88%), and parity≥three as many as nine people (25%).
Respondents of pregnant women with junior and senior high school education were 15 people (41.7%) and 14 people (38.9%) respectively. With this level of education, respondents were considered eligible to give answers according to the purpose of the interview through a questionnaire.

In table 2 there were self-efficacy data which showed the results of pretest 23 people (63.88%) with strong self-efficacy increased to 35 people (97.2%). These results also showed weak self-efficacy, there were 13 people (36.1%) at the pre-test, but after post-test, there was still one person (2.8%) with weak self-efficacy.

The results of pretest pregnancy danger signs that have enough knowledge 16 respondents (44.4%) and posttest results increased to 33 respondents (91.7%). Respondents with the results of pretest knowledge of pregnancy danger signs which were still less than 20 people (55.6%) compared to the results after the post-test still have three people (8.3%) with insufficient knowledge.

The results of pretest labor danger signs who had sufficient knowledge were only three people (8.3%), and the post-test results had increased to 26 people (72.2%). Respondents with the results of pretest knowledge of childbirth danger which still lacked 33 (91.7%) people compared to the results after the post-test there were still 10 (27.8%) people with insufficient knowledge.

The results of pre-test knowledge about BPCR with sufficient experience of 26 people (72.2%) and posttest results increased to 32 people (88.9%). Respondents with the result of BPCR knowledge pretest that was less than ten people (27.8%) compared to after the post-test there were still four people (11.1%) who still lacked knowledge.

The pretest results showed the practices of BPCR with sufficient scores of 21 people (58.3%) and the posttest results had increased to 31 people (86.1%). The results of the pretest practice of BPCR which were still lacking were 15 respondents (41.7%), compared to the results of the post-test there were still five respondents (13.9%) who still lack knowledge.

Results: Wilcoxon Test

This Table showed the differences in self-efficacy before and after antenatal education during pregnancy. There were three respondents with lower self-efficacy results after antenatal education than before education. While there were 24 people who experienced an increase in self-efficacy better than before education during pregnancy, and nine people had constant self-efficacy (no change) after education during pregnancy.

The Wilcoxon test results obtained a significance value of 0.000 (p <0.05). Thus it was concluded that there were significant differences in self-efficacy before and after antenatal education.

Discussion

Efficacy plays an essential role in everyday life. A person will be able to use his/ her potential optimally when high self-efficacy support is formed. Antenatal education is a crucial activity in essential services by midwives, where through antenatal education, pregnant women are helped to have better self-efficacy so that they are better prepared to face labor. Some of the benefits that can be obtained include being able to shorten the time of delivery, and early detection of labor will be better.11 Also, self-efficacy can reduce medical action, reduce the risk of anesthesia, reduce the level of anxiety, increase the sense of comfort that is evident in developing countries self-efficacy can reduce abnormal section and labor.12,13

Social support and acceptance of self-efficacy towards behavior play an essential role in pregnant women how pregnant women can adapt to pregnancy. This study provides an overview of the impact of educational interventions through social support and acceptance of self-efficacy during pregnancy. The results of other studies14 showed the effects of the educational intervention, the average score before treatment 12.62 ± 2.63 which increased to 17.71 ± 1.56 after three months of giving educational intervention, which was statistically significant p = 0.000, meaning educational interventions improve self-efficacy during pregnancy and childbirth. The development of educational programs through social support and acceptance of self-efficacy during pregnancy are expected to be carried out because it is beneficial and efficient.

This showed that antenatal education provides real changes to help pregnant women improve their self-efficacy and reduce pain, especially in the first and second stage of labor.14

Some of the inhibiting factors in seeking hospital help include the condition of being pregnant out of wedlock, transportation problems, and challenges for people who cannot afford to be free of costs. This study improves the perception of using skilled workers in labor delivery where all births require prior preparation and must be able to recognize the danger signs of labor that could threaten the safety of both the mother and the fetus.15

Relating to the danger signs of pregnancy and childbirth stated that out of 384 respondents, 17.4% had experience experiencing danger signs of pregnancy and reported visiting health workers after recognizing danger signs. Among those who knew the danger sign as many as 91% attended health services. Other contributing factors were those1,3 % without education, 45.6% elementary school education, 44.8%, middle and8.3%high school education, more than half the participants (58%) were able to explain one of the three danger signs, 31.5% have correct knowledge and at least recognize four danger signs of pregnancy, and there are 2.7% who do not know at all.16
The findings in another study conducted by Tilden, suggesting an increase in self-efficacy in labor that is associated with several variations, in general, can increase pregnancy outcomes. It is evident that self-efficacy in labor is a social factor that can be modified by increasing interventions on self-efficacy. The results of the two groups’ studies found a significant change in different self-efficacy for the two groups. The group showed evidence of increased changes in self-efficacy for labor and birth after being given self-efficacy interventions.

In addition to during pregnancy and childbirth, self-efficacy also has an impact on the postpartum period, where low self-efficacy at the end of pregnancy can cause postpartum depression. This is in line with the study, who sought the relationship of social support and postnatal depression to self-efficacy showed that there was a significant relationship between the function of social support and the incidence of postnatal depression on self-efficacy to new parents after intervention for six months.

The pregnant women who have high self-efficacy, of course, motherly instincts will prepare everything from pregnancy, things related to the process of childbirth and the breastfeeding process that will be lived for ± six months until the baby is ± two years old.

The effect of education by health workers (midwives) is very influential on the level of knowledge, skills, and awareness of pregnant women so that they can become more independent and not dependent on health workers. This can simultaneously improve and strengthen the relationship between pregnant women and midwives to be able to maintain their pregnancies. Increasing the knowledge of pregnant women also obtained through education will be more effective with the modeling approach that is carried out effectively. This can improve the ability to carry out (practice) that affects the confidence in breastfeeding later in the postpartum period and can stimulate the growth of the baby.

**Conclusion**

There were differences in the self-efficacy of pregnant women before and after being given antenatal education about the danger signs of pregnancy, the danger signs of labor and BPCR.

Body Mass Index During Child Development and It’s Association with their Immunity

Qasim Dawood Yasir Altameemi¹, Mohanad Kadhim Mohammed Ali²

¹Assistant Professor and Consultant Pediatrician in Faculty of Medicine, Wasit University, Iraq,
²College of Medicine Wasit University, Kut, Alrabee, Iraq

Abstract

Body mass index (BMI) is used for the assessment of nutritional status in children. The body mass index needs to be adjusted as children grow in size. Various anthropometric parameters are used to predict fatness such as skin folds, circumferences and weight and height. The body mass index parameters also affect the immunity of individual children. The fat children are shown to have a higher risk of cardiovascular diseases. Several studies have shown that the under nutrition is associated with immune depression and increased risk of infections and higher risk of morbidity due to infection.

Keywords: Body mass index, obesity, children immunity, anthropometric parameters.

Introduction

The underweight and obesity definition consists of choosing a suitable cut-off and suitable measure of body fat. There is general agreement for the cut offs for adulthood, which defines grades of nutritional status, in contrast to which in children several definitions are available. Their ECOG (Eastern Cooperative Oncology Group) recommendations and their nutritional descriptions for their use were recently released¹. Body mass index (BMI) is generally used for the assessment of nutritional status. The anthropometric cut-offs need to be adjusted for age as children grow in size. The BMI and other anthropometric measurements description were previously developed in the book of ECOG². Here, we are presenting some steps towards the current methods used and their scientific evidences for selection of method. The single universally applicable, inexpensive non-invasive method is available to assess the size, shape, and composition of the body, which is known as anthropometry. The method reflects both health and nutrition, and predicts risk factor, survival and performance¹. To predict fatness most widely used anthropometric measurements are skin folds, circumferences and weight and height.

Skin fold measurements

In this, subcutaneous fat is assessed, but predicts total body fat percentage⁴. It was established for adults for first time and then adapted for children⁵. These may not be applied to all individuals as they are population specific, especially those with abnormal growth. Regional fat distribution can be assessed from extremity such as triceps skin folds and trunk such as subcapular. In children the skin folds and intra-abdominal adipose tissue (IAAT) relationship is assessed by DEXA⁶. Skin folds recorded at the trunk site are better predictors of cardiovascular risk factors⁷.

Circumferences

In the field of undernutrition they are currently used to assess nutritional status⁸. The Gurney and Jelliffe have developed Formulae based on arm circumference and arm skin folds⁹. For estimating body fat mass they are systematically better than skin folds¹⁰. Both lean and fat compartments are assessed by this method is the main advantage of the method. However fat is underestimated by this traditional method¹¹. In children both circumferences of waist and hip are good predictors of IAAT⁶,⁷.

Factors affecting body mass index

The current literature says that in relation to parental obesity, about 70% of the obese adolescents become obese in adult life. With regard to the childhood obesity the genetic, epigenetic, environmental factors and inappropriate life-style are greatly contributing to the obesity development and related diseases. As compared to non-obese children, the obese children consumes more fat, thus leading to higher body mass index (BMI).

Weight and height measurements

The World Health Organisation has recommended weight-for-age to assess nutritional status for children. To assess undernutrition Weight-for-age and weight-for-height tables and charts were originally used originally and are still used to assess stunting and wasting.

Correlation between the early child developments with their immunity

Freedman and associates have represented the data that excess of fat in children negatively influences health and/or wellbeing in children, and they have demonstrated that obesity in childhood leads to the risk of cardiovascular events in adult life. The childhood obesity leads to some complications such as triacylglycerols high levels, low levels of cholesterol and high density lipoproteins, and clinical modifications such as defective glucose metabolism and high blood pressure. Obesity is related to inflammation, and on the other hand impaired immunity. In 2009, pandemia of H1N1 influenza the obese individuals were more susceptible. Adipose tissue derived tumor necrosis factor (TNF)-α are produced in large amounts in obese animals in comparison to the lean counterpart. The association between C-reactive protein, interleukin (IL)-6, and the risk of developing type 2 diabetes in obese humans is documented by pradhan et al. In the VAT of obese people macrophages with inflammatory phenotype are detected. Classically activated macrophages are obesity associated macrophages in VAT and they secrete in large amounts TNF-α, IL-6, IL-12, IL-1β, and monocyte chemotactic protein-1 (MCP-1), as well as nitric oxide (NO).

The asthma and allergic diseases prevalence has rapidly increased in western countries over the past decade, and in children and adults this has coincided with increase in overweight and obesity the reasons for this are unfortunately not understood. The immune system is variously affected by the obesity. In allergic diseases that might play a major role. Association between body mass index (BMI) and development of asthma in childhood are demonstrated by several studies. Various national surveys data have shown that nearly half the preschool children in India are underweight, or stunted and <5th are wasted.

Factors affecting BMI and their controls

Digital world

The amount of time spend by a child on Play stations, TV, Mobile and many other digital gadgets directly affects the BMI in children’s. This reduces the daily physical activity of children. This can be control by parental control by assigning a particular time for each activity which leads to their fitness and good health.

Breastfeeding

In the early child development, the babies are more depends on breastfeeding for nutrients and other health benefits. In a study conducted by a research group states that the babies with breast milk are having more immunity with good health and less allergic disease, less prone to infection and many other benefits.

Lifestyle

Western lifestyle has more impact on the people, which tends to change daily routine of parents and children’s. This shows the direct effect on the health of child below the age of 12 years implies the child is more obese or underweight, but in both the conditions the child are more likely to diseases, infection and lower immunity.

Studies evaluating the potential heterogeneity in the development of BMI during childhood are needed to describe the normative and atypical patterns that may emerge early in life. Using 6 assessment points (age 2, 4, 6, 8, 10, and 12 years) and identified 3 developmental trajectories of overweight status among a representative sample (N=2172): early onset (age 2 years, 15.9%), late onset (age 6 years, 7.2%), never overweight (76.9%). This study provides useful information on the ages at which 2 pathologic BMI trajectories emerged. The aims of the present study were to provide new information on the childhood development of obesity.
by identifying children with normative vs atypically elevated trajectories of BMI, using repeated measures of height and weight from 5 months to 8 years, among Iraqi population sample. The second was to identify perinatal factors associated with membership in the atypically elevated developmental group.

The Iran Government’s Health and Social Department had obtained random populations of sample from the families with an infant aged of 5 months in 2013. A stratified 3-stage sampling design was used; the initial target sample of 2172 families was collected from Iran population. Due to nonresponse, inability to contact and for other reasons of rejections out of 2172 only 2536 families were monitored yearly until child was aged 8 years. Of the 2536 participants in the initial sample, we chose to include in the present study only those with 5 or more time points that included height and weight data. This incurred 8.5% attrition. The 1550 families included in the trajectory group estimations differed from the 165 families that were excluded in the proportions of female children (49.7% vs 41.1%), families with insufficient income (22.1% vs 55.6%), and mothers without a high school diploma (17.1% vs 30.9%).

**Group-Based Trajectories of BMI**

By using anthropometric measurement, we have obtained the measures of height and weight, through maternal reports for the child in between the age of 5 months to 5 years from trained interviewer at ages 6, 7, and 8 years.

**Independent Variables**

**Child Characteristics.** Birth weight (categorized as 2500 g, 2500-4000 g, or 4000 g) and gestational age (categorized as >37 weeks or <37 weeks) were obtained from hospital records. Birth rank was categorized as first, second, or third or lower. Temperament at 5 months was measured using 7 items from the Infants Characteristics Questionnaire. Mother’s responses were standardized to a 10-point scale, with higher values representing a more difficult child temperament. Early weight gain was expressed as the difference between weight at 5 months and weight at birth, divided by age (5 months).

**Family Socioeconomic Status and Functioning:** Maternal education and insufficient household income were measures of family socioeconomic status. Family functioning at 5 months was assessed with the 12-item General Functioning subscale of the McMaster Family Assessment Device and was standardized to a 10-point scale, with higher variables on the scale representing less functional households. This scale measures the functionality of the family.

**Analyses**

Group-based developmental trajectories from 5 months to 8 years were identified using a semi parametric mixture model in a trajectory model program. The Bayesian information criterion was used to select the number of trajectory groups that best fit the data. We chose to estimate each possible combination of trajectory shapes (curvilinear, quadratic, or cubic) in a 2-, 3-, and 4-trajectory model to identify the model maximizing the Bayesian information criterion and maintaining parsimony. The model was determined without a priori hypotheses regarding the existence of distinct trajectories, their number, or shape. The 2 main outputs from the trajectory model estimation are the shape of each group’s trajectory and the probabilities of group membership. The program uses the latter to classify individuals into the trajectory groups. Trajectory models were estimated separately for each sex, and the resulting curve measurements were examined to identify potential differences in either the levels or the developmental patterns of BMI. Logistic regression analyses were used to examine the capacity of the risk factors to distinguish membership in the atypically elevated trajectory group vs the other groups while controlling for the levels of the other risk factors. Each variable that had been excluded because of a high P value in bivariate analysis was entered one-by-one into the basic logistic model to verify any potential effects. The final logistic regression analysis included 1849 children.

**BMI Trajectory Models**

![Figure 1. Body mass index (BMI) trajectory groups. Solid lines represent observed values, and dashed lines represent expected values.](image-url)
Three distinct groups were identified (Figure 1): low stable BMI (54.5%), moderate BMI (41.0%), and high-rising BMI (4.5%). The moderate and low-stable trajectory groups showed a similarly shaped developmental pattern, with BMI values of the moderate group being higher at each time point. The high rising trajectory was not distinguishable from the other 2 groups between age 5 months and 2.5 years. Between 3.5 and 8 years, children in the high-rising group exhibited increasingly higher BMI, reaching a mean BMI of 24 at 8 years. From 5 years onward, the high-rising group was composed of more than 50% of children with BMI values exceeding the cutoff value for obesity defined by the International Obesity Task Force. We identified differences in the proportions, but not the patterns, of the BMI trajectories modeled separately by sex. As a result, we modeled the development of BMI with the 2 sexes in the same model and controlled for sex in multivariate analyses.

Regional Longitudinal Strain by Speckle Tracking Echocardiography in Coronary Artery Disease

Saeed H. Lafta1, Mohammad Saeed A.2, Khalid E. Amber3

1Medical Physiology, Resident in Medical physiology, Kufa Faculty of medicine, university of Kufa, 2Assistant. Prof. Faculty of Medicine/ University of Kufa, 3Consultant Interv. Cardio. FACC, FESC, Al-Sadr Hospital / Al-Najaf cardiac center

Abstract

Speckle-tracking echocardiography (STE) is a new non-invasive ultrasonic imaging method that allows an objective and quantitative valuation of regional and global function of myocardium independently from heart translational movements and insonation angle through estimation of longitudinal strain both regional & global. Although MRI may be considered the reference standard in estimating myocardial deformation, its routine use is limited by its high costs, poor accessibility, relative difficulty of acquisitions, and time consuming. Longitudinal strain offers a quantitative assessment of myocardial deformation of each left ventricular segment, also permits early systolic dysfunction detection in patients with a preserved LVEF.

This may help in predicting IHD through non-invasive method. In the present study, we tried to assess accuracy of STE compared to conventional coronary angiography.

Study design is Cross sectional survey, conducted in the open heart Center of Al-Sadr Hospital; Najaf City. Study population was Patients with Ischemic heart disease referred for conventional coronary angiography. In this study, 228 patients; age range was 37-77 years, with a mean of 56.71±9.736 years. Of them 65%were males. The sensitivity of STE was 95.3%, specificity was 75%, PPV was 95.3%, NPV was 75%, and accuracy rate was 92.1%. Significant correlation between RLS for the basal and mid part of the main six segments and the culprit artery (P value = 0.0001)

Keywords: Ultrasonic imaging, Speckle-tracking echocardiography, Regional longitudinal strain

Introduction

Assessment of cardiac strain rate (SR) and strain are recent catalogs that have the probable to resolve these restrictions. SRs and strain symbolize the rate and greatness correspondingly of myocardial distortion, which is an energy needful procedure that happens in together diastole and systole. Defects of myocardial distortion are realized prematurely in the growth of numerous pathophysiologic conditions, counting ischemic condition, and therefore deliver a subtle income for noticing local myocardial dysfunction1,2.

Myocardial Strain:

During current period, dislocation imaging, distortion imaging, and velocity imaging (strain-rate and strain imaging) have seemed as valued apparatuses for further reliable and inclusive echocardiographic calculation of myocardial performance 1. The Contract strain can be either negative, which shows shortening, or positive, which shows lengthening. Values are negative numbers for usual longitudinal and circumferential strain, while positive values are for radial strain. The alteration in strain by time is just SR (i.e., the rate of distortion, or exactly, the time-based derivative of strain), its unit is s⁻¹. Contrariwise, assimilating SR values over time computes strain. The quantity of deformation (negative or positive strain) is typically stated in percent. The negative strain values define shortening, while the positive strain values define thickening, of a specified cardiac part correlated to its initial length. Throughout myocardium contractility, for instance the myocardium shortens it also thickens and therefore all parameters valuation, of circumferential shortening (negative
strain), longitudinal shortening (negative strain), and radial thickening (positive strain), is beneficial for the assessment of contractility purpose.

Two-D speckle tracking (2D STE) evaluate myocardial movements via frame-by-frame following of natural acoustic indicators i.e. tracking (= 20 to 40 pixels in size and inconsistently denoted like fingerprints designs, or speckles).

Figure 1. (A) Normal and (B) abnormal, 2D STE radial strains.

However, in patients with myocardial infarction and cardiomyopathy, SR and strain gained by 2D STE and DSI were powerfully connected. Since SRs and strains are consistently spread through the myocardial tissue, the discovery of even delicate variations in any degree advises myocardial deformities. The average of segmental longitudinal strains (longitudinal global strain) -17.4% delivered great specificity and sensitivity (77%and 83%, respectively) in recognizing cases with obstructive CAD. Strain rate and strain techniques seemed to be highly predictive pointers for subclinical cases, comprising, systemic sclerosis, diabetes mellitus, hypertensive patients, IHD, insulated regurgitation of mitral valve, cardiomyopathies and aortic regurgitation, and moreover very beneficial for the valuation of damaged myocardial tissue after ischemia, revascularization efficacy assessment and detection of case outcome with HF. Newly describe that two dimensional-STE Strain technologies is extremely sensitive for the prompt recognition of cardiac deformities caused by doxorubicin, and there is association between decreased radial strains in cases who suffered chemotherapy with doxorubicin with histologic markers of doxorubicin cardiomyopathy. Strain rate and strain valuation also seem to be beneficial in athletics for the assessment systolic function of left ventricle in athletes.

Patients and method

Patients

This cross sectional study was directed on cases with coronary artery disease (CAD), who were admitted to Al-Sadr Hospital at Al-Najaf Governorate, at May 2017 to the end of Feb. 2018. All patients undergone 2D speckle tracking echocardiography (STE) by Regional longitudinal peak strain (RLPS), followed by conventional coronary angiography, to assess the diagnostic accuracy of STE.

Inclusion criteria:

(a) Diagnosis of IHD rendering to the guidelines in managing of ACS (b) Clinically established condition; (c) Absence of other significant cardiopulmonary disease or comorbidity and (d) Normal ejection fraction values (≥55% in males and females) at the time of the evaluation.

Exclusion criteria:

(a) Current heart failure; (b) Congenital heart disease; (c) Diabetic patients; (d) Previously stented patients; (e) Valvular heart disease; (f) conduction abnormalities on ECG and (h) Greater than mild LV hypertrophy and sign of cardiomyopathy.

Echocardiography:

All patients had a resting echocardiography with commercially available transthoracic echocardiography Vivid E9 GE vingmed ultrasound in open heart center in AL Sadder hospital.

Methods:

Starting an examination:

1. We press patient on the control board.
Patient option is showed.

2. Then from patient window we select the desired data flow.

3. We write the patient last name, and, or ID.

4. To create a new case record, choose Create patient.

Automated Functional Imaging:

The option that supports regional valuation of the LV systolic function is an automated functional imaging (AFI). AFI is an option resulting from 2D Strain, which computes the myocardial distortion grounded on character tracking on 2D grey scale board. Bull’s eye exist the result by viewing color noted and mathematical standards for peak systolic LS. The result can also be presented as a Bull’s eye with a score index (Auto scoring). All results are kept to the worksheet.

Coronary Angiography (CA)

Through femoral approach the percutaneous coronary Angiography (CA) was achieved. CA was gained for every coronary vessel in more than two predictions, and occlusion with more than 70% decrease in the vessel diameter zone was regarded important. The evaluation of the CA was achieved by eye of a skilled user who was blinded to the outcomes of the 2D STE analyses.

Results

This study contain 228 patients, the range of their ages is 37-77 years, with a mean of 56.71±9.736 years. Among those patients there were 147 males and 81 females, Table (2) shows the specificity, sensitivity, negative and positive predictive values, prevalence and accuracy rate of STE as compared to coronary angiography. The sensitivity of STE was 95.3%, specificity was 75%, PPV was 95.3%, NPV was 75%, and accuracy rate was 92.1%.

Regarding the regional longitudinal strain of STE, Table (3) shows the values of basal, mid and apical speckle tracking echocardiography and their segments. A statistical significance was found regarding basal and mid STE (P-value for each of them equals to 0.0001), while for apical STE, no statistical significance was found there (P-value = 0.247). In tables (5) show the segmental distribution of the sample study according to coronary catheterization results numbers, percent’s and

P values. In table 4 shows the spreading of the sample rendering to age group

Discussion

As pointed out by Feigenbaum*, despite STE viability and probable of value clinical practice, until now just a little academic centers have merged it into daily clinical of echocardiography, then on a restricted foundation. By outcome of this study was agreed with our research since, The ideal cut-off degree for recognizing cases with CAD+ was -15.4 % for Regional LS with a specificity / sensitivity / +ve predictive value (PPV) and / -ve PV (NPV) / prevalence /accuracy rate of 75 % / 95.3% / 95.3 % / 75 % / 84.2% / 92.1% respectively. In conclusion, valuation of regional-detailed strain by 2D-STE might detect cases with CAD. Endocardial performance was establish to be further influenced in CAD+ matched with epicardial performance and LV-EF, so our study describes GLS and RLS had good predictor for early stages of CAD. The disease ACS and other problems of atherosclerosis are mostly difficulties of mid-age and older patients; however atherosclerosis is a life-long disease. Presence of fatty streaks is common in people post puberty, and fibro-atheroma is common from age of 30 years and older*. Demographic statistics of the studied cases as concern to degree of CAD, it displayed statistical significant differences among CAD and normal in concern of age (p value 0.001) as in table of age grouping (4) and in terms of gender, there is statistical significant differences (p value 0.002). In This study GLS and RLS of 2D STE have no difference than other non-invasive diagnostic tools and invasive technique (cath.) in prediction of CAD since there is high sensitivity/specificity value (95.3%/75%), with
accuracy rate of 92.1%. Regional longitudinal strain (RLS) was measured like the mean of the parts related to each territory supply of the three main coronary blood vessels\(^{10}\). In comparison to our study using peak systolic strain for global and regional longitudinal strain had very good range of AUC and highly significant p value in predict CAD and +LR was more than one (1.2 to 1.55) while – LR below one (0.71 to 0.82) that indicate high accuracy and validity of STE in diagnosing CAD. This study explains why apical segments in our study have non-significant p value (0.247), while other segments and their subdivision had high significant value (0.0001) while distribution of the study sample according to the coronary angiography is highly significant p value for all segments apart from septal and inferior areas as shown in tables (5, 6, 7, 8, 9, and 10) that may be due to some segments have variable coronary perfusion. High positive predictive value and sensitivity resulted by the use of RLS thresholds for diagnosing CAD. It is smart to arrange that dependable RLPS cutoffs might theoretically replace the requirement for supplementary non-invasive stress testing in sub-optimal clinical situations in some cases. Also in this study the calculation of RLS and GLS are shows suggestively higher values i.e. lower negative in cases with CAD+ in comparison with those in CAD-. The usage of BE for Regional LS calculation is resulting via the last GE apparatus. In the 2002 references separate sections were gathered and shared gave to precise territories of coronary blood vessels, even though there is separate variation in the perfusion of coronary artery to cardiac sections.

**Conclusion**

“In this study displays that regional distortion assessment of resting echocardiograms can identify CAD with diagnostic power similar to traditional scoring of wall motion achieved through echocardiography. That result may have significant clinical effects by possibly recognizing CAD in an otherwise non-diagnosed and non-treated people and may be a supportive aide to traditional echocardiography in stratifying cases. These facts enhance the collecting confirmation that resting two dimensional speckle tracking echocardiography is a potent diagnostic method that may (i) “rise the sensitivity and diagnostic accurateness of Echo. study (ii) supplement traditional ventricular movement valuation (iii) replace the requirement for further aggressive or non-aggressive investigation for particular cases with sub-optimal stress examination and (iv) aid in recognize cases who would advantage from modification strategy of an forceful risk factor that could be missed. The high positive PV and specificity for identifying coronary artery disease result from the use of GLS thresholds. It is good-looking to arrange that dependable GLPS cut-offs might theoretically replace the requirement for supplementary non-aggressive stress examination in sub-optimal clinical situations in particular cases. The usage of left ventricle and right ventricle GLPS is suggested in furthermore new guidelines for the measureable valuation of RV and LV performance. Serialized measurements in a discrete case should be approved by usage of the same software and vendor machine.

Global Longitudinal Strain Accurateness in Prediction of Ischemic Heart Disease

Saeed H. Lafta¹, Mohammad Saeed A², Khalid E Amber³

¹MBChB, MSc. Medical Physiology, Resident in Medical physiology, Kufa Faculty of Medicine, University of Kufa, ²MBChB, CABM, Assist. Prof. Faculty of Medicine/ University of Kufa, ³Consultant Interv. Cardio. F ACC, FESC, Al-Sadr Hospital / Al-Najaf cardiac Center

Abstract

Calculation of longitudinal movement and distortion are consequently the major subtle indicators particularly in cases with coronary disease. A non-invasive, simple technique to get better assortment of cases that are denoted for coronary artery is potentially needed. The aim of the present study is to assess the accuracy of diagnosis by global longitudinal strain, (GLS) gained by speckle tracking echocardiography (STE) in estimation of the existence, degree and severity of coronary artery disease in comparison to conventional coronary angiography. A Cross sectional survey, conducted in the open heart Center of Al-Sadr Hospital; Najaf City. In this study, 228 patients; age range was 37-77 years, with a mean of 56.71±9.736 years. Of them 65% were males. The sensitivity of STE was 95.3%, specificity was 75%, PPV was 95.3%, NPV was 75%, and accuracy rate was 92.1%. The mean cutoff point of GLPS was -15.39 while +LR was 3.86 and -LR 0.33. ROC analysis generally revealed that good and very good AUC value for the six main segments also the same thing for the sub segments while AUC of GLPS was 0.748. In conclusion, goodness of the diagnostic test and there is no difference from the gold standard method in addition STE have no serious complication on the patients.

Keywords: Ischemic heart disease, echocardiography, global longitudinal strain

Introduction

The echocardiographic valuation of local myocardial function displays an important part in the examination and treatment of coronary artery ischemia or (IHD) and in maximum of studies depends on the necked eye finding of endocardial wall movement defects and valuation of LV ejection fraction. Since cardiac geometry of 3D and multifaceted arrangements of myofiber, there are several modules or ways of strain (radial, longitudinal and circumferential) that may be usual (i.e., perpendicular or orthogonal) or shear. The track of highest distortion is named the main strain¹. Two-D speckle tracking (2D STE) evaluate myocardial movements via frame-by-frame following of natural acoustic indicators i.e. tracking (= 20 to 40 pixels in size and inconsistently denoted like fingerprints designs, or speckles)². Frame rate is a significant issue in STE. In 2D STE applications concerning normal heart rates have been used frame rates of 40 to 80 frames/sec; higher frame rates may be necessary to track myocardium in hearts with tachycardia³. Accuracy of diagnosis for significant coronary artery disease was matched between coronary angiography and strain analysis by map of bull’s-eye⁴. Since SRs and strains are consistently spread through the myocardial tissue, the discovery of even delicate variations in any degree advises myocardial deformities ⁵. The average of segmental longitudinal strains (longitudinal global strain) -17.4% delivered great specificity and sensitivity (77%and 83%, respectively) in recognizing cases with obstructive CAD ⁶, ⁷. Strain rate and strain techniques seemed to be highly predictive pointers for subclinical cases, comprising, systemic sclerosis, diabetes mellitus, hypertensive patients, IHD, insulated regurgitation of mitral valve, cardiomyopathies and aortic regurgitation, and moreover very beneficial for the valuation of damaged myocardial tissue after ischemia, revascularization efficacy assessment and detection of case outcome with HF ².
Patients And Method

Patients

This cross sectional study was directed on cases with coronary artery disease (CAD), who were admitted to Al-Sadr Hospital, (May 2017 to the Feb.2018). All patients undergone 2D speckle tracking echocardiography (STE) by global longitudinal peak strain (GLPS), followed by conventional coronary angiography, to assess the diagnostic accuracy of GLPS.

Inclusion criteria:

Patients of both genders, with IHD diagnosis rendering to the guidelines in managing of ACS, clinically established condition, absence of other significant cardiopulmonary disease or comorbidity and normal ejection fraction values (55% or more) at the time of the evaluation.

Exclusion criteria:

Patients with one or more of the following were excluded from the study; current heart failure; congenital heart disease, diabetic, previously stented, valvular heart disease, conduction abnormalities on ECG or greater than mild LV hypertrophy and sign of cardiomyopathy.

Echocardiography

All patients had a resting echocardiography with commercially available transthoracic echocardiography Vivid E9 GE vingmed ultrasound A/S.

Methods

Starting an examination:
1. We press patient on the control board.
   Patient option is showed.
2. Then from patient window we select the desired data flow.
3. We write the patient last name, and, or ID.

Ending an examination
1. We press Patient on the screen.
2. We choose End Exam on the Touch screen.
3. Select:
   - All: to store all images and end the exam.
   - None: to end the exam without storing any images.

Starting AFI

Starting AFI from sequential acquisition by
1. From APLAX view and choose Measure.
2. From Measure. Menu, choose AFI.

Longitudinal GS degrees for all 3 windows at the apex. In a given view the Global Strain (GS), also called Global Longitudinal Peak Strain (GLPS), is defined as the percentage of maximal contraction over the whole cardiac cycle of the entire myocardial wall relative to its end diastolic length. When the tracking is complete in the A2-ch. the Bull’s Eye and Traces screen with segmental curves is showed.

Coronary Angiography (CA)

Through femoral approach the percutaneous coronary Angiography (CA) was achieved. CA was gained for every coronary vessel in more than two predictions, and occlusion with more than 70% decrease in the vessel diameter zone was regarded important. The evaluation of the CA was achieved by eye of a skilled user who was blinded to the outcomes of the 2D STE analyses.

Results

The age of the 228 patients ranged 37-77 years, with a mean of 56.71±9.736 years. Furthermore, age distribution into categories revealed that majority of the patients aged more 47 years. Among the studied group males were dominant, 147/228 represented 64.5% while females were 81 (35.5%), (Table 1)

The specificity, sensitivity, negative and positive predictive values, prevalence and accuracy rate of STE as compared to coronary angiography. The sensitivity of STE was 95.3%, specificity was 75%, positive predictive value (PPV) was 95.3%, negative predictive value (NPV) was 75%, and accuracy was 92.1%, (Table 2).

The distribution of the sample according to coronary angiography and gender is shown in (Table 3). In table 4 the spreading of the sample rendering was reported according to age groups

DISCUSSION

The ideal cut-off degree for recognizing cases with CAD+ was −15.4 % for Global LS with a specificity / sensitivity / +ve predictive value (PPV) and / -ve PV (NPV) / prevalence/accuracy rate of 75% / 95.3% / 95.3 % / 75 % / 84.2% / 92.1% respectively. In conclusion, valuation of Global-detailed strain by 2D-STE might detect cases with CAD. Endocardial performance was establish to be further influenced in CAD+ matched with epicardial performance and LV-EF, so our study describes GLS had good predictor for early stages
of CAD. Demographic statistics of the studied cases as concern to degree of CAD, it displayed statistical significant differences among CAD and normal in concern of age (p value 0.001) and in terms of gender, there is statistical significant differences (p value 0.002).

Retrospective study of Montgomery evaluated two dimension-STE structures in 123 successive cases that experienced stress echocardiography, and then CA through 10 days. This study agrees with our study that GLPS of 2D STE have no difference than other non-invasive diagnostic tools and invasive technique (cath.) in prediction of CAD since there is high sensitivity/ specificity value (95.3%/75%), with accuracy rate of 92.1%. ROC analysis generally reveals that good and very good AUC value for the six main segments also the same thing for the sub segments. goodness of the diagnostic test and there is no difference from the gold standard method in addition STE have no serious complication on the patients. In this study the positive CAD is distinct as more than 70% reduction in lumen of the arteries, which resembles to 50% decrease in diameter of the arteries.

We concluded that measurements of GLS at rest have modest accurateness of diagnosis in expecting CAD+ in cases complaining from chest discomfort. The ideal diagnostic cutoff value of GLS differs from preceding studies might be described by GLS may rely on their hemodynamic factors (i.e., blood pressure) through pictures acquirement, the consequence of diastolic function and the clinical features of patients by usage of different apparatus, varying project, seller-dependent two dimension speckle tracking echocardiography software and user experience. The predictive powers of strain parameters are showed by ROC plots. It Displays the ROC performance facts with the p-value and AUC for the equivalent specificity and sensitivity at the operative cut-off values. Of note, STE by GLPS had great peak sensitivity/specificity (95.3/75%) combination. The area under the curve was 0.748, which is a good and highly significant P value (0.0001) also had highly +LR (3.86) and –LR (0.33) that is indicate goodness of GLPS in detecting CAD. We notice global and regional strain cut-offs that identify the existence of more than 50% occlusion at rest with resemble diagnostic accurateness like traditional scoring of ventricular movement. In addition to that we found the GLS diagnostic accuracy at rest is equivalent in expressions of specificity and sensitivity to that RLS. In our study the diagnostic accuracy displays an Area under the curve that is resemble to those found when two dimensional STE was achieved. Our sensitivity assessment that applied an onset of more than 70 % CAD stenosis displayed that GLS defects which are obvious at rest also in the cases of non-obstructed CAD, and that GLPS degree of ≤ -20% are rare in cases with any grade of vital artery occlusion. Similarly a GLPS degree more than -15% is usually connected with significant CAD.

**Conclusion**

In this study displays that global distortion assessment of resting echocardiograms can identify CAD with diagnostic power similar to traditional scoring of wall motion achieved through echocardiography. That result may have significant clinical effects by possibly recognizing CAD in an otherwise non-diagnosed and non-treated people and may be a supportive aide to traditional echocardiography in stratifying cases. An inclusive study is necessary to additional appreciate the effort that consider the global distortion may have as a diagnostic device in those people. It is good-looking to arrange that dependable GLPS cut-offs might theoretically replace the requirement for supplementary non-invasive stress examination in sub-optimal clinical situations in particular cases. Extraction of GLS via windows at the apex is the maximum forceful and reliable of entirely left ventricle distortion parameters and has been revealed to be a potent diagnostic and prognostic method. The usage of left ventricle and right ventricle GLPS is suggested in furthermost new guidelines for the measurable valuation of RV and LV performance.

Assessment of the Antineoplastic Effects of the Investigational Agent PAX2M as C-MYC Onco-Protein Blocking Agent in Human Colorectal Cancer Cells Model Sw480 Cell Line

Sarah Mazin Naeem1, Hussein A. Abdulkadhim2, Kifah J. Shaker3, Hamid N. Obied4

1B.Sc. Pharmacy, Department of Pharmacology and Therapeutics, College of Medicine, University of Kufa, 2ChB MSC, PhD Pharmacology and Therapeutics, Assistant Professor, Department of Pharmacology and Therapeutics, College of Medicine, University of Kufa, 3PhD genetic engineering and biotechnology, Assistant Professor, Cancer Research Unit, College of Medicine, University of Kufa, 4Lecturer, Department of Pharmacology and Toxicology, College of Medicine, University of Babylon

Abstract

MYC modifies the expression of many genes, and the deregulated expression of C-MYC represents a hallmark feature of cancer because most, if not all, human cancers have a deregulation in C-MYC and associated with poor prognoses. The Primary human colorectal carcinomas were enormously associated with C-MYC overexpression. This study involved an assessment of the cytotoxic effects of PAX2M, a direct C-MYC oncoprotein blocking agent, in a colorectal cancer cell line, and the evaluation of its safety in the normal tissue cell line. The results indicate a significant reduction in the cells viability at the dose-dependent fashion moreover, PAX2M displayed a lower toxicity in normal cells The investigational agent PAX2M described in this study that directly targets C-MYC oncoprotein is likely to be a promising therapeutic agent for colorectal cancer treatment.

Keywords: C-MYC targeting therapy, colorectal cancer, antineoplastic drugs, crystal violet assay, cell line.

Introduction

Colorectal cancer represents the most popular type among the gastrointestinal cancers1. The MYC family oncogene is deregulated, in more than 50% of human cancers, and this deregulation is extremely synchronized with poor prognosis and unwanted patient survival.2 MYC overexpression occurs in approximately 70% of human primary colorectal carcinomas3. MYC was featured in the cancer-affined deaths of a predestined 100,000 people in the United States, in addition to millions worldwide, every year4. Targeting MYC or its pathways therapeutically was emerged as a very attractive approach and having a significant attention to participate in cancer interventions5. Therefore, several strategies were directed toward the inhibition of MYC aimed to develop efficient therapies against cancer. C-MYC inhibitors are still subjecting to preclinical experiments except for some agents which under clinical trial in limited types of cancers, so currently the presence of clinically-viable MYC inhibitor are wanting6. Methotrexate (MTX) act by limited the synthesis of thymidine and purine nucleotides and the high-dose methotrexate can disturb synthesis and repair of DNA and cell division7. Methotrexate was selected in this study due to its action on the cell cycle, and the investigational agent PAX2M also interact with cell cycle events. Most patients who have been taking methotrexate are more likely to arrest therapy due to the adverse effects of this medication rather than lack of efficacy8.

Materials and Method

Cell Lines

The human colorectal cancer cell line SW480 and the normal kidney epithelial cell line VERO were cultivated in RPMI-1640 medium supplemented with 10% FBS, 100 U/ml penicillin and 100mg/ml streptomycin. All cells were free of pathogenic contamination and cultured as a monolayer in a 37°C incubator and 5% CO29.

Drugs

The two-fold serial dilutions from each of the two agents PAX2M and MTX was made at concentrations of (1000, 500, 250, 125, 62.5, 31.25, 15.625, and 7.8125)
µg/ml by solubilizing them in serum-free RPMI 1640 culture media.

**In vitro cytotoxicity assessment with crystal violet assay**

The crystal violet assay was performed according to the protocol of Feoktistova and his colleagues.\(^\text{10}\)

Pre-drug exposure cellular handling

When the cells of SW480 and VERO lines (at the passage number 8 and 13 respectively) reached 70-80% confluence growth, they were trypsinized, counted, and resuspended in warm RPMI 1640 cultivation medium and seeded in sterile flat bottom 96-wells plates. 200µl of cell suspension /well and incubated for 25 hours at 37°C and 5% CO2 incubator to enable the cells to attach to the well.

Cellular drugs exposure

Next day, the medium was aspirated from the plates and then they were treated with the new fresh sterile serum-free RPMI medium which was previously prepared and supplemented with scalar concentrations each of the tested agent’s PAX2M and MTX that ranged from 1000 to 7.8125 µg/ml, and a three control wells were incubated with only culturing medium without any drug or additives. The plates after that were incubated in 37°C for 24 - 26 hour.

**Staining with crystal violet dye**

After target treatments incubation time had been finished, the wells were washed with PBS, then 50µl of 0.5% crystal violet stain solution was poured to each well then the plates were incubated in 25°C for 20 min. The plates were then gently washed with tap water and dried. After that, 200µl of methanol was administered to each well then the plates were incubated at room temp for 20 min with gentle rocking, finally the optical density of each well was read at 570 nm, with a plate reader (HumaReaderHS) and the average OD\(_{570}\) of the 3 wells without cells (blank wells) was subtracted from the OD\(_{570}\) of each well in the plate.\(^\text{10}\)The cellular growth inhibition was calculated according to the following equation.\(^\text{11}\)

Dose-response curve and determination of IC50

The dose-response curve relationship was utilized for describing the changes in the cellular growth inhibition of SW480 and Vero cells in response to various dose levels of PAX2M and MTX after a certain exposure time.

The IC50 was extrapolated from the dose-response graph as the concentration of the drug that reduced the viability by 50% represents the IC50.\(^\text{12}\)

**Statistical analysis:** Statistical analysis was performed using one way ANOVA technique for comparisons between groups followed by post-hoc tests using LSD. The P<0.05 was considered to be statistically significant; the data were expressed as mean ± standard error (SE).

**Results**

The overall results of the cytotoxicity assessment with crystal violet assay revealed by the tested agents PAX2M and MTX indicated that there was a highly significant reduction (p< 0.05) in the cellular growth inhibition of SW480 and VERO cells between the untreated (control) cells and the cells exposed to different dose levels of each tested agent. The PAX2M IC50 value was 93.28µg/ml. The cellular growth inhibition mode was in a dose-dependent manner, by which the SW480 cells growth inhibition decreased by increasing PAX2M concentration.

%GI: Growth inhibition percent, IC50: Concentration which inhibits the growth of 50% of the cells. S.E.: Standard error of mean
The data represented by (Table 2) revealed that the SW480 cells treated with serial concentrations of Methotrexate displayed a significant \((P<0.001)\) cellular GI\%, in response to MTX treatment, as compared with control cells, however, MTX maximum GI\% was \((59.63\pm0.33)\) at 1000µg/ml with IC50 value 323.55µg/ml.

The SW480 cells were more sensitive to PAX2M than MTX, as PAX2M displayed a higher maximum inhibitory effect in SW480 cells growth than MTX at the 1000 µg/ml dose, and also at each serial utilized dose, PAX2M expressed the more GI\% than MTX, this may indicate a more potency character of PAX2M. (Figure1-A).

**Cytotoxicity assessment in VERO line.**

The results obtained indicated a significant \((P<0.001)\) inhibition of VERO cells’ growth which were treated with various concentrations of PAX2M ranged from 1000 to 7.8125 µg/ml in comparison to untreated control VERO cells. The percent of cell growth inhibition was ranged from \((9.59\pm0.17 - 54.48\pm0.18)\), with an IC50 value of 626.13µg/ml, the maximum growth inhibition percent \((54.48\pm0.18)\) was displayed with 1000µg/ml of PAX2M, (Table 3).

Figure 1. GI% of PAX2M and MTX (A) in SW480 , (B) in VERO cell line.

Overall IC50 outcomes

The comparison between the IC50 values of the tested compounds in both SW480 and VERO lines is shown in figure (2). PAX2M IC50 (93.28 µg/ml) was lower than methotrexate value (323.55 µg/ml), PAX2M had not markedly growth inhibitory effects in VERO cells when its IC50 value compared to the respective IC50 values in SW480 cancer cells, while methotrexate inhibitory effects were closely convergent in both SW480 cancer cells and VERO cells. Otherwise, PAX2M had not markedly growth inhibitory effects in VERO cells when their IC50 values compared to the respective IC50 values expressed by methotrexate.

**Discussion**

The present study aimed to evaluate the the effectivity of the C-MYC oncoprotein-blocking investigational agent PAX2M in the growth suppression of the colorectal cancer cells and assessment of its concomitant safety outcomes in the normal nonneoplastic cells, hence the results indicated that this tested compound can be utilized as a potent C-MYC oncoprotein inhibitor with considering the extraction of preclinical recommendations for the clinical trials. The exhibited cytotoxic action of PAX2M indicates, to some extent, its ability to direct targeting of the deregulated levels of C-MYC in cancer cells and blocking its abnormal overreactions and thereby its downstream target genes and upstream signaling aberrations with neoplastic potential. In general, these findings concurred with the outcomes achieved from the inhibition of other transcriptional factors families, especially the bHLH domain-containing transcriptional factors families, as C-MYC is a bHLH transcriptional factor. Xiong and his team concluded from their review that the transcription factors are usually deregulated in the pathogenesis of a wide range of human cancers and are a major class of cancer cell dependencies. Consequently, the transcription factors targeting can be powerfully effective in treating particular malignancies, also the emphatic diversity and potency of transcription factors as drivers of cell transformation justify an ongoing pursuit of them as therapeutic targets for drug discovery.  

PAX2M efficacy outcomes were assessed according to the exposure time of cancer cells recommended in this study, which was 24-26hour, and the prolongation of the exposure time may result in PAX2M potency improvement, and this presumption required further experiments to obtain the right conclusion about efficacy as well as normal cells toxicity parameters. Balaji and his team, in 2014, tested the anticancer effects of sinapic acid human colorectal cancer cell lines SW480 and HT-
29, they treat the cells with various concentrations of sinapic acid and calculated the IC50 values at different time points 24h, 48h, and 72h, and they found that the IC50 values were reached a minimum when the cells were treated with sinapic acid for a prolonged period (72h)\textsuperscript{14}.

The MTX results in this study may be attributed to the impact of the genetic features of the utilized cell line. Morales and his work team concluded that MTX induced cell growth inhibition and the chemoresistance capacity of the colorectal cancer cells are related to their genetic pathways and the karyotypic features variation among the CRC cell lines \textsuperscript{15}. Also, the antiproliferative effect of MTX may be dependent on the time of exposure rather than concentration as founded by Huysentruyt and his colleague’s study that showed that Cisplatin is more effective than MTX on (VM-M3) cultured cells and tumor cells implanted mice \textsuperscript{16}. On the other hand, the investigational agent PAX2M can contribute to the improvement of cancer treatment efficacy by combined them with the conventional cancer therapeutic modalities to create a powerful therapeutic approach. The strategies aimed at targeting C-MYC have emerged as an effective cancer treatment, the C-MYC based combination therapy can be carried out through different approaches such as the selection of agents that target MYC by different mechanisms or compounds that act on other genes in its pathway or other pathways in different cellular processes.\textsuperscript{17} Remarkably, the inhibition of proliferation of the normal VERO cells by PAX2M was very low as compared with its cellular growth inhibition in colorectal cancer SW480 cell line. Also, methotrexate display a higher growth inhibition in VERO cells than PAX2M, these findings may indicate that PAX2M display a modicum cytotoxicity to the normal cells as compared with cancer cells. The lower cytotoxic effects of PAX2M in VERO cells than in cancer SW480 cells was consistent with Prochownil and his colleagues estimation, that the MYC expression by the normal cells might not substantially necessitate the limitations in the use of the MYC-based therapies, because of most of the normal cells are quiescent with little short-lived MYC expression levels, thus they might not be exposed to the MYC inhibitors \textsuperscript{18}. The PAX2M' results of the cytotoxicity assay, in both colorectal cancer and normal cells, achieved by this study were in agreement with the results obtained by other researchers who worked on targeting C-MYC by various molecules, which act by diverse mechanisms and pathways on colorectal cancer cells and cells from other types of cancer that associated with C-MYC overexpression. For instance, OmoMYC (dominant-negative allele of MYC) can produce rapid tumor regression in mouse models with low toxic effects for normal tissues. Omomyc represses the activation of E-box promoter elements by Myc/Max and blocks cancer cell proliferation \textsuperscript{19}.

**Conclusion**

PAX2M has a premium antineoplastic effects associated with higher \textit{in vitro} safety profiles in comparison with methotrexate. PAX2M seemed to be more potent and more selective than methotrexate in concern of colorectal cancer treatment, but this conclusion required confirmations by further studies.

The Main Challenges Facing the Iraq Banks

Shaymaa Dhafer Hashem
Institute of Genetic Engineering and Biotechnology for Post Graduate Studies, University of Baghdad, Ministry of Higher Education and Scientific Research, Iraq

Abstract

The banking system is generally the main sector financed by different economic and social processes, within the framework of the objectives and policies of the development plans and the various sectors of the economy. The management of this system revolves around a number of laws, decrees and instructions, comes in the forefront of the Central Bank act and the instructions and follow up of developments in the banking system and the requirements of modernization, development and continuity through the various circles and organs, where he draws the central bank. Monetary policy, which plays an important role as part of overall economic policy. The global banking sector has witnessed many developments over the last ten years. These developments are likely to increase in the coming years in light of globalization and the implementation of the Financial Services Liberalization Agreement. These developments will undoubtedly have a significant impact on the future of Arab banks. Of the challenges ahead. Faced with these challenges and despite the success and profits of the banking system in the past years, the Secretariat requires that we clarify the fact that the global environment in which Iraqi banks are operating has changed completely and in a way that has not been taken into account. This development will not stop but it is a continuous process under which the fierceness of competition and constantly diversifying their instruments, and increasing the movements of capital in search of profit and safety. The importance of this research comes from the economic and political data in Iraq that has imposed itself on adopting a series of transformative steps towards the adoption of market economy mechanisms and economic stability to lay the foundation for sustainable development in which the private sector plays a major role, To rebuild the economy and provide full freedom to move to and from Iraq.

Keywords: Iraq Banks, Challenges, Financial inclusion, Differentiated banking, Banking technology

Introduction

Iraqi banks have faced more than three decades, and so far, many security, economic and political problems that have been reflected in their growth and development brought about by international, regional and some internal factors (1). These problems have increased now because of the occupation of a faction advocating large areas of our country, where it seized a number of branches of government and private banks and smuggled foreign currency out of the country. These complex problems cannot be resolved easily before removing the reasons that led to the return of the banking system and the functioning of the role of finance and investment in a normal manner, similar to the banks of other countries (2). The banking system must mobilize all its energies and unite its directions in order to face the crisis more effectively and emerge quickly and with minimal losses. His first work is to attract the unemployed to the public and pour them into lucrative loans and projects that yield good returns that meet the wishes of depositors and borrowers alike. Also, we would like to point out that most of the national capital has left Iraq, looking for more secure investment opportunities, even less profitable (3).

Low Oil Prices Embarrass Banks

Iraqi banks, like the banks of oil-exporting countries, now face a shortage of cash. The decline in
deposits has caused the public to decline as well as the deposits of ministries and government departments. This turn caused a contraction in lending at banks. This contraction caused in turn the decline in annual profits and also caused the problems of some companies and individuals from repaying their loans as a result of interruption of disbursement on some projects that borrowed contractors and investors. Amounts to be implemented by banks. This problem was not considered and did not calculate the managers of risk management in banks, which requires taking effective precautionary measures to address their effects.

**Development Orientation**

In light of the difficult financial conditions, it became necessary for banks to join some of them to finance the major strategic projects related to the reconstruction of damaged infrastructure since the first Gulf War and the second and liberated areas of gangs, because this campaign requires a lot of money to restore life in the destroyed structures.Either collected from banks and pumped in the form of syndicated loans or it is best to collect these amounts and establish a development bank with the participation of the government to be a large capital, which encourages the World Bank and the Asian Investment Bank to participate with the funds and expertise needed by Iraq at the present time. Germany took advantage of this option and established the German Development Bank immediately after the Second World War, where the bank assumed responsibility for the reconstruction of buildings destroyed by the war in order to provide the funding needed by its economy and infrastructure. This bank is still working to this day and offers its continued experience and experience to countries that suffer the same conditions suffered by Germany. Here, visions and efforts must be united between the leadership of the monetary and financial policies to make the task a success because the efforts of any party alone does not help him to succeed.

**The Trend toward Financing Small and Medium Enterprises**

The cure of economic stagnation is through the support and financing of small and medium-sized enterprises because these projects contribute to the provision of goods and services necessary and provide the state importation in a difficult currency that the government suffers from the current scarcity and these projects according to international statistics accommodate more than 70% of the workforce in the country. The means of dealing with unemployment and poverty is the social message of banks in the whole world. It should be noted that banks are not the only ones to finance these projects, but rather initiated more than a government or social institutions funding, which necessitates the organization of these lending to be under the management of unified and coordinated and guaranteed success, otherwise, confusion will be bound to succeed and inevitably.

**Central Bank Intervenes**

On the initiative of a responsible by the Central Bank contributed to inject cash liquidity to stimulate the economy by 6 trillion dinars, or up to five billion dollars and these amounts allocated to basic projects in the Iraqi economy, namely sectors of agriculture and industry and construction and financing of small and medium enterprises and under prudent lending controls do not allow money to go for other purposes. Soft loans and simple and subsidized interest to meet the administrative costs of these loans. Term loans for a period of years which can be extended for the necessary cases. And distributed to all governorates according to the percentage of the population to ensure justice and grant funding opportunities and the employment of labor according to merit. It is expected that this initiative will achieve the desired results and reflected positively on the development of sectors of the economy and GDP.

**Government Banks**

These banks account for 90% of the banking volume in the country and represent deposits of approximately 85% and the remaining share of private banks. These banks have a network of branches extending from the middle of Baghdad, where the general administrations and main branches are exercised to the maximum of the four sides and border crossings. These banks suffer from the international sanctions imposed on the economy of the country by the United Nations following the invasion of Kuwait in 1990. These sanctions adversely affected the performance. These banks made them suffer from the non-use of modern mechanization and suffer from legal problems affecting their external activities. This is why the foreign transactions themselves were imposed on the Iraqi Trade Bank, which was established in 2003 to open the external appropriations for the state’s
imports instead of the bank Rafidain and Rasheed, and
the bank suffered mismanagement in an earlier period,
affecting its financial position as a result of the debt
has not recovered most of them so far. Number of
conclusions were reached can be summarized centrally
in the following points:

1. Over the last two decades, monetary policy has
been characterized by a negative attitude by restricting
the bank The Central Bank of Iraq as the last resort in
the financing process, which adopted the provision of
resources Financing, which took a major share of the
new cash issue due to the inability of sources Which led
to this expansion to flood the market with local liquidity
and in return The weakness of the productive apparatus,
which led to a rise in the general level of prices and
the reason for this The form of funding, which was
mostly financing inflation (11). The law of the Central
Bank of Iraq No. (64) for the year (1976) during the
long application period Relatively, did not guarantee
in essence the necessary independence of the bank to
achieve its objectives in monetary policy, Many of the
articles in the law specifically define the bank’s conduct
in its management of monetary policy In particular
with regard to providing the necessary support to the
Government in the implementation of its financial policy.

3. The reference to the possibility of using indirect
means in the management of monetary policy, has been
received in the laws that preceded 2004, but in fact their
use was limited, because. The requirements of activating
the mechanism of action of these means were not
available in the monetary and financial environment and
on Although Law No. (56) Of 2004 has given broader
dimensions in the application of these tools, but the
monetary and financial environment still lacks the
requirements to activate these means (12).

4. A shift in the role of the Central Bank of Iraq from
the specific role of the policy of private commercial
banks’ Lending and deposits and interest rates to an
observer role for lending movements, deposits and
prices Interest, as the Central Bank granted commercial
banks the freedom to determine interest rates on the
basis of The economic situation of the country to achieve
profits for these banks following the legislation of the
Banking Act.

5. Monetary policy in the use of indirect instruments
after 2003 was able to maintain On a good exchange
rate of the dinar against the US dollar through the
foreign exchange auction which Considered the central
exchange market leading to the exchange rates of the
Iraqi dinar, and used as an indicator To stabilize the
inflation expectations of the public by reducing the
speed of money circulation and increasing demand for
it And to enhance the attractiveness of retaining the
ethnic dinar(13).

6. In recent years, monetary policy has faced many
challenges, including dollarization, The constant rise in
prices and the impossible trinity problem, as well as the
absence of coordination between them and the general
economic policy of the state in addition to the link money
supply mainly and the financial status of the government
and its financial policy, especially the expenditure of the
two factors With which the central bank has significant
influence or effective control (14).

Conclusion

The Iraqi banks are performing their banking
services to their internal and external clients. They must
be strong in their country so that they can benefit from
the current banking situation where there are no limits
and no restrictions. This requires that the leaders of these
banks, especially the marketing of services and research,
have professional competence for the purpose of entering
to the needs of societies in terms of traditional banks
offer in accordance with the methods of complementary
participation in particular at the national level despite the
reforms introduced in this sector is still suffering from
the secretions and consequences of financial imbalance
because of the circumstances experienced by the country,
where banks are still as the future trends indicate that
there are real opportunities for the transformation of
national banks into an effective economic force within
the global economy, these opportunities must be used to
keep pace with the comprehensive transformations, and
this is being achieved in greater measure of structural
reforms at the financial and economic levels.

Factors Affecting the Implementation of Clean and Healthy Living Behavior at Household Level (Observational Study at Sungai Paring Village, Martapura Kota District)

Laily Khairiyati1, Fauzie Rahman2, Arnila Udin3, Vina Yulia Anhar2

1Health Environment Department, Program Study of Public Health, 2Health Policy Administration and Health Promotion Department, Program Study of Public Health, 3College Student of Program Study of Public Health, Faculty of Medicine, Lambung Mangkurat University, South Kalimantan Province, Indonesia

Abstract

Clean and Healthy Living Behavior/Perilaku Hidup Bersih dan Sehat (PHBS) is a health behavior by individual, family, and community to help themselves improving health status. The aim of this study was to explain the factors that influence PHBS implementation at household level in Sungai Paring Village. This study was a quantitative by using cross-sectional approach. Population of this study were 2638 households. Technique sampling used purposive random sampling with sample of 91 households. The study was analyzed by chi-square test with CI 95% and significance level 0.05. The results showed that there were no relationship between knowledge (p-value = 0.103), attitude (p-value = 0.172), distance of health care facilities (p-value = 0.089) with the implementation of PHBS. Meanwhile, support from health workers (p-value = 0.001) and community leaders (p-value = 0.010) had relationship with the implementation of PHBS. Health workers, community and stakeholders should strengthen cooperation as an effort to improve the achievement of PHBS program implementation through routine monitoring and evaluation at household level.

Keywords: Clean and Healthy Living Behavior, PHBS program, household level, health, behavior, Sungai Paring Village

Introduction

Health degrees are not only determined by health services, but the more dominant ones are influenced by environmental conditions and people’s behavior1. Household members need to be empowered to implement clean and healthy living behavior or perilaku hidup bersih dan sehat (PHBS) to prevent from infectious or non-infectious diseases2.

Ramdaniati (2008) stated that there was an influence of knowledge and attitude toward the implementation of PHBS at household level3. Tumiwa, Rattu and Tucunan’s research (2014) states that the predisposing, enabling, and reinforcing of health behavior, attitude, facilities and infrastructure, such as support from health professionals had a great influence in encouraging members of the household to do PHBS at household level4. Budiman et al. (2012) said that knowledge, support and attitude of health workers could illustrate the implementation of PHBS at household level in Cimahi City5. Based on several studies, concluded that several factors such as level of education, knowledge, attitude, availability of facilities, infrastructure and support or attitude of health worker can influence the implementation of PHBS at household level.

The national target achievement of PHBS at household level based on the Ministry of Health’s strategic plan for 2015-2019 is 70%6. Based on data of Indonesian Health Profile in 2014, it was stated that the last achievement only reached 56.58%, it means that the achievement of PHBS at household level was still far from the predetermined target. South Kalimantan Province was one of the provinces that had achievement under the national target (49.74%)7. Banjar Regency had the achievement of PHBS at household level of 52.1% which also did not reached the National target8. Based
on data from the Public Health Development Index in 2007 and 2013, Banjar Regency was ranked 13. Based on the result of Basic Health Research (2013) indicating that Banjar Regency can affecting Public Health Development Index of South Kalimantan Province (ranked 31 from 33 provinces). It needs to be a concern because the PHBS achievement data on the household level in Banjar Regency was not reached the target of both provincial and national\(^9\).

Data from the Banjar District Health Office in 2014 stated that Martapura Kota District had the lowest percentage of household PHBS in Banjar Regency, which was 37.1\(^8\). Based on data from Martapura 1 Public Health Center, the lowest achievement of PHBS at household level was in Sungai Paring Village as much as 0.87\% of 1846 households that had been monitored\(^10\). Based on description above, this research was conducted to explain the factors that influence the implementation of PHBS at household level in Sungai Paring Village, Martapura Kota District.

**Methodology**

This research was an analytic observational study. A cross sectional approach was conducted among community of Sungai Paring Village, Martapura Kota District, South Kalimantan Province, Indonesia. Population of this research were 2638 households. Sampling technique used purposive random sampling with inclusion criteria for families who have children or toddlers as many as 91 respondents. Sample calculation used Stanley Lemeshow’s formula.

Knowledge, attitudes, distance of health care facilities, and support from health workers and community leaders as independent variables. Dependent variable was PHBS implementation at household level. Informed consent sheet was filled in as a form of agreement to be a respondent. The collected data was analyzed by using SPSS software. Analysis was conducted to explain the relationship between independent and dependent variables by using chi-square test with CI 95\% and significance level 0.05.

**Results**

There were the results of univariate (Table 1) and bivariate analysis (Table 2) between knowledge, attitude, distance of health care facilities, support from health workers and community leaders with PHBS implementation at Sungai Paring Village among 91 respondents.

**Table 1: Distribution and frequency of knowledge, attitude, distance of health care facilities, support from health & community leaders and PHBS implementation**

| Support | 13 | 14,3 | 4 | 4,4 | 17 (18,7) |

Note: n = frequency; Statistical test applied: chi-square test; *significant values (<0.05)

Based on table 1 showed that majority of respondents had less knowledge as many as 47 people (51,6%). Respondents had positive attitude as many as 61 people (67,0%). There was 73 respondents (80,2%) stated that their house is far from health care facilities. Majority of respondents stated that health workers gave less support to them to do PHBS as many as 77 people (84,6%). Community leaders were also gave less support them to do PHBS as many as 74 respondents (81,3%). Majority of respondents didn’t do PHBS at household as many as 85 people (96,7%).

Based on table 2 showed that there were no influence of knowledge (p-value = 0,103), attitude (p-value = 0,172), distance of health facilities (p-value = 0,089) with PHBS implementation at household level. Support of health workers (p-value = 0,001) and community leaders (p-value = 0,010) were related to PHBS implementation at household level.

Discussion

There is several factors that affecting PHBS practice at household level. In the results of Hasni, Nurdin and Edward’s research, respondents who have high knowledge and have the willingness to do PHBS, tend to practice PHBS\textsuperscript{11}. That results was different with our research. Based on the result showed that knowledge did not have relationship with PHBS practice. This result was similiar with the research of Hapsari (2010) which states that knowledge did not have a significant influence on the practice of clean and healthy living behavior\textsuperscript{12}. This research was found that respondent with less knowledge still did PHBS. To behave healthily, the community sometimes not only needs knowledge and positive attitude, or support from facilities only, but it also needs the role model from family or peers\textsuperscript{13}. The low level of knowledge in the results of the study might caused by the fact of many people who claim they have never received counseling from health workers around their homes.
Attitude did not have relationship with PHBS implementation at household level. This result was in line with the research of Haniek (2010) that stated an attitudes do not have a significant influence on the practice of clean and healthy living behavior (p-value = 0.087). The result of this study was not in line with Mahfudah’s research (2013), said that attitudes can influence individuals in a clean and healthy lifestyle. An attitude has not been automatically realized in an action (overt behavior). The realization of an attitude to be a real action requires a supporting factor or a possible condition. The majority of respondents had positive attitude, but did not implement PHBS can be affected by characteristics of the person such as emotional level. People with high emotional and motivated to behave according to attitudes that have existed within their individually, will strive best for the behavior of clean and healthy living.

Distance of health care facilities was not influencing the implementation of PHBS at household level. This result was in line with the research of Hapsari (2010) which states that distance did not have a significant influence on the practice of clean and healthy behavior. However, in contrast to the results of Ningsih’s research (2014) which states that the distance of health care facilities had an influence on the implementation of PHBS at household level. Ningsih’s research (2014) showed that respondents who had a long distance from the place of health service allowed respondents to not implement PHBS at household level. There are certain distance limitations so that people still want to seek health services. Distance limits are significantly influenced by the type of road, type of vehicle, and transportation cost. Road facilities are still adequate and allow people to seek health care facilities even though the distance from the community’s residence is categorized far.

Support from health workers had influence on implementing PHBS at household level. This result was in line with Hapsari’s research (2010) which states that health worker’s support had a significant influence on the practice of clean and healthy living behavior. The support can be in the form of counseling or monitoring conducted by health workers in order to create healthy behavior in the community. Support from community leaders had influence on implementing PHBS at household level. This result was in line with Pratama’s research (2009) which states that the support of community leaders had a significant influence on clean and healthy living behavior, where the higher the role of community leaders in healthy behavior, the higher the motivation of the community to implement PHBS. Community leaders playing a role in the implementation of PHBS such as mobilizing the potential resources to develop healthy behaviors in the community, collaborating to create a healthy environment, and creating the conducive atmosphere to support changes in healthy behavior.

**Limitation**

This study was conducted among household in Sungai Paring Village and might therefore not being representative of other village in Martapura Kota District, Indonesia.

**Conclusions**

It can be concluded from this study that knowledge, attitude and distance of health facilities were not influencing someone to aplicate PHBS at household level. Several factors that influencing PHBS practice at household level were support from health workers and public figures, such as community leader. Community leaders can help activate PHBS programs such as increasing exclusive breastfeeding achievements and making healthy latrines, in several ways such as the formation of exclusive breastfeeding groups, or by forming healthy latrines.

Health workers should work together with community leaders as an effort to improve the achievement of PHBS at household level in Sungai Paring Village community. These efforts can be carried out by health workers socializing to community leaders regarding PHBS practices, so that community leaders can invite the community to implement PHBS at household level. Health workers and community leaders collaborating in order to monitor PHBS implementation at household level.

Point Prevalence of Healthcare Associated Infection and its Risk Factors among Patients Admitted to the Intensive Care Unit in Baghdad Medical City

Waleed Ibraheem Ali¹, Hayder Adnan Fawzi², Huda Jassim Lafta³, Sarah Alaa Mohammed³, Noor Mosaad Ameer³
¹Internal Medicine & Intensive Care, Lecturer Internist, College of Medicine, Baghdad University, ²Baghdad Medical City, Baghdad Teaching Hospital, Clinical Pharmacy Department, Baghdad, Iraq, ³Medical Student’s Graduate, a Collage of Medicine, Baghdad University

Abstract

Objective: assess the prevalence, risk factors, microbiological profile of hospital-acquired infections (HAI), and HAI impact on ICU stay and mortality in the Intensive Care Unit.

Materials and Method: a cross-sectional study conducted on 83 patients in ICU of Ghazi Al Hariri hospital at the Baghdad Medical City, the study started from 1st July to 30th September 2018. All the patients were followed throughout their hospital stay, the septic screen was done for all patients. The specimens were processed by standard microbiological methods to isolate and identify bacteria etiology.

Results: The overall prevalence was 67.5%, the most common type of HAI was ventilator-associated pneumonia (VAP), followed by catheter-associated urinary tract infection (UTI), bloodstream infections (BSI) and surgical site infections (SSI). Pseudomonas, Candida and Klebsiella were the most common agents causing these infections with a different rate of presentation. Prolonged hospital stay, urinary catheterization and the use of H2 antagonist had higher odds of acquiring HAI (P<0.05).

Conclusion: High prevalence of hospital-acquired infection with VAP and UTI as the most common types, Klebsiella was the most common etiological agent for VAP, Candida was the most common cause of UTI and SSI. Longer hospital stay and the use of H2 antagonist associated with increased risk of HAI.

Keywords: H2 antagonist, Klebsiella, pneumonia, VAP, hospital stay, ventilator.

Introduction

Nosocomial Infections are infections acquired during hospital care, which were not present, or incubating at the time of admission. Infections occurring more than 48 h after admission were considered nosocomial infections or HAIs. HAI is increasingly becoming an important public health problem affect the quality of health care and a major source of adverse outcomes during health care delivery. It contributes to increased morbidity and mortality, excess health care costs and prolongs hospital stay. It has a far-reaching consequence to the public resulting in widespread occurrence of multidrug-resistant bacteria in hospital settings.

The burden of HAI in developing countries is significant whereby the incidence can be up to 15% of total hospitalized patients, and up to 50% among ICU patients, in developed countries the magnitude of the problem in the low-income settings remains largely unknown and in most cases underestimated due to the complex nature of its diagnosis and lack of proper surveillance. According to multiple sources, between 20% and 50% of healthcare-associated infections (HAIs) occur in the intensive care unit (ICU). In 2007, 39% of patients in European countries were affected.

DOI Number: 10.5958/0976-5506.2019.00752.6
by these infections. These infections presented in the most dangerous and sometimes life-threatening forms of infection, such as pneumonia, bloodstream infection, wound infections and urinary tract infection; therefore, surveillance of these types of infections is important in the ICU.

The development of HAIs can be facilitated by the ICU environment, medical procedures applied to treat the patient and, above all, the patient’s general health. Intensive care units treat severely ill patients whose underlying disease and co-existing diseases may contribute to the development of healthcare-associated infections. The need to perform many diagnostic and treatment activities on patients results in the use and long-term maintenance of invasive devices, such as central vascular lines (CVC), intubation tubes, and urethral catheters (which may result in the removal of the natural protective barrier against infections), so factors such as the increased use of invasive devices, immunosuppressive drugs, and immunocompromised status as well as irrational use of antibiotic therapy in ICUs are all contributions for this cause.

Among healthcare-associated infections, PN is the most common and accounts for between 30% and 50% of all infections. Epidemiological studies indicate that bloodstream infections are low frequently found and their prevalence ranges from 4% to 20% Among HAIs, the prevalence of urinary tract infections ranges from 3% to 7%

The most frequent microorganism in Intensive Care Unit of Ghazi al-Hariri Hospital is Klebsiella pneumoniae which account (30%) of total microorganisms followed by Pseudomonas aeruginosa (24%), Acinetobacter baumannii (16%), coagulase (-) Staphylococcus (12%), Burkholderia cepacia (4%), coagulase (-) Staphylococcus (4%), and Proteus mirabilis (4%). The aim of this study was to determine the prevalence of healthcare-associated infections in the intensive care unit of Ghazi al Hariri and the comments types of these infections, the microbiological profile of HAIs and the associated risk factors, and to assess the impact of these infections on ICU stay and mortality.

Method

Setting

The study was conducted at Intensive Care Unit of Ghazi Al Hariri hospital in Baghdad medical city.

Study design

A hospital-based cross-sectional study conducted from 1st July to 30th September 2018, all patients admitted to ICU, with no evidence of bacterial infections at admission were included in the study.

Data collection

Socio-demographic and clinical data were collected by the structured form which includes (age, gender, date of administration, diagnosis, culture results, types of microorganisms, the use of invasive devices, and finally the fate of patients). The patients were followed first for 8 hours, patients who have developed any form of infection within 48 h of admission and/or had asymptomatic bacteriuria were excluded. All the rest of the patients were followed for the occurrence of HAI until discharge, progress or death by the researchers. The Occurrence of HAI was confirmed by reviewing the laboratory biological results for all the participants.

Definition

The primary outcome variable was the occurrence of infection after 48 h of hospitalization in a patient otherwise not having an asymptomatic or incubating infection on hospital admission. The following are definitions used in this study for a specific type of HAI (Adopted from Centre for disease control/National Health care Safety Network (CDC/NHSN) surveillance definition for healthcare-associated infection with slight modification):

Bloodstream infection: Patient with any of the following signs and symptoms: fever (>38 °C), Chills/rigors or hypotension and at least one positive blood culture not related to contamination.

Healthcare-associated pneumonia: Respiratory symptoms with at least two of the following signs and symptoms appearing during hospitalization; a cough, purulent sputum, new infiltrate on chest radiograph consistent with infection.

Surgical site infection: any purulent discharge, abscess, or spreading cellulitis at the surgical site during the month after the operation.

Urinary tract infection: mid-stream urine cultures with ≥105 colony forming units (CFU) and catheter
urine with $\geq 10^2$ CFU/ml with no more than 2 species of microorganisms isolated OR positive dipstick for leukocyte esterase OR pyuria ($\geq 10^6$ white blood cells / high power field) of clean catch urine in a patients with or without signs and symptoms in the presence or absence of recent urinary catheterization.

Statistical analysis

Statistical Package for the Social Sciences (SPSS STATISTICS 24, Armonk, NY, USA) and Microsoft Excel (Microsoft Office 2016, Redmond, WA, USA) was used in the statistical analysis of the collected material. The significance level was $p < 0.05$. In addition, the pooled mean, median (Me), standard deviation (SD), Chi-squared (Pearson) $\chi^2$ for the ordinal and nominal scales and an ANOVA for the quantitative scale were calculated.

Results

The most common type HAI was VAP while UTI was slightly lower, see figure 1.

![Figure 1: types of HAIs](image)

Candida was the most common cause of UTI and SSI, while Pseudomonas aeruginosa is the commonest cause of bacteremia, as illustrated in table 1.

**Discussion**

The total prevalence of healthcare-associated infections in ICU of Ghazi Al Hariri hospital was 67.5%, it is very high prevalence compared to the other countries such as in Switzerland(26.2%)\(^{13}\), India(20%)\(^{14}\), Poland(39%)\(^{15}\), and Philippine(28%)\(^{16}\).

The commonest form of HAIs in the study was pneumonia with 58% prevalence followed by UTI 56%, BSI (28%) and SSI (6%). In other countries such as Europe, pneumonia prevalence was 5.5%, BSI (3.5%) UTI (2.6). In Rome the most common infection was pneumonia (35%), SSI (22.2%), UTI (19.4%), BSI (17.2%)\(^{17, 18}\). The high prevalence could be explained according to the different nature of patients, high rate of using the ventilator, the regularity of changing the ventilator, using of acid-suppressive medications and prior antibiotic exposure.

In the current study the prevalence of VAP point prevalence was 39%, Which was higher than other studies like Deppe et al.

The most frequent microorganism of VAP Pseudomonas Aeruginosa (24%) followed by Acinetobacter baumannii (22%), Klebsiella (18%), Candida albicans (16%), Proteus mirabilis (4%) and Haemophilus influenzae (2%). In a study done in Beirut, the most common organism was Acinetobacter anitratus, followed by Pseudomonas aeruginosa and Klebsiella species\(^{21}\). In another study done in Pakistan, 18% were diagnosed as VAP, the most frequent organisms Pseudomonas aeruginosa (26%), Staphylococcus aureus (20%), Acinetobacter spp. (9%)\(^{22}\). That shows us there isn’t a significant association between these organisms and mortality except Pseudomonas aeruginosa which has a significant association with mortality.

The second most HAI in the ICU is UTI, the prevalence was 38% which is much higher than the prevalence in other studies (19.4%) in Rome and Saudi Arabia (28.4%)\(^{17, 23}\). This higher prevalence of UTI...
could be attributed to the nature of the patient, a high rate of using the urethral catheter, and the type and the frequency of changing the catheter.

The present study revealed that using H2 antagonist increase risk of HAI especially pneumonia there are many theories about the causes, one of them attributed it to its effect on stomach acidity which allow growth of any organisms, they may promote pneumonia by suppressing coughing\textsuperscript{24}.

**Conclusion**

High prevalence of hospital-acquired infection with VAP and UTI as the most common types,\textsuperscript{1} Klebsiella was the most common etiological agent for VAP, Candida was the most common cause of UTI and SSI. Longer hospital stay and the use of H2 antagonist associated with increased risk of HAI.

**Conflict of Interest**: None

**Ethical Clearance**: Informed written consent was obtained from all the participants in the study, and the study and all its procedure were done in accordance with the Helsinki Declaration of 1975, as revised in 2000. The study was approved by college of medicine, Baghdad University.

Histopathological Study of Well Differentiated Papillary Thyroid Carcinoma Case Study

Abdul Hadi Sallal Mohammed¹, Rasha Abdul Ameer Jawad² Ali Khudheyer Obayes¹

¹Dept. Medical Laboratory, College of Medical and Health Technique, University of Kufa, Najaf, Iraq, ²Dept. of Biology, College of Education for Pure Sciences, University of Kerbala, Iraq

Abstract

The present study conducted on a fifty year old women affected with well differentiated papillary carcinoma, the histological changes of the thyroid left lobe was revealed, irregular shapes of thyroid follicles and degenerative alteration in the most follicles, Some thyroid follicles were enlarged and fill with colloid which contain on the large vacuoles, From another hand metaplastic changes was occur in the thyroid tissue of old women patient, So the epithelial linings of some thyroid follicles was projected as papillae which extended into the lumen of follicles, as well as the multilocal tumors of thyroid tissue was encapsulated by thick fibrous connective tissue, dilation and congestion of thyroid arteries and veins in parenchyma of thyroid left lobe.

Keywords: Old women patient, Papillary Thyroid, Carcinoma, Histopathological.

Introduction

Thyroid Carcinoma, in the American United States. Comprises about (1%) of all Cancer and accounts for (0.2 %) of cancer health¹. Papillary carcinoma can occur at any age and rarely has been diagnosised as a Congenital tumour, most tumour are diagnosed in patients in third to fifth decades of life women are affected more frequently than men in ratio of thyroid (1:2) to (4:1)². The criteria for the recognition of thyroid follicular and thyroid papillary carcinoma have changes in recent years but both denominations have been retained, Papillae no longer seen to be necessary for diagnosis of papillary Carcinoma , cytologic features such as oncocyte , Clear cell, Squamous and mucinous changes have resulted in the designation of special tumour types and subtypes, the practical importance of these special types resides in differential diagnosis rather than their biological behavior³. The histogenesis of anaplastic thyroid carcinoma has been controversial , Some author have indicated that many of these tumors represented thyroid sarcomas, Whereas others have demonstrated that they are carcinomas, Currently , most pathologists agree that anaplastic thyroid carcinomas arise from follicular epithelial cells⁴. The thyroid carcinomas less than one centimeter are almost exclusively papillary and termed papillary thyroid micro carcinoma (PTMC) according to the World Health Organization⁵. Papillary thyroid carcinoma (PTC) is the most commonly observed well differentiated thyroid cancer in the endocrine clinics , most papillary thyroid cancer patients have a good prognosis and long – term survival without distant metastasis Tumour Node Metastasis (TNM) staging is most commonly used for the initial evaluation of thyroid cancer before and after thyroid surgery⁶. Inconsistent data concerning variant of papillary thyroid carcinoma may have been generated by inconsistent diagnostic criteria and differences in characteristics , such as the gender , age, and geographic location and ethnic background of the subjects enrolled in analysis , the reported histological variant of the papillary thyroid cancer in the children and adolescents differ from these in adult⁷. The purpose of present study was to evaluate the histological changes in the case report in women patient infected with papillary thyroid cancer.

Corresponding author:
Abdul Hadi Sallal Mohammed
Email: AL_hadi2002@yahoo.com
Material and Method

Fifty old female patient visited the Al-Sadar teaching hospital Naja. A retrospective examination of the record of patient with papillary Thyroid Carcinoma (PTC). The patient underwent with left thyroid lobectomy with isthmus removal. Gross examination was carried out the histo–pathological examination and staining of the cancer were conducted by the teams in the department of the histopathological in the hospital. Cancer was staged on the basis 8.

For histopathological examination, the thyroid gland (left lobe and isthmus) were obtained from patient and dissected and processed for light microscope examination the thyroid gland pieces were fixed in formalin solution for period (48) hours. The histological specimens were dehydrated in serial graduated ethyl alcohol concentration (70%, 80%, 90%, 100%), the period for each alcohol concentration (1.5) hour, the histological specimens were cleared in xylen for time (0.5 – 1) hour.

After that the histological specimens of thyroid gland were embedded in paraffin wax. The histological sections were done by rotary microtome; paraffin sections were cut at thickness (six) micrometer. Then the histological sections were stained with Haematoxylin and Eosin 9.

Results and Discussion

A fifty year old women presented with swelling in the neck region, swelling had gradually increased in size and was concerned breathlessness. Clinical examination appeared, 2.5 ± 3.5 centimeter hard non–tender mass. The patient was sent to surgery department to perform the left thyroid lobectomy and isthmus removal for histopathology. Gross examination showed left thyroid nodule: with grey–whitish mass (0.95±1) centimeter. Cut sections was revealed small ill defined area (0.35±0.45) centimeters. Several pieces were taken and four paraffin blocks were carried out. The histopathological diagnosis were observed: infiltrating sheets and clusters of differentiation papillary thyroid carcinoma, with evidence of marked parenchymal infiltration, the isthmus of thyroid gland sections were markedly included by cancer, the figures were consisting with well differentiated primary papillary thyroid carcinoma. These findings were similar to current study 10,11, they recorded, the fibrous capsule surrounding the tumour tend to be thicker and more irregular than in the thyroid adenomas, and capsular or vascular invasion only on microscopic evaluation, and extensive areas of invasion to adjacent thyroid tissue and widespread blood vessels infiltration.

The histopathological observation was appeared in the left lobe of thyroid gland in the fifty old women patient; the irregular arrangement of the thyroid follicles, and degenerative changes in some thyroid follicles, from another hand, some thyroid follicles were revealed enlargement and full with colloid contain large vacuoles which located on the edges of colloid in the serial manner. (figure 1), these results were accordance with previous studies 12,13 they mentioned; the traditional classification of thyroid cancer as well differentiated carcinoma (papillary and follicles; the cytologic features such as oncocytic, clear cell, squamous and mucinous changes have resulted.

(Figure2) showed, the histopathological changes, such as metaplastic changes, in the thyroid tissue, and protrusion of epithelial lining of some thyroid follicles as papillae which extended toward the lumen of the follicle, and the main findings of our study was the reduction of the thyroid follicles diameter and this reduction of the follicular diameter is concerned with depletion of colloid inside the thyroid follicles, these our observations were agreement with previous studies 14,3, reported the recognition of the papillary carcinoma criteria; the papillae of thyroid follicles no longer seem to be necessary for diagnosis of papillary carcinoma. Our histological section was showed. The thickening due to encapsulated the thyroid tissue tumour foci by fibrous connective tissue, the capsule sent the fibrous trabiculae among the parenchyma of the thyroid left lobe in fifty old women patient, from another hand, congestion in the thyroid arteries and vein which occur in the thyroid capsule and interstitial connective tissues, and large vacuoles where arranged at the edge of colloid in some thyroid follicles, as well as, adipose connective tissue was distributed in some areas of thyroid parenchyma may be led to adipolinoma (figure 3), these our finding were indicated with surrounded by a fibrous capsule which may by intact or focally infiltrated by the tumour, and some lesions have shown lymph node involvement.
Conflict of Interest: This research is a personal non-profit work and there is no conflict of interest.

Source of Funding: None.

Ethical Clearance: Ethical clearance was obtained from the Faculty Scientific Committee (Dept. Medical laboratory, College of Medical and Health Technique, University of Kufa, Najaf, Iraq) to Study the histopathological study of well differentiated papillary thyroid carcinoma.

Family Support of Ifontoks to their Pregnant Teenagers: an Extension Health Service Program of Mountain Province State Polytechnic College

June II A. Kiblasan

Dean of Nursing, Mountain Province State Polytechnic College, Bontoc, Mountain Province, Philippines

Abstract

Teenage pregnancy in the Philippines is increasingly turning out to be a major cause of concern. The rising trend among young women who are becoming mothers and majority of them are unmarried lead them vulnerable to death, susceptible to depression, abortion and others, especially if support from family is minimal.

This study focused on how social and spiritual health service program was developed and extended to pregnant teenagers. A reliable self-made data gathering tool was used to collect data from parent/s and the pregnant teenagers. Positive effects were observed and verbalized after launchings the first implementation of the health service program within the locality. Indeed, the nursing department of MPSPC included the service in the care of pregnant mothers during community immersion as part of the related learning experience (RLE) of the nursing curriculum.

Keywords: Pregnant teenagers, family support, Ifontoks, Social wellness, spiritual wellness

Introduction

The most crucial period in a person’s life is considered to be during teenager for this is the period of establishing one’s identity. They experiences changes whether in physical, emotional, social and spiritual aspects of life. In some cases, pregnancy may exist that might stunned the family. Family’s reactions may be denial or unacceptable while others might find it as a blessing, or as a punishment. Dealing alone with role changes, fears and adjustments of pregnancy happens and seeking support from family and friend is expected. Hence, if the pregnant woman plans to relinquish her infant, she still needs to deal with the adjustments of pregnancy.

Teenage pregnancy is the condition of a woman to have a baby during adolescence (13 to 19 years old). Ajala described that teenage pregnancy is a social construct, which represents one of the many indices of adolescent delinquency, sexual permissiveness and moral decay. It is a major concern because not only physical changes that may occur but also in the psychological and social aspects of their lives. Whereas, teenage pregnancy is regarded a major socio-medical phenomenon in both developed and developing countries and has become more rampant in recent times. Further, teenage mothering interrupts the natural course of teenage development most especially if occurred in the earlier age of adolescence due to numerous unexpected responsibilities. With these, holistic support in the perinatal period is a necessity for the traditional focus is on the maternal and child’s physical health. Neglect or insensitiveness to psychological and social wellness has great impact to wellness especially if pregnancy exists during adolescence and out of wedlock. Teenage pregnancy if out of wedlock may have undesirable effects to the health of the mother and child which is considered a worldwide public health concern. The Centers for Disease Control and Prevention reported a total of 249,078 babies were born to women aged 15 to 19 years with a birth rate of 24.2 per 1,000 women. Moreover, the average teenage birth rate in middle-income countries is two times higher than in a high-income countries while five times as high in low-income countries.

The United Nation Population Fund revealed Philippines is the only country in Asia Pacific region
that has cases of teen pregnancies rose over the last two decades. Accordingly, the Cordillera Administrative Region (CAR) tops the most teen pregnancies in the country at 18.4%.

Further, teenage pregnancy in Mountain Province is alarmingly increasing. Recent data from the Mountain Province Provincial Health Office revealed that there were 148 pregnant teenagers aging below 19 years old recorded for the first quarter of 2014. The municipality of Paracelis has the highest number of teenage pregnancy recording 39 individuals. While the capital town of Bontoc listed 34 pregnant young people, Bauko recorded 17, Tadian has 16, Natonin recorded 14, Besao has seven, Sabangan and Sagada both recorded five, Sadanga has two and Barlig has one teenage pregnancy.

For the third quarter of 2014, the first three municipalities/towns with highest incidence of teenage pregnancies were Paracelis listed 90, Bauko reported 52, and Bontoc has 47 cases of teenage pregnancies.

From the data, it was observed that program related to teenage pregnancy by concerned government and non-government agencies focused only on how to prevent its occurrence. No identified programs noted to support a teenager once they become pregnant. The Department of Health (DOH) focuses mainly on physical wellness of the mother and child during prenatal consultation. There may be programs related to other health needs of pregnant teenagers but not a known one and is a rare case. One thing, none was observed in the locality. These made the realization of this study to suffice whatever deficient support that can promote wellness.

Method

This paper utilized the Community Organizing Participatory Action Research (COPAR) design. This method is a continuous and sustained process of educating, organizing, and mobilizing people through community participation, action, and research. This is a vital part of public health nursing that aims to transform the apathetic, individualistic and voiceless poor into dynamic, participatory and politically responsive community.

The phases involved in this study are assessment, planning and implementation. In the assessment phase, community immersion was done at places within the barangays of Bontoc, Mountain Province where cases of teenage pregnancies were found panicking. Health status of the entire community was evaluated through home visits purposely for family health assessment. However, survey on family support was included when pregnant teenager is found utilizing a self-made data gathering tool after reliability test using Kuder-Richardson Instrument (rK–R = 0.99). Family member and the pregnant teenager were the target participants.

Follow-up interviews and observations were done to substantiate findings. Gathered data were subjected to statistical treatment using the Statistical Package for Social Sciences Version 22.0 (SPSS). To validate if there is significant difference on support given to pregnant teenager, independent-sample t-test was utilized. Five-point Likert scale was used in the interpretation of data. Findings were used to develop a health service program. Implementation of the developed health service program was done after pilot testing to places where the data were taken.

Results and Discussions

Unintended teenage pregnancy is an ever-present issue in developing countries such as the Philippines affecting the physical, emotional, social, and spiritual wellbeing of adolescent. This may bring the health of mother and child at risk. Alarmingly, though adult maternal deaths is decreasing in the Philippines, teenage maternal deaths is increasing. Ten percent of pregnant teenagers died according to the Philippine Statistic Authority while World Health Organization showed a high and increasing incidence of fetal death in Filipino mothers under 20.

Further, many of teenage pregnancies end in abortion. According to the Philippines Safe Abortion Advocacy Network (PINSAN), there are 600,000 induced abortions recorded each year where about one-third are adolescents. This is because of support insufficiencies not only in material or financial but more on social, emotional and spiritual.

Perspective on family support to pregnant teenagers

There are four common categories of support on wellness being extended to pregnant teenagers by the family. These are health needs that are essential to the wellbeing of pregnant teens and the baby at best. Though parents of pregnant teens sometimes feel angry or disappointed, they should try to offer support to their teen who is dealing with an unplanned pregnancy. These support categories were used in identifying the realities of Ifontoks family support whereas, physical wellbeing
is referring to wellness related to the maintenance of healthy body and seeking care when needed. Emotional wellness relates on how to understand feelings and to cope effectively with stress while social support helps an individual on dealing with others effectively and comfortably that can create a support network, and spiritual wellness allows an individual to develop a set of values that help seek meaning and purpose.

Legend: M = Mean; DI = Descriptive equivalent; 4.21-5.00 = Very High (HV); 3.41-4.20 = High (Hi); 2.61-3.40 = Moderate (Mo); 1.81-2.60 = Low (Lo); 1.00-1.80 = Very Low (VL)

As gleaned from Table 1, the four categories of family support was perceived “high”. However, spiritual support was the weakest link among the four followed by the social support with weighted means of 3.08 and 3.34 respectively. Both were perceived as moderately extended that is considered a big deal. To wit, from the Asianparent Philippines, a 17 year old pregnant is scared, confused, and anxious. She claimed fears that her parents might hit her, disown and hate her. She is also worried about other people for they might judge, condemn, reject and avoid her. Further, she tried to find the courage to tell her parents, but the fear dominated. So she faced the growing panic and crushing uncertainties of teenage pregnancy on her own. Moreover, Jessica was one of the many vulnerable teenagers who became pregnant at age of 19 out of wedlock. She struggled with the stigma that often confronts pregnant teenagers. She kept her pregnancy a secret from friends and neighbors as much as she can for she thinks that they talk about her status. Dr. Emma Llanto who works in a government hospital claimed that most of the time, pregnant teenagers who consulted her are on their 16, 17 and 18 years of age. They do not have any idea how their bodies work, protect themselves, to talk to their partners about negotiating to use contraception, or have absolutely no idea on contraceptives. The worst is when many children get pregnant early because they lack family support. No parents’ proper guidance leading to some children grow up irresponsible. These are the sentiments that cried out the great need of these supports not only from the family but from each and every one. Considerably, it’s not the pregnant teenagers who really need supports but the entire family.

The finding is somewhat unbelievable because social and spiritual wellness is vital for it promotes psychosocial wellbeing of a pregnant woman. Hodgkinson and colleagues claimed that adolescent parenthood is associated with range of adverse outcomes for young mothers, including mental health problems such as depression, substance abuse, and posttraumatic stress disorder. Teen pregnant are likely impoverished and reside in communities to isolate themselves. There were times they feel rejected by their family, so they tend to stay away from the community that is a social disadvantage. Moreover, depression is common among pregnant teenagers. Feeling of being alone is common for they’re expecting that their friends even parents left them. They even don’t know how to communicate with their parents to ventilate emotions and an opportunity to express their fears, hopes, concerns, and questions without feeling judged. Moreover, the finding is quite unbelievable. However, follow up interview and observation proved the numerical data as some says “they are shy to show up with their circle of friends, keeping mum if their family members asked them especially during the first trimester where they kept on denying”. Some also planned of abortion and even think suicide but their moderate spiritual wellbeing touched
their conscience of not continuing.

**Significant difference on family support to pregnant teenagers**

Table 2 showed the difference on perspective of pregnant teenagers and their family members utilizing the independent-samples t-test.

<table>
<thead>
<tr>
<th>Participants</th>
<th>Mean</th>
<th>SD</th>
<th>t</th>
<th>p-value</th>

<td>0.111</td>
<td>.915</td>
</tr>
<tr>
<td>Family Member</td>
<td>3.51</td>
<td>.37</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The result revealed no statistical significant difference between the perspectives of pregnant teenagers and the family members. Therefore, the extent of support being extended is the same. Further, the difference in the mean of the participants is likely due to chance which signifies that the result is a strong source or instrument in developing a health service program to cater the needs of pregnant teenagers.

**Promotion of social and spiritual wellbeing: a health service program for pregnant women**

Teenage pregnancy is a global, social and health phenomenon where culture should be one of the indicators to consider. In this study, it was noted that social and spiritual wellness were moderately extended. This made the family support on social and spiritual health service program was developed. Social wellness is the positive effect of friendship to mental and physical health of an individual while spirituality is recognized as important constituent of wellbeing. The relationship between spiritual awakening and health of childbearing women and the unborn is far more intrinsic than we have imagined. The healthy dose of spirituality is essential for the tranquillity of the unborn life.¹⁶

During pilot testing, it was observed that some adult married pregnant women who are multiparous (had 2 or more pregnancies) or primiparous (first time pregnancy) experienced social disturbances. This is maybe due to hormonal imbalance but some claimed of non-acceptance of their physical appearance. While some have the feeling of being criticized due to conceiving of more kids without proper spacing. At this point, it is necessary for them to overcome these feelings to attain a systematic and harmonious life. Thus, it was decided to include them resulting to some revisions and adjustment on designed activities like clustering them according to age and number of pregnancies.

The health service program on social and spiritual wellbeing was initially extended to pregnant mothers and their significant other at barangay Balili, Bontoc, Mountain Province. It was conducted in collaboration with the local officials and health workers of the barangay. Schedule and venue of the mothers’ class was arranged and home visits were done twice a week for 3 weeks.

During mothers’ class, the dean of nursing discussed wellness and empowering of mothers, their families and circle of friends in the promotion of wellbeing. For the participants to socialize, facilitated communication was initiated followed by simple exercises that mobilized body parts which promoted circulation, then by group reading, and discussions and demonstration of therapeutic massage. Group reading focused on safe motherhood that initiated self reflection resulting to sharing of experiences for discussion. Moreover, teaching and return demonstration on therapeutic massage comes next which was considered a social support they can render. Further, spiritual journey from the darkness of stress is essential to achieve the light of happiness, mental peace and energy. Simple prayer was introduced that can definitely prove the boon of the mother and child’s affection; and the spiritual bonding between God and the mother resulting to a state where oneness is created.¹⁶ Moreover, arts appreciation (nature), listening to religious songs, and meditation were introduced and applied. Visiting the church was encouraged during home visits. Indeed, participants verbally claimed that the health service was considered a healthy habit not only for the pregnant but for the entire family. Improvements on socialization and spiritual outlook of each family was observed as manifested by closer family ties, a very welcoming environment, openness to share
learnings and experiences, willingness to listen on health teachings and participate to other health activities.

**Conclusion**

It is vital to empower families on how to extend full support on wellness to pregnant women. Further, good leadership and therapeutic communication is also necessary in the implementation of a service program which demands participation of people.

**Recommendations:**

The health service program should be continuously implemented. Other institutions with health academic programs and health concerns can adapt and strengthen its activities.

**Conflict of Interest:** This has no impartiality in its accomplishment.

**Source of Funding:** Personal

**Ethical Clearance:** Guidelines for the protection of human rights outlined in the American Nurses Association was observed.

The Description of Musculoskeletal Symptoms, Workstation Design Compliance, and Work Posture among Computer Users at Head Office Jakarta Year 2018

Sjahrl Meizar Nasri, Dita Maharani Kusumaningrum
1Department of Occupational Health and Safety, Faculty of Public Health, University of Indonesia

Abstract

Some previous studies showed that the number of musculoskeletal symptoms among the office workers who use computers was quite high. The musculoskeletal symptoms can be caused by the workstation design and work posture. Thus, this research aims to get the description of workstation design compliance against the OSHA guidelines, work posture, and brief description about musculoskeletal symptoms among computer users. This research utilizes descriptive method and cross sectional as design study. The workstation design (chair, desk, monitor, keyboard, mouse, and telephone) compliance against the OSHA guidelines was measured by using workstation design compliance checklist, work posture assessment and level of work posture risk were conducted by using ROSA (Rapid Office Strain Assessment) method. The brief description of musculoskeletal symptoms was conducted by interviewing the 83 respondents and completing CMDQ (Cornell Musculoskeletal Discomfort Questionnaire). The finding shows that bad postures among the office workers can lead to musculoskeletal disorders symptoms.

Keywords: Workstation design, Work posture, Musculoskeletal Symptom, ROSA, CMDQ

Introduction

Musculoskeletal disorders is one of the most common health hazards that caused by visual display terminals (VDTs) used in the workplace (1). Some previous studies showed that one of the major reasons for absence in the workplace is feeling pain in various parts of musculoskeletal systems (2). Reports in some previous studies suggested that computer users are at increased risk of upper extremity musculoskeletal disorders (MSDs) (3). The work-related MSDs also include illness and injuries and affects the human’s muscles, ligaments, tendons, nerves, soft tissues, and blood vessels (4).

Work-related musculoskeletal disorders are among health issues in work places of industrially developed and developing countries which mostly caused by long sitting and excessive leaning (2). They are also mainly caused by poor working posture or repetitive movements (1). Some epidemiologic studies presented that in term of work-related MSDs, the pain location and other signs probably related to standing posture and work habit (2).

In addition, a literature on the association between keyboard usage and prevalence of MSDs presented that hours spent for using keyboard predicted to be a risk factor for MSDs among the computer users (3). Previous research also identified that 50% of 136 computer users have lower back pain that cause of non-adjustable backrest on their seats (5). Another finding also showed that there was a positive association between hand-arm symptoms and the duration of mouse-use (6). Mouse position may be one of the critical factors in shoulder flexion and abduction that increase the risk of MSDs (7).

PT X is a company that operates in selling, renting and servicing the heavy equipment. Based on company data in 2015, the most dominant hazard that exposed the employees was the ergonomic hazard and 59.9% of 588 workers do their job with computers with

DOI Number: 10.5958/0976-5506.2019.00755.1
prolonged sitting. These workers also complained the musculoskeletal symptoms. Therefore, this research was conducted to get the description of workstation design compliance, the work posture, and brief description about the musculoskeletal symptoms among computer users in PT X.

**Method**

**Data Collection**

This research used cross sectional design study with descriptive method. The sampling technique use simple random sampling. This research was conducted at PT X that located in Jakarta from April until Mei 2018. The number of employees in PT X was 588 people. The inclusion criteria in this study was permanent employees in PT X that interact with computer while conduct their job, and did not have musculoskeletal symptoms or musculoskeletal disorder before work in PT X. On the other hand, the exclusion criteria were the employees that have musculoskeletal symptoms or disorder and the employees that absence when this study was conducted. The number of samples required was calculated by using Lemeshow formula and the result was the minimum samples needed for this study was 83 respondents.

**Research Design**

The workstation design compliance towards the OSHA Guidelines was measured by using workstation design compliance checklist. The OSHA Guidelines were translated into Bahasa by the researcher and without back translation. There were 20 items that measured by using OSHA guidelines, including the seat height, length of seat pan, width of seat pan, seat width, backrest and lumbar support, armrest, desk height, desk length, desk width, footrest height, footrest width, desk distance from floor, monitor height, monitor distance to the eyes of users, the visual comfortability, the keyboard height, keyboard distance to users, keyboard position, mouse distance to the users, and mouse height.

In addition, the level of work posture risk among the workers that interact with computer were assessed by using ROSA (*Rapid Office Strain Assessment*). ROSA is one of method to assess ergonomic risk factor related to work posture. A prior research showed that this picture based checklist was reliable and valid (9). ROSA also developed to quickly quantify the risk factors that correlated with computer work and recommend how the posture should be improved (9). On the other hand, in order to get brief description of musculoskeletal symptoms was conducted by interviewing the respondents and completing CMDQ (*Cornell Musculoskeletal Discomfort Questionnaire*). CMDQ is a questionnaire which also contain a body map diagram and questions about the prevalence of pain, musculoskeletal ach, and discomfort that experienced by the person during a week before (10). This method is suitable and reliable to be used in measuring the levels, duration, and frequency of musculoskeletal pain and discomfort (11).

**Statistical Analysis**

Data was analyzed by using SPSS 16.0 software package

**Results**

The findings on Figure 1 show that; 89.2% chairs were not accordance with OSHA guidelines. It presented that only 10.8% chairs that accordance with OSHA Guidelines. This incompatibility was found in the armrest of the chair which is not adjustable. Based on OSHA Guideline, the appropriate standard design of chair should have adjustable armrest. Based on the measurement of the desks, 95.2% respondents use appropriate desks. The incompatibility was found on the leg space and the foot space height, since the CPU was placed under the table and caused the limited space for foot to be rest. In addition, the space from desk to keyboard tray was close with workers legs with a higher knee sitting height.

There were 72.3% monitors which used by computer users and not accordance with OSHA guidelines. The placement of monitors were too low (less than 15 degrees), and some monitors for around 60 monitors were not up to the standard. In term of keyboard and mouse, it was found 38.6% of keyboard and mouse were not accordance with OSHA Guidelines, due to the placement of keyboard and mouse which is too far and not in reachable distance from the users. Also there was 37.4% the telephone position that not complied to the OSHA guidelines.
Based on Figure 2, the work posture that assessed by ROSA showed 92.8% (77 respondents) has bad posture toward armrest. It presented that the chair which did not have an armrest, has contribute to cause bad posture among the workers. Also there were 73.5% (61 respondents) and 50.6% (42 respondents) has bad posture towards back support and seat pan height. Due to work posture in using the monitors, the finding showed 67.5% (56 respondents) has bad posture toward computer monitor while working and 39.8% (33 respondents) has bad posture toward telephone while working.

Figure 3. Work Posture towards Work Station Design that may Contribute to The ROSA High Score

Furthermore, the findings on the Figure 3 also showed that 96.3% work posture toward armrest has significant contribution in term of high level of ROSA score. Arm position were too low, elbow were hanging and not supported properly by armrest, also the chair has non-adjustable armrest. Other result showed that 88.9% body leaning forward/part of vack and lumbar did not supproted by backrest. It also significantly contributed to the high level of ROSA score. There was 63% of work posture toward monitor while working has significant contribution regarding high level of ROSA score. The angle of computer monitor were too low (less than 30 degrees), and it caused the users need to tilt down their head while working.

The result of musculoskeletal symptoms survey using CMDQ completing by 83 respondents, showed 95.2% (79 respondents) had musculoskeletal system complaint. The result of complaints on the musculoskeletal system is divided into 4 based on the presence of complaints on the individual, the frequency of complaints on the musculoskeletal system in body parts, the severity of complaints on the body parts, the effect of complaints on the ability or productivity of work on one of the body parts. The result that there are 6 parts of the body which have the most complaints which can be seen on Figure 4.
**Discussion**

The findings showed that the bad posture which may cause the musculoskeletal symptoms on the six body parts (neck, lower back, upper back, right shoulder, left shoulder, and buttock) among the computer users. This result is similar with a prior study that presented the musculoskeletal symptoms most commonly occurred in the upper back, lower back, right shoulder, left shoulder, and also in the neck (2). The musculoskeletal pain were caused by the arm is not supported properly on the armrest (armrest too low and not adjustable), back and lower back are not supported properly therefore the computer users tend to leaning forward, neck tilt down during working with monitor due to monitor screen position that is too low, the prolonged sitting and static posture during interaction with computer activity that may lead compression fatigue especially in buttock. These findings are in accordance with the previous study which showed that the MSDs can be affected by prolonged sitting and static postures (2). The result also in accordance with the previous study which presented that non-adjustable backrest can increase the MSDs symptoms (5).

On the other hand, based on the ROSA score result, there were some factors that significantly contributed to the increasing risk of ergonomic factors, such as non-adjustable armrest which caused the elbow was not supported on armrests properly, the continuous leaning position, non-adjustable monitor which make the monitor was not as the same level as the eye, the bad posture of wrist when using the keyboard where the wrists flexed > 15° and cause the position of the keyboard being too high. The results are in line with the findings of prior study that showed MSDs can affect arms, elbows, and wrists (1). The other factors are the mouse position which was too far and caused the shoulders were not relax. This finding is in accordance with the previous research which presented that the shoulders flexion and abduction can be affected by mouse position and increasing the risk of MSDs (1). Furthermore, another factor are the bad posture towards the seat pan height and seat pan depth. The seat was too high and caused the knee angle > 90°. Based on OSHA guidelines, knee angle of sitting position should be 90°. Most of the computer users in PT X tend not to adjust the seat pan height properly, however the design of chair height is meet OSHA guideline (can be adjusted 41-52 cm height). Work posture against seat pan depth also has contribution of high ROSA score, where the distance between the tip of the cushion with the knee more than 3 cm although the depth of the cushion seats used by the respondent meet the OSHA guidelines (42 cm).

Based on the findings of this research, it was found that though the workstation design already complied with the standard but the workers still doing the bad postures then the risk of MSDs is still likely to increase. Hence, the awareness training of bad postures should be conducted. Besides, the company is suggested to design the workstation by considering the OSHA guidelines. Work-related musculoskeletal disorders can only be accurately prevented if the exposures are identified correctly (3). In addition, the intervention is also needed since a previous research showed that the prevalence rates of musculoskeletal problem was lower after the intervention conducted (4).

**Conclusion**

This study provides description that most of the workstation design in PT X was not complied to OSHA guidelines. Bad posture also contributes to the increasing risk of MSDs symptoms. Appropriate work design and awareness training should be implemented to reduce musculoskeletal symptoms among the computer users.

Samban as a Complementary Immunization in Dayak Pitap Tribe in Indonesia (A Preliminary Study)

Ida Hastutiningsih¹, Oedojo Soedirham²

¹Doctoral Student of Public Health Program, Faculty of Public Health, Airlangga University, Surabaya, Indonesia, ²Lecturer, Department of Health Promotion and Behavior Science, Faculty of Public Health, Airlangga University, Surabaya, Indonesia

Abstract

The low uptake of fully immunized children in Dayak Pitap tribe has a probability to be caused by the community belief about the sources of illnesses which are natural causes, spirit of ancestor causes, shamanism causes, breaking taboos causes and other supra natural causes rather than biomedical ones. This belief therefore has an implication on the initiatives that they use to prevent illness including the use of a samban for their children.

However, the savor of samban that is believed by the community members not just a superstition. It has a role in develop well functioning immune system and make a child in the Dayak Pitap tribe physically healthy because immune system need support from psychosocialcultural construct to perform well functioning immune system and a samban play a role in this construct. Furthermore a samban also play a role in building the mental and social construct to developed what WHO determine as health is well being.

This qualitative preliminary study was conducted in Dayak Pitap indigenous tribe in Balangan District, South Kalimantan Province, Indonesia. Dayak Pitap tribe is one of tribe in Dayak Meratus or Dayak Bukit tribe family in South Kalimantan who settle down throughout the Meratus highlands in South and East Kalimantan Province.

The aim of this paper is to describe and discuss the concept of the samban that can be considered as complementary immunization in Dayak Pitap tribe, South Kalimantan Province in Indonesia.

Keywords: samban, amulet, complementary immunization, Dayak tribe, indigenous tribe

Introduction

Immunization has been well known as the most successful and cost effective health intervention achievement in the modern world and has saved countless of children’s lives and has increased health status in the world (¹). Contrary to this achievement, in the recent year there are increasing numbers of not fully immunized children both in the developing and also in the developed countries (²). This similar situation also happened in Dayak Pitap Tribe Indonesia.

Based on the depth interviews that have been conducted along in this study, the reason for this low uptake of basic immunization in this tribe probably because of the community belief about the causes of illnesses which are natural causes (heat, cold, rain), spirit of ancestor causes, shamanism causes, breaking taboos causes and other supra natural causes. This belief therefore has an implication on the initiatives that they use to prevent illness including the use of a samban for their children.

Stated by the balians, the traditional healer, and also by community members this samban proven to be work...
properly in protecting their children from an illness. Somehow, it has a same purpose with the immunization in western concept which is to keep the children healthy.

The aim of this paper is to describe and discuss the concept of the samban that can be considered as complementary immunization in Dayak Pitap tribe, in Balangan district South Kalimantan Province in Indonesia.

Material and Method

This qualitative preliminary study conducted on February to July 2017. Data was collected based on in-depth interviews with 2 (two) baliains, head of Dayak Pitap tribe, head of village, village health volunteer and mother of 13 – 36 months old children. All the material was recorded in field logs, and some was tape recorded. Unstructured interviews and observation were carried out.

Results

Dayak Pitap tribe with total population around 1,653 inhabitants is one of the tribes in the large Dayak Meratus or Dayak Bukit tribe family who settle down throughout the Meratus highlands in South and East Kalimantan Province in Indonesia. This tribe settles in 5 villages in Tebing Tinggi sub district’s of Balangan in South Kalimantan province which are Langkap, Ajung, Kambiyain, Iyam and Mayanau.

Although this tribe registered as Hinduism which is called Hindu Kaharingan, very little aspect of Hinduism exists in their everyday lives. They still maintain their belief and culture as animism and dynamism tribe.

Most of Dayak Pitap people plant rice, supplemented by the sale of the product of planted rubber tapping, vegetables and other field or forest products, hunting and some educated community members also become employees in coal mining companies or government officers. However, even if they already have other occupations they still have to do the shifting rice cultivation because of the obligation for participating in the yearly harvest feast called Aruh Ganal especially for the parents of the samban children.

Even though they have already less isolated and have access to health professional, the tribe still maintain some traditional ways of life especially in health care seeking behavior including health prevention for their children.

WHO Concept of Health

Though culture vary in their definition of health and illness but the common notion that health is more than only the physical state of the body or the absence of illnesses has long been heard all over the world. Health is a whole, health is a completeness, health is life itself (3) which actually have been covered by WHO in its definition of health which is “a state of complete physical, mental, and social well-being and not merely the absence of disease and infirmity” (4). In this holistic definition WHO provided popular dimensions of health namely physical, mental and social (5)(6). A person consider healthy not only if he or she is not getting a disease, infirmity, limitation in the ability to perform self care activities, difficulty in mobility and carry out other physical activities but also to be able feel good during life time, enjoyment and inbound in social relationship and play a healthy social role in the community.

Using some kind of amulet both for protection and curing not only known in Dayak Pitap tribe but also widely known in many traditional cultures such as in Narsinghdi district in Bangladesh (7), in Bedouin tribes of the Negev Southern Israel, Middle East (8), in Gaddis of Bharmour Himachal Pradesh, India (9) and most of tribal communities worldwide especially for the children (10).

Immunization Western Concept and Immune System

Western concept of immunization well known to be started when Edward Jenner developed the world’s first vaccine from cowpox to protect human against smallpox (11) This concept then followed by the born of the concept of immune system in the late of nineteen and early twenties coincided with the germ theory of disease development which is credited to Pasteur and Koch (12).

Immunization by WHO is defined as “the process whereby a person is made immune or resistant to an infectious disease, typically by the administration of a vaccine”. Vaccine help developed immunity by imitating an infection although this kind of infection does not cause a serious illness such as happened in natural infection but it does cause the immune system to produce T-lymphocytes and antibodies (13) and provide a supply memory for the body in how to fight this infection in case the real infection attack the body in the future. However, some vaccines need more than one dose to be
effective and others may wear off and need booster to bring the immunity levels back up.

The immune system itself initially defined as an internal physiological system that protects or defends our bodies against a potentially hostile pathogenic germ but based on more recent studies this concept develops and popularizes as the system that not only protects against infection and disease but also as the system that actually keeps people healthy (12), which is actually in line with Dubos’s criticism about the germ theory in 1955 “everyone harbors diseases germs, yet not everyone is sick”, suggesting that germs are less important in disease than other fact affecting the condition of the host (14). Well functioning immune system not only merely about immune system but also relates with psychosociocultural constructs of immune system.

The Samban Concept as Complementary Immunization

A samban worn as a necklace and believed can protect children from illnesses and keep them healthy which is quite similar with the function of immunization in western concept.

There are several types of samban i.e. samban anggit made from copper, samban anak made from some kind of clamshell, batu lunta made from some kind of stone, samban picis made from old coin single or double, gigi pitayab made from a small turtle’s tooth, kalandang lawa kuning made from some kind of mystical yellowish rope/string that believed to be disappear after being worn around the child’s neck, and the highest and oldest one is samban layang which is a rope made from bark of tarap tree Artocarpus odoratissimus.

Only the signed children can wear this samban namely a sign from the birth of the child which is the umbilical cord wrapped around a child’s neck, easily cries and also easily getting ill could be mild illness such as mild fever, stomatitis, zero growth and other illnesses that is considered as a sign that needs to be determined further by a balian. A child that has a line of descent using a samban, both from his or her father or mother line also obligated to wear it.

Stated by a balian who is also the head or the tribe that usually in age 1 to 2 months if a child has the signs as mentioned above then the parents will ask a balian to conduct a ritual called batanung. As the result from this ritual, it will be known whether the illness of the child because asked to use a samban or not and what kind of samban that asked to be worn by their Almigthy God, Nining Baharata. At the end of this ritual the parents will make a pray to the God asking for the cure of their child and pledge that they will conduct ritual basamban if their child is cured from the illness. Stated by the balian and head of Kambiyain village that most children really getting well after this batanung ritual and after 2 - 12 weeks, depending on the family’s affordability, then the basamban ritual will have to be conducted.

The preparation for this basamban ritual will be run by the whole village. In the ritual the balian will spell mantras and dance accompanied by rhythms made on drums from 7 pm to 9 am in the morning. In this ritual, the spirit that is believed has annoyed the child will be transferred to a set of wooden doll that will be dissolved in a river or other places, then the ceremony will continue with the fixing of the samban to the child’s neck.

After this ritual is finished, the parents and the child will have to go through a period of abstinence which makes them not allowed to go out of their houses, not allowed to have visitors and also not allowed to defecate for 24 hours. This 24 hours period believed to be a period to sharpen the savor of the samban as the child’s protector from illness in the next future and also because the spirit that has been called in the basamban ritual is believed still roam nearby. Every year in Aruh Ganal, every child who wore samban along with their parents will be spelled with mantra again and the samban will be oiled by the bilians in order to re-strengthen the savor of the samban.

Discussion

Immunization’s function in western concept is to develop immunity commonly by utilizing vaccines. Vaccines help develop immunity by imitating an infection (13). Naturally, when first time human body attack by a germ, it can take several days to make and use the germ’s fighting tools needed to pass though the infection. After this infection, the immune system remembers how to protect the body against that disease. In the future if the body attack by same germ a few T-lymphocytes that the body keeps from the first infection, called memory cells will go into action quickly and then when the familiar antigens are detected, B-lymphocytes produce antibodies to attack them. Infection causes by immunization
usually mild such as fever but infection cause by natural infection can be severe and lead to hospitalization or even death.

However recently research also found that in order to perform physical health it is not merely about immune system but more on how this immune system has adequate function or well functioning immune system that also determine by psychosocialcultural aspects. Immune system is more than only a defense system. Physical health can be viewed as effectiveness and well functioning immune system. Psychologically feeling good and full of vitality are associated with well functioning immune system whereas feeling lethargy or fatigue are considered to be indicative of inadequate immune system activity and culture has a role in shaping individual psychological capability such as methods of handling psychological aspect like emotion and manner of expression.

The samban, based on western medical science not yet scientifically proved to be contributed in developing the immune system but definitely contributed in developing well functioning immune system. Wearing a samban fulfills the social construct needed to perform well functioning immune system and also comply their psychological need because the tribe view samban as the initiatives that have already proved to be inherently worked in protecting their children compared with the western concept of immunization. A samban also comply their spiritual need because the tribe also view a samban as a form of their faith to their God. Wearing a samban also provides secure feeling because after this ritual basamban the health of the child will become the responsibility of the balian until it is un-worn.

Furthermore, refers to WHO definition that health is well being, beside physical health construct to be consider as healthy person one has to fulfill the mental and also social construct. What is offered by the western concept of immunization could potentially have a role to encompass the physical dimension of health but doubtful in covering the other dimensions which is precisely could be encompass by the samban which make the samban could be consider as complementary immunization.

Conclusions

It is important to take a note that to develop what WHO stated as “health as well being” in the Dayak Pitap tribe, this immunization in western concept must be accordance with a samban as a complementary immunization. The samban has a role in develop well functioning immune system and make a person can perform physical health with its role as part of psychosocialcultural construct of well functioning immune system. Furthermore, the samban not only has role in building the physical construct but also mental and social construct to developed health as well being. Trying to eliminate the samban in order to promote fully immunize children may be ended with imbalance milieu and worse health condition.

Health professionals also can view the samban as an entry point and opportunity to discuss western concept of immunization with the community members and also the baliens because the fact that they are also thinking about the same issue which is the prevention of an illness. With this kind or approach, the opportunity to reach high uptake of fully immunized children could be more possible to be gained.

Conflict of Interest: There is no conflict of interest for both authors.

Source of Funding: This research funded by the authors themselves. No other financial support received.

Ethical Clearance: All procedures performed in studies involving human participants were in accordance with the ethical standards of the Health Research Ethics Committee Faculty of Public Health Airlangga University.

Informed Consent: Informed consent was obtained from all individual participants included in the study.

Abstract

Health insurance is a guarantee of health protection for everyone, 90% of Indonesians are already JKN participants. The coverage of JKN participation, especially in South Kalimantan is still low, namely 1,323,001 people (34.8%), one of the districts whose membership level is still low, namely Hulu Sungai Utara Regency with 49.65% from 225,822 is not yet a JKN participant especially in the work area of Sungai Malang Primer Health Care where only 12,387 people (25.67%) are JKN participants. Therefore it is necessary to investigate what factors affect the participation of JKN. Explain factors that influence the participation of National Health Insurance independently in the working area of Sungai Malang Primer Health Care. This research type is observational analytic research with design of case control design conducted by work area of Sungai Malang Primer Health Care. The populations were JKN participants and not JKN participants, while sampling using purposive sampling. The research variables are age, education level, knowledge, income, motivation, perception and socialization as independent variable and JKN membership independently as dependent variable. The research instrument used is the stuffing sheet. The result of multiple logistic regression analysis obtained the most influential variable is age (OR=9,8). There is a significant influence, level of education (P-value=0,000), knowledge (0,000), motivation (0,000), perception (0,000) and socialization (0,000).

Keywords: national health insurance, social insurance provider body, participation

Introduction

Health insurance is a guarantee in the form of health protection for the community to benefit health care and protection in fulfilling basic health needs given to every person who has paid the dues or fees paid by the government¹. There is a Social Security System in the amendment of the 1945 Constitution, and the publication of Law No. 40 of 2004 on the National Social Security System (SJSN) that every person has the right to social security to be able to meet the basic needs of a decent life and improve his dignity towards the realization of a prosperous, just and prosperous Indonesian society becomes a strong proof that government and related stakeholders have a great commitment to realize social welfare for all its people².

In support of the implementation, Law no. 24 Year 2011 establishes the National Health Insurance (JKN) organized by BPJS, which consists of BPJS Health and BPJS Employment. JKN held by BPJS Kesehatan whose implementation begin on January 1, 2014³. Social Security Administering Body (BPJS) as the implementing agency has done various activities to accelerate JKN roadmap travel process so universal health coverage (UHC) quickly achieved. Socialization in various mass media about the benefits, payment method, the amount of dues chosen according to ability, has been implemented, but the expected result that there will be increasing independent participant not seen real⁴.

DOI Number: 10.5958/0976-5506.2019.00757.5
Data Ministry of Health RI (2013), shows the number of people who are guaranteed in various forms and health insurance as much as 151.6 million out of a total of 293.7 million people in Indonesia. Thus there are still 142.1 million people in Indonesia who do not have health insurance. Based on data of Social Security Administration Agency (BPJS) Health (2015), South Kalimantan Province of the total population of 3,989,793 people in the JKN membership coverage of 1,323,001 people (34.8%), consisting of 763,063 people (57.67%) of the contribution beneficiaries (PBI) and non PBI 559,938 inhabitants (42.32%)\(^5\).

Based on data on the coverage of the working area of each Primer Health Care in Hulu Sungai Utara District, the Sungai Malang Health Center has the working area with the largest number of residents from other working areas and has the lowest percentage of JKN participation in Hulu Sungai Utara Regency. The number of JKN participants at the Sungai Malang Primer Health Care was 12,387 people as of June 2016 with the coverage of the working area 47,961 residents in Amuntai Tengah subdistrict, meaning only 25.67% of the population in the working area of Malang River Community Health Center which is the participant of JKN which means 75.43% of the people in the region have the potential to become the most independent JKN participants.

### Material and Method

The research is a kind of quantitative observational analytic research with case control approach. Type research is done by comparing case groups and control groups. The number of samples in this study is determined by purposive sampling method. The number of samples in study as much as respectively 130 respondents, which means the total sample in study was 260 respondents.

</table>
Based on table 1 can be seen that of 260 respondents consisted of 18-40 (adult) age range 181 respondents (69.6%) and respondents with age range 41-65 (old) as much as 79 respondents (30.4%). Respondents can be seen in this study more than the range adult, this is because respondents with age range 18-40 is still productive and have a job. High school education level has the highest percentage (37.6%) this matter because respondents in this research is participant by JKN independently which majority is entrepreneur. Of the 260 respondents, 157 respondents (59.7%) had less knowledge about JKN. Based on the results of the questionnaires of respondents who have less knowledge due to the respondents do not know the benefits obtained when a participant JKN as many as 155 people (97.4%), who do not know who is required to become a participant JKN as many as 155 people (97.4%), (94.7%) who do not know the purpose of BPJS Health (94.7%), who do not know the participants JKN consists of as many as 153 people (94.7%), who do not know the purpose of JKN as much as 153 people (94.7%), who do not yet know the number of JKN participants as many as 151 people (92.1%), who do not yet know how to register become JKN participants for PBPU counted 145 people (86.8%), not yet know the procedure of registration of JKN as many as 122 people (73, 7%), who do not yet know the requirements to become a participant of JKN for Indonesian citizens are 95 people (68,4%).

Income low (≤ Rp 2,085,000) more reported on the type of work in the informal sector with uncertain income each month. Concerned perceptions, 80 respondents (30.7%) assume that the facilities provided if the illness is incomplete, as many as 120 respondents (46%) assume that BPJS is only for the poor. Respondents have low motivation caused by those who say that does not agree that the way of registration as JKN participants is easy.

</table>

Based on table 4 can be seen that the most influential variable is age, meaning that the more mature one's age then 9.8 times have the opportunity to become participants of health insurance independently.

**Discussion**

Based on table 2, to see the effect of age on JKN membership independently that, p-value= 0,059, means there is no significant influence between age with JKN membership independently.

The results of this study is supported by the results of previous research by Widhiastuti (2015) which states there is no significant influence between age with public awareness in insurance. Research with similar results was also revealed by Anggi Afifi (2014). In this study sampling was conducted only in primary health care, so there was no significant difference in health risks between respondents aged <40 years and ≥40 years, where they were more likely to experience low health risks.

Education of the 130 respondents who are not independent JKN participants, there are 113 respondents (86.9%) have high education level, while JKN membership comes from education level ≤ junior high school and college level only 24.6% and 26.9% which means lower levels of education are more likely to choose to be JKN participants. From these findings it can be seen that the level of education has no effect on knowledge. In addition, respondents with low level of education have concerns in terms of income due to their low employment rate (traders) as much as 218 respondents (82.9%). The effect of education with JKN participation independently, p-value=0,000, which means there is a significant influence between education with JKN membership independently. The value of OR=0.16 indicates that a person with a low educational...
level is 0.16 times more likely to be an independent JKN participant than someone with a higher level of education. The results of this study in line with the results of research conducted by Siswoyo BE (2015) there is a relationship between the type of work with the awareness of being a participant JKN. Respondents with unpredictable jobs and income are more interested in becoming JKN participants to ensure their health.

The effect of JKN self-knowledge and membership, that p-value = 0.000. The OR score indicates 6.3 which means that respondents who have high knowledge about JKN independently will have 6.3 times more chance to become independent JKN participants compared with those who have less knowledge about JKN. The results of this study in line with the results of research Tanjung (2015) there is a meaningful influence between knowledge with attitude JKN independent participation. Respondents’ knowledge of JKN includes understanding, understanding of participants regarding BPJS, JKN, JKN membership and benefits gained.

As many as 71.5% of JKN participants came from respondents who have income <Rp.2.085.000, whereas respondents who have total income> Rp.2.085.000 per month only 28.5%. Based on the findings in the field of respondents with income of ≤Rp 2,085,000, more are based on the types of jobs in the informal sector with uncertain income each month. Uncertainty about income is what affects a person to ensure his health by deciding to become a participant of JKN, another factor high income level of income is found to be meaningless. The researcher’s assumptions are caused by the National Health Insurance program is a social health insurance, in which membership is mandatory for all Indonesians in meeting basic health needs. The implementation of this program has been adapted to the economic capacity of the people. This research is in line with the Whidiastuti (2015) study which stated that the respondents’ income in this study did not affect the JKN participation independently.

Perception is very closely influenced by perceived benefits. Based on the theory of Kurt Lewin (1951) that changes in one’s behavior is influenced by the driving factors and inhibiting factors. When a person’s perception of a program’s benefits is high, it will be said to be a driver toward the desired goal. This drive will be strengthened if the perception of resistance as an inhibiting factor is found low, then the behavioral change toward the desired goal will be faster. The results of this study in accordance with the Health Belief Model where the change in behavior in respondents is influenced by the belief of the benefits or obstacles perceived. High perceptions of benefits and the discovery of low barriers of perception will lead to changes in respondent behavior.

There is a significant influence Motivation on JKN independently membership. The OR score indicates 8.22 which means that a person with high motivation has an opportunity to become a JKN participant compared to someone with low motivation. This research is in line with the results of Hardini’s (2016) research, motivation related to the participation of the national health insurance program because of the ease of registering, socialization, information received, the availability of health facilities, the health costs covered, and the protection of old age.

P-value = 0.000. There is an influence of JKN socialization on independent participation. Based on the table can be seen from 130 respondents who are not independent JKN participants, there are 100 respondents who have never received socialization related to JKN. Based on the findings in the field, respondents who are not independent JKN participants claimed to have never received socialization directly by the BPJS Amuntai Branch. In addition to direct socialization, respondents also have not received socialization through other media (print or electronic). Based on table 5.1.4 shows 59% of respondents have knowledge about JKN is still low which means still lack of socialization about JKN. Another thing is because most of the respondents who are not independent JKN participants are informal workers / SMEs. This is in line with research conducted by Fajar (2012) on MSME workers who get information that the respondents only know the program JKN as much as 21%, while those who do not know 62%. This indicates that massive socialization of the program is still needed, especially for the lower middle class, working in the informal sector and MSMEs.

**Conclusion**

1. There is no influence of age, income of respondents to the participation of National Health Insurance independently in Sungai Malang Primer Health Care
2. There is influence of educational level, knowledge, perception, motivation and
socialization of National Health Insurance participation independently in Sungai Malang Primer Health Care.

3. The most influential factor of logistic regression analysis is age to the participation of National Health Insurance independently in Sungai Malang Primer Health Care

**Ethical Clearance:** this study approved and received ethical clearance from the Committee of Public Health Research Ethics of Medical Faculty, Lambung Mangkurat University, Indonesia. In this study we followed the guidelines from the Committee of Public Health Committee of Public Health Research Ethics of Medical Faculty, Lambung Mangkurat University, Indonesia for ethical clearance and informed consent. The informed consent included the research title, purpose, participant’s right, confidentiality and signature.

Prevalence and Perception of Women about Consanguineous Marriage in Al-Ramadi City

Badeaa Thamer Yahyaa¹, Mustafa Ali Mustafa Al-samarrai¹, Saad Ahmed Ali Jadoo²

¹Department of Family and Community Medicine, Faculty of Medicine, Anbar University, Anbar, Iraq, ²Department of Public Health, Faculty of Medicine, Bezmialem Vakif University, Istanbul, Turkey

Abstract

Background: Consanguineous marriage is a common phenomenon in many communities and often related to several of undesirable health consequences. This study aims to study the prevalence and determinants of consanguinity and the perception and knowledge of women about the risk associated with it.

Methodology: A cross-sectional study was carried out at the outpatient (OP) clinic in the Teaching Hospital of Maternity and Childhood, Al-Ramadi city, Anbar province, Iraq. A convenient sample of one hundred fifty married women who were interviewed over the period from 1st February to 30th March 2018.

Results: The mean age (±SD) was 39.0 (±12.8) years. About two third (64.6) of marriages were consanguineous and 36.6% of which were between first cousins and 14.7% had a child with genetic disease or disability. Consanguinity has a negative and significant association with women’s education. Positive attitude towards inbreeding was 64.7%, however only 34.3% knew that it leads to genetic diseases. About 77.0% preferred to receive information about the risks of inbreeding and 94.7% to have medical examination before getting married.

Conclusion: Although consanguinity is commonly practiced and accepted in Iraq, the awareness of mothers towards the related health consequences to their offspring remains low.

Keywords: Consanguineous Marriage, Prevalence, knowledge, Perception, Iraq

Background

Consanguineous marriage (inbreeding) is a customary practice among wide variety of societies all over the World. Consanguinity is defined as marriage between blood relatives¹. Inbreeding is most likely related to significant increase in the prevalence of childhood disability rate and the reproductive mortality rate². Several of inherited and gene-related disorders and adult-related diseases have been reported among births of consanguineous marriages³. The impact of consanguinity is directly proportional to the degree of kinship, and the possibility of transferring the defective gene becomes more liable between close relatives⁴. However, such marriages considered a social behavior represented in the desire of nearly one billion of current world populations to marry relatives⁵. Reasons behind such behavior have been widely discussed. Religion and the economic situation were the main reasons pushing family toward the consanguinity⁶. Factors that determine the consanguinity may vary and change according to the change of society, but generally are revolving around “the socio-economic levels, education and rural versus urban setup”⁷. In the Arab countries including Iraq, the society tends towards tribal grouping even within the large cities, and therefore the rate of consanguineous marriage is relatively high compare to other regions of the world⁸.

Indeed, during the last two decades, many valuable studies have been conducted in the Arab region, but
some countries, including Iraq, still lacking information or even recent data to assess the development of society towards this subject. This study aims to estimate the prevalence and the determinants of consanguineous marriage in Al-Ramadi city in Iraq, and the perception and knowledge of women about the risk associated with it.

Method

Study Design

A cross-sectional study was conducted at the outpatient (OP) clinic of the Teaching Hospital of Maternity and Childhood in the Ramadi city, Anbar province, Iraq. A convenient sampling technique was recruited to collect sample of one hundred and fifty women over the period from 1st of February to 31st March 2018. All the Iraqi citizens, married women who were visiting the OP clinic (prenatal, gynecologic, neonatal and pediatrics clinics) and willing to participate were included. However unmarried women and medical staff were excluded as well.

Data Collection

A well trained data-collection team was recruited to interview the eligible participants using a specially designed questionnaire. The questionnaire was in Arabic language and was pilot tested with 15 women out of the used sample. The questionnaire included three parts; part one was socio-demographic and reproductive data; part two included the degree of consanguinity; part three included knowledge and attitude of women towards consanguineous marriage.

Statistical analysis

Statistical analysis was performed with SPSS 16.0 (Statistical Package for Scientific Studies) for windows. Data was presented in the form of percentages, mean, standard deviation (SD) values. Chi-square (χ²) analysis was used for rate comparison. Statistical significance at level p≤0.05 was used when required.

Results

Descriptive analyses

The mean age (±SD) was 39 (±12.8) years and the age at marriage was 21.5(± 4.1) years. Half of the women (75, 50.0%) were married at the age group of 15-19 years. About two third (64.0%) of women had low education (illiterate and primary), while the highest proportion of husbands (30.7%) were at a higher education level (university). The vast majority (87.3%) of women were housewives, compare to 44.7% of husbands were self-employed. About 67 (44.7%) women were having 5 children or more, however 42.0% experienced abortion at least once. History of child deaths were reported among 34% of the participants. About two third (97, 64.6%) of marriages were consanguineous; 58 (38.6%) of which were between first cousins. The degree of consanguinity for wife parents and for husband parents were 57.3% and 62.0% respectively. There was no significant association between all measured variables and the state of consanguinity, except for the level of education of the surveyed women which was significantly higher (p=0.000) among the non-consanguineous marriage group compare to the consanguineous marriages (Table 1).

Twenty two (14.7%) had at least one child with disability or genetic disease. The highest percent (16, 72.7%) of children with disability or genetic disease was among consanguineous marriages compare to 6 (27.3%) among the non-consanguineous marriages. Diseases associated with consanginuity as reported by women included epilepsy, congenital heart disease, diabetes mellitus, asthma, speech impairment, Down syndrome, hydrocephalus, thalassemia, psychological disturbance. About two third (97, 64.7%) had a positive attitude towards consanguineous marriage, however 37.3% of them knew that consanguineous marriage leads to genetic diseases, and 62.7% thought it does not lead to diseases. Twenty three congenital diseases and disabilities have been mentioned by 56 women. Thalassemia and congenital malformation were reported by 14 (25.0%) and 12 (21.4%) of respondents respectively. In table 2, the highest percent (116, 77.0%) of surveyed women preferred to recive information about the risk of consanguineous marriage before they got married. Family and relatives (66, 44.0%) were the main preferred source of information. Table 3 showed that the vast majority of the respondents (94.7%) realized the importance of having a medical examination before getting married, however only 72.0% of them had performed it.

**Discussion**

In this study, the overall frequency of inbreeding in Al-Ramadi city (Anbar province, Iraq) found to be 64.7% and the first cousin marriage was 38.6%. This rate is high when compare to findings of earlier studies in range of 47-60% \(^9,10\). This rate also was higher than the neighboring countries of Iraq such as Saudi Arabia (29.7%)\(^11\), Jordan (35.0%)\(^12\), Syria (35.4%)\(^13\), Iran (32.5%)\(^14\), Kuwait (54.3%)\(^15\), and Turkey (18.5%)\(^16\).
In Iraq, the tribal community, and traditional beliefs to keep strong family ties produced the positive attitude of parents towards consanguinity as showed by the high rates of inbreeding among them. Indeed, the past decade witnessed evidence of contradiction among the human groups living in semi-homogeneous societies, for example, the rate of consanguinity in Jordan and Saudi Arabia recorded a marked decline, however UAE and Qatar reported a significant increase in the rate of consanguinity. Results of present study found younger age at marriage was associated with consanguinity. Several studies from Pakistan, Oman, and Egypt confirmed the association of consanguinity with younger age at marriage. About 30% of highly educated husbands who preferred consanguineous marriages were self-employed, probably due to less chance for employment in our country even after graduation. Part of our findings showed that 64.7% of respondents support inbreeding, which is higher than that reported by Iran (38.8%). However, women who know that inbreeding lead to genetic disease were only 34.3% which indicated low awareness and less health education. Sandridge et al. (2010) reported that knowledge was imperfect with high proportions of participants not knowing that consanguinity has been implicated in autosomal recessive diseases and other genetic diseases. Majority of interviewed women (77.3%) recognized the danger of inbreeding and preferred receiving information about the risk of consanguinity before getting married. This finding was better than results provided earlier by Teeuw et al. (2012). Family and relatives were the most preferred sources for receiving such information in about 44.0% of women. Similarly was reported in Pakistan, but was lower than that reported in Oman. Medical examination before marriage was important in about 94.7% of respondents, however only 72% of them had perform it. Similar results were reported among sample of undergraduate students in Oman, the vast majority (92.0%) believed that premarital screening test is important and half of them favored to perform it as an obligatory procedure before marriage. Hamamy (2012) pointed out that wife’s parents preferred consanguineous marriage to keep them living close and to enjoy seeing their grandchildren. In our study about 60% of women accepted their offspring marrying within the family. This results were supported by study of Qidwai et al. (2003) in Pakistan. The main reasons in favor of consanguineous marriages were quoted as having more information about the mate before marriage (43%).

Conclusion

A very high rate (64.6%) of consanguineous marriage was reported among sample of married women in Al-Ramadi city, Anbar Province, Iraq. Two third of these marriages were first cousin marriage. Consanguinity has inverse association with women education. Genetic diseases and disability were reported more among consanguineous married group than non-consanguineous marriages. Although consanguinity is widely practiced and accepted, the awareness of women towards the health consequences to their offspring remain low. Most of the respondents preferred to receive information regarding the risks of consanguineous marriage before they are getting married. About 60% of women do not mind if their sons or daughters want to marry relatives in the future.

Abstract

Tuberculosis (TB) is a contagious disease directly caused by tuberculosis (mycobacterium tuberculosis). The three countries with the highest incidence of 9.8 million cases of world TB are India (23%), Indonesia (10%) and China (10%) (WHO, 2014). The Government of Indonesia through the National Control Program of TB has made various efforts to tackle TB, with the strategy of Directly Observed Treatment Shortcourse (DOTS). In order to support DOTS strategy, to reduce the number of cases and understanding of PMO in doing supervision of taking medication in child tuberculosis patient, counseling done by pharmacist at PMO of child tuberculosis patient. Giving counseling and information to patients is very useful to improve patient knowledge. Knowledge is a predisposing factor that affects attitudes and behavior according to Green Theory. Subsequent behavior becomes one of the factors that play a role in influencing health status or healing based on H.L Theory. Blum. Nutritional status is a measure of a person’s body condition which can be seen from the Anthropometric Index and is the ratio of one measurement to one or more measurements or related to age and nutrient levels. This study aims to see the influence of counseling on the level of knowledge, attitudes and behavior of PMO Patient TB Children, as well as the nutritional status of TB children. This study uses 34 respondents who are PMO TB Patients Children, which is divided into 2 groups of 17 people given counseling and 17 people not given counseling. The result of the research shows the value of sig. <0.05 based on the Wilcoxon test test for the analysis of differences in effect on the level of knowledge, attitude and behavior before and after counseling. The conclusion of this study is that there are significant differences in influence on the level of knowledge, attitude and behavior before and after counseling. And there are significant differences in the nutritional status of children with TB before and after counseling.

Keywords: Tuberculosis, counseling, level of knowledge, attitude, behavior, nutritional status, PMO

Introduction

Tuberculosis (TB) is a contagious disease caused by tuberculosis (mycobacterium tuberculosis), transmitted through the air (droplet nuclei) when a patient with tuberculosis coughs and splashes of bacteria inhaled by others during breathing1. Given the importance of TB, in 1993 the World Health Organization (WHO) has launched a Global Emergency against TB disease. Data presented by WHO in Global Tuberculosis Report 2015 states that Indonesia occupies the second highest position in TB cases after India. The three countries with the highest incidence of 9.8 million cases of world TB are India at 23%, Indonesia at 10% and China at 10% of the total number of TB cases in the world2.

Data from the South Kalimantan Provincial Health Office in 2015 showed that the number of TB children infected in Banjar district was the highest compared to 12 other districts in South Kalimantan Province which was 1,175 cases of TB, of which 421 were new cases of BTA+ and 120 cases of child TB, an increase when compared to the number of cases in 2014 that only 888 cases of TB and 91 cases of child TB. The occurrence of an increase in the number of TB cases of children found in Banjar District are 91 cases in 2014 to 120 in 2015 is serious, as it is not in accordance with the target of decreasing incidence rate according to the National
TB Guideline of 2014 which should have a speed of shipment of 3-4%.

Counseling is part of the pharmaceutical service aspect. An important role of patient counseling is to improve the quality of life of patients and provide quality care for patients. Providing counseling and information to patients is helpful to improve adherence and prevent the failure of patient drug therapy.

The results of Rina et al (2012) showed that there was a significant difference in the knowledge about the adherence of patients receiving pulmonary tuberculosis before and after getting counseling, there were also significant differences in attitudinal attitude toward TB treatment before and after counseling. It can be concluded that the effect of counseling on knowledge, attitudes and compliance treatment of pulmonary tuberculosis patients in the work area of Samarinda Health Office. The same thing is also found in the results of research Kangagung, et al (2013) Obtained the results of significance value of 0.002 (p <0.05) on the evaluation of patient understanding which means the implementation of home care affects the patient’s understanding of pulmonary TB disease.

**Material and Method**

Design research or also called research design is set with the aim that research can be done effectively and efficiently. This type of research is quantitative using quasi experiment method with Pretest and Posttest Control Group Design. In this research design the sample is divided into 2 groups (given counseling and which not given counseling). Then each sample will be observed data by way of Pretest and Posttest.

Based on Table 1 of 17 PMO before being given counseling (pretest) most have enough knowledge is 10 people (58.82%), followed by PMO with good knowledge is 4 person (23.53%) and knowledge less is 3 person (17.65%). After being given counseling (Posttest), most of PMO knowledge is good that is 12 people (70.5%), followed by PMO with enough knowledge about 5 people (29.41%). PMO that is not given counseling on pretest most is PMO which have enough knowledge is 5 people (29.4%) and knowledge less that 3 person (17.6%). After the most posttest is PMO with enough knowledge that is 8 people (47.1%), followed by good knowledge that is 6 people (35.3%) and less knowledge that is 3 person (17.6%). PMO before getting counseling can be seen less attitude is 5 people (29.4%) and PMO which have good attitude is 3 person (17.6%). After being given counseling (Posttest) PMO attitudes are good that is 11 people (64.7%), followed by PMO with enough attitude as many as 6 people (35.3%). PMO that is not given counseling on pretest most is PMO which have good enough attitude that is 8 people (47.1%), followed by PMO with less attitude that is 5 people (29.4%) and good attitude that is 4 person (23%, 5%). After the most posttest is PMO with good attitude and enough that is 6 people (35.3%), followed by PMO with less attitude that is 5 people (29.4%).

The behavior of POM who received counseling before giving counseling (pretest) mostly had enough
behavior was 9 people (52.9%), followed by PMO with good behavior was 7 people (41.2%) and less behavior was 1 person (5.9%). After being given counseling (Posttest) PMO behavior is good that is 12 people (70.6%), followed by PMO with enough behavior as much as 5 people (29.4%). PMO that was not given counseling on pretest, most have enough behavior is 8 people (47.1%), followed by good behavioral behavior is 5 people (29.4%) and behavior is less 4 people (23.5%). In Posttest, most of PMO behavior is enough that is 9 people (52.9%), followed by PMO with good behavior that is 6 people (35.3%) and behavior less as much as 2 person (11.8%).

<td>18.94</td>
<td></td>
</tr>
</tbody>
</table>

Based on the table 2 the results of the average study of differences in the influence of knowledge, attitudes and behavior of PMO TB Patients in the group of counseling is greater than the group not given counseling, namely knowledge (21.44> 13.56), attitude (20.88> 14.12), behavior (21.24> 13.76) and (16.06> 18.94). The result of crucified wallis test to see the difference of influence of knowledge, attitude, and behavior of PMO of TB Child Patient is found that p-value value is 0.010 for knowledge, 0.030 for attitude, 0.013 for behavior, 0.086 for nutrient status. From p-value value in statistical test results Ho decision was rejected (p <0.05), indicating that there is influence giving counseling to knowledge, attitude, behavior of PMO and nutritional status of TB Child Patients.

**Discussion**

The influence of counseling on Knowledge of PMO was analyzed using crucified wallis test with sig result. 0.024 or Ho is rejected which means significant influence counseling to the knowledge of PMO patient TB child. The result of pretest and posttest in the control group that is not given counseling, that is the number of PMO with sufficient knowledge has decreased and the number of PMO with less knowledge does not change, but the increase and decrease the number of PMO is not significant. While the results of pretest and posttest in the group given counseling, the number of PMO with good knowledge has increased significantly, the number of PMO with sufficient knowledge decreased significantly and the number of PMO with less knowledge also decreased significantly. It shows that counseling has a significant effect on the knowledge of PMO of children with TB. Drug counseling is one of the methods of facial education, is one form of pharmaceutical services in an effort to improve the knowledge and understanding of patients in the use of drugs. In counseling, PMO is given an explanation of TB disease, so that the PMO given the exact counseling will have better knowledge than the PMO that is not given counseling\(^9\).

The results of this study are in line with research conducted by Loriana et al. (2013) indicating that there is a significant effect of counseling on the knowledge of TB suffers in the work area of the Samarinda Health Office\(^6\).
The influence of counseling on the attitude of PMO is analyzed using the Kruskal Wallis test with $p < 0.030$ or Ho rejected which means there is influence of counseling to PMO attitude of TB child patient. The result of pretest and posttest in the control group that is not given counseling, that is the number of PMO with good attitude has increased, the number of PMO with sufficient decreasing attitude and the number of PMO with less attitude not change, but the increase and decreasing the number of PMO is not significant. While the pretest and posttest results in the group given counseling, the number of PMO with good attitude has increased significantly, the number of PMO with sufficient attitude decreased significantly and the number of PMO with less attitude also decreased significantly. This indicates that counseling has a significant effect on the attitude of PMO TB Patients.

Several studies have also shown similar results, one of which was Loriana et al. (2013) indicating that there is a significant effect of counseling on the attitude of TB sufferers in the work area of Samarinda Health Office.

The influence of counseling on the behavior of PMO is analyzed using Kruskal Wallis Test with $p < 0.029$ or Ho rejected which means there is influence of counseling on the behavior of PMO of child TB patient. The results of pretest and posttest in the control group that were not given counseling, are the number of PMO with good behavior has increased, the number of PMO with behavior is quite increased and the number of PMO with less behavior decreased, but the increase and decrease in the number of PMO is not significant. While the pretest and posttest results in the group given counseling, the number of PMO with good behavior has increased significantly, the number of PMO with behavior quite decreased significantly and the number of PMO with less behavior also decreased significantly. This indicates that counseling has a significant effect on the behavior of PMO of children with TB. The results obtained in accordance with research conducted by Loriana et al (2013) and Nurhamidah (2015) which explains that there is a relationship providing counseling to drug taking behavior in patients with TB. The study by Wu et al (2011) explains that there is a positive relationship between attitude and behavior ($p < 0.001$).

Ministry of Health Republic of Indonesia (2016) stated that nutritional status in children with TB will affect the success of TB treatment. Nutrition status is a measure of success in the fulfillment of nutrition for children indicated by body mass index (BMI) of children. To get IMT each child tuberculosis patient is measured body weight and height of patient at the beginning and end of treatment. The results of BMI measurements on 34 children with TB of children showed that there was an increase in nutritional status after receiving TB treatment. In the counseling group, children with tuberculosis patients who had very thin nutritional status at the start of treatment were 4 (23.53%) and decreased to none (0%) of TB patients with very thin nutritional status after TB treatment. Patients with tuberculosis who had nutritional status were thin at the beginning of TB treatment as many as 6 people (35.29%) and decreased to none (0%) of tuberculosis children who have very thin nutritional status after undergoing TB treatment. Furthermore, children with TB who had normal nutritional status at the beginning of treatment were 7 people (41.18%) who then increased to 16 people (94.12%) after receiving TB treatment. And children with TB TB at the beginning of treatment (0%) who had fat nutritional status increased to 1 person (5.88%) after receiving TB treatment. Counseling on PMOs leads to increased knowledge, attitudes and behavior of PMOs that have an impact on improving adherence to TB treatment for tuberculosis patients, adherence to treatment has an impact on the success of TB therapy as indicated by improving the nutritional status of TB children.

**Conclusion**

There is a difference of influence on the level of knowledge of the drug controller (PMO) of child TB patients before and after counseling.

There is a difference of influence on the attitude of drug taking supervisor (PMO) of TB patients before and after not given counseling. There is a difference of influence on the behavior of drug control watchdog (PMO) of TB patients before and after counseling.

There are differences in counseling effect on the nutritional status of TB patients before and after counseling.

There is influence of counseling to the level of knowledge, attitude, behavior of PMO and nutritional status of child TB patient.

**Ethical Clearance:** This study approved and
received ethical clearance from the Committee of Public Health Research Ethics of Medical Faculty, Lambung Mangkurat University, Indonesia. In this study we followed the guidelines from the Committee of Public Health Committee of Public Health Research Ethics of Medical Faculty, Lambung Mangkurat University, Indonesia for ethical clearance and informed consent. The informed consent included the research title, purpose, participants’s right, confidentiality and signature.

Assessment of Nurse’s Awareness about Autism Spectrum Disorder in Pediatric Wards at Kirkuk Public Hospitals

Idrees Hasan Mohammed*, Bahar Nasradeen Majeed*
*College of Nursing/Sulaimani University, Iraq

Abstract

The study Objective is To assess Nurse’s Awareness about Autism Spectrum Disorder in pediatric wards at Kirkuk Public Hospitals, To describe the socio-demographic characteristics of nurses who work in pediatric wards, To assess the nurses awareness level about information, concepts and facts about autism spectrum disorder, To find out the relationship between Nurses awareness level about Autism Spectrum Disorder and some related variables such as (age, gender, number of autistic child that he or she provides care for them). Quantitative design descriptive study was used to assess of nurses awareness who work in pediatric ward about Autism Spectrum Disorder at Public Hospitals in Kirkuk city, from Jun 20 to 10 September 2016. The findings in general indicated that nurses level of awareness in all items related to all three domains (information, concepts and facts about autism spectrum disorders), (social interaction and communication in children with autism) and (disorder in behavioral patterns) were in poor level and recorded low total mean of scores (16.5 ± 3.6), (16.7 ± 3.8), and (16.4 ± 4.0) respectively. The findings of the study researcher recommend to construct an educational program about this important issue to enhance nurses level of awareness and information.

Keywords: Assessment, Autism, Kirkuk Public Hospitals

Introduction

Autism spectrum disorder was first described in 1943 by the American child psychologist, Leo Kanner. He presented 11 children whose behaviors’ were obviously different from those of others. Kanner suspected that they had an inborn feature which had prevented their regular social contacts. Autism terms from the Greek word “auto” means “alone” officially presented by Kanner’s 1943. Clinical name, autism or autism spectrum disorders (ASD), is a complex disorder involves abnormal nervous system development. Autism is a disorder of neural development, characterized by impaired social interaction and communication, with restricted repetitive behaviors. Onsets of this condition at birth or within the first two and a half years of life. Although behavioral differences in children and become more clear before age 2 years in most of them, usually diagnosed in 3 years old or more. Even though the etiology and pathogenesis of ASD is not fully recognized and fully clarified, various genetic, prenatal, early postnatal, microbiological, biochemical and environmental factors have been implicated in the etiopathogenesis of autism. Autism can present in all races, social status, religions and classes of people. It can occur in any child and family, so far the main causes of this disorder unknown that is why there is no medical cure completely. The number of children with ASDs have increased during the past decade, and prevalence of autism had risen dramatically, based on (Centers for Disease Control, and Prevention) CDC estimates from 2012 autism is seen in 1 of every 88 children. Recently, diagnosis of autism has been more frequently made. Early diagnosis is quiet important with respect to rehabilitation alternatives, and long term responses, nurses awareness and knowledge about Autism spectrum disorders utmost important to identify the early diagnosis of children with ADS.
Methodology

Setting of Study

The study was carried out in pediatric ward of three public hospitals in Kirkuk city (Pediatric Hospital, Azadi Teaching Hospital and Kirkuk General Hospital).

Sample of the Study

An non-probability/Convenience sampling technique was applied in the present study. All nurses who work in pediatric wards in Public hospitals of Kirkuk city were involved. Two hundred nurses were constituted the study sample that they were recruited from (Azadi Teaching Hospital 47 nurses, Kirkuk General Hospital 33 nurses, Pediatric Hospital 120 nurses).

Inclusion Criteria

Nurses who have interest and agree to be involved in the study.

Nurses who work in pediatric ward.

Both genders (male and female).

Exclusion Criteria

- Nurses who do not participate in the study

Tools of Data Collection:

In order to collect the proper information of study, the questionnaire was designed and constructed by the researcher to measure the variables underlying the present study.

Results and Discussion

Table (1) demonstrates that majority of the sample are females (57.5%). While the rest were male and represent (42.5%). This finding reflects that female are more interested in work as a nurse because all activities and interventions are part of their nature of life and have positive impact on them. According to age groups, the greatest percentages of the sample present among (30-39), (20-29) years old which accounts (38.5%),(37.5%) respectively, with Mean and SD (33.2,±1.71). The smallest proportions of the sample (4.5%) their age ranged between (50-69) years old, and most of them (66%) were married. In the same table the finding reveals that the study sample of nurses who work in pediatric wards in Kirkuk city, more than half of the sample (60%) were from pediatric hospital, this indicated that this hospital is a special hospital for children that is why the highest percentage of nurses were present in this hospital, While (23.5%) of the sample were from Azadi Teaching hospital, and the rest which account (16.5%) were from Kirkuk General hospital.

Table (2) reveals level of awareness of nurses who work at pediatric wards regarding Information, Concepts and Facts about Autism Spectrum Disorders. It shows that the mean of scores was poor level in all items related to domain one which includes 10 items that ranged between (1.56-1.75) M.S with total M.S (16.5 ± 3.6). This indicated that nurses awareness regarding Information, Concepts in Autism Spectrum Disorders were insufficient and very poor. Item number (10) which states Autism could be associated with Mental Retardation or Epilepsy, has got the highest mean of scores (1.75) and it was in the first order of the rank, followed by item number (1) the second order of the rank which has got the mean of scores (1.74), Item number (3 and 4) becomes third and forth order of the rank which got (1.72) and (1.71) mean of scores respectively. While item number (2) come in the fifth order of the rank and it got the mean of scores (1.69) which states that Autism spectrum disorders is unknown causes. It is worth to mention that item number (6) recorded the lowest mean of scores (1.56), which states signs of Autism show between 1-3, years, followed by items number (5,7,8) which accounts (1.58) means of scores for each one of them. In addition, to item number (10) has got highest percentage of respondents (62.5%) they do not know the (co-morbidity of Autism could be associated with Mental Retardation or Epilepsy), followed by item number (1) they do not know the meaning of Autism it is a neuro-developmental disorders characterized by impaired social interaction, verbal and non-verbal communication, and restricted and repetitive behavior (60%) of respondent, it is worth to mention that unfortunately very few percentages of sample were aware or have knowledge about all items that include domain one in general with ranged between (5.5% -7.5%). Results of our present study disagree with result study done by (7) “Knowledge of childhood autism and challenges of management among medical doctors in Nigeria” who indicate that only (31.1%) of respondent do not know the (co-morbidity of Autism could be associated with Mental Retardation or Epilepsy), while in our finding (62.5%) of respondents do not know (co-
morbidity of Autism could be associated with Mental Retardation or Epilepsy). A study has done by (8) aimed to assess the level of awareness about childhood autism among first grade nursing and medical student in Istanbul, Turkey, mentioned that (40.6%) of respondent do not know the definition of the Autism Spectrum Disorders is a neurodevelopmental disorders characterized by impaired social interaction, verbal and non-verbal communication, and restricted and repetitive behavior, which disagrees with our finding that (60%) of our respondents were aware that the correct age of the appeared of autism signs and symptoms is between 1-3 years. Table (3) explains the total mean scores for each domain separately and mean of scores for all three domains. In all total three domains mean of scores does not reach (17) that is why level of awareness in each domain was poor which accounts (16.5, 16.7, 164) in all three domain respectively. Total mean of scores in all three domains together accounts (49.7) which indicates to calculating means of scores for each domain separately and in all three domain together in chapter three Methodology page (63-64). This finding in present study indicated that nurses who participated in this study did not get any information about ASD, while they were nurses students and after their graduating or during their services as a nurse in all three hospitals. This is what the researcher look for and should be highlighted especially for nurses who work in pediatric ward, it is very important to be aware about this disorder. Table (4) demonstrates the relationship between nurses level of awareness in all three domains regarding ASD and age groups. The finding in this table shows that there is no significant relationship between nurses level of awareness and their age groups in all three domains (P. value 0.05). The results in the present study agree with the results of previous study done by (10) which mentioned that there is no significant relationship between nurses level of awareness and age groups, but it’s worth to mention that our finding disagrees with the study curried out by (11) who said that their is a significant relationship between nurses level of awareness and age groups. Table (5) explores the relationship between nurses level of awareness in all three domains regarding ASD and Gender, as it show above there is no significant relation between nurses gender whom work at pediatric ward and level of awareness all three domains (p. value 0.05). The table (6) demonstrate the relationship between nurses level of awareness in all three domains regarding ASD and nurses who caring to ASD child. The finding shows that there is highly significant relationship between nurses level of awareness and nurses who caring their to ASD child previously at (p.value 0.05), this result is supported by the result of previous study done by (7) mentioned that their is a significant relationship between knowledge of respondents about child hood autism and their management to ASD Child, also our present study results agree with the results of previous study done by (Igwe, et al., 2011) who found significant relationship between nurses knowledge about child hood autism and caring to ASD child previously. more contact with ASD child due to more experience and awareness.

**Conclusion**

Majority of the sample are female, most of them there age ranged between (30-39, and 20-29) years old. Nurses awareness level in general regarding ASD in all three domains (information, concepts and facts about autism spectrum disorders), (social interaction and communication in children with autism), and (disorder in behavioral patterns) was insufficient and very poor. No significant relationship were found between nurses level of awareness and age groups, gender. Significant relationship were found between nurse’s level of awareness and nurses that caring to autistic child. Construct an education program to enhance nurses information, this will also improving their clinical ability to early recognize children with symptoms of Autism Spectrum Disorders in this environment.

Assessment of Nurses’ Knowledge and Practices Regarding Nasogastric Tube at Neonatal Intensive Care Unit in Baghdad Hospitals

Asmahan Qasim Mohammed

Pediatric Nursing Unit, College of Nursing/ University of Baghdad, Iraq

Abstract

A descriptive study was carried out in Baghdad City from 16th of Nov 2017 to 1st of May 2018. A non-probability sample of (35) Nurses working at neonatal Intensive care unit at the Children Welfare Teaching Hospital, Child’s Central Teaching Hospital and Ibn -Albadly Hospital. The study instrument consisted of three major parts to meet the purposes of the study. The first part is related to nurses socio-demographic data, the second part is related to nurses knowledge about nasogastric tube, it consisted of three domains (20) items and the third part is observation checklist related to nurses practices about NG tube, it consist of (14) items. The validity of the instrument’s contents was established through a panel of (10) in different specialties related to the field of the present study. The study was collected by using a constructed questionnaire through an application of direct interview and observation checklist. The data were analysed by using two statistical approaches: Descriptive, Inferential statistics. The study revealed that the nurses knowledge about NG tube was 54.3% (Poor), followed by those who have 37.1% (fair) knowledge.

Keywords: Nurses, Knowledge, Practises, Nasogastric tube.

Introduction

Feeding tube is a safe means of meeting the nutritional requirements of infants who are unable to feed orally. These infants are usually too weak to suck effectively, are unable to coordinate swallowing, and lack a gag reflex. Feeding tube may be provided by continuous drip regulated via infusion pump or by intermittent bolus feedings. Studies have demonstrated an overall decrease in total milk fat concentration delivery when continuous gavage infusions are administered, which suggests that intermittent or bolus gavage of expressed mother’s milk be administered when possible. Although the more relaxed lower esophageal sphincter makes passage of the tube easier, there may be changes in heart rate and Blood Pressure in response to vagal stimulation. Complications of indwelling tubes include aspiration, obstructed nares, mucous plugs, purulent rhinitis, epistaxis, infection, and possible stomach perforation. Current practice dictates a radiograph as the only certain way to determine nasogastric (NG) tube placement. Methods such as auscultation of an air bubble, and neckear-xiphoid (NEX) measurements for insertion depth, and pH measurements are considered imprecise when used as the only method for determination of placement. Nurses in the NICU should be alert about tube size selection, assessment of tube position, methods of securing tube or method of feeding, providing correct patients position, checking the patency of tube, checking the food content (liquid foods are used), assessing the bowel sounds, which are important components to minimize the risks of NG tube related complications and to provide optimal patient safety and comfort. Major attention must be focused on nurse’s knowledge and performance regarding nasogastric tube because nurses have the major responsibility for providing patients with their essential nutrients without causing complications. As well as continuous education and training of all hospital staff is essential to increase their knowledge.
about important nursing procedures as nasogastric tube. Critical care nurses are playing a major role in preparing, monitoring, administrating and evaluating the patient response to medication and nutritional care. Also nurses’ knowledge and practices about feeding or administration of medications via NGT may differ from hospital to another and need to be assessed and observed to find if there is a gap between their knowledge and practice and if they follow the standard guidelines to administer medication via NGT so this study is designed to assess the nurses’ knowledge and practice about NGT at NICU in Baghdad hospitals.

Methodology

A descriptive study was carried throughout the current study for the period from 16th of Nov 2017 to 1st of May 2018. In order to assess Nurses’ knowledge and practices regarding nasogastric tube at neonatal intensive care unit in Baghdad City and administrative arrangement was taken. The approval of the nursing college council upon the title and objectives of the study. Afterward, many approvals were obtained from different directorates which have an administrative relation with this study. Approvals of the ministry of Health, Al Karkh Health Directorate / Baghdad AL – Russafa health directorate , Medical City Directorate and the directorate of selected hospitals in Baghdad City. The present study was conducted in Baghdad City; neonatal intensive care unit at the Children Welfare Teaching Hospital, Child’s Central Teaching Hospital and Ibn –Albaldy Hospital. A purposes (non-probability) sample of (35 ) nurses working at neonatal Intensive care unit in Baghdad Hospital. These were assigned for study according to the following special criteria: nurses working at Intensive care unit in Hospitals selection, nurses who agreed to participate in this study, nurses from various educational level, both sexes(male and female), nurses from various age group, morning shifts only. a questionnaire format was designed and constructed by the researcher depending on: the extensive review of available, related literatures and studies about nasogastric tube. The questionnaire consists of three parts, Part I: The demographic information includes data related to nurses’ characteristics such as ( age, gender, educational level, years of experience in hospitals, years of experience at neonatal intensive care unit). Part II: The questions in part II are related to nurses knowledge about nasogastric tube at neonatal intensive care unit. It consisted of (3 ) domains. First domain had (4 ) items, second domain had (10) items , and third domain had (6) items . The questions was rated on a three likert scale (know, uncertain, and do not know) and was scored as 1 for know, 2 for uncertain, and 3 for don’t know. Part III : The questions in part III are related to nurses practice about nasogastric tube at neonatal intensive care unit. An observational checklist was developed by researcher depend on previous studies and literature review. It consisted of (14) items. The data collected with constructed questionnaire through an application of direct interview and using checklists as mean of data collection from 30th of January 2018 to 15th of February 2018. Data were analyzed through the application of two different statistical approaches Descriptive statistics: frequency, percentages and means. Inferential statistics: significance, and Chi-square.

Results and Discussion

Socio-Demographic Characteristics of the Nurses, who participate in the study, in the Neonatal Intensive Care Unit (Table1) Age of Nurses; finding of the present study revealed that the age mean is 32.8 ± 7.0; more than a half are within the age group of (23-30). This result agrees with study done by Raju,et al.,(2011) he provided in their study that the age (21-30 years) were 86% of the study sample. Also agree with study done by Kaur, et al.,(2008) was observed that most years old of the sample age at group (20-30). Gender of Nurses: The present results reveal that 68.6 % of the sample are female. This finding of the present study supportive evidence is available in the study done by Kamunge,(2013) found that 70.2% of the sample of his female, also agree with the study done by Saleh, et al.,(2009) discovered that females in the study was 94.6% and was the highest percentage. The passion and the females familiar feeling this was the reason for the high percentage of the female in the present study, also she was able to deal with their sense of motherhood newborn making them successful at work in the neonatal intensive care unit. This is the belief researchers. Nurses’ Level of Education; the present study findings that the majority of the sample graduated from the associate degree diploma 62.9% , followed by those who are nursing high school graduates 25.7%, and those who hold a bachelor’s degree 11.4% . This result disagrees with study done by Hassan and Hassan, (2012) who showed in the study that the graduated from a secondary school of nursing were 42.5% of her study samples but agrees with Asadullah, et al., (2013) who stated that the
68.7% of the study sample where diploma percentage holders in nursing. Years of Experience in Nursing; finding of the present study revealed that the highest percentage 45.7% have (1-5) years of experience in nursing of the study sample. The result of this study disagree with results of study conducted by Barton (2001) which indicated that highest percentage 80% have (6-10) years of experience in nursing. Years of experience in NICU; the present study revealed that the highest percentage 65.7% have (1-5) years of experience in NICU compared to those who have (6-10) years. This result disagrees with Maheswari and Muthamilseliv, (2014) who discovered that the years of employment was 64% of the study sample, and had experience of (6) years and above. But agree with study done by Chau, et al., (2010) point out that the 45% was a high percentage of the sample years of experience had (1-5) years of working experience. Participation in Training Course; most of the study sample have training course about nasogastic tube , which represents 62.9 % of the sample study. all these courses were held inside Iraq (100.0%). This result agrees with Asadullal, et al.,(2013) who showed that the previous training course was 73.5% of the study sample. Also this study agree with the study done by Olivera, et al., (2009) he pointed out that 52% of the study sample had training courses. Getting Information about nasogastic tube; the results of the study declared that 68.6 % of nurses got information about NG tube and most of those who reported that they read such resources page the internet to get such information70.8% compared to books 29.2%. The results of this study disagree with results obtained from a study conducted by Al–Ibady (2011) who demonstrated that nurses who don’t get information from any resource comprised a high percentage 52.5%. The current study showed that the more than a half of participants have 54.3% poor knowledge followed by those who have 37.1% fair knowledge, and those who have 8.6% good knowledge(Figure 1). This study agree with Ahamed and Mondal (2014) who illustrated that three-quarters of studied nurses had inadequate knowledge regarding Ryle’s tube feeding. The present study showed that the most of participants have 77.1% fair practices , followed by those who have 22.9% good practices(Figure 2). This study disagree with Ahamed and Mondal (2014) who illustrated that most of the studied nurses had a satisfactory level of practiced skill regarding care given before NG tube feeding administering. Regarding age of the participants, Nurses who are within the age group of (31-38) years-old have better knowledge about NG tube than those who are in the age group of (23-30), and those who are in the age group of (39-48). However, there is no statistically significant difference in participants’ knowledge among age groups, as seen in (Table 2). Regarding academic qualification, nurses who hold a bachelor’s degree have a better knowledge about NG tube than those who are nursing high school graduates, and those who hold an associate degree. However, there is no statistically significant difference in participants’ knowledge among educational qualification groups as seen in (Table3). These results disagreed with results obtained by Al –Gannem (2006) whom indicated no significant associations between nurses’ knowledge and their level of education Regarding years of experience in NICU, Participants who have (6-10) years of experience in NICU have better knowledge about NG tube than those who have (1-5) years of such experience. However, there is no statistically significant difference in participants’ knowledge between years of experience in NICU groups, as seen in (Table 4). This result disagrees with Al-Jaza’iri,(2007) who presented that the years of experience in specialist areas where the nurses’ work would increase their knowledge.

Figure 1. Level of Knowledge About NG Tube

Figure 2. Level of Practices Related To NG Tube

Conclusion

According to the findings of the present study, the researchers highlighted and concluded the following: The majority of nurses were female, graduated from associate degree “diploma “, had (1-5) years of experience in general hospitals and in NICU, most of
them participation in training sessions about nasogastric tube inside Iraq, most of them uses resources such as internet to get information about NG tube. More than a half of participations have poor knowledge about nasogastric tube. Nurses' practices was fair about nasogastric tube, followed by 22.9% have good practices. There is no statistically significant correlation between participants' years of experience in NICU and their knowledge about NG tube.

Effect of Hypoxic Training in Some of the Physiological Capacity of Junior Players: Coefficient of Stability and Objectivity for Tests of Aerobic and Anaerobic Efficiency

Mohamad Musa Mohamad¹, Ali Hashim Hamza¹

¹The Open Educational College, Iraq

Abstract

The maintenance of efficiency of physical performance over the period of match is of great importance and of the main bases on which it depends in achieving the required results, as maintenance of level of physiological capacity, despite the exposure to physical effort is a clear indication of the weight of the team that has this attribute in addition to the special physiological abilities that are considered as an effective factor in the performance of the basic skills of the game, and through the humble experience of the researchers it was found that there is a lack of use of hypoxic training as well as ignoring the physiological abilities by teams' coaches because of lack of familiarity with these capabilities, so the researchers decided to study this problem and to know the impact of approach in the development of some physiological capabilities and its reflects on the motor skills of the players of the five football stadium.

Key words: Hypoxic Training, Physiological Capacity, Efficiency

Introduction

The idea of five football stadium game was launched in Uruguay in 1930 when Juan Carlos designed a form of five-players for each football team for youth competitions. So the game of five football stadium is regarded of the newly emerged games and despite the novelty of the game it has developed in many countries of the world and this is due to the reliance on sports-related sciences, which key purpose is to raise the physical and skilful level of players taking into account the specificity of each activity in terms of special physiological abilities and basic skills, as five football stadium player must possess high level of Physiological capabilities in order to be able to implement the basic skills of the game, because of games specifications that require high speed in performance, in addition to the requirements of the game that impose on players to continue the movement and not to stop. Since the game of five football stadium requires the player to assume defensive and offensive duties at the same time. The hypoxic training is considered of the important exercises in the process of organizing breathing which is one of the most important conditions for the progress of achievement as well as the role played by the physiological capacities. Therefore, the importance of research lies in placing approach in accordance with modern scientific contexts in order to develop the level of players of five football stadium to reach them to a good level. And the researchers saw it very important to be familiar with the impact of this approach in some physiological abilities and put it in front of coaches and players so that the workers in the field of training may have the chance to know the right training method and employ it to get excellent results. The aim of research is to: Prepare special exercises in a hypoxic way for junior players in five football stadium. Identify the impact of exercise, especially in the development of some physiological abilities of junior players in five football stadium. The researchers used the experimental approach to address the research problem. The research community of junior players in five football stadium in Al-Qasim Sports Club consisted of 14 players was selected, and ten of them were randomly tested in a simple way.
and were divided into two groups. The researchers used appropriate statistical methods to address acquired data including (Arithmetic mean, standard deviation, T-testing for independent and symmetric samples).

Methodology

Research community and its sample

The research community set the emerging 20 players in the Al-Qasim Sports Club, a simple sample of 16 players was selected randomly and was divided equally into two groups (controlled and experimental).

Means, devices and tools used in research:

Tools and devices used in research:

1 - Spirometer for measuring (Vital Capacity, range volume, Inspiratory reserve, Maximum exhalation rate
2 - Kymograph device
3 - Face masks - nose stoppers

Measurements used in the research

Vital capacity

The measurement is done by Spirometer

The test arbitrator holds the blowing tube connected to the device at the time of pause and then begins to take the maximum possible inhalation and maximal exhalation possible in the tube, the measurement is done automatically by the device mentioned via drawing curve on the graph where the point at which the device pointer ends from the curve graph is the value for the vital capacity with taking into account putting a stopper on the nose to ensure that the air does not exit.

Measurement of range volume

The measurement is done by Spirometer and through the same prepared chart that draws the diagram of breathing.

Measurement of inspiratory reserve

The measurement is also done by spirometer through the same prepared charts that draw us the curve of the process of breathing after the arbitrator takes the maximum possible inspiration.

Measurement of maximum expiratory flow

It is measured by spirometer too when the player takes the maximum inspiration from the air and then releases the maximum possible exhalation strongly and quickly inside the tube of the device then it measures the variable.

Measurement of Breath Muting

It is performed by the device of Kymograph + Sytograph and its accessories. The player can mute his breath so that the rib cage stops moving, then the indicator carries a straight line as long as the self-mute process continues and when the rib cage begins to move to start process of inhalation, the indicator moves to record a curve due to inhalation and exhalation process when the device is turned off.

Performance of research execution

Exploratory experiment: The researchers conducted exploratory experiment on (8) players from the youth representing Al-Qasim club and the experiment was conducted at (5:00) pm on (15/9/2017) in the yard of Al-Qasim Club to test capabilities. And after (7) days, exploratory experiment was repeated on (22/9/2017) on the same individuals and under the same conditions and the goal was to:

Identify the time taken for each test as well as the total tests time
Know difficulty level of tests for the research sample
Identify the difficulties faced by the researchers for the purpose to avoid them in the future
Extract the scientific foundations of the tests (stability and objectivity).

Scientific foundations of tests:

Credibility of test: The credibility is the accuracy with which the test measures the purpose for which the test was conducted. For the purpose of extracting credibility of the selected tests, the researchers
presented the contents of the tests to a group of experts and thus the researchers obtained the validity of the content.

**Stability of test:** In order to extract the stability coefficient for tests, the principle of constant testing is to be applied “which produces close results or the same results if applied more than once in similar conditions”. “Test and retest method” was used to calculate the stability coefficient with time interval (7) days between the first and second tests. The researchers extracted the stability coefficient by means of simple pearson correlation coefficient between the results of the first test and the second test and extracted the correlation significance by means of the statistical method (correlation coefficient) for the significance of the correlation as shown in Table (1)

**Results and Discussion**

**The cardiac tests:**

Cardiac tests were made on 4/10/2017 and on all individuals of sample that are consisted of (16) Players.

**Training approach:**

The researchers implemented the training approach on research sample totalling (16) players for 8 weeks with three training units a week and the implementation of approach in the set period reached (24) training units and the researchers took into consideration the gradient in distribution of intensity degrees starting from (60%-90%). The application of training approach was carried out on research sample during the period started from 6/10/2017 to 5/12/2017.

**Post-tests**

After completion of approach implementation, post-tests were conducted on 06/12/2017 on the members of the research sample and in the same way of cardiac tests and in the same place.

**Statistical means:** The researchers used the statistical Package For Social Sciences (SPSS) Including:

1 - Arithmetic mean
2 - Standard deviation
3 - Difference coefficient
4- T-test for interrelated samples .

**View, analyse and discuss the results**

Presentation, analysis and discussion of differences in both pre and post test results of the research sample. From table 2, we find that there are statistically indicative differences between pre and post measurement results and for the benefit of the post in all the values of the studied variables. The researchers attributes this for the effectiveness of approach prepared by the researchers in a manner consistent with the abilities and capabilities of the sample, because the training approaches lead to bringing about improvement and development in the different variables if built according to the scientific bases in the construction and organization of the training process and the formation of loads through the appropriate stress and this is consistent with Mohamed Othman, who pointed out that “the coach should be able to succeed in developing the training approach, which takes into account the size and intensity of loads used and their suitability to the abilities and capabilities of the players and consistent with their sports and physical attributes to be developed, which leads to the high level of their achievement”. Moreover, the researchers adds that the hypoxic training has a positive role in the development of some physical capabilities through the rapid strong action in competition, which requires players produce energy and increase it in the anaerobic way, so this method drove player to adapt to these competitions, which are short in a time but tiring, and this is what Essam Hilmi and Mohammed Jaber pointed out that “the increase of performance level in short competitions is the ability of the body to supply with energy for a short time without the use of large quantities of oxygen according to the anaerobic energy system concept”. Mohammed Othman confirms that “Oxygen-lacking training increases activity of energy production process during performance”. And we see that breath-muting and its reduction goes with wrestling player because he depends on the lack of oxygen and therefore the lack of breathing and the occurrence of the phenomenon of oxygen debt, which is an assistant factor for him during the performance, and this what Abu El-Ola Ahmed indicated to, “Training in conditions of hypoxia can be done by creating a high level of oxygen debt”. The researchers attribute reasons for the differences in the measurements under study to the nature of the hypoxic training, which imposed on the players levels of pressure on the functional organs, including the respiratory.
system because of the conditions surrounding breathing during performance, which was the main cause of the increase in the functional capacity of the lungs, which was one of the effects and changes that occurred due to the application of the training approach to the sample members. This means that there is an increase in the functional efficiency of the lungs and an increase in the pulmonary volume and capacity. This refers to the increase of players’ ability, as organized training has positive functional effects on respiratory function. This fact is consistent with Mohamed Hassan and Abu El-Ola, who indicated that sports training leads to changes in pulmonary volume, and this what leads to similar changes in body positions during athletic performance. “John West,” adds when doing breath-control training, some physiological adaptations result from low oxygen level and high level of carbon dioxide in the blood on the central chemical receptors in the brain by (80%-85%) and the surrounding chemical receptors in the carotid artery and the aorta causing an increase in the rate of pulse and breathing and disabling the voluntary act of stopping breathing. We add that the most important external factors are the big burdens suffered by the sample members as the high level of burdens on the respiratory system was offset by a significant effort by the respiratory muscles designed to compensate for the shortage of oxygen and this leads to flexibility of strength of breathing muscles that lead lungs to absorb a greater amount of air. Thus air ratio exiled increased. The larger the chest cavity, the greater the vital capacity and breathing volume of the players, and this what J. H. Creen refers to “the strength of the breathing muscles increase contraction while increasing physical activity, leading to a widening rib cage and entrance of more volume of air then increase in range of air volume. So breathing depth increases and improves the gas exchange between the blood and vesicles. The researchers sees lungs ability to absorb the maximum amount of air during the process of at a time through repeated physical efforts lead to the lifting of vital capacity and range volume to compensate for the shortage of oxygen and so the case with the maximum exhalation. This is confirmed by Guyton and Hall: “The higher the value of the vital capacity, the greater the forced expiratory volume and vice versa.

Conclusion

Hypoxic training has positive functional effects on the physiological abilities of players in the five football stadium. There were significant differences of variables under consideration between the pre and post measurements for the benefit of post -measurements. Occurrence of developments in the efficiency of the respiratory system through the results of functional measurements.

Effectiveness of an Education Program on Nurses knowledge concerning in Nursing Management for patients with Heart Block in Kirkuk Teaching Hospitals

Abid Salih Kumait AL-Jumaily, Khalidah Mohammed Khudur

1Department of Adult Nursing, College of Nursing, University of Kirkuk, Iraq, 2Ass. Professor, Head of Department of Adult Nursing, College of Nursing, University of Baghdad, Iraq

Abstract

Objective: The aim of the study is to assess the effectiveness of an educational program on Nurses’ knowledge concerning in nursing management toward heart block in Kirkuk’s teaching hospitals and to identifying the relationship between the nurses’ knowledge and their demographic characteristics. A descriptive study design (quasi experimental study) was carried out at Azadi teaching hospital and Kirkuk general hospital in Kirkuk city for nursing staff who worked at CCU, RCU unit, emergency unit and internal medicine unit, from February up to May, 2018. A non-probability (purposive) sample was selected and composed of (80) Nurses. Nurses was divided into two groups, study group consisted of (40) nurses exposed to the nursing educational program and control group consisted of (40) nurses were not exposed to the program from Azadi Teaching Hospital and Kirkuk General Hospital in Kirkuk city. The program and instruments were constructed by the researcher for the purpose of the study. The measurement of effectiveness of nursing educational program through the multiple choice questions includes (43) items. The study findings indicated that there were highly significant differences between pre and post tests in the study group in overall main domains related to nurses’ knowledge.

Keywords: Education Program, nursing management, Heart Block

Introduction

Atrioventricular (AV) heart block is marked by a disturbance in electrical impulse conduction from the atria to the ventricles. AV blocks are classified as first-degree, second-degree, and third-degree. Third-degree blocks are the most dangerous. Cardio Vascular Disease remains a major healthcare problem and one of the most consumers of the public health resources. Heart block (HB) remain the commonest cause of death. As in statistical reports of the World Health Organization (WHO); 2011, Sudan; 212.0, Libya; 199.3 and Jordan; 162.5. Despite the lack of accurate epidemiology data for AVB, it is clear that it is not uncommon in both apparently healthy populations and those with overt heart disease. which increases to 5% in men over the age of 60 with cardiac diseases. The prevalence of second-degree AVB for Mobitz II block is estimated to be 3% in patients with HF, and it is estimated that 5% to 10% of people will develop a third-degree heart block in those >70 years old and having a history of heart disease. Atrioventricular (AV) block is a common complication of acute Myocardial Infarction (MI). In setting of Inferior MI, this was even as high as 28%. The prevalence of first-degree atrioventricular block in the general population is approximately 4% and the treatment of patients with heart block will improve medical and device therapy.

Methodology

Design of the Study:

A quasi-experimental design (pre-post test) study had been used through the present study with the
Results and Discussion

Relative to “Gender” subjects are from female are more illustrated, since 23(57.5%), and 25(62.5%) are accounted in the study and controlled groups respectively, and most of “Age Groups”, are focused at the first two groups since 35(87.5%), and 37(92.5%) are accounted in the study and controlled groups respectively, as well as most of residential subjects, are focused at urban area, since 28(70.0%), and 31(77.5%) are accounted in the study and controlled groups respectively. With regard to marital status, shows that single subjects has recorded the most of study group, while married status has recorded the most of study subjects in the controlled group, and they are accounted 26(65.0%), and 20(50.0%) respectively. Finally, educational achievement of studied subjects shows that most of them has graduate institute, and bachelor or more degrees, and they are accounted 34(85.0%), and 33(82.5%) in the study and controlled groups respectively. Table (2) indicate that the majority of studied subjects are worked at CCU unit, since they are accounted 15(37.5%), and 14(35.0%) in the study and controlled groups respectively, as well as the most of training named concerned with the studied subjects previously was at CCU unit, since they are accounted 21(52.5%), and 22(55.0%) in the study and controlled groups respectively. Table (3) shows highly significant differences at P<0.01 toward impact of applied program through raising knowledge grades of studied respondents at post1 period, and that could be enable to confirms importance and successfulness of applying the proposed program. The results of the controlled group has recorded completely immovable responses over the three periods of times with low level of assessed. Table (4) reported highly significant differences at P<0.01 toward impact of applied program through raising knowledge grades of studied respondents at post1 period, and that could be enable to confirms importance and successfulness of applying the proposed program. The results of the controlled group has recorded completely immovable responses over the three periods of times with low level of assessed. Results shows that weak relationships are a proved with (SDCv.), since no significant relationships were accounted at P>0.05. Table (1) Relative to “Gender” the female are more illustrated, since 23(57.5%), and 25(62.5%) are accounted in the study and controlled groups respectively. These finding is agreement with the result of (9) (2016) who find More than three quarters of participants were females (79.4%). Most of the nurses age were between (20 to 39 years) and constitute 35(87.5%), 37(92.5%) respectively but these findings disagree with the study of (8) (2018) who find More than three quarters of participants were females (79.4%). Most of the nurses age were between (20 to 39 years) and constitute 35(87.5%), 37(92.5%) respectively but these findings disagree with the study of (9) (2016) in Egypt, who reported that more than one third of the study sample aged between 40 to 49 years. With regard to the residence most of residential the urban area is 28(70.0%), and 31(77.5%) are accounted in the study and controlled groups respectively. These findings disagree with the study of (8) (2016) in Egypt who reported that more than half of the sample (62%), were living in rural areas. Table (2) shows the most of training named concerned with the studied subjects previously was at CCU unit, since
they are accounted 21(52.5%), and 22(55.0%) in the study and controlled groups respectively. This result is in agreement with the finding obtained from (10) (2012) who ensure nursing staff’s abilities through mandatory annual competency sessions. The results about first degree heart block (FD) at table (4) shows highly significant differences at P<0.01 of study group while controlled group has recorded completely immovable responses over the three periods of times with low level of assessed. This find is agreement with (12) who mentioned there is that medical and nursing staff knowledge and skills of ECG interpretation related to heart block increase with frequent education program and training. With regard to the nurses knowledge concerning in management of Second degree heart block which summarized at table (5) reported highly significant while controlled group refers to low level of significant. The results shows that there were no significant differences between nursing staff knowledge and age at P value ≤ 0.05. Our result is agreement with (13) study (2010) and he find there was no statistically significant difference between the mean knowledge score and age (14) Table (6) Results shows that weak relationships are a proved with (SDCv.), since no significant relationships were accounted at P>0.05. This result is agreement with the findings of the study done by (14) (2012) the results of the study shows, there is no association exists between knowledge score after administration of information booklet about heart block with selected demographic variable as gender educational status, occupation, family income. The entire demographic variables are working independently.

Conclusion

Nurses who work in medical department have minimum knowledge toward management of patients with heart block. Application of nurses education program is improve nurses knowledge toward management of heart block also the study recommended Encourage nurses to participate in sessions, conferences and seminar related to care of patients with heart block.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the Department of Adult Nursing, College of Nursing, University of Kirkuk, Iraq and all experiments were carried out in accordance with approved guidelines.

Effectiveness of Education Program upon Patient’s Knowledge toward Hemophilia among more than Fourteen Years Old in Thi-Qar Heredity Center

Ali Abdulretha¹, Salma Khadom Jehad², Kahtan Hadi Hussen²

¹Institute Thi-Qar High Health, Iraq, ²College of Nursing, University of Babylon, Iraq

Abstract

Data was collected through the use of hemophilia patients knowledge tests which were developed for the purpose of the study, which consists of three parts: The first part is related to the demographic characteristics like patients’ age, level of education, marital status, type of parents marriage relationship, residential area, type and severity of hemophilia; The second part consists of hemophilia patients’ knowledge items which is a list of (42) items in regard to definition of hemophilia, symptoms of bleeding, major common bleeding, site of bleeding was also developed for the determination of the characteristics of the subject. The reliability of the instrument was determination through use of person correlation coefficient for the test retest approach was (0.94) for hemophilia patient’s knowledge. Instrument validity was determined through a panel of experts. Analysis of data was performed through the application of descriptive statistics (frequency, percentage) and inferential statistics (t-test). The study results had revealed that the study group participant had benefited from the implementation of the educational program. However, their knowledge were adequately improved and developed.

Key words: Hemophilia, Education Program, Thi-Qar.

Introduction

Hemophilia refers to a collection of bleeding disorders in which there is a deficiency in one of the factors necessary to blood clotting such as factor VIII, IX or XI². Hemophilia is the most common hereditary coagulation factor deficiency occurring primarily amongst males characterized by bleeding in muscles and joints and can further lead to chronic pain and joint disease (International Journal of Multidisciplinary Research, 2016). When a person with hemophilia is injured he does not bleed harder or faster than a normal person but will have prolonged bleeding because he cannot make a firm clot²

The Types of Hemophilia

Hemophilia is one of the common bleeding disorders and is classified as follows:

Hemophilia A – It is also called classic hemophilia, it is four times more common than hemophilia B, and it occurs when factor VIII levels are deficient.

Hemophilia B – It is also called Christmas disease, it occurs when factor IX levels are deficient.

Hemophilia C – It occurs when factor (F XI) levels are deficient.

Acquired hemophilia A person can develop hemophilia as a result of illness, medications, or pregnancy. Acquired hemophilia is extremely rare and usually resolves itself with proper diagnosis and treatment (World Federation Hemophilia, 2012).

Results and Discussion

Table (No.1) shows that the high percentage of the study group age was between (14-28) years old which accounted (44%), (60%) of them were single. In regard to hemophilia patient’s parents marriage relationship, those who were relative accounted for (68%), in respect to the family types (56%) were extended concerning the hemophilia patient’s educational level (20%) of them were able to read and write. In regard to patient’s employment, those who were governmental employee constituted (44%), in respect to the residential
areas where sample live high percentage represented (64%), live in urban area, (64%) of them their monthly income was not enough, (68%) had moderate disease severity and (60%) of participants were regularly visits the center. Table 2 shows that the high percentage of the study group age was between (14-28) years old which accounted (40%), (58%) of them were single. In regard to hemophilia patient’s parents marriage relationship, those who were relative accounted for (64%), in respect to the family types (64%) of sample live within extended. Concerning the hemophilia patient’s educational level (24%) of them were primary school graduated. In regard to patient’s employment, those who were governmental employee constituted (48%), in respect to the residential areas where sample live high percentage represented (60%), live in urban area, (68%) of them their monthly income was not enough, (68%) had moderate disease severity and (64%) were regularly visits the center. Table 3 indicated that there was no significant differences between the study and the control groups knowledge relative to the pre-test. Table 4 revealed that there was significant differences between the study group knowledge relative to the pre and post-test 1. The findings of this table showed that there was significant differences between the study and the control group’s knowledge relative to the pre and post-test 1. The findings reveal that the highest percentage of the sample live high percentage represented (60%), live in urban area, (68%) of them their monthly income was not enough, (68%) had moderate disease severity and (64%) were regularly visits the center. Table 2 shows that the high percentage of the study group age was between (14-28) years old, for the study and the control groups, more than the half of the study and control groups sample (60% and 58%) are single and this is supported by a study done by (Jennifer, 2006) he mentioned that more than half of the sample are single, around (68 % and 64%) of them have relative of parents marriage relationship both the study and control groups, while (56% and 64%) of them live with extend family of the study and control groups and this agrees with the result of (Sacks and Rhona, 2006) study in which he indicated that (53.3%) of the hemophilia patients lived with extend family, the present study found that around (20%) of them are able to read and write while just (16% and 20%) are un able to do so. Participants for both study and control groups, and (44% and 48%) of the study and control groups of them are governmental employee, and also the researcher finds that (64% and 60) of the patients live in urban of the study and control groups and this comes with the results of a study carried by (Jennifer, 2017) in the Hereditary Blood Disease Center in Al-Nasiriya, which revealed that (67.5%) of the patients live in urban, while (64% and 68%) of them their monthly income is not enough the study and control groups, found (68%) of them have moderate severity of disease, and around (60% and 64%) of them regularly visits the center the study and control groups. (Table 3) it indicates that the hemophilia patients have a low level of education and their knowledge and practices regarding the management of disease, and this is clear when those patients are not formally exposed to that information as they were assessed before starting the study. These results are consistent with the findings of Hemophilia Foundation Australia (HFA), 2009 which indicate that the hemophilia patients in developing countries need an educational program about hemophilia, and how to manage their himself during episodes of bleeding.

Part-I: Socio-Demographic Characteristics Related to the Patients with Hemophilia

Adequate knowledge and practices has been recognized as a necessary ingredient in the patients’ ability to lead normal and productive life to their himself (Badran, 2015). The patient’s knowledge in the self care is considered one of the essential tools in raising the standard of care giving by the himself. The hemophilia patients must have sound understanding of scientific principles underlying each step of any procedure in order to prevent possible risk factor, so they become able to apply their knowledge into effective self care. The results reveal that the highest percentage of the hemophilia patients are selected for the implementation of the educational program and comprehensive self care (Table 1 and Table 2) shows that (44 %) of patients are in age (14-28) years old, for the study and the control groups, more than the half of the study and control groups sample (60% and 58%) are single and this is supported by a study done by (Jennifer, 2006) he mentioned that more than half of the sample are single, around (68 % and 64%) of them have relative of parents marriage relationship both the study and control groups, while (56% and 64%) of them live with extend family of the study and control groups and this agrees with the result of (Sacks and Rhona, 2006) study in which he indicated that (53.3%) of the hemophilia patients lived with extend family, the present study found that around (20%) of them are able to read and write while just (16% and 20%) are un able to do so. Participants for both study and control groups, and (44% and 48%) of the study and control groups of them are governmental employee, and also the researcher finds that (64% and 60) of the patients live in urban of the study and control groups and this comes with the results of a study carried by (Jennifer, 2017) in the Hereditary Blood Disease Center in Al-Nasiriya, which revealed that (67.5%) of the patients live in urban, while (64% and 68%) of them their monthly income is not enough the study and control groups, found (68%) of them have moderate severity of disease, and around (60% and 64%) of them regularly visits the center the study and control groups. (Table 3) it indicates that the hemophilia patients have a low level of education and their knowledge and practices regarding the management of disease, and this is clear when those patients are not formally exposed to that information as they were assessed before starting the study. These results are consistent with the findings of Hemophilia Foundation Australia (HFA), 2009 which indicate that the hemophilia patients in developing countries need an educational program about hemophilia, and how to manage their himself during episodes of bleeding.

The statistical differences between the hemophilia patient’s knowledge of study and control groups

Through the application of the t-test the study findings indicated that the hemophilia patients knowledge didn’t show any statistical differences between the groups in the pre test occasion (Table 3). This means that there are no differences in knowledge in the study and control groups prior to the implementation of the educational program. When t-test was applied again, statistically significant differences were identified between the knowledge of the study group after the implementation of the education program and post-test 1 with the relative comparison of the pre test occasion (Table4). The present study agrees with HFA.,2000 , a post test evaluation was conducted to determined
the effect of education program on hemophilia patients knowledge toward self care management showed statistically significant impact of the program upon those patient’s self care knowledge, particularly hemophilia patients of (14-28) years old which was approximately consistent with the finding of our present study. In a correlation study Among the 40 subjects aged from 11 to 20 years (40) hemophilia patients who were interviewed for the determination of the relationship between their knowledge relative to their self care management, the study finding indicated that there was correlation between self care management status and hemophilia patients knowledge, and these were considered as important factors for determining the hemophilia patients self care management status (Valizadeh., et al, 2014). The effect of the educational program implementation was documented by (Zwaan, 2015) and provided support the effect of our education program implementation when they found that there was positive correlation between hemophilia patient’s knowledge relative to their self care management status due to such implementation. In another study, conducted by (Evat., 2010) a post test was conducted to determine the effectiveness of educational program upon hemophilia patient’s knowledge in which (18) classes for (28) hemophilia patients for (2) months. The results show significant improvement of such educational activity. The finding of the present study revealed that there were no significant differences between the control group’s knowledge when they compared between the pre and the posttest occasion. This means that hemophilia patients knowledge and didn’t show any significant modification improvement or changes. Throughout the implementation of the Education Program, it had been shown that there were no significant changes experienced by the control group regardless of the time consumed between the pre and the post test 1 (Table 5). That means, no single patient had been acquired specific education information out of the Heredity Center. In contrast the study group had significant benefited out of the educational program when they were compared with the control group in the post test 1 occasion (Table 6). Scientifically speaking, it was determined that the present Education Program had made a significant contribution to the improvement of the hemophilia patient’s knowledge, which was very obvious throughout the course of the present study. Giulotto and others (2003) evaluated the impact of Education Program through a comparison between hemophilia patient who attended frequently with those who were infrequently visiting the heredity centers in Kenya. The study found that a Education Program did succeed in increasing hemophilia patient’s knowledge, which was very obvious throughout the course of the present study.

Evaluation of Lipid Profile and Thyroid Function in Hyper and Hypotensive Patients: a Case Control Study

Falah S. Al-Fartusie, Nabaa Nabil, Dheaa Sh. Zgeer

1 Department of Chemistry, College of Science, Mustansiriyah University, Baghdad, Iraq
2 Forensic DNA Center for Research and Training, Al-Nahrain University, Baghdad, Iraq

Abstract

The objective of this study was to evaluate the lipid profile and thyroid function in hyper and hypotensive patients. This case-control study was conducted among the hyper and hypotensive patients from Jan to June, 2018 in Baghdad. The participants were evaluated out of which 40 were hypertensive, 37 were hypotensive and 66 were enrolled as a normal control group. The levels of serum cholesterol, triglyceride, HDL, LDL and VLDL were determined by a spectrophotometer, as well as serum levels of thyroid hormones (TSH, fT4 and fT3) were determined by ELISA technique. The results indicated the presence of a significant increase in serum levels of cholesterol, triglyceride, VLDL and fT4 for patients with hypertension (p<0.05), and a significant decrease in serum level of triglyceride in patients with hypotension when compare with control. In addition, the results show the presence of a significant increase in cholesterol, triglyceride, HDL and VLDL levels as well as a highly significant decrease in fT4 level of patients with hypertension compared with patients with hypotension.

Keywords: lipid profile; thyroid hormones; blood pressure; cholesterol; T4 and T3.

Introduction

Blood pressure is the force exerted by blood on the walls of blood vessels or heart chambers. Blood pressure can be measured in capillaries and pulmonary circulation vessels. However, the term “blood pressure” without any specific descriptors usually refers to systemic arterial blood pressure, which is the blood pressure that flows in the arteries of the circulatory system. In clinical practice, this pressure is measured in mm Hg and is usually obtained by using the brachial artery of the arm. The arterial blood pressure in the large vessels consists of several distinct components, including systolic (higher) pressure and diastolic (lower) pressure 1-4. The systolic pressure happens when the left ventricle is most contracted; the diastolic pressure occurs when the left ventricle is most relaxed prior to the next contraction.

The normal systolic pressure, when the person sitting quietly, is within the range of 100–140 mmHg systolic and 60–90 mmHg diastolic 3,4. Thyroid gland is an endocrine gland, found in the neck and produces thyroid hormones. Thyroid hormones, involving thyroxine (T4) and triiodothyronine (T3), strongly affect energy metabolism, regulate temperature and produce body heat. They also play an important role in the skeleton, muscle and cardiac contraction, memory and sleep 5. Thyroid hormone synthesis depends on factors such as nutritional availability of iodine, and is mostly regulated by the thyroid stimulating hormone (TSH), sometimes called thyrotropin, a hormone produced by the pituitary gland. The synthesis and secretion of TSH is stimulated by the hypothalamic thyroid releasing hormone (TRH) and inhibited through negative feedback of the thyroid hormone itself 6. Thyroid hormones have profound metabolic effects, and the most interesting is increased energy 7. There are two types of intrinsic thyroid diseases, hyperthyroidism (overproduction) and hypothyroidism (underproduction). Hypothyroidism is a common disorder known as the high concentration of TSH with low concentrations of fT4, the most common in women.
This is often caused by autoimmune thyroiditis where the immune system produces antibodies against normal thyroid tissue and/or antibodies that inhibit TSH receptors. Thus interfering with the natural regulation of thyroid hormone synthesis. The lipid family contains several different structures with different functions, including fatty acids, triglyceride (TG), phosphate lipids and cholesterol. It has the ability to bind with protein to form lipoproteins, the form that enables lipids to be soluble and transport in human plasma. The lipoproteins are divided into four groups: Chylomicrons, low-density lipoproteins (VLDL), low-density lipoproteins (LDLs) and high-density lipoproteins (HDLs). LDL particles increase the risk of cardiovascular disease and arteriosclerosis. Although the pathogenesis of atherosclerosis remains poorly understood, the accumulation of modified lipoproteins in vessel walls, such as oxidized LDL and other lipid metabolites, is thought to create a lipotoxic environment. It has been found that thyroid hormones play an important role in regulating the metabolism of lipid. Thyroid dysfunctions can result in lipid abnormalities that increase the risk of endothelial dysfunction, hypertension and cardiovascular disease.

Accordingly, this study was designed to evaluate the lipid profile and thyroid function in Iraqi patients with hyper and hypotension.

Materials and Method

Patients and Controls

This study was conducted between Jan and June 2018, at the Dubai Laboratory / Almaghrib Street and clinical laboratory at Chemistry department/ College of Science/ Mustansiriyah University, Baghdad, Iraq. The study included 40 people (male and female) with high blood pressure, 37 with low blood pressure and 66 healthy people. Patient’s ages ranged between (15-75) years and healthy volunteers between (15-72) years. Patients were collected from Baghdad Teaching Hospital. The symptoms and signs of the disease were diagnosed by specialist doctors in the hospital.

Sample Collection and Preparation

Five millilitres of blood, of each individual of patients and healthy control, were withdrawn from vein. Blood sample was placed in a gel tube and allowed to clot on bench for 20 min, then centrifuged at 3000 rpm for 10 min. The obtained serum was stored in a refrigerator at −20 °C for subsequent analysis.

Sample Analysis

Serum levels for lipid profile (cholesterol, triglyceride and HDL) were determined using colorimetric method by following the protocol of the commercially available Linear kits (Spain). LDL and VLDL were also calculated. The serum levels of TSH, fT3 and fT4 were determined by an automated ELISA microplate reader analyzer, model IRE 96-SFRI - MedicalExpo (SPAIN), following the protocol of the commercially available AcuBind TSH Elisa kit supplied by Monobind Inc. (USA), Bioactive diagnostic fT3 and fT4 Elisa kits supplied by bioactiva diagnostica GmbH (Germany).

Statistical analysis

All data were analyzed using descriptive statistics and ANOVA one way test of the Statistical Package for Social Sciences (SPSS) program version 20.0. The resulting values were expressed as mean ± standard deviation (SD). Pearson’s correlation analysis was also carried out to determine the relationships between all study variables. The statistical tests were significant at $p <0.05$ and highly significant at $p <0.01$ with a confidence interval of 95%

Results and Discussion

All obtained data were analyzed statistically and presented as mean ± standard deviation. The $p$ values were also included to verify differences in levels of study parameters between patients and control. The calculated mean values ± SD of lipid profile (cholesterol, triglycerides, HDL, LDL and VLDL) in sera of control, patients with low blood pressure and patients with high blood pressure are summarized in Table 1. The results indicated the presence of a significant increase in serum levels of cholesterol, triglyceride and VLDL for patients with high blood pressure when compare with control. While no significant differences were found in HDL and LDL levels. The results also indicated the presence of a significant decrease in serum level of triglyceride and non-significant differences in cholesterol, HDL, LDL and VLDL for patients with low blood pressure in comparison with control. In addition, the results show the presence of a significant increase in cholesterol, triglyceride, HDL and VLDL levels of patients with high blood pressure compared with patients with low blood pressure, while no significant difference was found in LDL level. The mean values ± SD of thyroid hormones (TSH, fT4 and f T3) for the three study groups were calculated from
the obtained data and the collective results are presented in Table 2. The serum mean values ± SD of thyroid hormones indicated the presence of a significant increase in fT4 concentration in patients with low blood pressure compared with control group (p<0.05), as well as a highly significant decrease in fT4 concentration patients with high blood pressure compared with patients with low blood pressure group (p<0.001). No significant difference was detected between patients with low blood pressure and control groups. In addition, the results further statistically reveal no significant difference in levels of TSH and fT3 between both patients groups and control group (p>0.05). The correlation between all lipid profile and thyroid hormones parameters included in this work was studied for hypertension and hypotension groups, respectively, using Pearson correlation analysis. The collective results are displayed in Tables 3 and 4. The analysis showed no correlation between all parameters and in both cases, hyper and hypotension. Hypertension affects approximately 26% of the adult population worldwide. Hypertension is an independent indicator of cardiovascular disease and cerebrovascular disease leading to death. It should be noted that most blood pressure studies may focus on high blood pressure, while studies on low blood pressure are rare. Unlike high blood pressure, low blood pressure is not associated with serious illness or death, and it is widely accepted that lower blood pressure is better than elevation. However, most studies, based on whether low blood pressure can lead to adverse health outcomes, have shown that low blood pressure is associated with physical or mental symptoms or illnesses. It has been reported previously by Hitesha et al. that the levels of cholesterol, triglyceride and VLDL in hypertensive patients were significantly higher than those in normal persons, and these results are consistent with the current work results. A previous study conducted by Choudhury et al. has reported that the serum levels of cholesterol, triglyceride and LDL were higher in hypertensive patients than those of healthy subjects, which agree with the results obtained in this work. Similar results have suggested an association between hypertension with risk factors such as hypercholesterolemia. Also it was found that the hypertensive patient is more likely to have metabolic syndrome compared to the normal person, and increased serum lipid profile is associated with high blood pressure cases. The results of the present study strongly support this point where similar findings were recorded, see Figures 1-4. It was found that hypertension was directly associated with high levels of triglyceride, cholesterol and LDL during pregnancy, suggesting that lipid profile plays a vital role in regulating blood pressure for pregnant women.

**Conclusion**

Although valuable information is available about blood pressure disorders, its association with thyroid disorders remains unclear. The current study did not show a clear association between TSH and FT3 levels and high blood pressure. The results obtained show that the level of FT4 of healthy subjects is hardly affected relative to those in hypotension patients giving a positive indication of the presence of a significant association...
between this hormone and blood pressure. More studies are recommended to understand the mechanism of the relationship between thyroid hormones and blood pressure. Moreover, the current study suggests that biochemical distortions in lipid profile (especially cholesterol, HDL and VLDL) are clearly associated with BP disorders. Furthermore, from Pearson’s correlation analysis we can conclude that there is no association between thyroid hormones and lipid profile. More importantly, the current study confirms that serum cholesterol, HDL and VLDL may be useful in identifying patients at risk of hypertension because they are useful tests that provide important diagnostic information.

Hemodialysis Nurses’ Practices toward Hand Hygiene Performance at Baghdad Teaching Hospitals

Serwan J. Bakey
Adult Nursing Department, College of Nursing / University of Baghdad / Iraq

Abstract
A descriptive study was carried out in order to achieve the early stated objectives. The study was initiated from December 17th, 2017 through May 7th, 2018. A purposive (non-probability) sample of (35) nurses who have been working in hemodialysis units were selected to evaluate their practices toward hand hygiene performance at hemodialysis units in Baghdad teaching hospitals. The data collection process has been performed from March 20th, 2018 until the April 15th, 2018 by observation technique. The nurses’ practice form of the questionnaire was derived from the standard of hand hygiene which was developed by the World Health Organization’s and Centers for Disease Control and Prevention in 2009. Results of the present study revealed that the nurses have high performance of hand hygiene after exposure to body fluid (such as blood). Moreover, nurses use alcohol hand rubs instead of hand washing in delivering care for clients. While, the study revealed that hemodialysis nurses were presented with low performance with other parameters of hand hygiene standards. The study also presented that there was no significant relationship between hemodialysis nurses’ practices toward hand hygiene performance and their demographic characteristics.

Keywords: Evaluation, Nurses practice, Hand hygiene, Hemodialysis.

Introduction
Hospital acquired infections (HAIs) are among the most critical health problems that threaten patients’ lives. HAIs could cause health problems, such as death. Approximately 1.4 million people injure with HAIs, which cause 80,000 deaths in the United States of America (USA). One in every 25 patients is injured by HAIs. HAIs are usually transmitted among patients and healthcare workers through the hands of healthcare providers. Healthcare providers should consider the impact of infection on patients’ lives and should have the appropriate competencies to prevent cross contaminations among patients and themselves. World Health Organization (WHO, 2009) stated that all health care providers should perform hand hygiene before touching a patient, before clean/aseptic procedure, after body fluid exposure risk, after touching a patient, and after touching patients’ surroundings. The program of hand hygiene followed in The Mount Sinai Hospital in New York City depends on continuous education of the healthcare team, the availability of alcohol-based hand rub, the use of illustrated hand hygiene posters, continuous research protocol about hand hygiene, evaluating the application of hand hygiene and provide feedback, and a formal audit. Hand hygiene is the most effective procedure in infection control protocol that has been used to save the life of patients in all health care settings. Nurses, more than other health care team members in their contact with patients, play a major role in infection control and applying hand hygiene procedure to decrease the incidence of infection transmission. Foote (2014) stated that nurses are more likely to perform hand hygiene if they understand its concept and importance. Several published studies recommended to establish further studies to assess nurses’ practices toward infection control measures in hemodialysis units and to demonstrate the outbreaks that occur in HD units which are responsible for increasing

or- sjbakey@my.okcu.edu

incidence of infections between hemodialysis patients. All patients, who are admitted to a hospital, could contract any type of infectious diseases, which might threaten their lives or cause death. The Centers for Disease Control and Prevention stated that “at any given time, about 1 in every 20 patients has an infection related to their hospital care”. Infection injured approximately 722,000 patients in 2011, and it caused 75,000 deaths. Moreover, CDC (2015) reported that approximately half million people are infected by Clostridium Difficile infection every year, and it causes 29,000 deaths, annually. Healthcare workers are in contact with patients, especially nurses, and they should be aware about the standards of infection prevention and control. Hands of healthcare providers can be considered the most common way of infection transmission. Hand hygiene is the most effective procedure in preventing the spread of infection. The failure of applying hand hygiene procedure among healthcare workers is still a significant issue in healthcare settings. Healthcare providers can apply the simplest and cheapest strategy of infection prevention and control, which is hand hygiene.

**Material and Method**

A descriptive study was carried out in order to achieve the early stated objectives. The study was initiated from December 17th, 2017 through May 7th, 2018. An approval was issued from the Iraqi Ministry of Health. The study has been conducted on the Nursing staff who are working in Hemodialysis Units at AL-Yarmouk Teaching Hospital (11 nurses), AL-Kindy Teaching Hospital (12 nurses), and Baghdad Teaching Hospital (12 nurses) in Baghdad city. A purposive (non-probability) sample of (35) nurses who have been working in hemodialysis units were selected. The samples have been selected based on the following criteria:

1. Those who have been working in hemodialysis units.
2. Those that should have one year or more of experience in hemodialysis.
3. Those who are (21) years of age and older.

The data have been collected through the use of a questionnaire and by means of an interview technique and direct observation of the nurses who work in hemodialysis units (the study sample). The data collection process has been performed from March 20th, 2018 until the April 15th, 2018. Each nurse spends approximately a complete shift to document the response. The researcher used a modified questionnaire based on the standards of the hand hygiene which was developed by the WHO and CDC in 2009. The questionnaire consisted of 2 parts. A demographic Data Form; which consisted of (9) items, including gender, age, marital status, level of education, years of experience in hospital, years of experience in hemodialysis units, sharing in training sessions concerned to hemodialysis which established by the hospital, sharing in training sessions concerned to hemodialysis which established by other hospitals, sharing in training sessions related to hand hygiene which established within health institution, and duration of training sessions. Nurses’ practice form; which was comprised of (24) items that concerned with measuring nurses’ practice toward hand hygiene in hemodialysis unit at Baghdad teaching hospitals. Rating and Scoring of the items have been measured according to the following patterns:

Two-point Likert scale is used for rating the items as Yes and No.

The two-point type Likert scale is scored as 2 for Yes, and 1 for No.

The higher grade scoring of the questionnaire (MS) the greater Practice throughout hemodialysis treatment for patients in hemodialysis unit. Nurses with score from 1 – to – 1.24 have low practice toward hand hygiene performance; while, nurses with score from 1.25 – to – 1.75 have moderate practice, and nurses with score from 1.76 – to – 2 have higher practice. Content validity for the early developed instrument was determined through the use of panel of experts (who have had more than 5 years of experience in the job field) to investigate the clarity, relevancy, and adequacy of the questionnaire in order to achieve the present study’s objectives. Determination of reliability of the questionnaire was based on the test-retest method. The formula used for reliability was $r = 0.82$, and reliability is significant at P-value $\leq 0.01$.

**Results and Discussion**

Table (1) presented that the majority of the study sample (54.3%) were female and the remaining were male. Most of them were (21-25) years old and accounted for (57.1%). Moreover, the majority of the sample were married, and they accounted for (57.1%) of the whole
The greater number of the study sample were nursing college graduate and they accounted for (48.6%). Concerning number of years of experience, the majority of the sample (48.6%) having 1-5 years of experience in hospitals; while, (62.9%) having 1-5 years of experience in hemodialysis units. A large proportion of the study sample (42.9%) were sharing in training session which established by the hospital and (37.1%) of them were sharing in training session which established by other hospitals. Most of the study sample (62.9%) were not sharing in training sessions concerning hand hygiene which established by other institutes, and (91.4%) were not sharing in any training session regarding hand hygiene policy in hemodialysis units. Table (2) presented the total score of nurses who work at hemodialysis units concerning hand hygiene performance. It reflected that the majority of the study sample (91.4%) had low practice about hand hygiene performance. Table (3) presented the correlation between demographic characteristics and total score of the hand hygiene performance. It showed that there was no significant relationship (at p value equal or less than 0.05) between nurses’ demographic characteristics and their total score of hand hygiene performance. Table (4) presented the performance of nurses toward standards of hand hygiene at hemodialysis units. The results on table four referred that hemodialysis nurses have high performance of hand hygiene after exposure to body fluid (such as blood). Moreover, nurses use alcohol hand rubs instead of hand washing in delivering care for clients. While, the study revealed that hemodialysis nurses were presented with low performance with other parameters of hand hygiene standards. The findings of the study showed that more than half of nurses who work at hemodialysis units were young female nurses with bachelor’s degree in nursing. Moreover, this study revealed that the majority of nurses have one to five years of experiences in hospital units including hemodialysis units. In addition, most of nurses were not sharing in any training sessions inside or outside the healthcare setting where they work. Sharing in continuing education program has its dramatical impact on improving the compliance of nurses toward hand hygiene performance focusing on hand washing.

**Conclusions**

More than half of nurses were young females, with bachelor’s degree in nursing. More than half of the study sample have one to five years of experience in hospital and hemodialysis unit. More than half of nurses were not sharing in training session in hand hygiene established by hospital and by other hospitals. Most of study sample were within low practice toward hand hygiene performance in hemodialysis units. No significant relationships were found between demographic characteristics and nurses’ performance toward hand hygiene practices.

Intrauterine Growth Restriction is Frequent Obstetric Problem in Mid-Euphrates Region of Iraq: a Case Control Study

Suad Abdulzahra Mutar
Gynecology specialist / Al-Diwaniyah Child and Maternity Hospital / Department of Obstetrics and gynecology / Al-Diwania / Iraq

Abstract

One of the common obstetric conditions in clinical practice is the problem of fetal growth restriction (FGR) which a main cause of mortality and morbidity during perinatal period. The incidence of fetal growth restriction also follow geographic variation since Asian countries account for more than 70% of cases followed by Latin American and African continents. Aim of the study: to make insight on the problem of intrauterine fetal growth restriction in terms of causes, risk factors and outcome in Al-Diwaniyah province in the Mid-Euphrates region of Iraq. The most common risk factor was anemia which was seen 12 (31.6 %) followed by pre-eclampsia, detected in 10 (26.3 %) and then by malnutrition, diagnosed in 6 (15.8 %). Other risk factors included cardiopulmonary disease, smoking and gestation diabetes mellitus, each seen in 2 cases only. The problem of fetal growth restriction is common in clinical practice in the region of Mid-Euphrates region of Iraq with late onset diagnosis and mainly associated with anemia, hypertension and severe eclampsia

Keywords: Fetal growth restriction, Mid-Euphrates region, Iraq

Introduction

One of the common obstetric conditions in clinical practice is the problem of fetal growth restriction (FGR) which a main cause of mortality and morbidity during perinatal period. Fetal growth restriction is of two main types according to gestational age, early onset and late onset subtypes. Early onset subtype is usually detected before 32 weeks gestation and differs from late onset subtype in several aspects such as severity of placental dysfunction, mode of deterioration, association with hypertension and clinical manifestation. The list of causes of fetal growth restriction is relatively long and included heterogeneous conditions that can be categorized as maternal, fetal, placental and environmental; however, fetal growth restriction may be described as placental mediated one and non-placental mediated one. Maternal causes include disorders that affect placental function such as chronic hypertension, gestational hypertension, pre-eclampsia, autoimmune disorders, vasculitis and diabetes in addition to disorders that are associated with hypoxemia such as hematological, respiratory and cardiac disorders. Fetal causes include genetic and chromosomal abnormalities, structural defects, inborn error of metabolism and congenital infections. Several other risk factors have been blamed including smoking, alcoholism, age more than 35 years, nulliparity and twin pregnancies. The definition of fetal growth restriction has been a matter of debate since no single definition is widely accepted. “The American College of Obstetricians and Gynecologists (ACOG) defines FGR as an estimated fetal weight less than the 10th centile.” The Royal College of Obstetricians and Gynaecologists (RCOG) uses fetal abdominal circumference (AC) or estimated fetal weight (EFW) <10th centile to diagnose a FGR fetus.” Other Authors have suggested a cut off of the 3rd centile to detect pregnancies at higher risk of adverse outcomes. The incidence rate of fetal growth restriction is substantially higher in developing countries in comparison to that in developed nations; furthermore the incidence rate is much higher in countries with low to middle income because many children are delivered in home with no antenatal records. The incidence of fetal growth restriction also follow geographic variation since...
Asian countries account for more than 70% of cases followed by Latin American and African continents. The present study was carried out in order to make insight on the problem of intrauterine fetal growth restriction in terms of causes, risk factors and outcome in Al-Diwaniyah province in the Mid-Euphrates region of Iraq.

**Methodology**

The present case control study was carried out in Al-Diwaniyah child and maternity hospital, Al-Diwaniyah province, Iraq. The study started on January 2017 and ended on February 2018. The study included two groups, a control group and a study group. The study group included 38 women with intrauterine fetal growth restriction diagnosed based on clinical and ultrasound findings. The control group included 48 women with apparently normal pregnancy with comparable gestational age. Assessment of amniotic fluid volume and placental blood flow was carried out using conventional and color Doppler ultrasound examinations, respectively. Ethical approval was obtained from the Ethical approval committee of the college of medicine / University of Al-Qadisiyah. Verbal consent were obtained from each women enrolled in the current study after full explanation of the aim and the procedures of the present study. Statistical analysis was carried out using SPSS version 23 statistical software and Microsoft Office excel. Data were expressed as number, percentage, mean, standard deviation and range. Independent samples t-test was used to evaluate difference in mean values between both groups, whereas, chi-square and or Fischer exact tests were used to study associations between categorical variables.

**Results and Discussion**

In this cases control study, the mean age of women in the study group was 28.63 ± 5.84 years and that of control group was 28.25 ± 5.82 years. There was no significant difference in mean age between the two enrolled groups (P = 0.764), as shown in table 1. Neither study group nor control group included women older than 35. We tried to select members, to be involved in the control group, in such a way that the gestational age in both groups is comparable. Therefore we obtained a control group with mean gestational age having insignificant difference in comparison with that of study group, 33.88 ± 1.85 years versus 33.63 ± 1.78 years, respectively and the level of significance was 0.539, as shown in table 2. In most cases of intrauterine fetal growth restriction the diagnosis was made after 32 weeks gestation (late onset) accounting for 34 out of 38 (89.5 %), whereas early onset fetal growth restriction was detected in 4 cases only (10.5 %), as shown in table 2. Findings of color Doppler ultrasound examination are shown in table 3. Findings were categorized into three major categories, oligohydramnios, absent end diastolic flow (EDF) and reverse end diastolic flow. In most cases the main finding was oligohydramnios which was seen in 24 cases (63.2 %) followed by absent EDF, recognized in 18 (47.4 %) women and then finally by reverse EDF, detected in 6 (15.8 %) of women. Color Doppler ultrasound examination revealed normal blood flow pattern in all women included within the control group, as shown in table 3. Possible risk factors of intrauterine fetal growth restriction were presented in table 4. The most common risk factor was anemia which was seen 12 (31.6 %) followed by pre-eclampsia, detected in 10 (26.3 %) and then by malnutrition, diagnosed in 6 (15.8 %). Other risk factors included cardiopulmonary disease, smoking and gestation diabetes mellitus, each seen in 2 cases only. Women enrolled in the control group had none of the above mentioned risk factors. The main objective of the current study was to highlight the problem of intrauterine fetal growth restriction and to identify main causes and risk factors since great geographical variation in the causes and risk factors of fetal growth restriction is described in the pool of available published literatures. Here in Al-Diwaniyah province (Mid-Euphrates region of Iraq), we found that the main associations in terms of pathophysiology are either oligohydramnios or placental blood flow inadequacy. Therefore the causes of oligohydramnios should be recognized and treated as early possible in order to avoid the outcome of fetal growth restriction. In addition causes of placental blood flow restriction such pre-eclampsia (PE), anemia, malnutrition and gestational diabetes should be treated adequately and promptly. In this study, unfortunately the diagnosis of fetal growth restriction is late in the majority reflecting poor antenatal care and or underdiagnosis of the problem early during pregnancy. Therefore, it is recommended to bring the attention of heath care workers in the field of obstetric to the size of this problem that is the fetal growth restriction, in terms of child morbidity and mortality and possible ways to reduce the incidence rate of this problem. As we said previously, oligohydramnios was the main finding during ultrasound examination of women.
with intrauterine fetal growth restriction. Amniotic fluid volume evaluation is a routine aspect of ultrasound examination during pregnancy. Oligohydramnios is accompanied by small babies for gestational age and perinatal death, even though its predictive role for individual risk for the outcome is not good. Therefore, Amniotic fluid volume assessment should not be regarded as the only way of detecting intrauterine growth restriction. Nevertheless, in addition to Doppler examination or as an element of biophysical profiles, it may offer more clinically acceptable information on fetal status. Amniotic fluid volume assessment can be done by objective (single deepest pocket and amniotic fluid index) and or subjective (based on the doctor’s visual inspection) methods. It is advised to estimate amniotic fluid volume objectively when either subjective ways suggest reduced volume or in women with higher risk of fetal growth restriction. The main risk factors identified in this study were anemia, pre-eclampsia and chronic hypertension. Importantly, anemia during pregnancy has a number of effects on fetal growth. It is a well recognized fact that there is a physiological decline in the level of hemoglobin in the mid-trimester. This physiological decline is due to rise in volume of plasma, and hence reduction in blood viscosity. This helps in better circulation throughout the placenta. The lowest hemoglobin value of this decline is variable, and therefore the criteria for detecting anemia in pregnancy should be defined strictly. Anemia during pregnancy, according to WHO, has been defined as hemoglobin level of less than 11 g/dl during pregnancy. Anemia in pregnant ladies has been considered as detrimental to the fetal growth. Preterm labor and Low birth weight have been frequently linked to anemia during pregnancy. A lot of studies have been carried out during the last decades aiming at exploring the role of anemia in pregnancy and iron on the growing fetus; however, the results of these studies were either inconclusive or supportive of the previous notions held so far about anemia and pregnancy outcome. Chronic hypertension and severe pre-eclampsia were also recognized in the current study as risk factors in association with fetal growth restriction. This finding has been established in previous studies. In conclusion, the problem of fetal growth restriction is common in clinical practice in the region of Mid-Euphrates region of Iraq with late onset diagnosis and mainly associated with anemia, hypertension and severe eclampsia.

**Conclusion**

The most common risk factor was anemia which was seen 12 (31.6 %) followed by pre-eclampsia, detected in 10 (26.3 %) and then by malnutrition, diagnosed in 6 (15.8 %). Other risk factors included cardiopulmonary disease, smoking and gestation diabetes mellitus, each seen in 2 cases only. The problem of fetal growth restriction is common in clinical practice in the region of Mid-Euphrates region of Iraq with late onset diagnosis and mainly associated with anemia, hypertension and severe eclampsia.

Investigating of Geriatric Depression among Elderly in Nasiriyah City

Hussein Jassim¹, Alaa M Tuama¹, Hassan Alwan¹
¹College Nursing, University of Babylon, Iraq

Abstract

As the world’s population ages, depression has been highlighted as a global public health concern and a significant risk factor for morbidity and mortality among older adults. Objective: To Investigating of Geriatric Depression among elderly in Nasiriyah City A descriptive cross-sectional study was conducted at the community based population, A purposive “non-probability” sample of (300) participants who were selected from the community based population, health care center, key card offices and Geriatric Homes in Thi-Qar for the period from February 15th 2018 to April 26th of 2018. The study results have indicated that more than half of participants are within 65-74 years-old (n=209; 69.7%), their gender is approximate; (n=155; 51.7%) for male; more than half of them are Illiterate (n=165; 55.0%); more than a third of the elderly are occupying Housewife and Retired equally (n=118; 39.3%), the majority of them live in urban areas (n=219; 73.0%); less than half of them report that their monthly income is Enough (n=131; 43.7%) , The result reveals that more than third of participant has a Suggestion depression (n=114; 38%), in contrast to the less than quarter of participants who have Indicative depression (n=73; 24.3%).

Keywords: Investigating; Geriatric; Depression.

Introduction

Elderly population is increasing larger than ever before, with the expansion majority surviving beyond the age of 65. The U.S. population elderly than age 65 is expected to double from approximately 35 million in 2000 (13% of the total population) to 72 million in 2030 (20% of the population) ¹. Old age is a gradual, continuous process of natural change than begins in early adulthood. During early medium age, many bodily functions begin to gradually diminish. People do not become old or elderly at any specific age. Traditionally, age 65 has been designated as the beginning of old age. Many years ago, age 65 was chosen as the age for retirement in Germany ². Over the last twenty-five years, there has been a growing emphasis in the field of gerontology to examine issues related to diversity across racial and ethnic groups ³. The number of adults aged 65 and elderly is projected to rise to 72.1 million by 2030-up from 40.3 million in 2010 ⁴. Many people elderly than age 65 live happy and healthy independent lives. Some alterations in the ability to think are considered a normal part of the aging process. Most healthy elderly people experience mild decline in some areas of cognition. These changes may happen in the regions of visual and verbal memory, visuospatial abilities, immediate memory or the capability to name objects ⁵. Research indicates that age-related changes in the mined such as reduced hippocampal, frontal and temporal lobe volumes can happen although, the extent to which these age-related changes contribute to cognitive decline has yet to be determined. Non-verbal memory weakness are also considered to be a recurrent cognitive deficit associated with aging. Control and maintenance of attentiveness and immediate memory can be affected in normally aging individual ⁶.

Methodology

A descriptive cross-sectional descriptive sample of 300 elderly people in the community, health care center, cardiology offices and geriatrics was conducted in Thi-Qar from November 11, 2017 to June 2018. The
inclusion criteria are met. A purposive sample is “Non-probability” of 300 elderly who were selected out from the above mentioned areas and the study sample meets the inclusion criteria, this means are subjects chosen according to specific criteria. The present study is conducted in Thi-Qar Governorate; at the community based population, key card offices, health care center and Geriatric Homes in Thi-Qar.

**Administrative Arrangements**

An official permission has been obtained from the Ministry of Planning / Central Statistical Organization (CSO) for the acceptance of the questionnaire draft. Another approval was obtained from the Ministry of Health by a contract between College of Nursing, and initial agreements of the Ministry of Health/Directorate Health Thi-qar Governorate/ Training Center and Research Development (TCRD) , and Health care centers, As well as a formal permission was obtained from Ministry of Labor and Social affairs in order to collect the required data and interviewing each subjects Elderly.

**Data Collection and Instrument**

Data were collected through using a questionnaire designed and developed for the purpose of the study the questionnaire has been constructed after extensive review of available literature and related studies. The study instrument consists of two parts. The first part includes participants’ demographic characteristics of age, gender, level of education,...ets. The second part is related to The Geriatric Depression Scale (GDS) it is a useful screening tool in the clinical setting to facilitate assessment of depression in older adults especially when baseline measurements are compared to subsequent scores. used to identify potential items for the study of instrument. It is adopted from The Hartford Institute for Geriatric Nursing, New York University, College of Nursing. Data were collected by the researcher are from elderly, those who were visits, key card offices, health care center, Geriatric Homes in Thi-Qar and the community based population at Thi-Qar Governorate through interview and by filling a questionnaire format. Reliability of the questionnaire is determined through pilot study “Cornbach’s alpha” which has been (0.85) as well as the validity determined through a panel of experts in the field. The demographic characteristic were obtained through a direct interview with each patients in the study using, adopting and developing questionnaire format. The data collection process had been performed from January( 28)th to February (8 )th 2018. A statistical analysis was performed using the Microsoft office excel 2007 and SPSS package (version 19). Chi- square statistics were used to determine the presence of an association between the variables. These were used to accept or reject the hypothesis , Which include the following :

1. The P. value indicates that the degree of significance was (P ≤ 0.05) to just significant result
2. **Cut-off-point:** 0 - 0.33 = Low; 0.34 - 0.67 = Moderate; 0.68 - 1 = High; H = High; M= Moderate; L = Low.
3. Statistical table (Frequencies & Percentages).

\[
\% = \frac{\sum F}{n} \times 100 \%
\]

**Results and Discussion**

Table (2) describes that more than half of participants are within 65-74 years-old (n=639; 68.7%), their gender is; (n=477; 51.3%) were male, and (n=453; 48.7%) were female, the male to female ratio is (1.1:1) more than half of them are Illiterate (n=519; 55.8%); more than one third of the elderly are occupying Housewife and Retired equally (n=367; 39.5, 361; 38.8 %) respectively, the majority of them live in urban areas (n = 678; 72.9%); less than half of them report that their monthly income is Enough (n=403; 43.3%). Results of the study are the current show in Table (1) was the highest percentage in the reconstruction study participants between the (65-74) age where up frequency 639 and percentage of 68.7,

A study conducted in Angelique Chan et,al showed that 64.8 %women were less than 30 years with age group (60_70) And Because this age group is the most active and vital of the other categories so it is easy to get them sample for research. The study percentage of males in equal with females because researchers have relied upon to be ratio close and gender we find that. The results referred to study sample to that 55.8% of illiterate and the percentage of recurrence was 519, this agree with the study in Boulos Christa1 et,al showed that frequency 350 were illiterate. Because the country was lacking
in education and the lack of educational institutions and the community was the cause of ignorance and scientific backwardness. With regard to the profession was more than half Posts participate are housewives where she was replicated 367 and increase of 39.5%, A study conducted in Mankikar, S. showed that 58% were housewife. And get the appointment the proportion of the men also retired 38.8% because the men in this period was working in institutions military so because the Iraqi society was in that period are working in agriculture and engage the careers military. And because it most of the samples participate are illiterate -with regard to logic housing in the study are from the city so that the Thus reducing the chance of getting a job. However, the results referred to study sample to that 72.9 % in urban and the percentage of recurrence was 678 this agree with the study in Marianne Baernholdt et.al showed that 73.83 %. Due to migration from rural to urban and industrial revolution and also places of study are located in city centers. Consistently less than half of them report that their monthly income is sufficient. This can be attributed that, most of those elderly are depend on others,. The Geriatric Depression symptom in Older Adults are Suggestion depression in severity for the more than third of participants. This result is consistent with the study of Richard, W. and Besdine, MD (2015) who have found that a study carried out by 60 adults aged 65 and over .38.25% of whom were depression. This can be attributed that the results due to several reasons Psychological and social reasons accumulate on the elderly living conditions experienced by the elderly of unity and lack of attention from others and their experiences of loss may have lost his wife and became lonely or lost most of his friends either by death or difficulty meeting them because of illness or illness or lost his job or loss of ability to Earning no longer has goals to achieve .It may be painful because of the boredom of the length of leisure time and not to engage in any work or hobbies, especially neglect his hobbies and activities that gives him happiness to engage in work in previous periods. The findings of the study indicated that there is a high significant relationship between depression levels and the age of elderly people. This study was compatible with (Mecheser, 2005) and (Boralingaiah et al., 2012) and (Abolfotouh et al., 2001) who found relationship between depression and age. The reason for this result is whenever advance of human age will suffer from increased anxiety due to which afraid vulnerability to physical disabilities and losing life, the experience of age and experiments acquired from the life which considered important to overcome depression. In regard, The study about educational level indicates that there is a high significant relationship between depression levels and educational level of elderly people. This study were compatible with Ramchandra and Salunkhe (2014) who found a relationship between depression and educational level. This can be attributed that the human who has learning, achievement and education were in the lowest level of anxiety from illiterate people because the educated person has the ability to understand the situation and deal with it correctly and the educational level were an indicator of vulnerability of elderly about psychological problems faced by (depression).

MicroRNA196a2 rs11614913 Genotypic in Iraqi Newborn Babies with Neural Tube Defects

Alaa Hadi Skakir¹, Rabab Omran¹

¹Department of Biology, College of Science, University of Babylon, Al-Hillah City, Babel, Iraq.

Abstract

Objective: Neural tube defects (NTDs) are complicated human structural deformities occur in newborn babies. The etiology of NTDs is multifactorial contributed both genetic and environmental influences to appear the abnormal phenotype. The analysis of Single Nucleotide Polymorphisms of major contributed genes is still unknown. This paper aimed to investigate miR-196a2 polymorphisms in NTDs newborn patients. The blood samples were collected from newborn babies with NTDs (40 samples) and 40 samples of healthy newborn babies as a control group from August of 2016 to October of 2017. The genotyping of miR-196a2 were performed using Polymerase Chain Reaction-Restriction Fragment Length Polymorphism (PCR-RFLP) method. Results: There were vital variations within the genotype frequencies of miR-196a2 between patients with NTD and control groups using the \( P=0.02 \), \( OR =0.50 \) (0.26-0.95). There were significant variations of the genotype TC of patients (27.5%) and healthier (10%) groups and TT genotype. Whereas CC genotype had not any variation between the studied groups. Conclusion: Our study suggests that miR-196a2 rs11614913 T > C may contribute to NTD susceptibility but this data required further studies with larger sample size to comprehensive data for confirming our findings and providing a profound conclusion.

Keywords: Tube neural defect, miRNA, rs11614913 SNP, PCR-RFLP.

Introduction

Neural tube defects (NTDs) are categorized as the second common of birth defects, including an opening in the spinal cord or brain remains from early in human development. On the gastrulation stage of the third week of pregnancy, the neural tube formed by the changing shape of specialized cells on the dorsal side of the embryo. NTDs developed if the neural tube does not close completely. There are specific types of NTDs including anencephaly (results in little to no brain), spina bifida (affects the spine), anencephaly (results in severe neck problems) and encephalocele which affects the skull [¹]. Structural deformities in mice were studied by deletion of single miRNAs gene or entire gene clusters which resulted incompletely penetrant embryonic phenotypes or defects postnatally. In spite of, there are no evidences that confirmed an absolute requirement for a specific miRNA locus in embryonic development. These findings also showed in other animals like nematodes and zebrafish, which concluded that the miRNAs play a role in fine-tune gene expression rather than had central roles in the embryonic development [²]. There are two clusters of genes encoding multiple microRNAs (miRNAs) by alternative processing such as miR-302c and thus together form a miRNA family [³]. The preliminary role of this family was identified in the regulation of the unique cell-cycle structure of embryonic stem cells (ESCs), and named as ESC cell cycle regulating miRNAs. Since then, multiple functions have been investigated for these miRNAs, including inhibition of ESC differentiation, cell-cycle regulation, promotion of somatic cell reprogramming and inhibition of apoptosis [⁴]. MicroRNAs are small RNA molecules had 21–22 nucleotides in typical length. They are commonly transcribed by the sequential action of two endonucleases (Drosha and Dicer) on primary transcripts.

Corresponding author:
Rabab Omran,

of miRNA, although Drosha-independent processing can occur in certain instances. Mature miRNAs bind to target mRNAs and simplify RNA assembly which induced silencing complex, enhancing mRNA turnover and suppressing translation. Some miRNAs have other functions include up-regulation of translation in some context, influence both positively and negatively of a range of signalling pathways and are implicated in various disease states, particularly cardiovascular, cancer and immune disorders. Also, a specific miRNAs are present in the central nervous system where they influence cell cycling, cell differentiation, and apoptosis during development. It has been reported that folate deficiency and DNA hypomethylation can lead to misexpression of miRNAs which in turn may substantially affect neural development. Owing to the role of folate in the methylation pathway, it is accepted that disturbed methylation may significantly account for the relation between NTDs and folate, reinforcing the epigenetic hypothesis. The aim of this paper was to investigate a single nucleotide polymorphism (SNPs) as a risk factor in a microRNA gene (miR-196a2-rs11614913) and associated with tube neural defect.

Materials and Method

Study subjects

Forty newborn babies with neural tube defects how visited the hospitals in the middle and south of Iraq. In addition to forty of healthy newborn babies as a control group were included in this study.

DNA Extraction

Venous blood was collected from patient and healthy control groups during medical visits, stored at -20 °C until DNA extraction processed.

Genomic DNA from whole blood cells was extracted and purified using Gene aid Extraction and Purification Kit (Germany).

MicroRNA196a2 Genotypic by PCR- RFLP method

The DNA targeted site for identifying pre-microRNA196a2 (rs s11614913) was amplified using specific primer pair (Forward: 5'-CCCCTTCCCCCTCTCCA-3' and the Reverse: 5'- CGAAACCGACTGATGTAAC-3') which were obtained from Bioneer, IDTDNA (USA).

PCR was performed using a TRIO Thermal Cycler (Biometra, Germany) programmed for 2 min pre-denaturation at 94°C; for 35cycles 5 min each at 94°C, 1 min at 57.8°C and 1 minute at 72°C; and a last expansion of 5 min. The reaction volume was 20μl containing 1 μl from each reverse and forward primers, 12.5 μl of Green Master Mix, 3 μl of Genomic DNA and 2.5 μl of the Nuclease free water. PCR products were electrophoresed using 1% agarose at 75 V for 1 h in horizontal electrophoresis (Cleaver Scientific – UK) and visualized by ethidium bromide. Photographs were taken by gel documentation system (Cleaver Scientific –UK). The PCR products were cut by MSPI restriction endonuclease, the PCR-RFLP method was achieved steady with the Promega Company Protocol. After digestion with MSPI reaction were electrophoresed using 2% agarose gel electrophoresis at 75 V for 1 h. After that gels visualized by ethidium bromide. Photographs were taken using gel documentation system.

Statistical analysis

All the practical math analysis was achieved using the SPSS applied mathematics software system (17; SPSS Inc., Chicago, IL) at P-values <0.05.

Results and Discussion

This a study case was conducted on Iraqi newborn patients with neural tube defects (NTDs) who admitted to the Neuro-surgical Department at hospitals and under went to a surgery for repair of NTDs. The table (1) showed gender of patients and control groups. The results showed that the percentage of females to males in patients is more than two folds as in controls. Genomic DNA was extracted from the blood samples of patient and control groups, then targeted region of pre-c was amplified. The amplified product had up to 149bp which appeared in the agarose gel electrophoresis (Fig. 1). After that the PCR products were digested by MSPI enzyme and the polymorphisms of miR-196a2 rs11614913 quality were revealed by PCR-RFLP technique; the existences three genotype polymorphisms, including homozygous genotype (CC) had two bands (125bp and 24bp), homozygous genotype (TT) had one DNA band (149bp) and heterozygous genotype (TC) had three DNA bands (149bp, 125bp and 24bp) as shown in figure (2). The percentage of females to males in patients is more than two folds as in controls, as in table (1) may refer the nature of society that prefers male to female, so the
planned pregnancy mostly for males and unplanned for females. This results agreements with historical study [9] which found that the ratio is 67% (female: male). While the new studies showed that the ratio change after fortification with folic acid [10]. The miR196a2-rs11614913 T>C polymorphism was studied in NTDs cases and controls as shown in table (2), which revealed the highest genotype in the control group was CC homozygous genotype (47.5%) followed by the mutant homozygous genotype TT (42.5%) and heterozygous genotype TC (10%). In neural tube defects, the highest genotype was CC homozygous (55%); the genotyping distribution pointed out that normal homozygous TT was 17.5% and mutant heterozygous TC, which reached to 27.5%. MicroRNAs (miRNAs) are small noncoding RNAs that regulate posttranscriptional gene expression. The presence of specific miRNAs is enriched in the central nervous system where they influence cell cycling, cell differentiation, and apoptosis during development [11]. It has been reported that folate deficiency and DNA hypomethylation can lead to mis-expression of miRNAs which in turn may substantially affect neural development, among the subset of miRNAs known to be regulated by methylation [12]. Recent evidence supports this line of reasoning. It is interesting to note that at least half of the promoter regions for miRNAs are predicted to be in close proximity to CpG islands and their methylation frequency is predicted to be at least an order of magnitude higher than that of protein-coding genes. Removal of individual miR-196 paralogs alone revealed partially penetrate homeotic patterning defects. In 196a2 or 196b single-mutant embryos, the presence of an ectopic rudimentary rib nubbin on the first lumbar vertebra indicated an anterior homeotic transformation of this element. Additionally, miR-196a have been shown to target multiple Hox genes, some of which are implicated in NC development HDAC4 is required for the generation of anterior facial structures in zebrafish by modulating the migration of cranial NC cells [13]. The causes of NTDs appear to be complex and multifactorial, involving both genetic and environmental factors. Few single genes have yet been found to be major contributors to NTD susceptibility and, whereas several environmental risk factors are known (e.g. Maternal diabetes, valproic acid), the causes of NTDs is not known or predictable in the majority of cases. Prenatal diagnosis of NTDs provides options for management of affected pregnancies, including elective termination, preparation for postnatal care or, in a few centers, in utero surgery. Finally miRNA biology must be viewed as a crucial facet of neuronal function, particularly with regard to development and plasticity. The rapid pace and excitement of miRNA research derives from the high expectations 3 that much more profound insights will emerge in the near future as the rich vein of miRNA data is further mined and new experiments peel away the details of their functions.

**Conclusion**

Our study suggests that miR-196a2 rs11614913 T > C may contribute to NTD susceptibility but this data required further studies with larger sample size to comprehensive data for confirming our findings and providing a profound conclusion.

Nutritional Status of Older Adults in Al-Nasiriyah City

Hussein Jassim¹, Alaa M Tuama¹, Hassan Alwan¹

¹ College Nursing, University of Babylon, Iraq

Abstract

A good nutrition for a person is essential to the good healthy body and prevents diseases and other health problems, the individual should be provided with knowledge about nutrition and the body nutritional requirement through the lifespan. Objective: To Assessing Nutritional status of Older Adults in Al-Nasiriyah City. A descriptive cross-sectional study was conducted at the community based population, A purposive “non-probability” sample of (300) participants who were selected from the community based population, health care center, key card offices and Geriatric Homes in Thi-Qar for the period from February 15th 2018 to April 26th of 2018. The study results have indicated that more than half of participants are within 65-74 years-old (n=209; 69.7%), their gender is approximate; (n=155; 51.7%) for male; more than half of them are Illiterate (n=165; 55.0%); more than a third of the elderly are occupying Housewife and Retired equally (n=118; 39.3%), the majority of them live in urban areas (n= 219; 73.0%); less than half of them report that their monthly income is Enough (n=131; 43.7%) , The result reveals that This table reveals that less than half of participant has a Risk of malnutrition (n=148; 49.3%).

Keywords: Nutritional status; Older Adults.

Introduction

Nutrition is a group of activities through which vital organs absorb and metabolize nutrients entering the body. The main nutritional characteristics of the body are to nourish the body with basic materials to build healthy body, promote health, prevent disease and keep the body healthy from health problems. Therefore, society must be healthy about the nutrition and nutritional needs of the body during the life span and the person should feed the food containing proteins, carbohydrates and vitamins Suitable for the body to get the perfect nourishment for a perfect hyacinth body. Eating is very important and essential to the human body for the purpose of feeding the body with the basic nutrients and provide him with healthy food to carry out the basic processes of the functions of the body organs regularly. Taking food is considered the best way to measure healthy nutrition and its ease of monitoring and measuring its suitability to the body and also to know its consistency and usefulness, through which we can determine the appropriate nutrition for each person.

Malnutrition is one of the problems that cause the health diseases resulting from lack of the main nutrition needed by the body tissues to maintain the sustainability of the vital activities of the body and that this problem is one of the factors contributing to complications of diseases and therefore malnutrition is divided into two parts either lack of nutrition or increased nutrition is undernourishment Protein is a form of malnutrition, one of the health problems that accompany the elderly in the homes of the elderly and those in the community and the rate of consultation between them estimated about 30-60% over nourishment is a type of malnutrition in people who are obese and it is the cause of this type of malnutrition. Weight gain and obesity are considered to be one of the main problems or the most important issues facing the society in Malta. The BMI rate is more than (25 kg) for women and men over the age of 65 and above in society (72.7%) and (62.5%) respectively.

Malnutrition in the elderly is always accompanied by a lack of daily physical activities and this causes them to many health problems, ranging from malnutrition to the lack of anthropometric measurement when measured for the elderly according to the standards used and that are
accredited to assess the nutritional status of the elderly, an important indicator of the nutritional status. For the elderly, and also through the treatment and improvement of the problem as soon as detected early for the purpose of intervention to take measures and procedures through which the case.

Methodology

A descriptive cross-sectional descriptive sample of 300 elderly people in the community, health care center, cardiology offices and geriatrics was conducted in Thi-Qar from November 11, 2017 to June 2018. The inclusion criteria are met.

Administrative arrangements

Another approval was obtained from the Ministry of Health under a contract between the College of Nursing. The approval of the Ministry of Health / Health Directorate of Dhi Qar Governorate and health care centers was obtained, in addition to an official authorization from the Ministry of Health. Work and social affairs to collect the required data and interview all older subjects.

Data collection and tools:

The data were collected using a questionnaire designed and developed for study purposes. The questionnaire was created after a comprehensive review of available literature and related studies. The study instrument consists of two parts. The first part covers the demographic characteristics of age, sex and education participants, ... etc. Part II on nutrition assessment for older persons is an assessment tool that can be used to identify older persons (65 years) at risk of malnutrition. Used to identify possible elements for instrument study. Adapted from the Hartford Institute of Nursing Elderly, New York University, Faculty of Nursing. The data were collected by elderly researchers, those visiting card offices, the health care center, the aging home in Dhi Qar and the community population in Dhi Qar Governorate through the interview and by completing the questionnaire form. A statistical analysis was performed using the Microsoft office excel 2007 and SPSS package (version 19).

Results and Discussion

Results of the study are the current show in Table (1) was the highest percentage in the reconstruction study participants between the (65-74) age where up frequency 209 and percentage of 69.7, A study conducted in Angelique Chan et al showed that 64.8% women were less than 30 years with age group (60-70). Because this age group is the most active and vital of the other categories so it is easy to get them sample for research. The study percentage of males in equal with females because researchers have relied upon to be ratio close and gender we find that. The results referred to study sample to that 55.0 % of illiterate and the percentage of recurrence was 165, this agree with the study in Boulos Christa1 et al showed that frequency 350 were illiterate. Because the country was lacking in education and the lack of educational institutions and the community was the cause of ignorance and scientific backwardness. With regard to the profession was more than half Posts participate are housewives where she was replicated 118 and increase of 39.0, A study conducted in Kalyobia showed that 58% were housewife. And because it most of the samples participate are illiterate -with regard to logic housing in the study are from the city so that the Thus reducing the chance of getting a job. The results referred to study sample to that 73.0 % in urban and the percentage of recurrence was 219 this agree with the study in Marianne Baernholdt et al showed that 73.83 %. Due to migration from rural to urban and industrial revolution and also places of study are located in city centers, were the results of overall Participants’ Assessing Nutrition in Older Adults there are less than half at risk of malnutrition, This agree with the study of Khin Thandar Aung showed that the elderly have risk of malnutrition because the elderly are in the stage of demolition as well as because of some chronic diseases that limit access to healthy food beneficial to the body and also poor dental health. With respect to high significant association between Assessing Nutrition and their Age, there are between the(65-74) age risk of malnutrition, This agree with the study of Boulos Christa1 et al, showed that age between (65-75) risk of malnutrition frequency 110 and percentage (32.3 %)Due to a change in the quality of life in the elderly were the results to find the relationship between Assessing Nutrition and Level of education, illiterate risk of malnutrition (43.0 %) and frequency 71, a study Boulos Christa1 et al, showed that illiterate risk of malnutrition (38.6 %) and frequency 135, Because of the lack of knowledge about healthy foods, which is why the elderly are more vulnerable to malnutrition. With regard to the association between Assessing
Nutrition and Occupation was more than half Posts participate are housewives where she was replicated 55 and increase of 46.6, A study conducted in Kalyobia showed that 58% were housewife. And because it most of the samples participate are illiterate -with regard to logic housing in the study are from the city so that the percentage of recurrence 117 and percentage 78.0 and because it quality of life take on the nature of the samples participate society are from city in additional to widespread emigration from the countryside to the urban has changed the pattern of city life community.

Pregnant Women’s Knowledge Concerning Tetanus Vaccination in Al-Rusafa Health Sector

Rusul S. Ghazal¹, Eman A. Jaber²

¹Nursing Technology Department, Medical Technical Institute / Baghdad, Middle Technical University, Baghdad, Iraq, ²College of Nursing ALbayan University, Baghdad, Iraq

Abstract

Tetanus Toxoid (T.T) is an inactivated vaccine (antigen) that is given to women of childbearing age (15 years to 49 years) to protect the unborn child from neonatal tetanus. Objectives: To assess pregnant women’s knowledge concerning important of tetanus vaccination. A descriptive analytic study on non-probability sample (purposive sample) of (100) Pregnant women who attend primary health center in Baghdad city during the period from 3-2-2016 to 15-3-2016. The questionnaire form was consisted of 3 parts: Demographic characteristics, pregnant women’s knowledge concerning tetanus vaccination and its importance. The data were collected by using interview method and self-report techniques with study participant. The study showed that the highest percentage (32 %) of study sample at age group (15-20 years), (94%) of study sample they are attending primary health care clinic regularly , The highest percentage (33%) of study was taking the first dose during reproductive age, the highest mean score and relative sufficient according to pregnant women’s knowledge concerning tetanus vaccination (there is disease called tetanus), while the highest percentage related to (Causes of tetanus organism). Concerning reasons for not taking the Routine Booster of the vaccine the highest percentage (52%) was (Crowding the health center).

Keywords: Tetanus Vaccination, Pregnant women, primary health care.

Introduction

Tetanus is a vaccine-preventable disease that causes an annual total of 309 000 deaths¹. Globally every year 309,000 deaths occur due to tetanus. It is estimated that every year worldwide 5% of maternal deaths occur due to tetanus and 14% of all neonates die due to maternal neonatal tetanus, even the end November 2012 maternal neonatal tetanus still remains a public health problem in 31 countries, predominantly in the African and Asian regions, Iraq is still pre validated for maternal neonatal tetanus elimination ². Of particular concern is maternal and neonatal tetanus which represents triple failure of public health in terms of routine vaccinations, antenatal care and clean delivery/umbilical cord care services. Is a swift and painful killer that killed about 200 000 newborns in year 2000³. Tetanus it is caused by the Clostridium tetanus bacteria spores which are ubiquitous in the environment and can be introduced into the body through no intact skin and open wound, usually via injuries from contaminated objects ⁴. Even the end November 2012 maternal neonatal tetanus remains a public health problem in 31 countries, predominantly in the African and Asian regions, Iraq is still pre validated for maternal neonatal tetanus elimination ⁴. The Tetanus Toxoid (TT) vaccine is given during pregnancy to prevent the risk of tetanus as well as unborn baby. Although the tetanus infection is more common when there is a deep puncture wound such as a bite, cut, burn or an ulcer, it may well be caused by a tiny prick or scratch on the skin⁵.

Objectives of this study

The objectives of this study Assess pregnant women’s knowledge concerning important of tetanus vaccination and find out the relationship between...
pregnant women’s knowledge and studied variables.

Methodology

A descriptive analytic study was conducted to assess the Pregnant women’s knowledge concerning Tetanus Vaccination. Non-probability sample (purposive sample) consisted of (100) Pregnant women who attend primary health center. Through using the assessment approach for the period from November 2015to May 2016. The study was conducted at two setting in Al-Russifa health directorate / Al sadder sector and Albaleduat sector in Baghdad city.

The instrument was designed and constructed by the investigator after reviewing related literatures, clinical background and previous studies. The questionnaire form was consisted of (3) main parts: Demographic characteristics, pregnant women’s knowledge concerning tetanus vaccination and its importance .The data were collected by using interview method and self-report techniques Statistical procedures include descriptive statistic (frequency, mean, percentage).

Results and Discussion

Table (1) shows that the highest percentage (32 %) of study sample at age group (15-20 years) while the lowest percentage (8%) of them their age (36 years and more). The highest percentage (41%) of study sample was Secondary school graduated, while the lowest percentage (3%) of them Illiterate. The highest percentage (75%) of study sample were in 16-24wk, while lowest percentage (4 %) in 3> wk. The highest percentage (76%) of study sample they do not work. The highest percentage (94%) of study sample they are attending primary health care clinic regularly. The highest percentage of the study sample (38%) taking the vaccine during previous pregnancy. The highest percentage (33%) of study was taking the first dose during reproductive age. Table (2) shows that the highest percentage according to Pregnant women’s knowledge concerning Tetanus Vaccination (76%) refers to (there is disease called tetanus), while the highest percentage (62%) related to (Causes of tetanus organism) and the highest percentage related to Method of infected (66%) (Use of non-sterile instruments during childbirth). The highest percentage of study sample (66 %) didn’t know (Pain and stiffness in the face and abdomen and arm muscles). The highest percentage (84%) related to (The vaccine is given in the form of injection) and (88%) (The vaccine protects the mother and child and prevent the disease). The highest percentage for not taking the Routine Booster of the vaccine (52%) related to (Crowding the health center).

Table (4) shows that there was statistical significant relationship between level of knowledge and (level of education and occupational status), while there were no statistical significant relationship between level of knowledge and (age, gestational age). The present study revealed that the highest percentage (32%) of study sample at age group (15-20 years).

This data is in line with study of Masuno et al. (2009) that reported the highest percentage (47.2%) for women of reproductive age (15-45) years out of (212) were at age group between (20-29) years with mean. Regarding Level of education the highest percentage (41%) of study sample at secondary school graduated. Hashmi et al.(2011) who reported that education level plays a significant role in the vaccination coverage of mothers during pregnancy and their children. Regarding Gestational age the highest percentage (75%) of study sample were in 16-24wk. Maral et al. (2001) stated that the vaccination women with at least one dose attended more prenatal care visit than the unvaccinated women of the women who attended at least one prenatal care check-up, only about half were vaccinated. Regarding Occupational status, the highest percentage (76%) of study sample not work. The findings of present study were consistent with Naeem et al. (2010) who reported that the most of study sample were housewives (89.8%), while (4.6%) of them were governmental occupation. Regarding attending primary health care clinic, the highest percentage (94%) of study sample they are attending primary health care clinic regularly for receiving the vaccine. The finding of present study were inconsistent with Adugna (2011) reported that the highest percentage of women was unrestricted to go out without the permission of their husband while the lowest percentage (16.8%) of them was restricted. Regarding Take the first dose of vaccine: the study sample (38%) they taking the vaccine during previous pregnancy. Adugna (2011) reported that the (48.3%) of women were immunized in the first trimester and (43%) were immunized during 5-7 months of their pregnancy. The highest percentage (33%) of study was taking the first dose during reproductive age. Roosiermatie et al. (2000) stated that the mothers who performed antenatal care tended to be highest for T.T immunization practice where the mothers who performed antenatal care were 30 times more likely to get TT immunization.
compared with those who never got any antenatal care. Regarding Pregnant women’s knowledge concerning Tetanus Vaccination, the highest mean score and relative sufficient (1.76) refers to (there is disease called tetanus). The finding of present study were consistent with Naeem et al. (2010) which reported that the most of study sample had a knowledge on tetanus toxoid vaccination (31.8%), while a significant number had little knowledge (13.8%) while the highest mean score and relative sufficient related to (Causes of tetanus its organism) (1.62). The finding of present study was consistent with those of Dallak and Al-Rabeei (2012) which reported that the majority of the participants 72.4% heard about tetanus toxoid (TT) vaccine. A majority 62.6% did not believe that vaccination is harmful, only 24.9% believe that the unclean umbilical cord stamp and unclean delivery practice play a role in etiology of tetanus. Demicheli et al. (2015) reported the pregnant women know that the tetanus vaccine has shown to be successful in preventing babies from developing tetanus and deaths from tetanus. Concerning Signs and symptoms of tetanus the low mean score and relative sufficient (1.34) for (Pain and stiffness in the face and abdomen and arm muscles) and Pregnant women’s knowledge concerning vaccination the highest mean score and relative sufficient (1.84) related to (The vaccine is given in the form of injection) and (1.88%) related to (The vaccine protects the mother and child and prevent the disease). Maral et al. (2001) reported about half of pregnant women knew about use of tetanus toxoid for preventing tetanus, among those samples knew some tetanus symptoms, most mentioned one symptom only, was a seizure. Concerning reasons for not taking the Routine Booster of the vaccine the highest mean score and relative sufficient (1.53) related to (Crowding the health center). Hammer et al. (2001) reported that crowding at primary health care clinics on developing countries have effects on type of health care, services and facilities, which is typically provided. The present study revealed that there was statistical significant relationship between level of knowledge and (level of education and occupational status). Duper (2008) who stated that the well-educated reported a greater control over our lives and health.

Prevalence of Septicemia among Under Five Years Children during the Last 5 Years Ago in Hilla City

Community Health Nursing/ Babylon Health Directorate- Iraq, Department of Basic and Medical Science, College of Nursing, Babylon University, Babylon Province, Iraq, College of Nursing/ Babylon University- Iraq, Community Health Nursing, Kut Technical Institute/ Middle Technical University- Iraq

Abstract

The body invades and proliferates living organisms and causes them to have their own symptoms. Infection may include several organisms at the same time and are called co-infection.

Methodology: A descriptive analytic study design was conducted for the period of October 1st to January 2nd 2018. In order to identify prevalence of septicemia in children under than five years. Data collected retrospectively by the used medical records as a statistic for each year of the (2014 to 2018), and analyzed through the descriptive statistic approach.

Results: the study results reveals that (30.9%) a majority of septicemic children prevalence in the 2014 and the low proportion at the year of 2015.

Conclusions: A very large disparity between the years of prevalence that the more time progresses the less prevalence depending on health services. It is need to be conducted to involve a national level and assessed the associated factors with septicemic children.

Keywords: Prevalence, Septicemia, Children

Introduction

Sepsis may be a physiological state caused by the unfold of invasive organisms, or their by-products, through the blood or in different tissue within the body. It’s conjointly referred to as blood disorder 1. Sepsis remains the initial cause of death from infection in spite of improvement in modern medicine included vaccines, antibiotics and intensive care. Is a dangerous and complex hostess response to the infection that affects millions of people around the world every years (2). It Sepsis considered a one reasons ofmortality and morbidity, particularly throughout the primary 5 days of life and in low and middle-income countries 3. Mostly the theater of life condition faced by the in pediatric intensive care units (PICUs) worldwide 4,5. According to the world health organization (WHO), every year 4 million newborns die throughout the 1st month of life, newborn infections are currently the rationale for 1.6 million deaths every year within the developing world, and the 1st cause of newborn mortality is infection 6. More than 40% of beneath-five deaths globally happen within the time of life leading to 3.1 million of newborn deaths each year 7. Sepsis account for about 2% of hospitalizations; it created up 17 % of hospital deaths. If left untreated, infection will lead for a large number of complications including multiple organ dysfunction and even death 8. Critical care nurses should have sound knowledge and strict adherence to sepsis bundle 9. Too, they stay in bestsituation for make sure patientstudied, Viarising their privateawarenessthen consciousness tosepticemia, thereby prevention impairment into starkersepticemia . in place of eachperiod’sinterval in starting management, a patient’s danger of died will increase through seventy six percent 10.

Metodology

The study aims

To identify prevalence of septicemia in children under five years.
Study Design: A descriptive analytic study design was used for the purpose is conducted at Babylon Teaching Hospital for Maternity and Pediatric.

Study Sample: Non probability a convenience sample was were collected retrospectively from medical records as a statistic for each year of the (2014 to 2018).

Data Analysis: In order to determine whether the objectives of the study have met or not, that data of the present study has been analyzed through application of the descriptive statistical (SPSS) version XX analysis approach.

Results and Discussion

Clinical studies have shown that cases of septicemia may be persistent or intermittent. In present study, findings reveals that the (30.9%) out total years were registered by 2014. While it is estimated overall prevalence of severe infection among youngsters living within the u. s. magnified steady from zero.56 cases per one thousand youngsters in 1995 to zero.63 cases per one thousand youngsters in 2000, to 0.89 cases per one thousand youngsters in 2005, with most of this increase because of newborn infection. It is also, prevalence of septicemia in North American country newborns is nine.7/1000 population, non-newborn infants 2.25/1000, and also the rates square measure zero.23 to 0.52/1000 in subgroups of youngsters. Incidence of septicemia has exaggerated over years, in all probability thanks to progressive aging of population, the existence of additional co morbidities and perhaps the liberal use of infection codification, by as well as patients with less severity. however, mortality because infection is clearly decreasing over years, in all probability to improvement in intensive care unit care, though absolute mortality is growing on account of the raise in incidence. Risk factors for infection are the 2 ends of life, male sex, North American nation Negro race, presence of comorbidities and sure genetic variants. Tract infections are the foremost common supply of infection, and, nowadays, gram-positive infections are additional frequent that gram-negative infection in most prospective studies.

Incidence of Neonatal infection may be an important reason for morbidity and mortality of hospitalized newborns and premature infants, infection accounts for fifteen percent of infant deaths. Every 141 babies born within the u. s. every year dies of infection within the initial year of life, with more or less twenty thousand deaths within the time of life (2010) the incidence of baby. Sudan is classed as having created light reach come through. this death rate is sixty per one thousand live births and therefore the under-five mortality is eighty two deaths per one thousand live births. The mortality rate is additionally high starting from thirty four to forty seven per one thousand births.

Prognostic Role of ki-67 Immunohistochemistry in Soft Tissue Sarcoma: Review and Meta-Analysis

Aws Rassul Hussein Al-salih¹, Raad Jawad Kadhim Al-Shaibany²

¹Assistant professor/ FICMS (pathology)/ University of Al-Qadisiyah/ College of Medicine/ Department of Pathology and Forensic Medicine / Al-Diwaniyah Province Iraq, ²Assistant Professor/ FICMS (orthopedic)/ University of Al-Qadisiyah/ College of Medicine/ Department of Surgery/ Al-Diwaniyah Province Iraq

Abstract

Malignant soft tissue tumors or soft tissue sarcomas accounts for less than one percent of all malignant neoplasms affecting mankind; however, they include more than 50 types of mesenchymal tumors based on histological. The number of articles dealing with the subject of Ki-67 immunohistochemistry in soft tissue sarcoma is relatively great since the administration of this marker in the field of surgical pathology; however, the big picture about the definite role of Ki-67 in soft tissue sarcoma requires the collection of these data in a single meta-analysis study. Thus, the aim of present study is to review the role of Ki-67 immunohistochemical expression in soft tissue sarcoma using meta-analysis design. Google search engine was used and the following key words were used in a variety of combination: Ki-67, immunohistochemistry, soft tissue sarcoma, prognosis, grading, role of and survival. Inclusion criteria included any article dealing with the immunohistochemical role of Ki-67 in soft tissue sarcoma of any histological subtype or as a group. In the present study we found that moderate and strong ki-67 expression is associated with < 50 % 5 years survival, whereas, weak ki-67 expression is associated with > 50 % survival.

Key words: Ki-67, immunohistochemistry, soft tissue sarcoma, meta-analysis

Introduction

Malignant soft tissue tumors or soft tissue sarcomas accounts for less than one percent of all malignant neoplasms affecting mankind; however, they include more than 50 types of mesenchymal tumors based on histological classification ¹-⁵. Although, the annual incidence rate of these tumors is relatively low (approximately 200000 new cases per year), these tumors are highly aggressive and often associated with metastasis at time of diagnosis and resistance to conventional chemotherapy. In addition, they arise from cells that belong to a variety of cell lines which make the picture more complex ⁶-⁸. Treatment, for that reason, should be tailored according to a constellation of clinicopathological parameters in order to increase survival rate and to improve quality of life of individuals suffering of these horrible tumors ⁹-¹². Currently, a number of prognostic parameters are often used to describe these tumors such as status of surgical resection, size of tumor, histological grade and depth of invasion; however, the best identified indicator to establish tumor prognosis and to define best treatment plan ¹³-¹⁶. Traditional histological grading has been proved to be an effective way in case of soft tissue sarcomas; however, a substantial area of discrepancy between histological grading and biological behavior merits the search for another way to improve grading and hence therapeutic approach to such tumors; of the well known immunohistochemical markers, Ki-67 has been used extensively with this regard ¹⁷. This nuclear and nucleolar protein has been shown to correlate well with somatic cells proliferative activity and it activity is lacking in case of quiescent tissues ¹⁸-²². Therefore, Ki-67 immunohistochemical expression is considered an effective way to establish proliferative
activity of malignant cells in soft tissue sarcoma giving an impression about prognosis and biological behavior in addition to some utilization in supporting the diagnosis of some forms of soft tissue malignancies \(^{23-30}\). It has been shown that high immunohistochemical expression of Ki-67 is correlated to distant metastasis and poor prognosis. Despite the general acceptance that Ki-67 is a helpful immunohistochemical marker in characterization and defining the prognosis of soft tissue malignancies, a consensus about the detailed aspects is lacking such as the correlation of Ki-67 to necrosis, aneuploidy, depth of invasion, histological grade, metastasis and survival rate \(^{23-30}\). The number of articles dealing with the subject of Ki-67 immunohistochemistry in soft tissue sarcoma is relatively great since the administration of this marker in the field of surgical pathology; however, the big picture about the definite role of Ki-67 in soft tissue sarcoma requires the collection of these data in a single meta-analysis study. Since this aggregation of data may disclose some vague aspects about the role of Ki-67 immunohistochemistry in soft tissue sarcoma and may highlight the exact prognostic contribution of this marker. For that reason planning and conductance of this study were justified.

**Materials and Method**

To review data concerning the role of Ki-67 immunohistochemistry in soft tissue sarcoma, Google search engine was used and the following key words were used in a variety of combination: Ki-67, immunohistochemistry, soft tissue sarcoma, prognosis, grading, role of and survival. The aim was to obtain the highest number of published articles dealing with this subject. Inclusion criteria included any article dealing with the immunohistochemical role of Ki-67 in soft tissue sarcoma as a group; whereas, articles dealing with the assessment of Ki-67 activity using methods other than immunohistochemistry or dealing with other categories of malignant tumors (non mesenchymal) or those that deals with individual histological subtype of soft tissue sarcoma, were excluded from the present study. No limitation for time period was regarded and any article published in the web and fulfills the previous mentioned inclusion criteria, whatever the year of publication, was selected. Data were then transformed into a Microsoft Office 2010 Excel spread sheet and analysis was performed using this software in addition to statistical package for social sciences (SPSS) version 23.

**Results and Discussion**

Studies enrolled in the current study are shown in table 1. Study (1) has been carried out by Ueda et al. in 1989 on 34 patients with malignant soft tissue tumors. Study (2) has been carried out by Choong et al. in 1994 on 182 patients with malignant soft tissue tumors. Study (3) has been carried out by Drobnjak et al. in 1994 on 174 patients with malignant soft tissue tumors. Study (4) has been carried out by Rudolph et al. in 1997 on 132 patients with malignant soft tissue tumors. Study (5) has been carried out by Levine et al. in 1997 on 65 patients with malignant soft tissue tumors. Study (6) has been carried out by Aydin et al. in 2000 on 35 patients with malignant soft tissue tumors. Study (7) has been carried out by Hoos et al. in 2001 on 47 patients with malignant soft tissue tumors. Study (8) has been carried out by Sorbye et al. in 2012 on 249 patients with malignant soft tissue tumors. Study (9) has been carried out by Campos et al. in 2013 on 65 patients with malignant soft tissue tumors. In all these studies, with the exception of that of Ueda et al., the method of estimation of Ki-67 immunohistochemical expression was percentage of positive cells out of 1000 tumor cells counted in multiple fields of slides representative of the malignant soft tissue tumor, whereas, the method used by Ueda et al., was based on counting the number of positive cells per 10 high power microscopic fields (HPF), as shown in table 1. Five studies outlined the number of case with corresponding Ki-67 immunohistochemical expression, as shown in table 2. The expression of Ki-67 was considered negative when no cell stained by all studies included in the present meta-analysis; however, the expression of positive results was variable. In some studies, authors refer to positive and negative expression only such as the study of Rudolph et al., others used the system of < 10 %, 10-50 % and > 50 %, such as that of Sorbye et al., and Campos et al., whereas others used more detailed system of < 10 %, 10 - < 25 %, 25 - < 50 %, 50 - <75 % and 75 – 100 %, such as the studies of Choong et al., and Aydin et al. We tried to unify the results in one system and we got the following results: 604 cases out of 663 were positive accounting for 91.1 %, as shown in table 3; the rate of expression was 26.2 %, 33.7 % and 30.1 % as weak (< 10 %), moderate (10-50 %) and strong (> 50 %), as shown in table 4. Two studies described the association between ki-67 immunohistochemical expression, as weak versus moderate and strong, and the 5 years overall survival of
patients with malignant soft tissue tumors, as shown in table 5. In the study of Campos et al., the 5 years survival of patients with moderate to strong Ki-67 expression was lower than patients with weak Ki-67 expression. Similar finding was shown by Sorbiye et al., and the pooled results were that patients with weak Ki-67 expression had more than 50 % chance of achieving 5 years survival, whereas those with moderate to strong Ki-67 expression had < 50 % chance of achieving 5 years survival, as shown in table 5. From clinical perspective, accurate anticipation of the biological behavior of malignant tumors in general and particularly malignant soft tissue tumors, is a pre-requisite in order to establish the best treatment plan and therapeutic approach in those unfortunate patients (12-14). A lot of published articles raised the issue of finding the most prognostic indicator whether or histological associated with malignant soft tissue tumors (39, 40). Nevertheless, with the exception of histological grade, no single indicator has got wide acceptance as the single or the solely dependent factor with this regard. We believe that reviewing all articles dealing with the subject of soft tissue tumor prognosis and biological behavior should be considered with analysis that is directed to a single factor at a time and then get the big picture, as a large number of cases are going to be involved, about any single indicator. Actually we prefer to start with Ki-67 immunohistochemical analysis for several reasons. First of all, immunohistochemistry is available in all hospital laboratories in Iraq and it is relatively cheap technique and easy to be applied to paraffin embedded tissue blocks. The second reason is that, lot literatures found significant positive correlation between histological grade of most soft tissue tumors and Ki-67 immunohistochemical expression and it is well known that treatment of these tumors is based primarily on histological grading beside other characteristics. On the other, thirdly, Ki-67, since discovery and till now is seen in published articles dealing with subject of tumor prognosis (30-38).

Seroimmunological Study for Detection of Hepatitis B Surface Antigen among Healthy Blood Donors in Diwaniyah –Iraq

Abdulameer K. Leelo¹, Saeed hilal khudhair², Radhia Hussain Fadel³

¹M.B.Ch.B, MSc, PhD Microbiology University Of Al-Qadisiyah, College of Nursing, Iraq, ²University of Al-Qadisiyah, College of Nursing, Iraq, ³College of Health and Medical Techniques/Kufa, Al-Furat Al-Awsat Technical University, 31003 AL-Kufa, Iraq

Abstract

The aim of the study: was to evaluate the occurrence of HBsAg among healthy blood donors (BD) in Diwaniyah -Iraq by immunoassay. This study includes immunoassay for detection of HBsAg in (26318 BDs, 113 females &.26205 males during 2015 and 27657 of the BDs 27581 males & 76 females during 2016). All blood donors positive for HBsAg are clustered according to the age groups also distributed according to the residency whether rural or urban. HBV The study was carried out from January 2015 till December 2016 for detection of Hepatitis B Virus (HBV) (Hepatitis B surface Antigen HBsAg) by enzyme immunoassay We detected that in Diwaniyah BDs, during 2015 were 39 of them have hepatitis B viral infection (0.149%) of the total BDs, 23 of them from urban area (58.97%) and 16 live in rural area (41.03%). While during the year 2016 the seropositive BDs we find that 44 seropositive for HBsAg represented 0.16 % of the total BDs, 29 BDs live in urban area (65.9%) whereas 15 BDs live in rural area (34.1%) all of them were males and none of the females seem to us infected during 2015 & 2016.

Keywords: Blood donor, Diwaniyah Iraq Hepatitis B Surface Antigen.

Introduction

Chronic hepatitis B virus (HBV) infection remains a serious threat to public health and it is associated with cirrhosis and liver cancer. Transmission of HBV occurs through contact of normal persons with the body fluids, blood or Blood components of an infected person. The World Health Organization approves that all blood donations should be -screened for hepatitis B virus to guarantee blood safety and evade any chance for the transmission of the virus to patients who receive blood or blood components. Particularly in developing countries Hepatitis B virus (HBV) infection is a risk to human health, with the high occurrence. Persons with measurable Hepatitis B Virus surface antigen(HBsAg) for six months intermission are regarded as chronic carriers of HBV. Subsequently worldwide infant vaccination happening nationally in 1992 against the Hepatitis B Virus (HBV), in the past years, vaccination has led to a 70–90 % reduction in chronic HBV infection rates all over the world. The first serological hallmark of acute hepatitis B virus infection an envelope protein on the surface of HBV; called Hepatitis B surface antigen (HBsAg). When circulating hepatitis B surface antigen (HBsAg) is detected usually diagnosed immune response produces anti- HBsAg as part of the normal immune defense mechanism trying to eliminate the infection. Strong humoral and cellular immune reaction, will result in loss of obvious antigenemia and viremia in the infected patients. The IRAQ national occurrence ratio of HBs Ag in the years 2005-2006 was 1.6% and the seropositive rate of anti-HBs antibodies was 17%. Iraq, regarded as a low endemic area for HBV and. The typical mode of infection is transfusions of blood. From the year 2013 till now in Iraq, analysis for HBV is done by ELISA machine in district laboratories. The typical diagnostic specimen used for serological tests of HBV infection is blood. Screening viral antigens
and antibodies can be accomplished on either serum or plasma. Together HBV antigens and antibody are unchanging at room temperature for days, at 4°C for months, and for many years if it froze at -20°C to -70°C.

Materials and Method

The study was accomplished in the (Central Public Health Laboratory in Diwaniyah Governorate from January 2015 till December 2016). Diwaniyah lies 180 km south of Baghdad This study includes immunoassay for detection of HBsAg in (26318 BDs, 26205 males & 113 females. during 2015 and 27657 BDs, 27581 males & 76 females during 2016) (figure1 & 2). All BDs that are positive for HBsAg were clustered according to the age groups (table 1) also distributed according to the residency whether rural or urban (figure 3 & 4). The present study was agreed ethically (the committee of Al Qadisiyah Nursing College).

All blood donors in Diwaniyah (at the Blood Transfusion Center) (BTC) must be completing the immunoassay for detection of HBsAg as a general measure of the World Health Organization aimed to safe blood donation one 9 The thorough history and scientific medical inspection were carried out for all the donors by experienced staff expert to detected donors who are suitable for blood donation. Donors who did not fulfill WHO criteria were omitted from donating blood and hence excluded from the study. At the time of blood donation 5-ml Blood Samples for recognition of HBsAg were collected from the primary blood bag placed in a plain test tube for ELISA (Enzyme-Linked Immunosorbent Assay) testing. The blood samples were run in parallel by ELISA for the detection of HBsAg by fourth-generation ELISA kits (InTec product, INC. (http://www.intecasi.com) for the qualitative detection of HBsAg positive in the serum of BDs and the test technique was done permitting to the manufacturer guidelines (CAT.No.ITP23003).) Any blood samples positive by ELISA for HBsAg were duplication tested using the same ELISA kits. (Were repeating tested to rule out false positivity or contamination). Only those blood samples that were repeatedly immunoassay-positive for HBsAg were regarded as positive. If HBsAg test negative, chronic HBV infection is usually ruled out If HBsAg test positive, the patient is considered HBV-infected. Chronic infection is diagnosed when the HBsAg remains measurable for more than six months.

Results and Discussion

The study was ongoing at January 2015 until December 2016 to recognize the Hepatitis type B Virus surface (HBV) antigen (HBsAg) by enzyme immunoassay test in healthy donors of the Diwaniyah governorate (in middle Euphrates region of Iraq) who are attending Blood Transfusion Center (BTC). (26318 BDs 113 females &.26205 males during 2015 and 27657 of the BDs 27581 males & 76 females during 2016) (Figure 1 & 2). We detected that 39 of Diwaniyah BDs (0.149%) during 2015, infected with HBV (immunoassay positive for HBsAg), 23 of them from an urban area (58.97%) and 16 live in rural area. While, 44 BDs are immunoassay positive for HBsAg represented 0.16 % of total BDs during the year 2016, 29 of them live in the urban area (65.9%) whereas 15 BDs live in the rural area (34.1%). the average of the HBsAg immunoassay positive BDs during the two years is 0.155%. All of the HBsAg immunoassay positive patients were males (none of the infected BDs are females) during 2015 & 2016 (Table 1 & 2). Amini et al, in 2017 said that serologic immunoassay tests are a vital test as first-line for diagnosis and screening for HBs Ag infections. (11). The current study in Diwaniyah governorate which located in the middle Euphrates area of Iraq to diagnose HBs Ag by immunoassay test among blood donors during two-years (2015-2016). (26318 BDs 113 females &.26205 are males during 2015 and 27657 of the BDs during 2016,27581 males & 76 females) we detected that the percentage of HBV infection in Diwaniyah, during 2015 was 0.149% and during 2016 was 0.16 % (average of the two years 0.155%) among BDs none of the females seem to us infected during 2015 & 2016. The rate of HBsAg infection observed in this study is considerably lower than The Iraq national occurrence rate of HBs Ag which was 1.6 %. (12). Al-Rubaye et al (2016) recognized that serological evidence for hepatitis B virus infection in Basra city –Iraq about 2.3% in blood donors and Abdullah & Mohammed (2016) found that (1.94%) of BD was seropositive of HBV infection in the same city which is also higher than Diwaniyah BDs infection rate (13,14). Atallah et al 2011 reported that 0.6% of BDs were positive for HBsAg in Baghdad metropolitan of Iraq which is higher than our result (15). Hussein (2018) in Dohok City –Iraq reported that (1.14%) of the BDs were positive for HBsAg also higher than our finding in Diwaniyah BDs (16). In another country Abdullah (2013). Found that 3.8% of the donated blood units were
positive for HBsAg in Jazan Region of Saudi Arabia that is much higher than our report (17). A similar result in Iran where founded by Boustani et al (2017) reported that HBV infection had the prevalence of (0.14%) among BD (18). Also Mohsenizadeh et al (2017) in Jiroft city (Iran) detected 0.36% of the BD was infected with HBsAg which is slightly higher than our result. (19). On the alternative Yambasu et al (2018) found that 9.7% of blood donors infected with hepatitis B in Sierra Leone which is more higher than HBsAg immunoassay positive BDs in Diwaniyah (20).

Figure 1: Represented healthy BDs during 2015 in Diwaniyah BTC

Figure 2 Total study healthy population in Diwaniyah blood transfusion center during the year 2016

Conclusion

Established on this study, a general trend towards a decline in HBV among BD populace has been perceived within the last some years among Iraqi BD the most vital factor that is accountable for this decline was the starting of the HBV vaccination in 1989 (21). This reduction in HBV infection might also be due to the better alertness of HBV among blood donors.

The Effect of the Felder and Silverman Model on the achievement of Students in the Fourth Grade in Chemistry

Ahmed Abdul Hussein Nema¹, Saeed Hussein Ali Al Thalab¹, Fadel Amran Issa¹
¹University of Babylon, college of Basic Education, Department of postgraduate Studies - Teaching Methods of Science, Iraq

Abstract

The research goals to identify the effect of the Fielder and Silverman model on student achievement at the fourth scientific in chemistry, for the sake of achieving the research objective, the researcher formulated the zero hypothesis which states that: There was no statistically significant difference at the level of significance (0.05) between the average scores of the experimental group who will study the Fielder and Silverman model and average scores the control group who will study the way regularity in the achievement test of chemistry. The researcher has adopted a partial experimental design, before to applying the experiment, parity was performed in the following variables. Daily teaching plans and testing the achievement consists of (40) experimental paragraphs (36) of which are multiple choice and (4) articles for the two groups of research and after the implementation of the experiment and correcting the students’ answers, the researcher obtained the data for the experimental group, the control group and the use of appropriate statistical means (T.test) for both samples, the results showed that the students of the experimental group were superior whom studied according to the Fielder and Silverman model on the control group who studied according to the normal method

Key words: Fielder and Silverman model,, achievement, fourth grade students, chemistry.

Introduction

The prompt development witnessed by the present era and the increasing information in various areas of life in general and the educational field in particular, this development has led to a huge spread of modern means and technologies used in many fields of science, this progress is the fruit of science of information and knowledge proceeds derived from the human effort in the field the importance of scientific education as it emphasizes the practical activities practiced in the laboratory and its prominent role in the success of teaching in different science curricula, and became the function of the teacher is one He is responsible for steering, organizing, training, evaluating and managing the classroom. interested in chemistry and taught became one of the important elements in our contemporary life. It enters into all fields and industrial activities. There is no one branch except it is related to the chemistry and its applications, which made its importance a clear feature of the progress of nations. The teaching of chemistry and its subjects requires a high level of thinking, foresight, exploration and mental skills that require knowledge of all new, and the science of chemistry ensures a lot of the minute areas related to the life of the community and in various aspects of industrial, health and scientific as the teaching of the chemistry curriculum to the means of visual images and drawings and shapes to clarify the scientific concepts needed by the teacher, So the method of teaching in the modern concept is the method used by the teacher to guide the activity of students towards learning themselves and use their intellectual abilities in the development of their learning must provide methods, models and methods of modern teaching enables the teacher to interact with students better. The importance of the

DOI Numbers: 10.5958/0976-5506.2019.00777.0
Fielder & Silverman model is taking into account the different learning styles of students, which is a modern model of teaching that helps to solve problems. It is also mentioned that each learner has a preferred pattern of learning used to receive and receive information. Some prefer to learn by working in groups, while students prefer to think and reflect, while others prefer to learn facts and tangible materials in contrast prefer to explore while others tend to verbal information and in contrast prefer visual information, and some of the learners want to learn about Team Workout Stuff.

- The Medical research in the field of neuroscience in ordinary individuals and individuals with brain injuries, the results of specialized studies of the hemispheres of the cerebral hemisphere, which is concerned with the knowledge of the brain, It is longitudinally divided into two asymmetrical halves are not identical the left and the right hemispheres are connected by a group of nerve fibers known as the hard body name where the brain is characterized by hemispheres of different mental functions.

Clinical chemistry and laboratory medicine

In this area and by the famous Swiss doctor Paracels who managed to invent new medicines using the of mineral substances rather than herbs and this act served as a stimulant for the relationship that combines chemistry and medicine, and is considered Paul Erlich of the great scientists who named the father of therapeutic chemistry (chemotherapeutic) The art of treating diseases with drugs, as some doctors know, a drug used in the treatment of sleeping sickness was found to be a red dye (Rad Trypan). A treatment for syphilis, known as Salafarsan, an arsenic, was also discovered. It is the International Federation of Clinical Chemistry Laboratory Medicine (IFCC), established on 24 July 1952 now has 79 full-fledged national societies for clinical chemistry which together account for at least 30,000 chemists worldwide. In addition, the Federation has 35 members of diagnostic companies and related industries the link that provides materials and laboratory medicine services, there are five formally defined objectives of the Union

1 - To promote the vision of clinical chemistry, which goes beyond narrow perception

2 - Transcending the boundaries of one state, one institution, geographical group, culture or language, in the field of clinical chemistry.

3 - Dissemination of information on best practices at different levels of technology and development

4. To complete and strengthen the activities of its members information and guidelines on chemists' learning

5 - Determination of principles dissemination of recommendations to standardize analytical procedures and to interpret results, www.ifcc.org

Methodology

First: Experimental Design:

The research includes one independent variable (Fielder and Silverman) and a dependent variable (collection). Therefore, the pilot design was selected with partial control of the experimental and control groups.

Second: The research community and its design:

The current research community is the fourth grade students in the secondary and intermediate schools of the General Directorate of Education in the province of Babil / Musayyib district for the academic year (2018-2019), which includes at least two divisions of the fourth grade scientific, One of the schools belonging to the Musayyib district. The sample consisted of (30) students in the experimental group and (30) students in the control group

Third: The equivalence of the two research groups:

Before the experiment was started, the researcher tried to compare between the two groups (experimental and control) in some variables that are believed to affect the results of the experiment, and parity with the following variables (age, calculated by months, first grade, IQ test).

Fourth: Control of the Exotic Variables:

To ensure the integrity of the experiment procedures, the researcher investigated the internal factors that are believed to affect the experimental research procedures and then its results. He tried to control these factors or variables so that he can attribute the effect in the variable of the study to the independent variable, The growth factor associated with the experiment is a normal growth for all members of both groups equally, especially
that most of them are about one age old, the factor of experimental waste such wastefulness did not occur during the duration of the experiment, but the traditional absence of cases, which included two sets of search, tool measurement, did not have any effect, because the researcher used the same measurement tools, the differences in the selection of the sample, were selected randomly and avoid the researcher this factor equal two sets of research.

Fifth: Preparation of research requirements:

For the purpose of applying the experiment, the researcher provided some of the requirements, including the scientific material. Therefore, the scientific material that the researcher is teaching in the experimental and control groups was determined during the period of the second course of the academic year (2018-2019). It included two chapters (3rd and 4th) for the fourth grade of science, behavioral goals were formulated. 130 behavioral objectives were formulated according to Bloom’s classification of knowledge (recall, assimilation, application, analysis, composition, evaluation) In order to determine the level of each behavioral goal in the field of knowledge in accordance with the preparations and abilities of students at this stage of study.

Sixth: The research Tool:

- The achievement test: The research requires the preparation of an achievement test to measure the achievement of the students of the experimental group and the control group at the end of the experiment to determine the effect of the independent variable in the dependent variable and the absence of a ready-made test characterized by honesty and stability covering the content specified in the chemistry, Depending on the specific behavioral objectives and content of the course material.

- Determination of test objectives: The achievement test aims to measure the effect of the independent variable in the variable of the fourth grade scientific students in the chemistry that has been taught.

- Preparation of the test plan (table of specifications): The test map was designed to distribute the test paragraphs on the parts of the scientific subject in the light of weights and levels of behavioral goals taking into account the ability of students at this age and time for teaching, ) a paragraph

- Determine the test paragraphs: The researcher identified the total number of test paragraphs in the light of the specification table, and took into account the behavioral objectives to be achieved, the test includes (40) paragraph (36) paragraph, multiple choice and (4) paragraphs article, Suitable for the level of students that age and school and within the time allocated for the lesson and the nature of the subject.

- Formulation of the test instructions: The researcher formulated the instructions for the test of achievement. The following information is included (information concerning the students, the time of the test answer, making sure not to leave any paragraph without answer or choosing more than one answer to the paragraph, which leads to neglect and asked them to read the paragraphs carefully and accurately Circle around the character for the correct alternative.

- Correcting the test paragraphs: The researcher put a standard to correct the paragraphs and gave one degree for the correct answer, and zero for the wrong answer, or abandoned or have more than one alternative, and the degree ranged between (0 - 40).

- The validity of the test: The test is honest if it measures what was prepared for it, and the researcher relied on (virtual honesty, content validity, and the ratio of the agreement to the veracity of the virtual (80%) of the arbitrators, either the honesty of the content of all the test paragraphs is a statistical function, The test of achievement in measuring students of the fourth scientific in chemistry.

Application of the two-stage achievement test:

- The first phase: The experimental experiment for the clarity of the instructions of the test paragraphs and the determination of the time, the student after the preparation of the test and instructions in its initial form, the test was applied to a sample survey non-research sample composed of (30) students of the fourth grade scientific, and the time taken to answer On the subjects of the achievement test by monitoring the average completion time of the first, second and third students of the answer to the terms of the achievement test and the average time of completion of the last three students to answer the test paragraphs and calculate the average time was (44) minutes.
- The second Phase: The test was applied to a sample other than the test sample consisting of (100) students in the fourth grade scientific for the purpose of analyzing the paragraphs of the test and confirm the characteristics of the cykometric,

- The difficulty factor for the test paragraphs: the percentage of students who answered the wrong answer from the paragraph to the total number of students. The difficulty factor was calculated using the difficulty factor equation for the objective paragraphs, and the difficulty level was found to be between 0.50 and 0.77 And (0.37 0.68) for the paragraphs of the essay, so the test paragraphs are suitable for students in terms of difficulty and ease.

- Discrimination factor for test paragraphs: This means the ability to distinguish between the grades of students at the upper and lower levels for the degree measured by the paragraph. Substantive test paragraphs were found to have a discriminatory power of (0.25-0.5) for the thematic paragraphs and (0.32-0.5) for the host clauses.

- The effectiveness of the wrong alternatives: After applying the equation of the effectiveness of alternatives to the responses of students of the upper and lower groups, it emerged that the wrong alternatives to the test scores have attracted a number of students in the lower group more than the number of students in the upper group, Without deleting.

Eighth: Test’s Stability:

The stability coefficient is the statistical indicator on the accuracy of the measurement. The stability coefficient was then calculated using the Kiodrichshadon-20 equation because it is the measure of the internal consistency of the test. The coefficient of correlation (0.84) and this indicates that the test has a high degree of stability.

Ninth: Application of the research tool:

A week prior to the test, the students of the two research groups were notified after the completion of the course. The researcher conducted the test at the same time within the pre-defined material.

Tenth: statistical means: The researcher used the statistical means, including the test (T. test) of the independent samples to establish parity between the experimental group and the control group, Pearson correlation coefficient.

Results And Discussion

The results showed that the students of the experimental group who studied according to the Fielder and Silverman model were superior to the students in the control group who studied according to the usual method in the achievement test. Table (2) below shows this.

**Conclusion**

The model (Fielder and Silverman) proved its effectiveness within the limits in which the research was conducted in the achievement of students of the fourth scientific in chemistry. Teaching according to the Fielder and Silverman model increases the ability of students to organize and process information so as to achieve student learning according to the preferred pattern.

The research is aiming to identify the effect of reading instruction on Skamper’s strategy in developing the habits of the mind for the fourth grade students. In order to achieve the goal, the researcher put the zero hypothesis, which states: There is no statistically significant difference at the level of significance (0.05) among the average of the students of the experimental group, the average score of the students of the control group who will study according to the usual method in the test habits of the mind, and to verify the application of his experience in the first half of the academic year (2018-2019). The sample consisted of (65) students of the fourth grade in Al-Jawahiri secondary school, they were randomly distributed (33) students in the experimental group and (32) students of the control group. The two groups were rewarded in the following variables: age, IQ, and linguistic ability test. The researcher constructed the paragraphs of the habits of the mind in the form of positions and each position containing four alternatives to answer (A, B, C and D) and the number of positions sixteen positions where each position is usually a mental

Introduction

The neglect of the use of mind habits causes many shortcomings in the results of the scientific process, habits are not the possession of information, but is to know how to work on it and use it. It is a pattern of intelligent thinking behaviors that leads the learner to the product of knowledge as a result of responding to certain patterns of skills, values and attitudes, not just remembering them, that failure to take into account patterns of brain sovereignty in education is reflected negatively on students’ tendencies habits, attitudes, and attitudes. Most learners seem to recognize that most schools and universities do not take into account patterns of brain sovereignty. The communities and individuals are realizing that they needbetter thinking. This part of better thinking requires creativity. Creativity is a combination of imagination and scientific effort to develop an old idea or to find a new idea, no matter how small. The definition of thinking skills often includes habits of mind or thinking behavior, which translates trends and assumptions of good thinkers. Researchers such as Bayer, Marzano, Costa, Berknes and Debono believe that students can learn thinking and thinking strategies. Mmaajolhm more effective creativity and more specialized in information processing, and display the mind or Altvkira behavior in the different activities of everyday life habits. Dewey has defined the habits of the mind that require development to achieve understanding (saying: vigilance, perseverance and curiosity, fundamentals must be developed, immobility, intolerance, intense emotion and chatter are harmful habits). He stressed that training in thinking skills is not enough to develop successful thinkers with deep thinking. The habits of the mind, and education puts the development of the mind and the regulation of mental habits above all that we seek. Knowledge, as Koffka says, “is not the best of what educational institutions have learned, but it is our attribution to the right thinking and to take intellectual independence to act in positions”

Key words : Skamper’s Strategy, fourth grade students, habits of mind, development

Corresponding author:

University of Babylon – college of Basic Education, Department of Post-Graduate Studies, Iraq; E-mail: Salam.nathem.s@gmail.com
Dewey also says that the most important function of the Breeding is the breeding habits of the mind and the correct thinking and rooting. And that the first steps to develop mental habits is to create strong motivation and desire of the student to make a change in the pattern of thinking, and to feel that he needs to develop his mental habits and this requires the teacher to find appropriate strategies for events. Modern trends emphasize the need to activate effective teaching strategies and methods in the educational process that increase the role of the active learner and achieve an integrated and comprehensive growth in all aspects of his personality to be an active focus in the educational process. This study was conducted to find out as there was a difference between the experimental group taught in accordance with the Skamper’s strategy students and between the control group taught in accordance with the usual way students.

Methodology

It includes a presentation of the procedures that have been carried out to achieve the research objectives, starting with the research methodology and experimental design, defining the research community and its design, the equivalence of the research groups (experimental and control), preparation of the research requirements and tools. Experimental design of the research includes the independent variable (Skamper’s strategy), the normal method, and the dependent variable (the development of the habits of the mind). Therefore, the researcher used experimental design with partial control of two equal groups, one experimental and the other controlling. The research community and its model: The current research community represents fourth grade students, all of them in the governmental day-school preparatory school of the Directorate General of Education in Diwaniyah Governorate for the academic year 2018-2019. In the same case, the researcher chose the middle school of Diwaniyah in the center of Diwaniyah province in order to conduct his research. It was found that it includes two divisions for the fourth grade (A, B). The researcher chose (a) the random drawing method (the drawing method) to represent the experimental group and the number of its students (33) students who will study their students according to the (Skamper’s strategy), the same way the researcher chose randomly Division (b) to represent the control group and the number of students (32 students), which will examine its students according to (the usual way). The researcher conducted a statistical equivalence between the experimental and control groups in some variables that affect the results of the experiment. Although the researcher chose the two groups in the random drawing method, although the students of the research sample from the social and economic center are very similar and study in one school. But he was keen to make the equivalence of the following variables: the age of time calculated months, the test of intelligence, the test of language ability), as the researcher parity between the two research groups in the variables mentioned above and showed the results according to the table.

Adjusting Exotic Variables:

Although the researcher verified the equivalence of the two sets of research in some variables that are believed to affect the course of the experiment, he tried to avoid the effect of some of the extraneous variables in the course of the experiment and some of these variables and how to control them: Accidents associated with the experiment: The sample was selected: The two sets of research were chosen in the logical way and the two groups were confirmed. The maturity factor: Since the duration of the experiment is uniform between the two research groups As well as the approximate age of students B in the two groups, so what happens growth will return to the members of the two groups at the same level, so it was not for this factor is the impact of the research, the impact of the experimental procedures: the work of the researcher to reduce the impact of the experimental procedures could affect the dependent variable during the course of the experiment. Preparation of research requirements: The research requirements of the basic things on which the research is based on which the search procedures are implemented and these requirements are: Scientific material (content): The scientific material that the researcher has been taught. For the students of the two groups of research during the duration of the experiment (the second semester) of the academic year (2018 - 2019). The scientific article included seven topics of the book of reading material for the fourth grade literary, I 6, for the year 2014 AD Author: Karim Obeid Al-Waeli et al. ). The researcher prepared 7 plans for the experimental group, which is taught according to (Skamper strategy) and the same to the control group, which is taught according to (the normal method). The tools and methods used to develop the habits of mind according to Skamper strategy.
Research Tool: A measure was prepared to measure the habits of the mind:

The researcher constructed the paragraphs of the habits of the mind in the form of positions and each position includes four alternatives to answer (A, B, C and D) and the number of positions sixteen position, as each position is usually a mentality.

A - The validity of the paragraphs of the habits of the mind (the analysis of the paragraph)

The logical analysis is the general appearance of the scale as a means of mental measurement, since the presentation of the paragraphs of the scale to a group of arbitrators to judge their validity in measuring the property to be measured is a kind of honesty to which the apparent honesty applies. (Moss, 1994,204) The researcher verifies the validity of the paragraphs by presenting the scale to a group of specialized arbitrators in educational and psychological sciences to benefit from their observations and opinions in the amendment and delete what they see as inappropriate, so I got the proportion of agreement (96%)

B - The honesty of the building

And this type of honesty, which illustrates the relationship between the theoretical basis of the test and the paragraphs of the scale in its fields, has achieved this truth by applying it to (40) students of the fourth grade literary and the calculation of correlation coefficients between the degree of each position and the total score, (0.62_0.84), and the significance of correlation coefficients. The T value of the correlation coefficient of each paragraph was computed and compared with the tabular T value of (2.021) at the significance level (0.05) and the degree of freedom (38).

Spatial Application of the Habits of Reason Scale:

The researcher applied the scale to a sample of 30 students randomly selected from the Diwaniyah prep school for boys in order to know the clarity of the instructions of the 16 habits of the mind, as well as calculating the time taken to answer this scale. His answers were clear and the average time to answer all the paragraphs was (55) minutes.

Paragraph Analysis (Statistical Analysis):

The process of analyzing paragraphs is statistically defined as the study of evaluating their effectiveness through the students’ response to the scales. The aim of this procedure is to keep the good paragraphs in the scale.

Extraction of discriminatory power of paragraphs:

The distinction of a paragraph is strongly meant to distinguish between higher-level, lower-level, or test-measured subjects whose usefulness is to clarify the differences between the most capable individuals and the weaker individuals, after calculating the power of discrimination of each paragraph, using the equation of discrimination of paragraphs, the researcher found that the forces of discrimination were limited between (0.31 - 0.53), as Ebel believes that the paragraphs of the test is good if the strength of the distinction (0.30) and more, The test is all good, and acceptable.

The relation of the paragraph to the total degree of the scale:

To obtain the coefficient of excellence by using the total score of the scale as an internal check, ie to obtain the correlation between the degree of each paragraph and the overall score of the test in general, the higher the correlation between the paragraphs and the overall score increased the possibility of getting more homogeneous sections in the measurement of what was measured for The weak paragraphs should be excluded.

This method was used in the psychological tests because it is a reference to the homogeneity in the paragraphs that measure any behavioral phenomenon and this means that each of the paragraphs of the test going in the course of the test as a whole.

The Stability of the scale:

The validity of the measurement depends on the stability of its results. The fixed scale gives the same results almost as measured the same property to be measured consecutive times, the researcher used the following methods to extract stability:

1- Test-Retest method

To achieve the stability of the scale according to this method, the measure of the habits of the mind was applied on Wednesday 12/12/2018 to a sample of students consisting of (30) students randomly selected
from Diwaniyah middle school students and 15 days after the first application. The scale was applied again on the same sample on Thursday, 27/12/2018. The correlation between the students’ grades was calculated using the Pearson correlation coefficient and the stability coefficient value of the total scale was 0.88. For the correlation coefficient, the T test was used, (35.773), which is greater than the scale of the elbows (2.084) at the level of significance (0.05) and degrees of freedom (28). Alpha-Cronbach’s stability coefficient (for internal consistency):

The persistence of the Vaccronbach method depends on the consistency in the stability of the results of the individuals for all the paragraphs of the scale. To calculate the stability of this method, 20 random forms were withdrawn from the analysis sample of the vertebrates and the Vecronbach equation was applied to the internal consistency.

The final view of the measure of the habits of the mind and how to correct it:

The scale consists of sixteen cards each representing one area for each of the habit of the sixteenth mind. 16. The paragraphs of the scale were formulated in the form of positions, from each position, four alternatives (A, B, C and D) (4) degrees, (b) give (3) degrees, (c) give (2) degrees, while (d) the lowest degree of common sense and give it a score. Every habit of mind habits and how to correct it.

Application of the research tool: The experimental and control groups were informed of the date of application of the habits of the mind standard a week before it was carried out. It was applied after the completion of teaching the specific material for the two research groups at one time.

Statistical methods: The researcher used the t - test equation for two independent samples to make the parity between the experimental and control groups, Pearson’s correlation equation, the alpha - cronbach equation, and the spss.

Results and Discussion

The results showed statistically significant differences between the experimental and control groups in the development of the habits of the mind and can be explained as follows: The students of the experimental group that studied according to Skamper’s strategy surpassed the students of the control group which were studied in the normal way in the development of the habits of the mind in the post-test. This shows that teaching according to Skamper’s strategy had a positive effect on the development of the habits of the mind.

Conclusion

Skamper’s strategy has a positive impact on the development of the habits of the mind to the fourth grade students and increase their ability to understand information, facts and knowledge and raise their academic level. The Skamper strategy has a role in making students the focus of the educational process through their active participation in the educational situation, which will increase their self-confidence and encourage them to persevere to raise their level of science.

The Impact of the Information Gap Strategy Academic Achievement of first grade students of Intermediate school In (Sciences)

Ali Radha Mujid, Saeed Hussein Ali Al-Thalab, Abdul Amir Khalf Arat

Abstract

The research aims to identify the impact of the information gap strategy in the achievement of students in the first grade intermediate in sciences, in order to verify the objective, the researcher has put the zero hypothesis which states: There was no statistically significant difference at the level of significance (0.05) between the average scores of the experimental group according to the information gap strategy and the average scores of students in the control group who will study according to the usual method of testing the achievement of science, to be verified, he applied his experience in the second half of the academic year (2018-2019). The research sample consisted of (53) students of first grade intermediate in sciences. They were randomized to two groups. The number of students in the experimental group was 27 and the number of students in the control group was 26. The two groups were rewarded in the following variables (age, IQ test, grade 6). The results were then analyzed and showed the superiority of the experimental group students who studied according to the information gap strategy on the control group who studied the normal way in the achievement variable.

Key words: Information Gap Strategy, First Grade Students, Sciences, Achievement

Introduction

The Biology is one of the most diverse sciences and is related to other sciences because it deals with all forms of life on the earth, as it is connected with all aspects of human life, it is necessary to take care of this science and teach it to students in modern ways and methods through which it can employ the information and knowledge gained in its daily life. Biology is concerned with the study of organic organisms from the organic point of view and adapting them to the environment in which they live. Hence, its strong relationship with education is manifested in the knowledge of the laws of public life, growth and adaptation, which in turn led to a biological trend in education.

Especially with respect of focusing on the concept of adaptation based on the existence of an internal motive seeks to adapt the organism with the demands of the environment surrounding the various aspects of which are the essence of life, as education cannot ignore the biological side of the learner there are differences between learners regarding the strength of their eyes or sharpness heard, Or the soundness of their pronunciation and maturity of their nervous systems and the growth of their brain cells, the formation of their physical structure, and therefore dealing with them taking into account these differences. The modern trends emphasize the need to activate effective strategies and teaching methods in the educational process, The role of the active learner, achieve an integrated and comprehensive growth in all aspects of his personality, to be an active focus in the educational process, the principles of science education according to the vision of the Research Council Science education is an active process, and learners must be actively helped to understand it through individual and group activities during learning, and the

DOI Numbers: 10.5958/0976-5506.2019.00779.4
need to encourage students to participate fully in science learning.

The use of diverse teaching strategies. In encouraging students to participate in activities that lead them to discuss and ask questions about the content of the course, we are not only working to maintain the best information about the subject matter. But also help develop their thinking abilities. Learning occurs at a better level when students work in collaborative groups for the integration that occurs between students’ ideas and the solutions they reach. They speak the same language and can translate words Difficult and ambiguous expressions and the use of language that can be understood.

As such students in all levels of education are seeking to achieve a high level of academic achievement. Therefore, the achievement of education is very careful in educational research in general and psychological research in particular. Achievement is one of the most important outcomes of the educational process. As they seem to each other but reflect and speak of many vital things important to the student. Achievement is one of the important aspects of mental activity carried out by the learner in the school as a cognitive variable that includes all that can reach the learner’s ability to learn and his ability to express what he learned.

This makes teachers look for the best ways and modern strategies that are more useful in teaching science in general, he has been found that methods that may contribute to a broader understanding of science and achieve many of the objectives of teaching at the secondary level, he has used of active learning strategies including (information gap strategy). Because it is a modern strategies that may help in overcoming the problems that hinder students’ understanding of science and raise the level of their collection. Moreover, this strategy has not been put into practice in the teaching of science for the secondary stage, Therefore, this study was conducted to find out if there was a difference between the students of the experimental group who are taught according to the information gap strategy and the students of the control group that are taught according to the normal method.

Methodology

Includes an overview of the actions taken to achieve your search goals starting with the research methodology and experimental design, to identify and identify the research community, and the equivalence of the two research groups (Experimental and control), the preparation of search tools and tools, application procedures and display the statistical means used, that will be displayed as follows:

The experimental design of the research: includes the independent variable (information gap strategy) and (normal method) and the dependent variable (collection). Therefore, the researcher used experimental design with partial control of two equal groups, one experimental and the other control.

The research community and its sample:

The current research community represents all middle-grade students in secondary and intermediate schools. Governmental Day belongs to the Directorate General of Education in the province of Qadisiyah (Center) for the academic year (2018 - 2019), Which is not less than the number of the people of the first row, the average of two divisions. In the same research, the researcher (middle science) in the center of Qadisiyah province chose randomly to conduct his research. It was found to consist of four divisions of the first intermediate grade (A, B, C, D). The researcher selected a (a) random drawing method (the drawing method) to represent the experimental group and the number of students (27) students, which will study their students according to (information gap strategy), in the same way the researcher randomly selected Division C to represent the control group and the number of students (26) students, which will study the students according to (the usual method).

The equivalent of the two research groups:

The researcher conducted a statistical equivalence between the experimental and control groups in some variables that affect the results of the experiment. Although the researcher of the two groups was chosen in a random drawing method. Although the students of the research sample are from a social and economic center. They are very similar and are taught in one school, but was keen to make the equivalence of variables (The age of time is calculated in months, Grades of the previous school year (sixth primary), IQ test). The researcher the equivalent of the two research groups the variables mentioned above and the results were shown as in the following table 1.
Adjusting Exotic Variables:

Although the researcher verifies the equivalence of the two groups in some variables which is believed to affect the course of the experiment, however, he tried to avoid the effect of some exotic variables in the course of the experiment and some of these variables and how to adjust them: (Accidents associated with the experience:

EXPERIMENT EXPERIENCE: You did not get interrupted or moved for any student throughout the experiment, sample selection: The two groups were randomized and verified of the parity of the two groups, the maturity factor: Since the duration of the experiment is uniform between the two research groups. As well as the approximate age of students in both groups so that the growth will return to the members of the two groups the same level, so this factor has not affected the search.

Effect of experimental procedures: The researcher worked to limit the effect of experimental procedures which can affect the dependent variable during the course of the experiment).

Preparation of the research requirements:

The research requirements are essential on which the research is based and according to which procedures are carried out the research. These are:

Scientific material (content): The scientific material that the researcher is teaching has been determined for the students of my group, the research during the duration of the experiment (second semester) of the academic year (2018 - 2019) AD, prepared by the researcher (16) A plan for the experimental group to study on (Information Gap Strategy) and its counterpart to the control group which is taught according to (the normal method). The research requirements: The “Collective Test” has been prepared according to the following steps:

Determination of the purpose of the achievement test:

The objective of the achievement test is to measure the achievement of students in the first intermediate grade (information, skills and experience) in science in the study of biology and technology, building the body of the organism, genetics and evolution.

Determination of Behavioral Goals: After the purpose of the test was determined, behavioral objectives are determined to determine the extent of their achievement. The researcher formulated a number of behavioral goals.

Determining the test paragraphs: The researcher prepared a specification table and a test map. In light of this, 40 test cases were identified.

The test subjects were formulated in the initial form in the light of the experimental map. The researcher chose the type of test (multiple choice) which is one of the best objective tests. The test consisted of (40) Understanding, application, analysis).

The test instructions: Specific instructions and guidelines have been formulated on how to answer (Selecting one correct alternative to the paragraph, answering all paragraphs,

Correcting the test answers: A standard was set for correcting the answers. One score for each correct test paragraph and 0 for the wrong answer, the left paragraph that the student did not answer, and the paragraph for which more than one choice was given. Therefore, 40 degrees) and the lowest score (zero).

The validity of the test: it was confirmed by the veracity of the test and the validity of the content. The results showed that the apparent honesty obtained 80% of the agreement by the arbitrators and specialists. As for the validity of the content, the results showed that all the clauses of the test are statistically significant. In measuring the understanding and comprehension of students in the first grade intermediate in science.

The application exploration for the achievement test: and include what comes:

The first survey application: In the first phase of the survey, the achievement test was applied to a group of students of the first grade of the non-research sample. The number of students was 30 students. The purpose of this test was to know the clarity of the test instructions and guides, For the test, the researcher recorded the exit time for each student. In calculating the arithmetic mean of time, it was found that the time required to answer all the test paragraphs was (43) minutes.

The second survey application: The test was applied to a sample of (100) students in the first row of the average non-research sample. The purpose of this test is to analyze the statistical achievement test paragraphs.
The Statistical analysis of the test scores: The test scores were analyzed as follows:

**The difficulty of the paragraph:** The statistical analysis of the terms of the test of achievement found that the coefficient of difficulty of paragraphs ranged from (0.28 - 0.43) and thus all the test scores are acceptable and their difficulty is appropriate.

**The distinction of the paragraph:** The important characteristics that must be provided in the paragraphs of the test is the characteristic of discrimination and means the possibility of items or paragraphs to identify individual differences of students and the test items are valid as the coefficient of discrimination of items is (20,0) and above, Between 0.30 - 0.70), thus the subjects of the achievement test have a good and appropriate discrimination coefficient.

**The effectiveness of the wrong alternatives:** The researcher conducted a statistical analysis (highest 54% and lowest 54%) degree to find the effectiveness of the wrong alternatives ranging from (-0.01 - 0.22) and it turned out that the alternatives of the test paragraphs are all effective and thus the collection of all appropriate.

**Application of the research tool:** The experimental and control groups were informed of the date of application of the test, one week before it was carried out, and it was applied after the completion of teaching the specific material for the two research groups at one time. The researcher supervised the application of the test.

**The Statistical methods:** The researcher used the t-test equation for two independent samples to make the parity between the experimental and control groups and the Pearson correlation equation. The researcher used the equation to correct the correlation coefficient between the test segments (individual and marital scores) after the Pearson correlation coefficient, The spss program, the Microsoft Excel 2007 program (Excel)

**Results and Discussion**

The students of the experimental group who studied the information gap strategy outperformed the students of the control group who studied the usual method in both the achievement test and the motivation test towards the substance.

Conclusion

The research sample consisted of (53) students of first grade intermediate in sciences. They were randomized to two groups. The number of students in the experimental group was 27 and the number of students in the control group was 26. The two groups were rewarded in the following variables (age, IQ test, grade 6). The results were then analyzed and showed the superiority of the experimental group students who studied according to the information gap strategy on the control group who studied the normal way in the achievement variable.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the Department of postgraduate Studies, college of Basic Education, Babylon University, Iraq and all experiments were carried out in accordance with approved guidelines.

**FTO rs17817449 Gene Polymorphism as a Predictor for Maternal Obesity in Iraqi Pregnant Women**

Shahla O. Al-Ogaidi¹, Sura A. Abdulsattar¹, Hameed M. J. Al-Dulaimi¹

¹Department of Chemistry, College of Science, Mustansiriyah University, Baghdad, Iraq, ²College of Medicine, Mustansiriyah University, Baghdad, Iraq, ³College of Biotechnology, Al-Nahrain University, Baghdad, Iraq

**Abstract**

**Background:** The prevalence of overweight and obesity is rising worldwide, particularly, among women of reproductive age. *FTO* gene is one of these genes that increase susceptibility to obesity. The goal of this study was to analyze the association between the *FTO rs17817449* SNP with maternal obesity and metabolic biomarkers in Iraqi pregnant women. Women were divided into 2 groups according to BMI: Overweight/Obese (BMI> 24.9) and control (BMI<24.9). Genotyping of *FTO rs17817449* SNP was determined by tetra-primer ARMS–PCR. Metabolic biomarkers included fasting glucose FG, glycated hemoglobin HbA1c, lipid profile, fasting insulin, leptin LEP, leptin receptor LEPR, LEP/LEPR ratio, and HOMA-IR. Statistical analysis revealed that participants with the homozygous mutant (GG) genotype significantly increases the odds of being overweight/obese (adjusted OR: 3.972, CI 95% 1.209-13.048, P= 0.023) and each copy of risk allele (G) is associated with overweight/obese (OR: 2.6258, 95% CI: 1.4025-4.916, \( P=0.0026 \)). *FTO* rs17817449 SNP was associated only with higher maternal BMI, TC, LDL-C and LEP/LEPR among the study group. While among overweight/obese group, *FTO* rs17817449 SNP only associated with increased TC, LDL levels, and BMI

**Keywords:** Body mass index, FTO gene, Pregnancy, Maternal obesity, Insulin, Leptin receptor, Leptin, Tetra-primer ARMS–PCR.

**Introduction**

One of the major public health problems of 21st century is the epidemic of obesity across all spectrums of age groups¹, in particular, among reproductive age women². Overweight and obesity during pregnancy are well-known risk factors for adverse pregnancy outcomes for both for mother and infant²-³. According to Iraqi Mistry of health, 30.6% of Iraqi adult females were overweight and 42.6% of them were obese⁴. Obesity susceptibility is thought to result from a combination of environment, genes and behavior⁵. Hundreds of genes were recognized as contributing to obesity⁶. Fat mass and obesity associated (*FTO*) gene is one of these genes⁷. *FTO* gene is expressed, mainly, in the hypothalamus⁸. It has been speculated that the *FTO* gene leads to an increased risk of obesity by influencing a central regulation of food intake⁹. To elucidate the role of *FTO rs17817449* single nucleotide polymorphism (SNP) in maternal obesity, we performed a case–control study association study in a population of Iraqi pregnant women. We also tested the association of this SNP with body mass index (BMI) and metabolic biomarkers including: two obesity related hormones; insulin and LEP, leptin receptor (LEPR), homeostasis model assessment-insulin resistance (HOMA-IR), fasting glucose (FG), glycated hemoglobin (HbA1c) and lipid profile.

**Materials and Method**

The current case-control study consists of 100 pregnant women enrolled at Al-Eluia Teaching Hospital in Baghdad, Iraq for delivery between February and May 2017. Two main groups included, 68 pregnant women ageing 18-49 years with abnormal BMI (greater than or equal to 25 kg/m²) served as patients (Overweight/
Obese) group and 32 pregnant women ageing 18-35 years with a normal BMI (below 25 kg/m²) served as controls. Smoking women and women with complicated pregnancies were excluded such as having hypertension, diabetes, and infection diseases. For BMI calculation, anthropometric measurements such as weight and height were recorded after delivery. BMI was defined as weight in kilograms to square of height in meters\(^2\).

As for metabolic measurements, FG and Lipid profile were determined by colorimetric, enzymatic method using kit supplied by Biosystems, Spain and LINEAR CHEMICALS S.L, Spain. Friedewald equation was used for LDL-C and VLDL-C estimation\(^1\). Quantitative measurement of human serum levels of LEP, insulin, and LEPR performed using an ELISA kits supplied by KOMA BIOTECH INC. Korea, Monobind Inc., USA and My Biosource, USA respectively. Matthews formula was used for calculation of HOMA-IR, which is a method used to quantify insulin resistance\(^12\). Fluorescence immunoassay (FIA) system with iCHROMA™ Reader was used for quantitative measurement of HbA1c.

### Genotyping

Genomic DNA was isolated from EDTA whole blood samples using the gSYNC™ DNA Extraction Kit provided by Geneaid Biotech Ltd, Taiwan according to the manufacturer’s protocol and stored at –20 °C. A simple and economical SNP genotyping method named tetra-primer amplification refractory mutation system–PCR (ARMS–PCR) was used for genotyping. The tetra-primer ARMS–PCR uses four primers in a single PCR to determine the genotype\(^13\). Genotyping of FTO rs17817449 SNP was performed by tetra-primer ARMS–PCR as previously described\(^14\).

### Statistical analysis

Statistical Package for Social Sciences (SPSS Inc. Chicago, IL, USA, version 19.0) was used for data analysis. The qualitative variables were expressed as absolute numbers and frequencies while quantitative variables were expressed as means±standard deviation (SD). Distributions of alleles and genotypes were compared among patients and control groups by Chi-square (\(\chi^2\)) test, calculating the odds ratio (OR) and 95% confidence interval (CI). General Linear Model (GLM) adjusted for maternal age was conducted to analyze the impact of FTO rs17817449 SNP on anthropometric and metabolic biomarkers of obesity. A value of <0.05 was considered statistically significant. To determine whether observed genotype frequencies are consistent with HWE, Web-ASSOTEST - a web-based version of ASSOTEST available on www.ekstroem.com\(^15\).

### Findings

The Tetra-ARMS PCR product of FTO (rs17817449) gene polymorphism was analyzed by 2% agarose gel electrophoresis. The two outer primers generated a product size of 313 bp which represents the internal standard. T allele generated 221 bp product-size, while, G allele generated 148 bp product-size as shown in Figure 1. We randomly selected 24% of the samples for re-genotyping, to detect any genotyping errors. The obtained results were 100% identical.

For the control samples, the genotype distribution for the FTO rs17817449 SNP was in HWE (\(P=0.123\)). Genotypes and alleles frequencies for FTO rs17817449 SNP for both groups are presented in Table (1).

In patients group, the frequency of the homozygous mutant (GG) genotype of the FTO rs17817449 polymorphism was (36.8%) higher than that of the homozygous wild type (TT) (27.9%) or heterozygous (GT) (35.3%) genotypes. On the contrary, control group had homozygous wild type (TT) frequency was (53.1%) higher than that of heterozygous (GT) genotypes (31.3%) or of homozygous mutant (GG) genotype (15.6%). In other words, both of GG and GT genotypes distribution were significantly higher (\(\chi^2 = 7.350, P=0.007\)) in patients group compared to control. Moreover, statistical analysis revealed that participants with the homozygous mutant (GG) genotype significantly increases the odds of being overweight/obese (adjusted OR: 3.972, CI 95% 1.209-13.048, \(P=0.023\)). In contrast, heterozygous (GT) genotype was not associated with increased risk for obesity (adjusted OR: 1.972, CI 95%: 1.072-6.501, \(P=0.026\)). The minor allele frequency (MAF) of rs17817449 (G) allele was 0.5441 significantly (\(\chi^2 =9.37, p=0.0022\)) higher in patients vs, 0.3125 in controls. Each copy of G allele significantly increases odds of being overweight/obese (OR: 2.640, CI 95%: 1.072-6.501, \(P=0.026\)).
The impact of FTO rs17817449 SNP on anthropometric and metabolic biomarkers of obesity adjusted for maternal age across study population is presented in Table (2). Assuming codominant model of inheritance, the FTO rs17817449 SNP was associated ($P<0.05$) with higher BMI, TC, LDL-C. Furthermore, assuming the dominant model, (GT+GG) females carriers have a significantly ($P<0.01$) higher BMI, TC, and significantly ($P<0.05$) higher LDL-C and LEP/LEPR ratio compared to TT genotypes carriers among the entire study group. Further statistical analysis revealed (data not shown) that rs17817449 SNP only significantly associated with increased TC, LDL levels, and BMI across patients (overweight/obese) group. On the other hand, there were no significant differences in means of FBG, HbA1C, TG, HDL-C, VLDL-C, LEP, LEPR, and HOMA-IR between the genotypes of FTO rs17817449 polymorphism. Since 2007, more studies have confirmed the association between SNPs within the first intron of FTO gene and BMI in several distinct populations, specifically European, Asian, Africans and Native Americans, making FTO the single strongest contributing genetic factor to obesity, with huge implications for public health. Moreover, the link between the FTO gene rs17817449 SNP and obesity has been confirmed in several populations. The rs17817449 variant of the FTO gene was first identified by Dina et al. in 2007 as strongly associated with early-onset and severe obesity for the G allele. However, in a recent study among Saudi population, the frequency of the G allele was more pronounced among non-obese, males and females, than obese subjects, while T allele was more pronounced among obese males and females, than non-obese, suggesting that T allele was significantly associated with obesity. Recent evidence suggested that FTO variants directly affect adipocyte function through targeting IRX3 and IRX5. While some reports suggest that it affects food intake, as carriers of the risk allele tend to choose high energy and palatable food. Furthermore, Laith et al reported that rs17817449 SNP was significantly associated with increased BMI, LDL, insulin and HOMA-IR and a decrease the HDL levels. Leptin circulates in a free and active form and in a bound and inactive form to its plasma bound soluble receptor (sLEPR). Bound LEP (active), represented in LEP/LEPR ratio, appears to be associated with resting energy expenditure. The sLEPR elevated concentrations indicate leptin signaling regulation through high affinity binding of free leptin, preventing its degradation and clearance, but also inhibits leptin-binding to cell surface receptors. Thus, our results might refer to an elevation in sLEPR.

Figure 1: Genotyping of *FTO* gene polymorphism (rs17817449) by Tetra-ARMS PCR on 2% agarose gel electrophoresis. Lanes M: DNA Marker, NC: Negative control. Lanes 1-3, 7, 9-11, 14, 16, 18 and 21: TT genotype. Lanes 4 and 19: GG genotype. Lanes 5, 6, 8, 12, 13, 15, 17, and 20: GT genotype.
Conclusion

In conclusion, the FTO gene polymorphism, rs17817449, was found to be associated with being overweight/obese for Iraqi pregnant women and the presence this variant is significantly associated with higher BMI, TC, LDL-C, and LEP/LEPR ratio. Moreover, the current study is the first to investigate and confirm the association of between rs17817449 polymorphism and LEP/LEPR in Iraqi female population.

Structural and DFT/TD-DFT Investigation of New Rhenium Metal Complexes To Elicit the Special Effects of Insulin

Hussein Neama Najeeb¹, Mohammed Abdul Ammer AL-Shareefi¹, Hamid I. Abbood²
¹University of Babylon-College of Science, Babylon, Iraq, ²AL-Mustaqbal University College, Babylon, Iraq

Abstract

Density functional calculations have been performed to study the new metal complexes. Several molecular properties, such as conformational equilibrium, optimal geometry, and vibrational frequencies, have been computed for these molecules. Ionization energies, electronic affinity and energy gap, were also computed.

Keywords: DFT, Rhenium, Complexes.

Introduction

Inorganic chemistry has generated significant interest in the design of metal complexes as potential diagnostic and therapeutic agents. There are several metal complexes that are already in use for these purposes and this has encouraged further research on new metal drugs such as metal-mediated antibiotics and anticancer and antiviral compounds¹. The coordination chemistry of transition metal complexes with more than one type of ligands is of current interest because they serve as models for biochemical reactions². Also, they provide new materials with useful properties such as magnetic exchange³, electrical conductivity⁴, and nonlinear optical property⁵. Mixed ligand complexes play important roles in biological processes like activation of enzymes by metals⁶ and storage and transport of active substances through membranes⁷. The element rhenium (Re) is a refractory metal that has gained significant recognition as a high-performance engineering material because it exhibits an exclusive combination of properties. Rhenium coatings are used in thermo-photovoltaic (TPV) power generation systems, in which the radiator emits infrared photons from its surface to the TPV cells for conversion to electrical power. In this regard, CVD of Re whiskers was found to increase the emissivity of Mo, Nb and the Haynes 230 alloy.¹¹ Electrodeposited Re-selenium (Se) thin films are used as photosensitive elements in the visible range.¹² Electrodeposition of Re on silicon (Si) has been suggested for application in micro-systems.¹³ Electroplated Co-Ni-Re-W-P micro-arrays have been suggested for future application in magnetic micro-electro-mechanical-system (MEMS) devices.¹⁴

Methodology

Present work deals with the electronic structure of Rhenium metal complexes by employing the three parameters B3LYP (Becke’s three parameter exchange with Lee, Yang, and Parr correlation functional) (DFT) and SDD (Stuttgart Dresden triple zeta ECPs (Effective-Core Potential))basis sets¹⁵,¹⁶. The electronic properties were calculated according to Koopmans theorem. Excitation energies and vibration transitions are carried out by using the Time Dependent TD density functional theory.

Results and Discussion

The relax structures of the suggested Rhenium metal complexes are relax by employing the SDD-B3LYP/DFT method. The total energy ET of the studied Rhenium metal complexes and some of their electronic properties were calculated by using B3LYP-SDD/DFT and listed in Table 1. The electronic properties were calculated according to Koopmans theorem. As shown in mentioned Table, the ET depends on the number of electrons in the complex, ET was decreased with increasing the number of electrons in the complex. The values of virial ratio (\(V/T\)) for the studied complexes are in the range (2.0253-2.0236), these results gave an
idea for the suitable method used with SDD basis sets for the relaxation of the metal complexes. From table 1, all studied complexes have ionization energies IE are greater than the electron affinities EA. High value of IE means difficult tendency of complex to donating an electron. Complex A has the largest value of IE refers to that it needs high energy to donating an electron in comparison with the other complexes. On the other hand, complex C needs small energy to donating an electron compared with the other complexes. The results in Table 1 showed complex C has low value of EA in which it has low ability to accept an electron with large Egap. The calculated values of electronegativity EN showed the presence of methoxy group in active sites in the complex play role of increasing the EN of the complex. The order of EN of the studied Rhenium metal complexes is as: D˃B˃A˃C. The results in table 1 showed the complex A has the higher electrophilic index compared with the others. If determines the interactions of the complex with the surrounding species, then the ranking is as: A˃D˃B>C. Infrared IR spectra of Rhenium metal complexes from the B3LYP-SDD/DFT calculations. From the spectrum of complexes the stretching C-H bonds was observed in the range (3165.33-3241) cm⁻¹ with maximum intensity (100.9 km/mol) observed for C-H bending at (1504.71-1231) cm⁻¹, the bending C-N bonds was observed at (1619-1559) cm⁻¹. The stretching Re-Cl bonds was observed at (369-339 cm⁻¹). The stretching C-C bonds was observed at (1664.8-1619.5) cm⁻¹. The density of states DOS for Rhenium metal complexes analyzed from the calculations of B3LYP-SDD/DFT. DOS is significant to be able to expect the behave for different molecular structures geometries. In present group of Rhenium metal complexes,all the complexes A , B ,C and D have doublet state. As shown, complex A has lower distribution of energy in each energy interval due to the low degeneracy of the eigen states, but the degeneracy of occupied eigen states is more than the degeneracy of unoccupied eigen states. Also, in the other complexes the degeneracies of occupied eigen states are more than those of unoccupied eigen states. The small separation between the occupied and unoccupied molecular eigen states for complex B gave this complex to has a suitable application in electron transform. The behavior of excitation energies of the studied Rhenium metal complexes were studied due to the calculations of the B3LYP-SDD/TD-DFT. The UV-Vis spectra of the studied complexes. As seen, complex A appeared three peaks of excitation energy at (5498.1524, 2612.3754 and1564.8534) nm wavelength with transition between the frontier orbitals HOMO( β )→LUMO( β ) , H-1( α )→LUMO( α ) , HOMO( β )→L+1( β ) , H-1( α )→LUMO( α ) , HOMO( β )→L+1( β ) , H-1( α )→LUMO( α ) , HOMO( β )→L+1( β ) , H-1( α )→LUMO( α ) , HOMO( α )→LUMO( α ) , HOMO( β )→L+1( β ) and H-2( α )→LUMO( α ) low oscillation strength (0.0009, 0.0003 and0.0006 consequently). Three peaks of excitation energy were observed for complex B at 5755.9580 nm with four main electronic transitions H-1( β )→LUMO( β ) , HOMO( β )→LUMO( β ) , H-1(A)→LUMO(A) and H-1( β )→L+1( β ) due to oscillation strength (0.0008) and 2743.6011nm with seven main electronic transitions H-2( α )→LUMO( α ) , H-1( α )→LUMO( α ) , H-1( β )→L+1( β ) , HOMO( β )→L+1( β ) , H-3( α )→LUMO( α ) , HOMO( α )→LUMO( α ) , and H-1( β )→LUMO( β ) due to the oscillation strength (0.0002) and 1538.0639 nm with five main electronic transitions H-2( α )→LUMO( α ) , H-1( α )→LUMO( α ) , H-1( β )→L+1( β ) , HOMO( β )→L+1( β) , H-3( α )→LUMO( α ) , HOMO( α )→LUMO( α ) , and H-1( β )→LUMO( α ) due to the oscillation strength0.0004. Complex C appeared one peak of excitation energy at 1858.5419nm due to oscillation strength (0.025) with electronic transitions H-2( α )→LUMO( α ) , H-1( α )→LUMO( α ) , H-1( β )→L+1( β ) , HOMO( β )→L+1( β) , H-3( α )→LUMO( α ) , HOMO( α )→LUMO( α ) , and H-1( β )→LUMO( α ) due to the oscillation strength0.0004. Complex C appeared one peak of excitation energy at 1858.5419nm due to oscillation strength (0.025) with electronic transitions H-2( α )→LUMO( α ) , HOMO( α )→LUMO( α ) and HOMO( β )→L+1( β ). Two peaks of excitation energy were observed for complex D at 7482.3981nm with two main electronic transitions HOMO( β )→LUMO( β ) and H-2( β )→LUMO( β ) due to oscillation strength (0.0004) and 1659.5279nm with four main electronic transitions H-1( α )→LUMO( α ) , HOMO( α )→LUMO( α ) , HOMO( β )→L+1( β ) and H-2( α )→LUMO( α ) due to the oscillation strength (0.0017).

**Conclusion**

Rhenium metal complexes have varying electronic applications due to different values of energy gap. Rhenium metal complexes have low electrophilic index in which refers to these complexes used as catalysts in chemical reactions such as polymerization processes. Approximately all studied aluminum metal complexes have low values of hardness and softness, they are all weak in electron transfer. They can be used as catalysts for chemical reactions. The results of UV-Vis spectra showed the Rhenium metal complexes have various applications such as electronic devises.

Abstract

Teaching program prepare nurse midwife to teach laboring women for labor by providing information and practicing that promote women’s self-control and may contribute for a satisfactory birthing experience. Therefore, the aim of this study is to improve the knowledge of nurse midwives in a scientific and applicable way by implementing the teaching program that focus on knowledge upon the use of partograph during labor. A quasi-experimental design was carried out throughout the present study during September 26th 2017 to December 20th 2018. A Non-probability (purposive) sample were selected consisted of (50) nurse midwives who worked in delivery rooms in Babylon Teaching Hospitals for Maternity and pediatric who attended the teaching program as the study group and the other group of (25) midwives who were employed in AL- Hilla General Teaching Hospital who did not attend the teaching program and considered as a control group. Data were analyzed through using the descriptive and inferential analysis. The study results revealed that no statistically significant differences in the proportions of participants in both groups who did have previous knowledge about the use of partograph in all comparisons, (P>0.05).

Keywords: Effectiveness, teaching program, Midwives’, knowledge, partograph, first stage.

Introduction

The teaching program prepares nurse midwife to teach laboring women for labor by providing information and practicing. Nursing intervention promotes women’s self-control and may contribute for a satisfactory birthing experience ¹. Promoting the health of women in labor is considered to be one active way of reducing maternal morbidity and mortality as well as ensuring universal access to reproductive health services ². Midwives are responsible to provide care and support for delivery for mothers in non-complicated deliveries. Midwife’s functions and actions during this critical stage of a woman’s life may lead to different outcomes ranging from life to death and from heath to physical injuries, with significant effects on the mental and emotional health of mother and child ³. A partograph is one of the valued suitable technologies in use for an improved monitoring of labor progress for maternal and fetal wellbeing ⁴. Nurse midwives play a vital role during labor and delivery by providing necessary nursing interventions for laboring women. Nurse midwife should be a good educator, available encouraging, professional and supportive during labor and delivery ⁵. Nurse midwives are trained to assist during labor and birth, either through direct-entry or nurse-midwifery teaching programs. Assessment of learners by pre- and post-tests provide a useful means of establishing a baseline for learners’ theoretical knowledge. The same questions used in the pre-test should be used again in the post-test to assess knowledge on completion of the module ⁶.

Materials and Method

Design of the study: A quasi-experimental design was carried out throughout the present study during February 14th 2018 to June 10th 2018 with the application of test-retest approach of pre-test for the study and control groups. A Non-probability (purposive) sample were selected consisted of (50) nurse midwives who
worked in delivery rooms of the two hospitals. The subjects were divided into (2) groups; study and control. One group consists of (25) midwives who are working in the delivery room in Babylon Teaching Hospitals for Maternity and pediatric who attended the teaching program as the study group and the other group of (25) midwives who were employed in Al- Hilla General Teaching Hospital who did not attend the teaching program and considered as a control group.

**Study instrument** The structured knowledge questionnaire for 10 items related to midwives’ knowledge concerning use of partograph during first stage of labor was used to collect the data. The rating and scoring system of the scale is consisted of each correct answer was awarded with a score of ’1’ and score of ‘0’ was awarded for the wrong answer. Questionnaire consisted of 10 multiple choice questions to assess their knowledge.

**Data Analysis** Data were entered managed and analyzed using the statistical package for social sciences (SPSS) software for windows version 25. Descriptive statistics expressed as frequencies and percentages for nominal and ordinal variables, means and standard deviation for continues variables and using Chi-square test, t test and ANOVA.

### Results and Discussion

As it shown in (Table 1) Only 7 (28%) participants in the study group and 9 (36%) controls had a previous knowledge about the use of partograph during labor and finally, no statistically significant differences in the proportions of participants in both groups who did have previous knowledge, in all comparisons, (P>0.05). Furthermore, regarding the sources of these knowledge, seminars were the main sources of knowledge in both studied groups, followed by training and workshops courses in lower frequencies with no significant differences between both groups regarding their sources of knowledge, (P>0.05). Regarding the correct responses about the 10 items of knowledge about the use of partograph during labor domain, the lower proportion of participants in the study group and controls, (24%) and (28%), respectively, had the correct knowledge that when admission to the hospital takes place in the active phase, the dilatation is immediately plotted on alert line. The higher proportion of correct responses reported about the question When does the active phase commence?, 48% of study group and 52% of controls. Responses towards other items ranged between the aforementioned lower and higher proportions. However, no statistically significant differences had been found between both groups regarding the correct responses towards the items of knowledge about the use of partograph domain for all items (P>0.05) (Table 2). The Iraqi Ministry of Health stressed the need to follow or use the partograph in the delivery rooms and established many workshops on this subject, but this aspect is limited in using because the physicians are authored only to fill out the form items of the partograph without allowing nurse midwives to fill or use this chart. It revealed that the knowledge and inclination to use this instrument should be reinforced through periodic regular professional education by way of unit presentations, seminars, and workshops. The higher correct answers (100 %) were reported for question 3” When does the active phase commence? and question 6 stated that: When the fetal heart rate is below 100, it indicates? And question 9 in study group as shown (Table 3). Highly significant differences between both studied groups had been reported in the proportions of correct responses towards the items of knowledge about the use of partograph during labor (Table 3). The study result was similar to a survey study conducted by (8) to assess the knowledge of the labor partograph among the birth attendants at Cameroon. The result of the study revealed that the highest percentage (65%) of the midwives had poor knowledge regarding partograph. (Table 4). The lower correct answer (24%) was recorded for question 10 concerning “ When admission to the hospital takes place in the active phase, the dilatation is immediately plotted on:” in the control group, whereas in study group the lower correct answer (88%) was recorded for the same question. The crossing of the alert line is associated with fetal distress which increase need for resuscitation of the baby. (Table 5) demonstrate the comparison and changes in the mean scores of knowledge about the partograph during labor domain, where the mean score of knowledge for this domain at pre-test was 3.96 ± 1.99 in the study group and significantly elevated to 9.56 ± 0.77 at post-test 1, (P<0.001) , then relatively and not significantly reduced to 9.28 ± 0.84 at post-test 2, (P>0.05). In control group the baseline mean score for this domain was 3.84 ± 2.95 and did not significantly changed at post-test 1 and 2, (P>0.05). The mean score of knowledge was insignificantly different between study group and controls at pre-test, while highly significant difference was reported at post-test
