Effect of Thyroid Hormone Abnormalities on Hemoglobin A1c in Hemodialysis Patients Taking Erythropoietin

Hanan L. Al-Omary¹, Zainab M. Alawad², Buraq Husseini³
¹PhD, Assistant Professor; ²MSc, Assistant Lecturer; Physiology Department, College of Medicine, University of Baghdad; ³MSc, Assistant Lecturer, Doctor; Department of Anesthesia Techniques, Al-Nisour University College

ABSTRACT

Background: Hemoglobin A1c (HbA1c) is a widely used test for glycemic control. It is done for chronic kidney disease (CKD) patients. Renal disease is accompanied by thyroid abnormalities, which affect HbA1c, especially in those taking erythropoiesis-stimulating agents (ESAs). We aimed to find the effect of thyroid dysfunction on HbA1c in hemodialysis patients taking ESAs and those who do not.

Materials and Method: Fifty six patients were included in this study, which was done between September 2017 and June 2018, in Baghdad Teaching Hospital. Thyroid stimulating hormone, free T3, free T4 and HbA1c measurements were done. The patients were divided into 2 groups; those who took ESAs and those who did not, then they were subdivided into those with hypothyroidism and hyperthyroidism according to the Body mass index (BMI).

Results: Comparing HbA1c levels in hemodialysis patients taking ESAs and those who did not, showed no significant difference (5.79 ± 1.91 vs. 6.19 ± 1.64, \( P = 0.09 \)). The difference was also not significant in both hypothyroid and hyperthyroid patients in both high and low BMI patients. The only significant difference in HbA1c was between hyperthyroid and hypothyroid patients in those not taking ESAs, and having low BMI (4.97 ± 1.36 and 7.51 ± 0.87 respectively, \( P = 0.02 \)).

Conclusion: There is no significant influence of thyroid hormone changes on HbA1c levels in hemodialysis patients taking and not taking ESAs.

Keywords: Hemoglobin A1c, Chronic kidney disease, Thyroid dysfunction, Hemodialysis, Erythropoiesis-stimulating agents.

Introduction

Chronic kidney disease (CKD) is a universal problem causing great burden on the health system.¹ It is a prevalent state that influence more than fifty million people worldwide.² A lot of endocrinological deviations followed it, although pathogenesis is not settled yet.³ Thyroid hormones (THs) are mandatory for kidney development and for preserving water and electrolyte homeostasis. The kidney is responsible for THs metabolism and excretion.⁴ In CKD, level of thyroid hormones is usually aberrant.³ Different changes occur in the thyroid gland, these involve decreased thyroid hormone levels in the circulation, changed metabolism of peripheral hormone, reduced attaching to carrier proteins, potential decrease in hormone content in tissues, and a rise in iodine storing in the thyroid gland. Iodine excretion in urine decreases in CKD, which increasing inorganic iodine in the presence of iodine in the thyroid gland, which then makes the gland larger.⁵

Although the occurrence rate of hyperthyroidism is nearly the same in end stage renal disease (ESRD) patients and normal individuals, hypothyroidism is noticed in 3.4% of ESRD patients and 0.6% of normal individuals. This increased occurrence of hypothyroidism in ESRD
illustrates that searching for thyroid abnormal function, must be taken into account in assessing ESRD patients.\textsuperscript{5}

Thyroid hormones encourage erythrocyte formation, and hypothyroidism generally leads to hypoproliferative erythropoiesis. Moreover, thyroid hormones stimulate albumin metabolism, and its destruction is decreased in hypothyroidism. The cases which influence erythrocyte production cause incorrect increase or decrease in HbA1c.\textsuperscript{6, 7}

HbA1c is made up by the permanent attachment of glucose to hemoglobin across the lifetime of the red blood cells,\textsuperscript{8} and it constitutes about 60\% to 80\% of the glycated hemoglobin. In a hyperglycemic state, beta-chain of the hemoglobin increases glycation, making the assessment of HbA1c beneficial.\textsuperscript{9}

The American Diabetes Association (ADA) suggested the measurement of HbA1c for diagnosing diabetes and pre-diabetic state. It is the most approved method for evaluating chronic glycemia in diabetic patients.\textsuperscript{10} Low HbA1c levels, which are not because of lack of proper nutrition or anemia, were related to better survival in hemodialysis patients.\textsuperscript{8} An updated study found that HbA1c levels may show an underestimated glycemic control results in diabetic patients on hemodialysis.\textsuperscript{11}

Although some studies reported that erythropoietin intake might influence HbA1c in hemodialysis patients, this condition is not proved in people with CKD not on hemodialysis schedule.\textsuperscript{12}

We aimed to find the effect of thyroid dysfunction on HbA1c in hemodialysis patients taking erythropoiesis-stimulating agents (ESAs) and those who do not.

**Materials and Method**

Fifty six participants were included in this prospective study during the period between September 2017 and June 2018. They were thirty four females aged \(36.82 \pm 14.46\) years and twenty two males aged \(47.39 \pm 14.17\) years. The data were collected from the dialysis unit of Baghdad Teaching Hospital.

The patients enrolled were those with ESRD on regular hemodialysis, some of them were taking ESAs for at least four months.

Exclusion criteria: Diabetic patients, patients having hemoglobinopathy, and patients taking treatment for thyroid dysfunction.

The research was in accordance with the ethical standards of Helsinki Declaration of 1975, as revised in 2000. Informed consents were taken from the participants.

Demographic data, height, weight, smoking condition, and medications history were recorded.

The body mass index (BMI) was measured, a patient with BMI of \( \geq 25\) was considered obese, and a patient with BMI of \(< 25\) was considered non obese.\textsuperscript{13}

Blood (ten ml) was withdrawn, 5 ml was sent for HbA1c measurement and 5 ml was centrifuged and the serum was frozen then analyzed for free T3, free T4 and TSH.

HbA1 was analyzed within 24 hours of collection (refrigerated when not measured directly) by an automated high-performance liquid chromatography analyzer (ion-exchange chromatography) (HLC-723 G7; Tosoh Corporation, Tokyo, Japan or the Menarini HA-8160 A1C analyser). Free T3 (FT3) and free T4 (FT4) were determined by fluorimmunoassay method and TSH by immunoradiometric assay (IRMA).

All patients were on hemodialysis for 4 hours/3 times a week. The participants were divided into two groups, those who were on ESAs treatment (number=27) and those who were not (number=29), then they were subdivided into high BMI patients (number=30), and low BMI patients (number=26) and into hypothyroid (number=31) and hyperthyroid (number=25) patients.

All participants taking ESAs had hemoglobin \( \leq 10.5\) g/dl and were considered iron, vitamin B12, and folate replete before starting the treatment. Patients were considered iron replete after a serum ferritin level of \( > 200 \) \( \mu \)g/l or have taken intravenous iron at least 6 weeks before ESAs treatment. Darbepoetin \( \alpha \) (Aranesp) was given at 750 nanograms/kg (or 60 U/kg as intravenous bolus injection after each dialysis session) every two weeks and continued during study duration. ESAs dose was adjusted every month till reaching hemoglobin value of 10.5–12 g/dl.

Measurement of HbA1c in those taking ESAs was done after at least 4 months of the treatment.

The guidelines of the 2005 National Kidney Foundation Kidney Disease Outcomes Quality Initiative
did not obviously confirm a target HbA1c level for diabetic and ESRD patients, but levels of 6-7% was accepted.\textsuperscript{14} The ADA considered HbA1c levels <5.7% as normal, 5.7-6.4% as the pre-diabetic level and ≥6.5% as the diabetic level.\textsuperscript{15} \textbf{Statistical Analysis:} Statistical analysis was done by SPSS 20.0. Values were in mean ± standard deviation and using Independent samples T test where appropriate. A \textit{P} value less than 0.05 was considered significant.

\textbf{Results}

There were no significant differences between males and females regarding age and BMI (Table 1).

\textbf{Table 1: Age and BMI of hemodialysis patients}

Discussion

HbA1c may be influenced by the severity of kidney malfunction. This study found that HbA1c level is lower in patients taking ESAs than those who did not, however the difference was not significant.

In hemodialysis patients, blood loss during treatment and multiple blood tests cause reduction of erythrocytes survival. Shortened red blood cell survival, the transfusion of blood and erythropoietin also decrease HbA1c. This agrees with Ng et al, who found a reduction of HbA1c in patients treated with ESAs and iron therapy. The decrease of the HbA1c after ESAs or iron has been thought to be due to the production of new erythrocytes, leading to disturbance of young to old cells percentage, in addition to a change in red-cell glycation rates. Nakao and team mentioned a decrease in HbA1c in non-diabetic patients with CKD on hemodialysis after ESAs treatment. This reduction was higher compared with our results, which could be explained by the fact that iron therapy when given at the same time, most likely stimulated HbA1c lowering action.

Blood sugar binds with the hemoglobin to pinpoint a level for HbA1c. But, HbA1c results are only correct when erythrocytes have normal lifespan. Patients on dialysis have shorter red cell survival; which reduces the needed time for sugar to bind with hemoglobin, and resulting in lower HbA1c levels. It was shown that hemodialysis patients treated with erythropoietin have a transient reduction in HbA1c.

No significant differences were found in HbA1c between hyperthyroid patients taking ESAs and those who were not whether they have high or low BMI, although the level is higher in patients not taking ESAs. The same results were obtained in hypothyroid patients. HbA1c was higher in those with high BMI, this was in accordance with other researchers. However, Iso et al, and Koga et al, found no association between BMI and HbA1c.

Hypothyroidism and hyperthyroidism, cause changes in kidney function, and reticulocyte production. HbA1c was non-significantly different between hyperthyroid and hypothyroid patients in high BMI group whether in those taking ESAs or not. But the difference was significant between hyperthyroid and hypothyroid patients in the group of low BMI and was not taking ESAs, where it was higher in hypothyroid patients. This agrees with Kim and co-workers who...
found that HbA1c is spuriously high in non-diabetic patients with overt hypothyroidism.\(^6\) HbA1c was higher in hypothyroid patients than control subjects, and its levels were reduced by thyroid hormone treatment. THs potentiate erythrocyte formation, and hypothyroidism mostly causes hypoproliferative erythropoiesis.\(^{22}\) THs replacement increases erythropoietin, reticulocyte count, and mean corpuscular hemoglobin (MCH). The change in HbA1c value has a significant negative correlation with the change in reticulocyte count or MCH. All the above suggests that thyroid hormone treatment is accompanied by a reduction of HbA1c.\(^{6,23}\) Whereas, Ford and team reported a significant increase in HbA1c in the hyperthyroid group due to alterations of glycemic regulation in most hyperthyroid patients.\(^{24}\)

The limitation is a relatively small sample size as it was hard to find patients with thyroid problems especially hyperthyroid ones who have renal problems.

**Conclusion**

There is no significant difference in HbA1c level between hemodialysis patients who were taking ESAs and those who were not, in the hyperthyroid and hypothyroid patients having high and low BMI although it was lower in the treatment groups. The only significant difference in HbA1c was found between hyperthyroid and hypothyroid patients who were not taking ESAs and with low BMI being higher in the hypothyroid group.

Efficacy of the Health Promotion Model-Based Intervention in Enhancing the Health Responsibility of Middle School Female Student: A Randomized Controlled Trial

Hiba Abdul-Wahid Dawood¹, Afifa Ridah Aziz²
¹MSc, ²PhD, Professor; Pediatric Nursing Department, College of Nursing, University of Baghdad, Iraq

ABSTRACT

A randomized controlled trial (RCT) was conducted by applying the Health Promotion Model (HPM) to (1) determine the effect of the Health Promotion Model-based intervention in promoting the health behaviors for students, (2) identify the association between students’ age, family’s socioeconomic status (SES), body mass index (BMI), and the health behaviors, and (3) investigate the differences in the health behaviors between the groups of grade, SES, birth order, and BMI. The study included a simple random sample of (180) female students (90 students for the study group and 90 students for the control group), who aged 11-16-years who were selected from the middle school of “Al-Ahwaz “ in Al-Rusafa side in Baghdad City. Data were collected through a self-report instrument that used the Health-Promoting Lifestyle Profile.

The study results revealed that the HPM-based intervention has positive effects on students’ Health Responsibility, Physical Activity, Nutrition, Spiritual Growth, Interpersonal Relations, and Stress Management. Younger students demonstrated poorer Health Responsibility, poorer Nutrition, and poorer Spiritual Growth. The better the socioeconomic status, the better the Stress Management. Except for obese students, students with greater BMI enjoy greater the Physical Activity level. The researcher recommends the need to implement interventions based on the health promotion models; particularly the Health Promotion Model in improving adolescents’ health-related behaviors, the need to conduct similar studies on larger sample size in different areas across Iraq, and the need to include other factors that can have an influence on students’ health behaviors in future studies.

Keywords: Health Promotion Model; Health Responsibility

Introduction

Adolescents constitute 1.2 billion of the world’s population, about 90% of those adolescents live in low and middle-income countries. Promoting healthy practices during adolescence is considered an investment in countries’ future health and social infrastructure. Many risk or protective factors for future adult disease either start or are reinforced during this critical period of life (¹).

In Iraq, the total number of girls who age 10-14-years is estimated to 1.9 million; which constitutes 6 percent of total population (²). According to Iraq woman integrated social and health survey (I-WISH), girls who age 10-14-years-old reported that they need information about girls’ family right and duties (61.7%), dealing with adults (61.4%), free self-expression (61.1%), right nutrition (58.5%), dealing with the disabled (57.8%), child abuse and its combating (52.8%), dealing with males (51.1%), and sport activities (49.7%).

Health promotion is defined as the process of enabling people to increase control over, and to improve, their health, enables people to increase control over their own health (³).

Moreover, health promotion covers a wide range of social and environmental interventions that are designed...
to benefit and protect individual people’s health and quality of life by addressing and preventing the root causes of ill health, not just focusing on treatment and cure (6). For children and adolescents, health promotion is defined as those strategies that promote child and young people’s health, prevent disease in children and young people, and foster equity for children and young people, within a framework of sustainable development (5). This involves advocating for children and enabling their voices to be heard, promoting a broad sense of health and wellbeing, assessing health needs, implementing a range of public health interventions, seeing children in the context of their families and communities, and cooperating between a wide network of individuals and organizations (6).

Adolescence is a transition from childhood to adulthood and includes rapid developmental, physical, psychological, cognitive, and behavioral changes (7). Adolescence is viewed as an appropriate time to establish healthy habits and prevent future health complications (8).

Health-related values, beliefs, and behavior patterns that are typically formed during adolescence ultimately affect health outcomes in adulthood (9). Furthermore, the behavioral patterns during these developmental periods help determine young people’s current health status and their risk for developing chronic diseases.

Health Responsibility: Health responsibility involves an active sense of accountability for one’s own wellbeing. It includes paying attention to one’s own health, educating oneself about health, and exercising informed consumerism when seeking professional assistance (10-12). Adolescence is a transitional period accelerated by physical, psychological, social, cultural, emotional and cognitive changes (13). Throughout the adolescent years, the body and brain grow and change, and while trying to become adjusted to these changes, the adolescent must learn to negotiate new responsibilities and establish a new sense of self-identity and autonomy which is essential for independence (14-15). With this transition, opportunities and challenges present for improving health and preventing disease. As adolescents progress from childhood to adulthood, they take on increasing individual responsibility for their daily health habits. Trying to emulate adult roles and behaviors is normal and healthy in these adolescent years, but some adolescents experiment in ways that endanger their health and safety and contribute to the development of chronic disease in adulthood (16).

Purpose Statement: This study aims to determine the effect of the Health Promotion Model-based intervention in promoting the health behaviors for students; particularly health responsibility.

Material and Method

Study Design: The research design for this study was an experimental, randomized controlled trial design, control occurs to decrease the possibility of error and thus increase the probability that the study’s findings are an accurate reflection of reality and the researcher can reduce the influence or confounding effect of extraneous variables on the study variables, also controlling extraneous variables enable the researcher to identify relationships among the study variables accurately and examine the effects of one variable on another.

Study Population: The study population included middle school female students. The target population for this study was drawn from adolescents. The total number of students in this school was 780 who aged from 11-17-years-old, who were living in Baghdad City, who met the inclusion criteria mentioned below.

The researcher distributed (200) copies of the study questionnaire to the accessible students. The returned questionnaires were 190; 10 of them were incomplete. So, they were excluded from the data analyses. The final sample size was 180. Thus, the response rate was 95%.

Ethical Considerations: The research proposal was first reviewed and approved by the Department of Pediatrics Nursing. Thereafter, the student researcher (SR) obtained the approval of the Ministry of Planning and Development/The Central Organization of Statistics, and the Ministry of Education, Al-Rusafa II Directorate of Education.

The Health-Promoting Lifestyle Profile II (HPLP) was used to measure the health behaviors (12). The HPLP is a 4-point Likert type scale that is composed of 9 items. These items were measured on a 4-point Likert scale. Responses on this scale range from 1 (Never) to 4 (Routinely). Total scores range from 9 to 36, with a higher score means better health responsibility.

The study sample were randomly and equally selected from each grade (seventh, eighth, ninth). The simple random sample method was used to recruit study subjects.
The study questionnaire was given to participants to complete (self-reporting). Distributing questionnaires in person allow the researcher to explain the instructions before the participants start answering the questions. The questionnaires were also used to collect the data in three time points (pre-intervention, post-intervention I 6-weeks after intervention, post-intervention II 6-weeks after post-intervention I) in middle school. After completing the pretest phase, the researcher initiated intervention that is based on the six constructs of the Health Promotion Model. This intervention included 12 lectures about health responsibility. This intervention emphasized the behavior-specific cognition and attitudes that include: Perceived Benefits, Perceived Barriers, Perceived Self-Efficacy, Activity-related affect or feeling states related to each health behavior to oneself or to the situation, and Interpersonal and situational influences. These lectures were presented for students for each grade separately by data show. Each lecture lasted for 45 minutes.

The descriptive statistical measures of frequency, percent, mean, and standard deviation were used to describe participants’ demographics. The repeated measures analysis of variance (RM-ANOVA) was used to measure the difference in the Health Responsibility over time.

The age mean for participants in the study group is 13.53 ± 1.07; more than a third age 13-years-old (n = 33; 36.7%), followed by those who age 14-years-old (n = 29; 32.2%), those who age 12 and 15-years-old (n = 11; 12.2%), those who age 16-years-old (n = 4; 4.4%), those who age 11-years-old (n = 2; 2.2%). For the control group, the age mean is 13.64 ± 1.3; more than a quarter age 13 and 14-years-old (n = 24; 26.6%), followed by those who age 15-years-old (n = 16; 17.8%), those who age 12-years-old (n = 14; 15.6%), those who age 16-years-old (n = 8; 8.9%), and those who age 11-years-old (n = 4; 4.4%).
Concerning the SES, more than two-fifth in the study group are of the lower middle class \((n = 46; 51.1\%\), followed by those who are of the upper lower class \((n = 23; 25.6\%\), those who are of the upper middle class \((n = 20; 22.2\%\), and one who is of the upper class \((n = 1; 1.1\%\). For the control group, more than two-fifth are of the lower middle class \((n = 38; 42.2\%\), followed by those who are of the upper middle class \((n = 32; 35.5\%\), those who are of the upper lower class \((n = 14; 15.6\%\), and those who are of the upper class \((n = 6; 6.7\%\).

Regarding the BMI, the BMI mean for participants in the study group is \(22.59 \pm 5.2\); more than a half are of normal range \((n = 52; 57.8\%\), followed by those who are overweight \((n = 16; 17.8\%\), those who are underweight \((n = 14; 15.5\%\), those who have class I obesity \((n = 7; 7.8\%\), and one who has class II obesity \((n = 1; 1.1\%\).

For the control group, the BMI mean is \(22.6 \pm 3.6\); more than a half are of normal range \((n = 48; 53.3\%\), followed by those who are underweight \((n = 22; 24.4\%\),

Table 2: Descriptive Statistics for the Values of the Health Responsibility over Time

<table>
<thead>
<tr>

HR: Health Responsibility

There was a (a priori \(p = 0.01\)) significant difference \((F(1.123, 99.985) = 146.896, p = 0.01\)) in the Health Responsibility over time for participants in the study group. The omnibus effect (measure of association) for this analysis is .695, which indicates that approximately 69% of the total variance in the Health Responsibility values is accounted for by the variance in the administered intervention.
For the control group, there was no significant difference ($F(1.021, 90.840) = 2.255, p = 0.136$) in the Health Responsibility over time. The omnibus effect (measure of association) for this analysis is .025, which indicates that approximately 14% of the total variance in the Health Responsibility values is accounted for by the chance.

**Discussion of Findings**

This RCT used the Health Promotion Model as a theoretical framework to enhance female students’ health behaviors. There was a noticeable increase in the values of the Health Responsibility for the study group over time with a statistically significant difference. Moreover, approximately 69% of the total variance in the Health Responsibility values is accounted for by the variance in the administered intervention. This finding indicates the positive influence of the HPM-based intervention in enhancing students’ Health Responsibility.

**Conclusions**

The HPM-based intervention has positive effects on students’ Health Responsibility. The younger the student, the poorer the Health Responsibility.

**Implication for Practice:** There is a need to implement interventions based on the health promotion models; particularly the Health Promotion Model in improving adolescents’ health-related behaviors.

**Implications for Research:** There is a need to conduct similar studies on larger sample size in different areas across Iraq. There is a need to include other factors that can have an influence on students’ health behaviors in future studies.

**Implications for Education:** It is crucial to incorporate teaching materials that focus on promoting individuals’ health behaviors; particularly among adolescents into the curricula of different nursing programs.

**Conflict of Interest:** The researchers declare that there is no conflict of interest.

Detection of Rotavirus Genotypes with Conventional PCR in a Group of Iraqi Children with Acute Viral Gastroenteritis

Hiba Sabah Jasim
Department of Microbiology, College of Medicine, University of Baghdad

ABSTRACT

Rotaviruses are one of the major causes of acute viral gastroenteritis in children under 5 years old worldwide, the highest mortality is observed in developing countries. The genome of the rotavirus is composed of 11 segments of ds RNA, according to the antigenic characteristics of the middle layer protein VP6 the virus can be classified into A to I serogroups, the most common serogroup that can cause more than 90% of the rotavirus infections in human is the rotavirus A. This study aimed to detect the rotavirus genotypes in the children with acute viral gastroenteritis as this disease causes many deaths and cost the country a lot of money for treatment, additionally if the diagnosis of the virus is early the disease will be under control. Methodology: This study was conducted during March to September 2017; included 200 stool samples collected from hospitalized children. Samples were of two groups, 150 sample of patient with acute viral gastroenteritis, the other 50 samples were collected from healthy children also under 5 years old. The result considered positive if ELISA and/or PCR gave positive result, while considered negative if both of them gave negative result. Findings: The incidence of the rotavirus in the patient group was (70/150) while only two cases (2/50) of the control group showed positive result, the most prevalence serotype was G2P4 with (40/150) in the patient group, additionally this serotype was the only serotype that was detected in control group in both two cases that showed positive result with rotavirus. Conclusion: Rotavirus genotyping is a major risk factor of viral gastroenteritis in children as the percentage of the virus was high. Recommendation: Prophylaxis and treatment of children under 5 years old is very important especially for children that attend hospitals.

Keywords: Rotavirus, genotyping, ELISA, Conventional PCR.

Introduction

Rotaviruses are the major cause of acute viral gastroenteritis in children under five years old (1, 2). These viruses are the common cause of gastroenteritis in the world especially in developed countries (3, 4), rotaviruses infections result in an estimated of 400,000 to 500,000 deaths in young children (5).

Rotaviruses are nonenveloped viral capsid containing a genome of 11 double stranded RNA (6, 7). The outer layer of the virus is formed by VP4 and VP7 proteins. While the intermediate layer consists of VP6, a conserved region, which is useful in the genotyping.

The inner layer of is formed by VP2, VP1 and VP3 (8, 9), additionally the virus consist of nonstructural proteins with diverse functions, such as NSP1 play a role in the modulation of the immunity, NSP3 regulates the viral gene expression, and NSP4 play important role in the induction of diarrhea in infected cells (10, 11).

The virus enters the cells by receptors then form endosome. The viral protein in the third layer damage the membrane of the endosome, this will create a differences in the calcium concentration causing breakdown of VP7 into its subunits, then VP2, and VP6 accumulate around the dsRNA forming the double layer particle (DLP), which is transcriptionally active (12). The RNA is replicated and the DLPs are assembled, then the progeny of the virus released by lysis (13).

Serotypes of the virus are defined by using antisera to purified virus particles prepared in hyperimmunized
animals. By measure the reactivity of antibody with the two proteins (VP4 and VP7), which induce antibodies with neutralizing activity\(^{(14,15)}\). In most cases the antibody reactivity is against VP7. Because VP7 makes up a greater percentage, also induces more specific antibodies than VP4 does, possibly because VP4 is lost during preparation of virus. The serotypes of viruses, defined by ELISAs, also confirmed by molecular techniques, which greatly simplified virus characterization, additionally the early diagnosis and treatment of the disease\(^{(16,17)}\).

**Material and Method**

This study was included 200 stool samples, 150 was obtained from children with acute viral gastroenteritis attend to the pediatric department of Al-Emamain Medical City at Baghdad, Iraq from March to September 2017, the other 50 samples was collected from healthy children as control group.

All samples were diagnosed by latex agglutination detection of rotavirus using the Diralex Rota-Adeno Kit (Finland), another diagnosis of the virus by ELISA technique.

**RNA Extraction:** Extraction of RNA from stool samples was done using QIAamp® RNA Mini Kit (USA) according to the manufacture instruction.

Reverse transcriptase PCR was done in order to convert the nucleic acid RNA to cDNA, and the integrity was checked by PCR amplification of GAPDH which was performed according to Rameshkumar\(^{(18)}\). After cycling, the PCR products were electrophoresed in 2% agarose gel. Presence of 240 bp band means positive result, and this means that the quality of cDNA is good, all samples in this study were of good quality. Then concentration and purity of cDNA of each sample was measured using Nanodrope instrument.

Rotavirus antigen was detected by ELISA by removable well strips plates (USA), 90 µl of each sample was add to two wells of the plate coated with pre and post immunization serum, incubated in the optimum conditions of the reaction (37°C, 2 hours, washing 5 times), rotavirus antigen was detected by adding HRP conjugated to anti SA-11 antibody, then incubated for 90 minutes in humid conditions, TMB substrate was added and incubate in the room temperature for 15 minutes, the reaction was stopped by adding 1 M phosphoric acid (USA), the results was read at 450 nm.

**Rotavirus G and P genotyping:** For the genotyping of rotavirus, G and P typing methods were used; PCR was carried out separately for the VP7 and VP4 genes, using the products of the first PCR of VP7 and VP4 genes as templates. For G genotyping G1, G2, G3, G4, G8, and G9 specific primers, and for P genotyping, P4, P6, P8, and P9 specific primers were used in the PCR, the sequence of these genotypes was shown in table 1 and 2.

A negative control consisting of buffer only was included also non template control was added; finally electrophoresis amplicon visualization was performed using an UV light transluminator.

**Results**

This study showed the relationship between ELISA, and conventional PCR for detecting rotavirus 70 (46.7%) by PCR, while the percentage of the rotavirus with ELISA was 50 (33.3%). The incidence of diarrhea was more in the female group as 90 patients, while the number of male patients was 60, in control group the number of female was more than male, female samples were 30, while male samples were 20, as shown in table 3.

Table 7: This table shows the frequency of the rotavirus genotypes by conventional PCR

Discussion

Rotaviruses are with high diversity and can be differentiated into several different groups according to the antigenicity and gene composition of their VP6 (6, 7). The genome of rotavirus shows typical features which found in all rotaviruses regarded encoded proteins and conserved sequences at the genome segment ends. Each segment was found to encode one protein, with the exception of segment 10, which possesses two open reading frames (20, 21), for that reason this study was demonstrated to detect 24 different genotypes by PCR.

Rotavirus is a major cause of viral gastroenteritis in human especially children (22) using ELISA a good method for detection, additionally it’s of low cost and need simple experiences. However rapid and specific diagnostic method to detect the virus is needed to facilitate treatment of the disease (23).

This study detect the virus in 33.3% (50/150) from patients samples by ELISA, this result is similar to other Iraqi study which detect the virus in 37% (24), also other studies in neighboring countries such as in Jordan the prevalence of the virus was 33% (25), in Iranian study the incidence was 35% (26), while in Turkey the prevalence of the virus was 37% (27). While the detection of the virus by conventional PCR in this study was 70/150 which represented 46.7%, this result was similar to another Iraqi study which detect the virus in 42.45% (28), also these results similar to result in Kuwait as the prevalence was 44% (29), but the result of this study in the detection of the virus by PCR is less than the results in Oman which was 50% (30), also in Syria as the virus was detect in 61% of the samples (31).

The main objective of this study was to design a simple and sensitive PCR method for detection of a
broad range of rotavirus genotypes to be applied to routine monitoring of stool samples.

The method detect the presence of rotavirus in 70/150 isolates from patients group, also detect the virus in 2/50 isolates from control group as shown in (Table 7), involving 13 different G-P types from the 24 genotypes that was used in this study. The most prevalence was G2P4 which was detected in 57.14%, this result was similar to another Iraqi study as the detection was 53.33% (24).

In conclusion, this work reports the development, and application of PCR for the rapid detection of rotavirus genotypes. The results reported in this study highlight the inadequacies of non-molecular methods used for the routine detection of viruses and emphasize the importance of application of molecular to clinical services in hospital laboratories to provide definitive diagnoses, molecular methods could provide valuable information on the incidence of currently circulating viral strains, therefore lending itself to surveillance of viral transmission.

Effect of Adding Medicinal Plant Extracts to The Broiler Diets on Productive Performance

Huda Q. Al-Himdany¹, Fadhil R. Abbas², Ahmed A. Allaw³

¹College of Agricultural Engineering Sciences, University of Baghdad, Iraq; ²College of Agriculture, University of Al Qasim Green, Iraq; ³College of Agriculture, University of Tikrit, Iraq

ABSTRACT

Considering approaches to efficiently produce broiler, Therefore, this study was conducted to demonstrate the effect of adding some extracts to medicinal plants (Oleobiotec®) in increasing the efficiency of production performance of broiler, for the period from 12 February to 18 March 2016. In this study, 192 chicks (Ross 308) one day old were randomly distributed to four treatments, each including three replicates of 16 birds, which were: Control group T1 (without addition) and the treatments T2, T3 and T4 which received extracts to medicinal plants (Oleobiotec®) at concentrations 100, 150 and 200 mg/kg feed respectively. The results of this study indicated that the addition of Oleobiotec® to the broiler diet, particularly T3 and T4 enhance the production performance of broiler especially in body weight and weight gain. Also, the results showed a significant improvement in the feed conversion ratio for T3 (150 mg Oleobiotec®/kg feed). Also, the results revealed no significant effect in feed consumption rate in all treatments and for all periods except two week. Its was concluded from the results of this experiment that’s adding different levels of Oleobiotec® to the broiler diet enhance the productive traits of birds especially for the treatment T3 (150 mg Oleobiotec®/kg feed).

Keywords: extracts to medicinal plants (Oleobiotec®), Broiler, Productive performance

Introduction

The continuous use of industrial antibiotics as growth promoters in poultry diets led to the emergence of resistant bacteria, which prompted Europe Union countries to ban their use in 2006. The researchers encouraged the selection of many alternatives, including probiotics, prebiotics, Organic acids, enzymes, herbs and medicinal plants. Most of these substances are natural sources that work towards enhancing the environment of digestive tract and enhance immunity through its role as antifungal and antibacterial. Using of medicinal plants as additives to the broiler diets has great importance due to their containment of effective substances such as flavins, glycosides, polyphenols, terpenoids and saponens. Plant oils or extracts can be used as an alternative to antibiotics because these plants have antibacterial efficacy as well as their beneficial effect on the digestive system and improve immune status and support growth and public health without toxic residues that may be caused by drugs and antibiotics.

The Oleobiotec®, extracted from a number of medicinal plants and spices, has been used for nearly 12 years of research and experiments which contain effective substances that increase the metabolic rate of food and supply the body with oxygen and nutrients. It also contains phenolic compounds such as Thymol and Carvacrol, which are highly effective antioxidants and thus protect red blood cells from damage caused by oxidation as antioxidant activity improves through the transport of oxygen needed to form hemoglobin as well as contains both terpenoids and flavonoids within essential oils and spices which acts as anti-inflammatory and work to maintain the level of white blood cells within the normal range, also it contains an active substances as Cinnamaldehyde which has a significant role in enhancing the function of the immune system in the bird body. Furthermore, the Oleobiotec® contain Shogaol and Zingerone that’s act as antibacterial agents. Oleobiotec® product is a mixture of extracts of six medicinal plants, three of which are essential oils of each of the plants of Marjoram, Thyme, Cinnamon and the other three components are powder of spices for each of the Ginger, Turmeric and Pepper plants, this product specialized for poultry nutrition is a fine yellow powder added to the broiler diets by 100 g/ton.
Therefore, the aim of this study was to know the effect of adding the Oleobiotec® product to the diets on the production performance of the broiler chicks.

**Materials and Method**

This study was conducted in the poultry field of the Department of Animal Production at the College of Agriculture/Al-Qasim Green University for the period from 12 February to 18 March 2016 to investigate the effects of adding different levels of Oleobiotec® products to the diets on the production performance of broiler. In this study, 192 chicks (Ross 308) of one day old were randomly distributed to four treatments with 48 chicks per treatment, each treatment included three replicates of 16 birds. Chicks were weighed and distributed to the treatments which were: T1 control group (without addition) and the treatments T2, T3 and T4 received Oleobiotec® at concentrations 100, 150 and 200 mg/kg feed respectively. The chicks were bred in ground cages its dimensions are 2x2 m covered with sawdust, water introduced to the chicks ad libitum while diet was given to the chicks as starter and finisher diets (table 1). The experiment continued for 35 days and the productivity traits were measured for each week of the experiment which included body weight, weight gain, Feed consumption and Feed Conversion Ratio (FCR). Complete Randomized Design were used to study the effect of treatments on the studied traits and comparing the significant differences between the means using Duncan test 14, while the Statistical Analysis System (SAS) was used to analyze the data statistically15.

The results of effect adding different concentration of Oleobiotec® to the broiler diet on weekly weight gain (g) are summarizing in table (3). The result shows a significant increase (P <0.05) in weight gain (g) for the treatment T1 at one week of experiment compared with T3 which were 126.3 and 118.3 g, respectively. While the results revealed no significant differences between the treatments at, 3 and 4 weeks of experiment. Whereas, the treatments T3 and T4 indicate to a significant increasing (P <0.05) in the weight gain compared with the treatment T1 at 5 week of experiment which were 708.3, 687.3 and 559.6 g, respectively. Also, the cumulative weight gain revealed to a significant increasing (P<0.05) for the treatments T4 and T3 compared with control treatment T1.

The results of table (4) manifest the effect of the addition of Oleobiotec® to broiler diet on the weekly and accumulative feed consumption rate. The results of Table (4) showed that there were no significant differences between the experimental factors in the feeding consumption rate at the first, third, fourth and fifth week of the experiment.

The treatments T2, T3 and T4 appeared a significant decrease (P <0.05) in the feed consumption rate during the second week compared with control group T1. Also, the results revealed no significant differences between the experiment treatments in the accumulative feed consumption rate (1-35 day).

Table 5 shows the effect of supplementation different levels of Oleobiotec® product to the broiler diet on feed conversion ratio (FCR). At 1 week of experiment the results appeared a significant increase (P <0.05) in the FCR for the treatment T3 compared with T1 which were 1.3 and 1.22 respectively. while the results indicate to a significant decrease (P <0.05) in the FCR for the treatments T2 and T3 compared with control group T1 for the period 2 week which recorded 1.46, 1.44 and 1.69 respectively. No significant differences were found
between all treatments at the third and fourth week of age, while in the fifth week the results observed a significant decrease (P < 0.05) for the treatments T3 and T4 which reached 1.9 for each compared with the control treatment T1 which reached 2.29. As well as, accumulative FCR for the period from 1 to 35 days, showed a significant decrease (P < 0.05) for the treatment T3 compared with control group which were 1.68 and 1.79 respectively.

From the results of the present study, it was concluded that all enhancements observed in the productive traits for the treatments T2, T3 and T4 may be due to containing the previous treatment on different levels of Oleobiotec® product and its containing a number of medicinal plants and its active compounds improved the taste of diet and improve appetite and health of birds, then improved digestion and absorption, which had a positive effect on the qualities of productivity.

The birds that fed diet supplemented by 150 and 200 mg Oleobiotec®/kg feed enhanced the amount of feed consumed then improve the FCR which increased the birds weight and this significant enhancement in productive parameters may be due to containing the Oleobiotec® product to many effective compounds that acts as antioxidan316,17,18. The oils found in the Oleobiotec® formula are rich in essential fatty acids that enough the needs of body for growth. These ingredients also improve the nutritional value of nutrients trough stimulation the secretion of a number of digestive enzymessuch as Lipase, Amylase and Protease which has an important role in the process of digestion and absorption through its prominent role in the analysis of fat, carbohydrate and protein components19,20. The Oleobiotec® product contains aromatic oils that contain an active ingredients as Carvacrol, Thymol and Eugenol, which in turn stimulates digestion and increases the digestibility of nutrients as well as its role as antimicrobial, antiviral, antifungal and gas expeller, and these active substances promote metabolism of proteins, carbohydrates and fats, and thus increase the rate of growth21,22,23. These factors were reflected in the improvement of the productive parameters of the birds. These results agreed with Noaman and Allaw7, that’s confirmed the existence of a significant enhancement in the productive parameters when fed the broiler chicks on capsules containing different levels of Oleobiotec® at 50, 100 and 150 ppm three times per week.

Conclusion

The results of current study shows that supplementing 150 mg of Oleobiotec® per kg feed enhanced the productive performance traits of the broiler.

ABSTRACT

An automation system in industry is evolving significantly over recent years. Beside the quality of the system, one of the aspects determining the success of acceptance a new system is user’s perception. This research examines influential factors of user’s behavioral intention in building environment automation system practical use. A development model of the Theory of Planned Behavior (TPB) with three internal factors, Attitude (ATT), Subjective Norm (SN), and Perceived Behavioral Control (PBC), was developed to predict the behavior of managerial level when deciding whether to implement a new system, which was the Building Automation System (BAS) in pharmacy industry. The study found statistically significant support for the hypothesized model, indicating that the tested relationships between the factors and behavioral intentions to use BAS were positively significant. These findings can be served for explaining the behavior intention for users within the context of a building automation system.

Keywords: behavioral intention, theory of planned behavior, building environment automation, attitude, perceived behavioral control.

Introduction

In the past, less automation systems for building used towards energy and environmental management, primarily for monitoring of energy consumption, with insufficient control functions and high dependence on the human factor. Nowadays, Building Automation Systems (BAS) becomes increasingly popular to use in many types of building. In an industrial building, BAS was applied to control supply of electricity, lighting, cooling system, heating system, ventilation, etc.

In southeast Asia, Indonesia was the largest energy consumer, with 36% of the region’s total primary consumption (1). As of 2013, the country’s industrial sector was the sector with the highest share of total energy consumption by the amount of 33% (1). In order to respond to the competitive energy environment, in the current global economic crisis, Indonesia faces numerous challenges associated with growing energy demand and high-energy cost. To accomplish this advantage, many ASEAN countries have adopted the energy-efficiency programs, which focus on automation system in industries (2).

The current study aims to explore factors that influence user’s acceptance in building automation system that has been implemented in the industries. Several literatures exposed that the performance of the smart Building Automation System (BAS) benefits reduce energy expense expressively for electricity consumption, especially in commercial buildings (3-10). Similar studies that observed the users’ behavior in BAS or smart grid through structural equation modelling concentrated on residential housing, commercial housing and general-purpose use of energy (11-13) instead in industrial sector (10).
Materials and Method

Nowadays, BAS are currently being developed to be applied in buildings, namely the “green buildings”, for environmental and energy controlling \(^{(3)}\). Indeed, the application of these systems has become increasingly popular, revealing the ongoing interest of the scientific community on this topic \(^{(14)}\). The submission of a traditional quantitative control method based on the preset continuous values of physical parameters is not enough for users’ response in the indoor environment \(^{(10, 15)}\). The checking items contain of observing of consumption in lighting, production electricity supply for machines, heating ventilation air conditioning in building and several others \(^{(5, 8, 16)}\).

Theory of Planned Behavior (TPB) is able to investigate the factors of user’s behavior towards using information technology or in adoption new technology. Similar with TPB, Technology Acceptance Model (TAM) shows that users’ intention directly affects their actual behavior \(^{(10, 16-20)}\). The research uses an extension of TPB model by including TAM external factors, PEOU and PU. Behavior intention can be affected by perceived behavioral control, subjective norm, and attitude \(^{(21)}\). Attitude (A) can be described as the degree of which the users follows their negative or positive emotion to use new technology \(^{(16, 22)}\). Subjective Norm (SN) can be described as the perceived public burden to complete or not to complete the behavior \(^{(17, 21)}\). Perceived Behavioral Control (PBC) can be described as difficulty of control the behavior, which is assumed to “reflect past experience as well as predicted impediments and obstacles” \(^{(17, 21, 23)}\). PU means a degree to which a person accepts as true that using a certain system would enrich his or her job performance and PEOU means a degree to which a person accepts that using a certain system would be free of struggle. According to Davis, the perceived ease of use and perceived usefulness have direct correlations to the factor attitude and have associations with the behavior intention to use \(^{(24)}\). TAM is able to determine the perceived ease of use and perceived usefulness of technology applications can affect users’ utilization efficacy of system \(^{(12, 25)}\). Furthermore, in BAS behavior study, PEU and PU are reflected as the key factors that impact user intention to use smart monitoring. PU has a relationship to ATT \(^{(10)}\), while PU is a factor that was proposed by the authors, as proven in previous research has indirect relationship with PEOU \(^{(26)}\).

In addition to TPB model, this research also observes the correlation between the two constructs PEOU and PU. These relationships are not being investigated in previous studies that employed TPB as the theoretical framework. Following their illustration, we hypothesized that ATT, SN and PBC will influence BI, respectively. Finally, our study contributes to this gap literature by discovering the correlation between two core TAM variables and the three core TPB variables. The findings of these studies show that internal factors and external factors are crucial elements of user’s acceptance and adoption of new system. Therefore, our study examines the important role of those factors in understanding user participation intention. In summary, six hypotheses in Table 1 are assembled based on extension of TPB model in predicting adoption behavior of BAS usage.

The sample of this research is from Indonesia, which was considered as the biggest country in Southeast Asia. To assess our research model, we employed the online questionnaire survey from December 2014 to April 2015. The
respondents who have used BAS for building monitoring for more than 6 months were asked to join in the survey. Among the 157 respondents, 86% of the respondents are between 18 and 28 years old and 14% were between 29 and 38. All respondents filled out the same questionnaire, which are represent of six latent of behavior technological adoption factors in BAS. All the observed item was measured on a 5-point Likert-type scale with anchors ranging from “1 = strongly disagree” to “5 = strongly agree”\(^{(27)}\).

**Results and Discussion**

The confirmatory factor analysis was conducted to test a measurement all factors based on reliability and validity. next, a structural equation modelling (SEM) was used to examine the structural relationships among the factors in our model\(^{(10)}\). As displayed in Table 2, The result of the model shows positive values for six path correlations for both external factors and internal factors of TPB. Furthermore, most hypothesized path of the influencing factors to behavior intention of use BAS are statistically significant except for one paths, which is SN to BI (Hypothesis 5). PU positively correlated with ATT (Hypothesis 1), PEOU positively correlated with ATT (Hypothesis 2), and PEOU positively correlated with PU (Hypothesis 3). Moreover, in basic internal factors of TPB, ATT positively correlated with BI (Hypothesis 4), and PBC positively correlated with BI (Hypothesis 6).

This study used AMOS software for the reliability and the convergent validity statistical test of the questionnaire, as presented in Table 3. All the value of our factor loadings exceeded the recommended minimum measurement (0.7)\(^{(28)}\). The second measurement was Cronbach’s α, and each questionnaire item exceed the minimum measurement of the Cronbach’s α value (0.7)\(^{(29)}\). As shown in Table 3, the measure of composite reliability exceeds the minimum requirement (>0.6), and the last measurement, the six factors exceed the minimum measurement for the AVE measures (>0.5)\(^{(30)}\).

**Conclusions**

Our research model focuses on explaining the fundamentals how the attitude is formed and how it leads to the eventually adopting behavior intention of use BAS in pharmacy manufacturing. Therefore, the research framework integrates TPB with two external factors of TAM, in a complementary manner to completely predict system use of BAS in organizations. Past research which only reported part of this framework, focused on the social and technical factors affecting adoption behavior of smart grid. The validation of this framework is crucial in terms of developing a new research approach in a similar application.

The result explained the R2 and path correlation for all hypotheses. The relationships between PU (β = 0.784, p < 0.01), PEOU (β = 0.503, p < 0.01), and ATT were positive and significant. Next, PEU (β = 0.341, p < 0.01) has a significant influence on PU. The model testing results explained 63.8% of the variance in ATT. SN (β = 0.014, p > 0.05) was not significant affected BI, then hypothesis 5 were not supported. ATT (β = 0.624, p < 0.01) and PBC (β = 0.561, p < 0.05) positively and significantly affected BI, explaining the variance of BI (R2 = 56%). Finally, our study results demonstrate that ATT and PBC had a significant influence on BI. Hence, Hypothesis 4 and Hypothesis 6 were supported.

The latent variables of perceived ease of use and perceived usefulness were integrated as external factors into TPB. Those factors influence user’s intention through the attitude, perceived ease of use and perceived usefulness. The result from the framework model of extended TPB is very useful to provide an understanding of aspects of the user’s adoption of BAS technology in manufacturing. Finally, according to the result of path correlations, the final model contributes 56% (R2 = 56%) to the real situation, indicating that the research factors can represent 56% of total intention to use of BAS.

We expect the outcomes of this research to deliver insight for future study on enhancing the theoretical of TPB in BAS by collaborating with other related factors. The results from our study support that PU, PEOU, ATT, and PBC are become as an important role in predicting technology adoption behavior of BAS. Therefore, the system must be considered to distribute various controlling tasks in order to reduce the usefulness, and enhance ease of use of the system.

The Impact of Radiation on Total Thrombocyte of Hospital Radiology Workers in Kupang

Jannes Bastian Selly1,2, Andreas Umbu Roga2, Noorce Christiani Berek2, Luh Putu Ruliaty2, Jacob M. Ratu2

1Master Student Program in Public Health Sciences, 2Faculty of Public Health, University of Nusa Cendana, NTT Indonesia; 3University of Citra Bangsa Kupang, NTT Indonesia

ABSTRACT

Ionizing radiation that used in diagnosis and treatment process in hospital is not only providing the benefits, but also has negative impact on health. The officer in radiology installation of hospital has high risk of decreased number of thrombocyte, due to exposure experienced countinously during the work. The previous study using mice as object of research, found that exposure to ionizing radiation resulting in a decrease in the number of thrombocytes. Decreased total thrombocytes caused by the damage to cell. Thrombocytes destruction post-irradiation is 15 times faster than the recovery. This study aimed to analyze the effects of radiation exposure on the total thrombocyte of workers in radiology installation in hospital of Kupang. Subjects in this study were 20 workers from 3 hospitals selected by purposive sampling technique. This research was an observational analytic with cross sectional approach. Data used are exposure doses and blood examination results carried out together within a period of 1 year. The result was shown that the average dose of radiation exposure received by the officer during working for 1 year was 0.776 mSv. This value was still relatively safe because it was below the dose limits set by International Commision for Radiation Protection (ICRP). However the result of the analysis was shown that there was significant effect between radiation exposure dose received by the officer with total thrombocytes p-value 0.05. The regression equation was shown that the increase of 1 unit dose would decrease the number of thrombocytes was 10.3. The regression coefficient $R^2 = 0.197$ shown that the effects of radiation exposure dose against the decrement of total thrombocytes was 19.7%. It was recommended for the workers and hospital management to increase the efforts against radiation protection, thus the stochastic effects of exposure could be minimized.

Keywords: Thrombocyte, exposure doses, ionizing radiation, radiology installation

Introduction

The type of radiation used in the radiodiagnostic process is ionizing radiation. Interaction of ionizing radiation with the body’s cells can cause free radicals that harm the health (1). Radical compounds in the body form bonds within cells, causing cells to become abnormal and potentially become cancerous (2).

Workers at radiological installations have high risk affected by the ionizing radiation. This can happen because radiation exposure can occur continuously during the work (3). To control the activity of radiation workers, International Commission of Radiation Protection (ICRP) has set a radiation dose threshold for radiation workers at 20 mSv per year (4). These regulations apply to all the countries in the world, including in Indonesia. In addition to limiting the value of doses, radiation officers are also required to carry out periodic health checks to determine changes that occur in the body due to exposure to ionizing radiation (5).

The effects of ionizing radiation are grouped into two, namely the deterministic and stochastic effects (6). The deterministic effect occurs when the dose threshold value is exceeded. This effect will cause damage and cell death whose symptoms can be directly observed such as reddish skin and blistering. High doses, for example $\geq 100$ mSv, can cause central nervous system damage, followed by death within a few hours or days (6). Stochastic effect, there is no definite dose threshold

value. A small radiation dose even if it does not kill cells, but can turn cells into abnormal. These abnormal cells have the possibility to continue to divide and develop into cancer\(^6\). Stochastic effects of radiation exposure are known as the silent killer, therefore health checks for radiology workers must be carried out so that the initial symptoms or signs of initial damage to cells due to radiation exposure can be identified early and anticipatory steps can be taken to ensure the safety and health of radiology workers\(^4,5\).

Blood is a biological component that is sensitive to exposure to ionizing radiation\(^7\). Blood is composed of a combination of approximately 55% of blood plasma and 45% blood cells (erythrocytes, leukocytes and thrombocytes). Blood plasma is composed of approximately 90% water. Water (H\(_2\)O) is molecule highly susceptible to ionizing radiation. When it is exposed to radiation, free radicals will form\(^8,9\). Free radicals are atoms or molecules that have a free electron unstable. Free radicals will bind to other atoms or molecules on cells to become stable\(^9\). These ties make abnormal molecules formed in the body. This will provide a change in blood components\(^9\).

Bone marrow, especially the red marrow as a place of blood production, is also a tissue that is very sensitive to ionizing radiation as seen from the radiation coefficients for each tissue and organ shown in Table 1 below\(^10\).

*According to a Decree No. 01/Ka. BAPETEN/V-1999

**According to the ICRP No. 60 (1990)

The radiation coefficient of an organ or tissue shows the sensitivity of the organ or tissue to radiation exposure\(^10\). With the level of sensitivity of blood cells, this can be an indicator to evaluate the health of radiology workers\(^11\).

Thrombocytes are a component of blood that plays a role in the process of blood clotting when a wound occurs. The previous study in mice as experimental animals, it was found that the high-energy ionizing radiation, resulting in a decrease in the number of thrombocytes. Thrombocytes count decreased linearly with increasing doses of radiation. Thrombocytes recovery after radiation exposure occurs 15 times slower than the damage suffered\(^12\). Other studies have also found that high-dose radiation exposure in cancer patients undergoing radiotherapy impacts decreased thrombocytes count up to 29.96%\(^13\). Normal total thrombocytes were in the range of 150 to 400. Lower thrombocytes count is 150, identified as thrombocytopenia. Thrombocytopenia that is lower than 100 have a high chance of bleeding to cause death\(^14-16\). Therefore, this study was conducted in order to analyze the impact of radiation doses to the blood profile, especially thrombocytes.

**Methodology**

This research is an observational analytic research with cross sectional approach. The total respondents in this research are 20 workers from 3 hospital, they are Hospital of Prof. Dr. W. Z. Johannes, Wirasakti and Naibonat. Independent variable in this study was a dose of radiation exposure, while the dependent variable is the number of thrombocytes. The data in this research is secondary data dosimeter readings on individuals and the results of routine blood tests workers every year. Data radiation exposure dose for 1 year juxtaposed with the data results of blood tests in the same year.

**Findings**

**a. Characteristics of Respondents:** Respondents in this study were 20 workers consisting of 14 men (70%) and 6 women (30%). A total of 10 respondents (50%) aged between 25 and 35 years, 4 respondents (20%) aged 36 to 45 years and 6 respondents (30%) aged over 46 years. Based on the background of expertise, as many
as 16 respondents (80%) is radiographer, two respondents (10%) are specialists of radiology, and two other respondents (10%), respectively nurses and administrative personnel. Before working on the installation of radiological, every officer has conducted a complete medical examination and declared healthy. Furthermore, regular health check, including blood, for every workers. The type of individual dosimeters used by the respondents is the TLD (thermoluminesence dosimeter) badge. The reading of the radiation dose values in the TLD is done every 3 months. The results of exposure dose readings will be archived by the hospital management, so as to get a dose for 1 year, it will be accumulated value of the dose every 3 months for 1 year.

b. Dose Radiation Exposure: Based on the data search results is known that the average value of the exposure dose received by an officer for one year was 0.78 mSv. The highest dose received by the officer of 0.87 mSv, while the lowest dose of 0.73 mSv. Radiation exposure dose received by any officer for a year is still relatively safe, because it is below the limit values specified dose of 20 mSv per year\(^4\). Although the radiation exposure dose every officer did not show a high value, remain aware of the possibility of stochastic effects can occur\(^6\).

c. The Total Thrombocyte: The search results and tabulation of data showed that the average number of thrombocytes officer is 282.6 \(\times\) 10\(^3\)/mL. This value is still in the normal range of thrombocytes counts. But individually there are two workers who had abnormal thrombocytes count is 603 \(\times\) 10\(^3\)/mL, exceeding the normal value (thrombocytosis) and below the normal value (thrombocytopenia) is 63 \(\times\) 10\(^3\)/mL.

d. The Impact of Radiation Exposure Dose to Thrombocyte Amount: The analysis showed that the dose of radiation exposure have a significant influence on the number of thrombocytes in the radiation officer hospital radiology installations in Kupang. Linear curve effects of radiation exposure dose of the thrombocytes count is shown in Figure 1

**Figure 1: Linear curve effects of radiation exposure dose to the number of thrombocytes**

Regression equations to estimate the number of thrombocytes workers due to radiation exposure dose in accordance with the curve above is

\[
\hat{Y} = 178.3 - 188.6X,
\]

The above equation explains that the coefficient for the variable thrombocytes count officer was 178.3, while the coefficient for the radiation exposure dose is variable (-188.6). This value indicates that, when there is no radiation exposure or radiation dose is 0 mSv, then estimated the number of thrombocytes of officer is 178.3 \(\times\) 10\(^3\)/\(\mu\)L. When a dose of radiation exposure and the value is not zero, then the thrombocytes count will be amended. An increase of 1 unit dose radiation exposure, resulting in a decrease of thrombocytes by 10.3 \(\times\) 10\(^3\)/\(\mu\)L (17). Regulations set by the ICRP that the dose of radiation exposure to the workers should not be above 5 mSv every three months makes sense, because if the exposure dose of radiation received by the officer by 5 mSv, the thrombocytes amount is expected to decline by 51.5 \(\times\) 10\(^3\)/\(\mu\)L of 178.3 \(\times\) 10\(^3\)/\(\mu\)L becoming 126.8 \(\times\) 10\(^3\)/\(\mu\)L. This amount is below the normal amount of thrombocyte, that is 150 \(\times\) 10\(^3\)/\(\mu\)L and categorized by thrombocytopenia\(^{14}\).

In this study, a total of 2 workers have abnormal total thrombocytes, each thrombocytosis and thrombocytopenia. The person who experienced thrombocytopenia, is not the worker who received the highest dose of exposure. Likewise, respondent who experience thrombocytosis, was not workers who get the lowest dose. Therefore, according to the researchers, there are factors other than the dose of radiation exposure, causing the officer had thrombocytopenia. Need to do a
more complete examination by a doctor to both of these officials. This equation model can explain the effect of the radiation exposure dose to thrombocytes count at 19.7% ($R^2=0.197$). This means that there are factors other than exposure dose which causes a decrease in thrombocytes count by 80.3%.

Decreased thrombocytes count at the workers in this study amounted to 5.78%. This value is relatively lower when compared with previous studies that found that a decrease in the number of thrombocytes due to radiation exposure reached 29.96%\(^{(13)}\). Researchers assume that this occurs because of differences in the dose received by the study subjects. Radiation exposure dose in this study was only 0.776 mSv, whereas in the previous study it was 500 mSv. In addition, the respondents in this study are the workers who was in a healthy condition, while respondents in the earlier study are cancer patients undergoing radiotherapy process.

**Conclusion**

Although the radiation exposure dose received by workers is below the ICRP-determined threshold, it has a significant effect on changes in platelet count. Increased radiation exposure dose of 1 mSv predicted to reduce the number of thrombocyte at. Therefore, it is expected that the efforts of protection for personnel is maintained and even increased to minimize the radiation dose received. Health checks including routine blood tests also should be closely monitored, given in some hospitals have not done routinely. The results of monitoring and health checks can be a prognosis that can be anticipatory efforts in ensuring the health and safety of workers at hospitals radiology installation in kupang.

**Conflicts of Interest:** The author is a student of public health sciences and did not have a relationship with the respondents in this case are workers on the hospital radiology installation in Kupang. Therefore, any data and analytical results in this study show it is in accordance with the actual data obtained during the research.

**Statement of Informed Consent:** Before conducting the study, the authors explained about the process that will be conducted during the study. Things that are described include research procedures, benefits, and things that should be conducted by the respondents during the study. Furthermore, the authors give the informed consent sheet to the radiology workers. Statement in the informed consent sheet states the willingness of workers as respondents in voluntary research.

**Ethical Clearance:** This study using human as research subjects, therefore, before obtaining the permission, the author submitted ethical clearance to Health Research Ethics Committee, Faculty of Medicine Nusa Cendana University. This research had been permitted with ethical approval recommendation number 05/UN15.16/KEPK/2019 dated January 30, 2019.

Importance of Collaborative Intervention of Preconception Nutrition in Suppressing the Stunting Case in East Nusa Tenggara, Indonesia

Jeffrey Jap¹, Sri Sumarmi², Nyoman Anita Damayanti³
¹Doctoral Student, Program of Public Health, ²Lecturer, Department of Health Nutrition, ³Lecturer, Department of Health Administration and Policy, Faculty of Public Health, Universitas Airlangga, Surabaya, Indonesia

ABSTRACT

The result of Basic Health Research (Riskesdas) in 2013 on stunting case (short stature) in Indonesia reaches 37.2%. The basic cause of this stunting is due to anemia on women in pregnancy (37.1%). Malnutrition cases become one essential threat for women in pregnancy in Indonesia and East Nusa Tenggara in particular. In East Nusa Tenggara province, this stunting case is still a problem that requires immediate treatment. This can be seen from the proportion of stunted toddlers which is more than 50%. The purpose of this research was to find a form of collaborative intervention in order to cope with the stunting issues with specific targets for preconception mothers.

The type of descriptive research was literature study with qualitative approach.

The result indicated that the collaborative intervention related to preconception nutrition was to prevent the occurrence of anemia on women in pregnancy which endedup in stunting. Therefore, it was necessary to collaborate on all parties to intervene, especially during the preconception period.

Keywords: Collaboration, Preconception Nutrition, Stunting, Malnutrition

Introduction

Nutrition is a very important thing in life. Humans can perform all the works optimally if all the nutritional needs are fulfilled. Nutrition becomes the determinant of the quality of Human Resources (HR) of a nation.⁴ Indonesia itself has been dealing with nutritional problems for a long time and has been included in 17 countries out of 117 countries with high prevalence of stunting (37.2%), wasting (12.1%) and overweight (11.9%) on toddlers.²

Basic Health Research Results (Riskesdas) in 2013 shows that the most case of nutritional problems on toddlers in Indonesia is stunting (short stature) that reaches 37.2%. This is in line with the number of anemia case on women in pregnancy that reaches 37.1%. Stunting case becomes one threat for women in pregnancy in Indonesia and East Nusa Tenggara in particular. In East Nusa Tenggara Province, the number of stunted children is even higher, which is 51.77%. In fact, one of the districts in East Nusa Tenggara, namely South Central Timor (TTS) has stunting prevalence of 70.5%.³ This figure is above Afghanistan, which ranks highest in the world with the stunting prevalence of 59%.⁴ This is directly proportional to the economic condition of East Nusa Tenggara which is in the order of the three respectively poorest provinces in Indonesia; Papua 28.40 percent, West Papua 25.73 percent, and East Nusa Tenggara 22.58 percent.²

In other words, the quality of the baby born depends on the mother’s nutritional status before and during
pregnancy or preconception. A pregnant woman will give birth to a healthy baby if the level of health and nutrition are in good status. However, there are still many pregnant women who have nutritional problems, especially malnutrition such as Chronic Energy Deficiency (CED) and nutrition anemia.

Pregnant women who suffer from CED and anemia have greater risk of illness, especially in the third trimester of pregnancy compared with normal pregnant women. As a result, they have a greater risk of having a baby with Low Birth Weight (LBW), death during bleeding, laborious postpartum delivery for being weak and they are also vulnerable to have health problems. Generally, infants born with Low Birth Weight (LBW) cannot absorb new environmental stresses optimally, which may result in stunted growth and development, and it is considered as stunting.

### Material and Method

This research was a descriptive research type of literature study with qualitative approach. The use of qualitative method aimed to obtain data not only measured mathematically but explored its meaning. The main data sources in qualitative research were documents and journals. Journals taken based on titles with keywords; collaboration between LBW preconception nutrition. Inclusion criteria: 1) Related to collaboration, LBW and preconception nutrition, 2) International journals indexed by schopus. Exclusion criteria: 1) Year published from 2013 - 2018, 2) Having complete journal access. The number of journals can be as many as 75 journals and after passing the inclusion and exclusion criteria of 35 filtered journals.

### Findings

**Stunting and Nutrition Issues in the Preconception Period:** The cause of nutritional problems was very complex. Mothers’ preconception nutrition had a significant contribution in cases of malnutrition and stunting in children. The table 1 shows that Chronic Energy Deficiency (CED) in those who are pregnant tends to be higher than those who are not pregnant. This condition will affect the growth and development of the fetus in the womb. Therefore, the mother should be prepared as well as possible in order not to encounter CED during the pregnancy. If it is not anticipated as early as possible, then it will end up in Low Birth Weight (LBW) as in the table 2.

The central and local governments have made many breakthroughs to fix this problem, and after tracing it turned out that the intervention was much more focused at the time of conception and afterwards, such as; with PMT program, complementary feeding, improvement of posyandu service and community empowerment. PMT program denotes a program done by the government to improve children’s nutrition status by giving additional food to the children with malnutrition status or less nutrition status. Posyandu constitutes a regular program for family planning and integrated health, to give optimal health service for children under 5 years old. The result indicated that the stunting prevalence was still high and tendency of reduction was still very slowly. Basic Health Research (Riskeesdas) results in 2013 put East Nusa Tenggara in the position far above the national average with 51.77% of stunting prevalence. Not to mention, one of the districts in East Nusa Tenggara which is South Central Timor (TTS) has 70.5% of stunting prevalence. This figure is above Afghanistan which ranks highest in the world with 59% of Stunting prevalence.

### Discussion

The relationship between Micronutrients and Maternal Nutrition Status in Preconception will be presented below.
Micronutrients are the nutrients needed by the humans’ body in small amounts, but have a very important role in the formation of hormones, enzyme activity and regulate the function of the immune system and reproductive system\textsuperscript{11}. Micronutrients are vitamins (both water soluble and fat soluble) and minerals. Minerals are divided into two groups: macro-minerals and micro-minerals. Macro-minerals are minerals that the body needs at least 100 mg per day (e.g. calcium, phosphorus), whereas micro-minerals (trace elements) are minerals that the body needs which less than 100 mg per day (e.g. zinc, iron).\textsuperscript{10}

There are also micro-minerals which are needed only a few micrograms per day, such as cuprum and molybdenenum. Micronutrients are obtained from outside the body such as from food or supplements, because the body is unable to produce it in sufficient amount in accordance with the needs of the body. Micronutrients are extremely needed by the body, even though the body only needs very small amount of it.\textsuperscript{11}

For breastfeeding mothers, micronutrient status will determine the health, growth and development of infants who are breastfed, especially at the age of the first 6 months after the baby was born. Therefore, it is necessary to prepare before the conception period.\textsuperscript{12} The things which are prepared include preparing the prospective mother by providing nutritious nutritional intake so that there will be no micronutrients deficiency during the conception.\textsuperscript{13}

Here are some essential micronutrients that must be met during preconception; 1) **Vitamin A**; Vitamin A has really important roles in the preconception period, such as, boosting immunity, cell differentiation (cell shape and function changes), reproduction (keeping fertility to enter the conception), preparation of embryo growth, and growth and development of cells, including bones and teeth.\textsuperscript{11} 2) **Iron**; Iron is an essential mineral for the formation of haemoglobin which serves to carry oxygen from the lungs to all body tissues, electrons into cells, and form the necessary iron nutrient enzymes for cellular energy production, immune system, and brain function. During this preconception, iron has extremely important role to prevent iron deficiency during pregnancy and birth. If this is done, then there will be no baby stunting 3) **Zinc**; This is very important to be noticed by prospective mothers especially during the preconception period.\textsuperscript{12} 4) **Iodine**; Iodine is an important component in thyroid hormone synthesis, a hormone that regulates body temperature, basic metabolism, reproduction, growth and development, red blood cell formation and muscle and nerve function.\textsuperscript{14}

The results of research conducted by Sumarmi et al (2017) provide an illustration that there is a relationship between the mother’s body mass-index with micronutrient intake. So, the intake is necessary to prevent the occurrence of anemia on the mothers.\textsuperscript{15}

Solutions directly, nutrition problems are caused by low nutrient intake and health problems.\textsuperscript{16} In addition, nutrient intake and health problems are two things that affect each other.\textsuperscript{17} The indirect effect is the availability of food, the pattern of care and the availability of clean water, sanitation and health services.

Actually, East Nusa Tenggara already has the authorized capital to make a total revolution both for the micro and macro level. At the micro level, East Nusa Tenggara has REVOLUSI KIA program, which is a program to decrease the number of both mother and baby’s death during childbirth. This program has clearly decreased maternal mortality from 330 deaths (2008) to 128 (2015) and infant mortality from 1274 (2008) to 965 (2015). However, this program has not pressed the number of stunting.\textsuperscript{18}

One thing that causes why the mentioned figures is difficult to decrease because there is no maximum intervention in preconception.\textsuperscript{19} Preconception must be intervened not only by all health workers but all parties within the range of human life.\textsuperscript{3} Health workers should be the leaders in this matter. Quality nutrition services to women in preconception can be realized if all the existing professions in the Community Health Center (Puskesmas) and their networks and the public are able to perform collaborative health services by implementing six strategic steps as stated by Previous study describes the role of each health worker in the hospital is an effort to overcome the problem of nutrition through six things, namely; 1) creating work culture in the workplace, 2) affirming the role of nutrition in health, 3) determining diagnosis, 4) doing quick and precise intervention, and follow-up monitoring; 5) communicating and planning related nutrition issues well, 6) developing further handling of post-intervention and continuing education related to nutrition. In addition, collaboration is also needed from other parties outside the health sector.\textsuperscript{16} Collaboration with all other related sectors, either directly or indirectly, can provide a positive contribution.\textsuperscript{20} The Community Health Center (puskesmas) is necessary to
create a preconception period that is fully prepared and well-done towards conception.21

Another factor that should be well considered is the state of the family itself, one of them is the level of education. An improved level of education will have an opportunity to get better jobs where income is also more regular and in greater amount.22 In addition, if low levels of education do not improve the socio-economic conditions, that will end up in stunting (short stature) and malnutrition.23 Then the intervention of the government and all the people is necessary, especially the environment in which the mother lives. Another study on 115 families with toddlers in 2014 with household-level food diversity. The result shows that there is a relationship between food diversity and income (number and type).24 The poor are often able to survive and even rise again, especially when they have a network or social order that protects and saves them.22

The role of government in community empowerment becomes one of the alternative solutions. The bottom line is on improving the family economy.25 Government through various policies should pay more attention to improve family nutrition. With the presence of village funds and village-focused development, it is expected to boost the improvement of specialized micro-nutrients in the preconception period.15

Conclusions

Based on the exposure in the analysis and discussion in the preceding section, here are the main conclusions of the study. That preconception nutrition was very important to prevent stunting in children in East Nusa Tenggara. Therefore, it is necessary to have collaboration among the health professions and other related sectors to improve nutrition in the preconception period.

Conflict of Interest: There is no conflict of interest for every author.

Evaluation of Folic Acid Content in the Pregnant Women

Jinan Hussein Mutlag
Karbala Hospital for Gynecology and Obstetrics, Karbel, Iraq

ABSTRACT

Folic acid is a naturally available nutrient which is found in various foods like egg yolk, vegetables, legumes etc. It is involved in de novo DNA’s biosynthesis in growing cells and in transmethylation reactions. The present study aim to evaluate the correlation of folic acid content and pregnancy outcome in the Iraqi women. This case-control study (n=30 each) includes a pregnant women enrolled in Karbala maternity teaching hospital with 23rd to 25th gestational week. About 33.33%, 53.33% and 41.67% women were included in the age group of less than 20, 1-30 and 30-40 years, respectively. Folate deficient women showed significant decreased in the fetus weight as compared to the healthy women. The Folate deficient women showed lower serum folate (112.93 ± 22.18pmol/ml) as compared to healthy control (164.13 ± 31.38pmol/ml). The fetus birth weight is positively correlated with the presence of folic acid supplementation. From this study, we can conclude that folic acid supplementation is necessary for the child development. It should be taken before planning the pregnancy.

Keywords: Folic acid, gestational week, folic acid supplementation, Folate, birth weight

Introduction

Folic acid is an essential micronutrient for the fetal body development in the pregnant women, which human body cannot biosynthesize and from the diet, it must be obtained as a supplements. Folic acid is a naturally available nutrient which is found in various foods like egg, vegetables, legumes etc. It is involved in denovo DNA’s biosynthesis in growing cells and in transmethylation reactions. It also serves as enzymatic reaction’s substrate, involved in the biosynthesis of amino acid and vitamin metabolism. Neither folic acid nor folate is metabolically active so as to participate in metabolism both of them must be reduced. On absorption, folic acid is reduced to tetrahydrofolic acid (THFa) by dihydrofolate reductase (DHFR)\. The THFa is also called as folic acids, active form. From the gastrointestinal tract it is rapidly absorbed, mainly from the jejunum and duodenum. The natural folates bioavailability is reduced to 25-50% with respect to synthetic folates. It is seen in various clinical studies that there is increased demand of folate in pregnant women which lead to serum folates average reduction, due to uteroplacental organs and fetus growth, and perhaps to increased urinary folate excretion and catabolism.

Folate metabolism and pathways critical components are affected by number of genetic polymorphisms, and are associated with increased risk of neural tube defect (NTDs). Metabolism of folic acid generates the structure blocks of nucleic acid, and is important in the repair and synthesis of DNA. DNA destabilization may lead to aberrations in chromosome and potentially malignant transformations. A study was showed in pregnant women, as compared to the maternal serum, the THFa levels are higher in cord blood which may be for accumulation in fetus. Numerous studies have suggested that the risk of NTD’s may be reduced by folic acid supplementation.

There is also observational and clinical trial based concern that high levels of folic acid increase some diseases risk, like autism spectrum disorder, colorectal cancer and infant bronchitis. The world health organization recommends concentration of RBC folate>400ng/ml (906nmol/L) in reproductive age
women so as to achieve NTD’s greatest reduction\(^\text{16}\). Dietary folates good sources which are often cited includes leafy green vegetables, whole grains, broccoli, orange juice and legumes\(^\text{17}\).

Deficiency of folate is relatively common, even though it can be corrected easily by folic acid administration or supplementation. The human and animal studies have shown that the folates plays an essential role during brain and nervous system development\(^\text{18}\). Especially, women are predisposed to deficiency of folate during pregnancy, due to a rapid fetal growth period, and cell divisions high rates\(^\text{19}\). The maternal folate content is also associated with other outcomes of adverse pregnancy, such as malformation like fetal death, restriction of fetal growth, preterm delivery, preeclampsia, although detail these results remains inconclusive\(^\text{20}\). With this background, the present study aims to evaluate the correlation of folic acid content and pregnancy outcome in the Iraqi women.

**Material and Method**

This study included 60 pregnant women enrolled in Karbala maternity teaching hospital January 2019 to April 2019. The pregnant women with 23rd to 25th gestational week were included in the present study. The test was performed at Karbala maternity teaching hospital.

Fasting blood (n=60) was collected by a single puncture form the folate deficient group (FD group) and healthy participants after obtaining informed consent. The parameters like child birth weight, type of delivery and duration of pregnancy was recorded. Some socio demographic characteristics such as monthly income, education level, marital status, previous number of pregnancies etc. were also recorded.

The fasting blood was collected (2ml) in the plain vacutainers from the vein after getting participant oral consent. The samples were kept at room temperature for 30min. Followed by the centrifugation at 3000rpm for 15min. The serum was separated and kept at 20°C for further study. Serum folate content was estimated by commercially available kits (Sigma, USA).

**Statistical Analysis:** Results were presented as Mean ± Standard Error (SE). Obtained data were subjected to statistical analysis using GraphPad Instat (3.0, Trial Version). Unpaired t-test was done to estimate the statistical significance.

**Results**

A pregnant women attending at Karbala maternity teaching hospital were enrolled in the present study. About 97.3% response rate was observed. The average respondent age was 28.55 years. About 33.33%, 53.33% and 41.67% women were included in the age group of less than 20, 1-30 and 30-40 years, respectively.

**Folate deficient women showed decreases in the fetus weight:** Folate deficient women showed significant (p=0.0259) decreased in the fetus weight as compared to the healthy women. The birth weight of the fetus is shown in the Figure 2. This decrease in the fetus birth weight and due to other complications, about 76.67% women undergone the C-section delivery. While only 23.33% normal delivery occurs.

![Figure 1: The birth weight of the fetus delivered by FD group and healthy women](image)

Average weeks of child delivery were found to be about 37.73 and 39.51 weeks in women with folic acid supplementation and healthy women, respectively. The presence of folic acid deficiency leads to the premature delivery. However, the women are on folic acid supplementation, none of the women showed NTD. The fetus birth weight is positively correlated with the presence of folic acid supplementation. The folate content of enrolled women were depicted in the Figure 2.
Figure 2: The folate content of FD group and healthy women

Discussion

In the present study, we have done the evaluation of folic acid content in the pregnant women. Some studies from Iraq, Nigeria, and Sudan no one of NTD’s mothers was having periconceptional supplementation of folic acid. For the prevention of neural tube disease supplements of folic acid are generally essential means. For a childbearing age woman it is almost impossible to achieve the recommended external intake of folate 100% only from the natural folate food sources, and to achieve they have to drastically increase the utilization of pulses, vegetables, fruits, legumes in their diet. The natural folate absorption is not efficient like folic acid.

There is no any consensus regarding the folic acid correct daily dose needed in NTD prevention. The US institute of medicine’s current recommendation has considered 400 mcg of folic acid per day to be sufficient to get folates optimum cellular concentration at least after daily intake for 8-12 weeks. Many clinical studies regarding folate have demonstrated that supplementation of folate reduces the recurrence and occurrence of the neural tube defects.

In some parts of the India poor knowledge and low awareness was found concerning the deficiency of folic acid among pregnant women. Katre et al found that vitamin B12 increased dose, but not folic acid was found to be linked with lower levels of plasma total homocysteine in pregnancy. However, closure of the neural tube occurs by gestations 28 days much before the woman knows about the pregnancy and addresses an antenatal clinic these studies are important. Many of the countries are bringing policies to increase the prepregnancy folate status in ladies, by enhancing supplementation, utilization of foods which are folate rich and their fortification.

Women showing placental abruption or recurrent loss of pregnancy are reported to show mild hyperhomocysteinemia. Maternal use of folic acid with multivitamins is reported in the risk reduction of cleft lip without or with palate of cleft lip. The center for disease control and prevention (1991) have suggested that women with history of NTD affected pregnancy should ingest daily folic acid (approximate 4gm) before planning the pregnancy. Consequently, the U.S. Public Health Service (1992) have recommended approximately 0.4gm daily folic acid consumption to childbearing age women through diet, supplementation and fortification to prevent NTD’s.

During the period of pre-conception, stillbirths risks secondary to neural tube defect were about 41% lowered with supplementation of folic acid. Therefore, it was suggested that, for the benefit of public and reduction in recurrent NTDs risk, that targeted counseling of folic acid should be given to previous NTD affected pregnancy. On the constant supplementation of folic acid, there are several controversies in prevention of NTD’s during the 2nd and 3rd trimester of pregnancy, unlike its supplantations well recognized beneficial effects before and shortly after conception. Charles et al found supplementation of folic acid when from initial antenatal appointment time and onwards it is given is of no difference and no benefit in birth and gestational age of pregnancy and placental weight was observed, in contrast to the review of the Cochrane, which has reported that folic acid supplantations high doses may reduce the low birth weight risk. Similarly, Fekete et al reported folic acid supplantations no beneficial effect on either on gestational length or on placental weight. Hence, it is very necessary to do more research on the effect of folic acid supplantations in pregnancy, which is useful and necessary in the expand the further guidelines and recommendations for pregnant women.

In 2006, the world health organization and food and agricultural organization (united nations) have published guidelines for helping countries in setting the level of target fortification and their maximum and minimum levels, the legal minimum level etc. to be used for flour fortification of folic acid. The folic acid enriched cereal grain products mandatory fortification was authorized in 1996 and 1998, in US, it was fully implemented. Although, folic acid intake is increased by mandatory flour fortification programs, it is shown by research that
to all women of reproductive age, it does not reaches adequately\(^4\). For maximum benefit and to reach all population groups effectively additional food products with folic acid fortification might be needed\(^4\).

**Conclusion**

The Folate deficient women showed lower serum folate as compared to healthy control. Perhaps, this leads to lower birth weight of the child. The women are on folic acid supplementation, hence none of the women showed NTD. The fetus birth weight is positively correlated with the presence of folic acid supplementation. From this study, we can conclude that folic acid supplementation is necessary for the child development. It should be taken before planning the pregnancy.

**Ethical Clearance:** The blood was collected from the Karbala maternity teaching hospital after their investigation. Oral consent was taken before enrolled the patients in the study.

ABSTRACT

Bacterial infections have been identified as one of the causes of infertility, bacteria can cause immobilization and agglutination of spermatozoa. The aim of research was to detect the bacterial pathogens in seminal fluid culture from infertile men and determine the antibiotic sensitivity pattern in vitro. Seminal fluid samples were collected for culture and antibiotic sensitivity testing and were processed according to the standard techniques of microbiology. A total of 120 seminal fluid samples collected from human males admitted to the infertility centers in Najaf province, 74 (61.66%) of samples revealed positive significant growth of bacteria, while 46 (38.33%) samples were with no growth. Eleven species of different bacterial organisms were isolated.

Keywords: Staphylococcus, Infertility, Semen, E-coli.

Introduction

Urogenital tract infection in male is one of the important causes of infertility, worldwide since genital tract inflammation and infection have been associated with (8-35%) cases of male infertility4. Seminal fluid infection by bacteria refers to the presence of bacteria in seminal fluid samples2. Bacterial infection of seminal fluid may play a major role in infertility5. Male accessory sex glands infection is a major risk factor in infertility6. The direct effect on sperm function (movement, morphological form), deterioration of sperm formation, autoimmune processes resulting from inflammation and dysfunction of the attached sex glands6. Thus, the microbiological investigation of the male partners in the two contractile populations can be useful for detecting urogenital tract infection in males, especially non-symptomatic infection. The isolation of microorganisms from seminal fluid especially of infertile men had been widely reported4-6. It is always recommended that microbiological study of semen can be performed in asymptomatic infertile men with leukocytospermia. The most widely studied genital microorganism in relation to male infertility is Escherichia coli, which is the principal microorganism that causes prostatitis and epididymitis10. Infections have been recognized in the reproductive system of male infertility for decades11-14.

Materials and Method

Seminal Fluid Samples and Collection: A total number of 120 samples were collected from human males having urogenital tract infection through a period of 6 months (from Feb to July 2018). The specimens were collected from patients who referred to infertility centers in Holly Najaf. The samples have been labeled according to the sex and age of all patients and without delay cultivation. Seminal fluid specimens were collected from human male patients suffering from urogenital tract infection. The patient should not have a sexual activity for 3 days before collecting a semen sample, also asked to pass urine first, wash, rinse hands, penis before the specimens were collected, then start the sample collection. The specimens were collected into clean wide-mouthed 15 ml sterile plastic vials and incubated at 37 °C for 30 minutes for liquefaction, then seminal fluid analysis (SFA) was done to diagnose asthenospermia and leukocytospermia. Swabs were inserted into the specimens and then directly inoculated on
blood agar, chocolate agar and MacConkey agar. All plates were incubated aerobically at 37°C for 48 hrs.

Seminal Fluid Culture: All growing isolates on surface of blood agar, chocolate agar and macConkey Agar were identified according to some biochemical test including Oxidase test, Urase test, Citrate test, Indole test and motility test\textsuperscript{(15)}. Then all isolate streaked on CHROMagar\textsuperscript{TM} Orientiation medium (CHROMagar\textsuperscript{TM}, France), finally, the diagnosis was confirmed using Vitek2 compact system (Biomerieux, France) using ID cards to detect gram positive and gram negative bacteria.

Antibiogram Profile using Disk Diffusion Method: Antibiotic susceptibility test of different isolates were carried out according to the criteria of the Clinical and Laboratory Standards Institute\textsuperscript{(16)} using disk diffusion method by Kirby-Bauer method\textsuperscript{(17)}, developing cells were suspending then adjusted to a 0.5 McFarland standard tube and spread on surface of Mueller Hinton Agar by using disks commercially obtainable antibiotics(Bioanalyse, Turkey) including Amoxicillin(10µg), Amoxicillin + Clavulanic acid (30µg), ceftriaxone (30µg), cefepime (30µg), imipenem (10µg), meropenem (10µg), amikacin (30µg), ciprofloxacin (5µg), levofloxacin (5µg), and Doxycycline (30µg).

Results

Out of 120 seminal fluid samples collected from human males admitted to the infertility centers in Najaf province,74 (61.66%) of samples revealed positive significant growth of bacteria on culture media, while 46 (38.33%) with no growth (Figure-1-A). The bacterial isolates of the predominant growth from the clinical samples were considered in the study. Additionally, only one positive culture per a patient was included. Duplicate isolates from the same infective episode in the same patient were also excluded. The samples were collected from patients with different age groups started with the age of 20 years old reaching to 60 years old. The highest number of patients having seminal fluid infection was in the age group (31-40) years old 33 (44.59%) followed by the age group (20-30) years old 21 (28.37%) and the lowest number in age group (51-60) years old 8 (10.81%) (Figure-1-B). The distribution of gram positive and negative among the bacterial culture positive cases revealed that the gram positive isolates were 42 (56.75%), while gram negative bacterial isolates were 32 (43.24%) (Figure-1-C).
The distribution of pathogens causing seminal fluid infection, out of 42 gram positive bacterial isolates, the most predominant pathogen was *Staphylococcus aureus* 18 (24.32%) followed by *Enterococcus faecalis* 9 (12.16%), *Staphylococcus saprophyticus* 7 (9.45%), *Staphylococcus epidermidis* 5 (6.75%), *Streptococcus pyogenes* 2 (2.70%) and *Streptococcus pneumoniae* 1 (1.35%) (Table-1). While out of 32 gram negative bacterial isolates, the most predominant pathogen was *Escherichia coli* 15 (20.27%) followed by *Klebsiella pneumoniae* 7 (9.45%), *Neisseria gonorrhoeae* 5 (6.75%), *Pseudomonas aeruginosa* 3 (4.05%) and *Proteus mirabilis* 2 (2.70%) (Table-1).

Among gram positive organism, *S. aureus* was found (83.33%) sensitive to Imipenem followed by Meropenem (66.66%) and Ciprofloxacin (50.0%). In case of *S. saprophyticus* Imipenem was the drug of choice showed (85.71%) sensitive followed by Ceftriaxone, Meropenem and Doxycycline in percentage (57.14%). The effective antibiotics on *S. epidermidis* were Imipenem and Levofloxacin reaching to (80%) followed by Ciprofloxacin and Doxycycline reaching to (60%). *Enterococcus faecalis* was (100%) sensitive to imipenem followed by Meropenem (88.88) and Amikacin (77.77%). Also *S. pyogenes* antibiotic sensitivity showed that Imipenem antibiotic was most affective with percentage of (100%) followed by Ceftriaxone, Ciprofloxacin, Levofloxacin and Amikacin with percentage reached to (50%). The pathogen *S. pneumoniae* showed sensitivity to the antibiotics Imipenem, Ceftriaxone, Ciprofloxacin, Levofloxacin, Amikacin in percentage reaching to (100%), (Table-2). Among over all gram positive bacterial isolates, Imipenem was found to be (88.09%) sensitive, followed by Meropenem (73.33%), Amikacin (52.38%) and Ciprofloxacin (50.0%). Among gram negative bacterial isolates, *E. coli* was found highly susceptible to Imipenem (86.66%), followed by Meropenem (73.33%) and Doxycycline (60%). *K. pneumoniae* was highly susceptible to Imipenem (86.66%), followed by Meropenem (73.33%) and Ciprofloxacin (50.0%).
sensitive for Imipenem (85.71%) and equally sensitive to Ceftriaxone, Meropenem and Amikacin (57.14%). In case of *N. gonorrhoeae*, Imipenem was the drug of choice showed (100%) sensitive followed by Amikacin (80%) and Ceftriaxone, Ciprofloxacin and Meropenem in percentage of (60%) *P. aeruginosa* showed (100%) sensitivity to both Imipenem and Meropenem followed by Ciprofloxacin in percentage (66.66%). *P. mirabilis* showed sensitivity for all Meropenem, Levofloxacin and Doxycycline in percentage (100%) (Table-3). In overall gram negative bacterial isolates, Imipenem was found to be (87.50%) sensitive, followed by Meropenem (71.87%), Doxycycline (56.25%) and Amikacin (53.12%) (Table-4).

Discussion

Bacterial infection of the reproductive system can weaken the production of sperms or cause scarring and obstruction of the tubules that transport sperms and causing infertility. Testicular infection can stop sperm production by blocking the small testicular tubules in which sperms are produced called seminiferous tubules. The newly produced sperm are stored temporarily in the epididymis, a member alongside the testis that consists of coiled sperm ducts where semen final maturity as it slowly moves through sperm channels. Infections in the epididymis may interfere with the proper maturation of sperm and can block sperm transport. In this study 61.66% of seminal fluid culture was found significant bacterial growth. The commonest isolates were *S. aureus* (24.32%) followed by *E. coli* (20.27%), *Enterococcus faecalis* (12.16%), *K. pneumoniae* and *S. saprophyticus* (9.45%), both *S. epidermidis* and *N. gonorrhoeae* (6.75%), *P. aeruginosa* (4.05%), both *S. pyogenes* and *P. mirabilis* (2.70%), and *S. pneumoniae* (1.35%).

Similar studies conducted by other researchers, a local study in Babylon by (16) revealed that out of 70 bacterial isolates from male patients having seminal fluid infection gram positive bacteria constituted 44(62.9%) while gram negative bacteria constituted 26(37.1%) of isolates, coagulase negative staphylococci (CoNS) represented by *S. epidermidis* and *S. saprophyticus* were the common type of bacterial isolates 25(35.7%) followed by *S. aureus* 19 (27.2%), *E. coli* 12 (17.1%), *Enterobacter aerogenes* 8 (11.4%), *Acinetobacter baumannii* 4 (5.7%) and *Moraxella* spp 2 (2.9%). Other national studies, Mogra et al (1981) found that 42.9% significant bacterial growth, the type of organisms isolated were *S. faecalis* (31.4%), *E. coli* (17.1%), and coagulase negative Staphylococci (14.3%). Orji et al, 2007 reported *S. aureus* was the highest prevalent bacteria isolated (37.1%). The study (18) obtained 73% positive bacterial cultures. The most common aerobic organisms grown were Corynebacterium, *S. aureus*, *S. epidermidis*, *E. coli*, *P. mirabilis*, *K. pneumoniae* and Mycoplasma. Ekhaise and Richard 2011 found that *S. aureus* 7 (77.8%) were the most common isolates. However, it has been reported that the presence of bacteria in semen may affect fertility in several ways including sperm damage, which hinders movement, and changes the chemical composition of semen (19). Seminal infection could be the cause of the chronicity of urinary tract infection by acting as the reservoir of infection (20). Some possible pathophysiological mechanisms that lead to the development of infertility are linked to the presence of microorganisms in the ejaculation (18). Microbial infections of the semen are major causes of male infertility (20). The viability and integrity of the semen lies in its characteristic mobility (21). The negative effects of these microorganisms on the sperm reproductive potential were detected in *E. coli* and *S. aureus* infections among other microorganisms (22). Presence of *E. coli* in semen decreases sperm motility. Bacteria affect sperm motility by adherence (23-25).

ABSTRACT

The naming of pollutants in the form of particles refers to their physical characteristics or relative size. Dustfall describes large particles that can settle (fall) because it is influenced by its gravitational force. TSP or dust are smaller particles that can float in the air and follow the movement of the wind. PM10 or PM2.5 are very small particles (equivalent diameter of 10 microns and 2.5 microns) that can enter the human respiratory tract. The existence of these particles is interrelated because they originate from the same source, which is a solid which is mechanically destroyed. Because it comes from the same source and process, the presence of one type of particle under natural conditions will also be followed by the presence of other particles. This makes it possible to estimate the existence of other particles by measuring one of the selected types of particles.

This study aims to obtain an estimation model of PM10 and TSP levels through the measurement of dustfall concentration. Dustfall, TSP and PM10 measurements were carried out simultaneously at one coal haul roadside location for 24 hours divided per hour in each measurement set, air temperature humidity measurement, and observation of coal transport volume were also carried out in each measurement set.

The results of the study show that; air temperatures ranged from 26 - 35°C and air humidity ranged from 42 - 76%, dustfall levels ranged from 676.95 - 4,041.14 tons/km². Month, TSP levels ranged from 153.2 - 9457.8 µg/m³ and levels PM10 ranges from 145.0 - 7,603.4 µg/m³. The particulate matter in the air has a positive correlation with air temperature and has a negative correlation with air humidity. The model of TSP relationship with PM10 was TSP = 0.077 + 1.251 (PM10), the relationship between dustfall and TSP was dustfall = 935,702 + 305,333 (TSP), the relationship between dustfall and PM10 was dustfall = 938,719 + 393,762 (PM10).

It was concluded that there was a relationship between dustfall with the levels of TSP and PM10 individually, and the estimation model PM10 and TSP by the dustfall was a dustfall filled with 60% by TSP and PM10 and TSP filled with 77.8% PM10.

Keywords: pollutants, dustfall, TSP, PM10

Introduction

The naming of pollutants in the form of particles refers to their physical characteristics or relative size. Dust fall describes large particles that can settle (fall) because they are influenced by their gravitational force. TSP or dust are smaller particles that can float in the air and follow the movement of the wind. PM10 or PM2.5 are very small particles (equivalent diameter of 10 microns...
and 2.5 microns) that can enter the human respiratory tract. The existence of these particles is interrelated because they originate from the same source, which is a solid which is mechanically destroyed. Because it comes from the same source and process, the presence of one type of particle under natural conditions will also be followed by the presence of other particles. This makes it possible to estimate the existence of other particles by measuring one of the selected types of particles.2

**Method**

The coal transportation traffic disperses the Total Particles into ambient air in a certain amount. The total scattered particles consist of various sizes, ranging from large to small. In this study measurements were carried out on dustfall, TSP and PM10 simultaneously on one spot on the side of the road that was considered safe, which is 5 meters away on the edge of the coal haul road. Measurements were carried out for 24 hours divided per hour of observation, besides that, measurements were also made on the air temperature, air humidity and the volume of traffic passing by coal. The measurement data are analyzed statistically and see the third particle fraction of the type of dust.

**Results and Discussion**

The concentration of dust from direct measurements in the field is as follows:

Description: Quality standards According to PPRI No. 41 of 1999

- Dust Fall: 20 tons/km². Month
- TSP: 230 µg/m³
- PM10: 150 µg/m³

The concentration of dust fall in Total Suspended Particulate (TSP) and Particulate Matter 10 micron (PM10) is very high and has exceeded the maximum quality standard set by PP 41 of 1999. The high concentration of the three dust parameters is caused by:

- The first factor, is the density or volume of coal transportation traffic, recorded the volume of coal truck traffic passing a total of 5,283 units or an average of 220 units per hour. The high level of dust around the road, especially the special road for coal transportation, corresponds to several previous studies, such as; 3,4,7

- The second factor, is that the road conditions are less compact, so that when there is friction between the wheels of the vehicle and the road body and air turbulence due to vehicle speed (reaching 60 km/h) it triggers the dispersion of particles into the air around the road.

- The third factor, is air temperature and air humidity, these two factors are related to the nature of dust (Patty, 1976); During the day the air temperature can reach 35°C, with a low humidity of 42% and a correlation of air temperature with positive particle content, that is, the higher the air temperature the more the particle content, while the air humidity is negatively related, or the smaller the air humidity high particle content.

The percentage of PM10 from TSP ranges from 63.3% – 96.0% with an average of 77.8% (± 8.4%), while the dustfall content is filled by 60% of the concentration of TSP + PM10 obtained from the average measurement results of dustfall in the field = 1,616.59 tons/km². Month deducted by 970,638 tons/km². Month (Dustfall constant = 970,638 - 414,735 (TSP) + 912,450 (PM10)), to 645.95 tons/km². Month or 40%, it can be concluded that the remaining 60% of dustfall is TSP concentration and PM10.

Conclusions and Recommendations

Conclusion:

1. Measured Particulate Matter 10 micron (PM10) concentration ranged from 145.0 - 7.603.4 µg/m³, Total Suspended Particulate (TSP) ranged from 153.2 - 9,457.8 µg/m³ and dust fall ranged from between 676.95 - 4,041.14 tons/km². month.

2. The air temperature at the study site ranged from 26°C to 35°C and air humidity ranged from 42 - 76%.

3. The model for estimating TSP and PM10 by dust fall is
   a. PM10 and TSP fill 60% of dustfall
   b. PM10 fills 77.8% of TSP

Recommendation:

1. Determination of TSP and PM10 concentrations can be done by measuring the level of dustfall using a dustfall collector and the estimator using the model results of this study.

2. Further research on PM2.5 dust fraction by PM10 and TSP, because these three particulate parameters have the same unit

I. Vernadsky Crimean Federal University, Simferopol, Russia

ABSTRACT

True polycythemia is a clonal myeloproliferative process, from the group of Ph-negative myeloproliferative diseases, developing at the level of the stem hematopoietic cell with a subsequent violation of the proliferation and differentiation of hematopoietic cells. Purpose of the study is to analyze the features of the development of cardiovascular complications in patients with true polycythemia and to establish correlation between age of the patients, duration of the disease and the effectiveness of their symptomatic therapy. Materials and methods - An Assessment of the evolution of complications in cardiovascular system with patients suffering from polycythemia vera was evaluated, and a correlation was established between age of the patients, duration of illness, and the effectiveness of their symptomatic therapy. An analysis of 30 patients suffering from polycythemia vera – 23 men and 7 women were studied. Results - The main complications that develop as syndromes and symptoms in patients suffering from polycythemia vera were found and the probability of development of thrombotic complications were assessed. The possibility of progressing of complications in cardiovascular system were as follows, symptomatic arterial hypertension, coronary artery diseases(CAD) and hypertension, increases with age of the patients and with the length of the disease.

Keywords: Polycythemia vera (Erythremia, Vaquez-osler disease), Cardio-vascular complications, thrombotic complications, Myeloproliferative disease, JAK2.

Introduction

True polycythemia (syn. Erythremia) is a clonal myeloproliferative process, from the group of Ph-negative myeloproliferative diseases, developing at the level of the stem hematopoietic cell with a subsequent violation of the proliferation and differentiation of hematopoietic cells [2]. Ultimately, the uncontrolled formation of blood cells leads to pancytosis (erythrocytosis, thrombocytosis, leukocytosis) with symptoms of splenomegaly. The history of true polycythemia is conditionally divided into three eras. The first one is related to the description of the disease by the Frenchman Louis Vaquez in 1892 and in 1903 by the Canadian William Osler [3]. Increased blood viscosity and splenomegaly in their patients, prompted the idea that impaired blood formation is associated with enhanced proliferation of hematopoietic cells. At the same time, phlebotomy (bloodletting) began to be used as a “first line” therapy [5], and the disease was isolated into a separate non-zoological form, and erythremia was referred to as Vaquez-Osler disease. The second epoch is diagnostic at the beginning of 19th century in 1939, on the basis of a detailed analysis of blood parameters and trepanobiopsy, attempts were made to differentiate absolute polycythemia from relative polycythemia. It is worth noting that in this era they began to use radioactive phosphorus as a treatment for erythremia. Finally, the third era, when increased attention to Vaquez-Osler disease from all
diseases in hematology allowed scientists to create the American Polycythemia Research Group. This period, from 1967 to the present day, made many discoveries. First of all, research in the field of molecular genetic mechanisms of development and course of this disease contributed to the discovery of a mutation in the JAK2 gene as a trigger in the pathogenesis of erythremia [2]. This made it possible to revise treatment approaches, in particular, in addition to traditional phlebotomy and the use of antiplatelet agents, drugs from the group of Janus kinase (JAK), as well as hydroxyurea and interferon-α, are available for use in patients with true polycythemia. Analysis, collection and systematization of the obtained data on this disease led to the creation of diagnostic criteria of the WHO, 2008 [7].

Therefore, the study of cardiovascular complications in patients with erythremia is a very urgent task, the solution of which will improve the quality and duration of life of patients.

**Purpose of the Study**

To study the features of the development of cardiovascular complications in patients with true polycythemia and to establish the relationship between age, duration of the disease and the effectiveness of symptomatic therapy.

**Materials and Method**

The study analyzed data of 30 patients with erythema - 23 men and 7 women who were under observation in the conditions of the Department of Hematology and Chemotherapy of the Crimean Republican Oncological Clinical Clinic named after V. M. Efetov, Simferopol. The Patient’s registration was carried out from October 2013 to September 2016. The median age is 57.5 years (from 29 to 86 years). In order to verify the diagnosis of true polycythemia, we have used the WHO 2008 diagnostic criteria, which included 2 groups: large (hemoglobin level is more than 185 g/l and 165 g/l in men and women, respectively, including other signs increasing the volume of circulating erythrocytes, confirmation of mutations in the JAK2 V617F gene) and small criteria (results of trepanobiopsy; erythropoietin level; spontaneous growth of erythroid colonies without growth factors) [7]. The criteria were developed on the basis of a comprehensive clinical and laboratory picture, in order to evaluate true polycythemia in a patients.

The diagnosis of polycythemia vera is confirmed in the presence of two large and one small criteria or in the presence of the one large and two small criteria [7]. The distribution of patients in stages was carried out according to the clinical and pathogenetic classification. The determination of risk groups for the development of thrombotic complications in patients with true polycythemia was carried out by assigning scores to such signs as age, white blood cell count (WBC) and venous thrombosis in history.

The conservative therapy offered to our patients, for the most part, was aimed at relieving symptoms and reducing the development of complications (escuzan, therapeutic phlebotomy, aspecard, heparin, dipyridamole, hydroxyurea). In order to study the relationship between age, duration of the disease and the effectiveness of symptomatic therapy, Spearman’s rank correlation coefficient was used. Statistical data processing was performed using Microsoft Office Excel 2013, Statistica-10.

**Research Results**

By stages, patients with erythremia were distributed as follows: In Stage I - 5 patients, Stage IIa - 7 patients, Stage IIb - 10 patients and in Stage III - 8 patients. Despite the relatively latent course of erythremia, especially in the initial stages, in the studied patients, a group of syndromes and symptoms can be distinguished, which are the result of changes in the rheological properties of blood and pancytosis (see table 1). The most frequent complaints that were presented in patients were associated with damage to the cardiovascular system: increased blood pressure, headache, dizziness, shortness of breath, discomfort, and recurrent pain in the heart area. However, in patients with previous cardiac pathology, there is a sharp progression and deterioration in the debut of the disease. But among the majority of patients, complaints of the cardiovascular system were detected for the first time. Analyzing the findings, we grouped them into symptomatic hypertension 16.7% (n=5), hypertension 20% (n=6) and CAD 16.7% (n=5).

Plethoric syndrome was detected in 10% (n=3) of cases, the main manifestations of which were flushing of the face, palms, and pruritus. Changes in the bone tissue, which on the one hand are associated with impaired blood circulation in the vessels of the microvasculature and the appearance of microthrombus in the capillaries,
are a manifestation of the ossalgic symptom 10% (n=3).
In this case, patients complain of persistent pain in
the lower limbs, joints. On the other hand, enhanced
proliferation of pathologically altered hematopoietic
cells leads to bone marrow fibrosis - osteomyelofibrosis
10% (n=3). Phenomena of splenomegaly and portal
hypertension in patients with erythremia were detected
in 13.3% (n=4) and 3.3% (n=1) cases, respectively. At
the same time, the latter had an episode of spontaneous
bleeding from the veins of the esophagus.

Table 1: The main clinical syndromes and symptoms
in patients with Polycythemia Vera

<table>
<thead>

</tbody>
</table>
| Symptomatic arterial
  hypertension               | 5 (16.7%)                       |
| Plethoric                   | 3 (10.0%)                       |
| Ossalgic                    | 3 (10.0%)                       |
| Osteomyelofibrosis          | 3 (10.0%)                       |
| Splenomegaly                | 4 (13.3%)                       |
| Portal hypertension         | 1 (3.3%)                        |

The high frequency of thrombotic complications in
patients with erythremia makes it necessary to isolate
patients at risk. Thus, patients belonging to the low-risk
group (0 points) were identified in 23.3% (n=7) cases,
the intermediate-risk group (1-2 points) - 30% (n=9)
and the high-risk group (≥ 3 points) - 46.7% (n=14) of
patients with erythremia (table 2).

Table 2: Risk groups for the development
of thrombotic complications in patients with true
polythemia

</tbody>
</table>

By determining the Spearman’s rank correlation
coefficient, a direct relationship was established
between the following indicators: duration and
complications (0.686, T-crit. = 0.487 with p=0.05), age
and complications (0.931, T-crit. =0.487 with p=0.05).
Feedback between duration and effectiveness of the
treatment (0.694, Tcrit. =0.487 with p=0.05), age and
treatment efficacy (0.954, Tcrit. =0.487 with p=0.05).

Discussion

In WHO, MPN category includes seven
subcategories, the term “MPN” usually refers to the three
JAK2 mutation-enriched clinicopathologic entities: PV,
essential thrombocythemia and primary myelofibrosis
(PMF)[22]. PV and its sister diseases constitute stem cell-
derived clonal myeloproliferation that is characterized
by three mutually-exclusive “driver” mutations: JAK2,
CALR, and MPL, with respective distribution frequency
of ~99, 0, and 0% for PV, 55, 22, and 3% for ET and
65, 20 and 7% for PMF.[23] The most frequent MPN-
associated JAK2 mutation is the exon 14 JAK2V617F,
which is responsible for almost all the JAK2 mutations in
ET and PMF, and 97% of those seen in PV; the remainder
3% of JAK2 mutations in PV are spread across exons 12,
13, and 14.[24, 25].

The successes from recent years have helped to
make accurate and timely diagnosis of Vaquez’s disease,
and therapy as effective as possible. However, the
problem of cardiovascular complications in patients
with true polycythemia is not completely resolved and
is not sufficiently studied [6]. First of all, it is associated
with a cascade of changes that occur with the blood
of patients with erythremia. The most simplified is the
following scheme: an increase in the mass of circulating
erthrocytes leads to an increase in hematocrit, which
ultimately leads to a change in the rheological properties
of blood - an increase in viscosity. Such changes
increase the risk of thrombotic complications in patients
with erythremia, which in some cases become the first
manifestations of the disease, and in others may be fatal.
So, thrombotic complications are the main cause
death and disability in 12-49% of patients with true
colythemia, and every fifth patient has at least
one episode of thrombosis in the history [6]. But true
colythemia is not limited to thrombotic complications,
since the effect on the cardiovascular system leads to
the development of numerous complications which will be
discussed in our article. It should also be remembered that
the risk of various complications of the cardiovascular
system increases with the transition of the disease to the
terminal (anemic) phase [13, 14].
Diagnosis of PV often requires the presence of a JAK2 mutation, in addition to documentation of increased hemoglobin/hematocrit, to a threshold level established by the 2016 WHO criteria (>16.5 g/dL/49% for males and >16 g/dL/48% for females) [22]. In addition, bone marrow morphologic assessment is encouraged, in order to distinguish PV from JAK2-mutated ET [26,27,28] and obtain cytogenetic information, which has recently been shown to be prognostically relevant [29,30,31]. Clinical features in PV include mild-to-moderate degree of splenomegaly, mild-to-moderate degree of constitutional symptoms, including fatigue and pruritus, symptoms of hyperviscosity, leukocytosis, thrombocytosis, microvascular symptoms (visual disturbances, atypical chest pain, erythromelalgia, paresthesia), thrombotic and bleeding complications, and risk of leukemic transformation or fibrotic progression [32].

Conclusion

A variety of clinical manifestations and a high percentage of complications, differing in nature and severity, in patients with erythremia continues to create difficulties both in treatment and in improving the quality of life of patients [6]. Changes in rheological properties and increase in blood viscosity, according to the results of our research, have a greater impact on the cardiovascular system with the development of a number of syndromes and symptoms - hypertension, CAD, symptomatic arterial hypertension in 53.4% of cases. The age peak of morbidity appearing from middle-aged and elderly patients makes them more vulnerable to the development of thrombotic complications. In our study about true polycythemia, men from 40 to 70 years are more susceptible. The risk of developing complications such as hypertension, CAD, symptomatic hypertension increases with age and with the duration of the disease. When analyzing the effectiveness of therapy in patients with erythremia, an inverse relationship was established between the experience of the disease and age. Thus, the high age and long-term course of the disease makes the sensitivity to treatment low, which is associated both with thrombotic complications in patients of this age group and with the risk of progression of the tumor process with transition to leukemia, the development of intoxication syndrome, secondary myelofibrosis. In such cases, it is necessary to consider cytoreductive or targeted therapy, as a “first-line” therapy [3]. Of course, elderly patients with a long course of the disease and a high risk of thrombotic complications deserve special attention, since the question of achieving a full therapeutic response, controlling complications and improving the quality of life remains open.

ABSTRACT

Benzene is one of the substances included in the poison of air pollution. The Environmental Protection Agency (EPA) has classified benzene in Group A carcinogens for humans. The widespread use of benzene in the industrial world can have harmful consequences. The amount of exposure workers receive has a negative impact on their health. Workers at the petroleum refinery laboratory are workers at risk of exposure to benzene. The study aimed to measure the safe concentration limit in the Main Laboratory section of PT. Pertamina RU IV Cilacap. This was a cross sectional, observational, and descriptive study with 51 samples of PT Pertamina RU IV Cilacap laboratory workers. Variables of this study were benzene concentration in the workplace, working time per day, work respiration rate, worker height, weight, and body surface area, white mice body surface and weight, Km factor on workers (Human Km), Km factor on animals (Animal Km), No Observed Adverse Effect Level (NOAEL), safe human dose (SHD), and benzene safe concentrations (C safe) in the air for workers.

The result indicated that safe concentration (C safe) limit in PT Pertamina RU IV Cilacap was 0.03 ppm. It is less than the safe concentration set by Minister of Manpower and Transmigration Regulation No. 13 of 2011 which stated that the C safe is 0.5 ppm. It showed that the TLV in the Main Laboratory section of PT. Pertamina RU IV Cilacap is not safe for workers as benzene concentration in this laboratory is 16.67 times bigger than its safe concentration of benzene.

Keywords: Benzene, safe concentration, laboratory worker

Introduction

Benzene is one of the substances included in the poison of air pollution. The Environmental Protection Agency (EPA) has classified benzene in Group A carcinogens for humans. The widespread use of benzene in the industrial world can have harmful consequences. The amount of exposure workers receive has a negative impact on their health. Workers at the petroleum refinery laboratory are workers at risk of exposure to benzene. One of the chronic effects of being exposed to benzene is a bone disorder of the spinal cord which changes the blood profile.

Benzene enters the body through inhalation. It enters in the form of steam with the main absorption occurring in the lungs. A number of cases of benzene poisoning occurs through the respiratory tract in the workplace. Ninety per cent of those cases are because of inhaling the
benzene as much as ± 8 m³ of air for 8 hours/day every day long exposure, exposure frequency, and duration of exposure. The measures include the analysis of hazard identification, dose-response analysis, exposure analysis, risk characteristics, and risk management. The results of the average concentration of benzene from 8 point was 0.287 mg/m³. The average yield intake of all workers on non-carcinogenic effects was 0.0027 mg/kg/day. The average of workers intakes of carcinogenic effect was 0.0039 mg/kg/day. A total of 19 respondents (37.35).

Benzene as a toxic substance has a safe concentration. Based on research that has been done in the PT. Pertamina RU IV Cilacap, the average concentration of benzene measured at 8 points was 0.09 ppm. It is below the Threshold Limit Value (TLV) set by Minister of Manpower and Transmigration in its regulation No. 13 of 2011 which is equal to 0.5 ppm. However, this TLV can still bring health effects for the workers. Based on the Environmental Protection Agency (EPA) research, a long-term tolerance of benzene exposure in the air with a concentration limit of 0.004 ppm can cause case of leukemia one in 10,000 populations (2013).

Safe benzene concentration is needed as a benchmark for exposure limits that are permitted to avoid the occurrence of health effects for workers. However, many of safe concentration origin are not known. Research by Saridewi and Tualeka in 2012 shows calculation results of safe concentrations derived from NOAEL and Rfc values². Based on the weight of white mice, its body surface area (BSA) can be calculated using the following formula:

\[ \text{Animal BSA} = 0.09 \times W^{0.67} \]

Based on the description above, this study aimed to determine the Threshold Limit Value of benzene in the Main Laboratory section of PT. Pertamina RU IV Cilacap.

Material and Method

It is an observational, cross sectional and descriptive study. Subject for this study is 51 out of 85 workers of the Laboratory section of PT. Pertamina RU IV Cilacap. The object sample of this study is the air in the working area of Main Laboratory and Petrochemical and Gas Laboratory of PT. Pertamina RU IV Cilacap.

Primary data is taken from the measurement of benzene concentration in the air sample in the working area of Laboratory of PT. Pertamina RU IV Cilacap and the weight of experimental animal, white mice.
B. Workers Characteristic: The characteristics of workers in this study consisted of workers’ weight, height, working time and the average respiratory rate in the PT. Pertamina RU IV Cilacap. Table 2 shows the characteristics of workers.

Based on the average weight and height of the workers’, body surface area and respiration rate of the workers can be calculated using the following formula:

1. The Average of Workers’ Body Surface Area:
   \[ \text{BSA} = \sqrt{\frac{W \times h}{3600}} = \sqrt{67.159 / 3600} = 1.72 \text{ m}^2 \]
   
   **Annotation:**
   - BSA: Body Surface Area (m$^2$)
   - W: weight (kg)
   - h: height (cm)

2. The Average of Workers’ Respiration Rate
   \[ \text{BR} = 5.3 \ln W - 6.9/24 = 5.3 \ln 67 - 6.9/24 = 0.596 \text{ m}^3/\text{jam} \]

   **Annotation:**
   - BR: Breathing Rate (m$^3$/hour)
   - h: height (cm)

E. NOAEL: *No Observed Adverse Effect Level* (NOAEL) is a calculation that must be done to determine the extent to which the concentration of chemicals. NOAEL of benzene is 0.022 mg/kg (EPA, 2005). It is obtained by the calculation using the following formula:

\[
\text{NOAEL Benzene (mg/m³)} = \frac{3 \times 0.00013 \times 8}{0.1405} = 0.022 \text{ mg/kg}
\]

F. Safe Human Dose: Safe Human Dose (SHD) can be calculated using the formula of Shaw et al (2007):

\[
\text{SHD} = \frac{\text{NOAEL Animal Km}}{\text{Human Km}}
\]

**Annotation:**

- SHD: Safe Human Dose (mg/kg)
- NOAEL: *No Observed Adverse Effect Level* (mg/kg)

Based on the formula above, SHD can be obtained by calculating NOAEL, the average animal Km dan the average human Km as follows:

\[
\text{SHD} = \frac{0.022 \times 5.82}{38.95} = 0.003 \text{ mg/kg}
\]

G. Safe Concentration of Benzene: The calculation of safe concentration of benzene in the laboratory of PT. Pertamina RU IV Cilacap can be made using William (1985) as follows:

\[
\text{Safe Concentration} = \frac{\text{SHD} \times W}{\delta \times \text{BR} \times t} \left( \frac{mg}{m^3} \right)
\]

Conversion formula from mg/m³ to ppm is as follows:

\[
\text{Safe Concentration} = \frac{mg/m^3}{MW} \times 24.5 \text{ ppm}
\]

**Annotation:**

- Safe concentration: safe concentration of a toxic in the air for workers (mg/m³)
- SHD: Safe Human Dose (mg/kg)
- W: weight (kg)
- δ: % of substances absorbed by the lungs
- BR: breathing rate (m³/hour)
- t: working time (hour)

Based on the above formula, the results of the calculation of the safe limit of benzene concentration in the Laboratory section of PT. Pertamina RU IV Cilacap as follows:

\[
C_{\text{safe}} (mg/m^3) = \frac{(0.003)(67)}{(50\%)(0.596)(8)} = 0.092 \text{ mg/m}^3
\]

\[
C_{\text{safe}} (ppm) = \frac{(0.0092mg/m^3)(24.5ppm)}{(78.11mg/mol)} = 0.03 \text{ ppm}
\]

The calculation result of the safe concentration benzene in the air in the working area of the PT. Pertamina RU IV Cilacap can be used as a predictor of safe toxin concentration limits for workers in the workplace when the Threshold Limit Value (TLV) has not been established. It can also be used as a comparison with the current TLV set by other institutions.

**Discussion**

Trial activities in the Laboratory of PT Pertamina RU IV Cilacap which involves test samples in the form of crude oil and fuel-based products and non-fuel products containing benzene and which can evaporate
at certain temperatures and pressures is a source of benzene hazards for workers. Stages of handling the test sample require combustion or heating the test sample. It causes benzene to evaporate into the air in the working environment which later can cause negative effect for workers’ health. It is due to that benzene is in Group A of carcinogens for humans (EPA).

Workers in the Laboratory of PT Pertamina RU IV Cilacap work with a duration of 8 hours/day for 265 days/year. The results of interviews with 51 respondents found that 21.6% respondents reported to experience dizziness, 21.6% irritability, 17.6% sleep disorders, 13.7% breathlessness, and 11.8% nausea.

The measures include the analysis of hazard identification, dose-response analysis, exposure analysis, risk characteristics, and risk management. The results of the average concentration of benzene from 8 point was 0.287 mg/m³. The average yield intake of all workers on non-carcinogenic effects was 0.0027 mg/kg/day. The average of workers intakes of carcinogenic effect was 0.0039 mg/kg/day. A total of 19 respondents (37.35).

Calculation of safe concentration limit in PT. Pertamina RU IV Cilacap was carried out in some steps. It was started with the calculation of NOAEL, followed by calculation of SHD/Rfc and, as a final step, calculation of the safe limit of benzene concentration. Saridewi and Tualeka (2012) who conducted a study to determine the benzene safe concentration limits also performed such calculation steps using NOAEL and SHD/Rfc.

According to EPA, NOAEL (No Observe Adverse Effect Level) is an experiment in determining doses that do not indicate a statistically significant effect on toxic effects or biological functions¹. NOAEL benzene values in this study is 0.022 mg/kg determined by EPA (2005). Based on research results by Swaan et al (2010), the result of NOAEL benzene was 3.0 mg/m³ or equal to 0.022 mg/kg. The research conducted by Kruskal Wallis to determine NOAEL values by testing the expression of imuneractive interleukin-2 showed that the IRS score results were not significantly different so that they could be used as a reference for NOAEL values¹.

SHD (Safe Human Dose) or Rfc is a dose reference for humans. When the dose received by human exceeds the SHD/Rfc value, the risk for human health is also greater². Generally, in the previous study, the value of Rfc used was a provision determined by IRIS (Integrated Risk Information System) from US-EPA which was equal to 0.0086 mg/kg/day. However, this study obtained Rfc result of 0.003 mg/kg. It was derived from the calculation of NOAEL, Animal Km and Human Km. Saridewi and Tualeka (2012) used the Rfc calculation formula and get the Rfc value of 0.004 mg/kg. A research conducted at the Wedoro shoe factory, Sidoarjo, which used the same Rfc calculation formula, obtained the Rfc value of 0.0036 mg/kg.

The measurement result of benzene concentration in 8 different measurement spots in the working area of laboratory of PT. Pertamina RU IV Cilacap showed that its highest benzene concentration was 0.187 ppm and the lowest was 0.006 ppm. It is still far below the TLV set by Minister of Manpower and Transmigration in its regulation No. 13 of 2011, which stated that the TLV of benzene is 0.5 ppm.

The obtained safe concentration limit of benzene in the Laboratory of PT. Pertamina RU IV Cilacap is 0.03 ppm. It is below the TLV set by Minister of Manpower and Transmigration in its regulation No. 13 of 2011, which stated that the TLV of benzene is 0.5 ppm. It indicated that working area in the Laboratory of PT Pertamina RU IV Cilacap is not safe for workers as it is 16.67 times bigger than the safe limit in the Laboratory.

Benzene contains gasoline which can have an impact on blood hemoglobin levels. Exposure to benzene through the respiratory tract with certain doses can damage human blood cells. Benzene can provide an impact on the spinal cord which can cause aplastic anemia, immune cell damage and acute bleeding. It is proved by workers complaints of uncomfortableness of respiratory tract and eyes. The use of personal protective equipment (PPE) for workers such as masks is strongly recommended. It is also strongly recommended for workers to consume nutritious foods such as beef liver and salmon, to increase their immunity against benzene⁵.

**Conclusion**

1. NOAEL benzene in the Laboratory Section of PT. Pertamina RU IV Cilacap is 0.022 mg/kg.
2. SHD/Rfc benzene in the Laboratory Section of PT. Pertamina RU IV Cilacap is 0.003 mg/kg
3. Safe concentration of benzene in the Laboratory Section of PT. Pertamina RU IV Cilacap is 0.092 mg/m³ or equal to 0.03 ppm.

**Recommendation**

The Threshold Limit Value (TLV) of benzene concentration obtained from manual calculations of this study can be used as the TLV of benzene in PT. Pertamina RU IV Cilacap.

It is strongly recommended for workers to use personal protective equipment (PPE) such as masks during working hours, and for the company to provide high nutritious food for workers.

Saponin Maintaining and Dose Determining in Carica Papaya Leaf Cookies as a Breast Milk Booster (galactogogue)

Krisdiana Wijayanti¹, Hertanto W. Subagio², Martha Irene Kartasurya³, Sri Achadi Nugraheni³

¹Doctoral Student, Faculty of Public Health, ²Professor, Faculty of Medicine, ³Associate Professor, Public Health Nutrition Department, Faculty of Public Health, Diponegoro University, Semarang, Indonesia

ABSTRAcT

Background: Papaya leaf has been proven to increase breastmilk production as the saponin content increases oxytocin level. However papaya leaf has a bitter taste, therefore cookies form is a good alternative to increase compliance. Saponin content has to be maintained and the dose should be determined to be an effective breastmilk booster (galactogogue).

Objective: This study aimed to find the best process in 1. Minimizing the bitter taste of papaya leaf, 2. Maintaining saponin content of cookies, 3. Finding the highest dose of acceptable cookies, and 4. Determining the amount of cookies has to be consumed by lactating mothers as a breastmilk booster.

Method: For minimizing the bitter taste of Carica papaya leaf we compared the pH level of mashed papaya leaf after three different treatments. For saponin maintaining, we compared two different temperature and duration of baking processes. Hedonic tests were performed to find the dose of papaya leaf cookies which were acceptable. The number of cookies should be consumed was calculated based on amount of saponin in the cookies, which had been shown to have an effective outcome.

Findings: This study found that Carica papaya leaf which was boiled twice in 60⁰C for 10 minutes had the lowest pH compared to be soaked in 2.5% volume of quicklime (calcium oxide) solution or 10 minutes boiled in the cooked rice water. Baking Carica papaya leaf cookies in 60⁰C for 70 minutes could maintain saponin content compared to be baked in 130⁰C for 35 minutes. Hedonic test results showed that there was no significant differences in acceptability levels of Carica papaya leaf content between the groups. A hundred gram cookies with 40% carica papaya leaves contained 3.67g saponin, thus for 1.8g saponin intake/day in two cookies of 25g should be consumed.

Conclusion: The best method in reducing the bitter taste of Carica papaya leaf cookies was by boiling in 60⁰C for 10 minutes. Saponin content in the cookies could be maintained by 60⁰C for 70 minutes baking. The highest dose but acceptable taste of carica papaya leaf cookies was 40%. Two pieces of 25g carica papaya leaves cookies can be consumed as galactogogue.

Keywords: Breastmilk booster, Carica papaya, Cookies, galactogogue, saponin.

Introduction

Exclusive breastfeeding is important for baby’s growth and health¹. However, many problems occur in exclusive breastfeeding practice. One of the important problems was breastmilk production insufficiency. Many efforts have been conducted to increase breastmilk production, including medical treatment and herbal galactogogue consumption.² In Malaysia, 87% of insufficient breastmilk problems were overcome by herbal galactagogue because it is considered safer and more available.³ In Thailand herbal galactagogue such as banana heart (Musa acuminata), basil (Ocimum), water pumpkin (Lagenaria siceraria), pumpkin (Cucurbita) had been shown to be significantly associated with milk production.⁴ In Indonesia katuk leaves (Sauropsus androgynus (L) Merr) increased milk production to 50.7%.⁵

Some plants including Carica papaya leaf can increase milk production because they contain certain compounds and minerals. Compared to katuk leaves, papaya leaves contain manganese and potassium which increase prolactin and oxytocin hormones for milk forming and milk ejecting. Furthermore Carica papaya leaves are more available in Indonesia than katuk leaves. However, the bitter taste caused by of carpain alkaloid content in carica papaya is the main reason for their unconsumption. Preparing of Carica papaya leaves in the form of cookies, may enhance the acceptance level of papaya leaves as a source of saponin. Processing Carica papaya leaves into cookies has some benefits of a much better taste, easier to consume at any time and less perishable.

Materials and Method

The materials used in this study were Carica papaya leaves processed in the form of cookies. Several steps were carried out to get cookies that contained saponin from carica papaya leaves in a less bitter taste, acceptable in taste and proper dose in administering. The first step was reducing the bitter taste of Carica papaya leaves. The method of the first step was comparing pH level of the mashed leaves that already processed with three different treatments. The first treatment was boiling the leaves at 60°C for 10 minutes and discharged the water. Then the leaves were boiled again with the same temperature for another 10 minutes. The second treatment in minimizing the bitter taste of papaya leaves was soaking carica papaya leaf in 2.5% volume of calcium oxides solution (25g calcium oxides in 1000 ml water) for 90 minutes. The third treatment was boiling papaya leaves in the cooked rice water for 10 minutes. Cooked rice water was made by boiling 250g rice in 1000ml water.

The methods for maintaining saponin in carica papaya leaf cookies were found by comparing 2 baking processes (in different temperature and duration). The temperature which generally used for cookies is 130°C in 35 minutes. However saponin is damaged at temperature higher than 60°C of heating. Therefore we compared the saponin content of cookies baked in 130°C for 35 minutes and 60°C for 70 minutes. In 70 minutes, cookies were ready looked yellowish and have a crunchy texture. The method used in determining the degree of acceptability was hedonic test. Untrained panelists of breastfeeding mothers were employed in this test. They were provided with the cookies containing 0%, 10%, 20%, 30% and 40% carica papaya leaves. Then, they were requested to taste the cookies alternately, with 5 minutes space of time. Panelists were allowed to drink mineral water in order to neutralize the taste. After that the panelists were asked to gave a score according to the level of taste acceptance in the range of extremely like (6), very much like (5), moderately like (4), slightly like (3), neutral (2), unlike (1). Furthermore, data was categorized in accepted and not accepted. The accepted category toward the taste of cookies was determined when the panelist stated extremely like, very much like, moderately like, slightly like and neutral.

The process of making carica papaya leaf cookies is as follows: blending 40g Carica papaya leaves, mixing with 60g wheat flour, 50g sugar, 40g margarine, 17g egg yolks, 10g skim milk, 1g baking soda and 0.5g salt using an electric mixer. Round cookies with a diameter of 5cm was formed from the and then baked. Baking process was terminated when the cookies was cooked.

The taste of cookies was not accepted when the panelists stated dislike. Univariate analysis was used to find the distribution of accepted and not accepted cookies in several doses. Normality of data in each variable was tested using Saphiro Wilk test. Data analysis in the two group showed that all data was not normally distributed, therefore Mann-Whitney test were used to compare between scores of each dose Carica papaya leaves content with other dose in related with level of acceptibility.

The taste of cookies was not accepted when the panelists stated dislike. Univariate analysis was used to find the distribution of accepted and not accepted cookies in several doses. Normality of data in each variable was tested using Saphiro Wilk test. Data analysis in the two group showed that all data was not normally distributed, therefore Mann-Whitney test were used to compare between scores of each dose Carica papaya leaves content with other dose in related with level of acceptibility.

The dose of Carica papaya leaf cookies as breast milk booster was determined by calculating the saponin content. Saponin was tested using a UV-vis spectrophotometry method. Previous study done in Tehran on 2013 involving of 78 Iranian girl infants 0-4 months old showed that 1.8g saponin a day in the fenugreek seed tea was able to increase the breast milk production. Based on that finding the dose calculation could be done with the formula below:

\[
\text{Saponin content in the cookies} = \frac{1.8 \text{ g saponin}}{100} \times \frac{X}{100 \times 1.8}
\]

\[X = \frac{\text{Saponin content in the cookies}}{100} \times 1.8\]

The process of making carica papaya leaf cookies is as follows: blending 40g Carica papaya leaves, mixing with 60g wheat flour, 50g sugar, 40g margarine, 17g egg yolks, 10g skim milk, 1g baking soda and 0.5g salt using an electric mixer. Round cookies with a diameter of 5cm was formed from the and then baked. Baking process was terminated when the cookies was cooked.
sign of cooked cookies are yellowish color and crunchy texture. The same procedures were applied in making of 0%, 10%, 20%, and 30% of carica papaya leaf cookies.

Findings

The findings was explained based on 4 goals of of this research, which are:

**Reducing the Bitter Taste:** For reducing the bitter taste, three different methods were compared to find pH level as an indicator for a bitter taste, the lowest pH will be chosen as the sign of the least bitter taste from several methods. The lower the pH, the more acidic the solution. Lowering the pH produced the biggest increase in sourness of food and results in less bitter taste.16 Table 1 shows the pH levels resulted from different several treatments. It can be seen from the table that the lowest pH in carica papaya leaves was 7.70, therefore the best method in reducing bitter taste was boiling leaves twice in the temperature of 60°C.

**Table 1: pH levels of carica papaya leaf after three different treatments**

<table>
<thead>
<tr>
<th>Treatments</th>
<th>Ph level</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boiling twice in 60°C for 10 minutes</td>
<td>7.70</td>
</tr>
<tr>
<td>Boiling in cooked rice water for 10 minutes</td>
<td>7.84</td>
</tr>
<tr>
<td>Soaking in 2,5% calcium oxide solution for 90 minutes</td>
<td>8.13</td>
</tr>
</tbody>
</table>

The bitter taste in the Carica papaya leaf was caused by alkaloid carpain substance (C_{14}H_{25}NO_{2}). Boiling is the most practice method for bitter taste elimination, because of decomposition process of alkaloid carpain.9 Carpain is not related with the function of carica papaya leaf as a breast milk booster. Therefore reducing a bitter taste did not influence the effect of carica papaya leaves as a breastmilk booster. The most reason of the low enthusiasm in consuming Carica papaya leaf among Indonesia communities is the strong bitter taste.17 Therefore reducing the bitter taste will increase the acceptibility of Carica papaya leaves.7

**Baking Process:** Two methods of baking process were compared to find the best method in maintaining the saponin content of Carica papaya leaves. The saponin content should be maintained maximally for galactogogue purpose. Table 2 shows two different baking processes (based on the temperature and duration) of cookies and the saponin content after treatments.

**Table 2: Saponin content in 100g cookies after two different baking processes**

<table>
<thead>
<tr>
<th>Baking Process</th>

<td>Temperature of 130°C for 35 minutes</td>
<td>(-)</td>
</tr>
<tr>
<td>Temperature of 60°C for 70 minutes</td>
<td>3.67g</td>
</tr>
</tbody>
</table>

Table 2 reveals that saponin was totally damaged by the baking process of 130°C in 35 minutes. The heat of > 60°C damages the saponin structure.11 Therefore the best temperature of baking to maintain saponin content was 60°C. After 70 minutes, the cookies were already cooked and crunchy.

**Hedonic Test:** Thirty-nine breast feeding women were employed as panelists in the hedonic test. They were served with the cookies containing 0%, 10%, 20%, 30% and 40% carica papaya leaves. Table 3 shows the percentage of acceptability of several different doses Carica papaya leaf cookies.

</tbody>
</table>
Table 3 shows that the percentage of dislike panelist was slightly increased with the increasing amount of Carica papaya leaves in cookies. However, most of panelists accepted the taste of 0%-40% Carica papaya leaf cookies. Furthermore we also conducted acceptability test between two groups of cookies based on the amount of carica papaya leaf content.

*Mann-Whitney

Table 4 shows that there was no significant difference in acceptibility levels of Carica papaya leaf content between the groups. The acceptibility between 30% and 40% of Carica papaya leaves in the cookies was not different. Therefore we used 40% carica papaya leaf cookies for galactogogue purpose and use it for dose calculation.

Dose Calculation: The laboratory test shows that there was 3.67g saponin in 100g of 40% Carica papaya leaf cookies. This finding was used to calculate the dose of cookies. The need of saponin content for galactogogue based on previous research was 1.8g a day.\textsuperscript{14}

The calculation of the dose:

\[
X = \frac{100 \times 1.8 \text{ g}}{3.67 \text{ g}}
\]

\[
X = 49 \text{ g}
\]

Forty nine grams was rounded to 50g, thus 2 pieces of 25g Carica papaya leaf cookies fullfilled the need of saponin content as galactogogue. Two pieces of cookies a day was also feasible to be consumed as snack.

Other than saponin, Carica papaya leaves also contain potassium and mangan which also have galactogogue effect. Laboratory test results showed that there was 1.6mg/g potassium in the cookies. Women in 19-29 years old need 470mg potassium everyday. Lactating mothers need an additional 40 mg potassium per day. Thus potassium need of lactating mothers is 510mg/day.\textsuperscript{18} Two pieces of 25g Carica papaya leaf cookies contained 80mg potassium, which supplied 15.7% potassium need for lactating women per day.

Carica papaya leaf cookies contained 0.01mg/g mangan. The need of mangan for adult women is 1.8mg/ day. During lactation period, the women need additional 0.8mg aditional mangan per day. Thus 2.6mg mangan is needed by lactating mothers everyday.\textsuperscript{18} Two pieces of 25g cookies contained 0.50mg mangan which contributed to 19.2% mangan need for breastfeeding mother.

Mangan and potassium can stimulate the production and activity of prolactin and oxitocyn. Mangan content in Carica leaf cookies stimulated pituitary gland in producing prolactin, which increase breast milk production. Potassium deficiency caused tiredness and mood swings which inhibited oxytocin production. Potassium has relaxing effect, thus may stimulate oxytocin production which is needed for breast milk ejection.\textsuperscript{2}

Conclusion

The best process of making papaya leaves cookies which can be used as galactogogue was boiling leaves twice at \(\leq 60^\circ\text{C}\) before adding other ingredients and bake the cookies of 40% Carica papaya leaves in 60\(^\circ\text{C}\) for 70 minutes. Two pieces of 25g papaya leaves cookies every day can be consumed by lactating mothers as a galactogogue (breastmilk booster).

Factors Related to Competence in Prehospital Care

Ns. Kristianto Dwi Nugroho¹, dr Setyawati Soeharto², Yulian Wiji Utami²
¹Student Magister of Nursing, ²Lecturer, Faculty of Medicine, Brawijaya University, Malang, Indonesia, Sawojajar, Malang, Est Java, Indonesia

ABSTRACT

Pre-hospital service in Indonesia is a service which is relatively new and still in the development stage. The main priority of this development is human resource development by increasing competence. But unfortunately, Indonesia does not yet have core competencies in pre-hospital services. On the other hand, competency is not an independent matter, many factors are related such as work experience and personality characteristics. This study used cross sectional approach with paper-based survey method on 120 respondents from, 12 health centers (puskesmas), call center of TEMS and TEMS team in Hospital of Dr. Iskak. Experience had correlation with the competency of ambulance officers with sufficient correlation strength (p=0.000). Similarly, the personality characteristics had correlation that was also sufficient (p=0.000). Multivariate analysis found that experience was removed from the equation, and obtained the characteristics that related to competency. But the equation had a low strength (adjusted r square=0.232). In this study, competency related to two main variables, they were personality characteristics and experience. Experience was not only considered according to the length of working, but also how the people mastery their work. Neither the personality characteristic, had a role in the formation of a good competency. Personality characteristic was factor that related to the competency. The competency needed to improve the quality of pre-hospital service and reduce mortality experienced by the patient.

Keywords: Ambulance Officer competency; personality characteristics; experience

Introduction

Pre-hospital services in Indonesia have been started since the 1980s by Association of Indonesian Surgeon. But the lack of support from the government and various stakeholders resulted this service did not develop¹. The government initiated pre-hospital service that called by Sistem Pelayanan Gawat Darurat Terpadu (SPGDT) in 2016²,³. SPGDT has the aim to provide emergency service, reduce mortality and prevent permanent disability on patients².

Prehospital service in Indonesia is relatively new, thus it requires a special development to get the maximum service⁴. The first thing that should be conducted was by developing the human resource in pre-hospital service. Competency is a key factor in human resources development⁵. Various pre-hospital services and its competency due to there is no international consensus about this service⁶. Indonesia has not yet developed specific competencies that concerning to pre-hospital services, thus the researcher used the ambulance officer competencies that developed by the Paramedics Australasia⁷. In this competency, there are three main competencies that consist of professional practice, clinical practice, and professional knowledge.

Competency is not a variable that is completely free, many factors related to it⁸,⁹. Experience is a factor that related to the competency of ambulance officers. Although experience is not only measured by the length of work, but it’s measured by the reliability in handling problems in the work environment¹⁰,¹¹. Personality can also affect someone in solving problem, ability in working together, and establishing an interpersonal relationship. Those things are very necessary within the scope of pre-hospital⁸,⁹. Therefore, personality
characteristics and experiences in both directly or indirectly related to the competency of ambulance officers. Then, there is a question “Are personality characteristics and experiences related to the increasing of ambulance officers competence?”

**Material and Methodology**

The study was an analytic observational research and cross-sectional as a method of approach. The population in this study was all of health workers who served pre-hospital in Tulungagung that were often known as TEMS (Tulungagung Emergency Medical Services). TEMS had three main parts in conducting pre-hospital services, they were call center, TEMS team in Hospital of Dr. Iskak, and supporting team that consisted of 14 puskesmas throughout Tulungagung. The study was conducted from February to March 2019.

*Simple Random Sampling* was a sampling technique in this study. The following was several criteria in sampling process: (1) respondents worked in TEMS environment, (2) respondents were health workers (doctors, nurses, midwives), (3) respondents were able to read and communicate well. Total of 120 respondents obtained by using measurement method of “rule of trump’s”.

The instrument of competency assessment was arranged by researchers that developed from *Australasia Competency of Paramedics 2011*. There were three main competencies of officers, they were professional practice, clinical practice, and professional knowledge. The independent variable consisted of working experience and personality characteristics. In this study, the experience was not only measured by the length of working of respondents, but by how they understanding the work, procedures and control of existing equipment such as a tsunami, earthquake or volcanic eruption, affecting humans. In order to support emergency medical communication services in natural disaster areas where the telecommunications facility has been seriously damaged, an ad hoc communication network backbone should be build to support emergency medical services. Combinations of requirements need to be considered before deciding on the best option. In the present study we have proposed a Low Altitude Platform consisting of tethered balloons combined with Wireless Fidelity (WiFi). Variable of personality characteristics such as the ability to cooperate, creativity, timely and ambitious.

The questionnaire had been developed by the researcher which consisted of 38 questions. The answer of question in the form of Likert scale with 1 to state strongly disagree to 4 for strongly agree. Validity test was conducted in PSC (Public Safety Center) of Malang with Cronbach’s alpha (0.917), thus the questionnaire was reliable to use in research.

**Finding**

There were 150 questionnaires that were distributed in 14 puskesmas, call centers and TEMS team in Hospital of Dr Iskak. 136 questionnaires were returned and 16 questionnaires were excluded because there were incomplete data filled.

From the demographic data, more than half of respondents in this study were women (61.6%), mostly, aged between 25-34 years (45.8%). Nearly a third of respondents (30.8%) had worked less than 20 months in pre-hospital services. The most profession of respondents in this study was nurses who worked in TEMS (68.3%) and most of them work in puskesmas (84%).

The requirement to conduct bivariate analysis was by looking at the distribution of data. Normality test shows that the three variables are abnormally distributed (p=0.000), so the test used Spearman rank test. Bivariate analysis shown (table 1) that experience had correlation with the competency of ambulance officer (p=0.000). Similarly, the personality characteristics also had correlation with the competency of ambulance officer (p = 0.000).

Discussion

Demography: The demographic of respondents indicated that most of the puskesmas who have responsibility to maintaining the health of community. Good coordination that made the pre-hospital services more efficient with the officers\textsuperscript{17}. Coordination was always conducted by all of stakeholders in order to provide the services well, efficiently and optimally\textsuperscript{18}.

The demographic also found that more than two-thirds of respondents were nurses (68.3%). This was in accordance with the regulations in Indonesia that all of healthcare workers were health workers\textsuperscript{19}. This data also explained that more than a quarter of respondents had worked less than 20 months. But there were several respondents who had worked more than 20 months. Pre-hospital services in Tulungagung was start in in 2015\textsuperscript{20}. The respondents who had worked more than 20 months were respondents who had been working for pre-hospital service in each puskesmas or hospital independently and not coordinated, then become a system such as TEMS.

Experience: This study described that the experience of work had significant effect against competency (p=0.000). Experience was one important aspect in improving competency. Previous research had shown that the experience affected the improvement of competency and assess the deterioration of the client’s situation \textsuperscript{21,22}.

This study did not determine the experience according to the length of work, rather than how the officers mastery their work. The length of working of officer did not give guarantee that the officer also had good competency\textsuperscript{10}. The understanding of the work, and mastery of the procedures to be important in the experience of working\textsuperscript{12} such as a tsunami, earthquake or volcanic eruption, affecting humans. In order to support emergency medical communication services in natural disaster areas where the telecommunications facility has been seriously damaged, an ad hoc communication network backbone should be build to support emergency medical services. Combinations of requirements need to be considered before deciding on the best option. In the present study we have proposed a Low Altitude Platform consisting of tethered balloons combined with Wireless Fidelity (WiFi).

Experience played a key role in enhancing the competency of ambulance officers. This was according to research conducted by Steigerwald\textsuperscript{23} was shown that the experience of nurse was a key factor to improve the competency. Improving the experience could be enhanced not only by the length of work. The provision of training and simulation about as similar and complexity in the field could also be performed. Training and a good simulation had the advantage of reducing the risk that would be experienced by the patient\textsuperscript{24}. Good simulation also could increase the knowledge of nurse and other health professionals in providing services such as patients with cardiac arrest, myocardial infarction, trauma and stroke, while population-based studies including all diagnoses are few. We examined the diagnostic pattern and mortality among all patients brought to hospital by ambulance after emergency calls. DESIGN Registry-based cohort study. SETTING AND PARTICIPANTS We included patients brought to hospital in an ambulance dispatched after emergency calls during 2007-2014 in the North Denmark Region (580 000 inhabitants).

Personality characteristics: Personality characteristic was a psychological characteristic that reflected an individual’s response to the environment. Everyone had a different personality, but could possibly had the similar personality characteristics\textsuperscript{26}. Thus, personality characteristics had an important role against competency. Bivariate analysis shown that personality characteristics had correlation with competency (p=0.000).
Competency development was not only about training and experience, but extended into the domain of personality traits. Several personality characteristics such as curiosity, easy to get along with, creative, timely and ambitious affected the competency. Thus, human resource development in pre-hospital service was also necessary to improve the characteristics of each individual. A good development of individual characteristics effectively would be improved the competency of a group.

The personality characteristics which related with the improvement of competency was a feeling to conduct the entire job. The desire to always learn continuously to achieve maximum competency was a lifelong learning process that should be owned by an ambulance officer. Personality characteristics which related to the competency such as socializing and being easy to believe made the working environment in a team being good and related to the competency of ambulance officers.

The improvement competency through the building of good character for ambulance officers should to be conducted. Building the value of responsibility, friendliness, precision, emotional stability, and innovation were required. The improvement was accomplished by the addition of training, discussion and motivation in the formation of officers. Building the passion for self-respect was the beginning of the enhancement characteristics. Giving suggestions to always think positively also could be done. Building to the individual and organization to be enthusiastic, not afraid of being wrong and the spirit of finding solutions could also be carried out. The last thing that should be conducted was the improvement the knowledge of ambulance officers, that being the key to improve personality characteristics.

Most related factor: According in multivariate analysis, was found that personality characteristic was only one variable that related to the competency of ambulance officers. Adjusted r square of multivariate analysis has a value of 23.2%, it can be interpreted there was still other variables that affect competency by 78.6%.

This study shown that inner characteristic of ambulance officers had a stronger correlation. Motivation to work that was more optimally, confidence and positive thinking should be improved in order to improve the characteristics of ambulance officer. Building the right motivation to nurses and ambulance officers could be given to be able to improve competency indirectly.

The improvement of personality characteristics by conducting selection with people who had an interest in pre-hospital service. This greatly affected the characteristics of the inside of an ambulance officer. Good mentorship also seen to improve the characteristics of the personality of each ambulance attendant. Expected eventually to increase the overall competency of the ambulance officers.

It was undeniable that there were still many factors that affected competency. In this study, there were many factors that should be investigated. Factors related to the competency of ambulance officer should to be studied more deeply. Assessment factors related to the competency such as organizational culture, policy, professionalism factor, level of education and critical thinking also should be studied further.

Keep in mind that attitudes, knowledge and practices was a major aspect forming competency and different studies was needed. Limitation of this study was to assess the competency only of the aspects of respondents’ knowledge. That assessment only be based on the perspective of the service provider, so the result was less holistically. The research was conducted in several different places, so that it had different policies. Although every month they conduct communication, coordination, evaluation and regular training spot differences provide different perspectives ambulance officers.

Conclusion

The competency development could relate to two things, they were personality characteristics and experience. As an ambulance officer, high competency was needed in providing services. These competencies were needed to improve pre-hospital services and reduce deaths experienced by patients. Personality characteristics were more dominant factors when compared with experience as factors related to competency. Efforts to study and establish ambulance staff competencies should continue to be improved, especially in countries with relatively new pre-hospital services.

Empowerment of Coastal Communities Through Systems Approach in the Field of Environmental Health in Kendari City, Southeast Sulawesi Province, Indonesia

La Dupai¹, Nani Yuniar¹, Ruslan Majid¹, Arum Dian Pratiwi¹, Syawal Kamuluddin Saptaputra¹, Rahman¹

¹Faculty of Public Health, University Halu Oleo, Green Campus Bumi Tridharma, Anduonohu Kendari, Southeast Sulawesi, Indonesia

ABSTRACT

One of the health problems faced by coastal communities is community behavior in the management and utilization of environmental resources. Coastal area has problems like the limitations of environmental health facilities that cause the health status low. The study aimed to know the Coastal Community Empowerment with environmental health systems approach of Kendari. The type of study was qualitative. The informants was 12 people. Data collection uses in-depth interviews and Focus Group Discussion. Results of the implementation program appeared in three dimensions: a) Development of local communities through cross training sectors: agriculture and food, fisheries, private institutions, finance lending institutions and academics; and empowering youth groups through social activities. Empowerment through health village was carried out with: environmental cleanliness, family education, clean and healthy behavior, increasing family income, hydroponic planting methods, and utilizing plastic waste. b) Judging from the aspect of social policy, there was already the KOTAKU program (city without slums). c) Social action: Initiation of Movement 1 house 1 hand-washing, family medicinal plants, mobilizing to cleanliness the house yard, waste transportation services, coordinating with the Government to provide environmental health education, made a healthy smoke-free village. Conclusion: Community empowerment in order to improve environmental health behaviors can be more effective if using all potential stakeholders, education and training, local community development, social action and social policy. Recommendation: needin for socialization, education and training for the community, advocacy and collaboration across sectors of government agencies, and continuous supervision.

Keywords: Empowerment, Coastal Community, Environmental Health.

Introduction

The environment in coastal areas is generally an area that has very complex health problems like the limited of health facilities, the clean water, drainage, and sanitation services, as well as limited of infrastructure and facilities to create an environment and healthy behaviour in order to live productively.

The Regulation of the Minister of Health of the Republic of Indonesia mandates the restructuring of various steps in the field of management of natural resources, human resources, environment and institutions so that the Indonesian nation can catch up and have a parallel position and strong competitiveness in the international community association¹. Therefore, community empowerment is very important, as stated in Law Number 36 of 2009 concerning Health. In the Health regulation stated that: 1) 70% of the national development resources come from community contributions; 2) Community empowerment based on mutual cooperation, as a culture of Indonesian society; 3) Community behavior is the main factor in the occurrence of health problems, therefore the community itself can solve the problem through government...
guidance; 4) The government has limited resources in overcoming increasingly complex health problems in the community, while the community has considerable potential to be mobilized in prevention efforts in its area; 5) The potential of the community includes community leadership, community organizations, community financing, community material, community knowledge, community technology, community decision making processes, in efforts to improve health, this potential needs to be optimized; 6) Prevention efforts are more effective and efficient than treatment efforts, and the community also has the ability to make preventive efforts if efforts are made to empower the community, especially for clean and healthy life behavior.

Method

The type of study was qualitative study. The instrument was the researchers themselves using interview guidelines. Qualitative study is intended to explore social or human problems where community empowerment has interactions between individual communities and environmental health as a result of program objectives. This study was conducted in 2017 in the Coastal Region of Kendari City, Southeast Sulawesi Province.

Results

Local Community Development: This research seeks to gather information on the forms of local community development carried out by the local government and the involvement of stakeholders in developing the capabilities of individual communities in the research locations so that they have the ability to maintain health. Efforts to develop local communities focus more on the economic, education and health improvement sectors. In the economic sector, the development of local communities in the form of training and mentoring of working groups to improve the income sector includes:

“Here it is the usual training provided by the Food Service are groups of mothers, like the making of fish meatballs. Fish farming, catfish farming. Here there are already several working groups, but some have already succeeded in harvesting ... “(Key Informant, 47).

To increase community income, fishermen were given training fish meatballs production from the Food Security Service. The training was attended by housewives in the form of working groups hoping to increase household income to help the income of households. Likewise, the Fisheries Service provides training in the cultivation of sea fish and catfish by forming work groups to facilitate supervision and control of their development.

“For many years, the company has now planted live coral nurseries, the corals are cultivated, after four months, they are seen, not corals, a gathering place for fish, ornamental fish, and also some of employees here is from community... “(Key Informant 2.52).

Coral reef cultivation activities involve coastal communities. The cultivation activities are intended to safeguard coral reef ecosystems and how to catch legal fish and so that the marine ecosystem is maintained. This cultivation activity is carried out by private companies while still involving the community in the cultivation of coral reefs. The existence of these private companies provides positive value for the local area in reducing unemployment.

Social Policy: The policy and implementation of the “KOTAKU” program was promoted by the government is an effort to improve the quality of the residential environment. The program is very important and strategic to realize the commitment of all elements both government and community as development actors especially to create a clean housing environment and healthy.

“There are those who are running this KOTAKU program, this city is 100-0-100, 100 is for sanitation, 0 is slum housing, 100 percent is for water, irrigation, clean water ...” (Informant Key 1, 47).

Based on the interview results of the KOTAKU program, it is important to optimize sanitation because it is integrated in 3 program indicators, namely 100-0-100. 100 percent for the provision of proper sanitation for residents, 0 percent for reducing slum areas and 100 percent access to clean drinking water. Therefore, there is a need for awareness and active role of all parties by prioritizing the local wisdom of community both the government, religious leaders, community leaders and other components involved to make the program a success. Through this activity the standard of living of the community can be better, especially on health aspects by ensuring that all local communities are free from slums.
One indicator related to the “KOTAKU” Program is the problem of uninhabitable homes. Efforts are being made to change behavior through programs that are launched such as home renovation program for the poor community. This effort is one form of effort to get a decent place to live. Through this assistance, the involvement and active participation of the community is very much needed.

“Yes, if there is a government program, many of these home renovation program were carried out yesterday, there were also several houses that were repaired ...” (Community Leader L, 46).

Another form of the “KOTAKU” program activity, which is 100 clean water, is to ensure clean and healthy water concessions. To meet the needs of clean water, residents rely on one water source provided by the NGO called SINTESA. The Abeli District Government stated that the existence of the SINTESA greatly helped the community in providing clean water.

Social Action: Changing the culture of coastal communities to behave healthy is very difficult because of the many factors that influence it, so that specific approaches are needed by understanding the conditions of the local community. Therefore, the involvement of the local government is very important in understanding the conditions of the local community. The stakeholders made a number of breakthrough actions both initiated by the City government and the local Government.

Discussion

Local Community Development: Based on the results of this study, to improve the participation of the community in maintaining environmental health, it is necessary to revive community institutions such as local youth organization, one of the organizations that involve easy generation that serves to accommodate aspirations, as a place to cultivate nationalism, develop self-potential and become a moving community organization in the field of social welfare.

Social Policy: The KOTAKU program is one of the policies of the Central Government to accelerate slum settlement with 3 program indicator focuses which are the main concerns, namely access to livable sanitation, access to clean water and slum-free settlements. The program is in dealing with slums so that it builds a collaboration platform through increasing the role of the government and community participation. Community participation in development can be demonstrated in participation in the implementation of activities and in decision-making and monitoring and evaluation. The involvement of the community in this program as a village facilitator who overseeing program activities by being given training by professional trainers from the Government.

The results of this study found that home renovation program is one of the assistance provided to disadvantaged communities in the region. Determination of assistance through the local government discussion and proposed in accordance with the level of needs desired. The directive approach is based on the assumption that community workers as actors of change already know what is needed and what is best for the community, in this case the fulfillment of needs according to appropriate standards applies to the community.

The KOTAKU program activities is to increase the participation of the community in maintaining environmental health, so that the program will be effective if it conducts strategic socialization by prioritizing the community as the main actors.

Social Action: The involvement of community leaders are able to mobilize communities, provide motivation and desire to do something desired by these leaders, namely implementing healthy behaviors to realize the vision and mission of Healthy City. Exemplary, persuasion, and control from the community encourage people to act.

Various approaches taken by stakeholders and community components involved in policy making made by the local government so as to produce a garbage transportation service and create a clean and healthy environment include: First step, social enthusiasm. Giving social enthusiasm is an important component of community work practices to increase inspiration, enthusiasm, stimulate, mobilize and motivate others to do behavior. Second Step, negotiating and mediating with community leaders, religious leaders, RT/RW and mothers organization to convey related ideas so that the community environment is healthy. Through negotiation and mediation, local stakeholders convey the intent and purpose of the need to maintain environmental health, need to organize structured waste transportation services. The third Step, make consensus. The consensus
was generated after mediation, sociation. The intended consensus is in the form of a joint agreement between the community, community elements and stakeholders to agree on a clean Friday/Saturday service, and garbage transportation services with community self-help. Therefore an organized committee was formed through an agreement in order to have policy power. This is because the possibility of society not obeying the agreed rules by not paying self-help contributions due to various factors, especially economic factors.

To make the village smoke-free, there are several approaches taken. First step, coordinating with health agencies to provide health education related to PHBS, one of the indicators is smoking behavior. Counseling is intended to increase public knowledge and awareness regarding PHBS in general and specifically smoking behavior. The Second Step, conduct socialization to the public regarding policies that will be implemented with all the consequences. The essence of giving socialization is to increase community participation together to maintain health, especially the practice of PHBS. Through the socialization, a response and conflict reaction will be seen that might arise and a solution to overcome it.

Community empowerment through a healthy green environment system and a waste free environment can be seen from the aspects of input, process, output, and impact. In Kendari City, basically there have been efforts by regional governments to develop hydroponic planting methods. In addition to having a relationship with the environment, it also makes the environment greener because it uses the yard so that it obtains economic value for the local community. The program is also an inventory of PKK through the planting of family medicine which was later developed by the local Government because it became capital to familiarize the community to organize a clean and healthy green environment. In terms of environmental health aspects, the government’s efforts to develop hydroponic planting methods will help household-generated waste such as plastic bottles and others be recycled for planting media. Ecosystems relating to natural resource management, humans are directly involved in a series of activity processes that contain ecological processes.

Conclusion and Suggestion

The implementation of the coastal community empowerment program in enhancing the participation of the community in the field of environmental health appears in three main dimensions: a) Development of local communities through cross training sectors: agriculture and food, fisheries, private institutions, finance lending institutions and academics; and empowering youth groups through social activities. Empowerment through health village was carried out with: environmental cleanliness, family education, clean and healthy behavior, increasing family income, hydroponic planting methods, and utilizing plastic waste. b) Judging from the aspect of social policy, there was already the KOTAKU program (city without slums). c) Social action: Initiation of Movement 1 house 1 hand-washing, family medicinal plants, mobilizing to cleanliness the house yard, waste transportation services, coordinating with the Government to provide environmental health education, made a healthy smoke-free village. Conclusion: Community empowerment in order to improve environmental health behaviors can be more effective if using all potential stakeholders, education and training, local community development, social action and social policy. Recommendation: need in for socialization, education and training for the community, advocacy and collaboration across sectors of government agencies, and continuous supervision. In enhancing the role of community empowerment, it is necessary to provide assistance, education and training continuously by paying attention to aspects of socio-cultural conditions and financial capacity of coastal communities so that the support of the City Government like strong policies and regulations need to improve environmental health.

Study the Level of Interlukin-2 During and after Treatment in Sputum of Iraqi Patients with Pulmonary Tuberculosis

Liqa K. A. Alzubaidi1, Nisreen Sherif Alyasiri2, Luma yousif Mehdi3

1Department of Community Health Techniques, Mosul Technical Institute, Northern Technical University, Mosul, Iraq; 2Department of Nursing, AL-Suwaira Technical Institute, 3Department of Medical Laboratory Technologies, College of Health and Medical Technology, Middle Technical University, Baghdad, Iraq

ABSTRACT

The role of IL-2 as a biomarker for tuberculosis disease has been assessed. Lung infection with Mycobacterium tuberculosis induce T cell responses which is mainly regulated by interleukin-2 (IL-2). Recombinant human (rhIL-2) was administered with adjunctive immunotherapy to 30 patients diagnosed with primary tuberculosis (PTB), IL-2 level was observed in sputa at different intervals during treatment and at the mean time it was microscopically examined for acid fast bacilli (AFB). Thirty patients with latent tuberculosis after treatment (LTBat) in whom sputum production was successfully induced were also included. Placebo controlled trial patients were accredited twice injections of IL-2 on daily basis or placebo for the first 30 days of treatment. Subjects were followed for six months. The levels of IL-2 were increased in all patients compared to the control. Raised IL-2 level among LTBat patients was age dependent. Conversely, decreased IL-2 levels occur at the age 37 years and above. Increased IL-2 level in sputum enhanced bacillary smear clearance of patients with tuberculosis.

Keywords: Tuberculosis; IL-2; immunotherapy; Sputum

Introduction

Globally, Pulmonary Tuberculosis (TB) is the most unceasing life-threatening health issue that mainly attacks the lungs, and spread through the air via droplets of cough or sneeze carrying infectious M. tuberculosis or M. bovis. The World Health Organization (WHO) published many reports in this concern and narrated million cases come about every year, causing high morbidity rate especially among HIV patients and more than 1.8 million deaths per annum12. For long time, TB has been controlled adequately and treated using dual chemotherapy of pyrazinamide isoniazid, ethambutol, and rifampicin, as recommended by the world health organization3-5. However, conflicting affairs (e.g., prolonged uptake, intolerantness, and toxicity) are characterized compliance in patients under chemotherapeutic treatment. Nevertheless, Multi-drug-resistant tuberculosis has increased in rate not only in third world countries but also in developed countries6-7.

Interleukin 2 primarily produced by active T cells and its main function is to stimulate the differentiation and expand population of lymphocytes and plays central role in cell mediated immunity to infectious diseases8. Accordingly, administration of IL-2 was applied as a complementary biologic therapy to control many bacterial and viral infections, like leprosy, AIDS and leishmaniasis9-11.

Meantime, administration of rhIL-2 in addition to conventional treatment to patients with pulmonary tuberculosis could elicit the antimicrobial immune response, and betterment of sputum smear recognition for diagnosis of acid-fast bacteria12. Conversely rhIL-2 administration may increase T-cell activity vis a vis enhances bacilli reproduction and spread11. Therefore, we aimed to evaluate the level of IL-2 in sputa, other than
serum, of primary and latent TB patients and whether it can be used as indicator for disease progress.

**Material and Method**

**Subjects:** Eighty-five subjects, aged 17 to 50 years, thirty subjects with Primary Diagnosed TB, 30 subjects’ high sputum bacillary with latent TB, and 25 subjects as control were enrolled in this study. Tuberculosis patients were recruited from Merjan Teaching Hospital in Babylon. Cases that we had failed to induce sputum production effectively were excluded from the study. Patients with AFB-positive sputum of primary tuberculosis and AFB-negative sputum of latent tuberculosis were considered. Patients who show resistance to traditional treatment were also excluded. All patients in our study group were clinically examined by specialized Physicians. The study was ethically approved by the health committee center. All patients gave their consent for sputum collection.

**Treatment Allocation:** Patients were admitted to the hospital after being diagnosed for treatment and observation. Treatment included two months of chemotherapy (once a day pyrazinamide, rifampin, ethambutol and INH). The second course was four month long and included once a day both INH and rifampin) and twice daily injections of rhIL-2.

**Sputum Collection:** Morning sputum was collected after having a cup of hot water then the patients were asked to cough in a disposable collection cup.

Sputum sample for acid fast bacilli smear was collected on daily basis after two days and four days from day one of treatment administrations. Sputum was collected on weekly basis as well, from week one through week four, and after six weeks, and then monthly as long as the sputum can be effectively induced. For IL-2 level measurements sputum was processed after two weeks and six weeks of treatment. Subjects were followed for 6 months from day one of receiving treatment.

**Sputum Processing:** Collected sputum sample was processed without delay and as described\(^{13,14}\). Smear for AFB was prepared and processed for examination. The volume of remaining samples was measured and weighed as well. 0.1% of freshly prepared DTT (dithiothreitol) solution was added in twice the volume of sputum, followed by vortexing for fifteen minutes. The mixture was filtered using sterile gauze and centrifuged for ten minutes at 900 g. Supernatant was collected for interleukin-2 analysis or stored at −70 °C to be processed later.

**IL-2 Analysis:** ELISA (R & D Systems) was used to measure IL-2 concentration in sputum. IL-2 standard was reconstituted in DTT-PBS dilution buffer to limit any possible effect of DDT on IL-2 during sputum processing\(^{10}\). Serum was collected for ESR estimation as in Deice and Lewis\(^{13}\).

**Statistical Analysis:** Statistical SPSS version 20 software package was used for statistical study.

**Results**

Levels of IL-2 in primary tuberculosis (PTB), latent tuberculosis after treatment (LTBat) and control (CT) are shown in Table 1. IL-2 levels in both disease forms were higher than the control. However, the level of IL-2 in (LTB) group was slightly higher than the (CT) group. The mean ESR level in both disease forms were higher than the control.

*statistically significant p-value ≥0.05 n=number, IL-2=interleukin.

Level of IL-2 appear to be age dependant. For example, variation at age range (15-25) years was nearly double folds, and the range (26 -35) years was one and half folds the CT group. Relevance between aging and chronicity in LTBat group appear to be of high significance with p-value =0.002. However, at all age ranges the concentration means of ESR were high significant as illustrated in Table 3. The LTBat sputum smear negative were of higher IL-2 levels than LTBat sputum smear positive as shown in table (4).

Figure 2: Distribution curve of age range

Discussion

The present study cohort involved sputa of patients with primary Tuberculosis and sputa with positive acid-fast bacilli smear of patients with latent tuberculosis. Administration of human recombinant IL-2 were known to evoke clearance of sputum smear, however that was not confirmed in Iraqi patients of the present study either in those who receive treatment, newly diagnosed for TB or had TB. Previous study showed a moderate fundamental outcome of interleukin-2 that would be relevant with increment in the level of both CD25 & CD4 T cells as well as increment in serum. In current study IL-2 administration with lack of clinical response could be due to the fact that IL-2 had short term effect on immune criterions. However, similar studies postulated that a sustained immune response mediated by anti- \( M. tuberculosis \) included CD8 & CD4 T cells.

Our data show no relevance between rhIL-2 and clearance of acid-fast bacilli from sputum smear and release of IL-2 after 72 hours of being stimulated with
TB antigen could be a useful tool to distinguish between patients with LTB and those with active TB, finding in agreement with studies done using flow cytometry\(^\text{17}\). Many studies were done to evaluate IL-2 as a marker for infection with tuberculosis and concluded that it cannot be a reliable diagnostic marker alone and a second marker needs to be used to strengthen diagnostic outcome and they found that IFN-γ-secreting effector memory T-cells can be used as co-marker for this purpose\(^\text{18-19}\). Other researches documented the involvement of CD8 & CD4 T cells in immunity against *Mycobacterium tuberculosis*\(^\text{20-21}\).

Our data demonstrated a variable mean of IL-2 level among PTB and OTBat patients such finding analogue study done on African patients\(^\text{16}\).

It is well known that age is a key factor in immune system activity and responses and that was emphasized in tuberculosis patients the decline in interleukin-2 level is significantly associated with age increment as shown in tables (2,3).

AFB continually shed in sputum of active old TB patients in result of induction of monocytes by bacteria\(^\text{22-23}\).

We studied only one dosing chart of rhIL-2 which was selected based on available information from published data at the time of study design.

Previous studies found a distinctive correlation between administration of rhIL-2 treatment and improvement of sputum smear\(^\text{24-26}\). Our data show that and during the first month of treatment, daily increased level of IL-2 did not clear bacillary bacteria from sputum smear. Based on previously presented data, we could conclude that immunotherapy based on administration of rhIL-2 might participate in betterment of host immunity function and advancement of disease. A negative acid-fast bacilli smear could be a reliable approach in determining the validity of treatment and the virulence of a pulmonary TB\(^\text{27-29}\).

**Conclusion**

Treating TB with rhuIL-2 could enhance the smear conversion of TB. Levels of IL-2 in sputum was higher in primary tuberculosis patients than old tuberculosis after treatment. Our result indicate that IL-2 level could be used as indicator to determine severity of pulmonary tuberculosis.

Warm Footbath Minimize Osteo-arthritis Joint Pain on the Elderly in Surabaya’s Public Health Center

Muhamad Ibnu Hasan1, Elida Ulfiana1, Deni Yasmara1

1Faculty of Nursing, Universitas Airlangga Campus C, Mulyorejo street, Surabaya (60115), Indonesia

ABSTRACT

Background: Osteoarthritis joint pain is caused by degeneration process of cartilage bone and emphasized on weight bearing joints such as knees, hips, feet and the back. Warm footbath is one of hydrotherapies which used the modality of warm water to recover injury and minimize the symptoms of chronic joint problems.

Objective: This study aims to analyze the impact of warm footbath therapy to minimize osteoarthritis joint pain on elderly.

Method: This study employed a quasi-experimental design. The research samples were the elderly from a Mojo Public Health Center, Surabaya who suffered from osteoarthritis. The samples consisted of 20 respondents selected according to the inclusion criteria and were distributed into two groups, i.e. experimental group (n=10) and control group (n=10) by using purposive sampling technique. The independent variable of this research was the warm footbath while the dependent variable was the level of osteoarthritis joint pain on elderly. The data were collected by using The Western Ontario McMaster Universities Arthritis Index (WOMAC) questionnaire and analyzed by using Wilcoxon signed rank test and Mann-Whitney test with deviation level of p ≤ 0.05.

Result: The result of Wilcoxon signed rank test identified that there were differences between pretest and posttest in the experimental group (p=0.004) and the control group (p=0.011). Furthermore, the research result provided by Mann-Whitney also illustrated that there were significant differences between the posttest results of the experimental group and control group (p=0.035).

Conclusion: Warm footbath was proven to alleviate joint pain. The most dominantly declined osteoarthritis joint pain after a warm footbath was the pain resulted from standing.

Keywords: Warm footbath, joint pain, elderly, osteoarthritis

Introduction

Joint pain due to osteoarthritis causes negative impacts on the elderly’s daily life routine. Osteoarthritis is a joint degenerative process, a chronic condition which causes degeneration of bone cartilage and new bone formation as a reaction to the degeneration in the peripheral area and the subchondral area of the bone joint (1). The elderly who always experience osteoarthritis knee pain and are not in the long-term care facility become dependent in their efforts to fulfill their activity daily living or ADL at home, such as bathing, putting on clothes, and moving (2).

To minimize osteoarthritis pain, nursing intervention can be conducted through a collaborative and independent manner. The nursing intervention is carried out through cognitive behavioral approach and physical approach to minimize the pain. The physical approach can be performed through relaxation techniques. Warm footbath is one of the relaxation techniques that induces the body to relax, resulting in the occurrence of vascular vasodilation (3). This condition, mediated by intensified reflex axons mechanism in the circulation, causes an impact on the spread of algogenic substances that will

Email: elidaulfiana@yahoo.com
ease nociceptive pain. Warm footbath is useful for providing relaxation for the body, stretching muscles and pain as well as inducing the effect of reducing blockages in the brain and visceral (2).

The study on warm footbath has been performed previously with warm footbath effects on the anti-spastic effect in post-stroke patients as the research object. The study observed the changes on the stiffness level of the foot triceps using the MAS (Modified Ashworth Scale) indicator and controlled the observation of electromyographic changes by measuring the changes in F-waves parameters before treatment, immediately after treatment, and 30 minutes after treatment. The research results stated that there were differences in MAS scores before and after treatment, as well as in the description of the F-waves parameters comparison (4). Warm footbath is proven effective in minimizing the stiffness level in post-stroke patients. Based on the background of the problem, this study observed the effect of warm footbath to minimize osteoarthritis pain on the elderly (3).

**Material and Method**

This study uses quasi-experiment because this experiment does not have the characteristics of the actual experimental design since the variables need to be controlled or manipulated. Therefore, the research validity is insufficient to be classified as an actual experiment (5). In this research design, the experimental group was treated while the control group was not. Both groups, the treatment group and the control group, were preceded by a pre-test and after treatment and non-treatment activities, a post-test was conducted to remeasure the groups (6).

**Research Samples:** In this study, the sample population was the elderly with osteoarthritis joint pain disorders in Mojo Public Health Center, Surabaya, Indonesia. The method to determine the sample was the sample size application. The minimum samples size required by each group were 12 respondents or 24 respondents for 2 groups. The sample determination technique applied a method of specifying samples among the population in accordance with the researcher’s needs (research objectives/problems), so that the samples could represent the population characteristics that had previously been identified (7).

The sample inclusion criteria included elderly who were over 60 years old; diagnosed to suffer from osteoarthritis by medical personnel; had good cognitive function and able to take the WOMAC test; and were taking osteoarthritis treatment from the public health center of non-opioid NSAIDs and analgesics. The data on osteoarthritis joint pain on the elderly were assessed with the WOMAC index. There were five questions related to the pain, two questions related to joint stiffness and seventeen questions related to functional activities. This instrument is the most sensitive instrument in assessing osteoarthritis on knee or pelvis and is widely used in clinical trials (8).

**Data Analysis Method:** Data of post test were analyzed by Mann-Whitney test. Mann-Whitney is a statistical test (a comparative test of 2 dependent/independent samples) with a deviation level of $\alpha \leq 0.05$. When the results indicates that the value of $\alpha \leq 0.05$, H1 is accepted, meaning that there was a difference in the osteoarthritis joint pain alleviation in the elderly who were treated with those who were not.

Wilcoxon Sign Rank test p = 0.011 Wilcoxon Sign Rank test p = 0.004

Mann-Whitney test p = 0.035

The results from the statistical analysis using Wilcoxon Sign Rank Test indicated that p = 0.004 (α ≤ 0.05). This means that there was a decrease in the joint pain scores in the experimental group before and after the warm footbath intervention. The control group that was not treated with a warm footbath intervention showed that p = 0.011 (α ≤ 0.05) which indicated that joint pain decrease also occurred in the control group.

The analysis results of Table 5 suggested that the average pain score of the experimental group before the intervention was 7.80 with a standard deviation of 1.61, maximum score of 10, and minimum score 5. After the intervention, the average pain score in the experimental group decreased to 5.90 with a standard deviation of 1.197, a maximum value of 8, and a minimum score of 4.
Prior to the test, the mean value of pain score for the control group was 8.60 with a standard deviation of 1.89, a maximum score of 11, and a minimum score of 6. The average pain score after the test for the control group experienced only a slight decrease to 7.80 with a standard deviation of 1.988, maximum score of 10, and minimum score of 5. The results of the Wilcoxon Sign Rank test on the experimental group's pain score indicated that p score reached 0.004 (α ≤ 0.05) while in the control group, p score reached 0.011 (α ≤ 0.05). The result of the Mann-Whitney statistic Test on the pain score was that both the control and experimental groups indicated p score of 0.035 (α ≤ 0.05).

**Discussion**

The posttest analysis using Mann Whitney Test suggested that p score was 0.035 (α ≤ 0.05), indicating that there was a difference between the experimental group and the control group on the post-intervention pain score. The study results also found data on the decrease of the total pain score in each activity, including pain during walking on a flat surface, sleeping at night, sitting or lying down, and standing. There was no change in the pain experienced during climbing up and stepping stairs after a warm footbath with a total score of 20. A significant pain reduction occurred in the pain experienced when standing with the difference between the pretest and posttest scores reaching nine points.

Furthermore, of the 24 questions on the WOMAC index, the df score obtained was 22. At the significance level of 5%, the r score for the table reached 0.404. Meanwhile, in the statistical test, the difference between the scores of each variable and the total r score obtained r of all questions ranged from 0.452-0.830. This value was greater than the r table value (0.404). Thus, all questions were declared valid. The Cronbach Alpha test for the WOMAC index reached 0.951 which was above the minimum limit of 0.70. Thus, it can be concluded that the WOMAC index had a good reliability.

This is in accordance with the research conducted by Matsumoto (2000) where the stimulation of warm water in certain areas could increase the production of endorphin neuroregulators and induce an increase blood circulation to stimulate the release of endorphins, natural analgesic compounds in the body. This concept was based on pain modulation using the acupuncture method. Acupuncture is a pain modulation method that can trigger the release of endorphins. Acupuncture techniques increases local NO levels and cause hypervascularization. In addition, a large increase in local NO is believed to be capable of releasing a number of endorphins as natural analgesic compounds that can ease pain (4).

The pain subscales at WOMAC were set in 45% of 134 trials. Appropriate method reports in applying the WOMAC pain subscale were found in many cases. 52% of the study reports using the WOMAC subscale indicated inadequate results with ambiguous ranges of pain scores of 38% and only 10% became completely clear (9).

The pain experienced when climbing up and stepping down stairs constituted a question that had the highest value in comparison with the other questions with a value of 48. Joint pain when climbing up and stepping down stairs was experienced as severe pain by the majority of respondents. Severe pain was described by the respondents as pre-existing pain and it would increase when carrying out the activity (10).

The main cause of osteoarthritis joint pain is the cartilage bone degeneration which induces suppression of supporting bones and it gets worse with activities or weight supporting positions in the body (11). Stepping down the stairs induces an increase in the knee joint and causing pain. The more severe the symptoms of knee osteoarthritis experienced by a person, the lesser ability of the knee joint to absorb the impact of increasing body weight, especially in the initial phase of stepping down the stairs (2).

The decrease in osteoarthritis pain scores in the experimental and control groups were also caused by nutritional factors that could not be fully controlled by the researchers. Nutrition is an important component in the process of forming and healing an injury. Vitamin D plays a vital role in bone metabolism (12). These conditions may spur the emergence of the postulate that consumption of vitamin D, with adverse effects on the growth of osteoarthritis bone, may be involved in the changes in bone behavior at various stages of the osteoarthritis development (11).

Consequently, other physiological effects induced by warm footbath are the mechanism of pain reduction through the gate control theory and intensify the production of endorphin neuroregulators. The thermodynamic properties that will be received by the thermoreceptors with peripheral bemyelin fine afferent
fibers reached a speed of 30 m/s which is referred to as alpha beta fibers that feed on muscle spindles. This thermal stimulus causes activation of the diameter widening of myelin fibers, enabling it to “close” the nociceptive impulses gate before reaching the brain (13).

The stimulation of warm water in the area would increase the production of endorphin neuroregulators and induce an increase in blood circulation so that it could stimulate the release of endorphins, natural analgesic compounds in the body. This concept is based on pain modulation by using the acupuncture method. Acupuncture is a pain modulation method that can trigger the release of endorphins (4).

Warm footbath implemented for osteoarthritis joints utilized thermodynamic effects (heat flow) and hydrostatic pressure (buoyancy) of the warm water surface as a mechanism to ease pain. The hydrostatic force would relieve the joints when the feet were soaked in the water (14). The thermodynamic effects of warm water surface induced an increase in core body temperature, triggering a series of advanced processes that could reduce ischemia due to cartilage degeneration which often caused pain (15).

**Conclusion**

Based on the last statistical test employed, the pain when standing was experienced as a mild pain and often occurred in the morning, accompanied by stiffness and can be relaxed by using warm footbath. The respondents who were given the opportunity to relax and increase body temperature through the thermodynamic effects of warm footbath could minimize osteoarthritis joint pain through the increased synovium tissue vascularization and muscle relaxation.

**Ethical Clearance:** The research process involves participants in the survey using a questionnaire that was accordant with the ethical research principle based on the regulation of research ethic committee. The present study was carried out in accordance with the research principles. This study implemented the basic principle ethics of respect, beneficence, nonmaleficence, and justice.

ABSTRACT

Background: Tuberculosis is a contagious air transmitted bacterial disease caused by Mycobacterium tuberculosis. It mainly infects the lungs, but it may infect other parts of the body. It is considered a major community health problem globally, it is the world second largest cause of death in adults between the infectious diseases after HIV/AIDS.

Objective: This study was aimed to estimate the common types of tuberculosis in Al-Najaf city.

Materials and Method: This is a case-control study accomplished in the Advisory Clinic for Thoracic and Respiratory Diseases in Al-Najaf city, for the period from December 2017 to August 2018. A total of 70 individuals were included in this study, 37 were diagnosed with tuberculosis by specialist respiratory physician, and 33 were healthy controls. All data that include age, gender, residence, smoking, site of infection and history of diabetes were collected from all participants. The data were analyzed by using the statistical package social system (SPSS).

Results: This study show that pulmonary TB more frequent in men 11(61.1%) than in women 7(38.9%), pleural TB also has high male to female ratio 5(83.3%) to 1 (16.7%) respectively, and the incidence was also higher in males in bone, peritoneum and meninges TB. In contrast lymph node tuberculosis is found to be predominant in females.

It also found that tuberculosis was more frequent in age interval from (25-50) years old. It also shows that out of total 37 tuberculosis cases 28 cases (75.7%) were from urban area, compared to 9 cases (24.3%) from rural area.

Conclusion: Sex differences affect TB infection, it is significantly higher in male over female except in lymph node TB where it more frequent in female, TB most commonly infects economically active age groups (21-50 years old), it more frequent in urban areas than rural areas.

Keywords: M. tuberculosis, Najaf, TB

Introduction

Tuberculosis is a contagious air transmitted bacterial disease caused by Mycobacterium Tuberculosis. It is considered a major community health problem globally. In 2017 about 10 million people manifested with active tuberculosis, and almost 1.6 million persons die from TB globally. It is the world second largest cause of death in adults between the infectious diseases after HIV/AIDS, as it is results in death of about two million individuals annually 1.

In 2014 Iraq accounts for about 25% of the global TB burden. It is predestined that Iraq which accounts 3% of the total number of cases in the region, there were roughly 20000 TB patients and 4000 deaths yearly 2. Tuberculosis can infect both male and female and occur in any age and can attack any organ/tissue of the body 3. TB bacilli generally infect the lungs in approximately 80% of the cases, which leads to primary pulmonary tuberculosis. Extra-pulmonary tuberculosis (EPTB) represents nearly 20% of cases and affects many organs such as lymph nodes, intestine, meninges, bone and...
joints. Lymph node Tuberculosis (LNTB) represents the most common among other types of EPTB in multiple regions of the world representing 40% of EPTB cases.

The pathogen that causes Tuberculosis disease is Mycobacterium tuberculosis (M. tb), this bacterium included within the class Actinobacteria, and belongs to subclass Corynebacterineae. It is rod in shape about 1-10μm in length, and nearly 0.4 μm in diameter.

Some individuals are naturally more vulnerable to mycobacterial infections than others. Individuals who have high risk of getting mycobacterial infections include persons who have chronic renal failure, patients having insulin-dependent diabetes, individuals subjecting to immunosuppressive therapy, prisons residents and people inhabitant homeless shelters, peoples using intravenous-drug, and HIV infected individuals.

The prevalence of TB among diabetic patients was 1.8–9.5 times higher than in the general population in some Asian countries.

**Subjects and Method**

Ethically, data collection and the design of the study groups were accomplished after the approval on the research proposal was done by Research Ethics Committee of Najaf Health Directorate to work in its hospitals.

A case-control study conducted during the period from December 2017 to August 2018 in Al-Najaf city. A total of seventy subjects were included. Thirty seven tuberculosis patients including 21 (56.8%) male and 16 (43.2%) female, and the male to female ratio was 3:2, those patients were diagnosed according to laboratory, radiology and clinical investigations by specialist respiratory physician, and (33) healthy individuals as control who were attended the Advisory Clinic for Thoracic and Respiratory Diseases in Al-Najaf city.

All data that include: age, gender, site of infection, history of diabetes, smoking and residence have been collected from all participants, and appropriate statistical and descriptive analysis were performed using IBM SPSS V21.

**Results**

A total of 70 individuals were included in this study, divided into 37 (52.9 %) patients (males 21 (56.8%) and females 16 (43.2%)), their ages ranged between (14-75) years with mean value (43.86), the male to female ratio was 3:2 it is higher in males than in females, and 33 (47.1%) as a control group (males 22 (66.7) and females 11 (33.3)), their ages ranged from (16-72) and the mean value is (42.48) as in table 1.

The number of tuberculosis cases was more frequent in age interval from (25-50) years old which comprises 19 patients (51%) from the total TB cases, the lowest number of cases was in the age interval (>50) which is only 8 cases (21.6%), while in control group it include 8 individuals (24.2%) in (<25 years) age group, and 19 (57.6%) in age group (25-50 years), while the age group (>50 years) include 6 individuals (18.2%) table 1.

The impact of gender on the type of tuberculosis revealed the marked predominance of pulmonary tuberculosis in males in compare with females 11 (61.1%) and 7 (38.9%) respectively, this dominance is also observed in pleural TB 5 (83.3%) in males compared with 1 (16.7%) in female, and the incidence was also higher in males in bone, peritoneum and meninges TB. In contrast lymph node tuberculosis is found to be predominant in females while no males infection has recorded as shown in table 1.

It has been shown that diabetic patients represent 8 (21.6%) of TB cases and non-diabetic patients were 29 (78.4%) of total TB cases as illustrated in table 1.

In this experiment it has been found that 16 (43.2%) TB patients were smokers and 21 (56.8%) of TB patients were non-smokers as shown in table 1.

As shown in table 1 there is marked dominance of tuberculosis infection in urban than in rural area in Najaf city 28 cases (75.7%) out of total 37 Tuberculosis cases were from urban area, whereas 9 cases (24.3%) from rural area.

Discussion

The most infected age groups are (25-50) years while the lowest infected age groups were (<25) and (>50) years, and this does not mean that these age groups are less or not susceptible to TB infection, on the contrary these age groups are of high susceptibility to TB infection as a result of their deficient or weak immune system. This result agrees with Bhatt et al., 2009 who suggest that TB most commonly infect economically active age groups (21-50 years old), and also agree with the global burden of TB in developing countries who reported that 75% of TB infected cases are within the age group (15-54) years old which is economically active and most productive age.

This study shows predominance of TB in males in compare with females patients, with male to female ratio (3:2). This result matched with other studies done in Iraq by Al-Jubouri, 2010 and Al-Zubaidi, 2010 who point out the rate of TB was higher in male than female (3:2). World health organization reported that globally more men infected with TB than women, in (2017) however WHO mentioned that some places has more women than men such as Afghanistan, Iran and some part of Pakistan. Another study mentioned that males and females has equal TB incidence. In the current study, the cause of high incidence of TB in men may be due to the susceptibility of men to TB as a result of the nature of their lifestyle that characterized of being more exposed to predisposing factor like tobacco smoking, drug abuse and alcohol.

Pulmonary TB more frequent in men (61.1%) than in women (38.9%), pleural TB also has high male to female ratio 5 (83.3%) to 1 (16.7%), while lymph node TB found to be higher in women, these results agree with study done in Tunisia that mentioned the predominance of pulmonary TB in men over women and higher incidence of pleural TB in men, it also reported the predominance of lymph node TB in women. A study done in Hong Kong by Noertjojo et al., 2002 postulate that lymph node TB occur significantly higher in women, while pleural TB was significantly higher in men.

TB patients with diabetic consist of 8 (21.6%) while nondiabetic TB patients 29 (78.4%). This result agrees with systematic review done by Baker et al., 2016 showing high number of hyperglycemia in TB patients especially in Indonesia, Mexico and Iran that reported diabetes mellitus prevalence of 13%, 35% and 32% respectively. A cross sectional study done in south Texas and north Mexico it found high prevalence of diabetes in TB patients 39% in Texas and 36% in Mexico. The number of smokers in TB patients 15 (40.5%) and nonsmoking TB patients were 22 (59.5%), A study conducted in Iran by Ghasemian et al., 2009 has found that smokers were 2.1 times more likely to fell ill with pulmonary tuberculosis than non-smoker. A study done by Basu et al., 2011 predicts that smoking would increases the global TB cases by 18 million more and 40 million deaths between 2010 and 2050.

Tuberculosis has higher incidence among urban people than rural 28 (75.7%) versus 9 (24.3%) respectively. And this agrees with study done in Iran by Yazdani and Kazemnejad, 2010 has mention that 61% of TB patients were urban and 39% from rural resident. Another study done by Zadeh et al., 2013 also reported
the higher incidence of TB in urban area. The low number notification of TB cases in rural area probably, because of their limited access to health services and low knowledge about TB and poor health seeking.

**Conclusion**

TB most commonly infects economically active age groups (21-50 years old). Sex differences affect TB infection, it is significantly higher in males over females, except in lymph node TB where it more frequent in females. The TB situation appear to be worse in urban areas, with a significantly higher risk of infection compared to rural areas.

ABSTRACT

Background: Maternal mortality is an important indicator to assess the level of a country’s welfare and public health status. If the high maternal mortality rate means that the maternal health care system is still poor. Ammuntuli Bija Teanang na Beja-Beja (home visit) is an approach or alternative solution to improve maternal and child health.

Objective: This study was to determine the effect of the ammuntuli bija teanang na beja-beja model on the knowledge, motivation, and attitudes of midwives in the health services of pregnant women. This study was conducted in six health centers in Jeneponto Regency.

Method: This study used a “Pre-Experimental” design method with a “one group pre and post-test design”. Statistical analysis used was the Wilcoxon rank test. The population was 113 midwives with a study sample of 33 midwives in six Puskesmas in Jeneponto Regency. The sampling technique was purposive sampling.

Results: This study showed that there are differences in the knowledge, motivation, and attitudes of midwives in the health services of pregnant women before and after the intervention of the ammuntuli bija teanang na beja-beja model given. Significant changes occurred (p <0.05), namely; knowledge (p = 0.001), motivation (p = 0.001) and attitude (p = 0.001).

Conclusion: The administration of the ammuntuli bija teanang na beja-beja model has been able to improve the knowledge, motivation, and attitudes of midwives in the health services of pregnant women.

Keywords: Ammuntuli bija teanang na beja-beja, health services, midwives

Introduction

2012 Indonesian Demographic and Health Survey shows that the maternal mortality rate (related to pregnancy, childbirth, and childbirth) was 359 per 100,000 live births¹. Maternal mortality in South Sulawesi Province in 2014 was 138 people or 93.20 per 100,000 live births. Jeneponto Regency (193/100,000 live births) is ranked fourth after Bone (240/100,000 live births), Gowa (240/100,000 live births), and Luwu (293/100,000 live births)².

The high maternal mortality rate in Jeneponto Regency is due to bleeding, eclampsia, infectious diseases, and late referrals and low competence of midwives. This can be seen from a large number of midwife services, health services in Jeneponto Regency are still low³. Health care programs for pregnant women
Low knowledge, motivation, and attitudes of midwives are one of the important keys to the success of health services including improving health services for pregnant women. The basic causes of maternal death can occur because 1) Too late to recognize the danger and make decisions referring to health facilities; 2) Too late to reach a referral service facility, and 3) Too late in obtaining adequate services at the referral facility.

Several studies have identified factors that influence the low level of health services so that maternal and newborn mortality rates are still high. These factors are structural factors that lead to health inequalities of antenatal care (ANC), low quality of health workers, unavailability of potential equipment and drugs, ethnicity, and gender.

To improve maternal and child health, the World Health Organization (WHO) and UNICEF recommend that a home visit program is an effort that needs to be carried out by community health workers to address maternal and infant health problems and improve maternal and infant health services. One of the African sub-Saharan countries, Uganda, conducts home visits conducted by health workers (community health cadres, also known as village health teams) as a means to communicate health messages relevant to maternal and newborn health. In addition, Bangladesh, India, and Pakistan have conducted home visits by community health cadres’ programs designed to bridge public health problems. Efforts to prevent health problems have been carried out in various cases, including cardiovascular disease in cooks.

The home visit program on maternal and child health is a method used to provide broad results from early prevention and service interventions to families in need during the prenatal period or early pregnancy. Health workers strive to improve maternal services and the development of children by increasing parental knowledge, social support, the ability to overcome and solve health problems for pregnant women, access to the community and health services.

The aim of this study was to determine the effect of the current model of the ammuntuli bija teanang na beja-beja on the knowledge, attitudes, motivation, and abilities of midwives in the health services of pregnant women in Jeneponto Regency.

Materials and Method

This study used the method of “Pre-Experimental” design research with the design of “one group pre and post-test design”. Statistical analysis used was the Wilcoxon rank test. The population consisted of 113 midwives with a study sample of 33 midwives in six Public Health Center (Puskesmas) in Jeneponto Regency. The six Puskesmas includes Puskesmas Bontoramba, Puskesmas Bulusibatang, Buluoe, Bontomate’ne, Tolo dan Rumbia. The selection of Puskesmas is based on consideration of the low coverage of health services and consideration of geographical location includes Puskesmas in mountainous and lowland areas.

Table 1 shows that the respondents in the intervention group, the most age group was the 20-30 age group with 19 people (57.6%), 17 people living in the village (51.5%) with the highest education level were Diploma-III with 30 people (90.9%). The highest number of jobs is PTT with 26 people (78.8%). Respondents who had a service period of more than 5 years were 32 people (97.0%) and had never attended training, the highest number being 25 people (75.8%).

Source: Primary Data, 2018

Table 2 shows that there was a change in knowledge, motivation, and attitudes before and after the intervention where knowledge increased by 2.151 points, motivation increased by 5.812 points, the attitude changed by 5.515 points with p <0.005 knowledge (0.001), motivation (0.001) and attitude (0.001).

Discussion

Organizational determinants play an important role, especially in providing adequate resources to support teamwork, human resource management, and leadership. As suggested by policymakers, the government must encourage the use of these workers by updating policies, so that conditions where there is still a lack of midwives and facilities by implementing programs to increase staff and facilities4,12.

In this study, the characteristics of the subjects were found to be mostly good in the young age group, the interval of 21-30 years. This greatly facilitates the transfer of information because the group is still relatively easy to receive knowledge and change. Age is one of the things that affect knowledge because a person’s growing age can make changes to the physical, psychological and psychological aspects. On the psychological aspect, a person’s level of thinking is getting more mature. In
practice, the characteristics that influence the attitudes of nurses in service are age, education, functional positions, and length of work, while the doctors are age, education, and length of work. In this study, groups have similarities to the dominance of subject characteristics, namely age, education and years of service.

As the results of the study that a person’s beliefs are needed to involve themselves effectively in service. Sometimes, new graduate midwives often lack confidence in doing services, and this can interfere with safe and effective health services. Therefore, an intervention is needed that can provide support to develop the knowledge and experience of new graduates regarding the services of pregnant women. This is very important to increase the confidence of new graduate nurses.

A. Knowledge: After the Wilcoxon Rank test, the results of the study in table 2 show the value ($\rho = 0.001$), which means the value ($p < 0.05$) with the mean difference of 2.151. This means that there is a change in the knowledge of midwives in the health services of pregnant women before and after the implementation of the ammuntuli bija teanang na beja-beja model. Ammuntuli bija teanang na beja-beja is the language of the Makassar, it is hoped that the use of this term will further facilitate local implementation. This is appropriate, that resolving health problems by taking into account the local context will be more effective than medical actions. It does not only contain home visits of a health worker to the home of pregnant women and/or mothers who have babies, but it also contains respect for health workers to them. With home visits, it means that they are picked up and it is hoped that they can make use of health services at the Puskesmas.

Knowledge is a continuous formation by someone who is experiencing reorganization at any time because of new understanding. Knowledge in a constructivist view is not a fact from a fact being studied, but as a person’s cognitive construction of objects, experiences, and environments. A person’s behavior tends to be good if his knowledge is also high. Efforts to improve maternal health services can be done in various ways. One of the strategies is training activities. In some training and development of health services, it has not been fully implemented.

Although it is known that there is an influence of education (counseling) on knowledge and attitudes. Knowledge, skills, and motivation correlate with the performance of midwives. Meanwhile, work time does not have a correlation with the performance of midwives. Health education is an effort to increase one’s knowledge and abilities, by encouraging self-direction and being active in providing new information or ideas.

B. Motivation: After the Wilcoxon Rank test, the results of the study in table 2 show the value ($\rho = 0.001$), which means the value ($p < 0.05$) with the mean difference of 5.812. This means that there is a change in the motivation of midwives in the health services of pregnant women before and after the implementation of the ammuntuli bija teanang na beja-beja model. Motivation is someone’s special readiness to carry out a series of activities aimed at achieving a number of targets. Work motivation is something that originates from the individual’s internal (desires, hopes, needs, and preferences) which cause encouragement or enthusiasm to work hard.

The motivation of village midwives is a condition in the village midwives who can give strength, enthusiasm, the courage to be honest and enjoy what they do in order to achieve high performance. One of the factors to improve performance is motivation because the presence of motivation will encourage work morale, inspiration from work activities of employees to work better in order to achieve organizational goals. Motivational factors are factors that are related to what they do, namely the content of the work on the task that encourages achievement. Motivational factors are intrinsic originating in the individual or also called the content factor of work content.

C. Attitude: After the Wilcoxon Rank test, the results of the research in table 2 show the value ($\rho = 0.001$). This means that the value ($p < 0.05$) with a mean difference of 5.515 means that there is a change in the attitude of midwives in the health services of pregnant women before and after the implementation of the ammunition bija teanang na beja-beja model. The attitude is as an evaluative response. The response arises if the individual is faced with a stimulant that requires
an individual reaction. Evaluative Response means the evaluation process of an individual who gives a conclusion to a stimulus. In the form of good-bad, positive-negative, pleasant, unpleasant, which then crystallizes as a potential reaction to the object’s attitude 19.

The higher the attitude of supporting health workers, the higher the behavior of antenatal care visits. The lower the attitude of health workers who do not support the lower behavior of antenatal care visits. This is in accordance with Lawrence Green’s theory that the attitude of health workers who are reinforcing factors can influence behavior change 20.

This research still has various limitations, namely the small number of samples that have not been able to see the overall aspects related to health care for pregnant women. Activities in daily health services at auxiliary health centers and village health posts provide limited intervention and communication time when conducting research. This study only looks at how the influence of the ammuntuli bija teanang na beja-beja model on the knowledge, motivation, and cycles of maternal health services does not see the overall aspects that affect the health services of pregnant women such as environmental, social, economic and family support factors.

Conclusions and Recommendations

This study concluded that there was an influence of the midwifery on the knowledge, motivation, and attitudes of in the health services of pregnant women in Jeneponto Regency. This study suggests that the implementation of the ammuntuli bija teanang na beja-beja model is very useful to be a reference for midwives in improving health services for pregnant women in Jeneponto Regency and can be replicated in other areas according to local conditions.

Significant Statement: This research is expected to be a recommendation for the regional government (health office) to make regulations by implementing and developing models of ammuntuli bija teanang na beja-beja, which are able to improve knowledge, motivation and attitudes of midwives in implementing health services and becoming a momentum in improving effective maternal health services so that the handling of maternal mortality can take place comprehensively and sustainably.

Acknowledgments

Our thanks go to various parties, namely the Jeneponto District Health Office, Bontoramba Health Center, Bulusibatang Health Center, Bululoe Health Center, BontoMatene Health Center, Tolo Health Center, Rumbia Health Center and all informants that help this research.

Conflict of Interest: There is no any conflict of interest within this study and publication.

A Study on New Frontier of Integrative Medicine on Social Media with Special Reference to Chennai City

N. Manivannan¹, G. Mythili²

¹Associate Professor, ²Assistant Professor, Department of Commerce, VELS Institute of Science, Technology and Advanced Studies (VISTAS), Pallavaram, Chennai

ABSTRACT

The integrative medicine is sold on direct and also the indirect methods to the people. The public people are ready to bought goods and services from the organisation without taking a risk. The risk less people are choosing the social Medias recommendations, these kinds of recommendations may lead to promote the goods in to the customers hands very easily. The easiest method may followed by the way of social media. The social media convey one information about product to number people at single minutes of time. It contains the need, scope, objectives of studies and also using the tools of Chi-square test for analyzing the data. Based on the findings, appropriate suggestions have been made for increasing the number of users.

Keywords: Medicine, Customers, Media, Information, Users, Online service, product

Introduction

The dynamism of the market has been a major area of everyone’s concern. The alarming shift from just “selling the products” to “being into the customers” has given marketing a different phase from „push marketing” to more of communicating with customers. Earlier the companies were connecting with the customers through radio, television, print media, bill boards and other traditional advertising. Now with a realization that the main conviction source are our colleagues, friends and our social network, where we lend our ears and mind with a personal touch and usually get persuaded taking it as more true and honest.

At the same time, technology paved the way for new possibilities. TiVo & digital video recorders made it easy for us to bypass & ignore commercials in live T.V. MPG players helped us listen to music & podcast on demand, which similarly margin zed radio advertising, online retailer realized that they could increase dates by allowing visitors to their site to offer personal recommendation about products they were selling and of course, the social media industry was very successful. It the rise of mainstream social media has proceeds one thing. It may be for providing oneself with significant identification socially. But social media today captures a lot of unusual information about users. Sometimes that mundane information can include on experience, point view or negative, with your brand or with your Company. Today everyone can connect to their own little social circle of usually a few hundred people.

People don’t just hear about news, events, and so on from the local TV news broadcast and/or newspapers. People here about things from blogs, Twitter, articles, casual conservation. The term social media refers to the collection of technologies that capture communication, content, and so on across individuals, their friends, and their social naturals. Examples of social media include social networking sites like Facebook and Twitter, Blogging technologies like type pad and word press, crowed sourcing products like Wikipedia, Photo & video sharing sites like Flicker & You tube, & others. These technologies help users easily create content on the Internet and share it with others. Social media is the Infrastructures that helps user to become publishers of content that is interesting to them & their friends.

Healthcare Marketing is Everywhere, Socially Speaking: A quick scroll through your Facebook newsfeed on any given day probably turns up several compelling articles about wellness and medical research. It’s become the norm to see cutting-edge health news scattered throughout our social media channels with links to new studies being shared on timelines, retweeted on Twitter, even posted on LinkedIn and Instagram. Sometimes simple wellness tips about mindfulness or exercise can take on a life of their own across the several channels, going viral and then becoming water cooler talk or the latest “have you heard about?” fodder.

Alternatives are Welcome in the Social Sphere: As a marketing channel social media clearly has an edge, but is it a good match for the growing field of integrative medicine? The answer is absolutely 100% yes.

By definition, the practitioners of integrative medicine are open to thinking outside the box, using inclusive, holistic approaches that put the patient at the center of their own care. And the personal connection from practitioner to patient on social media is instant! Posts are presented right alongside user-generated content, taking up just as much weight and visual space as posts from friends and family. In addition, integrative medicine practitioners actively listen and rarely use a one-size-fits-all approach like mainstream medicine often does, and on social media that personal touch fits right in. More than ever it’s possible to build up one-on-one trust with a patient if they see reliable, helpful information coming from your page directly to their newsfeed on a regular basis.

Positioning your practice as an authority and a resource on social media goes a long way toward building confidence in your specific brand of medicine and promotes the positive influence of integrative medicine in general. Sharing helpful posts from fellow integrative pioneers spreads the message even farther and positions you as a thought-leader in the larger conversation, so don’t be shy about the share button.

The Newsfeed: Where Patients Meet Practitioners: By inviting the patient to take charge of their own health (and at the same time empowering them with information to do so) healthcare social media is at the forefront of progressive medicine. Social media also has the benefit of directly connecting patients with specific practitioners that have the unique skill sets to promote their wellbeing.

When a client reacts to your post or shares your links, your visibility goes up exponentially, opening the door to new patients who may be looking for the specialized care that can only be found in your niche.

The Great Conversation: Social media marketing is also unique in how it brings patients and clients back into the conversation. Traditional marketing and media such as print or commercials are a one-way messaging system (pretty useless for finding out what customers are really thinking) but social media is interactive by design. And since integrative medicine practitioners prefer to encourage patients to participate in their own care, social media marketing and integrative health are perfect partners. By including the interactive streams of Facebook, Twitter, and other popular outlets in our marketing strategies, we can help keep our patients in the driver’s seat of their well being.

Advantages of Social Networking Sites:

1. Facilitates open communication, leading to enhanced information discovery and delivery.
2. Allows employees to discuss ideas, post views, ask questions and share links.
3. Provides an opportunity to widen business contacts.
4. Targets a wide audience, making it a useful and effective recruitment tool.
5. Improves business reputation and client base with minimal use of advertising.

Benefits of Social Networking Sites to Business:

1. Increased awareness of the organization.
2. Increased traffic to website.
3. Greater favorable perceptions of the brand.
4. Able to monitor conversations about the organization.
5. Able to develop targeted marketing activities.

Objectives of the Study

- To understand the real situation of healthcare product qualities
- To make a awareness about the social media in metropolitan cities
To create a real value of product at the time purchasing

**Research Design:** Descriptive Research Design

**Sampling Method:** Since the population is large in number, the researcher undertook a sample survey. Convenient sampling method has been adopted to collect data from the respondents.

**Sample Size:** 310

**Method of Data Collection:** Surveys questionnaire method and Personal Discussion.

**Scope of the Study**
- All the level of organizational performance related to the customers with the efficient manner.
- The social media attract only the educated people so, they want to promote the business into the village level of people,
- Media activities all are goes to explain the real situation and value of the product at huge level.

**Limitations of the Study**
- The study only confined to Chennai city, the city have so many kinds of living hoods.
- The integrative medicine in social media is utmost developed in the study area
- The respondents all are eagerly waited for the answering of his personal questions.

**Review of Literature**

B.V.L. Narayana (2012) shows that populations with poor formal literacy rates show equivalent or even better health indices. These target populations have better attitudes, better access and consequently better utilization of health interventions. This utilization was dependent upon, first people becoming aware of existence of health conditions and understanding their impact. On being confronted with a specific health condition, this general awareness would prime specific health seeking behaviours. The success of such behaviours was crucially dependent upon access to corresponding health interventions. Thus a sequential model of general awareness-specific awareness-attitudes access-utilisation is developed.

**Abusaleh Shariff and Geeta Singh (2007)** made an attempt to discuss the issues associated with the demand and supply of the five measures of maternity care-antenatal care, blood pressure check up, place of delivery, use of trained help at the time of delivery and postnatal care. Econometric analysis is undertaken to find out the determinants of the use of reproductive health care services among rural Indian households. The focus on the role of education, information and economic factors as determinants of health care accessibility and their utilisation is the specialty of this analysis. Analysis shows that education and information variables significantly influence health seeking behaviour and as well increase the utilisation rates for prenatal, child delivery and postnatal health care.

**Srinivasan K. and Sharan Raka (2005)** focused their attention on the various aspects of religiosity and health. It is observed by various researches that the rural population of India, is very much influenced by religious beliefs. For example cultural formation of individuals closely inter linked with performance of individual’s daily routine. The study aimed to examine the impact of religious practices and rituals as aspects of religiosity on health with specific reference to rural individuals of India.

**Framework of Analysis and Analytical Tools**

**Chi-Square Test**

**CHI SQUARE**

Df: (r-1)(c-1)  (5-1)(4-1)  12.

Table value: 21.026, Calculated Value: 41.339

**Result:** Since the calculated value of Chi Square is greater than the table value of $X^2$, $H_o$ is rejected. So the respondents social media is influenced by awareness of medicine.

Hence there is evidence of association between social media respondent and awareness of medicine.
Findings

The new frontier of the integrative medicine on social media with the effect of the societal people is ready to accept the situational reasons. The people are believing the social information from the way of social media, the social media may goes to give a huge level of attraction. The attractive people are sharing the information to others only on the basis of truthfulness. The truthful people are arrange all details about the information of original data. So we make one the decision from the social media is transferred to other valuable one.

Recommendations

The number of suggestions are need to promote the medicinal value to the social people. The people taking the life style of his individual life may goes to develop the organizational performance. The social media may ready to accept the all the related suggestions from the social. The medicine is one of the important source of the ill health people, the medicine is very relative on the decease. The deceased people are required a original quality of medicine from the company. So, the company produced a original medicine for the purpose of general people.

Future of the Study: Schools of Social Work should be instrumental in training and including courses on internally displaced child populations in the curricula. By partnering with these affected populations during concurrent field work and through action research projects, many issues can be addressed and this vulnerable group empowered. There is an urgent need to obtain baseline data on internally displaced populations, especially children. This data will facilitate planning of programmes and intervention in areas of education, health, nutrition, child rights, career and for improving quality of life of children in these situations. As many more resettlement sites are planned, it is imperative that the existing services and living conditions in resettlement sites be evaluated. Lessons learnt from experiences of internally displaced child populations in resettlement areas need to be considered while planning rehabilitation and resettlement in the future.

Conclusion

There is a need for making existing services more accessible. Opportunities for service collaboration and partnership in addressing and advocating specific needs of children and their families need to be explored. It will be beneficial to create new service intervention/strategies, developing community-based approaches, sensitizing teachers/schoolmates about issues, facilitating social and supportive interactions and equipping displaced children with life skills, which will enable them, cope with demands of their life in the area of resettlement. There is also an urgent need for legal mandates, for policy and institutions to address humanitarian aspects of those affected. Greater commitment, involvement of state machinery, inter-sectoral coordination between all ministries, and adequate representation from the internally displaced themselves in rehabilitation and resettlement will aid in effectively addressing issues that concern them.

Implementation of Nutrition Education to Knowledge, Behaviour, and Performance of Junior High School Children

Nanik Suhartatik¹, Sri Handayani², Agatha Jumiati³

¹Departement of Technology and Food Industry, ²Departement of Teacher Training and Education, ³Faculty of Law, Slamet Riyadi University, Middle Java, 57136, Indonesia

ABSTRACT

The prevalence of obesity increases from year to year. One of the factors that causes obesity was food habits. Precautions need to be taken to undergo this phenomena. One effort that can be done was to provide nutrition education to children. This research studied the role of nutrition education given to school-age children (8th grade junior high school) towards knowledge, behavior, and overall performance. The study was conducted by giving pre-test and post-test to students who were divided into 2 groups. The first group treated with nutrition education, while the second group did not. Each group consisted of 37 students. The results showed that nutrition education have a strong influence in to knowledge, behaviour, and also the performance of the student. Students who are involved in research are included in the middle to lower class of economics so there are not many opportunities to choose food. Research needs to be done in other locations with middle to upper economic levels.

Keywords: nutrition education, school-age children, knowledge, healthy food

Introduction

There are 3 health problems in all countries, namely: malnutrition, obesity and chronic diseases. These problems arise mainly because of the lack of public knowledge about food habits. Today’s lifestyle is instantaneous, encouraging people to consume food without regard to nutritional adequacy. Some studies said there is an increase in the prevalence of obesity in school-age children. The value was twice greater than the previous one.¹,²,³ Obesity is a condition where body fat stored in adipose tissue is excessive.

Yaquin dan Nurhayati² said that 75% of elementary school children belong to normal weight, 8% are obese, and 2% suffer from obesity. Obesity is now categorized as a disease, no longer a symptom of disease (WHO). Meanwhile, the prevalence of obesity will increase in junior high school children reaching 5% and high school children reaching 6%.² The main factor that causes obesity is a poor diet. The prevalence of obesity in elementary school children is more influenced by the social status of parents, parental feeding that exceeds the AKG, offspring (genetic), and lack of physical activity.²

One factor that causes obesity is consumption of “fast food”.⁴ Food categories that are not provided adequately to meet consumer nutritional needs or better known as junk food. “Junk food” and instant food are part of today’s human lifestyle. This food has low nutrient compounds, high calories, unbalanced nutrition, has the potential to increase high blood pressure (due to high levels of sodium), and high cholesterol.⁵ This consumption habits will increase the risk of obesity and the diabetes epidemic.⁶ Some types of packaging are specifically designed to attract the interest of young children. These foods usually delicious, contain high sugar and fat, and low nutritional value.⁷

Such research has been carried out in some countries.⁵,⁸,⁹,¹⁰ One of the results showed that nutrition education in elementary school children has been shown to be effective in reducing consumption of “junk food” and that education carried out for girls is more effective than boys. This kind of study has never been conducted in Indonesia. Education is not only about the dangers of...
consuming “junk food” but also includes the importance of consuming milk-based foods, knowledge about nutrition, and oral health education. Pem et al. have mentioned that age factors influence the effectiveness of education, in addition to gender as well. This study aims to obtain information about the effectiveness of nutrition education in school-age children in food selection, especially for junior high school children.

**Material and Method**

This research was conducted in a junior high school in Surakarta, namely Muhammadiyah 4 Surakarta Junior High School. Educational techniques that applied to students include group discussions, asking and answering questions, group discussions, and brainstorming methods. A total of 74 students were involved in the learning session and divided into 2 groups. One group received additional knowledge (nutrition education) while the other group did not. The questionnaire was organized into 4 parts, including questions about demographic conditions, knowledge about junk food; questions about attitude, and finally about how often participants consume some junk food. Feasibility and validity test was conducted to the questionnaire before used.

Nutrition education is given once a week with a duration of between 45-90 minutes. Education material including food safety, food additive, and children nutritional adequacy. Retrieval of post-test data was conducted 1 month after giving the last material to see the effectiveness and efficiency of education. The data obtained is then processed by T test (to compare the average knowledge, attitude, and performance). Data analysis was continued by Mann Whitney, Friedman, and ANOVA tests.

**Results**

Respondents involved in this research activity was 74 students with a distribution of 25 men (33.8%) and 49 women (66.2%) between 13-15 years old. This school was dominated by students from the middle to lower economic circles, as evidenced by the amount of allowance received by each student. The first part of the questionnaire were to assess the respondent knowledge about junk food. According to the results, group with nutrition education have a significant different in answer between pre-test and post-test while the group with no treatment were still have the same answer. This part of the questionnaire aimed to identifying respondents’ knowledge of healthy, unhealthy food (junk food), and nutritional fulfillment (Table 1). Group with treatment have a different opinion about junk food after education, especially for the statement that junk food was an healthy food and some food may considered as unhealthy because of the additive inside.

The second part of the questionnaire was to examine the respondent’s behavior or response to junk food. In this section, respondents were asked to give ratings for 6 types of food or drinks that are included in the junk food category and give the reason why they choose the food. The food category were pizza, grilled meatballs, chocolate, soft drinks, energy drink, sport drink, or potato chips. A total of 29 respondents chose pizza as their favorite food during the pre-test and this number dropped to number 24 at the time of the post test. Based on the results of statistical analysis, nutritional education did not affect the selection of favorite foods or the frequency of consumption of foods belonging to junk food.

Most of the respondents chose to consume foods that are included in the junk food category because they are tasty and fast, affordable, easy to find, and because they like it, because they are served in large portions, and because the ads are interesting (Table 1). The results showed that 64.9% of respondents doesn’t consume junk food because they want to buy other people or because they are served with a relatively large portion (40.7%) or because of the influence of advertising (47.3%). Nutritional education apparently did not affect the respondents’ reasons for consuming junk food, except for questions number 3 and number 4. Between pre-test and post-test, the results were statistically different.

**Description:** Based on statistical analysis, 7 questions stated in this part of the questionnaire are valid with moderate reliability.

Based on the results of a nutrition education survey, 8.1% of respondents stated strongly agree and 33.8% agreed that consuming junk food would affect the mood. However, the number of respondents who stated that they did not or strongly disagree with this was also relatively the same, 39.2% and 12.2%, respectively. Each of these numbers has increased after being given nutrition education. Five students expressed doubt during the pre-test and this number changed to 0 (zero) during the post-test. Group with nutrition education have change their mind about junk food. Especially for the reason that junk food have an affordable price and also because they want to be like someone when they consume junk food.

The third part of the question was about how often respondents eats certain foods or drinks (Table 2 and 3). The types of food or beverages that were asked about included fruit-flavored drinks, energy drinks, sweetened water, sports drinks, ice cream, soft drinks, and so on. For types of food, which are asked including fast food (Pizza Hut, McDonalds, Popeye, Olive, Fried Chicken, etc.), potato/corn chips, sweet (chocolate, candy, cupcakes), fresh fruit, vegetables, biscuits and instant noodles. The results showed that between the post-test and pre-test. Consumption frequency for drink category gave a significant difference between pre and post test only for energy drinks.

During the pre test, respondents had a high tendency to consume energy drinks, but at the post-test this trend had decreased. This shows that nutrition education is said to have succeeded in changing the level of consumption of drinks classified as energy drinks. Other types of drinks were not statistically different between pre- and post test.

The types of food that are frequently consumed are fresh fruit, vegetables, and biscuits. These three types of food are consumed almost every day by most respondents. For biscuits, it is relatively varied because there are some respondents who also consume it infrequently. Three other types of food such as fast food, potato/corn chips, and sweet foods are included in the category of foods that are rarely consumed, starting from once a week to rare. Nutrition education did not affect to the respondent’s preference for various types of

food but most of respondent where decided to read the nutritional value from food label before buying the food. The category of drinks that are considered as invalid in this test and deleted from the list was tap water, while for the food category, the invalid ones was instant noodles.

**Findings**

Demographic condition were strongly influence the effect of the nutrition education to knowledge, behavior, and the performance of the student. The research was conducted at Muhammadiyah 4 Middle School in Surakarta that are dominated from the middle to lower economic classes and low academic abilities. In general, there are evidence that urban people prefer to send the children at an international junior high school or state junior high school. The school accommodates students in poor condition or even orphaned.

It was found that there were several types of food and beverage preferences which declined after going through nutritional education. Providing nutrition education needs to be done for children of lower age and better education techniques.10 The type of drink that is often consumed is a fruity beverage and the sweet one. Fruity drinks are often consumed compared to other types of drinks, ranging from daily to 1-4 times a week. Beverages that are rarely to infrequently consumed include energy drinks, sports drinks, ice cream, and soft drinks. In general, it can be seen that respondents who are between the ages of 13-15 years have known that these types of drinks should be consumed if needed. Pem et al. 12 also reported that nutrition knowledge to adults increase their willingness to consume more fruits and vegetable and reduce snack in the future.

Considering the reason the willingness of student to consume junk food, some recommendations must be done, including reducing the number of junk food ads during children program, health messages in junk food label or ads, increasing the awareness of the children to the health effect of junk food, highest standard for nutritious food, promoting the healthier food, and etc5.

**Conclusion**

Based on the results of research conducted at Muhammadiyah 4 Middle School in Surakarta, it was concluded that nutrition education had an effect on respondents’ knowledge, behavior, point of view, and habits. Nutrition education could change the respondent perception to some food, especially energy drink and sport drink. The reason why respondent chose some food was just because of fast and tasty, affordable price, lovely, easy to find and serve, and serve in bigger portion. Most of the respondents came from middle to lower economic circles, so they had relatively little allowance. The limitations make the respondent have not many choices to buy food. Supported by a school environment in suburban areas and away from crowds or food distributors. Implementation of nutrition education should be studied in different demographic environment.

**Conflict of Interest:** There was no conflict of interest between the author and the peer reviewer and with the editor.

**Source of Funding:** The author would also special thanks to founder, Slamet Riyadi University of Surakarta, Indonesia and the Head of Junior High School of Muhammadiyah 4, Surakarta, which allow us to do research in their school.

**Ethical Clearance:** The ethical clearance taken from dr. Oen’s hospital committee.

IL-18 -137G/C (rs187238) Gene Polymorphisms in Pulmonary Tuberculosis Iraqi Arab Patients

Nawal Mohammed Utba

Department of Biology, College of Science, University of Baghdad, Al-Jaderia, Baghdad, Iraq

ABSTRAcT

Tuberculosis (TB) primarily caused by Mycobacterium tuberculosis and remains a worldwide problem despite well documented, well publicised methods of prevention and cure. 80 pulmonary tuberculosis (PTB) patients without HIV infection were included in this study. Patients were divided into three groups; 40 MDR (multidrug resistant), 20 RD (Recently diagnosed) and 20 OC (Old cases). While the others 89 apparently healthy subjects (control group, (HC)). IL-18 serum level was assessed by using ELISA technique. However, polymorphism was analyzed using polymerase chain reaction-single specific primer (PCR-SSP), at the position -137 G/C (rs187238) in the promoter of IL18 gene. The median serum level of IL-18 for all patient groups was significantly higher than HC group. Comparing PTB patient groups to HC group revealed that none of genotypes or alleles showed significant differences between patients groups and HC group. The results are indicated that IL-18-137 alleles and genotypes showed no association with the risk of PTB development in Iraqi Arab population or protection against it.

Keywords: pulmonary tuberculosis, Multidrug resistance drug, IL18 gene polymorphism, ELISA, Iraq

Introduction

Tuberculosis primarily caused by Mycobacterium tuberculosis (MTB), continues to be one of the most important infectious causes of death and is a serious public health problem that has caused 1.6 million deaths every year over the world, especially in Asian and Africa. In Iraq, WHO reported that the incidence rate of TB was 42 per 100 000 populations in 2017. However, only 10% of people infected with MTB may develop into clinical disease, which indicates that some factors can devote to the pathogenesis of tuberculosis, including host immune response and gene environment interactions.

Many proinflammatory cytokines such as IL-1 family cytokines have been described to be elevated in response to infection with MTB. This family includes IL-18. IL-18 plays immunoregulatory role via the induction of IFN-γ which exerts changes in a variety of cell types. Elevations of IFN-γ have been found in the affected lung and bloodstream of patients with PTB. IFN-γ has been shown to be an important mediator of macrophage activation involved in controlling MTB. IL-18 promoter gene polymorphisms have been associated with various inflammatory diseases, and the functional significance of the SNP at position −137 is attributed to the higher transcription and protein production of IL-18. In order to investigate the possible role of IL18-137 SNP in PTB Iraqi patients, the genetic polymorphisms of IL-18 gene were evaluated and its impact on the serum levels in Iraqi PTB patients was investigated.

Materials and Method

Study subjects and Blood Samples Collection: A total of 169 individuals were included in this study, 80 individuals of them had PTB without HIV infection (patients group); they were referred for diagnosis and treatment to the National Reference laboratory of tuberculosis in Baghdad during the period from January 2017 – April 2017. Patients were divided into three groups; 40 MDR (multidrug resistant), 20 RD (Recently
diagnosed) and 20 OC (Old cases); their age range 12-76 years. While the others 89 apparently healthy Iraqi Arab subjects (control group (HC)), their age range, gender and ethnicity similar with patients group. All participants gave informed consent prior to participating in the research, which was approved by the local ethics committee at National Reference laboratory of tuberculosis in accordance with the Helsinki Declaration. A venous blood samples were collected from patients and control groups, and it was divided into two tubes; the first whole blood sample was dispense in an EDTA-tube, this blood was mixed gently then stored placed in the freezer at (-20°C) until further processing for DNA extraction. The second tube used for serum collecting by centrifuge at (3000 rpm) for 10 min.

Assessment of Interleukin-18 serum levels: Serum samples were collected from all the subjects and assessed for the level of IL-18 using Human IL-18 Enzyme linked immunosorbant assay (ELISA) kit (MyBiosorce, USA) according to the manufacturer’s instructions.

Detection of IL18 -137 G/C: DNA extracted by using the Wizard® Genomic DNA Purification Kit (Promega/USA) and the polymorphisms were analyzed using PCR-SSP, at the position -137 G/C (rs187238) in the promoter of IL18 gene according to9 with minor modifications. Reactions were carried out in a Bio-Rad PCR thermal cycler/USA. PCR reaction was performed with a final volume of 20µl consisting of 5 µl of 10ng DNA template, 1 µl of each of the reverse primer and sequence-specific forward primers, and 12µl of Nuclease - free water in Accupower® PCR PreMix tube; this tube contains DNA polymerase, dNTPs, a tracking dye and reaction buffer in a premixed format. IL18 -137 a common reverse primer 5’-AGGAGGGCAAAATGCACTGG-3’ and two sequence-specific forward primers 5’-CCCCAACTTTTACGGAAGAAAG-3’ and 5’-CCCCAACTTTTACGGAAGAAAAAC-3’ were used. An amplification product of 261 bp was detected. Reaction conditions consisted of initial denaturation at 94 °C for 2 min followed by 5 cycles of denaturation at 94 °C for 20 sec., and annealing at 68 °C for 1 min. then 25 cycles of denaturation at 94 °C for 20 sec., annealing at 62 °C for 40 sec. and extension at 72 °C at 40sec. lastly final extension at 72°C at 5 min. PCR products were visualized by 2% agarose gel electrophoresis stained by ethidium bromide.

Statistical Analysis

All statistical analysis was performed using statistical package for social science program version 17 for windows (SPSS INC., Chicago IL, USA). Results were expressed as median. Comparisons between groups were performed using mann whitney u test and kruskal-Wallis test for categorical data. P value of <0.05 were considered to indicate statistical significance.

Genotypes of IL18 -137 were presented as frequencies percentage, and significant differences between their distributions in PTB and HC were assessed by two-tailed Fisher’s exact probability (P). Also, odds ratio (OR), etiological fraction (EF) and preventive fraction (PF) were calculated to define the association between a genotype with the disease. These estimations were calculated by using the WINPEPI computer programs free online at http://www.brixtonhealth.com for epidemiologists.

Allele frequencies of IL18 -137 gene were estimated by direct gene counting methods, however, a significant departure from Hardy-Weinberg (H-W) equilibrium was calculated using H-W calculator for two alleles, which is available free online at http://www.had2know.com/academics/hardy-weinbergequilibrium-calculator-3-alleles.html. Significant differences between the expected and observed frequencies are assessed by Pearson’s Chi-square test.

Results and Discussion

Serum levels of IL-18: The median of IL-18 serum levels in PTB patient groups was 306.7 pg/ml with range from 133.7- 498.0 pg/ml in MDR, 310.9 pg/ml with the range of 134.1-488.5 pg/ml in RD and 280.5 pg/ml with the range of 104.2-493.0 pg/ml in OC. II-18 serum level was significantly higher in all patient groups than HC group (225.9 pg/ml with range from 40.5-453.2 pg/ml).

When the IL-18 serum level distributed according to gender, its median level in MDR, RD and OC groups were insignificant difference between males and females. While in HC males were significantly higher than females (Table 1).
A functional cytokine network is a central element in the homeostasis of the immune response and its alteration may lead to an abnormal immune response. Additionally, different pathological and infectious situations may alter the cytokine network, and further complicate the pathological events. Hence, studies have focused upon genes regulating the cytokine expression; in particular on gene polymorphisms that may influence the levels of expression and therefore the overall immune response.  

The results of this study was corroborates with results, they found that significantly higher levels of serum IL-18 in patients with PTB than in HC subjects and there was no significant difference in circulating IL-18 between the sexes in patients with PTB in Japan. Also with who found that there was significantly difference in the levels of serum IL-18 in patients with PTB than in HC subjects in Saudi Arabia. And with who found that In China, IL-18 is higher in MDR-TB than in HC, as well as with who reported that patients with more advanced pulmonary involvement, revealed significantly higher level for IL-18.

The results of present study agreed with\(^4\) who reported that Allele, genotype and haplotype frequencies did not differ significantly between HC and patients. The results suggest that the \(IL18\) gene promoter polymorphisms are not associated with susceptibility or resistance to PTB in south Indian population of Dravidian descent. But it’s not agree with\(^15\) who reported that with respect to the IL-18 gene polymorphisms, at -137 G>C variant, GG genotype was positively associated with tuberculosis in PTB patients with co-morbid diabetes mellitus. As well as In China, \(^16\)found that Polymorphism of the IL-18 gene promoter at position -137 is a potential host-susceptibility factor in tuberculosis in Chongqing. The people with allele C at that position may be protected against MTB infection.

IL-18-137 genotypes impact on IL-18 serum levels: For advance understanding of cytokines gene polymorphisms role in PTB patients, the impact of IL-18-137 gene polymorphism on its serum level was evaluated in patients and HC groups, because\(^17\) reported that it has been well documented that cytokines gene polymorphism have a functional importance and might be associated with high or low production of the corresponding cytokines.

The impact of \(IL18\)-137 gene polymorphism on its serum level was determined in patients and HC groups (Table-5). In patient groups, GG genotype showed the highest level (309.9 pg/ml) followed by genotype GC with 311.2 pg/ml and CC with 265.3 pg/ml. however, in HC, the GC genotype showed highest level (233.3 pg/ml) followed by GG genotype with 225.9 pg/ml then CC genotype with 136 pg/ml, and the IL-18 serum levels revealed significant variations (\(p<0.05\)) between HC genotypes. While there were no significant variations between the three IL-18-137 genotypes in PTB patients groups.

*Significant differences (\(P<0.05\)) in IL-18 serum levels between GG GC and CC genotypes in control group.
The results of this study was not compatible with who found that Isolated PBMCs with IL-18 -137GC/CC genotype were able to produce a higher level of IL-18 than those with IL-18 -137GG genotype, either spontaneously or in response to PM acetate plus calcimycin A23187.

Cytokine gene polymorphisms may change the structure and biological function of a certain cytokine coded by the defective gene leading to either increase or decrease of cytokine production. The inheritance of SNP may render people more susceptible or resistant to a certain diseases, therefore affecting cytokine secretion levels, and eventually may influence the progression of tumor.

Conclusion

The results are indicated that IL-18-137 alleles and genotypes showed no association with the risk of pulmonary tuberculosis development in Iraqi Arab population or protection against it, and the recorded OR, EF and PF values are in favor of such conclusion. Other studies for cytokines gene expression and polymorphisms will be required for this disease.

Risk Factors Related to Diabetes Mellitus

Noor Diani¹, Dhian Ririn Lestari²
¹Lecturer, Department of Medical Surgical Nursing, ²Lecturer, Department of Mental Nursing, Nursing School, Faculty of Medicine, Lambung Mangkurat University

ABSTRACT

The efforts to control diabetes mellitus are carried out by improving the management of the main risk factors for diabetes mellitus in primary health care facilities and community empowerment. Activities carried out in this study, data collection in the form of primary data was carried out by filling out questionnaires about risk factors related to diabetes mellitus which consisted of 13 items of questions which included risk factors for gender, age, genetics/heredity, obesity/BMI, diet, pattern of exercise/activity, smoking, hypertension and stress. Sampling technique is done by non probability sampling method through purposive sampling. The results showed a mean age of 54.34 years. The lowest age of respondents was 34 years and the highest age of respondents was 70 years, male sex 26% and female 74%, had a family history of diabetes mellitus 58%, respondents who had a pattern of eating/drinking were sweet 90%, had sports activities 58%, has a normal body mass index of 56% and who has a body weight of more than 30% and obesity 6%, has a smoking habit of 16%, has a history of hypertension 54%, has stress in life 30%. These factors will reduce the occurrence of diabetes mellitus and keep blood sugar levels stable.

Keywords: diabetes mellitus, risk factor, primary health care facilities, community empowerment

Introduction

Diabetes mellitus is a metabolic disease which has a collection of symptoms since an increase of blood glucose levels above normal values (hyperglycemia). It is because decreasing in the body’s ability to react with insulin, impaired insulin secretion, or both.¹,²,³ There is an increasing prevalence of diabetes mellitus throughout the world related to the increasing population, increasing life expectancy, urbanization that changes traditional lifestyle into a modern lifestyle, the prevalence of obesity increases, and physical activity are lacking.

Efforts to control diabetes mellitus are implemented by improving the management of the main risk factors for diabetes mellitus in primary health care facilities and community empowerment.⁴ Those efforts will be effective and efficient if we can identify specific diabetes risk factors that are specific to the diamond mining community in South Kalimantan that is Cempaka sub-district in Banjarbaru. Health problems in the mining area are important to know in South Kalimantan.

Specific risk factors possessed by people with diabetes mellitus in the Cempaka Village need to be identified and analyzed as base developing preventive efforts for diabetes mellitus in the community in the Cempaka Village area. There was no research has been conducted on the analysis of risk factors associated with diabetes mellitus in the community of Cempaka Village. Based on the phenomena and results of previous studies, researchers are interested to conduct research on the analysis of risk factors associated with diabetes mellitus in the community of Cempaka Village.

Method

The research method used is research carried out on a set of objects that usually aim to see a picture of the phenomena that occur within a particular population.⁵ This study describes the risk factors associated with the incidence of diabetes mellitus.
The population in this study were all patients with diabetes mellitus in the Cempaka village. Sampling is done by non-probability sampling method through purposive sampling where this technique is used to select samples between populations according to what the researcher wants (goals/problems in the study) so that the sample can represent the characteristics of the population.5

Data collection in the form of primary data was taken on by filling out questionnaires about risk factors related to diabetes mellitus which consisted of 13 items of questions which included risk factors for gender, age, genetics/heredity, obesity/BMI, diet, exercise/activity patterns, smoking, hypertension, and stress.

Based on the analysis of patients with diabetes mellitus, it is known that the average age is 54.34 years. The lowest age of respondents was 34 years and the highest age of respondents was 70 years with a standard deviation of 6.787 years. Age affects the risk and incidence of diabetes mellitus where according to Sudoyo, ages that have reached more than 30 years will experience anatomical, physiological and biochemical changes.6 Then blood glucose levels will rise 1-2 mg/dL/year when fasting and will rise 5, 6-13 mg/dL/year at 2 hours after meals. In middle adulthood various behaviors that often affect health such as nutrition, smoking and physical activity that causes obesity so this behavior increases the risk of developing diabetes.

</table>
Gender Risk Factors in Diabetes Mellitus: The results of the data analyst respondents in table 3 were 26% male and 74% female sex. Where women suffer from diabetes mellitus more than men. This study is the same as the results of research conducted by Isnaini which shows that sex frequency tends to be greater in women compared to men.7

This research is in accordance with the research conducted by Trisnawati which shows that the number of respondents is female more than male respondents.8 In the study conducted by Samodra also showed the same results namely more respondents were female than male respondents.9 According to Irawan, women are more at risk of developing diabetes because physically women have a greater chance of increasing their body mass index. Post-menopausal monthly cycle (premenstrual syndrome) syndrome that makes the distribution of body fat easily accumulated due to the hormonal process so that women are at risk of developing diabetes mellitus.10

Genetic or Hereditary Risk Factors in Diabetes Mellitus: The results of the analysis of the data seen in table 3, found that those who had a family history of diabetes mellitus were 58% and those without a history of diabetes mellitus were 42%. Other factors that contribute greatly to the prevalence of diabetes mellitus are hereditary or genetic factors. People who have a family history of diabetes mellitus are more at risk than people who have no history of diabetes mellitus.

This is similar to previous studies that showed the occurrence of type II diabetes mellitus would increase two to six times if parents or siblings experience this disease, the risk for type II diabetes in identical twins is 75-90%, which indicates that the factor genetic (hereditary) role in the incidence of diabetes mellitus in a person.11

Risk Factors for Diet in Diabetes Mellitus: The respondent’s data are found in table 3 which has a sweet food/drink consumption pattern of 90% and those who do not consume sweet foods/drinks 10%.

It can be seen that people with diabetes mellitus have a diet that likes sweet foods and drinks as the consumption of sweet and fatty foods is significantly associated with the incidence of diabetes mellitus. This is in accordance with the research conducted by Wicaksono who reported that the habit of consuming sweet foods has a two-fold risk of developing diabetes mellitus and makes blood sugar levels tripled three times.12

Risk Factors for Physical Activity in Diabetes Mellitus: In this study data (Table 3) obtained respondents who have sports activity 58% and those who do not exercise 42%. In contrast to the research conducted by Dolongseda who got the results that the pattern of physical activity in patients with diabetes mellitus was the respondent with a mild activity pattern of 96.0% and moderate activity patterns of 4.0%.13

It is found that many people with diabetes mellitus who do physical activities have very good conditions. This is because exercise plays a role in regulating blood glucose levels. The main problem in diabetes mellitus is a lack of response to insulin (insulin resistance) so that glucose cannot enter the cell. Membrane permeability to glucose increases when muscles contract because muscle contraction has insulin-like properties. Therefore, during physical activities such as exercise, insulin resistance decreases. Physical activity in the form of exercise is useful as blood sugar control and weight loss in diabetes mellitus.14

Risk Factors for Obesity in Diabetes Mellitus: The results of the data analysis of respondents (Table 3) who have a Normal Body Mass Index of 56%, and those who weigh more than 30%, and are obese 6%. According to Sari, the cause of diabetes mellitus is the lack of production and availability of insulin in the body or the occurrence of impaired insulin function, which is actually enough. Insulin deficiency is caused by damage to a small part or most beta cells of Langerhans Island in the pancreas gland which functions to produce insulin. That being because of hereditary factors, viruses and bacteria, toxic substances, and excessive weight nutrition (obesity) that can cause diabetes mellitus due to insulin, those who want to spread into cells are blocked as a result of sugar accumulating.15

This study nearly 56% of respondents possessed Normal BMI, this could be because the ones related to the physical activity carried out by people with diabetes
mellitus have an effect on maintaining BMI in people with diabetes mellitus.

Based on the interviews with patients of diabetes mellitus, they initially had obese weight but when they suffered from diabetes mellitus they lost weight. This is in accordance with the signs of diabetes mellitus, namely weight loss.

**Risk Factors for Smoking in Diabetes Mellitus:** The results of the data analysis of respondents (Table 3) who had a 16% smoking habit and who did not have a smoking habit were 84%. Where all who smoke are men. Smoking is known as a risk factor for coronary heart disease. However, after years, data collection research shows that smokers who smoke for a long time/chronic have a higher risk of developing insulin resistance. In diabetic patients, it is known that smoking exacerbates metabolic control. It can be proved that a larger dose of insulin is needed for the same metabolic control in nonsmokers in diabetic patients.16

**Risk Factors for Hypertension in Diabetes Mellitus:** Based on the respondent’s data analysts (Table 3), who have a history of hypertension are 54% and those without a history of hypertension are 46%. This is similar to previous studies with 54 subjects with diabetes mellitus. It is known that 66.6% of subjects suffer from hypertension, and the rest 33.4% of subjects have normal blood pressure, people with diabetes mellitus have hypertension.17

Many studies have found an association between increased hypertension in patients with diabetes mellitus. People who suffer from diabetes mellitus, especially type 2, have a risk of 2 to 4 times more susceptible to death due to cardiovascular disorders than people who do not suffer from diabetes mellitus and hypertension occur 2 times more vulnerable in patients with diabetes mellitus than non-diabetes mellitus in the same age group. In addition, diabetic patients accompanied by hypertension increase the risk of coronary heart disease, stroke, nephropathy, and retinopathy. In fact, diabetes accompanied by hypertension increases by 75% of morbidity and mortality in people who already have previous risk factors.18

**Risk Factors for Stress in Diabetes Mellitus:** Data of respondents (Table 3) who have stress in their lives are 30% and those who do not have stress in their lives are 70%. In patients with diabetes mellitus when interviewed, they said that they often think about the disease, so that they feel disturbed according to where various reactions arise after patients know that they have diabetes, ranging from feelings of fear, anxiety, stress, depression, anger, and even rebellion.19

People with diabetes mellitus have a high level of stress and anxiety, which is associated with treatment that must be followed and the occurrence of serious complications. The stress experienced by sufferers is related to therapeutic or therapeutic regimens that must be undertaken such as diet or eating arrangements, control of blood sugar, consumption of drugs, exercise and other things that must be done throughout his life. In addition, the risk of complications of the disease that can be experienced by the sufferer will also increase stress on the sufferer, which disturbs his quality of life.20

In diabetics, quality of life is the main goal of care, as much as possible good quality of life must be maintained in people with diabetes mellitus. It is because low quality of life and psychological problems can worsen metabolic disorders, either directly through hormonal stress or indirectly through complications.21

**Conclusion and Recommendation**

There are still many people who are not aware of the risk factors for the disease to maintain blood sugar stability for people with diabetes mellitus.

The need for public education is related to the factors that influence the disease and the incidence of diabetes mellitus so that people have a healthy quality of life.

Association of Hunting Behavior and Malaria Incidence: A Cross Sectional Study on Nuaulu Tribe Community in Mesoendemic Area of Malaria

Nur Baharia Marasabessy1,2, Oedojo Soedirham2, Yoes Prijatna Dachlan3
1Polytechnic of Health, Ministry of Health Maluku Province, Indonesia; 2Department of Health Promotion and Behavioral Sciences Faculty of Public Health, 3Faculty of Medicine, Universitas Airlangga, Indonesia

ABSTRACT

Background: The Nuaulu tribe is one of the indigenous tribes in Maluku Province, Indonesia which becomes the area of malaria endemics. This tribe still adheres to the customs and habits of its ancestors, one of which is hunting. It is carried out to fulfill the needs of life and the implementation of traditional rituals performed from afternoon to morning or days in the forest, depending on the obtained sustenance. The hunting location in a forest that is far from the residential area. Hunters are often exposed to mosquitoes from entering the forest to returning home.

Objective: this study aims to reveal the profile of TNF-α and IL-10 related to hunting habits in tribal community in malaria mesoendemic area.

Method: Cross sectional study was conducted in Sepa Village, Indonesia during July-August 2019. Each subject was asked to complete a questionnaire asking about demographic and the desired study factor. Laboratory evaluations used thick and thin blood films were prepared from venous blood, stained with Giemsa stain, and examined by two microscopists for detection of malarial parasites and parasite species. Inclusion criteria were being aged 18 years ≥ n ≤60 years, being a resident of Sepa Village and being willing to participate in the study. A total of 84 subjects were included in this study.

Result: 40 subjects were with hunting activities and 44 were not. Only three subjects (3,6%) were positive malaria. We found no significant association (p=0,243) between hunting behavior and malaria incidence, even no malaria sufferers in subjects with hunting behavior. We found significant association (p=0,000) between hunting behavior and gender.

Conclusion: our study showed that hunting behavior did not cause malaria incidence in the Nuaulu Tribe community. Malaria sufferers were only found in non-hunting groups.

Keywords: hunting behavior, malaria incidence, Nuaulu, tribe

Introduction

Malaria is caused by protozoa of the genus Plasmodium and is responsible for high levels of morbidity which has a serious impact on socio-economic development in endemic areas. Plasmodium vivax is the main species that cause malaria, responsible for 80% of cases in Indonesia (1). Malaria is a complex disease involving genetic factors inherent in parasites and hosts, geographical and environmental aspects(2). During the infection, antibody-mediated and cell-mediated immunity plays an important role in achieving clinical immunity (3,4). A research showed that the successful completion of malaria infection depends on the hosts’ ability to induce adequate levels of pro-inflammatory and regulatory cytokines during the main stages of infection. Thus, the adjustment between the inflammatory and anti-inflammatory response seems to be a determining factor in clinical outcome of the disease(5).
Maluku Province is one of the endemic provinces of malaria in Indonesia. The Nuaulu tribe is one of the isolated tribes in Seram Island, Central Maluku Regency, Maluku Province, Indonesia. This tribe still adheres to the customs of its ancestors, one of which is hunting. It is carried out to fulfill the needs of life and the needs of the implementation of traditional rituals performed from afternoon to morning or even days in the forest that depends on the sustenance. The hunting location is in a forest that is far from the residential area. This habit makes the hunters in this tribe are often exposed to the mosquitoes. Support by preliminary data, the recognition of the public is that they are very often bitten by mosquitoes from entering the forest to going back to home again to the settlement. However, this is not considered a problem since there is an interest in fulfilling the hunters’ needs of life and their families’.

Acquired immunity studies of malaria in endemic areas originally provide a greater potential for understanding the regulation of human immune responses to malaria parasites. However, little is known about malaria-specific immunity acquisition in areas that are unstable, mesoendemic or hypo-endemic transmission (6). The overall profile of cytokine production is still contradictory due to differences in the study population and the level of endemicity in the region, and other factors which require further investigation (7). This study aims to reveal the profile of TNF-α and IL-10 related to hunting habits in tribal community in malaria mesoendemic area.

Material and Method

The type of the present research is an observational analytic study with a cross-sectional design used to determine the associated of hunting behavior and malaria incidence on Nuaulu tribe community. The research areas were Rohua Hamlet and Bonara Hamlet, Sepa Village, Amahai Subdistrict, Central Maluku Regency, Indonesia. The research population was the indigenous people of the Nuaulu tribe who lived in the research areas. The sample was part of the study population that met the inclusion criteria, i.e. people aged 18 to 60 years, living in the research area for at least the last 3 years and were willing to be the research respondents. Age limitation was meant by considering that the ages of 18 to 60 are adults who often carry out hunting activities. The sample was determined using simple random sampling. Malaria examination is carried out through microscopic examination using thin blood preparations and thick blood. Examination of malaria slides were carried out in the parasitology laboratory of the Center for Environmental Health Engineering and Surabaya Disease Control.

Data analysis was done using the IBM Statistic Package for Social Science (SPSS) version 21.0 software. Variable were analyzed using the chi-square test. Ethical clearance was obtained from The Ethics Committee of Faculty of Public Health, Universitas Airlangga, Indonesia (Ref: No: 245/KEPK/22th May 2018).

Findings

The demographic characteristics of study subjects are summarized in table 1. Of the 84 subjects, 60.7% were male, 54.8% were aged 18-31 years, 57.1% of subjects had a low education level and 40% of subjects always carry out hunting activity.

| Table 1: Demographic characteristics of study subject (N = 84) |
|------------------|------------------|
| Variabel         | Number (%)       |
| Gender           |                  |
| Male             | 51 (60.7)        |
| Female           | 33 (39.3)        |
| Age              |                  |
| 18-31            | 46 (54.8)        |
| 32-46            | 18 (21.5)        |
| 47-60            | 19 (22.7)        |
| Education        |                  |
| Low education    | 48 (57.1)        |
| Higher education | 36 (42.9)        |
| Hunting behavior |                  |
| Hunting          | 40 (47.6)        |
| Non-hunting      | 44 (52.4)        |

Microscopic examination of malaria. Giemsa-stained thick and thin smears were showed none of the hunting group (0%) was infected plasmodium in their blood samples, whereas in non-hunting group showed that three samples out (7%) of 44 samples was found to be positive for Plasmodium in their blood samples. The plasmodium found in these three people was *p.vivax*.

Discussion

Hunting becomes one culture of the Nuaulu people who are at risk of malaria infection which is still maintained today. Results of the interview found that hunting activities are carried out with the aim of fulfilling the daily needs of life and the part of traditional rituals event according to the communitys’ trust, which according to Ellen (8) is classified as animism. Hunting activities are carried out from late afternoon to tomorrow morning or depending on the sustenance obtained. Being exposed to mosquitoes in the forest is common since they are always bitten by mosquitoes from entering the forest until going home. However, this is considered normal because they think that there is something more crucial than being bitten by mosquitoes, i.e. to fulfill the needs of the families and many people.

Forest ecosystems are well known to support transmission of malaria, significantly contributing to the global disease burden. A global assessment reports that “closed forests within areas of malaria risk cover approximately 4.8 million km²” (9). Almost half the malaria risk is estimated to occur among people living in forested areas (1.4 billion) accounting for 11.7, 18.7, 35.1 and 70.1 million population respectively from 1.5 million km2 in the Amazon region, 1.4 million km2 in Central Africa, 1.2 million km2 in the Western Pacific, and 0.7 million km2 in South-East Asia (10). Corresponding forest areas containing these malaria risk zones are 11.16 million to 15.71 million km2, 6.53 million– 7.80 million km2, 1.93 million– 5.19 million km2, 2.70 million–2.72 million km2 (9,10). Controlling malaria in these forested regions of the world has been a major challenge (11). Most studies of forest malaria are focused on local factors associated with malaria transmission. These include distance from forest, impact of deforestation and reforestation, effect of forest on microclimate, vector bionomics, Plasmodium species survival, and human activities in forests (12).

The results confirmed there were no significant association between malaria incidence with hunting behavior. The incidence of malaria only occurred in groups where the people did not hunt. On the other hand, there were no malaria sufferers in the hunting group. It was possible because while carried out hunting activities, the Nuaulu tribe consumed a lot of high-protein hunting foods such as pork (Sus scrofa), deer (Cervus molucencis), cuscus (Phalanger sp) and other wild foods obtained in the forest such as reptiles and eggs, bats, maggots (including sago worms), fruits and leaves.

Infection of the human body may occur if the first defense (innate immunity) cannot block the invasion of pathogens to the body (13). The immune response is
very dependent on the ability of the immune system to recognize foreign molecules (antigens) contained in potential pathogens and then generate the right reaction to getting rid of the source of the antigen in question. Clinical manifestations of malaria, including hematological changes, have been associated with several factors, such as demographic characteristics, the levels of malaria endemicity \(^{(14)}\), nutritional status \(^{(15,16)}\) and malaria immunity \(^{(17,18)}\). The immune system is a defense mechanism that can form a state of immunity to infection \(^{(19)}\), cells and molecules that are responsible for immunity to form the body immune system, as well as the collective and coordinated response of the immune system to the recognition of foreign substances, is called an immune response \(^{(20)}\). If the immune system is exposed to substances that are considered foreign, then there are two types of immune responses that may occur in the form of the response of innate and adaptive immunities.

The plasmodium examination showed that of the 84 people of the research objects, there were only three people who were positive for malaria, indicating that the immune system was good because they lived in an endemic area where malaria can infect them, but with the low malaria illness. The parameters that can modulate immune responses include nutritional status, changes in circulating cytokine levels, expression of adhesion molecules, chemotaxis or mobility changes and generation of reactive species. The immune response is also influenced by factors such as age, gender, biological rhythm, and lifestyle. The search for activities during hunting activities in the Nuaulu people concluded that the activities carried out during hunting were food gatherings, exercises or physical activities, the use of herbs to prevent fever and periodically being bitten by mosquitoes.

**Conclusion**

Our study showed that the incidence of malaria is not associated with hunting behavior and even the incidence of malaria only occurs in groups that do not hunt.

**Conflict of Interest:** The researcher has no conflict of interest with subjects research and related parties at the study site or with other parties related to this research.

ABSTRACT

Ammonia is an alkaline gas with colorless and a strong odor characteristics. It can be formed naturally in the air, soil and water. Ammonia is also produced by humans and animals as part of normal biological processes. This study aims to determine the safe (C safe) concentration of ammonia gas in Chicken Farms in Lembak Village, South Sumatra Indonesia. This study was an observational with a sample of 14 chicken farm workers taken by purposive sampling. This study was analyzed based on primary and secondary data and processed through safe C calculations by determining the weight of experimental animals (W animals), body surface area of the experimental animal (BSA of experimental animals), workers’ body weight (W), workers’ body surface area (BSA), workers’ breathing rate (BR), benzene concentration in the workplace (C), factor Km in animals (Animal Km), factor Km in humans (Human Km), highest dose of toxin without effect (NOAEL), and reference concentration of ammonia gas on workers (RfC).

The measurement results of the highest concentration of ammonia gas in the chicken farm around Lembak Selatan village, Sumatra was 0.006 mg/m³ (0.0086) ppm and the average concentration of ammonia gas from 14 measurement points on the farm was 0.003214 mg/m³ (0.0046 ppm). The concentration level is below the threshold value set by PERMENAKER No. 5 of 2018, OSHA, NIOSH and ACGIH of 25 ppm. In contrast to these results, the manual calculation of safe (C safe) concentration of ammonia gas was 0.022 mg/m³ (0.031 ppm). With these results, the concentration of ammonia gas in the chicken farms of Desa Lembak Sumatera Selatan Indonesia is in the safe category. Nevertheless, prevention measures are needed to prevent the increase level of the gas.

Keywords: Ammonia gas, safe concentration, husbandry workers, husbandry

Introduction

Ammonia is an alkaline gas with characteristics of colorless and has a strong odor. About 80% of commercially produced ammonia is used in agricultural fertilizers. ². Ammonia can be formed naturally in the air, soil and water. It is also produced by humans and animals as part of normal biological processes¹. Animal husbandry contributes to the presence of dangerous ammonia in the environment that comes from the biological processes of animals in it. Ammonia is a constituent of animal feces and urine when nitrogen-
rich proteins in feed are not fully converted into animal products such as meat, milk, wool, and eggs.

Ammonia can react directly at certain levels of exposure. At a level of 5 ppm it is almost undetectable. At 20 ppm ammonia can have a different odor but can still be tolerated. 100 ppm ammonia can now be very visible and somewhat uncomfortable when inhaled. At 500 ppm ammonia will irritate the throat, lungs, mucous membranes, skin and eyes that breathing equipment is needed at this level for exposure in a very short time. At 1000 ppm or 0.1% ammonia becomes very toxic and a gas cartridge mask is required. At exposure rates above 2000 ppm, death can occur in less than 30 minutes.

Based on health effects and the dangers that can arise due to exposure to ammonia, various regulations regarding the threshold value of ammonia exposure have been made through careful calculations. OSHA, ACGIH, and NIOSH determined ammonia exposure to workers at a maximum of 25 ppm with a duration of 8 hours and 35 ppm for ammonia exposure for 15 minutes. Indonesia also regulates the threshold value of ammonia exposure which is equal to 25 ppm or 17 mg/m³ through the Peraturan Menteri Ketenagakerjaan Number 5 of 2018 concerning Occupational Safety and Health at the Work Environment.

This journal draws references from the research of Desheila et al (2017) on the Analysis of the Risk of Ammonia Gas Exposure to Chicken Farm Workers in Lembak Village, South Sumatra. The present study discusses Reference concentration of ammonia (NH3) of 0.028 mg/kg/day, real time intake of respondents in the range 0.0020 (mg/kg)/day, and lifetime respondents’ responses in the range of 0.7671 (mg/kg)/day, as well as the risk received by respondents to exposure to ammonia gas (RQ <1). The previous research explained that the results of the measurement of ammonia gas concentrations in 14 average air sample points were 0.003214 mg/m³. Compared to the threshold value stated in PERMENAKER No. 5 of 2018, this level is still far below the threshold value of 25 ppm or 17.41 mg/m³.

Previous research on the Analysis of Ammonia Gas Exposure Risks at Chicken Farm Workers in Lembak Village, South Sumatra, did not explain the safe limits of ammonia gas concentrations in chicken farm workers and Rfc calculations using No Observed Adverse Effect Level (NOAEL). In the present study, the authors calculated Rfc and safe concentration of exposure to ammonia gas in the air using No Observed Adverse Effect Level (NOAEL).

Material and Method

This study is an observational study which aimed to determine the safe concentration of exposure to ammonia gas in chicken farm workers in Lembak Village, South Sumatra. The study population was chicken farms in Lembak Village, the subject sample was chicken farm workers taken by purposive sampling which was 14 workers, and object samples was ammonia level in the chicken farm air. Data collection was carried out by interviews using questionnaires, weight measurements using scales, and direct measurement of ammonia concentration.

The variables of this study were the weight of experimental animals (W animals), body surface area of experimental animals (BSA of experimental animals), body weight (W), body surface area of workers (BSA), workers breathing rate (BR), ammonia gas concentration in workplace, Km enzen in animals (Animal Km), Enzen Km in humans (Human Km), highest dose of toxin without effect on experimental animals (NOAEL), enzene reference concentration on workers (RFC), and safe concentration of ammonia gas in air for workers (C safe). Analysis of research data to determine the safe concentration of ammonia gas in the air for workers (C safe) was conducted manually.

Result

A. Characteristics and Surface Area of Experimental Animal Bodies: Toxicity testing of a compound is generally carried out using experimental animals. This is because the response to toxic compounds between humans and animals is similar. The experimental animals used in this study were white mice. Below is the table of characteristics and surface area of white rats as experimental animals:

<table>
<thead>
<tr>
<th>Experimental animals (white mice)</th>
<th>W (Kg)</th>
<th>BSA (m²)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>

<tr>
<td>Average</td>
<td>0.14067</td>
<td>0.024165</td>
</tr>
</tbody>
</table>
The surface area of white mice is calculated using the following formula.

\[ BSA = 0.09 W^{0.67} \]

Where

BSA: Body Surface Area (m²)
W: Weight (kg)

B. Workers’ Characteristics, Body Surface Area, and Respiratory Rate:

As many as 14 workers of chicken farm in Lembak Selatan Selatan Village participated in this study with the lowest body weight of 14 kg, the highest body weight of 75 kg and an average body weight of 51.85 kg. Based on the results of the respondent’s questionnaire, the exposure duration was 24 hours. This is because the workers stayed in the farm area that they were continuously exposed to ammonia gas produced by chickens. In the present study, the average height used was the average height of Indonesian adults of 159 cm. Body surface areas and officer breathing rate were calculated by using the following formula.

1. The average body surface area of the workers

\[ BSA = \sqrt{W \times h / 3600} = \sqrt{51.85 \times 159 / 3600} = 1.51 \text{ (m²)} \]

Where

BSA: Body Surface Area (m2)
W: Weight (kg)
h: Height (cm)

2. Average workers’ breathing rate

\[ BR = \frac{5.3 \ln W - 6.9}{24} = \frac{5.3 \ln 51.85 - 6.9}{24} = 0.58 \text{ m}^3/\text{jam} \]
where

BR : Breathing Rate (m³/hour)
W : Weight (kg)

Based on calculations carried out on chicken farm workers in Lembak Village, South Sumatra, the average body surface area of workers was 1.51 (m²) and the respiratory rate of workers was 0.58 m³/hour on average.

C. Concentration of Ammonia Gas:

The highest concentration of ammonia gas in the chicken farm in Lembak South Sumatra is 0.006 mg/m³ (0.0086 ppm) and the average concentration of ammonia gas from 14 measurement points on chicken farms was 0.003214 mg/m³ (0.0046 ppm). The mg/m³ conversion to ppm was calculated by the following formula.

\[ C = 24.45 \times \frac{C \text{ (mg/m³)}}{\text{mol}} \]

Where:

C : Concentration in the air (mg/m³)
MW : Molecular Weight Amonia (17.031 g/mol)

The highest \( C \) = 24.45 × 0.006 mg/m³ ÷ 17.031 = 0.0086 ppm
C average = 24.45 × 0.003214 mg/m³ ÷ 17.031 = 0.0046 ppm

D. Animal Km and Human Km:

Determination of animal km and human km is the first step in determining the safe limit of ammonia gas toxin dose. Calculation of animal km and human km are as follows:

1. Animal km

\[ \text{Animal Km} = \frac{w_{\text{animal}}}{\text{BSA animal}} \]

Where:

Animal Km: Km factor in experimental animals
W : Weight (kg)
BSA : Body Surface Area (m2)

<td>0.024223</td>
<td>5.820914007</td>
</tr>
</tbody>
</table>
Based on the calculation of animal km above, the average animal km yield of chicken farm workers in Lebak Village, South Sumatra Indonesia is 5.82.

**2. Human km s**

\[
\text{Human Km} = \frac{w}{\text{BSA}}
\]

Where

- Human Km : Km factor in humans
- W : Weight (kg)
- BSA : Body Surface Area (m²)

<table>
<thead>
<tr>
<th>Number of sample</th>
<th>W (Kg)</th>
<th>BSA (m²)</th>
<th>Human Km (W/BSA)</th>
</tr>
</thead>
<tbody>
<tr>
<td>14</td>
<td>51,85</td>
<td>1,51</td>
<td>34,3</td>
</tr>
</tbody>
</table>

The above human km calculation is obtained from the average body weight of the worker. Based on the above calculations the results of human km chicken farm workers in Lembak Sumatra Selatan Indonesia are 34.3.

**E. No Observed Adverse Effect Level (NOAEL):**

NOAEL can be defined as the highest experimental point without side effects. According to U.S. The Environmental Protection Agency (EPA), No Observed Adverse Effect Level (NOAEL) from ammonia is 4.9 mg/m³ (0.036 mg/kg). Calculation of conversion from mg/m³ to mg/kg is as follows:

\[
\text{NOAEL ammonia (mg/m³)} = \frac{4.9 \times 0.00013 \times 8}{0.1405} = 0.036 \text{ mg/kg}
\]

**F. Inhalation Reference Concentration (RfC):**

Shaw et al. (2007) in Saridewi and Tualeka (2017) also explain that the determination of reference concentration on workers or the Inhalation Reference Concentration (RfC) can use the following formula:

\[
RfC = \frac{\text{NOAEL}}{\text{animal Km}} \times \frac{\text{human Km}}{}
\]

Where:

- RfC : Inhalation Reference Concentration (mg/kg)
- Animal Km : Km factor in experimental animals
- Human Km : Km factor in humans

Calculation of Inhalation Reference Concentration (RfC) obtained from the NOAEL value, Animal Km average, and the Human Km average shows the following results:

\[
RfC = \frac{\text{0.036}}{5.82} = 0.0061 \text{ mg/kg}
\]

**G. Safe Concentration of Ammonia Gas in Chicken Farm Workers in Lembak Village, South Sumatra Indonesia**

The following is a safe C calculation with Rfc using No Observed Adverse Effect Level (NOAEL):

\[
C_{\text{safe (mg/m³)}} = \frac{(rfc)(W)}{(\delta)(BR)(t)}
\]

Where:

- C safe : concentration of toxin in the air that is safe for the community (mg/m³)
- RfC : Inhalation Reference Concentration (mg/kg)
- W : Weight (kg)
- δ : % of substances absorbed by the lungs if unknown then 100%
- BR : Human breathing rate (m³/hour)
- t : Working duration (hour)
- MW : Molecular Weight

\[
C_{\text{safe (mg/m³)}} = \frac{0.0061 \times 51.85}{100 \times 0.58 \times 24} = 0.022 \text{ mg/m³}
\]

In ppm, the conversion calculation is as follows:

\[
C_{\text{safe (ppm)}} = \frac{0.022 \times 24.45}{17.031} = 0.031 \text{ ppm}
\]
Based on the above calculations, the safe concentration of exposure to ammonia gas in Lembak village, West Sumatera Indonesia chicken farm workers is 0.022 mg/m$^3$ (0.031 ppm).

**Discussion**

Determination of the safe concentration of ammonia gas in the chicken farm workers in Lembak South Sumatra Indonesia is based on calculations involving No Observed Adverse Effect Level (NOAEL) in it. No Observed Adverse Effect Level (NOAEL) used in this study came from U.S. The Environmental Protection Agency (EPA) is equal to 4.9 mg/m$^3$ or equivalent to 0.036 mg/kg$^1$. In the study conducted by Abdul Rohim Tualeka and Juliana Jalaludin (2018) by using white mice, it was determined that NOAEL ammonia was 0.0154 mg/kg/weight$^{14}$. Another study by Abdul Rohim Tualeka, Jihan Faradisha and Rizky Maharja (2018) stated that NOAEL obtained from calculations with experimental animals was 0.0103 mg/kg/body weight$^{10}$.

Calculation of Inhalation Reference Concentration (Rfc) was carried out by using NOAEL originating from U.S. The Environmental Protection Agency (EPA) shows value of 0.0061 mg/kg. These results are smaller than that of ammonia gas Rfc found in previous studies on the Analysis of the Risk of Ammonia Gas Exposure to Chicken Farm Workers in Lembak Village, South Sumatra by 0.028 mg/kg. The results of ammonia Rfc gas in the present study is higher than the chronic Rfc determined by U.S. Environmental Protection Agency (EPA) of 0.5 mg/m$^3$ (0.0037 mg/kg).

Based on the results of this study, the value of safe concentration of ammonia gas for chicken farm workers in Desa Lembak, South Sumatra Indonesia is 0.022 mg/m$^3$ (0.031 ppm). This value is higher than the average concentration of ammonia gas from 14 measurement points in the Lembak Village farm in South Sumatra, which is 0.003214 mg/m$^3$ (0.0046 ppm). Ammonia gas in the chicken farms of Desa Lembak, South Sumatra Indonesia is in safe category for workers.

While ammonia gas in the Lembak Village chicken farm is within safe concentration limits, an increase in the number of livestock will potentially increase the exposure of ammonia gas to workers. The presence of ammonia gas exposure is possible to disturb the comfort of workers and local residents. Therefore, it is necessary to attempt the use of personal protective equipment such as masks to reduce the level of ammonia gas inhalation for workers as well as cleaning livestock from urine and manure regularly and periodically. If it is possible, it is necessary to check regularly for checking the concentration of ammonia gas and checking the health of workers regularly.

**Conflict of Interest:** All authors have no conflicts of interest to declare.

**Source of Funding:** This is an article “Determination of Ammonia Gas Safe Concentration in Chicken Farm Workers in Lembak Village, South Sumatra Indonesia” of Occupational Health and Safety Department that was supported by Faculty of Public Health, Airlangga University.

ABSTRACT

A descriptive correlational design was used. This study aims to (1) assess body image, and (2) find out the association between body image and some sociodemographic characteristics for primiparous women. The study included a convenience sample of 200 primiparous women who were selected from four maternity hospitals in Baghdad City. The study instrument consists of the sociodemographic characteristics, the reproductive information and Body Appreciation Scale. Data were collected using a self-report tool. Data were analyzed using the statistical package for social sciences (SPSS) for windows, version 24.

The study results revealed that more than a half perceive themselves as having; from their point of view, good body image (n = 111; 55.5%). The researcher concluded that more than a half perceive themselves as having; from their point of view, good body image.

Keywords: Body Image, Primiparous Women

Introduction

A woman’s body undergoes many transformations during the nine months of pregnancy. Some of these physical changes are visible, such as an expanding belly and weight gain, while others are well known, such as an enlarged uterus, morning sickness and backaches. However, a few bodily changes may be unexpected and catch some women by surprise (1).

During pregnancy mothers reported how they felt about their changing shape and appearance and their concerns for their body after the birth alongside considering how they would feed their baby after it was born. Those who held higher concerns for their appearance or who were trying to limit their food intake during pregnancy were less likely to plan to or start breastfeeding at birth, or if they did so, only breastfed for a short period of time (2).

Body image describes the cognitive, affective and behavioral aspect of one’s body. Negative body image is common during pregnancy and extends to the postnatal period. Women can be distressed by bodily changes in pregnancy, although the association between breastfeeding and maternal weight and body image such as changing shape and weight gain and breastfeeding duration (3).

It traditionally has focused on describing and predicting negative body image such as body dissatisfaction, body shame, and body preoccupation, body appearance has been defined as accepting, holding favorable opinions toward, and respecting the body, while also rejecting media-promoted appearance ideals as the only form of human beauty (4). Body image concerns to be high among postpartum women (5) and are a source of significant psychological distress. In addition, body image concerns have been shown to be associated with to negative eating and feeding related outcomes including maternal disordered eating, and lower rates and shorter duration of breastfeeding (6).
Weight gain (within the recommended range) and changes in body shape and appearance are an expected and healthy element of pregnancy. However, growing numbers of women appear to be concerned about their weight gain and appearance during pregnancy and may be at risk of developing a negative body image\(^7\).

Body image describes the cognitive, affective and behavioral aspects of one’s body\(^8\). Negative body image is common during pregnancy and extends to the postnatal period \(^9\). Women can be distressed by bodily changes in pregnancy, although some report feeling liberated \(^10\). Pregnancy can trigger or intensify negative feelings about the body or disordered eating \(^11\).

Body image dissatisfaction during pregnancy can have a negative impact on both mother and baby. It can be linked to unhealthy eating, dieting and purging behaviors. In turn these behavior’s increase the risk of low infant birth weight and premature delivery \(^12\) with higher levels of miscarriage and caesarean delivery\(^13\) amongst pregnant women with disordered eating. Conversely, poor body image can sometimes be associated with increased weight gain as the woman binges or comfort eats\(^14\). A factor that has been associated with infant macrosomia, caesarean section and later childhood overweight\(^15\).

An extant literature suggests that body dissatisfaction may increase new mothers’ risk for depression. These depressive symptoms may contribute to body dissatisfaction by increasing negative attributions and evaluations related to body weight and shape, as well as decreasing the likelihood of women engaging in positive body-related activities including physical exercise and self-care\(^16\). Conversely, prenatal and postpartum depression may contribute to body image concerns\(^7\). This study aims to (1) assess body image, and (2) identify the association between body image and some sociodemographic characteristics for primiparous women.

**Method**

**Study Design:** A descriptive correlational design was used.

**Setting:** The study was conducted in either obstetric ward or delivery room at stage four of labor in four hospitals at Baghdad City.

**Sample and Sampling:** A purposive sample of (200) postnatal primiparous women who were delivered in four maternity hospitals. The (200) of study sample distribute in Al-karkh Maternity Hospital at (50 sample) Al-karkh side and three Maternity hospitals (150 women) in Al-Russafa side.

**Inclusion Criteria:** The inclusion criteria included (1) Postnatal primiparous woman, and (2) normal vaginal delivery or caesarean section.

**Study Instrument:** The study instrument includes women’s age, levels of education, occupation, family monthly income, BMI, and residency. Body mass index was computed by dividing the weight (kg) on height (cm)\(^2\). The score of less than 18.5 is underweight, 18.5-24.9 is within normal, 25-29.9 is overweight, 30-34.9 is class I obesity, 35 or greater is class II obesity.

**Reproductive Status:** This part includes woman’s age on marriage, abortion, mode of delivery, indication of CS, baby’s condition after birth, baby’s weight on delivery, and baby’s gender.

**The Body Appreciation Scale:** The body appreciation scale (BAS) is based on (Avalos et al, 2005). This scale is a 5-point Likert type scale that is composed of 10 items. These items were measured on a 5-point Likert scale. Responses on this scale range from (Never=1) to (Always=5). Total scores range from 10 to 65 degree, with a higher score indicating greater body appreciation.

**Data Collection:** Data were collected for the period from December 30\(^{th}\), 2018 to February 10\(^{th}\), 2019. Data were collected through either a self-report or structured interview during morning shift. It took 20-30 minutes.

**Data Analyses:** Data were analyzed using the statistical package for social science (SPSS) for windows, version 24. The statistical measure of frequency, percent, Mean, and standard deviation (SD), linear regression, ANOVA, and independent-sample t-test were used.

![Figure 1: Study sample body mass index](image-url)
With respect to study sample BMI, the mean BMI is 26.7 ± 4.0; less than a half are overweight (n = 94; 47.0%), followed by those who are within normal limit (n = 63; 31.5%), those who are obese class I (n = 36; 18.0%), those who are obese class II (n = 4; 2.0%), and those who are underweight (n = 3; 1.5%).

The mean of women’s age on marriage is 19.1 ± 0.6; more than a half reported that they get married between 14-20-years-old (n = 111; 55.5%), followed by those who get married between 21-27-years-old (n = 75; 37.5%), those who get married between 28-34-years-old (n = 10; 5.0%), and those who get married between 35-42-years-old (n = 4; 2.0%).

Concerning the number of abortions, the mean number of abortions is 1.22 ± 4.1; the majority of women who experienced abortion have one abortion (n = 37; 84.1%), followed by those who have two abortions (n = 5; 11.3%), and those who have each of three and four abortions (n = 1; 2.3%) for each of them.

Concerning child’s weight on delivery, the mean weight was 2424.4 ± 612.7 gram; most of children weigh between 2.000-2.500 gram (n = 141; 70.5%), followed by those who weigh 2.550-3.000 gram (n = 38; 19.0%), those who weigh 3.050-3.500 gram (n = 11; 5.5%), those who weigh above 3.500 gram (n = 8; 4.0%), and those who weigh less than 2.000 gram (n = 2; 1.0%).

There is no association between women’s age, BMI, age on menarche, abortion and their body image.

**Discussion**

The highest scores for body appreciation are for the items “My behavior reveals my positive attitude toward my body; for example, I hold my head high and smile”, “I take a positive attitude towards my body”, “I feel that my body has at least some good qualities”, “I respect my body” respectively.

More than a half perceive themselves as having; from their point of view, good body image, followed by those whose body image as average, and those whose body image as poor.

The result shows that the higher body appreciation scale and the study sample satisfied in their body image.

There is no statistically significant difference in women’s body image among the groups of age, level of education, women’s occupation, family’s monthly income, and BMI. These findings indicate that these
women, regardless of their age, level of education, women’s occupation, family’s monthly income, and BMI have almost invariant perception of body appreciation.

Conclusions

Women perceive themselves as having form their point of view good body image, however body image has no influence on women’s breastfeeding self-efficacy.

Recommendations

There is a need to raising women’s awareness about the importance of health, well-being, and function of the body. This can help in improving body image postnatally through prenatal health centers. Also, support new mothers, family, peer, and health professional, by focusing at body image women’s needs and de-stigmatizing weight issues through sport classes during postnatal period.

Role of Adropin in Women with Polycystic Ovary Syndrome

Rana Ali Hamdi1, Hanan Naama Abas2, Fatin Abdul Aziz Alsaeed2
1Department of Biochemistry, College of Medicine, University of Baghdad; 2Infertility Center, Baghdad Teaching Hospital

ABSTRACT

Objective: Evaluate serum adropin levels in women with polycystic ovary syndrome (PCOS) and compare their levels with BMI matched healthy controls. Also investigate the relation between serum adropin levels with insulin resistance and lipid profile.

Materials and Method: A case-control study included 78 women from 21 to 40 years of age. Women were divided into two groups: group (1) included 39 women with PCOS and group (2) included 39 healthy women (as controls). Each serum sample was analyzed for assessing adropin, fasting glucose, fasting insulin, HOMA-IR, and lipid profile.

Results: Mean serum adropin levels was significantly lower in women with PCOS as compared to healthy controls (P=0.001). Additionally, significant negative correlations were found between serum adropin levels and serum triglyceride (r= -0.418, P=0.04), total cholesterol (r= -0.842, P=0.0001) and HOMA-IR (r= -0.436, P=0.03) in patients group.

Conclusion: Low serum adropin may participate in the metabolic defects seen in polycystic ovary syndrome such as dyslipidemia and insulin resistance that in turn associated with other health problems such as hypertension, diabetes mellitus, and cardiovascular disease.

Keywords: Polycystic ovary syndrome, adropin, insulin resistance, lipid profile, insulin

Introduction

Polycystic ovary syndrome (PCOS) is a common hormonal disorder in women of reproductive age characterized by irregular menstrual periods, hyperandrogenism, and polycystic ovaries defined by ultrasound 1. Insulin resistance (IR) and metabolic syndrome are more prevalent in PCOS women 1. Dyslipidemia is a common metabolic defects in women with this syndrome which include decreased serum high density lipoprotein-cholesterol (HDL-C) and elevated serum cholesterol, triglycerides (TG), low density lipoprotein-cholesterol (LDL-C), and very low- density lipoprotein cholesterol (VLDL-C) 2. Thus, PCOS women more prone to cardiovascular disease, hypertension, diabetes mellitus type 2, and obesity 3,4.

Adropin is a peptide hormone 5 which has a role in energy homeostasis and maintain the metabolism of glucose and fatty acid 6,7. Previous study found that adropin has a role in controlling the expression of hepatic lipogenic genes and the PPARγ receptor (peroxisome proliferator-activated receptor gamma), which have important role in lipogenesis 7. Furthermore, an animal study showed that adropin affects angiogenesis, raised blood flow and capillary density, and has important role in endothelial cells protection 8. According to above information the present study aimed to evaluate serum adropin levels in women with polycystic ovary syndrome and compare their levels with body mass index matched healthy controls. Also investigate the relation between serum adropin levels with insulin resistance and lipid profile in women with this syndrome.

Method

This case-control study included 78 women from 21 to 40 years of age. Women attended to Infertility Center in Baghdad Teaching Hospital during the period from
June 2017 to October 2017. Informed consent was taken from each women. The present study was approved by the Ethical Committee of the College of Medicine/University of Baghdad.

Women were divided into two groups: group (1) included 39 women with PCOS and group (2) included 39 healthy women (as controls).

Diagnosis of PCOS were done according to Rotterdam criteria when two of three criteria are present, these involve oligoovulation and/or anovulation, clinical and/or biochemical hyperandrogenism and polycystic ovaries as shown by ultrasound.

Exclusion criteria included women with hyperprolactinemia, Cushing’s syndrome, congenital adrenal hyperplasia, androgen secreting tumors, and thyroid diseases.

Serum investigations involved adropin which was measured by enzyme linked immunosorbent assay (ELISA) (Kamiya Biomedical Company), fasting serum insulin was measured by ELISA kit (Monobind Company), and fasting serum glucose was measured by spectrophotometer using kit supplied by (Human Company). In addition, lipid profile including total cholesterol, triglycerides, HDL-C were measured by spectrophotometer using kit supplied by (Human Company) while LDL-C and VLDL-C were measured by following equations:

\[
LDL - c = \text{Total Cholesterol} - (\text{VLDL} + \text{HDL})
\]

\[
\text{VLDL} = \frac{\text{TG}}{5}
\]

Likewise, homeostasis model assessment of insulin resistance (HOMA-IR) calculates the IR according to following formula:

\[
\text{HOMA-IR} = \frac{\text{Fasting plasma glucose (mg/dL)}}{\text{Fasting plasma insulin (μU/mL)/405}}
\]

A HOMA-IR value of 2.5 or above were considered as insulin resistant.

Furthermore, body mass index (BMI) was calculated as weight in kilograms per height (square meter) [weight/(height\(^2\)], women were considered as normal weight at BMI (18.5-24.9 kg/m\(^2\)), overweight women at BMI (25-29.9 kg/m\(^2\)) and obese women at BMI ≥30kg/m\(^2\)

**Statistical Analysis:** Data were analyzed using computer facility of SPSS-20 (Statistical Package for Social Science – version 20). The results were expressed as numbers, range, and mean ± SD (standard deviation). Significance of difference of quantitative data was assessed using Student-t test. Also, Pearson correlation was calculated for the correlation between two quantitative variables with its t-test for testing the significance of correlation. Statistical significance was considered whenever the P value was equal or less than 0.05.

**Results**

Patients and controls were matching for age and BMI. In addition, significantly higher fasting serum glucose, insulin, HOMA-IR, total cholesterol, TG, LDL-C, and VLDL-C levels were found in patient’s compared to controls. However, serum adropin and HDL-C levels were significantly lower in patients compared to controls as shown in Table 1.

In addition, significant negative correlations were found between serum adropin levels and serum triglyceride ($r = -0.418$, $P = 0.04$), total cholesterol ($r = -0.842$, $P = 0.0001$) and HOMA-IR ($r = -0.436$, $P = 0.03$) in patients group as illustrated in Figure (1-1), Figure (1-2), and Figure (1-3), respectively.

Discussion

In the present study, higher levels of fasting serum glucose, insulin, and HOMA-IR were found in women with PCOS as compared with BMI matched healthy controls. This results are in agreement with previous studies \(^{11, 12}\). Hyperinsulinemia, peripheral IR, and impaired glucose tolerance are major metabolic disturbance seen in PCOS \(^{13}\). Hyperinsulinemia found in PCOS may cause by functional problems in the insulin \(^{14}\). Insulin receptors have been expressed in ovaries \(^{15}\). Thus, insulin has the ability for enhancing the synthesis of sex steroid hormone and ovarian growth, leading to increased intra ovarian androgens and disrupting the normal folliculogenesis. The resultant, development of numerous ovarian cysts and ovarian enlargement \(^{14}\).

This study also revealed that higher serum levels of total cholesterol, TG, LDL-C, and VLDL-C, with lower levels of HDL-C in women with PCOS compared to BMI matched healthy controls similar to the results of other studies \(^{16, 17}\). It was shown that dyslipidemia is common in PCOS independent to BMI. Insulin resistance has important role by enhancing lipolysis and altered expression of lipoprotein lipase and hepatic lipase which are important enzymes in lipid metabolism \(^{18}\).

In addition, our findings showed that serum adropin levels were significantly lower in women with PCOS as compared with those BMI- matched healthy controls. This result agrees with previous studies done by Yildirim et al \(^{19}\) and Sen et al \(^{20}\) who showed low levels of serum adropin associated with metabolic feature of PCOS \(^{19, 20}\).

Moreover, our study found significant negative correlations between serum adropin levels and serum TG, total cholesterol, and HOMA-IR in women with PCOS which consist with previous report done by Yildirim et al \(^{19}\).

In this regard, Butler et al noticed that decreased adropin level regarded as risk factor for IR and other characteristics of the metabolic syndrome, such as dyslipidemia \(^{21}\). Moreover, study by Kuhla et al proposed that increased expression of adropin gene lead to reduce lipogenesis in an animal’s study \(^{22}\).

On the other hand, prior research found that lipid abnormalities in PCOS were associated with IR independent of obesity \(^{23}\). Insulin resistance found in PCOS leads to raised TGs average that caused by raised lipogenesis, reduced clearance, decreased fatty acids oxidation, and raised releasing of VLDL by the liver, leading to increased circulated TGs concentration. Additionally, IR may be involve in catabolism of HDL-C and formation of LDL-C particles \(^{24}\).

Conclusion

Low serum adropin may participate in the metabolic defects seen in polycystic ovary syndrome such as dyslipidemia and insulin resistance that in turn associated with other health problems such as hypertension, diabetes mellitus, and cardiovascular disease.

Conflict of Interest: None

Ethical Clearance: Informed written consent was obtained from all the participants in the study, and the study and all its procedure were done in accordance with the Helsinki Declaration of 1975, as revised in 2000. The study was approved by the College of Medicine/University of Baghdad.

Source of Funding: The work were supported by authors only.

ABSTRAcT

This study was designed to research activity *Daucus carota* seeds alcoholic extract on the fertility of male albino mice that treated with H$_2$O$_2$ by changing the body weight, testis, secondary sex organ weights and sperm parameter and hormonal changes (Testosterone, FSH, and LH). This experiment used thirty-two (8-10) weeks’ old albino male mice. These mice were separated into four sets; the first negative group was given physiological saline, the second group was given the alcoholic extract (400mg/kg), the third group was given H$_2$O$_2$ (0.05%) in the drinking water, the fourth group was given both H$_2$O$_2$ (0.05%) and the alcoholic extract (400mg/kg) during (35) days. The results showed: The third group (H$_2$O$_2$) showed significant (P<0.05) decrease the weight of bodies, and significant (P<0.05) increase in testes, prostate and seminal vesicle weights by comparing with control and second group. The result shows a significant decrease in ratios of motility, live sperms and sperm concentration. Also, the concentration of Testosterone, FSH and LH show a significant reduction in the first group when equated with control. While fourth group (H$_2$O$_2$ (0.05%) and the alcoholic extract (400mg/kg) gave significant increase in weights of body and testes, prostate, seminal vesicle weight; this group gave results nearly that in control group result in all reproductive parameters such as hormones concentration, sperms motility and concentration so that the alcoholic extract could provide protection for oxidative stress of H$_2$O$_2$.

Keywords: Carrot seeds, sperm parameters, sex hormones, Hydrogen peroxide.

Introduction

Carrot generally belongs to Umbelliferae, and it mostly limited to the moderate regions of Asia, Europe and Africa. Distinctive parts of this plant are utilized as a part of the treatment of a wide range of illnesses containing kidney failure, asthma, dropsy, infection, leprosy, worm troubles, etc. In perspective of various physiological and pharmacological activity of carrot extract including antibacterial, antifungal, anthelmintic, and, hepatoprotective. Pharmacological impacts demonstrated that carrot exhibited anti-fertility properties in female as a contraceptive the extracted root of carrot has the activity to be hypolipidemic effect, and anticancer. Carrot has experienced expansive phytochemical activity by containing active ingredients that have been isolated. These include volatile oils, steroids, triterpenes. Recently, in reproduction, the pharmacological researches show that *Daucus carota* seeds reveal anti-fertility possessions in females.

It has been demonstrated that the extract carrot seeds and their fatty acids can identify the estrogen cycle of the adult female mice and decrease an ovary mass substantially. They likewise originate when they used the extract of carrot seed (CSE) that lead to the reserve of 5,3-β-hydroxysteroid dehydrogenase and glucose-6-phosphate dehydrogenase, both necessary primary enzymes complicated in ovarian steroidogenesis, in ovaries of mice. In an additional report, it was significantly diminished after the desperate nourishing of carrots by utilizing a sequestered rabbit ovarian, and it was formed from human chorionic gonadotropin-induced progesterone secretions and progesterone.

Materials and Method

Plant Collection: The carrot seeds utilized in the extraction were processed by drying the plant rosette and collect the seed only, washing the seed and drying in the room temperature.
Preparation of the Alcoholic Extract: The carrot seeds (100 g) were macerated ethanol (95.5%) for 6-8 hours. The method was repeated thrice. Later the filtration, and the deposit concentrated by vacuum in a rotational evaporator yielding a 24.31% at 50°C ethanolic extract of carrot seeds.

Experimental Animals: Forty adult male albino mice weighing (30-36) g were acquired from Biotechnology Research Center, and treated mice were rendered with food and water ad libitum. Male mice were indiscriminately separated into four groupings in table 1, containing eight mice in each group. Which incorporate; first negative group was given physiological saline, the second group was given the alcoholic extract (400mg/kg), the third group was given H2O2 (0.05%) in the drinking water, the fourth group was given both H2O2 (0.05%) and the alcoholic extract (400mg/kg) during (35) days In each group animals were killed by vertebrate disengagement. Testes fixed with Bouin fluid (BDH Inc, Toronto, Canada). Then obtained Spermatozoa from the second ends of epididymides by crumbling in 500 µl TCM199, and kept at 37°C in incubator5% CO2 and the percentages of motility and dead and abnormalities of spermatozoa were measured.

Microscopical Examination: Spermatozoa were surveyed by WHO laboratory manual for capability, motility rate of life to dead sperm and abnormal sperm.

Statistical analysis: The analysis was achieved to relate the different groups by using ANOVA-test. That was determined at P<0.05.

Hormonal Analysis: The intracardiac Blood collect from the animals was centrifuged at 2,000 rpm to isolated serum for measuring FSH, LH, Testosterone hormones.

Results

The result in tables (2), (3) refers to the effects of carrot seeds alcoholic extract (ACSE) administration on body weight show a significant increase in the body weight and in the (testis, prostate, seminal vesicle) weight when related to the control. Administration of H2O2 (0.05%) a negative reactive oxygen producing aminoglycoside (15), affected a reduction in the body weight and (testis, prostate, seminal vesicle) weight significantly at what time equated to the control. When this running of H2O2 (0.05%) was administrated together with (ACSE 400 mg/kg) the body weight and (testis, prostate, seminal vesicle) weight was significantly (p<0.05) elevated from (292.65 ± 14.17, 320.12 ± 50.92, 367.26 ± 18.61) into (329.68 ± 17.16, 267.16 ± 20.90, 406.02 ± 26.35).

sperms compared to the control group. It is indicating the protective effect of (ACSE) against Hydrogen Peroxide-induced necrosis. The motility value directs the efficacy of the extract in the repairs of motility of sperm in mice as the expression of Hydrogen Peroxide running.

**Discussion**

The increase of body weight belongs to the effect of (ACSE) by increasing the activity in some hormones that essential to raise the rate of metabolism include growth hormone and thyroid hormone, that increase the appetite, facilitate the digestion, as well as (ACSE) was characterized as appetizing, and it was included high protein and carbohydrate content that agree with \(^{16}\), in addition the increase in (testis, prostate, seminal vesicle) weight belong to the positive relation between the increase in body weight and the reproductive organs \(^{17}\) as well as this increase belong to the increase in the Testosterone which refer to the rise in the Testosterone levels cause increase in the reproductive organs weights and size \(^{18}\) while the decrease occurred by using \(\text{H}_2\text{O}_2\) agree with \(^{19}\) that observe the rats treated with alloxan (the same effect of \(\text{H}_2\text{O}_2\) as oxidative stress) cause absence of Insulin which effects the (Epinephrine and Glucagon)hormones were stimulated lipolysis.

In addition the deficiency of Insulin in the blood cause cells starvation and decrease in calories that lead to decrease in body weight \(^{20}\) the deficiency of glucose concentration in the cells exhaustion the energy causes catabolism so that cause a decrease in body weight and make changes in reproductive organs (testis, prostate, seminal vesicle) \(^{20}\). The counting of sperm is a vital consideration for the evaluation of the properties of chemicals on spermatogenesis \(^{21},^{22}\). The cause of increase the motility and live sperms in the treated group with (ACSE) belong to the same reasons such as hormonal effect that share in the regulation of male reproductive system, as well as the extract, contain several materials like carotenoids \(^{23}\), flavonoids, vitamins (A,B, C, D, E) and As carrot seeds are rich of antioxidants \(^{10},^{23}\), that were pr otected the plasma membrane of sperm against the oxidative

Stress comes from the presence of free radicals in the seminal fluid, while the decrease the motility and live sperms and

Increase in abnormal sperms in the group treated with H2O2 belongs to the effect of H2O2 in the cells which was called oxidative stress that mean the effect of producing the free radicals generated via metabolism in the presence of O2 24. The oxidation destruction raised peroxidation of lipid and caused the modification in the membrane possessions resulting in germ cell death at all phases of development, and a reduction in sperm counting 22, the using was with H2O2 in the same time give protective activity against H2O2 and give results near the normal state when compare with control the extract contain several materials like carotenoids 23, flavonoids, vitamins (A, B, C, D, E) and other compounds work as antioxidants 10 these antioxidants can release the free radicals, prevent producing them and make it inactive 26. Hormones elevate in the hormones (Testosterone, FSH and LH) level during treatment with (ACSE). This reveals that extract applies its impacts on the male reproductive system via sex hormones 27. Hormones were raised after administering the extracted representative, the heightening impact of the extract on the hormones was very essential in spermatogenesis 21 and positive effect on the interstitial tissues that were containing Sertoli and Leydig cell responsible of producing the hormone, as well as the extract containing (choline) 28. Which consider the essential substance to produce (Acetylcholine) important in stimulating the gonads so increase the level of (FSH, LH), whereas the extract containing chemical compounds such as cholesterol, Ascorbic acid was necessary to produce Testosterone from (pregnenolone and androstenedione) 29. The presence of (Zn) in the extract has an active role in Testosterone production that agrees with 30. This is possible that interstitial cell necrosis crops up from a decrease in this hormone. The decrease the hormones (Testosterone, FSH and LH) in the group treated with H2O2 belong to the oxidative stress of H2O2 on the spermatogenesis and induction of apoptosis and oxidative damage 31.

The Ethanolic Extract of Ajwa Fruits inhibits Nephrotoxicity and Deterioration of Some Blood Biochemical Properties Induced by Gentamicin in Male Rats

Saher Mahmood Jwad¹, Wijdan Kamal Noor², Bushra Abbas ALzubaidi²
¹Professor, ²Assist.Prof., Biology Department, Faculty of Education for Girls, University of Kufa, Iraq

ABSTRACT

The current study was designed to assess the probable preventive influences of extract of Ajwa fruits on the renal functional performance and some biochemical parameters of the blood, so this investigation was performed in the Biology department animal house/Faculty of Education for Girls. Sixty male Albino rats of Sprague–Dawley were equally divided into four groups, each group was comprised fifteen males: the first group was (the control), that orally submitted to 0.9% normal saline solution, the second group was intraperitoneally injected with 80 mg/kg of Gentamicin, the third group was subjected to 1 mg/kg of Ajwa fruits alcoholic extract orally + 80 mg/kg of Gentamicin antibiotic intraperitoneally, the last group was orally treated with Ajwa dates alcoholic extract (1mg/kg). The treatments of all laboratory animals were one time at day and continued for three weeks. Regarding the statistical analysis of study, there was a noticeable decline in the levels of erythropoietin hormone, total protein, albumin, as well as reduced glutathione (GSH) in serum, in the opposite, urea, creatinine and malondialdehyde (MDA) levels in serum were significantly raised at the group that intraperitoneally injected with Gentamicin when compared with the other groups of the experiment, the other groups, that orally given Ajwa fruits extract + gentamicin antibiotic, and the extract of Ajwa dates only, no differences were noted in these criteria in compared with control group.

Keywords: Ajwa fruit extract, Gentamicin, Erythropoietin.

Introduction

The group of antibiotic that named aminoglycosides especially Gentamicin have been exerted potent efficacy against severe infections of the bacterial micro-organisms which include whole gram–negative and few gram positive bacterial types¹². Many researchers reported that both groups of antibiotics, the aminoglycosides and aminocyclitols might cause adverse alterations in the blood parameters that related to functions of the kidneys, particularly the increment in the serum creatinine³ and extensive changes in cells of the proximal tubules, which diagnosed before the appearance of this modification in the blood markers⁴.

1. Preparation of laboratory animals: Sixty male rats from Sprague –Daley strain were used in the study, weighing 185–224g, and their ages less than three (12) weeks, had been purchased from the(National Center for Control and Pharmaceutical Research)–Baghdad/Iraq.

DOI Number: 10.5958/0976-5506.2019.02537.3
after that they housed in special steel cages for the laboratory animals to care under the typical controlled laboratory conditions, moreover the sawdust of animal cages’ displaced for 2 to 3 times at week. In relation to the water and feed (that was enriched with protein), provided for ad libitum consumption.

When the males became sexually matured, (their ages 12 weeks) the experiment was performed.

2. Preparation of Gentamicin: This antibiotic with the dose of 80mg/kg brought from Baghdad pharmacy/Alnajaf, and then each animal intraperitoneally given the proper concentration according to its body weight.

3. Ajwa dates: Concern to Ajwa dates, were brought from Saudi Arabia (AL-Madinah AL-Munawwarah), after that the fruits identified and classified by the Biology department taxonomist in the Faculty of Education for girls.

4. Preparation of Ajwa dates alcoholic extract: The alcoholic extract of Ajwa dates was prepared according to\(^{11}\)

5. Grouping of the study

A. The I group was a control, comprised (15) of males that were orally treated 0.9% physiological normal saline solution (once daily) for three weeks.

B. The II group was injected with Gentamicin antibiotic (80mg/kg) intraperitoneally one time at day for the period of three weeks, contained (15) male rats.

C. The III group was orally administrated with Ajwa dates alcoholic extract (1 mg/kg)+Gentamicin (80 mg/kg) by intraperitoneally injecting once daily, for three weeks, and composed of (15) males.

D. Finally the III group was (15) male Albino rats, orally subjected to (1 mg/kg) of Ajwa dates alcoholic extract, one time at day, as well as for three weeks.

Regarding the concentration of Ajwa dates alcoholic extract that used in the study according to\(^{12}\), whereas the Gentamicin concentration determined by the study\(^{13}\).

6. Animals sacrificing and collection of blood samples: The laboratory animals were anesthetized by using diethyl ether, after that the blood taken from each male by the heart puncture to get (5 ml) blood, then the blood was put in gel tubes for the estimation.

7. The biochemical analysis of the blood

A. Serum erythropoietin level evaluation: To estimate the erythropoietin level in serum, the Enzyme–Linked Immunosorbent assay, and the kits that were used in this investigation purchased from Biomerieux, furthermore the absorbance was 450 nm\(^{14}\).

B. Serum urea level estimation: In relation to urea level in serum, the method of\(^{15}\) was depended and the kits were equipped from Biomerieux France Company, as well as the absorbance was read at 580 nm.

C. Serum creatinine level estimation: The creatinine level in serum was evaluated according to\(^{16}\) and the reagents were purchased from Biomerieux (France Company), while the absorbance (490) nm by using the spectrophotometer.

D. Serum total protein level estimation: The method\(^{16}\) was depended to estimate the total protein level in serum, and the kits were equipped from Biolabo Company at (550) nm.

E. Serum albumin level estimation: As regard with albumin level assessment, the method of\(^{18}\) was used, and the kits, as well as the Bromocresol green reagent. In addition, the absorbance carried out by spectrophotometer at 650 nm.

F. Serum reduced glutathione level estimation: The level of reduced glutathione was assessed according to\(^{19}\) the kits and reagents were used in this evaluation purchased from BLH50-USA Company, concerning the absorbance (405 to 414) nm by using the spectrophotometer.

G. Serum malondialdehyde level estimation: As regard to the malondialdehyde level in the serum, the method of\(^{20}\) used, and the kits, as well as the reagents were brought from Biolabo at 530 to 540 nm.
8. The statistical analysis of the study: To analyze the results of the study, version 26 of the Statistical Package Social Sciences (that was SPSS) and Analysis of Variance test were depended, moreover the Least Significant Difference named L.S.D used to extract the differences between the means, the probability level was P < 0.05(21).

Results

The analysis of the study results, indicated to a noticeable reduction (P < 0.05) in the following parameters, erythropoietin, total protein and albumin, as well as reduced glutathione levels in contrast, urea, creatinine, and malondialdehyde (MDA) levels in the serum were remarkably increased in the group that injected with Gentamicin intraperitoneally when compared with experimental groups, as shown in the tables 1 to 7 respectively.

Discussion

According to the results, there was a remarkable decline in the erythropoietin level at the group that injected with Gentamicin, this may be attributed to the adverse effects of this type of (aminoglycosides) on the renal tissues which is considered the primary site for erythropoietin bio-synthesis in the mature mammals, that confirmed by study of (22) Another study has been added that the mainly location(s) of erythropoietin production in laboratory animals which is a specialized peritubular cell, presented in proximal tubular region of the kidney(23-25)Furthermore, hydroxyl radicals may be mediated the (aminoglycosides) pathogenicity because the higher activity of Gentamicin to induce inhibition in both, activity of Na (+)–K (+) – ATPase pumping, and the DNA replication in renal proximal tubules of rat’s kidney, as well as a consequent renal injury(2).

A study by(26) had been demonstrated that, the nephrotoxicity of this type of antibiotic characterized by a decline in urine concentration capacity, mild glycosuria, tubular proteinuria, and reduced ammonia excretion, in addition to the glomerular filtration rate decrement. In relation to the observable increment in the oxidative stress index (MDA) and in the opposite, the reduced level of glutathione(GSH) at the experimental group that intraperitoneally injected with Gentamicin in compared with the other groups of study may be proposed to the toxic impacts of antibiotic on all body tissues especially the sensitive renal tissues, and consequent increased production of detrimental free radicals because potent activation of phospholipids peroxidation, which causes substantial consumption of the glutathione molecules and responsible for detoxification process of various damaging reactive species particularly the end product of oxidative stress(MDA), thus serum glutathione levels accordingly decrease(27) These data could be suggested to potent preventive and curative properties of Ajwa dates including: antioxidant, anticancer and antiinflammatory, as well as antiabetic(28-30). Overall the effective potentialities of Ajwa dates, may explain to it’s strong chemical ingredients like: carbohydrate constituents, different types of proteins, lipids(31,32)Ajwa fruits possess active antioxidants including, carotenoids and numerous phenols(33) in addition to various necessary vitamins like C, B1, B2 and A(34).With regard to the essential phenols of dates, especially vital acids like p–coumaric, ferulic, and sinapic, as well as procyanidins, in

Conclusions: The extract of Ajwa fruits exhibited protective and ameliorative effects on some biochemical and oxidative stress parameters, it alleviated or prevented the erythropoietin level reduction that induced by Gentamicin antibiotic, therefore, we recommend to use Ajwa variety to reduce nephrotoxicity and hemotoxicity of aminoglycoside group because its natural, nutritional and strong bioactive anti-oxidative contents.

Correlated Levels of Anti-Inflammatory Interleukins (IL-4 and IL-10) with Allergic Conjunctivitis (AC) in Iraqi Patients

Nihad Khalawe Tektook1, Osamah Jihad Abdul Qader2
1Assist Prof., Department of Medical Laboratory Techniques, College of Health and Medical Technics, Middle Technical University, Baghdad; 2Assist. Professor, M.B.Ch.B.–F.I.B.Ms.OPHTH.–F.I.CO, College of Medicine, Tikrit University, Iraq

ABSTRACT

Background: Allergic conjunctivitis (AC) is caused by an allergic reaction, most common form was hypersensitivity reaction (type 1), that caused to perennial or seasonal AC. Current study was done in the Hospital of Ibn-AL-Hythem for eyes infections in Baghdad from September-August of 2018, one hundred and thirty-two serum were collected from allergic conjunctivitis patients after diagnostic by a specialist ophthalmologist according to have symptoms, who included 60 male and 72 female, with range age (15-51) years. Used the enzyme-linked immunosorbent assay (ELISA kit) from (Pepro-Tech Company, UK) for estimating levels of both Interleukins (IL-4 and IL-10) in patients serum.

Results: Current study showed higher significant in age group (≥ 35 years) as percentage (57.6%) compare to age group (25- 35) as (28.1%), also significantly higher in females (54.5%) than males (45.5%), also level of IL – 4 in allergic conjunctivitis patients was (23.91 ± 2.09) compare to control (21.02 ± 2.99), so significantly increased levels of IL-10 in allergic conjunctivitis patients (14.99 ± 2.30) than control (11.10 ± 1.99).

Conclusions: Current study were concluded higher significant of allergic conjunctivitis Iraqi patients in age group (≥ 35 years), and the AC in females higher than males, as well as level of IL – 4 in allergic conjunctivitis patients were significant with control, and significantly increased levels of IL-10 in allergic conjunctivitis patients compare to control.

Keywords: interleukins (IL-4; IL-10) ; allergic conjunctivitis(AC) ; Iraqi patients

Introduction

Allergic conjunctivitis(AC) (or name as “allergic rhinoconjunctivitis,” was most commonest allergic eye disorder, in the last decades in Iraqi patients, so allergic diseases were increased dramatically (1). Allergic eye usually are associated with others allergic conditions, such as dermatitis (atopic eczema) and allergic rhinitis (hay fever) , so th causing of eye allergies are similar to the allergic rhinitis (hay fever) and allergic asthma(2).

Allergic conjunctivitis is type of IgE-mediated hypersensitivity a wide term that recognised as 6 types including perennial allergic conjunctivitis(PAC);seasonal allergic conjunctivitis (SAC), contact lens-induced; atopic keratoconjunctivitis (AKC) drug-induced, and vernal keratoconjunctivitis (VKC) (3). However, both (VKC) and (AND) have pathophysiological and clinical pathophysiological characteristics completely different from (PAC) and (SAC), although some common markers of allergy (4). AC common manifests as itchy, red eyes, or watering which included the symptoms of ocular symptom scores(5).

Cosmetics and Medication can play important role in causing of eye allergies, Any types of irritant, whether infectious, environmental, or manmade, can cause symptoms that consistent with an allergic of an eye, AC is caused by allergen-induced inflammatory response(AIIR), that allergen (such as animal dander...
pollen; and other environmental antigens\(^6\) will be interacting with antibody (IgE bound to sensitized mast cells) causing clinical ocular allergic expression (COA). The pathogenesis of (AC) is predominantly an IgE-mediated hypersensitivity reaction. Activation of mast cells WHICH induces enhanced tear levels of the histamine; leukotrienes; prostaglandins and tryptase, and this early response lasts clinically (20 minutes –30 minutes) \(^2\), also, the degranulation of Mast cell to induces activated the vascular endothelial cells, that turn the expresses chemokines and adhesion molecules such as vascular cell adhesion molecules (VCAM) and intercellular adhesion molecules (ICAM), so the other chemokines secreted \(^2\).

Many cytokines that derived from Th1, such as IL(2, 3) and IFN-\(\gamma\), that mediates recruitment of the macrophages, while the cytokine that derived from Th2, such as IL (4 and 5), that participates in both chemotaxis and activation of the eosinophils \(^7\), therefore aim of current study to assess levels of cytokine interleukin 10 (IL-10) and IL-4 in allergic conjunctivitis (AC) patients.

### Material and Method

**Sample Collected:** Current study was done in the Hospital of Ibn-AL-Hythem for eyes infections in Baghdad from September - August of 2018. One hundred and thirty-two serum were collected from allergic conjunctivitis patients after diagnostic by a specialist ophthalmologist according to have symptoms such as Redness in inner eyelid or white of eye; Itchy eyes; Blurred vision; Increased amount of tears; and Swelling of the eyelid (fig.1), who include 60 male and 72 female, with range age (15-51) years.

<td>Significant</td>
</tr>
</tbody>
</table>

Results in table (2) showed the level of IL – 4 in allergic conjunctivitis patients was (23.91 ± 2.09) compare to control (21.02 ± 2.99), so significantly increased levels of IL-10 in allergic conjunctivitis patients (14.99 ± 2.30) than control (11.10 ± 1.99), these results were shown in Fig.4.

Figure 4: Comparative levels of interleukins (IL–4 and 10) in allergic conjunctivitis patients and healthy

Discussion

Current study showed more prevalence of allergic conjunctivitis patients in age group (≥ 35 years) as percentage (57.6%) compare to age group (25-35) as (28.1%), this similar results with Fasasi et al., 2014 who showed more prevalence of AC in age groups (17 -33) years as (43.6%), followed by ≥16 years as (42.3%) (8). Ocular allergy is a higher prevalence in the western countries comparing to Africa and Asia (9). Allergic conjunctivitis(AC) in (12–13) year old schoolchildren, was(19%), about (6–30) % of general population, who diagnoses with Allergic conjunctivitis(10), who represents ≥ 90% of all ocular allergies(12).

The current study showed the allergic conjunctivitis are commoner in females (54.5%) than males (45.5%). These results are consistent with the results of previous studies as (13;14;8), whilst differ with the results of researcher Hall and Shilio, 2005, who showed males more predominate than females (15).

Both Interleukin (4 and 10) are anti-inflammatory cytokines which mainly functions via suppressing the pro-inflammatory (16).

During active the inflammatory of allergic eye diseases, the cytokines of T-helper cell (Th1 and Th2) were secretion and over expressed (17). cytokines of Th2 as interleukins (IL- 4; IL-5 ; IL- 9 ; IL -10 and IL-13) will promoting different elements of allergic inflammation as (isotype-switching from IgG1 ; propagation of the
Th2 phenotype) to mobilization eosinophil; maturation and activation mast cell and synthesis immunoglobulin (IgE), that important for allergy \(^{(18)}\).

Interleukin (IL)-4 plays a very important role in inflammatory and fibrotic events in many human diseases \(^{(19)}\). In Inflammation, such as post-cataract surgical or non-allergic cause slightly increased in production level of IL-4, but high produced level from IL-4 were related to allergic reactions \(^{(20)}\), and increased level in the serum of allergic individuals \(^{(21)}\), so IL-10 an anti-inflammatory cytokine (Th2-type cytokine) is secreting by different cell types as (B-cells; T cells; macrophages and monocytes under various conditions of immune activation \(^{(22)}\)). although IL-10 is been shown to suppress a broad range of inflammatory responses and is known to be an important factor in maintaining a balance of overall immune responses \(^{(23)}\). Thus, used IL-10 in developed novel therapy for many human diseases such as autoimmune diseases and allergic responses \(^{(24)}\).

**Conclusions**

1. Significantly higher of allergic conjunctivitis patients in age group (≥35 years), also significantly higher in females than males.
2. High level of IL-4 in allergic conjunctivitis patients was (23.91 ± 2.09) compare to control, so significantly increased levels of IL-10 in allergic conjunctivitis patients compare to control.

Costal Cartilage Graft Combination with V-Y Composite Chondromucosal Advancement Flap for Correction Unilateral Cleft Lip Nasal Deformity

Ali Adwal Ali¹, Yasir Naif Qassim²

¹Department of Surgery, College of Medicine, University of Kirkuk, Kirkuk, Iraq; ²Department of Surgery, College of Medicine, University of Baghdad, Baghdad, Iraq

ABSTRACT

Background: Cleft lip nasal deformity is a complex deformity that involves nasal skeleton and soft tissue envelop. This study attempts to improve suboptimal results.

Aim: The main goal of this work is to correct the nasal shape to be relatively normal.

Patients and Method: The sample consisted of (25) patients who have post cleft lip nose deformity. The patients have repaired unilateral cleft lip in infancy but still have a nasal deformity. This study was done during the period from March 2013 to March 2018 using a combination of chondromucosal advancement flap and costal cartilage graft. The patients selected were (17) females and (8) males whose ages ranged between 18 to 28 years.

Result: The study was conducted on patients with post cleft lip nasal deformity in order to obtain a relatively normal-looking nose. Costal cartilage graft was applied to all patients. The good-looking outcome was achieved from the combination of V-Y chondromucosal flap and costal cartilage graft.

Conclusion: V-Y chondromucosal flap when combined with a tough and rich source of cartilage, such as costal cartilage, will increase the rate of patient’s satisfaction.

Keywords: Cleft lip nose, Costal, Cartilage graft, Chondromucosal flap.

Introduction

The deformity of the cleft lip nasal is the result of tissue hypoplasia and malposition of the nasal structures. Considerable debate is one of the etiologic factors of the deformity of the nasal cleft. An intrinsic factor attributes the cause of deformity to the cartilage hypoplasia. Furthermore, another theory relates it to extrinsic factors. However, Sadov et al. proved that there is no histological difference between the non-cleft side and cleft side lower lateral cartilage (LLC). Atheron et al. related nasal deformity to the deformed LLC rather than cartilage deficiency. The studies of Kim et al. and Ai-Qun et al. supported these findings. Huffman and Lierle attributed nasal deformity to extrinsic factors that alter nasal structures. Mainly, from the upper lateral cartilage (ULC), the LLC is drawn downward and outward and away. The most significant defect is the malposition of the alar cartilage. The alar cartilage is displaced in a posterior and caudal position, carrying with it the medial crus which in turn displaced downwards. Hence, the nose adopts the flat appearance, and the nostril is horizontally oriented. Table (1) lists the distinctive unilateral cleft nasal abnormalities.

<table>
<thead>

<tr>
<td>2.</td>
<td>Shortened cleft side columella with introversion of lateral crus.</td>
</tr>
</tbody>
</table>
3. Lateral bowing of medial crus.
4. Cutaneous webbing between the ala and columella.
5. Lateral, inferior and posterior alar base displacement.
6. Decreased cleft side projection.
7. Deviation of the septum to the non-cleft side.
8. A symmetric maxillary base.

Several operative techniques and variation on the surgery time have been adopted. Each has its advantages and disadvantages. In this article, V-Y chondromucosal composite advancement flap that used by Basta et al. is taken to reposition the cleft side LL cartilage in combination with costal cartilage graft to support the projection of the tip.

**Patients and Method**

This is a prospective study, involving 25 patients with unilateral cleft nasal deformity of variable degrees of severity. There were 17 females, and 8 males with ages ranged between 18-25 years with a mean of 21.5 years. None of the patients underwent secondary rhinoplasty before 18 years of age. Pre-operative photographic documentation is performed for all patients in AP, lateral and basal views to obtain objective measurements of columellar length, nasal apex height and alar base width so as to have a standard measurement to compare them with the postoperative results.

**Surgical Technique:** A conventional open rhinoplasty was applied to all patients using columellar and rim incisions to expose the lower lateral cartilages and distal parts of upper lateral cartilages. After that, a superomedially based V-Y advancement composite chondromucosal flap was designed on the cleft side (see Figure 1).

As shown in Figure 2, once elevated and advanced medially, an interdomal stitch using prolene (5/0) is positioned to improve the cleft side LLC “V” flap and its adherent underlying nasal mucosa. Subsequently, Tajima stitch using prolene (5/0) is employed to hang the LLC to the contralateral ULC to improve the tip contour and projection and hence to improve the symmetry. The V flap is closed in Y fashion using interrupted 5/0 PDS or vicryl sutures. Columellar strut graft using costal cartilage is inserted between the medial crura of LLC and fixed in position using prolene 5/0. In some cases, L-strut costal cartilage graft is applied to those patients with severe nasal deformity. Then, the internal incisions are closed using vicryl 5/0 and skin incisions using prolene (5/0).

**Figure 2:** The V-Y chondromucosal composite advancement flap elevated and advanced medially

Then, addressing the malpositioned ala is performed through a full-thickness peri alar incision. The ala is brought into a position that nearly mirrors the contralateral side and then fixed in position using 5/0 prolene sutures.

Costal cartilage graft is used to enlarge the alar rim base and the retruded acute columello-labial angle. Tough alar rim graft was used to overcome skin and soft tissue deformities. Upside scored onlay graft is used on the LLC of the affected side to overcome the deformity of the lower lateral cartilage. While the diced cartilage graft is used on both sides to overcome the three-dimensional asymmetries on the LLC and ULC (see Figure 3).

**The Types and sites**

- **Dark blue:** extended columellar strut
- **Light blue:** up scored
- **Red:** onlay graft
- **Green:** alar rim graft
- **Yellow:** diced graft
- **Purple:** alar base graft

**Figure 3:** Types and sites of cartilage graft used with chondromucosal flap
Donor sites of cartilage graft are closed in layers after proper hemostasis. The patients were followed up for 6-18 months postoperatively. During the follow-up period (6-18 months), the objective measurements of the columellar length, nasal apex height and alar base width were assessed and compared with that of the preoperative measures. Patients were inquired about the overall aesthetic appearance.

**Results**

The study was carried out during the period from March 2013 to March 2018. 25 patients (17 females and 8 males) have enrolled with ages ranged between 18-28 years. In all patients, there was no skin membrane ischemia or cartilage graft infection. Costal cartilage graft was applied to all patients. The majority of these grafts were in the form of a columellar strut, onlay grafts, diced grafts, meshed grafts, alar rim graft and spreader grafts.

As shown in Figure 4, a comparison of pre-operative versus post-operative objective measurements revealed an increase in columellar length and nasal apex height with a decrease in alar base width (see Table 2).

As for the subjective perception, the majority of the patients (85%) were satisfied with postoperative results. Whereas the remaining patients (15%) were complaining of some residual nasal tip asymmetry and deviation. However, none of them seeks for any revision of the surgery. The mean follow-up period was extended to one year.

**Discussion**

Historically, surgeons showed hesitation to a surgical intervene during the early ages lest it restricts the nasal growth. However, over the past three decades, early and aggressive interventions have become standard practice. Currently, secondary rhinoplasty represents a complicated combination of the original deformity and the effect of initial attempts of repairing. The goals of nasal cleft reconstruction are to address the dysmorphic alar cartilage and vertically short columella on the cleft side and to restore nasal symmetry and projection.

Although different surgical procedures have been suggested to address the problem, only a few of them were well and consistent. V-Y advancement technique of LL cartilage is one of these procedures that reposition the deformed alar cartilage into the normal site. However, it works well in simple deformities, which means that this procedure did not have encouraging results in severe deformities.

In 1977, Nishimura and Ogino described two V-Y flaps to correct the deformity through a closed rhinoplasty approach. Their results were promising in restoring tip projection and nostril shape. However, the authors recognized stenosis as a late complication. This is most probably due to the extensive incisions that involve most part of nostril rim.

Besta et al. modified the approach of Nishimura et al. by adopting single V-Y chondromucosal composite advancement flap figure (2). This modification avoids incisions along the alar base. They achieved agreeable results in improving nostril symmetry and tip projection. However, there was a residual deformity in those patients with severe nasal deformity due to deformed cartilage and skin membrane.

Deviated septum is a key factor responsible for nasal tip deviation in a patient with unilateral cleft nasal deformity. Hence, excision of the curved caudal portion of the septum with columellar cartilage strut graft (fixed or hanging) is needed in almost all cases in addition to a spreader graft on the concave side.
From the above observation, the patients were approached by employing the approach of Besta et al. This was performed using V-Y chondromucosal composite advancement flap to reposition the lower lateral cartilage in normal position and rigidly buttressed the nasal tip using columellar strut with septal extension graft, placed in between the medial crura of lower lateral cartilages, sutured in place. Bilateral alar rim grafts were used to support alar rim and overcome severely deformed soft tissue; while spreader grafts were used routinely. On the other hand, diced grafts were used to fill the irregularities and symmetry on both sides in both vertical and horizontal planes. In this study, As shown in Figure 5 and 6, the costal cartilage of both case 1 and 2 seems to be an excellent source of cartilage grafts.

Agarawal and Chandra stated that residual tip deviation toward the cleft side post-operatively is attributed to the memory of the skin and soft tissue membrane over the cartilaginous tip vault. Hence, the use of an alar rim graft and scored onlay graft in this study seems to help overcome the memory of both skin and underlying cartilage.

Figure 5: Case (1): pre and post-operative photos for the 21 years old male patient, Costal cartilage graft used, spreader graft, columellar strut, alar rim, onlay graft above lower lateral cartilage, diced graft.
Figure 6: Case (2): pre and post-operative photos for the 18 years old female patient. Costal cartilage graft used, alar rim graft, alar base graft, L-strut graft, spreader graft, onlay graft on the LLC.

Conclusions

The V-Y chondromucosal composite advancement flap when combined with rigid columellar support using cartilage strut grafts provided aesthetically agreeable result in terms of tip projection and nostril morphology.

Conflict of Interest: The authors declare that we have no conflict of interest.

Source of Funding: The authors have no sources of funding, so it is self-funding research.

Ethical Clearance: This study was conducted with approval from the research ethics committee at the Department of Surgery, Faculty of Medicine, University of Kirkuk, Kirkuk, Iraq.

Assessment of Barriers to Implement Nursing Processes

Tameem Thamir Mayouf1, Ahmed Zuhair Abd Al-Qader1, Mohammed Tariq Ali1

1College of Nursing, Mosul University, Mosul, Iraq

ABSTRACT

Background and Aim: Nursing process is a global concept because (it represents the corner stone) and the focus of nursing fundamentals, which make nursing activities coordinated and planned. However, nursing processes are not activated in our health agencies, although nurses have a good knowledge about nursing processes. Therefore, this study aims at assessing the obstacles that prevent the implementation of nursing processes in hospitals in the city of Mosul.

Materials and Method: A descriptive design was used from 10 of December 2017 until the 27 March 2018, the study samples were 313 nurses working at different medical wards.

To collect data, structured self-administered questionnaire was used, data were done by SPSS Version 24 software to identify factors in multivariate bivariate analysis.

Results: the majority of nurses had no prior implementation of nursing processes in clinical setting, about half of samples agreed that lack of cooperation between the nurses can be an obstacle to implement nursing processes, most nurses responded that there is no policy to implement nursing processes. In addition, there are no format, equipment and motivation to apply it.

Conclusion: Females are more than males in the study. Most samples agreed that lack of knowledge about the nursing process may be a hindrance to the nursing process as well as a lack of motivation to use it. About half of nurses had poor knowledge regarding nursing process. The study recommends increasing workshops and trainings for nursing process among practicing nurses through continuous nursing education and mentorship units.

Keywords: Assessment, Barriers, Nursing and Process.

Introduction

Nursing Process are a systematic and continuous method that enables the nurse to provide high-quality care to the patient through the use of problem-solving skills and critical thinking, since it adopts critical thinking to solve health problems, it follows different steps towards patient care.1

The nursing care based on the nursing process should include plans for actions, implementation and evaluation of the goals that are known to each patient. The nursing process meet the health needs of the community because of identification, diagnosis and solving health problems that help nurses make decisions using critical thinking.2

Nursing process include five Phases which are: Assessing, diagnosing, planning, implementing and evaluating. Assessment is a continuous, dynamic, integrated process include: collecting, organizing, validating and documenting data in a manner that can be retrieved when needed, Assessment includes collection of subjective and objective data from multiple sources can draw a close image of the patient’s condition and extent of progress, which identify the patient’s health problems and needs.

Nursing diagnosis is the process of analyzing the data collected by the nurse about the patient’s condition, the diagnosis helps in identifying the patient’s health problems and then determining his daily needs. The care and planning of the patient is the primary goal and purpose of the whole picture is what the patient needs.4

Planning begins to provide care to the patient by identifying the priorities and objectives that lead to achieve the expected outcomes desired by the patient where the results are achieved through the identification and then the application of nursing interventions.3
Implementation start when a nurse performs the pre-planned nursing interventions included in the nursing plan. In order to evaluate the patient’s changing needs, the nurse must have the knowledge, experience and skill that helps the nurse determine the progress of the patient’s condition by monitoring the patient’s response after the implementation of the nursing interventions identified in the pre-care plan.

The study aimed to determine the factors that affect the implementation of nursing process, and assess the level of nurses’ knowledge regarding nursing process.

Methodology

Study Design: A descriptive cross-sectional-design was used to assess the obstacles and factors that prevent the implementation of nursing process in Mosul hospitals.

Study Area: The study was carried out in four teaching hospitals in Mosul city, including several specialties such as medical-surgical, pediatric and maternity.

Study Population: The study samples were 313 nurses working at medical units, surgical units, maternity units, Psychiatry units, and Accident and Emergency departments.

Study Instruments: A pre-tested semi-structured questionnaire was used to collect data from nurses on barriers of the implementation of nursing process.

Tool I: Nursing Process Questionnaire: This tool includes two parts:

Part 1: General characteristics of nurses: including age, gender, academic achievement, years of practice and implementation of nursing process.

Part 2: Nurses ‘Knowledge of Nursing Operations: This section covers 23 MCQ questions that assess the level of nurses’ knowledge of nursing care.

Tool II: Factors affecting the implementation of nursing process

This tool was modified from (Akbari & Shamsi, 2011), and used to present the nurses’ view of the factors limiting the application of nursing process. Each nurse responds with yes or no to each of the 17 factors to answer yes (1) and no (0).

Period of study: From 10 December 2017 until the 27 March 2018

Data collection and entry: The questionnaire was administered by the researcher. Upon nurses filling the questionnaires, they were checked for completeness. Data was entered into the computer in preparation for data analysis.

Data analysis: Results were analyzed using SPSS version 24. Variables were measured using frequency and percentage. After obtaining official approvals from hospitals and during the period of data collection, written consent was obtained from the nurses participating in the study while maintaining the confidentiality of participation during the whole study.

Discussions

This study identify the Obstacles that limit the implementation of nursing process among nurses in selected hospitals, the socio-demographical results of the this study showed that females constitute the highest percentage of study samples, which constitute 60.1% in comparison with males which constitute 39.9%. These findings are similar to studies of Ndayi, Zeray, and Mbithi that found 77% of nurses were females, 61.5% of study participants were females and 66.4% of respondents were females, respectively.8,9,10 This study has different findings than those by Fadia which found 91% of study samples were females.7

In the current study, only 11.5% of nurses had less than 4 years of experiences, and these results are not supported with the studies that were conducted in Ethiopia which found that 36.6% of nurses’ experiences are below 5 years. They are also not supported with the study of Mbithi which contacted in Nairobi that found 26.5% of study participants had years of experiences below 5 years.11,9

The study represents that 25.2% of nurses had 5-9 years of experiences, these results are supported by Mbithi who found 29.4% of respondents had 5-9 years of experiences, also supported by Yihun that found 23.1% of nurses had 5-10 years of experiences.9,12

According to the educational level of the nurses, the result represents that 30% of nurses hold Institute degrees, while 25% of nurses hold baccalaureate degree in nursing. These results are not accepted by Mbithi, Fadia, Zeray, and Yihun studies in which they found 57.5% of nurses had Diploma degree while 30.6% of nurses had B.Sc. degree, about 94.0% of nurses hold BSc in nursing, 65.7% of Respondents were holding Diploma and 34.3% of Respondents were hold BSc in nursing, and 44.5% of study participant hold Diploma. Respectively.7,9,10,12

It was observed that the majority of the samples (100.0%) never implemented nursing process previously. The study revealed that most nurses (100%) have not carried out the practice of nursing process previously. This result strongly agreed with the study of Fadia which found that (100%) of samples had never performed nursing process in clinical situation, this result is not agreed with the studies of Yihun and Fisseha, both found (35%) and (18.7%) of respondents were implement nursing process respectively.7,12,13

Nurses should be aware of nursing process and their parts in order to be able to apply processes effectively and equitably. From the total number of nurses, (61.7%) of them have insufficient background about the nursing process or some part of it, this result may be explained by Fadia which represents that 63% of nurses were select lack of sufficient information as the obstacles that effect on implementations of nursing process, and may be unexplained by Zeray which found that 83.3% respondents’ opinion regarding lack of sufficient information as a factors that effect on implementations of nursing process.7,10

The majority of nurses (97.1%) indicated that there were no motivations to using nursing process in clinical setting, similar result by Fadia which found 100% of nurses agree about no enough motivation in using nursing process, while different result by Zeray that represent 58.8% of nurses indicate lack of motivation for implement nursing process.7,10

The result of the study showed that, 88.2% of Participants agreed that Staff qualification Can limit the application of nursing processes. This result is accepted with Fadia’s study that found 93% of nurses agree about lack of education can be barrier to implementation of nursing process, while this result is not accepted with
Dennis’s study that represented 59% of nurses agreed that educational level may effect on application of Nursing Process.7,14

Also, 49.1% of the Participants that gave their opinions on the lack of cooperation among them, which may be one of the reasons that prevent the practice of nursing process in clinical setting. This result may be explained by Fadia’s study that found 39% of nurses believe that lack of cooperation among them leads to non-application of the nursing process.7

All nurses (100%) who participated in the current study gave their opinions that there is no formal chart for writing nursing process in all health care agencies, this result is strongly agreed with the study of Fadia which found that 100% of nurses gave their opinions about no format in clinical setting to writing nursing process.7

The success of the implementation of nursing process is related to the importance of time utilization and its suitability with the workload, 87% of the participants agreed that there is not enough time for the nurse to apply nursing process. This finding is in line with the Ndayi and Fadia studies, which found that the majority of nurses (62.6% and 100%) attributed one of the reasons for non-application of nursing process is lack of time.7,8 While this result is not corresponding to Zeray, Dennis and Shahnaz studies found that (49% and 7.3%) of nurses attributed a lack of time as one reason to implement nursing process.10,13,14

Nursing process should be placed within the policies of health agencies so that the nurse can implement it into the clinical setting. In the current study, most nurses (100%) have not responded to apply nursing process because the policy of health institutions does not allow this, different opinion by studies of Ndayi and Fadia both found that (17% and 53%) of nurses agree that there are no rules in hospital to implement nursing process, respectively.7,8

In addition to insufficient time, lack of equipment can lead to non-implementation of nursing process, therefore, the majority of nurses (70%) instructed that non-applying of nursing process to insufficiency of equipment, this result is consistent with the studies of Zewdu, Fisseha and Mbithi who represented that (61.2%, 75.4, 71.5 and 63) of nurses said the lack of equipment can be barrier to implement nursing process.5,9,11,13

While different results by Shahnaz and Yihun studies which found that the nurses were asked a question, lack of equipment for the implementation of nursing process were (25.8% and 48%).12,15

The nurse to patient ratio and workload are among the criteria that increase the level of health care for the patient. Therefore, the current study proved that the majority of nurses (55%) gave their opinions about low nurses to patient ratio and (47.3%) of nurses agree that workloads can be one of the obstacles to implementing nursing process. This result is accepted with Shahnanz study which represented that (43.5%) of samples gave their opinions that The lack of full implementation of nursing process is that the ratio of nurses to patients is disproportionate to the workload, while this result is not accepted by Zeray and Ndayi studies which they found (63.7%, 75.6%) of nurses have listed a shortage of nursing staff as a barrier to the implementation of nursing process.10,15

The study showed that 36.7% of nurses had an average knowledge of the nursing process while 48.9% of them had poor knowledge’ level, this result may be explained by Mbithi which found that only 3.7% of study samples had poor level of knowledge in compares with average level which was 35.1%.9

Conclusion

Females are more than males in the study, quarter of the samples had graduated from college of nursing. The majority of nurses have never applied the nursing process in a clinical case at all.

The majority of nurses agreed that the lack of motivation for the implementation of nursing process is an obstacle to either nursing process and a lack of scientific background for nurses. Most nurses reported that nursing process were not applied for lack of time and workload, and also they have been reported that the policy of health agency does not allow for the implementation of nursing process and the absence of a format to applying it.

Nearly half of the nurses involved in this research had low level of knowledge of nursing process

Recommendation: The researchers recommend that continuous nursing education units intensify workshops and nursing training workshops involving nurses working in the field of health.
The researchers also recommends that the department of health Nineveh/department of nursing to follow the program mainstream the nursing process as an input to expand its application in clinical situation.

There is a need for similar future studies to follow up the application of nursing process in the clinical situation.

**Ethical Considerations:** The official approvals were obtained from the provincial health department, county health administration committee and the hospital administration and the approval of the concerned parties who will participate in the research in writing after the purpose of the research has been explained in addition to its objectives

**Source of Funding:** Self

**Conflict of Interest:** The authors has no conflict with interests in the study declaration.

ABSTRACT

The World Health Organization (WHO) has warned that in the decade 2020-2030 tobacco will kill 10 million people per year, 70% of which occur in developing countries. The purpose of this study was to determine the smoking behavior of adolescents in the coastal area of Sinjai Regency and the factors related to smoking behavior in adolescents in the coastal area of Sinjai Regency. The method used in this research is cross-sectional study. The study population was adolescents aged between 13-16 years as many as 231 people. The research sample of 50 people. The study was conducted in Pattongko Village, Tellulimpoe District, Sinjai Regency. The study was conducted October 1 - 28 2018, by monitoring smoking behavior in adolescents in coastal areas in Sinjai district. The results of the study explained that the smoking behavior of adolescents based on frequent/high categories was 41 respondents (82%) and rarely/low was 9 respondents (18%); and health risks experienced by adolescents in the risk categories of 39 respondents (78%) and 11 respondents (22%). Adolescent smoking behavior in the frequent/high category that experiences a risk of 32 respondents (78.0) and no risk for 9 respondents (22.0%); while in the category of rare/low who experienced a risk of 7 respondents (77.8%) and no risk of 2 respondents (22.2%). Where the chi square test results of 0.000. That is, there is a relationship between smoking behavior with health risks experienced by adolescents.

Keywords: Life Skill Education, Cigarette Control

Introduction

Cigarettes are one of the leading causes of death in the world and are the only legal product that kills up to half of its use. Smoking habit causes at least 30 types of diseases in humans, in fact smoking is difficult to eliminate and rarely recognized by people as a bad habit(1).

Smoking is a habit that is carried out by the general public, the dangers of smoking will also lurk its future. The future of smokers will be bleak, see when they are addicted to consuming a cigarette. If it is fatal, then they will do everything they can to enjoy a cigarette. Diseases that arise will depend on the levels of harmful substances contained, the period of smoking habit, and how to smoke a cigarette (2). The younger a person starts smoking, the greater the risk that the person gets the disease when he is old. The smoking habit is very alarming, every time we encounter people in various ages, especially teenagers. Adolescence is a period where an individual experiences a transition from one stage to the next and experiences changes in both emotions, body, interest in behavior patterns, and also full of problems. Teenagers now often underestimate their health. They only think of what will make them happy, like cigarettes. Teenagers are more likely to use cigarettes at a young age without paying attention to the consequences that will be caused and lack of awareness of themselves so that they do not pay attention to the dangers of using these cigarettes (3).

The results of the study of teenage reasons for smoking include: trial and error, curiosity, just wanting to feel, being lonely, to look stylish, imitating parents, fun, relieving tension, so as not to be said sissy, a symbol of maturity, looking for inspiration. Other reasons are also as a stress reliever, saturation reliever, prestige, environmental influences, anti-acid mouths,
mouthwashes, pleasure. Moreover, excessive smoking can cause the death of 10% of the world’s population. This means that one in ten planet earth will die from smoking. Even in 2030 this figure will go faster, which is about half of smokers will die from smoking. Half of those who died are a group of young or productive age\(^4\).

The World Health Organization reports that smoking is the number one killer in the world. In its annual report, WHO states that in the 20th century around 100 million people died from smoking. If there is no attempt to control tobacco/cigarettes then during the 21st century at least one billion people of the world will die in vain, an increase of 10 times compared to deaths from cigarettes in the 20th century \(^5\).

Lots of evidence shows that smoking triggers various diseases and adversely affects health and the environment. Resistance to smoking occurs in almost all countries with different levels. Awareness of the dangers of smoking to health in developed countries causes the level of community opposition in developed countries is relatively strong compared to developing countries or underdeveloped countries. In the United States, one of the goals of The Healthy People 2010 is to reduce the prevalence of teenagers who smoke to reach 12% in 2010. By using simSmokemodel it is found that this is impossible to achieve, but can at least approach the expected results. For this reason, it is necessary to strengthen the cigarette tax, clean air, the prohibition of advertising in the media and global campaigns \(^6\).

Indonesia is the 4th most populous country in the world, with a population of 255.5 million people and an annual population growth rate of 1.38%. This large population, makes the country of Indonesia, a very promising market for various industries, including the cigarette industry. Cigarette consumption in Indonesia reaches 215 billion sticks per year. In Indonesia there are 60% smokers, 59% of them are men and 37% are women. Two out of three adult Indonesian men are smokers with an average cigarette consumption of 13 cigarettes per day\(^1\). This fact puts Indonesia in third place in the world with the highest number of adult male smokers below China and India. Even though the average age of starting smoking is 17.6 years, around 75% of Indonesian smokers start smoking before they are 20 years old. As many as 78.4% of those aged 15 years and over are exposed to cigarette smoke at home, 63.4% in government offices, 17.9% in health facilities, 85.4% in restaurants, and 70% in public transportation facilities \(^5\).

### Research Methodology

The method used in this research is cross-sectional study. The study population was adolescents aged between 13-16 years as many as 231 people. The research sample of 50 people. The study was conducted in Pattongko Village, Tellulimpoe District, Sinjai Regency. The study was conducted October 1 - 28 2018, by monitoring smoking behavior in adolescents in coastal areas in Sinjai district.

### Results & Discussion

The results of this study can be seen in table 1, that the smoking behavior of adolescents in the frequent/high category is at risk of 32 respondents (78.0) and not at risk of 9 respondents (22.0%); while in the category of rare/low who experienced a risk of 7 respondents (77.8%) and no risk of 2 respondents (22.2%). Where the chi square test results of 0.000. That is, there is a relationship between smoking behavior with health risks experienced by adolescents.

The results of the study showed that teenagers tend to have a great curiosity. Because adolescence is a period where someone is still looking for their true identity and unstable, especially on environmental influences. Teenager is a period where an individual experiences a transition from one stage to the next and experiences
changes in both emotions, body, interests, behavior patterns, and also full of problems.

Many studies have shown that teenagers are more likely to smoke than adults. Even based on the results of the reset shows that teenagers smoke every year is increasing. In general they claim to have started smoking between the ages of 9 to 12 years. Currently, of the 1,100 million cigarette smokers in the world, 45% of them are students.

Every year an estimated 4 million people die due to tobacco-related cases. Based on a 1999 report from the World Health Organization (WHO), around 250 million children in the world will die if tobacco consumption is not stopped immediately. The smoking habit for students starts because of lack of information and misunderstanding of information, being consumed by advertisements or persuaded by friends (7).

According to the results of the Indonesian Heart Foundation questionnaire as many as 77% of students smoke because of being offered by friends, association outside the home is also a matter of great influence on the mining of a teenager. It has often been found that teenagers will join in smoking when there is a friend who offers dangerous goods to him. Even more sad, if many teenagers think they will look cooler or more cool if you consume cigarettes (8).

One of the dangers of smoking for students is health. Adolescent health will be very disturbed, because indirectly there are thousands of toxic substances that enter their bodies. Also increases the risk of lung cancer and heart disease at a young age.

In addition, skin health is three times more likely to have wrinkles around the eyes and mouth. The skin will age prematurely or often called premature aging. In terms of reproduction, early smoking can cause impotence, reduce sperm count in men and reduce fertility in women.

Reducing the dangers of smoking cannot be done by filtering cigarettes because filtering cigarettes might only filter a portion of tar and nicotine but does not block even a poison from cigarette sap, and also cannot be done with menthol. Because menthol only affects the taste of smoke. It does not reduce the danger of smoking (9).

Even though it only exhales cigarette smoke without smoking it, it still has a risk of damages because: Most of the chemicals in cigarette smoke (including nicotine) can be absorbed through the mouth and nose. Nicotine can also be absorbed through the skin. The exhaled smoke will stay in the air for a long time and if you breathe again, the smoke will enter the lungs again. Most smokers do not realize that they smoke cigarettes when they exhale.

Most poisons in cigarette smoke are absorbed into the bloodstream. When a pregnant woman smokes, these ingredients pass from the mother to the baby’s blood. Baby smokers may be born underweight, not months old or unable to live. Mother babies who smoke are more likely to die in the first year. If they continue to live, they have a worse risk of contracting the lungs and also poor physical and mental development.

Smoking is one of the biggest causes of death and causes of premature death in human history that can be prevented. The current pattern of smoking allows 500 million people who are now living will eventually die from consuming cigarettes. More than half are children and adolescents. It is estimated that in 2030, tobacco is the single biggest cause of death worldwide, which causes around 10 million deaths per year (5).

The number of smokers from year to year continues to grow. Data presented by the American Health Association (1997) shows that tobacco kills more than 400,000 people worldwide every year. Every day, 3,000 children start smoking. Every year there are 1 million teenagers who become regular smokers and it is estimated that 1 out of 3 teen smokers will die young due to smoking habits. The age of beginner smokers is getting younger and younger (5).

In Indonesia, based on the Household Health Survey the number of smokers is around 32.9% men and 3.6% women. Smoking is a future threat to humanity. Especially in students who are the age of the formation of the next generation. Of course we cannot allow this to continue. Efforts should be made to reduce the increase in the number of active smokers among adolescents. Because with this increase also increasingly adds to the number of passive smokers. And the population of passive smokers is far greater. Among them are pregnant women, babies and toddlers, as well as funny and smart children (10,11).

The increasing prevalence of smoking in developing countries including Indonesia, especially among women and adolescents, causes smoking to become increasingly
serious. Even the phenomenon shows that this habit can be seen in students, especially health students themselves about the knowledge and attitudes of smokers students on the influence of smoking on Unhas son’s ramsis, obtained about 10 health students or about 7.5% of 152 samples. Moreover, the impact of smoking also increases on passive smokers, ie people who don’t smoke but are badly affected by smoking. Cigarette consumption in Indonesia is growing the fastest in the world and the main cause is beginner smokers, 44% smokers aged 10-19 years and 37% aged between 20-29 years. The total active smokers in Indonesia has reached 70% of the total population of Indonesia, or as many as 141, 44 million people. While the tendency of smokers among women and adolescents at the age of 15-18 years also shows an increase (6,12–14).

Conclusions

This study concludes that teenage smoking behavior based on frequent/high categories is 41 respondents (82%) and rarely/low is 9 respondents (18%); and health risks experienced by adolescents in the risk categories of 39 respondents (78%) and 11 respondents (22%). Adolescent smoking behavior in the frequent/high category that experiences a risk of 32 respondents (78.0) and no risk for 9 respondents (22.0%); while in the category of rare/low who experienced a risk of 7 respondents (77.8%) and no risk of 2 respondents (22.2%). Where the chi square test results of 0.000. That is, there is a relationship between smoking behavior with health risks experienced by adolescents.

ABSTRAcT

Objectives: To determine the effectiveness of the educational program on women’s knowledge about family planning.

Method: A quasi-experimental study was conducted between April 2nd, and November 10th, 2018. The study included a purposive sample of 50 women aged 15-29-years who were recruited from primary health care centers in Al-Diwanyah Governorate. This sample was randomly divided into two groups; study and control groups. Each group included 25 women. Data were analyzed using the descriptive statistical measures (frequency, percentage, arithmetic mean, mean scores, standard deviation) and the method of analysis of inferential analyses (t-test, Pearson correlation).

Results: The study results revealed that the educational program positively influenced women’s knowledge about family planning in the primary health care centers in the study group.

Conclusion: There were improvements in women’s knowledge about family planning that could reflect the positive influence of the educational program in the study group.

Recommendations: There is a need to continue applying the program to all governorates and to those who marry. A special men’s program on family planning should be implemented, because they represent the second part of responsibility. And to raise awareness of the whole community about family planning to determine reproduction through the media as collective awareness.

Keywords: Educational Program, Women’s Knowledge, Family Planning

Introduction

The widespread adoption of family planning represents one of the most dramatic changes of the 20th century. The growing use of contraception worldwide enable couples to choose the number and spacing of their children and has had tremendous lifesaving benefits. Yet despite these impressive gains, contraceptive use is still low and the need for contraception high in some of the world’s poorest and most populous places. There is a safe and effective family planning method for every woman that can enable her to protect her health and that of her children. More than half of all couples in the developing world are using family planning to delay, space, or limit future pregnancies, yet the need for family planning keeps increasing as the number of women of reproductive age continues to grow. An estimated (137) million women worldwide have an unmet need for family planning they are not using any method and report that they want to avoid a pregnancy.¹

In 1900, the world population was estimated to be about 1.7 billion. By 1999, it had risen to 6 billion (WHO estimate). Currently, 80% of the world population resides in less-developed countries and this figure will rise to 90% by 2050. So, family planning helps people have the desired number of children, which in turn improves the health of mothers and contributes to the nation’s social and economic development. In most developing countries, including Ethiopia, it is common practice for women to have too many children, too close to one another. As a consequence, the population size of the country has grown dramatically but economic growth has not kept in parallel with it. Such an unbalanced
population size will inevitably have a negative impact on the wellbeing of the nation. Family planning is one of the strategies which is proving to be effective in tackling these problems. (2)

United Nations Population Fund (UNFPA) is committed to closing the gap between the number of individuals who use contraceptives and those who would like to delay space or limit their families. UNFPA supports family planning services in countries around the world, usually within a broader context of reproductive health services. UNFPA supports family planning services in offering a wide selection of methods

1. reflect high standards of medical practice
2. are sensitive to cultural conditions
3. provide sufficient information about proper use or possible side-effects
4. address women’s other reproductive health needs

...imparts training for the use of various family planning devices. (3)

The development of modern contraceptive methods through scientific discovery, coupled with significant progress in the women’s health and rights movements, has paved the way to greater individual freedom and enhanced ability to decide on the number and spacing of children.

- These freedoms are enshrined in international human rights law, under the rights to health,
- to decide on the number and timing of children,
- to information,
- to privacy,
- to non-discrimination and
- to be free from inhumane and degrading treatment, as well as several international consensus statements. (4)

Study Design: A quasi-experimental design was used to guide this study.

Sample and Setting: A purposive sample of (50) women is selected throughout the use of non-probability sampling approach. The sample of the study includes women who visits the Family Planning Centers in Primary Heath Care Centers at Al-Diwanah. The sample is divided into study and control groups; each group includes (25) women.

Data Collection: Data were collected from April 8th, 2018 to September 13th, 2018 through the following techniques:

1. Each woman in the study is interviewed for the explanation of the study objectives (both the study and control groups).
2. All women in the study and control groups were exposed to pre-test.
3. All women in the study group were exposed to the Educational Program about Family Planning, at the same time in lectures-hall at Al-Taleea General Dispensary, in in Al-Diwanah Governorate.
4. All women in the study and control groups are exposed to post-test I immediately after implementation of the Educational Program about Family Planning.
5. All women in the study and control groups were exposed to post-test II four weeks after the post-test I.
6. Data were collected using self-reported study instruments, observation, and interview techniques.

Data Analyses

Data were analyzed using the statistical package (SPSS) ver. (22.0) for windows. The descriptive statistical measures Frequencies, Percent, observed Frequencies, Percent, Mean of score (MS), Standard Deviation (SD), repeated measures ANOVA, as well as scoring scales of 3 categories, are used, and such that (Don’t know, Not sure, and Know), and are responding with integer numbers (0, 1, and 2) respectively.

Relative to “Age at marriage” majority age (15–19) age-old (n = 12; 48%), and (n = 14; 56%) for the study and controlled groups respectively, while “Current Age” are seems to be distributed along age groups with focusing in middle of reproductive period. Most of occupational subjects are housewife (n = 17; 68%, n = 16; 64%) in the study and controlled groups respectively. Monthly income are focused at the first and second classes (n = 9; 36%; n = 14; 56%) in the study and controlled groups respectively. Regarding Educational Levels, most have primary, and secondary graduate levels (n = 17; 68%), as well as most have urban outskirts residency (n = 20; 80%) in each group. Finally, most of studied women has independent status (n = 20; 80%) in each group.

There was a (a priori $p = 0.01$) significant difference ($F(1.000, 24.000) = 140.333, p = 0.01$) in the women’s knowledge about the risks of sexually-transmitted diseases over time. The omnibus effect (measure of association) for this analysis is $0.854$, which indicates that approximately $85\%$ of the total variance in the women’s knowledge about the risks of sexually-transmitted diseases values is accounted for by the variance in the administered intervention.

**Discussion**

Analysis of evaluation of women’s general information presents dramatic change of the explains summary statistics of knowledge about family planning (contributes in spacing between pregnancies) in helping part of questionnaire’s items over time due to applying proposed of an educational program on women’s knowledge about family planning at primary health care centers in Al-Diwanyah Governorate with comparisons significant. Results of testing significant with reference of studied items, as well as scoring scales assessments concerning effectiveness of applying educational program were reported highly significant differences toward impact of program through raising knowledge grades of studied respondents at the post 1 period, and that could be able to confirms importance and successfulness of applying proposed program.

This result is consistent with that of the United Nations family planning allows individuals and couples to anticipate and attain their desired number of children and the spacing and timing of their births. It is achieved through the use of contraceptive methods and the treatment of involuntary infertility. A woman’s ability to space and limit her pregnancies has a direct impact on her health and well-being as well as to the outcome of each pregnancy. In this work which have succeeded in their methods of family planning, as well as the social, economic and political background of these family planning activities.

Explicated of this knowledge about benefit of family planning of mother, child, family, and community part of questionnaire’s items over time due to applying the educational program concerning women’s knowledge about family planning at primary health care centers in Al-Diwanyah Governorate including twenty items distributed for the study, and controlled groups with comparisons significant. Results of testing significant with reference of studied items, as well as scoring scales assessments concerning effectiveness of applying educational program were reported highly significant differences toward impact of program through raising knowledge grades of studied respondents at the post 1 period, and that could be able to confirms importance and successfulness of applying proposed program, and without loss of generality, item of “Provides a greater opportunity for the mother to nurse her baby and feed him long and sufficient breastfeed”, which reported no significant different along studied periods in the study group, since its initial has a highly responding in the pre period of time.

This study confirmed to family planning has several benefits including the health of mothers and their children. Others include socioeconomic benefits; i.e., women can advance their education and careers by delaying or limiting childbearing and this can bring better economic prospects to their household. family planning serves to reduce child and maternal morbidity and mortality by preventing unintended pregnancies and unsafe abortions. The number of maternal deaths that could be averted during childbirth as a result of a reduction in the number of pregnancies and induced abortions would be significant. family planning also enables birth spacing, ultimately reducing child mortality while enhancing the nutritional status of both mother and child. Consequently, this could contribute to significantly empowering women, achieving universal education for all, and achieving long-term environmental sustainability.

Women’s knowledge about family planning, the study results reported highly significant differences in women’s knowledge over time, and that could be able to confirms importance and successfulness of applying proposed program.

This study coincided with my studies, to support what regarding about women’s knowledge about the risks of sexually-transmitted diseases, displayed knowledge about prevention of STIs effects condom use. The level of knowledge about STIs is too low, and further education is needed. Reproductive health clinics and public campaigns/media may be suitable arenas for this. Further research on women’s status in relationships and its effect on sexual behavior is needed.
Conclusions

The researchers conclude that the education program positively affected on women’s knowledge about family planning. Unlike the control group where there was no improvement in their educational level, where has recorded results immovable responses over the periods of times with low or border low level of assessed.

Recommendations

The researchers recommend applying the program to all governorates. A special program needs to be done for men about family planning, because they represent the second part of responsibility. Raise awareness for the whole community about family planning to determine childbearing through the media (posters, advertising media) as a collective awareness.

Conflict of Interest: The researchers report no conflict of interest.

Source of Funding: This study did not receive any funding from any agency.

Ethical Clearance: A permission to conduct this study was obtained from the ethical committee in the College of Nursing, University of Baghdad.

Effects of Supplementation of *Thymus Vulgaris* and *Zingiber Officinal* Powder on Reproductive Performance of Ageing Broiler Breeder Male

Sameerah Hussein Amen¹, Rashid Hassan Hamid Al-Dalawi¹, A. K. shanoon¹

¹Department of Animal Production, College of Agriculture, University of Kirkuk, Iraq

ABSTRACT

Ginger rhizome and thyme leaf are used medicinally and to examine the effect of them powder on male reproductive system there for the powder were add to drinking water for two groups of male broilers breeder ROSS308, supplementation start in 46wk and end in 64wks age at levels 0.5% and 0.1% for each plant powder in diet where the other group was a control (without supplementation). Ejaculate volume, sperm concentration, Counts, movements, motility and abnormality where the main parameters were study. There were a significant increase (P<0.05) in ejaculate volume (ml) and sperm concentration (109 Ml-1), movements (%) and a significant decrease (P<0.05) in motility and abnormality (%), for the treatment of ginger and thyme 0.1%. Therefore our results refer to that of ginger and thyme conceder as pro-fertility properties in ageing male broiler which might be a product of both its potent antioxidant properties and androgenic activities.

Keywords: broiler breeder, ginger, thymus, reproductive performance

Introduction

The most of the new research about use of antibiotic aimed to minimized or prevent the use of certain antibiotics and hormones as stimulant for growth in the animal feed in many European countries and America as a result of the harmful effect of them on human health, due to the accumulation of remnants Ginger and thyme was used in a variety in human drags¹ and used in animal feed and poultry as antioxidants and as stimulant for growth²,³. Also, it was found that ginger has the properties of sex hormones and in particular hormones androgenic properties³,⁴. Used thyme leave in reducing the age of puberty in female of domestic rabbits.⁵ Noted that the ginger oil’s has a role in the conservation & protection of the DNA from oxidation by hydrogen peroxide (H2O2) and the protection from the harmful effects of the reactive oxygen species⁶,⁷. In a recent study, it found by⁸ that the supplementation of 100 mg/kg body weight/day of ginger had increased the percentage of alive sperm vitality and massive motility and in addition to that increase the concentration of testosterone in rats.

Materials and Method

Birds and Experiment design: The experiment was conducted in poultry farm by using 45male (9 male/treat) of the broiler breeder Ross308 at the age of 24 weeks and the experiment period were to 48 wks. of old. The birds were numbered, use of cages of dimensions (150 × 50 × 55) cm for the purpose of breeding birds therein, and the distribution & classification of birds & distribution of treatments are shown below:

1. The first group (G1) is a control
2. The 2nd group (G2) supplementation powder of thyme leaves 0.5% of diet (5kg/1000kg diet)
3. The third group (G3) is treating with supplementation of powder of thyme leaves in drinking water 0.5 of drinking water (10kg/1000kg diet)

4. The fourth group (G4) is treating supplementation of powder of ginger in the drinking water 0.5 of drinking water (500mg/L of drinking water).

5. The 5th group (G5) is treating supplementation addition of powder of ginger tubers 0.5 of drinking water (1000mg/L of drinking water).

**Semen Collection:** Semen samples were collected from birds five times per week and for two consecutive weeks to ensure daily production estimate of the actual sperm\(^{11,12}\) at the same time (8 am). The semen samples were by procedure described by\(^{13}\). Semen parameters (ejaculate volume, sperm count, massive movements, alive & dead sperm %) were done according to standard procedure\(^{12}\), described by\(^{14,15}\).

**Statistical Analysis:** Data from experiment were analyzed as a randomized complete block design with the three replicates (3 male each). Means were separated using Fisher’s protected least significant difference (P< 0.05). The results were expressed as mean ± S.E.M (standard error of means).

**Results**

**Ejaculate volume (ml):** The effect of powder of ginger and thyme on ejaculate volume of broiler breeder males Ross308 as shown in table 1, there is a significant

Discussion

In this study, the result of adding water of each of ginger and thyme produce a significant increase (P<0.05) in semen ejaculate volume, number of sperm in the ejaculate and massive sperm movement, a significant decrease (P<0.05) in dead sperm % and abnormal sperm %. The main pharmacological actions of ginger and compounds isolated there from include immuno-modulatory, anti-tumorogenic, anti-inflammatory, anti-apoptotic, anti-hyperglycemic, anti-lipidemic and anti-emetic actions. Ginger is a strong anti-oxidant substance and may either mitigate or prevent generation of free radicals. It is considered a safe herbal medicine with only few and insignificant adverse/side effects. All these effects may be attributed to the reason that ginger & thyme contain a broad spectrum of nutrients and chemical compounds that have a positive effect on the vital functions of a bird. It was found that ginger contains Capsaicin, Zingerone, Shagaols, gingerol, phenolic, curcumin, proteolysis, vitamin C and E. Also, thyme contains flavonoids, terponoids, thymol, carvacol and eugenol, and vitamin E. It has been observed in many laboratory studies the ability of these compounds to break the chain reaction of oxidation such as superoxide and hydroxyl and peroxyl radical. As well as the polyphenols prevent the oxidation of enzymes, that inhibit the oxidation free radicals. Because the sperm is more vulnerable & sensitive to free radicals, because of the high concentration of unsaturated fatty acids in sperm membrane.

This explains the low percentage of dead sperm and abnormal sperm morphology and increase the rate of massive movement of sperm in all groups treated with ginger. The present finding is similar to the result of. Also increase in testosterone concentration. These findings are consistent with previous studies, each of, who emphasized the act of antioxidants in protecting the DNA from oxidative damage. Also, an increase in the resistance of glutathione. In a recent study, done by who noted that the addition of led to significant improvement in semen particularly significant decrease in the proportion of dead sperm. Seen through the results of analysis of seminal plasma by the decline in cholesterol, protein, glucose of semen in the all treated groups as compared with control.

Conclusion

The present findings indicates that decrease the oxidation of fat and lower the level of glucose in seminal fluid. Which is depleted by the living sperm (30, 31, 32 and 33). Also it was observed in this study, this findings refers to the ability of ginger & thyme to influence the mechanisms of anti-lipid peroxidation. In previous study, it was observed that there is a positive correlation between the concentration of ginger & thyme & characteristics of semen.

Effects of Personality Type on Burnout in Korean Clinical Nurses: Focus on Personality Type D

Song, Hye-Suk¹, Lim, So-Hee²

¹Assistant Professor, Department of Emergency Medical Technology, 21, Chungjeong St., Dong-Gu, Daejeon, Korea; ²Assistant Professor, Department of Nursing, KyungMin University, 545, Seobu-ro, Uijeongbu-si, Gyeonggi-do,

ABSTRACT

This study is a descriptive investigative study conducted to identify the influential factors for burnout in relation to somatization symptoms, emotional labor, job satisfaction and turnover intention for personality type D nurses. Participants were 285 nurses working in general hospitals in a metropolitan area. A hierarchical multiple regression analysis was conducted in order to identify influential factors on burnout of study participants in relation to personality type D. As for type D, the explanatory power was 67 % (F=78.56, p<.001). Somatization symptoms (β=.45) was the greater the effect on burnout. In addition, a higher level of emotional labor (β=.27) and turnover intention (β=.17) increased burnout, whereas high job satisfaction (β=-.19) decreased burnout. In order to reduce burnout of nurses, personality type D nurses need to be examined from a human resource management prospective and this approach must be followed by continuous attention and adequate management.

Keywords: Nurse, Personality, Intention, Job satisfaction, Burnout

Introduction

Burnout is a phenomenon that frequently occurs to workers in personal service sectors, such as medicine, education and social services, which are continuously exposed to various types of unsatisfactory situations and have to suppress their emotions¹. As nurses interact with patients firsthand and provide medical services to patients in their practice, they are easily exposed to the risk of burnout². Nursing burnout has very strong ripple effects in that it affects not only the individual, but also his or her fellow nurses within the organization, resulting in group burnout³. The longer the burnout, the more negative the tendencies, such as a sense of failure, guilt, and regret, will undermine their nursing ability and job satisfaction. This, in turn, increases their level of stress and causes a vicious cycle.

A personality type is a temperament characteristic of individuals that does not easily change and can cause psychological stress and undermine physical health. It is therefore an important determinant for psychological and mental health⁴. In personality type D, the letter “D” stands for “Distressed” and refers to a personality type based on two concepts of negative emotions and social inhibition⁴. Type D can be characterized by depression, anxiety and socially inappropriate concerns and worries. It is known that type D subjects are more easily exposed to chronic stress compared to subjects of other personality types⁵. The type D nurses with a highly negative emotional state and a high susceptibility to stress can easily experience burnout, but there have not been sufficient studies conducted on this issue.

Burnout is a significant health issue experienced by nurses in clinical practice and the efforts to intervene and reduce burnout must be continued. Burnout undermines not only physical and psychological health of individual nurses, but also their ability to perform their duties, which accordingly diminishes the quality of their nursing service. Therefore, efforts are required to prevent and reduce the occurrence of burnout, and there is a need to identify influential factors associated with burnout for prevention and intervention. Therefore, it is

important to identify personality types of clinical nurses in relation to somatization symptoms, emotional labor, job satisfaction and turnover intention. The identified data will be used as important indicators for identifying influential factors for burnout by personality type. In this context, this study aims to identify the influential factors for burnout of personality type D nurses.

Methodology

Measurements

Personality type D: The Korean type D scale-14 (Korean DS14) developed by Denollet and translated by Lim, Lee, Ko. The tool consisted of a total of 14 items with a 5-point Likert scale. The reliability of the tool was Cronbach’s α=.94 in the study Lim et al. and Cronbach’s α=.86 in this study.

Somatization Symptoms: Somatization symptoms were measured using a physical measurement tool developed by Han, Jeong, Tag and modified and complemented by Lee. This tool consists of a total of 15 items with a 5-point Likert scale, the higher the severity of the physical symptom. The reliability of the tool was Cronbach’s α=.91 in the study by Lee and Cronbach’s α=.93 in this study.

Emotional Labor: Emotional labor was measured using an emotional labor measurement tool developed by Morris & Feldman and translated by Kim. This tool consists of a total of 9 items with a 5-point Likert scale, the higher the severity of emotional labor. The reliability of the tool was Cronbach’s α=.86 in the study by Kim and Cronbach’s α=.89 in this study.

Job Satisfaction: Job satisfaction of nurses was measured using a Minnesota Satisfaction Questionnaire tool developed by Weiss, Dawis, England and translated by Lee. This tool consists of a total of 20 items with a 5-point Likert scale, the higher the severity of job satisfaction. The reliability of the tool was Cronbach’s α=.88 in the study by Lee and Cronbach’s α=.83 in this study.

Turnover Intention: Turnover intention was measured using a tool developed by Lawler and translated by Park. This tool consists of a total of 4 items with a 5-point Likert scale, the higher the turnover rate. The reliability of the tool was Cronbach’s α=.88 in the study by Park and Cronbach’s α=.89 in this study.

Burnout: Burnout was measured using a tool developed by Pines, Aronson, Kafry and translated by Choi. This tool consists of a total of 13 items with a 5-point Likert scale, the higher the severity of the burnout. The reliability of the tool was Cronbach’s α=.94 in the study by Choi and Cronbach’s α=.90 in this study.

Data Sources: The study subjects were nurses at three general hospitals with 300 beds or more located in S city. The data was collected in the form of a structured questionnaire that were provided to nurses who were informed of the study’s purpose and agreed to participate in the study. The collection of data for the study was conducted after obtaining approval from the Institute Review Board (WKIRB-201801-SB-008).

Data Analysis

The collected data was analyzed using the SPSS 23.0 program. χ²-test of the general characteristics were obtained. A t-test was conducted to analyze the difference among variables in relation to personality type D. A hierarchical multiple regression analysis was conducted in order to identify influential factors on burnout of study participants in relation to personality type D.

Results

General characteristics of personality type D and the difference in relation to key variables: The general characteristics with differences observed in relation to personality type D were as follows: gender (χ²=9.95, p<.001), religion (χ²=13.22, p=.004), education level (χ²=18.66, p<.001) and working place (χ²=9.65, p=.008).

</tbody>
</table>

SD= Standard Deviation
The difference in key variables in relation to personality type D of subjects is shown in Table 1. The level of somatization symptoms was higher in type D subjects (M=2.75) than non-type D subjects (M=2.00) showing a statistically significant difference (t=-8.12, p<.001). The level of job satisfaction was lower in type D subjects (M=3.12) than non-type D subjects (M=3.33) showing a statistically significant difference (t=-4.46, p<.001). The level of turnover intention was higher in type D subjects (M=3.38) than non-type D subjects (M=3.16) showing a statistically significant difference (t=-2.14, p=.034). The level of burnout was lower in type D subjects (M=3.07) than non-type D subjects (M=2.55) showing a statistically significant difference (t=-6.70, p<.001).

**Analysis of influential factors on burnout of subjects in relation to personality type D:** To identify influential factors on burnout of subjects in relation to their personality types, the variables that showed a significant difference in general characteristics of the subjects were used as control variables.

As for type D subjects, two regression models were proposed through the hierarchical regression analysis. In Model 1 (constructed model), a control variable, the variable with a significant impact was working place and the explanatory power of general characteristics for burnout was 6%. The explanatory power of Model 2 (full model), which included independent variables, was 67%. With the general characteristics of the subjects under control, somatization symptoms had the greatest effect on burnout and the higher the somatization symptoms (β=.45) the greater the effect on burnout. In addition, a higher level of emotional labor (β=.27) and turnover intention (β=.17) increased burnout, whereas high job satisfaction (β=-.19) decreased burnout.

As for non-type D subjects, in Model 1, the variables with a significant impact were educational level and working place and the explanatory power of general characteristics for burnout was 8%. The explanatory power of Model 2 was 68%. With the general characteristics of the subjects under control, somatization symptoms had the greatest effect on burnout and the higher the somatization symptoms (β=.51) the greater the effect on burnout. In addition, a higher level of emotional labor (β=.33) and turnover intention (β=.31) increased burnout, whereas high job satisfaction (β=-.42) decreased burnout.

**Discussion**

In this study shows a higher level of somatization symptoms in type D subjects. A study conducted in Korea reported that 35.8% of patients with cardiovascular diseases, and 33% of patients with asthma had personality type D. Other study reported that Type D subjects showed increased fatigue. Based on the findings of the previous studies which reported that personality type D had negative effects on a physical aspect, there is a need to identify the relationship and analyze an in-depth causal relationship between personality type D and somatization symptoms for nurses. The study is indicating a lower job satisfaction in type D subjects. The existence of different personality types explains why individuals have different levels of job satisfaction. Therefore, it is recommended that various personality analysis methods, such as MBTI or Ennegram, be used for analyzing job satisfaction. In this study is indicating a higher turnover intention for type D subjects. Type D subjects have a more negative emotional state compared to non-type D subjects and repeatedly suppress their emotions rather than explicitly expressing them, subjecting them to psychological stress that leads to turnover intention. In this study, the scores for burnout for type D subjects was 3.07 and the score for non-type D subjects was 2.55. There needs to be a systematic approach to establish a strategy that will effectively reduce burnout for type D subjects.

The influential factors for burnout for type D subjects were analyzed and the results showed that the most influential factor was somatization symptoms. The study by Oh and Choi conducted on nurses supported the result of this study with the same result. In this context, there needs to be measures to prevent somatization symptoms and manage the symptoms at an early stage to address burnout of nurses. It is recommended for hospitals and nursing departments to provide administrative and institutional support to nurses as soon as they start working at hospitals in order to minimize burnout experienced by nurses.

The second most influential factor for burnout for type D subjects was emotional labor. The influential factor that affected the burnout of non-type D subjects was job satisfaction. Regardless of situations, type D subjects maintain a negative emotional state, such as anxiety, stress, tense or unstable in relationships with other individuals, and suppress the expression of their emotions or behaviors. In other words, type D nurses
experience greater displeasure with greater emotional labor and consciously suppress emotional expression, which results in a chronic negative emotional state that eventually causes burnout. In this context, nursing departments need to make efforts to identify type D nurses, implement emotional support programs to reduce burnout of nurses and foster a pleasant working environment, develop programs to mitigate nurses’ negative emotional state and help them express their emotions, thereby helping them develop a positive perception of themselves and establishing a new organizational culture.

**Conclusion**

This study identified the levels of somatization symptoms, emotional labor, job satisfaction, turnover intention and burnout in relation to personality type D and relevant characteristics as well as empirically defined the effects of personality type D on burnout. This study is significant in that it provides basic data for management of nurses and will be effect as basic data for development of concrete action plans and strategies for mitigating somatization symptoms, emotional labor, job satisfaction, turnover intention and burnout. In order to reduce burnout of nurses, personality type D nurses need to be examined from a human resource management prospective and this approach must be followed by continuous attention and adequate management. This study can contribute to advancement in nursing practice, systematic management of nurses, and productivity improvement.

Correlation of Maternal Education with Parenting and Child Nutritional Status

Sukmawati¹, Sirajuddin¹

¹Departement of Nutrition, Makassar of Health Polytechnic, Indonesia

ABSTRACT

Education levels is the key to childcare. Good education has an impact on the quality of the parenting style and nutritional status for under five years old. The objective of this study were to analyze the correlation of maternal education by care and nutritional status of children under five in Maros District in Indonesia.

Settings and Design: The sample were under five years old and selected by simple random sampling. Sample size were 156 children. The design of this study is a cross sectional study. Data analysis by spearman correlation test at 95% confidence level.

Method and Material: Child weight was measured by electronic SECA scale. Anthropometric data collected in Infants (0–11 mo of age) were weighed with their mothers and then the mother’s weight was subtracted to obtain infant weights. Recumbent length of children <24 mo of age was measured with the use of a measuring board. Nutritional status was assessed based on the WHO Multicenter Growth Reference Study Standards. Three indexes were derived from anthropometric measures, including weight-for-age z score (WHA), length-for-age z score (HAZ), and weight-for-length z score (WHA). This research was registered with the ethics commission of the Makassar Health Polytechnic.

Statistical Analysis Used: The data analyze were used to SPSS 16. Correlations between parenting style and z scores anthropometric were tested by Spearmen correlation at 95% confidence intervals.

Results: Distribution of nutritional status of children in the basic education group were normal as much as 67.1% while in the normal education group were 75.7%. Based on the HAZ index that basic education is 53.2% normal status compared in the education group 61.4%. Based on the WAZ index in the basic education group it was good status at 74.7% compared in continue education group were 77.1%. The results of the Spearman correlation analysis that education levels were correlated with parenting in the basic education group (p = 0.043) and in the continue education group it were not significant correlated (p = 0.417).

If respondents were grouped according to nutritional status (HAZ) and then conducted a correlation test the parenting pattern correlated with the value of the HAZ score in the continue education group (p = 0.026) but did not correlate with the basic education group (p = 0.057).

Conclusions: In the group of basic educated mothers, it is known that there is a correlation between the nutritional status of children according to the WAZ index while in the group of advanced educated mothers there is no correlation with the child’s WAZ status. In the group of continue educated mothers there was a correlation of HAZ nutritional status with parenting style.

Keywords: Education, Parenting and Nutritional Status of Toddlers

Introduction

The increase in the percentage of Stunting in South Sulawesi is that it continued between 2007, 2010 and 2013 which were 29.2%, 39.8% and 40.9% respectively. This percentage is a combination of children under five
who are short and short status based on indicators of height for age (HAZ) from the WHO Anthropometric reference. Various factors that affect of stunting. The both the intake and infectious diseases are direct factors. Prevention of stunting is important by overcoming indirect factors, namely parenting. Parenting is intended to care for feeding, child care, seeking treatment and child hygiene care. 1,2,3

Maternal education tends to have quality care for child feeding, because the reasoning is to work outside in the home. The habit of mothers working outside in the home is entrusting children to caregivers who are also from close families or helpers who are specifically employed. 4,5,6

The burden of the mother working outside the home seems to be a factor that correlates with the quality of child feeding care. The length of the mother’s work outside the home, especially during the critical period of growth is an aspect that deserves to be studied. Various underlying reasons include, for ethnic Bugis, whatever type of work the mother still has, she has a total role in responding to childcare. 7,8 Mother’s work should not neglect the care of child feeding, but at the same time sufficient skills and knowledge are needed to carry out parenting roles appropriately and efficiently. If this role is able to be carried out then the suspicion while children will not risk being short. This is what will be tested in this study.

The purpose of this study was to analyze the correlation correlation of maternal education by care and nutritional status of children.

Subjects and Method

The cross sectional study was conducted in Maros Regency, South Sulawesi, Indonesia, with a sample of 156 people using the random sampling method. Sample size is calculated based on proportional sample formulas.

Data were collected by trained enumerators on interview techniques and anthropometric measurements in April 2018. Questionnaires in this study had gone through trials with good validity and reliability. Question list consists of three parts. Child care patterns were divided into three parts, namely feeding, care, hygiene and medical care and were assessed based on parenting scores. Nutritional status is measured based on anthropometric data of the child’s height and weight. The indicators studied were, weight for age Z scores (WAZ), height for age Z scores (HAZ), weight for height Z scores (WHZ) The measurement uses 0.01 kg accuracy and 0.01 cm. Nutritional status for children for : Underweight: weight for age z scores < –2 standard deviations (SD) of the WHO Child Growth Standards median. Stunting: height for age (HAZ) < –2 SD of the WHO Child Growth Standards median. Wasting: weight for height Z scores (WHZ) < –2 SD of the WHO Child Growth Standards median. Overweight: weight for height Z scores > +2 SD of the WHO Child Growth Standards median. Processing data using SPSS version 16.0 from SPSS Inc. Descriptive data analysis with frequency, proportion, and median distribution. Test statistics with the spearman correlation test at 95% confidence. This study was approved by the Makassar Health Polytechnic Ethics Commission.

Results

The results of this study were presented in the following tables

The results of statistical analysis of the correlation of basic education with parenting, knowledge, and practice of breastfeeding, based on the nutritional status (WAZ) in the basic education group found a negative correlation for parenting (p = 0.043) but no correlation with knowledge and practice (p > 0.05).

The results of statistical analysis of the correlation of basic education with parenting, knowledge, and practice of breastfeeding, based on the nutritional status (HAZ) in basic education, found no positive correlation to parenting (p = 0.091), knowledge (p = 0.120) and breastfeeding practice (p = 0.293).

**Discussion**

Maternal education is directly related to parenting style feeding, care, treatment and personal hygiene. Mothers were known as the main caregivers of children for the composition of roles in Indonesian society in general. Indonesian people, especially urban areas, have applied the concept of gender equality in households. Based on this view, this time the discussion highlighted the point of view of basic education and continue education as the main domain. The main domain to find the point of difference in effects based on nutritional status in all three indexes WAZ, HAZ and WHZ.

This study were found the percentage of malnourished children and combined malnutrition were both basic education group than in continue education group. These results provide shown that children’s opportunities for malnutrition were greater in children whose parents (mothers) have basic education. The parental education is an investment in improving sustainable nutrition in rural communities based on nutritional status at WAZ.

Correlation analysis between parenting and nutritional status of children according to WAZ indicators were significant (p = 0.043). This fact that for mothers who have basic education, namely education up to a maximum of 9 years, the actual body weight of a child is influenced by the mother’s education. Especially for basic education in Indonesia, it is divided into
two groups, namely the age group of 6-12 years, and the age group 13-16 years, with a duration of 9 years of education. If the mother is only able to complete education in a group of 6-12 years, then she has the opportunity to work outside the house is limited. If the mother has an education group of 13-16 years, then the opportunity to work outside the home is greater, even if only as a operator worker at small industries. This social phenomenon has an impact on the pattern of mother’s care for their children. The value of parenting patterns will be better at a lower level than the higher ones, which is why in this study negative correlation values were found. Whereas specifically parenting knowledge and practice remains a positive and insignificant correlation.

The phenomenon of parenting in the basic education group is different from continue education group in this study. In the continue education group has a positive correlation was found in parenting with BBU nutritional status. The higher the mother’s education, the better the parenting style for her child. The upbringing pattern for the mother is further educated, even though she works outside the home but is good, because her education causes her to be able to provide better child care costs, so that the quality and quantity of nutrition is better.

The results found in the above data are consistent with the HAZ indicator. It was found that the percentage of children who were short was higher in the group of children from mothers who had basic education compared to advanced education. Various research reports report that educational factors are strong variables that influence the child’s height status. Height is even a good predictor for children’s social future. The reported academic potential and economic potential are positively correlated with the education status of both parents. In various countries with low literacy in nutrition science theoretically they will also have low nutritional status. The concept of education as an investment in improving nutrition is found to be positively correlated.

Before discussing that, it was also found that the energy and protein intake (Table 2) in the two groups also tended to be different. This difference can be seen from the percentage of energy deficit children in the group of children from basic educated mothers compared to advanced education. This proves that there are direct factors that cause children different nutritional status in both groups, namely energy and protein intake which is also lower in basic education than education.

Effectiveness of an Educational Program on Emergency Nurse’s Knowledge and Practice about Advance Cardiac Life Support at Emergency Medicine Department in Baghdad City

Talib Kalifa Hassan Al-Temimi1, Hussain Hadi Atiya2
1Clinical Nurse Specialist, Ministry of Health; 2Assistant Prof., Adult Nursing Department, College of Nursing, University of Baghdad

ABSTRACT

Objective: To evaluate effectiveness of an educational program on emergency nurse’s knowledge and practice concerning advance cardiac life support at emergency medicine department in Baghdad City.

Methodology: A Quasi-experimental design study was initiated. A quasi-experimental design is carried out to evaluate the effectiveness of an educational program on emergency nurse’s knowledge and practice concerning advance cardiac life support at the emergency medicine department in Baghdad City. The study was initiated 4th December 2018 to 3rd April 2019, and divided into (26) emergency nurses for the study group, which were exposed to the education program about Advance Cardiac Life Support (ACLS), and (26) emergency nurses have been assigned to the control group who share the same criteria of selection for the study group and are not exposed to the educational program. The questionnaire is composed of 3 parts: First part, the demographic data, the second part Knowledge test: it is composed of (30) multiple choice questions which covered relevant points from the major content area of the advance cardiac life support. The third part: Observational checklist. It is composed of (25) items and sub item which covered five domains of practices concerning Advance Cardiac Life Support. And presented Advance Cardiac Life Support (ACLS), according to priority, Airway and Breathing care, cardiovascular system care, disability, intra venues fluid and DC shock uses. The validity of the questionnaire, observational checklist, and educational program were being identified by a panel of 12 experts; the study Reliability of instrument was determined through pilot study was carried out on 3rd to 24 November 2018. Data were analyzed through the application of descriptive statistics analysis and the inferential data

Results: The study findings indicated that the education program has a positive effect on case group at post test

Conclusion: The knowledge and practice of emergency nurses were improved after educational program

Recommendation: Promote advanced training about advance cardiac life support and Employment of college or institution graduate nurses in emergency Medicine should be planned by the ministry of health.

Keywords: Emergency nurse’s, Advance Cardiac Life Support

Introduction

Advanced cardiac life support or Advanced Cardiovascular Life Support (ACLS) refers to a set of clinical interventions for the urgent management of cardiac arrest, stroke and other life-threatening cardiovascular emergencies, as well as the knowledge and skills to deploy those interventions. Advance Cardiac Life Support refers to as an emergency medical procedure in which the basic life support efforts of CPR are augmented by the establishment of an intra-venous line, drug administration, possible defibrillation, endotracheal intubation, and the control of cardiac arrhythmias that are performed in the two referral hospitals in Botswana. Advanced Cardiac Life Support (also known as ACLS) focuses on educating doctors, nurses and other health care specialists on how to properly treat patients who are in

Corresponding Author:

need of immediate cardiac treatment for strokes, cardiac arrest and other life threatening emergencies related to the heart and cardiovascular system. (4) ACLS is the training health professionals may receive in addition to cardiopulmonary resuscitation (CPR) training. ACLS is a set of established protocols for using CPR integrated with medications, defibrillation, and advanced airway for a cardiac emergency in the adult patient. The current ACLS class is a 2-day process taught using established guidelines written by the American Heart Association (AHA). (5,6) Cardiopulmonary resuscitation is a lifesaving technique that is performed when a person’s breathing or heart has stopped. The purpose of CPR is to move blood and therefore oxygen (which your body needs to survive) to the brain and heart. CPR involves three steps (C = Compressing the person’s chest to keep the blood circulating, A= Opening the person’s airway (the passageway between the nose/mouth and the lungs), B = Giving rescue breaths that fill the lungs with air). (7) Advanced cardiac life support (ACLS) affects multiple links in the Chain of Survival, including interventions to prevent cardiac arrest, treat cardiac arrest, and improve outcomes of patients who achieve ROSC after cardiac arrest. The 2010 AHA Guidelines for CPR and ECC continue to emphasize that the foundation of successful ACLS is good BLS beginning with prompt high-quality CPR with minimal interruptions, and for VF/pulseless VT, attempted defibrillation within minutes of collapse.

Methodology

A Quasi-experimental design study was carried out to evaluate the effectiveness of an educational program on emergency nurse’s knowledge and practice concerning advance cardiac life support. The study was initiated 4th December 2018 to 3rd April 2019, and divided into (26) emergency nurses for the study group, which were exposed to the education program about ACLS, and (26) emergency nurses have been assigned to the control group who share the same criteria of selection for the study group and are not exposed to the educational program., the instruments was constructed; the questionnaire is composed of 3 parts First part, the demographic data, the second part Knowledge test that is composed of (30) multiple choice questions which covered relevant points from the major content area of the (ACLS) (5) questions, Circulation (cardiovascular system) (5) questions, respiratory system and airway care (5) questions, Electrical and ECG of heart (5) questions, Conditions requiring advanced cardiac support (5) questions, Monitors, devices and tools used to support advanced cardiac life (5) questions, Electric Therapy, which includes DC Shock & AED Defibrillator. The questions were scored as correct question (2) points and the incorrect question (1) point. For the purpose of this study, the number of correct responses on the knowledge test questionnaire was used as the measure of the level of emergency nurses’ knowledge. The total scores of the test were 60 points. The cut of point was \( H = \text{High (R.S = 87.6\% - 100\%)} \), \( L = \text{Low (R.S = less than 75\%)} \), \( M = \text{Moderate (R.S = 75\% - 87.5\%)} \)

Part III: Observational checklist: This tool was developed to evaluate effectiveness of education program on emergency nurses practice concerning advance cardiac life support. This checklist was designed by the investigators based on extensive review of literature and relevant studies. The observational checklist was composed of (25) items and sub-items covered five domains of practices concerning ACLS. They are presented as follows (Advance cardiac life support, according to priority: consist of (5) items and sub items, Airway and Breathing care: consist of (6) items and sub items, Cardiovascular system care: consist of (8) items and sub items, Identify manage of dysrhythmia: consist of (4) items and sub-items, Illuminations and events among team members: consist of (2) items and sub items).

The researcher observed and checked for correct or incorrect performance and then the practices as mean
(3) or (2) corrections episodes were rated as always, (one) correct practice was rated as sometime and non-correct practice rated as never.

Observational checklist practices were observed emergency nurses prior to performing on mannequin and simulation scenarios during Implementation of an educational program on emergency nurses. The educational program consisted of six sessions and was carried over a four-months period in the Emergency Medicine Department.

Content validity for the early developed instrument is determined through the experts’ panel to investigate clarity, relevancy, and adequacy of the questionnaire to measure the concept of interest.

The educational program consisted of six sessions and was carried over a four-months period in the Emergency Medicine Department. The researcher observed and checked correct or incorrect performance. A practice checklist for emergency nurses was given to them prior to performing a manikin and simulation scenarios during either the morning or the afternoon times. The plan of the education program was discussed; the implementation of the program was introduced to the study group and has included the following:

1. Demographic data are filled by each emergency nurses in study and control groups at the emergency medicine Department in Baghdad City

2. Emergency Nurses Knowledge test (Questionnaire)

3. Emergency Nurses practice by observational (check list)

4. Implementation of an educational program is designed and presented in six sessions. Every session takes approximately three hours from (9-12) a.m. (Per day), and 5 days per week for two weeks (including pre-test and post-test both Knowledge and practice (study group).

The data were analyzed through the use of statistical procedures and using the SPSS (Statistical Process for Social Sciences) version 24 application Statistical analysis system.

Discussion of the Results

Part II: Discussion of the Difference in participants’ overall knowledge about ACLS: It is clear that six items of Emergency nurses’ knowledge (two for knowledge about CVS physiology, two for respiratory system physiology, one for ACLS indications, and one for electrical therapy) are of medium mean scores with low Relative Sufficiency (R.S) and their assessment is low and all other items in all subdomains are of low mean scores with low R.S. and their assessment is low in the pretest time.

In the posttest time, one item was of medium mean scores with low R.S. and their assessment is low. Furthermore, nine items (one for knowledge about CVS physiology, two for respiratory system physiology, one for cardiac electricity, one for ACLS indications, one for electrical therapy) were of medium score high-mean scores, and all other items were with high R.S. and their assessment is high with statistically significant differences in 19 items.

Roth, Parfitt, and Brewer (8) Nurses rotated through an ACLS OB course when their ACLS recertification was due. Two studies were done. Prior to the class, nurses participated in a maternal mock code drill during annual skills review, and performances were scored. One year later, nurses participated in maternal mock code drills. Results were compared with the previous year’s scores. In the second study, pre- and post-class surveys were completed reflecting nurses’ satisfaction and self-confidence with successfully completing elements of American Heart Association (AHA) algorithms following attendance at traditional advance cardiac life support classes versus ACLS OB.

Part III: Discussion of the Difference in participants’ practice related to ACLS: One item of Emergency nurses’ practices related to ACLS is of medium mean scores with low R.S. and its assessment is low, and all other items are of low mean scores with low R.S. and their assessment is low in the pretest time. In the posttest time, three items were of medium mean scores with medium R.S. and its assessment is moderate. Furthermore, all other items were with high R.S. and their assessment is high with statistically significant differences.

There is a statistically significant difference in nurses’ practice related to ACLS in the study group (p-value = .000). For the control group, there is no statistically significant difference in nurses’ practice related to Advance cardiac life support.

There was a noticeable increase in the mean score of nurses’ overall knowledge about ACLS in the study group from 41.11 in the pretest to 52.69 in the posttest. For the control group, there was a trivial decrease in the mean score of nurses’ overall knowledge about ACLS from 44.46 in the pretest to 41.80 in the posttest.

Nambiar, M., Nedungalaparambil, N. M., & Aslesh, O. P. (2016). (9) The emphasis for over a decade, a low level of knowledge on BLS and ACLS among healthcare workers, particularly the Keralite physicians in this study, is a matter of concern. A strict accreditation/licensing program and periodic revision of life saving practices is the need of the hour. Inadequate improvement in knowledge levels even after BLS/ACLS training also points to an urgent need for innovative educational programs with an impetus for novel life support skills training in healthcare curriculum. This would help improve.

Clinical practices motivate better emergency care and foster research among future health professionals in this field in addition to bettering resuscitation skills training.

Conclusions

1. Male nurses employment more than female employment.
2. The educational program in enhancing nurses’ knowledge about cardiovascular system physiology, respiratory system physiology, cardiac electricity, ACLS indications, devices and tools used in Advance Cardiac Life Support and defibrillations the positive out come.
3. Improvement in the practice of Emergency Nurses’ was clearly observed in the study group through comparing pre and post education program, a highly significant association between the study and the control group in the post observational checklist all domains (cardiovascular system physiology, respiratory system physiology, cardiac electricity, ACLS indications, devices and tools used in ACLS, defibrillations.
4. Concerning the demographics as determinants of ACLS knowledge and practices, nurses’ age, level of education, years of experience in emergency
room years of experience in nursing have no statistically significant influence on nurses’ knowledge domains and practices both in the pretest and posttest times.

**Recommendations**

1. There is a need to implement a similar study on larger sample size.

2. Applying the educational program in all sections of the emergency and the training of emergency nurses and continue education in all emergency department in ministry of health There is a need to incorporate the Advance Cardiac Life Support materials into the curricula of various nursing programs

3. It is necessary to dedicate a space in the continuing medical education (CME) activities for the Advance Cardiac Life Support.

4. There is a need to keep updated with the American Heart Association Guideline for ACLS and apply it in the health care organizations in Iraq.

5. Establishing a new department in the institutes, studying emergency and dealing with cardiac arrhythmia.

6. presentation of an educational program specialist can be designed to nurses toward emergency and critical care units. Nurses’ knowledge and practices were improved significantly concerning one of the most important areas of nursing care to provide for the cardiac arrest patients at the critical care areas. improvement obtained a previous training courses Knowledge and practice was improved nursing education among

7. Continuous In–service training programs for the purpose of updating the knowledge and skills of nurses working with cardiac arrest patients.

8. A periodic evaluation of the critical care nurses’ knowledge and practice as regards different nursing procedures at the intensive care unit must be carried out in order to obtain data which determine the level of knowledge and practice in advanced cardiac life support.

**Conflict of Interest:** The researchers report no conflict of interest.

**Source of Funding:** This study did not receive any funding from any agency.

**Ethical Clearance:** A permission to conduct this study was obtained from the ethical committee in the College of Nursing, University of Baghdad.

The Impact of Chess Games towards Comfortableness of Cognitive Mind on Elderly

Wildan Agung Wahyu Laksono1, Joni Haryanto1, Khoridatul Bahiyah1
1Faculty of Nursing, Universitas Airlangga, Mulyorejo street Campus C, Surabaya (60115), Indonesia

ABSTRACT

Background: Dementia is a part of neurodegenerative process that occurs in the elderly caused by a decline in the cognitive function. Playing a board games, for instance chess, can promote the elderly’s mood as well as provide more intense time to interact with each other. It is a means to reduce the dementia effect. Based on that notion, further research is required on the impact of playing chess to elders.

Objective: This study aims to analyze the impact of chess game towards a sound mind (cognitive) on the elderly with dementia.

Method: This study employed quasi-experimental study. The population in this study was elderly with dementia in Lamongan, Indonesia. The selected method to choose the research location and population was multistage sampling method, by randomly selecting a location to be the location sample in this research, as well as in deciding the sample population. The respondents in this study were 20 people, consisting of 10 people in intervention group, and 10 people in control group who were grouped by using the formula based on Judy Bean’s formula in her research. The independent variable was chess game, and the dependent variable was a sound mind (cognitive). The data were collected using MoCA-Ina questionnaires and then analyzed using Paired T-Test and Independent T-Test with a significance level of α ≤ 0.05.

Results: The results suggested that chess game could provide a sound mind (cognitive) on elderly with dementia in the intervention group (p=0.000), and there was no influence in the control group (p=0.758). There was a different level of sound mind (cognitive) between the intervention group and the control group (p=0.008).

Conclusion: It can be concluded that chess game could generate a sound cognitive mind for elders, that may lead to a declining effect of disease. Elders became more active in thinking than before and their long term memory span increased.

Keywords: chess game, sound mind (cognitive), dementia, elderly

Introduction

Dementia is a neurodegenerative process with cognitive decline symptoms, including memory, language, attention, executive function, and visuospatial function decrease. The symptoms of dementia include decreased memory, difficulty in communicating, and alterations in mood and habits (1). There are various ways that may be applied to maintain cognitive functions to keep the dementia level from being worse. Chess game is one of cognitive activities. Nevertheless, the impact of chess games towards a sound mind (cognitive) on elderly with dementia still requires a further research (2).

A cognitive function decrease is one of the dementia symptoms. Dementia is a neurodegenerative process with symptoms of cognitive impairments, including both short and long-term memories, as well as intellectual decline. The cognitive decline can cause a decrease in the comfort level, making it difficult for the elderly to receive information (3).
Comfortableness in mind of human brain can be achieved if the cognitive function is in a good condition. Cognitive function is the ability to recognize conditions associated with experience and intelligence. Cognitive abilities include memory, attention, executive functions, language skills and visuospatial functions (4). Fitzpatrick (2013) and Sitzman (2011) developed Kolcaba’s Theory of Comfort with the main concept referred to as the Health Care Needs defined as the need to obtain comfort and to rise from a stressful situation. The needs include physical, psychospiritual, social, and environmental needs obtained through monitoring, verbal and non-verbal reports, pathophysiological parameter-related needs, education and support, as well as the need for financial counseling and intervention (5).

Chess game is a game played by moving pieces from one cell to another, with the aim of capturing the opponent’s pieces. This game has two aspects, namely psychological and social aspects. In the psychological aspect, this game can stimulate the minds of the elderly who play it into a comfort state. On the social aspect, this game allows the elderly who play it to interact with each other, resulting in a social comfort increase (3). Chess games performed as interventions for 14 sessions in 2 weeks with the duration of 30 minutes can enhance the cognitive function. In this study, the duration lasted 60 minutes. The objective of this study was to analyze the impacts of chess game towards comfortableness of mind (cognitive) on elderly with dementia in Karanggeneng Village, Lamongan Regency, Indonesia.

Material and Method

The research design was a quasi-experiment, which is a research method that aims to reveal cause and effect by involving control groups in addition to the experimental group (6). In this research, a pre-test was performed before giving treatment, followed by a posttest after giving treatment.

Population, Sampling and Samples: The covered population in this study was 36 people with dementia aging 60 to 74 years-old. The inclusion criteria of this research were the elderly who were able to communicate, had the experience or could play chess, and were cooperative. The method used for the location selection was multistage sampling method, which was to randomly choose a location to represent sample locations in the study. This study selected one of the sub-districts in Lamongan from 27 sub-districts, followed by choosing one village from 474 villages randomly. The sample selection applied a simple random sampling approach to represent the population, determined by the researchers. This study employed two variables, i.e. chess game as the independent variable and comfortableness of mind (cognitive) as the dependent variable (7).

Data Collection and Processing: The instrument used to regulate the dependent variable in this study was the Montreal Cognitive Assessment that had been modified into Indonesian, abbreviated into MoCA-INA, both in the pre-test and the post-test. The complete MoCA-INA consisted of 13 test items covering 8 domains of visuospatial/executive (3 items), naming (1 item), memory (1 item), attention (3 items), language (2 items), abstract (1 item), repetition (1 item), and orientation (1 item). The highest score was 30 points. The score of 26-30 was translated as a normal condition while the score of less than 26 was labelled as below normal. Data is processed by Software Product & Service Solution (SPSS).

Paired T-test | p = 0.000
Independent T-test | p = 0.008

Table 2 demonstrates the results of the Paired T-Test statistical test in the intervention group where the p value obtained is less than α (α ≤ 0.05) namely p = 0.000. The different results were indicated in the control group where the p value were greater than α (α ≤ 0.05), namely p = 0.758. The results of the Independent T-Test statistical test in both intervention group and control group obtained p value of less than α (α ≤ 0.05), namely p = 0.008.

Discussion

Based on the research results, the average score of the pre-test of the comfortableness of mind (cognitive) in the control group was 20.10 and the average score of the post test amounted to 20.0 with an average score decrease of -0.1. The results of the Paired T-Test statistical test demonstrated a p value of 0.758. This means that there was no significant change in the value of comfortableness of mind (cognitive) in the control group. Eighty percent of the respondents in the control group had a smoking habit, and 40% of them had a hereditary history of dementia which was more than the percentage in the intervention group. In the control group, there was also no stimulation to retain comfortableness of mind (cognitive). The results of the Independent T-Test, as a comparison between the intervention group and the control group, proved that on the post-test, the chess game intervention generated a p value of 0.008.

In the visual function, the visual process begins with a series of cells and synapses that carry visual information from the environment into the brain to be processed. This process involves the retina, the optical nerves, the optical tract, the lateral geniculate nucleus (LGN), the optical radiation, and the striate cortex. Then, it proceeds further to the thalamus which is a part of the limbic system (9). Likewise, in the kinesthetic functions, stimulus is received by the skin which is the outermost part of the body. It is then passed on by afferent nerves to the spinal cord, then to the parabrachial complex, periaqueductal grey, and ends in the limbic system (10).

All stimuli and information that has arrived in the limbic system are processed by the hippocampus and amygdala. The hippocampus is a part of the limbic system that regulates memory formation, while the amygdala is a part that regulates emotions and feelings. The stimuli and information are then processed to the pre-frontal cortex (11). If conducted repeatedly, this process will...
affect the comfortableness of mind (cognitive) on the elderly with dementia.

Other factors that support an increase in the level of mind comfortableness (cognitive) are the level of the respondents’ education, employment, coffee consumption (lifestyle), and heredity factor (12). The higher the level of one’s education, the easier for them to receive cognitive stimulation in the brain. If the brain is often used to think actively, both in daily activities and in working situation, its performance can be affected and makes it capable of slowing down the cognitive function degeneration (13). In this study, comfort was obtained from the intervention of chess games, making the mind (psychology) and social state of the respondents comfortable (4). Mind comfortableness was also influenced by the intervening variables include internal factors such as genetics, age, and gender as well as external factors such as education, employment, and lifestyle (13).

In this study, the elderly who tried to minimize the impact of dementia would also be influenced by related institutions, including the elderly’s groups and communities, the community clinics, and also the hospitals (15). The elderly will also consider where they can seek treatment, by looking for institutions that have good policies and services to reduce the impact of dementia, as well as affordable prices in every health service (11). The limitations of this study is that the proportion of respondents were entirely male so that the results obtained cannot represent female clients.

**Conclusion**

Based on the objective of this study, which is to determine the impact of chess game towards the elderly with dementia, this study indicated significant results for the improvement of convenience of mind in elderly with dementia by providing chess game intervention. The elderly got easier to remember things and had sharper long-term memory towards everyday problems.

**Ethical Clearance:** The research process involves participants in the survey using a questionnaire that was accordant with the ethical research principle based on the regulation of research ethic committee. The present study was carried out in accordance with the research principles. This study implemented the basic principle ethics of respect, beneficence, nonmaleficence, and justice.

Lighting and Noise Levels in the Neonatal Intensive Care Unit (NICU)

F. Sri Susilaningsih¹, Siti Yuyun Rahayu Fitri¹, Ai Mardhiyah¹, Ermiati¹, Yanti Hermayanti¹
¹Faculty of Nursing Universitas Padjadjaran, Jl. Raya Bandung Sumedang KM 21 Jatinangor, Kab. Sumedang, Jawa Barat Province, Indonesia

ABSTRACT

Environmental aspect including noise produced by medical devices as well as lighting levels in Neonatal Intensive Care Unit (NICU) are pain and stress stimuli for neonates in Neonatal Intensive Care Unit (NICU). Pain response and stress reaction of neonates can affect their neurologic development, negatively affecting many aspects of their future life. In Indonesia, there is no data on noise level (sound intensity) and lighting level in NICU in Indonesia. This study aimed to identify lighting and noise levels in NICU using descriptive observational study design. This study was done in the NICU of a referral hospital in Indonesia. The mean lighting level in the incubator, NICU, and phototherapy box were 6 – 20 lux; 108 – 148 lux (mean 120.33; median 116.95); and 2000 – 3500 lux respectively. Moreover, the noise level in incubator and NICU were 45.73 – 62.84 dB (mean 53.63, median 53.4) and 59.03 – 76.07 dB (mean 64.15, median 62.18) respectively. NICU lighting levels was optimal for patient safety, however phototherapy produced high lighting level. Noise level was above the recommended 45dB standard. In conclusion, the stress potential of neonates in NICU was high.

Keywords: lighting, noise level, neonates, NICU

Introduction

Neonatal Intensive Care Unit (NICU) is an intensive care unit specializing in the care of ill or premature newborn infants. NICU is equipped with advanced devices to support premature babies, therefore it is not an ideal environment for the growth and development of the neonates.(1,2). NICU’s physical environment is very different compared to intrauterine environment, hence demanding the neonates to adapt physiologically to the environment. (3)

During treatment in NICU, premature infants receive medical and non-medical care due to their physiological limitations, resulting in stimulation or even overstimulation on their body. Stimulations such as lighting, noise and pain from repeated medical action will induce stress. Stress in premature infants can affect hypothalamic function which in turn adversely affect growth and neurological mechanism. (4)

Noise is of the stress inducer for premature neonates cared in NICU. The American Academy of Pediatric suggest that noise level for NICU is below 45 dBA. To support hearing development, NICU’s sound level should be similar to intrauterine environment. However, in reality, there were many unpredictable sound such as alarm, ventilator, radiant warmer, infusion pump, incubator, noise from nurse’s and family’s mobility, emergency trolley circulation, opening and closing of cabinets, garbage cans and doors, as well as sounds produced by air conditioners. (5,6). Another study showed that the most dominant sound is produced from incubator and health worker conversation. (7)

Previous study showed that noise level in NICU and incubator ranged between 52.6-80.4 dBA and 45.5-79.1

DOI Number: 10.5958/0976-5506.2019.02548.8
dBA respectively. (8) Another study identified that noise level in NICU was approximately 71.2 – 83 dBA. (6) This is above the noise level recommended by American Academy of Pediatrics. (9)

Excessive noise exposure may induce stress in premature infants. (10) Stress in preterm infants could generate disturbance and increase mortality rate. Moreover, noise in NICU was main cause of stress in preterm infants. (11) Stress caused by excessive noise exposure will affect their physiology such as increased blood pressure, heart rate, respiratory rate and decreased oxygen saturation, leading to increased oxygen demand and caloric consumption. (12) Long-term impact of noise exposure are disturbance of language development, growth, and hearing system. (7) High risk-neonates in NICU are 20 times more likely than infants in general room to experience hearing loss. (13)

NICU’s lighting play an important role in newborn development. Excessive lighting generates negative impact including weight gain disturbance, sleep disorder, and stress in infants. Moreover, it disturbs retinal development in preterm infants. (1,2)

Sudden changes of lighting also affect the visual function of preterm newborn due to their thin eyelids. An investigating showed that slowly increasing procedural lamp intensity allowed infant to adapt more easily and prevent decreased oxygen saturation. (14) Those, infants’ eyes should be protected from bright procedural lamps. (15)

The American Academy of Pediatric recommends that lighting level in NICU ranges between 10-600 lux. Light restriction in the NICU stabilize the physiological state of the newborn, including stable breathing, decreased heart rate, blood pressure and motoric activity, as well as shorter duration of mechanical ventilation and oxygen support. (3)

In addition to inappropriate exposure to noise and lighting, pain caused by invasive procedure also affect the growth and development of premature infants treated in NICU. 79% procedures conducted in NICU were painful. (4) Premature infants receive on average 5-15 painful procedures daily in NICU. (16) The number of painful procedures is directly correlated to delay in growth and brain function development. In addition, repeated painful sensations can activate stress signal and affect their growth and development in the future. (4)

There is no data on the lighting and noise level specific to NICU in Indonesia. Therefore, this study aimed to identify lighting and noise level (sound intensity) in the NICU.

**Material and Method**

This was a descriptive observational study. Data was collected using 2 instruments including sound-meter and lux-meter (Lutron series SL-4112P), checklist and documentation study. The study was conducted at the NICU of a provincial referral hospital in Indonesia. Lighting and noise levels were measured hourly (in 24 hours) for 11 consecutive days and performed on 8 incubators, 2 non-incubator beds and NICU space environment. We calculated the average value per day for 11 days and the average of each bed (incubator and non-incubator) and the NICU. The results is listed in graphs 1-3.

Microphone of the sound-meter and light sensor of lux-meter were placed 10 cm from the infant’s head to measure the noise and lighting level. The measurement equipment were all new and calibrated every day according to their respective manual.

Ethical clearance was obtained from the hospital prior to data collection.

**Finding**

The average lighting level in incubator (graph 1) ranged between 6 – 20 lux, in NICU 108 – 148 lux (mean 120.33; median 116.95), and in phototherapy box (graph 2) were 2000 – 3500 lux. Noise level in incubator (graph 3) was 45.73 – 62.84 dB (mean 53.63; median 53.4) whereas in NICU was 59.03 – 76.07 dB (mean 64.15, median 62.18).
Graphic 1: The lighting level in incubator and NICU area

Graphic 2: The lighting level of phototherapy box in NICU

Graphic 3: Noise level in the incubator and NICU area
Discussion and Conclusion

The result of the study regarding the description of lighting level and noise level consisted of two components, namely lighting level in incubator and outside incubator or NICU area. The lighting level of incubator with and without phototherapy were extremely different. Therefore the data were described differently between incubator with and without phototherapy.

Lighting level in incubator without phototherapy ranged between 6 – 20 lux; in non-incubator bed was 108 – 148 lux; while in phototherapy incubator was 2000 – 3500.

The recommended standard of lighting level for daily care in NICU is 10 – 600 lux (Figueiro, 2006), although 2000 is required special procedures that require adequate lighting (3,17)cost, energy and aesthetics, there appear different biological needs of patients, health care providers and family members. Communicational aspects of light, its role as a facilitator of the visual function of doctors and nurses, and its effects on the newborn infant physiology and development were addressed in order to review the effects of light (natural and artificial. Based on this recommendation, this study found that lighting level in this study was within normal limit. However, infants who received phototherapy received high intensity light, hence requiring monitoring and more effort to minimize the negative impact.

Environmental lighting play an important role in visual development (vision and visual) and visual cortex maturation. Excessive light exposure lead to immature eyes and is associated with poor clinical outcomes such as low weight, behavioral and sleep disorder, and increased stress level in preterm and seriously ill neonates. Sufficient lighting will stabilize neonates’ condition related to respiratory rate, blood pressure, motoric activity, and faster independence from ventilator and oxygen. (3,18)

This research found that noise level inside and outside of incubator or NICU area were 45.73 dB – 62.84 dB and 59.03 dB -76.07 dB consecutively. It showed that noise level inside an incubator was lower than outside of incubator or NICU area. Thus, infants placed outside of incubator were exposed to higher noise intensity compared to those inside the incubators.

The latest standard for noise level in NICU by American Academy of Paediatrics (AAP) was 45 dB for daily care and can be tolerated up to 50 dB for no more than 10% of the day, with a maximum level of 65 dB for no more than 1/20 seconds during measurement period. (19) According to this standard, noise level both inside and outside of incubators in NICU was higher than normal standard.

Excessive exposure to high noise level cause deafness due to damages in organ of Corti. In addition, noise also caused other disorders including increased adrenocorticotropic hormone (ACTH), poor cardiovascular response, effects on language development and sleep disturbance (19). A cohort study of 273 infants weighing less than 1500 grams and exposed to 65 dB of sound intensity showed that 10 infants developed sensorineural hearing loss. Moreover, from the study, 4 from 8 infants experienced bilateral hearing loss that require special education. Another finding suggest that mechanical ventilation and length of stay within the incubator significantly contribute to the hearing disorder. (19)

The lighting and noise level in NICU is originated from the devices in NICU itself such as ventilator, incubator, incubator transportation, apneustic monitor, phototherapy, central monitor and bedside monitor.

In conclusion, noise is an environmental aspect of NICU that could potentially cause stress and pain in neonates. Noise came from medical devices such as incubator’s motor, alarm of various devices, and voice of health workers. Lighting level for daily care was within normal limit, whereas lighting level of infants undergoing phototherapy showed very high values. Therefore, efforts should be made to anticipate unwanted effect of lighting and noise level on the infants. Pain assessment could indicate infant’s stress level and thus is very important and should be done routinely in order to cater appropriate interventions that meet the needs of infants.

Psychological Treatment for Major Depressive Disorder: Effectiveness of Cognitive Behavioural Therapy

Jirushlan Dorasamy
Masters, University of Monash, Melbourne, Australia

ABSTRACT

Major depression, as a recurring and disabling disorder, can have a negative effect on the psychological and physical well-being of patients. Various psychological and medical interventions are generally used for patients with major depressive disorders. Patients suffering from major depressive disorders (MDD) may be subjected to medication only or medication may be used concurrently with psychological interventions. Psychological interventions like cognitive behavioural therapy (CBT) uses behavioural and cognitive principles to treat patients suffering from MDD, by helping them to identify, understand and analyse how the interaction of their thoughts, moods and behaviours triggers and aggravates depression. CBT has been beneficial in treating patients suffering from comorbidity of MDD with other disorders. While there is empirical and theoretical evidence supporting the use of CBT under various treatment settings and patient characteristics, research findings indicate varying rates of adequacy of the treatment. Further investigation of potential prescriptive risk factors associated with MDD in different contexts can help to predict more unbiased and consistent responses to different CBT techniques. This will make a valuable contribution to improving the use of CBT techniques for patients with different depressive characteristics and across different treatment settings and modes of delivery.

Keywords: Cognitive Behavioural Therapy, Major depressive disorder, psychological interventions.

Introduction

As a common chronic disorder, MDD is ranked as a major cause of disability. In treating MDD, research shows that only medication can be used to treat patients suffering from MDD, or alternatively psychological interventions can be used concurrently with medication as a treatment option. Studies by Parik et al., Cuijpers et al. and Renn and Areán, argue that CBT can be effectively used as a psychological intervention (1-3). However, studies by Berking, Ebert, Cuijpers and Hofmann(4) and Bet(5) also indicated that while there is evidence of the efficacy of CBT, about 50 % of patients do not show significant clinical changes, while between 40 and 60% of patients relapse after acute treatment. While there is limited evidence to show that CBT can totally eradicate MDD, empirical and theoretical findings reveal that CBT can help to reduce the severity of MDD. However, the treatment adequacy of CBT for patients with different depressive characteristics and under varying treatment settings have shown to yield variances in treatment adequacy rates. Deepening an understanding and knowledge of CBT will add value toward improving CBT techniques, strategies and modes of delivery for patients with MDD, in an attempt to enhance their physical and psychological well being.

A diagnosis of Major depressive disorder (MDD) is characterised by at least a one 2-week major depressive episode(6), with patients experiencing significant impairment in functioning and clinical distress (7). MDD can recur due to factors like scarring from previous depressive episodes and inherent patient characteristics inclined toward recurrence (8). Optimizing the efficacy of interventions in the MDD phases is crucial to avoid the risk of recurrence, since the risk of recurrence escalates with each episode of MDD(9).

Risk factors and modes of delivery associated with major depressive disorder: CBT is based on the theory that depression is underpinned by behaviours, thought and beliefs that may be negative and incorrect (2). There are several risk factors associated with MDD. For example, early negative events like inconsistent disciplining can lead to maladaptive emotions associated with loss and failure, ultimately leading to depression (10). Additionally, adaptive thoughts can be hampered by negative beliefs emerging from automatic negative thoughts and cognitive distortions (9), invariably impacting how individuals perceive events.

Further, findings by Knapen et al. (6) points to high levels of physical impairment caused by obesity, that is associated with depression (11). The authors also cited other influences like medical diseases; drug and alcohol abuse; chronic stress and pain; and social influences impacting maladaptive behaviour and thoughts associated with depression (6).

Physiological stressors associated with depression can also be influenced by physical inactivity (12). For example, Knapen et al. (6) reported that individuals with metabolic syndrome, caused through physical inactivity, have a relatively higher risk to develop depression than individuals without metabolic syndrome. As argued by Titov (15) that since MDD is a complex disorder, with risk factors remaining inconclusive, perhaps ongoing research can provide more evidence on the associated risk factors.

In comparing various modes of CBT delivery, the meta analyses by Richards and Richardson (14) reported that psychological treatments using specific computer programmes and the internet were just as effective as face to face CBT. Renn & Areán (3) supported the use of both modes for CBT, especially among older patients who do not have close access to treatment facilities, may experience physical difficulty travelling, and cannot afford travelling. The use of technology for CBT treatment, not only increases accessibility, but it also broadens opportunities to use multiple modes of delivery.

Further, the study by Linde et al. (16) indicated that guided self-help by remote based therapists like using the telephone and video conferencing yielded similar effects as personalised face to face CBT. Additionally, Simon et al. (18) reported CBT with a live therapist delivering treatment by telephone improved treatment satisfaction and efficacy compared to ADM alone. While these studies show the benefits of CBT as a treatment intervention for MDD, research findings do not conclusively point to the efficacy of any single mode of delivery of CBT. It can therefore be posited that various factors pertaining to the patients physical, environmental and mental condition must be considered.

Benefits of cognitive behavioural treatment for major depressive disorder: CBT interventions like self-control, role play, restructuring thoughts and stress management specifically teach patients adaptive ways to replace dysfunctional thoughts, moods and behaviours and develop skills to regulate emotions, decrease feelings of worthlessness, help in managing stressful and emotional events, increase the capacity to solve problems and strengthens cognitive control (13,16,19).

Various meta analyses since 2009 have not challenged the findings that CBT is as effective as ADM when the severity of the depressive disorder is not considered and that the combination of both is more effective (1-3, 11, 18). However, research findings still support the claim that psychological treatments like CBT is more effective for patients with MDD compared to patients with minor depression (19). Further, when the characteristics of patients are considered, ADM is less effective than CBT for treating MDD. Examples include patients with MDD who may be unable to take medication because of additional health reasons or may have a tendency to respond poorly to medication. Further, Renn and Areán (3) reported that especially for older patients, psychological treatments may be more viable in view of higher vulnerability to the side effects of drug sides and for those suffering from cognitive impairment.

Additionally, CBT is beneficial for pregnant women who cannot be prescribed ADM because of the side effects on the foetus. Unlike ADM, CBT is effective for all age groups, sexes and individuals from different ethnic and cultural backgrounds. This suggests that a wider scope of patients can benefit from CBT, compared to other psychological and ADM treatments.

Additionally, studies by Cuijpers et al. (1) and Simon et al. (19) revealed that patients treated with ADM showed higher recurrence/relapse rates than those patients treated with CBT treatment during the acute phase. Supporting findings by Richards and Richardson (14) showed that CBT treatment in the acute phase enhanced the efficacy
of preventive psychological intervention. However, Bockting et al.\(^{(9)}\) argued that while CBT in the acute phase may inhibit greater chances of a relapse compared to ADM after both interventions were discontinued, the overall rate of relapse is frequently high. A suggested prevention strategy for a second relapse by Jarrett et al.\(^{(19)}\) is to continue the same psychological treatment used in the acute phase.

Regarding long term strategies to minimise the recurrence or relapse of MDD, findings by Berking, Ebert, Cuijpers and Hofmann\(^{(10)}\) and Bet\(^{(5)}\) indicated that CBT reduced the relapse or recurrence of MDD compared to active controls like ADM. While the studies reported that relapse risks were reduced if preventive CBT was provided after remission, further large scale research is needed to validate the benefits of psychological treatments as an alternative to the use of ADMs in the long term. Bockting et al.\(^{(9)}\) supports the view that CBT is a valuable intervention for patients who are at a greater risk of relapse. Meta analyses by Cuijpers et al.\(^{(1)}\) indicated that CBT used in the continuation phase also appeared to reduce the risk of relapse. However, since there is limited research showing the preventive effects of other depression-specific continuation therapies, additional research is needed to deepen an understanding of different interventions to manage MDD.

Meta analyses by Parikh et al.\(^{(2)}\) showed evidence that CBT was not only the most recognised and established first line treatment for acute and maintenance depression, but also most effective for patients who did not respond to ADM. Despite findings from various studies, further research is specifically needed to investigate the efficacy of CBT compared to other psychological treatments for patients who did not respond to ADM.

The use of the internet and computer based CBT to treat disorders that have comorbidity with MDD is not only more cost effective, but also accessible to patients who cannot access contact treatments or do not prefer contact treatment. In this instance, patients and health care systems are relieved of unnecessary constraints or limitations associated with contact treatments. For treatment settings that are either contact or non contact, optimal benefits are dependent on relevant and ongoing staff training and guidance, to ensure patients receive the requisite support in real time.

While research has shown the benefits of CBT, the meta-analysis by by Linde et al.\(^{(16)}\) and Simon et al.\(^{(18)}\) reported that apart from CBT, other psychological interventions also shared the enduring treatment effects after the discontinuation of the acute phase treatment. While these findings suggest that other psychological interventions also have enduring effects, there is no conclusive evidence showing which of the treatments have the highest enduring effect. Therefore, further research is needed to address the gap in evidence.

However, maximising the beneficial effects of any one psychological intervention or combination of interventions requires an indepth understanding of the predictors of various responses to different kinds of treatment and the nature of treatment offered in the various phases of depression. While several studies\(^{(9,10,13)}\) posited that unstable remitters and higher rates of past episodes of depression benefitted more from preventive CBT, studies by Jarrett et al. \(^{(19)}\) on relapse prevention did not support this. This may possibly be due to studies that did not have different groups with different rates of depression episodes. Further research in this regard, will be valuable in deepening an understanding of relapse prevention using CBT or a combination of interventions.

**Factors determining rates of treatment adequacy:** Structured facilitation by experienced health professionals is fundamental in helping patients to release negative memories and feelings and help them to understand maladaptive thoughts and behaviour through the use of appropriate CBT techniques that respond to the needs of the patient.

The study by Parikh et al. \(^{(2)}\) suggested that empathy, genuine respect and interest in the well being and safety of patients with individual differences strengthens the therapy alliance between the two. Further, feedback from patients is important to monitor treatment adequacy, symptoms and experiences and to determine timeously the need for changes in approach \(^{(2)}\).

In terms of specific environments, studies showed adequacy of CBT being more pronounced in specialised care than in primary care \(^{(17-19)}\), since patients with MDD received direct treatment from more educated and experienced practitioners, focusing specifically on psychological symptoms \(^{(5)}\).

The training of clinicians in evidence based treatment, access to experts, mentors and peers who provide invaluable first hand knowledge, on-going support, access to facilities and incentives for clinicians...
in evidence based treatment is a critical determinant of adequacy of treatment, since it helps clinicians to adapt practices to individual needs (3).

It is also important to consider the preference of patients, since enhanced patient outcomes is dependent on the needs of patients be addressed. For example, there is growing evidence that patients are increasingly preferring psychological treatment compared to ADM (2). However, studies by Renn and Areán (3) found that especially in older patients, factors like treatment costs, transportation costs and travelling difficulties mitigated their choice of treatments.

Ultimately, adequately resourced and managed treatment settings, qualified health professionals, addressing patient needs comprehensively and ongoing support are some of the critical determining factors for adequacy of treatment. In the absence of this, the efficacy of treatments like CBT can be compromised.

**Conclusion**

Various considerations determine the efficacy and adequacy of CBT to help patients to identify and replace maladaptive thoughts and behaviour. Unlike antidepressants which have dosages that are standardized, CBT is influenced by multiple factors like the training and experience of the therapist; treatment settings, patient characteristics, ongoing support and the quality of content. It is increasingly challenging to ensure that diverse and sometimes competing complexities are managed to ensure optimal success.

CBT is an effective psychological intervention to treat the various phases of MDD, provided the treatment is properly managed to improve physical and psychological well-being. Since much research also shows that treatments such as CBT can only reduce one third of the disease for those affected by MDD even under optimal prevailing conditions, further research on prevention strategies rather than treatment of MDD can greatly help in decreasing incidences of MDD (17). Additionally, despite expansive research reporting CBT as an effective psychological treatment, meta-analysis by Amick et al. (13) and Cuijpers, van Straten, Bohlmeijer, Hollon and Andersson (1) indicated that previous studies overestimated positive treatment effects. Their meta analysis drew attention to many CBT studies often focusing only on certain techniques of psychological treatment, specific modes of delivery or particular target groups. Demographic factors like gender and age; and clinical factors like recognition of the mental problem, comorbidity and recurrence were often not considered, thereby neglecting to analyse the influence of such factors on the adequacy of CBT. Therefore, it can be suggested that more representative studies can possibly generate strategies to optimize the efficacy and adequacy of CBT as a psychological intervention in treating MDD.

Finally, future research based on longitudinal studies can analyse specifically reported data by patients, with the aim of identifying a typology of potential risk factors and to help predict responses to different kinds of cognitive behavioural therapy that yield more unbiased and consistent outcomes. Despite widely published evidence on the effectiveness of psychological interventions, further research is required to address the aforementioned unresolved focus areas.

Value of Understanding Personality and Proactive Coping for University Students

Jirushlan Dorasamy
Masters, University of Monash, Melbourne, Australia

ABSTRACT
Coping in different situations involves the use of personal skills, attributes and various support mechanisms to manage challenging and stressful life experiences. There is a plethora of research focusing on coping as a response to a threat. However, there is currently increasing research focusing on coping as a proactive and future oriented strategy. Proactive coping draws on identifying resources that can be used to address challenges and pursue personal growth by overcoming negative outcomes associated with stressors. It is often argued that proactive coping is influenced by innate dispositions associated with personality traits. The Five-Factor Model is a trait based approach to understanding personality, which analyses emotion and cognition behavior. The model consists of Openness to experience, Conscientiousness, Extraversion, Agreeableness and Neuroticism. While experiences and situational factors can influence coping, personality traits can also affect coping ability. The Five-Factor personality model can be used to gain more indepth insight into how individuals with different personality traits cope with stressors. Further, it can be argued that there is a relationship between personality traits and proactive coping ability. The Five-Factor Model is used to argue that personality traits relate to proactive coping and that personality plays a critical role in coping styles and coping ability.

Since coping is multi dimensional in nature, individuals with different personality traits will cope differently during stressful situations, even in anticipation of stressful situations. Understanding the relationship between proactive coping and personality traits is important, especially for university students who often find themselves in stressful situations and cannot cope. Through the use of proactive coping strategies, students will be ready to manage stressors more effectively, ultimately enhancing their experiences through positive outcomes.

Keywords: Five-Factor Model, proactive coping strategies, personality traits,

Introduction
As an important adaptive strategy, proactive coping can help people to prepare for obstacles that are unavoidable. From the perspective of university students, proactive coping is necessary in helping them to adjust. The Five-Factor Model is used to show that proactive coping is associated with individuals who have personality traits that do not allow stressors to cause emotional distress. Rather their personality traits provide them with the capacity to consider stressors as challenges that encourages them to succeed. The paper identifies which of the five personality traits are predictive of proactive coping and the characteristics within the personality traits influencing proactive coping.

Initiating action in a problem-solving manner that reduces or removes the impact of stressors requires the use of coping strategies. Internal and external stressors can be managed through the use of behavioral and cognitive endeavours. The behavioral aspect includes strategies used to change a situation which is problem-focused coping or manage stressful emotions which is emotion-focused coping. The cognitive aspect includes the use of strategies that relate to how threatening or important the stressor is to the well-being of the person.
In anticipation of stressful events, individuals with proactive coping strategies actively seek new challenges that have not occurred. Proactive coping strategies are adopted to mitigate negative outcomes of potentially challenging situations\(^{(4)}\). Such coping which is challenge driven and future oriented, can enable people to prepare for stressors which are seen as challenging\(^{(1)}\).

It can be asserted that individuals with proactive coping strategies have personalities that make them think and behave in ways that support proactiveness in challenging situations. Since development of the personalities of individuals over time is largely influenced by personal memories, values, habits, attitudes, socialism and skills, their ways of thinking and behaving become distinctive. This is supported by Cervone and Pervin\(^{(5)}\) who argue that personality traits can be aligned to “psychological qualities that contribute to an individual’s enduring and distinctive patterns of feeling, thinking and behaving.” In this regard, the Five-Factor Model (FFM) provides a valuable multidimensional account of the structure of personality. The FFM consisting of Neuroticism, Extraversion, Conscientiousness, Openness to Experience and Agreeableness has more specific personality facets under each personality dimension. Neuroticism represents stress, depression and anxiety which is experienced differently by individuals. Extraversion is seen as a positive and warm trait. Conscientiousness is illustrated through the achievement of goals, morals and values. This personality factor is guided by the social aspects of life and oriented for future success. Openness to Experience is associated with being positive, creative, intelligent, and being amenable to try new things. Agreeableness is characterized of being supportive, trustworthy and nurturing\(^{(6,7)}\).

Coping is considered as constantly changing behavioral and cognitive efforts to effectively respond to particular internal and external demands on individuals. Research has linked coping strategies with different dimensions of personality\(^{(6)}\). Findings from past research have indicated that personality is one of the fundamental drivers associated with coping abilities, especially proactive coping\(^{(3,6)}\). Research has shown that personality traits can predict the coping strategies that individuals choose to use. Hambrick and McCord\(^{(3)}\) found that individuals who frequently used proactive coping strategies to manage their lifestyles, were most likely to espouse personality traits that were conducive to the successful use of proactive coping strategies. They concluded that proactive coping served as a buffer against negative outcomes. They claimed that this style of coping was effected by a proactive personality dimension that took initiatives, searched for opportunities and persevered until meaningful change occurred\(^{(3)}\). Instead of being constrained by situational impediments, proactive individuals seek opportunities to learn and are motivated to achieve higher levels of development. Such a personality trait is associated with positive outcomes.

Instead of giving up on stressful events, individuals with proactive personalities choose to rather identify the source of the stressor and find coping strategies to manage the stressor. The action oriented nature of such individuals is linked to their proactive personality of dealing with stressors. Hambrick and McCord\(^{(3)}\) found that the personality profile of individuals who demonstrate high counts of proactive coping ability is indicative of high levels of Conscientiousness, Extraversion and Agreeableness, while low levels of Neuroticism stems from depression and similar negative factors. This implies that proactive individuals experience lower levels of stress when addressing stress factors due to their proactive personality. Gan et al.\(^{(4)}\) supported this by arguing that proactive individuals who take purposeful and constructive actions based on appraisal of challenges and act ahead of time, experience lower levels of stress. Such purposeful and constructive actions is influenced by personality traits associated with Conscientiousness, Extraversion and Agreeableness. Therefore, it can be asserted that one of the ways to understand why certain individuals cope better by managing stressors in effective ways, an analysis of personality traits is integral. Personality traits impact positive coping outcomes. Evidence shows that proactive personality traits are negatively associated with avoidant, dysfunctional strategies that do not engage with the stressors in proactively. One such study by Major et al.\(^{(2)}\), revealed that individuals with proactive personality traits can mediate through challenges since they have the capacity to anticipate stressors. Such capacity enables them to use effective coping strategies to deal with stressful encounters.

It is valuable for university students to understand factors influencing their responses to stressors, as such
understanding can help them to mitigate the negative outcomes associated with stressful encounters. Entering an unfamiliar university environment can be accompanied by stressful situations for which most students may not be capacitated to deal with. Unanticipated, diverse, multiple and complex expectations within the university environment can lead to the inability to cope and maladjustment amongst students. University students endure stressful experiences emanating from academic, interpersonal, finance, living environment, health and self-imposed stressors. Gan et al.\(^4\) identified more specific stressors such as frustration, conflicts, pressures and changes in their study. Students who are disorganized and lack self-discipline may experience self-imposed stress. These negatively appraised stressors can be considered as consequences by students, rather than potential rewards.

Research points to coping styles and ways of coping that are influenced by the innate personality disposition of individuals. This points to the importance of recognizing the relationship between proactive coping abilities and the personality traits of individuals. Research shows that the personality of students within the university context impacts the ability to cope and influences adaptation through the use of proactive coping strategies\(^2, \ 8, \ 9\). In illustrating that proactive coping is commensurate with personality development, Douglas et al.\(^5\) argued that students with proactive coping personalities showed higher levels of time management which is associated with Industriousness and Orderliness. This was supported by evidence which showed that students who had study plans and completed their study requirements displayed personality traits linked to Orderliness, Industriousness, Intellect and Openness\(^8\). Such students transformed their mental capabilities into successful academic performance. They were able to do this through self-regulated learning that was founded on organizing themselves, setting goals and self-monitoring. These self management areas are associated with personality traits linked to enthusiasm, orderliness and industriousness. Further, Douglas et al.\(^6\) illustrated that university students who displayed traits associated with conscientious, showed time management behavior that produced positive outcomes and shared a positive relationship with industriousness. The implication is that individuals high on time management behavior, used their time productively and did not procrastinate making decisions. This helped them to cope with the completion of tasks, once they started. The authors further contended that if students have a state of mind that is work related and are motivated to invest time and effort into their work, then they will be inclined to show openness/intellect\(^8\). This was support in the findings by Akhtar, Boustani, Chamorro-Prenuzic and Tsivrikos\(^1\), which found a positive relationship between work engagement and openness/intellect. Therefore, it can be argued that since students with the openness/intellect trait have wide and insightful interests, the interest in working with new study material is reinforced. This type of proactive coping is positively associated with active planning, control, forward thinking and self-esteem. This claim is supported by Major et al.\(^2\) who stated that students who deal with the source of stressors, plan and take action, can be considered as forward thinking and active students. Such proactive action, is preceded by continuous engagement in active planning strategies. This is reflective of the personality trait known as openness to experience in the five factor model.

The study findings by Litman and Lunsford\(^9\) reported that students who coped with obstacles were generally students who showed higher levels of commitment and engagement with their work. Such an attitude toward their work helped them to experience positive outcomes. This supports the claim that there is relationship between a proactive personality and commitment. Additionally, the study by Hambrick and McCord\(^3\) reiterates the argument that students showed higher adaptive coping abilities, if they had a tendency towards social interaction, worked well in group settings and were able to get along with others. Evidence of strong correlations between coping and personality traits shows the dispositional influence of personality traits on the ability to cope. Based on the aforementioned findings, it is reasonable to assume that students can reduce stressors if they are willing to change, determined to succeed and not in depressive states. These high levels of positive emotions can be attached to traits of extraversion, conscientiousness, non-neuroticism and agreeableness. Such traits are conducive to students developing proactive coping strategies to manage stressful encounters.

However, a personality trait like neuroticism does not allow for successful proactive coping. It is can lead to higher levels of stress and maladaptive coping styles. The implication is that such students may use avoidance strategies when faced with new problems, as
they may be emotionally weak. Allen et al.⁶ argue that when students engage in avoidance coping behavior, they become disengaged. Such disengagement is generally associated with neuroticism. Based on the discussion, it can therefore be asserted that the higher order dimensions of the five factor model of personality such as openness to experience, conscientiousness, extraversion and agreeableness are associated with proactive coping strategies. Further, since openness to experience increases the ability to cope, some students will be better able to manage stressors than others.

**Conclusion**

Personality plays an influential role in determining how individuals cope in stressful situations. Understanding the influential role of personality in the context of coping is critical when analyzing how university students cope when faced with stressors. In the light of evidence pointing to students with exceptional coping abilities performing better when faced with stressors and experiencing less life stressors, this needs to be considered when university students are being guided to manage stressful obstacles. Further, in view of the relationship between proactive coping and the dispositional influence of personality pointing to high levels of extraversion, conscientiousness, and agreeableness amongst students who have high levels of coping ability, personality traits also require further analysis when assisting them to cope. Students can successfully manage to buffer stressors by using proactive coping styles.

The Five-Factor Model of Personality provides an important approach in understanding the key dispositions that influence the overall ability to cope. The innate relationship between personality traits and proactive coping is critical in understanding the coping abilities of university students. In view of extant literature on coping strategies linked to situational and dispositional factors, it can be concluded that personality is a fundamentally important consideration in trying to understand the ability to cope.

Effectiveness of an Education Program on Nurse-midwives’ Practices Related to Postpartum Hemorrhage at Delivery Room of Maternity Hospitals in Baghdad City

Azhar Hussein Ali¹, Ezedeen F. Bahaaldeen²

¹Nursing Teacher, Al-Yarmouk Secondary Nursing School, ²Assistant Professor, Maternal and Neonate Health Nursing Department, College of Nursing, University of Baghdad

ABSTRACT

Objective: To determine the effect of an education program on nurse-midwives’ practices related to prevention and management of PPH, and to identify the relationship between nurse-midwives’ practices related to PPH and their age, educational level, years of experience in nursing, years of experience in midwifery and training courses.

Methodology: A quasi-experimental design was conducted on a purposive sample of (97) nurses who are work in delivery rooms at six maternity hospital at Baghdad City for the period from May 27th, 2018 to December 10th, 2018. A questionnaire was used to data collection and consisted of two parts; part I socio-demographic characteristics, and part II nurses-midwives’ practices which consists of (54) items as an observational checklist distributed on (8) sub-domains related to management to prevent primary PPH.

Results: The results revealed that 87(89.69%) seem to be similarly distributed for whom age are less than 50-years-old, 56(57.7%) are secondary midwife graduates, 64(66.0%) are married, 51(52.6%) had (1-5) years in nursing and 56(57.7%) had (1-5) years of (experience) in the delivery room, number of training courses of PPH had (1-2) number. The overall assessment presents revealed that most were at a low and moderate levels of practice at the pretest period and became high level at posttest. Nurse-midwives’ practices not relationships within their age, education levels, and marital status. While, there is a relationship with the remaining variables (i.e. number of yrs. of total service, number of yrs. of service (experience) in the delivery room, and number of training courses related to pregnancy and childbirth).

Keywords: Nurse-midwives’ Practices; Postpartum Hemorrhage

Introduction

Postpartum hemorrhage (PPH) is one of the most common obstetric maternal complications and is among the three most common etiologies of maternal death globally. Its incidence is increasing and it affects 1% to 5% of all the deliveries (¹). Global advocacy groups describe maternal mortality as “avoidable” and “preventable”. This might be because over 70% of maternal deaths are due to five major complications (hemorrhage, sepsis, unsafe abortion, eclampsia and obstructed labor) and the clinical means to prevent either deaths arising from these complications (²).

The World Health Organization (WHO) currently recognizes the associated risk factor with PPH as increasing maternal age, fetal macrolecosmia, primiparity, multiple gestations, previous cesarean section, prolonged labor, fibroids, and episiotomy. However, many women present with these risk factors and do not develop a PPH. Therefore, the recommended practice is that women should benefit from active management of the third stage of labor, the only intervention known to prevent PPH (³). The causes of maternal mortality in 2017 from vital registration and bibliographic data were found to
be direct and indirect causes of obstetrics. PPH was the most common direct cause of maternal mortality in Iraq. Globally, 35% of maternal deaths are associated with PPH. The estimated mortality rate from bleeding in developed countries was below 13.4%. However, studies have shown the trend of increased incidence of PPH as a cause of severe maternal morbidity (near miss) in developed countries, such as Australia, Canada, United Kingdom and United States.

Methodology

A quasi-experimental “test-retest” design was conducted on non-probability (purposive sample) of (97) nurse-midwives who work in delivery rooms at six maternity hospital at Al-Karckh and Al-Russafa Health Directorates, Baghdad City. The educational program was program is constructed based on initial assessment data and implemented from May 27th, 2018 to December 10th, 2018. A questionnaire was used as a tool of data collection which consists of two parts; part I socio-demographic characteristics. Nurse-midwives’ practices include (54) items as an observational checklist which can be divided into (8) sub-domains related to prevention of primary PPH. These practices include the following:

1. Give the medicines expedited for delivery: composed of (1) items.
2. Feel the abdomen to make sure there is no second child: composed of (1) items.
3. The method of oxytocin giving: composed of (3) items.
4. The time given to oxytocin: composed of (6) items.
5. The position of the fetal before the umbilical cord clip: composed of (9) items.
6. Controlled traction of umbilical cord: composed of (7) items.
7. Uterine massage: composed of (9) items.
8. Direct care for postpartum hemorrhage: composed of (10) items. These sub-domains are related according to (3) level scale (always, sometimes, never) & scored with (3, 2, 1).

* HS: Highly Sig. at P<0.01; S: Sig. at P<0.05; NS: Non Sig. at P>0.05; Testing based on One-Sample Chi-Square test, and the Binomial test

There is a statistically significant differences in all socio-demographical characteristics. Relative to nurse-midwives’ age group, they seem to be similarly distributed for whom age are less than 50 years old ($n = 87; 89.69\%$) compared to those who age 50–60-years ($n = 10; 10.31\%$). With respect to level of education, the majority are secondary midwife graduates ($n = 56; 57.7\%$). With respect to nurse-midwives’ marital status, the vast majority are married ($n = 64; 66.0\%$), followed by those who are single, widow, and divorced ($n = 28; 28.9\%, 4; 4.1\%, n = 1; 1.03\%) respectively.
There is a statistically significant difference in nurses-midwives’ knowledge about prevention & management of postpartum hemorrhage (p-value = .000).

(*) HS: Highly Sig. at P<0.01; Sig. at P<0.05; Non Sig. at P>0.05; Statistical hypothesis based on Analysis of Covariance (ANCOVA).

Nurses-midwives’ practices not relationships within their age, education levels, and marital status, while strong relationships are proved with number of years of experience, years of experience in the delivery room, and number of training courses related to pregnancy and childbirth.
Discussion of the Results

The study result show that study participants are equally distributed relative to age whom age are less than 50-years-old. Muzeya (2015) reported that participants' age ranged from 21-50-years and above. The majority age 21-30-years and only one (2.2%) was older than 50-years (8). This finding is in agreement with Medoh (2017) who stated that the ages varied from 31 years to 60 years. The average age and the standard deviation of the participants who completed the quality improvement training was 40.27 and 8.82, respectively (8). All this study agreed with present study. Concerning educational levels, the majority of the sample are secondary midwife graduate level (n = 66; 56.7%). Muzeya (2015) found that the majority (75.6%) of participants had a Diploma in Nursing and Midwifery and (22.2%) had a degree in Nursing and Midwifery (9). Mohammed (2015) shows the majority of the sample are secondary midwife graduate level (n = 27; 35.1%), while leftover of Basic, High Education, and Bachelor are reported 22 (28.6%), 11 (14.3%), 17 (22.1%) (11). All these studies agree with present study. Relative to marital status, the vast majority of the sample are married (n = 64; 66.0%). Kyei et al (2018) show the vast majority of the sample are married (n = 189; 69.5%) (9). These studies agree with present study. Regarding the “Number of years in nursing”, more than a half had 1-5-years (n = 51; 52.6%). Fungai Muzeya (2015) reported that most of the participants had 2-years of experience or below, whereas 17 (37.8%) had between 3-5-years working experience that mean the vast majority of studied sample had (1-5) yrs. and they are accounted 35 (77.8%) is in agreement with present study (8).

Regarding the number of years in the delivery room, more than a half had 1-5-years (n = 56; 57.7%). Medoh (2017) have stated that there were 25 participants’ years of experience in nursing varied from 6-30 years, of studied sample are distributed for whom years of experience as a labor/delivery or postpartum nurse and or obstetric nurse are less than 6-years (n = 6; 40%) (9). This study result agrees with present study. Relative to “Number of training courses related to pregnancy and childbirth” shows that vast majority had (1-2) number (n = 42; 68.9%). Finally, “Number of training courses of PPH” shows that vast majority of sample had (1-2) courses (n = 32; 89.2%). Hassan and others illustrate the attendance of the studied nurses of any educational training related to placental examination during their work years, this study agreement with present study in that most of participants in the program did not attend any training courses related to pregnancy and childbirth or training courses of PPH (12).

Table (4-2-2) shows summary statistics of practices (Pre, and Post) periods due to applying proposed of program. The study results reported highly significant differences toward impact of program through raising nurse-midwives’ practices extremely, except item of “The use of Tranexamic acid, which is known as Cyclocapron which showed no significant different at P>0.05, as well as perfect similarity responses was obtained in light of pre/post periods.

Egenberg et al., (2017) reported the most important step in preventing maternal morbidity and mortality due to PPH is skilled attendance at birth and access to emergency obstetric care. Skilled attendance includes active management of the third stage of labor, such as administration of oxytocin to the mother soon after childbirth, controlled cord traction, delayed clamping of the cord, and uterine massage (13).

All studies are agree with the present study, which showed that nurses midwives were low or moderate practices in the management of postpartum hemorrhage compared to their knowledge and may be due to several reasons, for example the lack of training courses for nurses to prevent and management of postpartum hemorrhage as well as a lack of educational programs and awareness and supervision and make them mandatory to identify all the update in terms of science and practice and knowledge for the purpose to control of PPH and reduce the proportion of morbidity and mortality, in addition to the importance of the development of recommendations and guidance of the WHO in the form of Flexes or posters in the delivery room, Wards birth and emergency women’s groups. Note that educational programs must be implemented for longer periods to ensure that all points are applied and utilized by everyone.

Conclusion

The present study has come out with the following conclusions:

1. The education program was effective an increasing the practices of nurses-midwives toward prevention and management of postpartum hemorrhage.

2. The results of the present study confirm unequivocal evidence of the benefits of implementing the educational program in the continuous and significant improvement in the practices of nurses-midwives through the post-
test results of the study group, one month after the implementation of the educational program on prevention of postpartum hemorrhage and management to stop it.

3. There was no statistically significant of an educational program for “nurse-midwife’s knowledge and practices toward postpartum hemorrhage at delivery room of maternity hospitals in light of (SDCv., service years, and training variables).

Conflict of Interest: The researchers report no conflict of interest.

Source of Funding: This study did not receive any funding from any agency.

Ethical Clearance: The researchers obtained a permission from the ethical committee in the College of Nursing–University of Baghdad to conduct this study.

Effects of Pain, Disability, Social Support and Stress on Depression of Community-dwelling Elders

Hee Kyung Kim¹

¹Professor, Department of Nursing, Kongju National University, Gongju, South Korea

ABSTRACT

Purpose: The purpose of this study was to analyze the effect that pain, disability, social support, and stress have on depression in elders.

Method: The subjects of this study were 141 elders between 65 or above. The data were analyzed using descriptive statistics, t-test, ANOVA, Pearson’s correlation coefficient and stepwise multiple regression.

Results: With depression, pain had a positive correlation ($r=.26, p=.002$), disability had a positive correlation ($r=.25, p=.002$), stress had a positive correlation ($r=.47, p<.001$), but social support had a negative correlation ($r=-.42, p<.001$). Depression was set as a dependent variable for a multiple regression analysis. The analysis showed that stress ($β=.313, p<.001$), social support ($β=-.272, p<.001$), and economic status ($β=.201, p=.007$), and health condition ($β=-.178, p=.010$) had a significant effect on depression in elders. The regression analysis was statistically significant ($F=20.74, p<.001$).

Conclusion: Nurses that interact with the elderly in the local community must identify the source of stress to develop an intervention program and apply a social support program. By helping subjects check up on their own health condition and practicing health improvement practices, they should encourage the elderly to lead a healthy life. As economic status is a factor affecting depression, programs for depression management need to be developed.

Keywords: Elderly, Depression, Stress, Social support, Health condition

Introduction

The growth of the elderly population is a worldwide trend. Those aged 65 or older in Korea now account for 14.8% as of 2019, making the country an aged society.¹ Life expectancy in Korea as of 2015 is 82.06 years, which has seen the fastest increase rate among OECD countries in the past two decades. But the healthy life expectancy is 73 years, which indicate that longer life has led to increased physical and mental pain due to geriatric chronic diseases.² As such, policies are needed for aging and in particular measures to prevent aging and to maintain a healthy life. In terms of social relations, leisure activities including hobbies and volunteer activities must be widely adopted, while management of income and assets is needed.¹

Meanwhile, the elderly experience various stress factors and depression due to aging, including physical illness, death of a spouse, worsened financial situations, social isolation and undermined ability to carry out daily life. Depression in the elderly, compared to that in other age groups, has bad prognosis. Symptoms include sadness, memory loss, helplessness and frustration, which increases the risk of suicide² As such, nurses need to detect depression in the elderly early and address it.

The elderly living in local communities are likely to have at least one chronic disease and discomfort such as pain. As they age further, they experience further deterioration in the bodily functions, leading to more stress in everyday life and undermined physical and mental health.³ In such a situation, social support can help reduce depression and increase happiness.⁴ Preceding studies on the elderly show a correlation between stress...
and social support the elderly feel and their depression. Chronic pain and decreased bodily function experienced by the elderly lowers quality of life while social support is a major variable that reduces depression and quality of life.

As such, the objective of this study is to understand the degree of depression in the elderly living in local communities and apply the variables of pain, functional disorders, social support and stress to identify their correlation with depression to reduce depression and improve health in the elderly. In doing so, the study will provide basic data for the development of nursing intervention programs that can promote health in the elderly.

Method

Subjects: The elderly visiting 2 health centers in D city, 7 health centers in C province and 1 health center in S special city were used as subjects via a convenience sampling. Senior citizens who are active, who can communicate, who understand the content of the questionnaire and who gave their consent to participation in the study were used as study subjects. To verify the appropriateness of the size of the sample, G*Power 3.0 program was used to apply a significance level of 0.05, an effect size of 0.15, a power of test of 0.90 and six predictive factors that are needed for a regression analysis. This gave a sample size of 123 subjects. Considering the drop-out rate, a total of 150 copies of the questionnaire were distributed. 9 with insufficient responses were excluded and a total of 141 copies were used for the final analysis.

Instruments

Pain: The Visual Analog Scale [VAS] was used to measure for 4 weeks lower back pain, headache, joint pain or overall muscular pain on a scale of 0 to 100. ‘Not at all’ was given 0 point, ‘about medium’ was given 50 points and ‘very severe’ was given 100 points. Higher scores indicate greater pain.

Disability: The Oswestry Disability Index developed by Fairbank, Couper, Davis, & Brien and used by Lee was applied. For a total of 9 questions, higher scores indicate a more severe function disorders. In the study by Lee, Cronbach’s $\alpha=.89$ and in this study it was .88.

Social Support: The tool by Kim which is a revision of the MSPSS was used. This has a total of 12 questions. A higher score indicates greater social support. The confidence level in this study was .89.

Stress: BEPSI-K, the Korean version of a stress measurement tool revised by Lim et al. was used, which consists of 12 questions. A higher score indicates greater stress. The confidence level in this study was .89.

Depression: Short Form Geriatric Depression Scale consisting of 15 questions which was revised by Kee into a standardized Korean version was used. Responses were measured on a 2 point scale, with ‘yes’ being given 1 point and ‘no’ being given 0 point. A higher score indicates greater depression. At the time of the tool’s development, the confidence level was .84, and in this study it was .75.

Data Collection: Data were collected from April 11 to May 8, 2019. The researcher explained the objective and methodology of the study at a meeting of heads of local health centers. The heads of health centers who gave their consent to data collection were as follows: 2 centers in city D, 7 centers in C province and 1 center in S city. The researcher explained the objective and methodology of the study to the elderly who visited health centers and asked those who gave their consent to sign a consent form. It took about 20 minutes for subjects to fill out the questionnaire.

Ethical Consideration: To collect data for this study, approval from the ethics committee of K University was acquired (KNU-IRB-2019-20). During the study period the guidelines on ethical studies were observed.

Data Analysis: Using the SPSS/WIN 23.0 program, the general characteristics and variables were analyzed for frequency, percentage, mean and standard deviation. The difference in depression across different general characteristics was analyzed using a t-test, ANOVA and Scheffe test. The correlation between elders’ variables was analyzed using Pearson’s correlation coefficients. Multiple regression analysis was conducted to analyze the factors affecting elders’ depression.

Results

General Characteristics of Elders: The mean age of the elderly was 77.99 years, with those aged 80 or older accounting for the largest share at 45.5% (65 subjects). Most of them were women at 70.9% (100 subjects). In terms of their relationship with their spouse, cohabitation accounted for 50.0% (72 subjects). In terms of education, those who graduated from elementary school
or lower accounted for 82.5% (118 subjects). Those who responded that their health condition is average accounted for 58.3% (84 subjects). The number of diseases for which they take medication was 2 for 35.0% of subjects (49 subjects). Most common diseases were hypotension at 63.1% (91 subjects). The elderly who responded that they do not work out at all accounted for 37.4% (52 subjects) and those who responded that their exercise is not regular accounted for 37.4% (52 subjects). Those who walked as exercise accounted for 34.8% (50 subjects), and those who exercised 1-2 times on average per week accounted for 25% (36 subjects). The exercise duration was 30 minutes ~1 hour. The largest share of the elderly at 75.0% (108 subjects) responded that their economic status was average.

Pain, Disability, Social Support, and Stress on the Depression of Elders: The elders’ pain scored 55.21 points out of 100 points, and disability scored 2.45 points out of 6 points, social support scored 3.55 points out of 5 points. Stress scored 2.11 points out of 4 points and depression scored 0.25 points out of 1 point (Table 1).

Factors affecting depression of elders: Depression was set as a dependent variable for a multiple regression analysis. The self-correlation coefficient of Durbin-Watson was 1.677, and VIF value was 1.028~1.198 which is smaller than 10, indicating that there were no issues of multi-linearity. The analysis showed that stress ($\beta=.313$, $p<.001$), social support ($\beta=-.272$, $p<.001$), and economic status (poor) ($\beta=.201$, $p=.007$), and health condition (bad) ($\beta=-.178$, $p=.010$) had a significant effect on depression in elders. The regression analysis was statistically significant ($F=20.74$, $p<.001$), with the combined explanatory power of stress, social support, economic status, and health condition being 37.7% (Table 4).

Discussion

The elderly’s depression scored 0.25 points on a scale of 0 to 1, which was lower than preceding studies that looked at the elderly in local communities who scored 2.66 points out of 5 points, and 15.19 points out of 27. However, this seems to be due to the fact that the study was conducted on the elderly living in local communities as opposed to nursing homes and thus who were able to receive ongoing help from experts at local health centers. Pain, disability and stress in the elderly had a positive correlation whereas social support showed a negative correlation. This is similar to the findings of a study on those aged 60 or older with chronic lower back pain where it was found that more severe pain and disability were correlated with lower quality of life. In that study, the elderly with physical illness, compared to those without, had a higher degree of depression and the number of illnesses suffered was correlated with the severity of the depression. Physical health status, pain and disability cause inconvenience in daily life and cause stress, leading to depression and lower quality of life. As such, by reviewing the degree of pain and health condition of the elderly, help should be offered to them to reduce stress and depression.

In particular, factors affecting depression in the elderly were found to be stress, social support, disability and health condition. Such variables explained 37.7% of depression in the elderly. This is in line with the study conducted on the elderly aged 65 or older that found a positive correlation between daily stress and depression and a negative correlation between social support and depression, and how stress and social support were factors affecting depression. A study conducted on the elderly aged 60 or older and living in administrative areas of Gun saw that in the correlation between stress and depression, social support had a moderating effect, and as in general higher age meant higher stress and greater depression, psychological and social intervention such as social support is needed to improve health of the elderly. It was also noted that emotional support through the children of the elderly can help reduce depression. As such, by understanding the causes of stress and the social network of the elderly, social support programs can be operated such as counseling which can reduce depression.

The study found a negative correlation between perceived health condition and depression, with perceived health condition being the most important
factor affecting depression. Income sources also had an effect, which is in line with the findings of this study. An analysis of the causes and mitigating factors of depression in the elderly living at home found that the worse the health status and the more difficult the financial status, the more likely depression, and that social support and social activities had a major impact on depression. It was also in line with findings that reported how low physical and mental health and low financial status were correlated with greater depression. As such, the elderly need to take care of their own health with the help of experts to the point that they do not feel that their health is bad. To address financial difficulty, programs associated with volunteer work or job creation can be operated to offer more participation for the elderly.

Conclusions

Since the elderly, compared to other age groups, are more vulnerable in terms of their physical, mental and social situations, they are more prone to depression. The findings of this study suggest that stress, social support, health status and financial status must be considered as measures to mitigate depression in the elderly are developed. As such, health experts that focus on the elderly living in local communities must identify stress sources and develop a mediation program, as well as apply a program to boost social support so that depression can be mitigated. Help must also be offered to the elderly so that disease prevention and management can be done in daily life and the economic status of the elderly can be better understood. Measures to offer help through the local community network should also be considered.

ABSTRACT

Introduction: The only historical tradition of Indonesian law is customary law. For the indigenous people of Bengkulu City, customary law is the representation of the people spirit. Law is the representation of a nation’s spirit. Customary law is a living law as it represents the real feeling of the law believed by the people. Bengkulu customary law is one of the inherited cultural law as a tool to regulate the life of the indigenous people. One of the characters of customary law is that the ability to always consider the psychological state of the people so that the implementation of the law will be based on the feeling of justice and the need of law within the society. Every act done by indigenous people is mainly based on some factors, including psychological factor. It is in line with the fact that psychology as the science about psychic or human behavior. Therefore, it strongly relates to the study of law, where psychology view law as the representation of human behavior.

Material and Method: It was research which employed primary and secondary material, with descriptive qualitative as the research method.

Finding: Volkgeist is the spiritual manifestation or a spirit of a group of people. Society is empirical. It makes society is different from one another. Volkgeist is the terminology for something psychological and spiritual which were inherited and operated in some entities as language, folklore, custom, and behavior. The correlation between psychology and customary law is represented by the customary law of Bengkulu City. Law is formed from the given ratio and behavior in human. Behavior in human consist of motoric, perceptive, and cognitive aspects. The process also represents the customary law formation at Bengkulu City. It starts from human’s thinking, will, and behavior as the psychological manifestation of the indigenous people spirit of Bengkulu as customary law includes the implementation of psychology from each individual of which work, idea, and sense also included.

Conclusion: Volkgeist is a terminology with inherent psychological and spiritual meaning which is operated and manifested in the form of language, folklore, custom, and behavior. Related to that psychological aspect, the indigenous people of Bengkulu City are obedient to the customary law as the law contains ethical values and norms which well reflected the ethical wisdom. The ethical wisdom is a reference engraved on the spirit of the people. Values, norms, and cultural wisdom are the reflection of the way of thinking and psychological structure of indigenous people at Bengkulu City. It is because the customary law is the implementation of the society’s psychological aspects, which includes work, idea, and sense.

Keywords: Psychology, Customary Law, People Spirit, Indigenous People

Introduction

The only historical tradition of Indonesian law is customary law¹. In this modern era, Indonesian still have their respect for customary law. The existence of indigenous people in Indonesia is attached on the 1945 Constitution of the Republic of Indonesia the second
amendment in article 18 B section (2) and article 28 I section (3). Customary law is the law regulates relationship among the people as custom, habit, and morality in the indigenous community as it is obeyed and defended by the people, also the law with sanctions for violation determined by the authority holder and decision makers such as leader and judge. Particularly for indigenous people at Bengkulu city, the regulation is explained in the local government regulation of Bengkulu No. 29/2003 about the implementation of Bengkulu City Custom.

On the indigenous people of Bengkulu City, customary law is the reflection of people spirit. Law is the psychological reflection of a nation. Law is not the will of a state or something derived from God’s law. Instead, it is something we can seek from social life. There is no exact form and substance of the law. It fully depends on social development. Customary law is a living law as it represents the people feeling. However, custom with sanctions is the one defined as (customary) law. Customary law is a form of inherited culture of law which is used to manage the life within the indigenous community. As customary law commonly represented as a habit, the law tends to be unwritten law. The other character of the customary law is the ability of the law to pay attention and consider the psychological condition of society. It makes the function and application of the law are based on the feeling of justice and the need for law among society. Every behavior and action of people must be based on the psychological factor.

Based on the description above, the psychological analysis about customary law as the people spirit on indigenous people at the Bengkulu City of Indonesia.

**Material and Method**

The research employed primary and secondary material. Primary material gained through research about the empirical fact of human behavior documented in the form of behavior records. Meanwhile, the secondary material was gained through literary study. Descriptive qualitative was used as the research method.

**Finding**

A. Psychological analysis of customary law as the people spirit (volksgeist): People are not able to inherit the customary law from the people before them without looking back to the history of their ancestor. It emphasizes the importance of cultural tradition as revealed in some studies about law and social development. The importance of cultural tradition through historical approach in law was stated by Savigny that “Das Recht wird nicht gemacht est ist und wird mit dem volke” which means that law is not instantly made yet grow and develop in the national spirit.

The close historical view which became the icon of Savigny did not instantly change law into something stiff and out of date. In this case, the law is dynamic as the product of national spirit which always moves to the direction of the people interest. Law is formed through a long journey, from the bottom to the top. Law is a fundamental value of national spirit, not the randomly made value. Those concepts gave Savigny idea to deliver the concept of volkgeist (national spirit) when he learned about the law of a nation.

Volkgeist, volksseele, nationalgeist, geist der nation, or volkscharakter are known as national character. It can also be literally translated into the spirit of a nation. According to Herder, volkgeist is the manifestation of the people spirit. People or society is something empiric. It makes a society is different from one another. Every society has its character, especially for the indigenous people or society. Volkgeist is a psychological and spiritual terminology which inherent and operates in some entities such as language, folklore, custom, and behavior.
The importance of customary law might never be clearly formulated and firmly stated by the leader. Therefore, Savigny defines it as the law of people or volksrecht which exist comprehensively under the spiritual consciousness of the society. In this case, Margareth Gruter mentioned that the existence of people behavior in law is not limited as the customary law which is rooted in people idea. Instead, it has been programmed deep inside human idea, so that it is believed as the result of biological evolution of human.

B. Psychological analysis on the customary law of indigenous people at Bengkulu city: The correlation between psychology and customary law as the spirit of the people is represented on the customary law of Bengkulu city. The customary law is a kind of custom in people’s social life. It began when human come to the world, made family, and lived as a community, and then as a nation. By looking at the development, the law is formed since the process of God giving idea and behavior to human.

Behavior is stuck on people and represented by the motoric, perceptive, and the cognitive function as an individual. God creates human and gifted it with the mind or thought to well behave. The continuous behavior which forms individual habit can be spontaneously accepted by society as a form of custom. Besides, as a social being, a human cannot avoid the consequence of social interaction which may influence the other individual. Habit can be formed into custom by means of social interaction. Therefore, the habit can be slowly transformed into a custom which reflects people feeling (indigenous people of Bengkulu City). The society makes the custom as a valid regulation which should be obeyed by all of the society members and makes this into a customary law. The process shows the creation of customary law of Bengkulu city which begin from people idea, behavior, and will as the psychological manifestation on indigenous people spirit of Bengkulu City.

It is clear that customary law is one of the living and cultural aspects of Indonesia as a nation. It is because the spiritual structure and way of thinking which are well reflected in the customary law itself. According to Soepomo, by looking at the Indonesian (indigenous people of Bengkulu City) spiritual structure and way of thinking, the customary law is represented into some characters such as follow:

1. Communal: Based on customary law, a human is a creature within a social bond with a strong communal feeling. Indigenous people prioritize togetherness without ignoring individual deed.

2. Religious: The customary law has a religious value which is strongly related to Indonesian living aspects, of which the people believe in something magical and evaluate religious aspect as a real aspect in life.

3. Concrete: The system and management of Indonesian customary law is concrete. It means that people use a concrete symbol to represent their behavior and action as the representation of someone’s will.

4. Visual: The relationship over law can only be determined by a visual bond. The actualization of these values is integrated and true between saying and action.

The psychological aspects are also included in the customary law aspects, such as:

1. Reality aspect, which means that custom is always respected in any condition repeatedly and continuously to be obeyed and applied in everyday life.

2. Psychological aspect means that after believing that the custom is constant and continuous, people should also believe that the custom has its legal force and give the legal obligation to the people (opinion yuris necessitatis).

Related to those psychological aspects, the indigenous people of Bengkulu city are obedient to the customary law as the law contains the ethical value, and also the applied norms which are able to reflect the cultural wisdom value. It engraved as the reference for the society. Those ethical values are saved on the philosophical system of the indigenous people of Bengkulu City as Syara’ based custom. Syara’ is based on Kitabullah or the holy Quran. It proves that society has a religious way of thinking, or the belief of something sacred, also the assumption that every individual is an integral part of society. An individual deed is synchronized with the social deed.
Meanwhile, the prohibited norms in customary law society of Bengkulu City are *Cempalo mulut* (make someone else embarrassed), *Cempalo tangan* (damaging, ruining, vandalism), *Cempalo mato* (make a social call, adultery, social etiquette, land ownership, the duty to keep the environment, also etiquette in taking other’s goods). The customary penalty usually in a form of apologies, *setawar dingin*, and customary fines\(^21\).

The norms, values, and customary wisdom are the reflection of spiritual structure and way of thinking of indigenous people with the customary law of Bengkulu City. It is because customary law is also the implementation of psychology from the indigenous customary society which includes work, idea, and sense.

**Conclusion**

Psychological analysis on customary law as the spirit in indigenous people of Bengkulu City Indonesia showed that there is an integrated relation between volkgeist and customary law of Bengkulu citizen. Volkgeist is the terminology with psychological and spiritual meaning which inherent and operates as some entities such as language, folklore, custom, and behavior. The behavior has stuck on human which is represented through motoric, perceptive, and cognitive function and formed a single totality as a human. Related to those aspects of psychology, the indigenous people of Bengkulu City are obedient to the customary law, as the law contains ethical value and norms which reflects the cultural wisdom and strongly engraved on people spirit. The values, norms, and cultural wisdom are the reflection of spiritual structure and the way of thinking of indigenous people of Bengkulu City. It is because the customary law is the implementation of psychology on every individual of a group of customary society in a form of work, idea, and sense.

ABSTRACT

Objective: Periodontitis and diabetes are related and high blood glucose level plays an important part in this correlation. Corn silk has the property of anti-hyperglycemic and anti-inflammation. The aim of this study was to determine the capability of corn silk based Ethosomal gel to reduce blood glucose level and degree of inflammation in alloxan induced rats.

Material and Method: 15 wistar male rats with initial weight of 150 gram were included in this study. Alloxan was used to induce diabetes and 5-0 silk ligatures to induce periodontitis. Blood glucose level was analyzed before and after induction, 3 days after administration, and 7 days after. Degree of inflammation was examined with histopathology test.

Results: Blood glucose level in F1 is unstable (p=0.0583>p=0.05), whilst F2 and F3 both showed stable blood glucose decrease (F2: p=0.0086<p=0.05; F3: p=0.035<p=0.05). Anti-inflammation effects best shown in F3, which has mild inflammation (p=0.001<p=0.05). Whereas both F1 and F2 have moderate inflammation (F1: p=0.225>p=0.05; F2: p=0.423>p=0.05).

Conclusion: Corn silk based Ethosomal gel treatment manage to reduce blood glucose level and periodontitis in alloxan induced diabetic rats.

Keywords: Corn silk extract, Diabetes Mellitus, Ethosomal gel, Periodontitis.

Introduction

Periodontitis is a disease caused by specific microorganism that derived from dental plaque. These bacterian can cause progressive periodontal tissue and alveolar bone damage by inducing the formation of periodontal pocket, gingival ressesion, or both. Clinical signs of periodontitis are gingivitis, periodontal pocket, and loss of attachment. Diabetes itself is a risk factor for gingivitis and periodontitis, and the degree of glycemic control appears to play an important part in this correlation. Diabetes is a clinically and genetically heterogeneous group of metabolic disorders manifested by abnormally high levels of glucose in the blood. This hyperglycemia results from either a deficiency of insulin secretion caused pancreatic β-cell dysfunction or resistance to the action of insulin in liver and muscles, or both. Diabetes itself is a risk factor for gingivitis and periodontitis, and the degree of glycemic control appears to play an important part in this correlation. High glucose level in gingival crevicular fluid directly hinders fibroblast’s ability to heal itself by inhibiting the attachment and spreading of cells needed for wound-healing and normal tissue turnover. Abnormality in neutrophil’s adherence, chemotactic, and phagocytosis has been observed in some DM patients. Neutrophil’s impairment may inhibit bacterial killing in the periodontal pocket and significantly increase periodontal destruction. Apparently, this impairment can be subdued with better glycemic control. In conditions of sustained...
hyperglycemia, protein binds with glucose molecules and undergo glycation thus forms Advanced Glycation End Products (AGEs). AGEs formed on collagen increases collagen crosslinking. Due to this crosslinking activities collagens formed become highly susceptible to enzymatic degradation by collagenase, which is mostly present in active form in people with diabetes. Human gingival fibroblasts also produce decreased amounts of collagen and glycosaminoglycans in the hyperglycemic state.\(^7\) As a result of collagen crosslinking and collagen deficiency, collagen metabolism is disturbed, thus affecting wound-healing process.\(^7\) AGEs bind with RAGE (Receptor for AGEs) on the surface of monocyte; therefore monocytes are forced to stay in one place because it limits their migration. AGE-RAGE interaction induces phenotype changes in monocyte, which increase the production of cytokine TNF, Prostaglandin E (PGE), Interleukin (IL-1)\(^9\). Host immune response stimulates pro-inflammatory mediators such as IL-1, TNF- \(\alpha\), IL-6, IL-7 and a whole lot more PGE\(_2\), which promotes periodontal tissue damage.\(^9\) PGE\(_2\) is an important mediator in periodontitis process and bone destruction also plays important part in inflammatory response regulation. PGE\(_2\) surpresses lymphocyte production, collagen synthesis by fibroblasts, and bone osteoclast resorption.\(^10\)

Corn silk (\textit{Stigma maydis}) is made from stigmas, the yellowish thread like strands from the female flower of maize. It is a waste material from corn cultivation and available in abundance.\(^10\) Throughout the world corn silk has been used as a treatment of edema as well as for cystitis, gout, kidney stones nephritis and prostatitis.\(^10\) Corn silk contains numerous bioactive compounds such as volatile oils, steroids, alkaloids, sitosterol and stigmasterol and natural antioxidants such as flavonoids, saponins, tannins, and other phenolic compounds.\(^12,13\) Variation in secondary metabolite compound would affect its pharmacological activities. Phytochemical contents of plant are affected by various factors such as environmental conditions, season, plant age, growth factors, and leaf maturity.\(^14,15,16,17\) Flavonoids has the ability to inhibit \(\alpha\)-amylase and \(\alpha\)-glucosidase activities \textit{in vitro}, inhibit glucose transport, prevent cytokine induced \(\beta\)-cell damage, and ameliorate insulin resistance peripherally.\(^18\) Saponins can reduce blood glucose level by increasing insulin secretion, glucose uptake, and hamper glucose absorption in the small intestine. Alkaloid can decrease glucose absorption by inhibiting \(\alpha\)-glucosidase enzyme. Tannins and phenol can interact with protein and are capable of slowing down carbohydrate catabolism. Phenolic compound also has antioxidant properties therefore it can help repair damaged \(\beta\)-cell hence increasing insulin secretion.\(^19\) Aside from having anti-hyperglycemic activities, corn silk extract also has anti-inflammation, antioxidant, antidepressant activity, diuresis, and many more.\(^20\)

Ethosom gel is one of the Transdermal Drug Delivery System (TDDS) that can increase drug penetration despite being applied topically. The Ethosom itself is a lipid vesicle modified from liposomes. Ethosom is comprised from phospholipid, relatively high concentration alcohol (ethanol or isopropyl alcohol), and water. Ethosom vesicle sizes are varied from micrometer (\(\mu\)m) - 10 nanometer (nm). Ethosom needs lesser time to penetrate the skin and significantly increase transdermal drugs flux value. Ethosom also decrease the risk of GI Tract irritation due to orally administered medication.\(^21\)

### Materials and Method

**Animals:** Wistar strain rats weighing 150gram were purchased from local breeder in South Sulawesi. The rats were maintained at room temperature under alternating natural light/dark photoperiod and were fed twice a day with standard feed water was available \textit{ad libitum}.

**Chemicals:** Alloxan was used to induce diabetes and were purchased from Tokyo Chemical Industry. Metformin used for positive control was of generic brand.

**Corn Silk Extract Preparation:** Corn silk from 40 days old corns were obtained from local farmers in Jeneponto a region in South Sulawesi. The corn silk were washed and dried at room temperature (24.2 ± 1.0°C) till dried and an ethanol extraction was performed by adding 5L of ethanol 80% and 200gram dried corn silk. After 3 days of maceration process, the ethanol solvent was evaporated using rotatory evaporator.

**Corn Silk Extract Based Ethosomal Gel Formulation:** Three corn silk based Ethosom formulas were made (refer to Table 1). Lecithin and phosphatidylcholine were dispersed in heated distilled water (40°C). Corn silk extract entered lipid phase and stirred with magnetic stirrer for 5 minutes and 700rpm till it entered coloidal system. Propylene glycol and ethanol 96% were heated
till 30 °C and entered coloidal system. Lechitin or phosphatidicolin, corn silk extract, propylene glycol with ethanol 96% were mixed together and homogenized with magnetic stirrer for 5 minutes and 700rpm till Ethosom suspension was formed. The suspension were cooled in room temperature then stored in the refrigerator.

After the Ethosom formulas were made, they were put in gel system (refer to table 2) and corn silk ethosomal gel were made. Carbomer 940 was dispersed in distilled water that contain methylparaben for 24 hours. After that triethanolamine was added drop by drop whilst being stirred till a clear gel mass was formed. Ethosom (Formula A, B, C) mixed with a small amount of distilled water were added to the gel base and stirred till homogenized, after that glycerin and distilled water were added to the mixture.\textsuperscript{21}

**Experimental Design:** 15 rats were fasted for 8h and blood glucose level was measured with blood drawn from the vein in tail. Each rat’s weight was measured and then alloxan (150 mg/kg) dissolved in sterile saline were injected intraperitoneally. Three days after inducing diabetes, periodontitis was induced as well. 5-0 silk ligatures was tied around the mandibular first incisor and tied gently to prevent damage to the periodontal tissue. The ligature was thought to facilitate local accumulation of bacteria and thereby enhance bacteria mediated inflammation. One week after alloxan was administered blood sample were drawn again from the tail vein. One week after periodontitis was induced, 14 hyperglycemic rats (the blood glucose level greater than 126 mg/dL) were selected randomly and divided into 5 groups. Metformin dissolved in water were administered orally (positive control), each formula was administered topically once a day to each specified group, and the clear gel base without corn silk extract was administered once a day (negative control group). 3 days metformin, Ethosom gel, and clear gel base was administered blood sample were drawn again for analysis. 7 days after administration, blood sample were collected for final analysis and periodontal tissue were collected for histopathology test.

**The Periodontal Tissues were Embedded in Paraffin Blocks after Formalin Fixation:** After tissue fixation in formalin, tissue samples were processed in tissue processor machine. After being processed, the tissue samples then moved to embedding machine to make paraffin blocks. Paraffin blocks were then cooled down and trimmed with microtome after that moved to waterbath in 37 °C. The tissue sample were then taken out using slides that were numbered. Slide then heated on hot plate at 60 °C till the paraffin that surrounds the tissue melts. The section was examined after hematoxylin and eosin staining.

**Statistical Analysis:** All data were analyzed using students t-test. The data represents means and standard deviations. The significant level of 5% (P<0.05) was used as the minimum acceptable probability for the difference between the means.

**Results and Discussions**

The blood glucose level of hyperglycemic rats are presented in Fig. 1. The blood glucose level for negative control kept increasing because it hasn’t been given any treatment just a clear gel base as a placebo. The positive control, F2, and F3 level of blood glucose kept decreasing. In contrast with other experiments group, in F1 the blood glucose level decreased at first and starting to increase again. Eventhough, the final blood glucose level for F1 is still lower than it’s blood glucose level after being induced the p value shows no significance by landing a p value at 0.0583 which is slightly bigger than p value 0.05. This indicates that F1 can not stabilize blood glucose level and has no significance in lowering blood glucose level. Metformin administered orally to positive control group shows decreasing blood glucose level but apparently has no significance statistically with p value of 0.264. Experimental groups F2 (p=0.0086<p=0.05) and F3 (p=0.035<p=0.05) both shown decrease in blood glucose level and both have significance statistically.

Due to extremely large number of inflammatory cells such as leukocyte and PMN that are too many to count, the inflammation rate are shown with 3 different grades. 1 for mild, 2 for moderate and 3 for severe. As seen in fig. 2, negative control group has the highest inflammatory grade which is 3 and accompanied with cell necrosis (Fig. 3). Second highest inflammation grade is F2, in contrast to it’s blood glucose level and other experiment groups. Supposedly, the degree of inflammation decreases as the blood glucose level decrease. One other important factor to note when it comes to periodontitis is that stress also affects periodontitis by altering immune system response, delayed wound healing, hormonal changes, and changes in behaviour that supports periodontitis formation.\textsuperscript{22,23,24,25,26}
F2 control group has been observed to have high stress levels. In spite of having higher inflammation grade than negative control, F2 has new connective tissue formation. F1 falls into moderate category but has no statistic significance with p value of 0.225. Only F3 has low inflammation grade and statistic significance with p value of 0.001. This imply that corn silk extract based Ethosomal gel has the ability to reduce blood glucose level and inflammation response.

Conclusion

The results showed that corn silk extract based Ethosomal gel treatment markedly reduces blood glucose level and periodontitis in alloxan induced diabetic rats. With F3, lecithin and 0.025gram corn silk extract as the formula that manages to have both anti-hyperglycemic and anti-inflammatory effects.

ABSTRACT

The effects of the caper ethanol extract showed no significant effect on Hb, PCV, platelets, RBCs, and showed a significant effect between the treatments for total white blood cell count and neutrophil cell were observed on ethanol extract for caper plant highly significantly than the treatments T2, T3 and control Tc, and significantly increase in the weight of the mice in the treatment T1 compared with T2, T3 and Tc, also showed a decrease in spleen and liver inflation particularly in T1 compared with the Tc, and The results showed T1 had a significant effect compared with other groups with respect to IgA and IgM, showed increased significantly in a concentration C3, C4 that is related to treatment T1 compared with T2, T3, and TC, and was observed that the ethanol caper plant extract that gave a speed in wound healing after contaminated with the P. aeruginosa than the control group, the aim of these study to treated with C.spinosa administration orally that important to the enhancement and useful to supported immune response and pro-inflammatory response against any pathogenic foreign body.

Keywords: immunology, Capparisspinosa extract, in vivo.

Introduction

Capparisspinosa one of the plants that utilized in treating a few maladies since thousand years prior and utilized as nourishment and helpful, and it is broadly spread of the world, it is brought in Iraq.(¹) Shefallah or kabbr, Spain (alcaparro), Italy (capero), Turkey (kapari) and Russia (kapersy and kappertjes).(²) Trick plants were utilized in old periods, for instance, Egyptians, Babylonians, Greeks and Romans and furthermore utilized as sustenance and restorative, escape(³) plant has a place under family called capparaceae, and which have a high capacity to adjust to natural conditions. (⁴) The connection among trick and people can become to until to archæological age, found in China in 2800, it was utilized for therapeutic purposes (⁵) The trick considers from fragrant plants with the hard spines, round leaves, green and delicate, white blossoms or pink, with extensive silvery natural products bearing a genuinely long stalk, containing dark seeds with an unforgiving taste and a red coagulated substance with a sweet taste(⁶) A synthetic trial was completed on the distinctive pieces of C.spinosa as a rich hotspot for some concoction exacerbates that considered different auxiliary metabolites, for example, glycocapperin, rutin, spermidine, quercetin, stigmasterol, carotenoids tocopherols, campesterol⁷ explicit insusceptible framework.

Materials and Method

Capparisspinosa: Plant collection from the Abu Ghraib gardens area of the faculty of the veterinary medicine of Baghdad University, where the plant was collected in the period between July and until November, this period flowering season, the samples were taken from aerial parts (fruits, flowers, leaves, stem), The plant was dried before the process of grinding. also, Used Al-Badawi vinegar dates get from the markets.

Preparation of ethanol extract of Capparisspinosa Plant: The best and most effective method to extracting the active organic material crude from compounds in the plant used the Soxhlet apparatus. We used the plant and grinding or crushing by a blender apparatus into powder,
taken 50 g of plant powder and placed inside Thumble, 250 mL of ethanol then placed 95% after extraction, the extraction process was carried out within 24 hours and then concentrated by a rotary evaporator, Then put in frozen under -20 ° until used.

**Laboratory Animals:** The Swiss white mice used (mice Balb/c strain) at the age of 6-7 weeks in this study and were obtained from the Cancer Research Iraqi Center

**Immunization of mice:** The mice were divided into four groups and each group consisted of 10 mice

- **Group A:** Negative control (Tc) with saline phosphate precipitate solution (PBS).
- **Group B:** Treated of mice with ethanol caper plant extract (T1).
- **Group C:** mice treated material Iraqi dates Vinegar (T2).
- **Group D:** mice treated with a mixture of ethanol extract of the plant and vinegar (T3).

The mice were given 0.1 ml oral administration from each treatment for 20 days, after 21 days each group was divided into three groups. the first group was analyzed blood and immune tests.

**Collect Blood Samples:** Blood samples were collected via the cut vein and put in heparinized capillary tubes and white tube for other blood tests and separated the serum by centrifugation at 3,500 rpm after left blood for clotted in the refrigerator at 4 ° C for 30 minutes and was then kept in a deep freeze at −70°C until doing immunological tests.[8]

**Experience Wounds:** The mice were divided into three groups and each group consisted of three mice treated:

- **Group 1:** Negative control treated with the solution of phosphate saline (PBS)
- **Group II:** Treated with the solution of ethanol extract of the caper plant.
- **Group III:** Treated with the solution of Iraqi date vinegar.

Standard wounds of 1 cm were performed in the dorsal side after shaving and the wounds were injected with the 0.1 ml active isolate of P. aeruginosa, and follow-up until healing within 12 days after the infection.

**The Statistical Analysis:** The results of the study were presented through the Using of the SPSS program. In analyzing the data, while the LSD test was used to determine the least significant difference between the mean of the coefficients at the probability level (0.05). The T-test was also used to determine the differences between totals.

**Results and Discussion**

The C. spinosa plant is one of the important nutritional plants, flowers, and buds widely used in nutrition, the caper is also rich in protein, fat, carbohydrates, vitamins and minerals. [9] Caper plant is a source of flavonoids, Rutin and Quercetin, a very rich source of quercetin. [10] The effectiveness of these compounds comes from antioxidant action and also has anti-inflammatory properties and it was Immunomodulation using medicinal plants (or their compounds) can provide alternatives to the conventional therapy for a variety of diseases. [11]

Experiments were conducted on mice and observed the effects of the caper ethanol extract. Table (1-1) differences between the treatments showed no significant effect on hemoglobin Hb, PCV, thrombocytopenia (platelets), RBCs. This effects may be explained by the fact, that the mice did not have any significant effect with extract, may be treated mice did not obtain these extract for a long period time in the experimental may be one of the reasons for the absence of any effect between the tests [12].

The results table (2-1) of the statistical analysis showed a significant effect between the treatments (p <0.05), they were observed that the ethanol extract T1 of the caper plant highly significantly to the treatments T2, T3 and control Tc for the total white blood cell count (WBC), group T2 highly significant compared to the control group Tc, The treatments for neutrophil cells were also highly significant effect than control, lymphocytes cell reduction significant was observed in compared to control treatment. These differences are explained from by the possibility that this extract has stimulated and effected on the body from the effects of the chemical compounds found in the caper extract from substances such as Tannins, Alkaloids, Indoles, Polysaccharides, the results agree with. (13) When used caper extraction for treated administration rat, rabbit, and chicken.

The results of treated mice of the table (3-1) were found a significant effect in some of the treatments. There was a significant increase in the weight of the mice in the treatment T1 compared with other treatments T2, T3 and Tc, and they are no significant effect on the weight of the liver, but a significant increase was observed in the treatment of the T3 with the Tc and other factors, and also a significant decrease in the mice of spleen weight in the second and third treatment compared to Tc, furthermore, the results showed a decrease in spleen and liver inflation that treatment with the ethanol caper extraction and the vinegar solution group and their mixtures group compared with the control group. This result is explained by the biological activity of spleen and immune stimulation, which plays an important role in defending the body against germs and against other antigenic from original chemical component in plant, and the results of Table (4-1) showed that T1, T2, and T3 factors had a significant effect compared with Tc group with respect to IgA. It was observed that T1 and T2 were significantly higher with T3 and Tc, and also higher significantly for T3 compared with to Tc. The IgG test showed that the treatments T2 and T3 were higher significantly than T1 and Tc, and IgM test was showed treatment T1 was higher significantly compared with T3 and Tc. T3 also significantly affect compared with Tc group. These indicators of an immune response and evolution in humoral immunity may be due to chemicals compound from the secondary metabolism in the caper plant, for example, Quercetin, Alkaloids, Rutin, Indol-3-ylmethyl (14) that is related to activation of the immune response and the development of humoral immunity. This response begins with the interaction between the innate and acquired immune response(15). Also, The results agree showed a significant affect for high concentration for IgA and IgM in test groups than the control group(16).And the results agreed with (17) when using some of the chemical components given orally to
local rabbits as they led to a rise concentration for IgA and IgM. Also, the results agree with (18) that reported C. spinosa used to pseudomonas aeruginosa attenuated after that injected in white mice.

The effect of the dosages on laboratory mice for the complement protein concentration C3, C4 showed increased significantly in a concentration C3, C4 that is related to treatment T1 compared with T2, T3, and TC table (5-1), these results agree with (19) that found the immunization of laboratory mice produce a high level in C3, C4 of all treatments compared with the control group. caper plant compounds could eventually play an interesting role to control several pathologies by induces immune responses and enhances immunity host against pathogens, for example, IL-17 plays an important role, also strongly suggested in tumor development and in both inflammation and sporadic cancers of the liver, stomach, and colon. The Correlation between Interleukin-1A and Bone Destruction on Chronic Suppurative Otitis Media with Cholesteatoma

Muhammad Reza Mahardika¹, Artono¹
¹Department of Otolaryngology-Head and Neck, Faculty of Medicine, Universitas Airlangga, Jl. Mayjen Prof. Dr. Moestopo 47, Surabaya (60131), Indonesia

ABSTRACT

**Background:** Cholesteatoma is a benign lesion in chronic suppurative otitis media having the ability to induce bone around it. Bone damage is caused by osteoclasts and interleukin-1α (IL-1α).

**Objectives:** To analyze the correlation of IL-1α with the degree of bone destruction in chronic suppurative otitis media (CSOM) patients with cholesteatoma treated mastoidectomy surgery

**Materials and Method:** Prospective colectomy tissue collexatoma was taken during mastoidectomy surgery from 20 CSO patients with cholesteatoma. All tissues were processed then IL-1α was quantitatively tested with ELISA using IL-1α specific antibodies. Bone damage rates were categorized into mild, moderate, and severe degrees. Correlation of both variables was analyzed using spearman rank test (p <0.05).

**Results:** The results of IL-1α in cholesteatoma tissue in 20 patients were in the range of 25.01 - 35.00 pg/ml (30.76 ± 2.99). The degree of bone destruction is mostly in the weight category (65%). The result of analysis of both variables use spearman correlation test (r = 0.625; p = 0.003).

**Conclusion:** There is a strong positive correlation between IL-1 and bone damage rate in CSOM with cholesteatoma.

**Keywords:** cholesteatoma, interleukin-1a, bone destruction, chronic suppurative otitis media

Introduction

Chronic suppurative otitis media (CSOM) can cause morbidity and mortality and thus it remains a major health problem in the world. One of the morbidity and mortality is caused by bone destruction in CSOM patients with choloriatoma causing complications (¹). Cholesteatoma is a cystic lesion coated with a gradual squamous epithelium and contains keratin debris. Keratinocytes in the matrix and macrophages of perestatiechsteatoma express Interleukin-1α (IL-1α). IL-1α plays a role in the growth and maintenance of cholesteatoma homeostasis. The imbalance between resorption process and bone formation occurs in CSOM patients with cholesteatoma (²).

Bone resorption is primarily played by osteoclasts derived from monocyte/macrophage hematopoietic cells. The differentiation and function of osteoclasts is governed by the activator of nuclear factor-κB ligand (RANKL/RANK) receptor bond which will initiate the cascade of osteoclastogenesis. IL-1α increases RANKL expression in osteoblasts and macrophages. IL-1α also affects fibroblasts and osteoclasts to produce prostagagin E2 (PGE2) and collagenase that degrade bone matrix (³).

CSOM complications with cholesteatoma are mainly due to temporal bone destruction processes that can cause hearing loss, balance disorders, facial paresis, periosteal abscess, and intracranial complications (⁴). Bone destruction is divided into three degrees based on
the number of structures involved, i.e. mild, moderate, and severe destruction. IL-1α increases the amount of osteoclasts causing bone density to decrease. The thickness of the bone cortex decreases significantly when constrained by IL-1α.\(^5\)

IL-1α as a therapeutic target has been developed in several diseases with bone destruction, such as rheumatoid arthritis. The important role of IL-1α in the process of bone destruction in CSOM with cholesteatoma allows blockage of IL-1α as a therapeutic target as an adjunctive surgery. Based on the above explanation of the research whether there is a relationship between IL-1α with degrees of bone destruction in CSOM patients with cholesteatoma treated with mastoidectomy surgery.

Materials and Method

The subjects of this study were CSOM patients with cholesteatoma treated with mastoidectomy surgery in Dr. Soetomo General Hospital Surabaya, Indonesia from November 2016 to June 2017. The inclusion criteria of the subjects consisted of CSOM patients with cholesteatoma who were about to undergo mastoidectomy surgery at Central Surgery Installation Dr. Soetomo General Hospital Surabaya, Indonesia and patients who had sufficient pathological tissue for IL-1α examination. Subjects who met the criteria filled the informed consent prior to their involvement in this study.

This is an observational study with cross-sectional design and consecutive sampling method of 20 subjects. In the first step, 4 subjects were identified for their mean of IL-1α with simple random sampling. The collection of pathological tissue of cholesteatoma and skin of MAE was performed at Central Surgical Installation Dr. Soetomo General Hospital Surabaya, Indonesia. The operator took the pathological tissue in the form of cholesteatoma tissue and MAE skin during surgery, then put them into the plate and stored them on a cooler temperature of 40˚C for less than 2 hours. The degree of bone destruction is determined by the operator during the surgery. To take a specimen (examination material), curette, forceps, and tissue scissors were used during mastoidectomy surgery.\(^6\)

IL-1α ELISA examination was performed at the Clinical Pathology Laboratory of Dr. Soetomo General Hospital Surabaya. The tissue in the cooler was sent to the Clinical Pathology Laboratory of Dr. Soetomo in less than 2 hours, then stored at -800C in the Esco Lexicon II ULT freezer. Measurement of IL-1α levels was done quantitatively using the ELISA method. The cholesteatoma and skin tissues of MAE were processed using human IL-1α ELISA kit for lysates (RayBio, location, manufacture state) in accordance with the procedures stated in the kit. The absorbance value reader tool was set at 450 nm wavelength with Humareader Single. The ELISA examination was performed after the entire sample was fulfilled and performed by a Clinical Pathology Specialist Consultant doctor.\(^7\)

The results of the above tests were analyzed using the Shapiro-Wilk normality test first. The mean comparison of IL-1α cholesteatoma and MAE skin were analyzed using Mann-Whitney U test. The relationship between IL-1α with bone destruction was analyzed using Rank Spearman test. Data analysis was conducted using SPSS (SPSS, Inc., Chicago, IL) with p <0.05.

Table 1 above shows that CSOM patients with cholesteatoma in this study were mostly in the age group of 21-30 with 45%. Most of the subjects were male (55.00%) and Javanese (70.00%). The data also shows that severe destruction has the highest number in patient than other bone destruction case. Most of the patients with bone destruction are javanese tribe.
Table 2: Degree of IL-1α cholesteatoma

</table>

Table 3 shows the destruction of mild bone had IL-1α score was obtained 14.93 ± 4.36, medium bone destruction had the level of IL-1α obtained value 22.75 ± 12.18, and severe bone destruction had the level of IL-1α obtained value 31.98 ± 14.16 (r = 0.625; p = 0.003). The severe bone destruction has the highest score number than other degree. of bone destruction. Light degree bone destruction has the smallest score than other degrees.

Discussion

The levels of IL-1α in cholesteatoma with normal MAE skin were measured using Western Blot method. The mean of IL-1α concentration in cholesteatoma tissue in the study was 0.39 pg/ml, whereas the levels of IL-1α in normal skin were undetectable. No detection of IL-1α in normal skin in the study is likely due to the limit of skin IL-1α levels to be below the minimum level of IL-1α levels that can be detected by the reagents used. Calculation of IL-1α levels on culture of cholesteatoma tissue quantitatively using ELISA method. Levels of IL-1α were found to increase in the culture of the first day until the third day to reach the highest levels of 270 pg/ml. The IL-1α levels of 23 CSOM patients with cholesteatoma and in control group were compared using ELISA.

Interleukin-1α keeps the homeostasis of cholesteatoma in an autocrine way. Cholesteatoma expresses IL-1α continually and IL-1α provides a positive feedback by inducing formation of cholesteatoma keratinocytes (8). The thing that differentiates this study from the one mentioned above is probably the clinical characteristic of different patients. Most sufferers come to treatment in severe bone destruction conditions (1). The longer the suffering of CSOM with cholesteatoma will cause more cholesteatoma to form, causing the bone destruction to be heavier as well.

Bone resorption in tissue culture of cholesteatoma where bone resorption increases is directly proportional to elevated levels of IL-1α (9). A research examined the relationship between IL-1α and bone destruction in patients with CSOM with cholesteatoma using Western Blot examination (8). Medium bone destruction was most prevalent and there was a positive correlation between IL-1α levels and bone destruction (r = 0.597).

Osteoclasts are the main cells in the process of bone destruction in cholesteatoma. Interleukin-1α affects osteoclast formation and differentiation. Interleukin-1α is the most potent osteoclastogenic cytokine that plays a role during the inflammatory process in cholesteatoma. Experiments on IL-1α-blocked mice showed a decrease in bone resorption rates (10). The number of osteoclasts decreased significantly (p <0.01) in the bones of experimental animals with IL-1α constraints compared with normal bones while bone density was increased in mice with suppression of IL-1α (11). Bone resorption in tissue culture of cholesteatoma. Human cholesteatoma tissue cultures given antibodies toward IL-1α incubated on the calf bone medium of the experimental animals showed no bone resorption. This suggests that IL-1α plays a role in direct bone resorption, and resistance to IL-1α works by decreasing the number of osteoclasts causing the increase of bone density (12).

Interleukin-1α is not the only cytokine that plays a role in bone resorption in OMSK with cholesteatoma. Cytokine Tumor Necrosis Factor alpha (TNF-α) also has an important role in the process. A study in Japan provides the fact that there is an increase in TNF-α and IL-1 detected in cholesteatoma acquisita as well as congenital cholesteatoma compared to in normal KAE skin (1). The RT-PCR technique showed that messenger ribonucleic acid (mRNA) for IL-1α and TNF-α was detected in 5/5 cholesteatoma, whereas in congenital
cholesteatoma there was a strong mRNA expression for TNF-α in 5/5 cases but only weak for IL-1α in 4/5 cases (13). ELISA techniques obtain higher IL-1α levels in cholesteatoma acquisita than in congenital cholesteatoma, whereas TNF-α levels do not differ significantly in both cholesteatomas (14).

Interleukin-1α is a cytokine that plays a role in inflammation and increases bone destruction directly or through increased osteoclastogenesis in CSOM with cholesteatoma. Various studies on IL-1α inhibition have been performed on various diseases associated with bone resorption, including rheumatoid arthritis, gout, ankylosing spondylitis, and erosive osteoarthritis. Some IL-1α inhibitors include anakinra, rilonacept, and MABp1 are used as a therapy for rheumatoid arthritis and ankylosing spondylitis (15).

There has been no research on IL-1α antagonists as a therapeutic target in CSOM with cholesteatoma conducted previously. The provision of recombinant IL-1RA may be a new target for adjuvant therapy in addition to surgery on CSOM with cholesteatoma (2). The goal is to reduce IL-1α activity which reduces the inflammatory process as well as inhibits the growth of cholesteatoma and the process of bone destruction (16).

**Conclusion**

Bone destruction in CSOM with cholesteatoma is not only due to IL-1α. The cytokine TNF-α, PGE2, and Lipopolysaccharide (LPS) produced by bacterial infection also have a role in bone destruction, but this study does not measure TNF-α, and PGE2. This study also did not conduct bacterial cultures to determine the bacterial infection that will produce LPS.

**Ethical Clearance:** This research process involves participants in the survey using a questionnaire that was accordant with the ethical research principle based on the regulation of research ethic committee. The present study was carried out in accordance with the research principles. This study implemented the basic principle ethics of respect, beneficence, no maleficence, and justice.

**Conflict of Interest:** There is no report of conflict of interest of the research, as well as the conflict between authors so far the research has been conducted and documented.

**Source of Funding:** This study is done with the authors’ funds only, without external donation or funds.

Effect of Alcoholic Extract of *Opuntia Ficus Indica* on Semen Quality of Awassi Rams after Different Cooling Periods

Abd AL-Kareem Abd AL-Reda Hobi¹, Ahmed Mahdi Abbas AL-Helal¹

¹Department of Animal Production, College of Agricultural Engineering Sciences, University of Baghdad, Iraq

ABSTRAcT

This study was conducted to undertake the effect of adding alcohols extract of *Opuntia ficus indica* fruits (AEOFI), and its effect on some characteristics of Awassi rams semen during liquid storage at 5 °C for up to 72 h in Tris egg yolk (TEY) extender. To select the better concentration of alcohols extract. This experiment was executed at the farm Animal, Department of Animal Production, College of Agriculture, University of Baghdad AL-Jadreya campus during the period from the first October, 2017 to 27 th of March, 2018. Semen samples from three local Awassi rams were pooled and extended with Tris-egg yolk extenders containing (AEOFI) (0%, 0.5%, 1%, 1.5% and 3%), at a final concentration of 0.8 × 10⁷ sperm/ml. The sperm characteristics (individual motility, plasma membrane integrity and dead sperm) were evaluated at different time periods (0, 24, 48, 72 h) at cooling 5°C. Results showed that the supplementation of Tris egg yolk extenders with 1 % (AEOFI) contributed to enhance sperm individual motility, membrane integrity and decreased the percentage of dead sperm, during storage compared with the control group. In conclusion, (TEY) supplemented with 1% of (AEOFI) can improve the quality of Awassi ram semen. In addition, our results suggest that (AEOFI) in these concentrations can help to enhance Awassi ram semen quality during chilled storage.

Keywords: Awassi ram, Alcohols extract, Semen, Sperm characteristics, Tris

Introduction

Sperm cells have a high content of unsaturated fatty acids in their membranes. Therefore, sperm cells very susceptible to lipid peroxidation by free radicals such as hydrogen peroxide, hydroxyl radical and superoxide anion which could later lead to the structural damage of sperm membranes during the cooling storage of sperm. Many studies indicate that the quality of semen deteriorates during liquid storage for a long periods. Cold shock of sperm cells during the cooling process is associated with oxidative stress induced by free radicals which could later lead to the damage of cells. Impaired sperm function is a general cause of male infertility. A balanced generation of reactive oxygen species (ROS) and antioxidant enzymes is associated with normal physiological functions. Seminal plasma has an antioxidant system that seems to be very relevant to the protection of sperm, include superoxide dismutase, catalase, glutathione peroxidase and glutathione reductase. Therefore, the defensive role of the seminal plasma is reduced after applying sundry dilutions for semen storage. To outdo with such problems, the uses of lactoferrin in the semen causing decrease in the total number of bacteria in the semen. Subsequently, we suppose that possibly the (AEOFI) has ability of to improve the liquid preservation of Awassi rams semen. Thus, this study was conducted to explain the protective effect of various concentrations (0, 0.5, 1, 1.5, and 3 %) of (AEOFI) from *Opuntia ficus indica* fruits added in Tris-egg yolk extenders on sperm quality during the liquid storage of ram sperm at 5 °C for various periods of storage.

Materials and Method

Animals and Semen Collection: Semen samples from three mature Awassi rams (2-3 years of age and 52-60 kg
of Wight) were utilized in this study. The rams were drink, fed, housed and lit, conventionally. The study was carried out from the first October, 2017 to 27th of March, 2018. Animals were housed at the farm Animal, Department of Animal Production, College of Agriculture, University of Baghdad, Iraq. All the rams were in a good health. They were safeguard in equal managerial and nutritional situation throughout the periods of the study. The animals were kept in open front barrens, were fed singly with concentrated mixture (Containing 46% barley, 36% bran, 16% soybean, 2% minerals and salt mixed in the farm) of one kg per ram per day and water was given ad libitum. Thirty ejaculates were collected by artificial vagina during ten weeks. For collecting ejaculates, ram were penned with ewes in estrus. Ejaculates were evaluated and included in this study if the following norm were met, volume of (0.9-1) mL, sperm Concentration of (2.5-10^9) sperm per mL, motility (>70%).

**Semen Analysis:** The volume of every ejaculate was listed, sperm concentration was specified by taken (0.1mL) semen and diluted with (19.9mL) diluents solution, formed from (0.9%) Nacl, 0.01 Hgcl, 2 gm/L eosin stainelope the diluted semen was placed on hemocytometer with the sperm enumerated in five squares of one chamber. Sperm motility was identified as those sperm cells that demonstrated individual motility according to. Semen was laid on a heated glass slid, and scoring was performed at microscopic magnification of 400 x. The mean value was used for data analysis. Assessment of the percentages of dead sperm was performed using an eosin–nigrosin staining method. Assessment of the percentage of Sperms plasma membrane integrity was performed according to method, a semen sample 30 μL was mixed with 300 μL distilled water (pH 7.2, mOsm 05) and incubated at 37 °C for 5 min, after incubation a drop 15 μL of the treated mixture was placed on a warmed slid and covered with a cover slip, a total of 200 sperm was counted in six different microscopic fields at 400 x, the percentage of spermatozoa with swollen and curved tails was recorded.

**Dilution of Semen and Addition of (AEOFI):** Semen samples were diluted by using the basic extenders were Tris 3.63%, fructose 0.5%, citric acid 1.9%, streptomycin 100 mg, penicillin 100000IU and egg yolk 19.2 mL. The diluted semen sample was divided into five group. The first group Tris egg yolk only without any addition considered as control group. The other four treatment group were adding the alcoholic extract of the Opuntia ficus indica fruits (AEOFI) with different percentage which were 0.5%, 1%, 1.5%, 3% for T1, T2, T3, T4 respectively.

**Statistical Analysis:** Data were analyzed by SAS (2012) computer program using completely randomized design (C.R.D) to study the effect of treatment for any time according to model:

\[ Y_{ij} = \mu + \text{Ti} + e_{ij} \]

Where, \( Y_{ij} \) is the value of observation \( j \) to treatment \( i \), \( \mu \) the general mean of the characteristic, Ti effect of treatment \( i \), eij : random error which is naturally distributed at an average of zero and a variation of e. Duncan test was used to compare the significant differences between means.

**Results**

In this study there was no significant differences \( p>0.05 \) were found between individual Awassi rams in the estimated parameters. The results of our study revealed that the addition of 0.5% and 1% (AEOFI) in TEY can significantly increase (\( p<0.05 \)) in the percentage of individual motility compared to the control groups after storage period at (0, 24, 48, 72 h) (Table 1). The percentage of individual motility declined gradually in all concentration of AEOFI (0, 0.5, 1, 1.5, 3%) with Tris egg yolk containing diluents when preserved at 5 °C from 0 to 72 h which was declined markedly (Table 1).

(TEY): Tris egg yolk, AEOFI : alcohols extract of Opuntia ficus indica fruits, C: Control group TEY only, T1: TEY + 0.5% AEOFI, T2: TEY + 1% AEOFI, T3: TEY +1.5% AEOFI, T4: TEY + 3% AEOFI, Values are expressed as mean ± SEM, Means carrying different big superscript letters within the same column are significantly varied at \(^{\ast}\)p<0.05. Means carrying different small superscript letters within the same row are significantly varied at \(\ast\ast\)p<0.01.
Discussion

This study was designed to determine the effect of alcohols extract of *Opuntia ficus indica* fruits (AEOFI) addition in cooling extender on the individual motility, plasma membrane integrity and dead of Awasii rams spermatozoa. Cooled extender is a better alternative to frozen semen if it is used in a short time of storage. The quality of sperm after liquid storage needs to estimate before practical implementation in the farm. The lowering in the percentage of individual motility of sperm during long period of liquid storage in the present study was agreed with 9. Oxidative stress due to undue production of ROS has been related with defective sperm profession. The ROS attack polyunsaturated fatty acids in the sperm plasma membrane that led to loss in a membrane fluidity and integrity16. Many studies have reported that membrane lipid peroxidation in sperm are associated with reactive oxygen species ROS production17,18. And addition methionine to semen19 and ascorbic acid3. And addition lycopene on ram semen to prevent oxidative stress in rams spermatozoa during liquid storage, and addition cactus seed oil during liquid storage to improvement of ram semen quality20. That led to the addition of other natural herbs on the ram spermatozoa can enhance ram sperm quality like colve bud21 and rosemary22,23.

Conclusion

This study implies that supplementation of TEY with an suitable concentration of alcohols extract of *Opuntia ficus indica* fruits (AEOFI) has a beneficial effect on ram sperm parameter during liquid storage at 5˚C. The (1%) concentration of AEOFI can enhance sperm quality variables such as individual motility, plasma membrane integrity and decreases dead sperm. Therefore, this AEOFI can be considered powerful natural antioxidants that can be added in extender for semen cooling.

Motivation in Health Behaviour: Role of Autonomous and Controlled Motivation

Adeline Y. L. Tam¹, Rohaizat Baharun², Zuraidah Sulaiman³
¹PhD Candidate, ²Professor, ³Senior Lecturer, Azman Hashim International Business School, Universiti Teknologi Malaysia, Johor Bahru, Johor, Malaysia

ABSTRACT

Introduction: Self-Determination Theory (SDT) emphasizes effect of motivation quality (autonomous and controlled motivation) in influencing behaviour. SDT explains the involvement of motivation in many areas, particularly health behaviour.

Purpose: This paper reviews the application of both autonomous and controlled motivation in predicting health behaviour in the literature.

Methodology: Published journals or articles containing quantitative studies that applied either autonomous and controlled motivation or both as independent variables that predicted health behaviour were included in this review. Articles from the past ten years (2009 to 2018) were reviewed. Health behaviours were further categorised into illness treatment and recovery, reduced health risks, and general health.

Findings: Review results indicated that autonomous motivation was consistently related to various health behaviours for short- and long-term. Controlled motivation was either insignificantly or negatively related to health behaviours.

Implication: This paper adds to our understanding of the influences of motivation on health from the perspective of SDT. This paper also contributes to the healthcare literature by providing insights into the extent to which both types of motivation influence health behaviour.

Keywords: autonomous motivation, controlled motivation, health behaviour, Self-Determination Theory, health maintenance

Introduction

Health-related habits are not changed by act of wills, but rather motivational and self-regulatory skills¹. Motivation factors are not only associated with engagement in health behaviour, but also long-term health behaviour change². Self-Determination Theory³ (SDT) has showed particular promise in explaining the nature and role of motivation for various health behaviours⁴. SDT is distinct from other motivation theories in that it conceptualises motivation by its quality rather than its quantity (level of motivation)². The SDT constructs, autonomous motivation (AM) and controlled motivation (CM), were applied to explain individual involvement in various health behaviours. Nevertheless, few studies⁷-⁸ have reviewed how AM and CM influence health behaviours.

This paper reviewed two main constructs of SDT, AM and CM, their roles in predicting health behaviour in the literature. The objectives of this study are twofold. First, this study examined the influence of AM and CM on health behaviours in the literature; Second, this study compared the influence of AM and CM in conducting health behaviour. This paper deepens our understanding of how motivation influences health from the SDT perspective.

**Literature Review**

SDT defines motivation as the psychological energy directed toward a goal. White pointed out that using motivation to capture need fulfilment could explain ‘why a behaviour occurs’ due to individual intentions, attitudes, and beliefs. AM is defined as engaging in a behaviour because it is perceived to be consistent with intrinsic goals or outcomes that emanate from the self. Autonomous motivated behaviours are initiated and regulated through choice as an expression of oneself. According to SDT, people are inherently inclined to engage in behaviours consistent with their interests, life values, and important goals and hence AM explains individual actions. AM was found to be reliable in predicting healthcare intentions, triggering initiations, and promoting behaviours persistence, as well as short-term and long-term behaviour.

CM reflects engagement in behaviours due to external pressures (for instance, to gain rewards, avoid punishment or meet expectations), and/or internal pressures (including obtaining perceived approval from others or avoiding feelings of shame, guilt, or anxiety). CM behaviours are characterised by heteronomous initiations that are pressured and coerced by intrapsychic and environmental forces, and thus do not represent true choice. SDT proposed that AM is more effective than CM in promoting behaviour persistence because behaviour guided by CM will cease when the external contingency no longer exists.

**Health Behaviour:** Health behaviour in this review refers to various individual behaviours to promote or maintain their own health. The health behaviours accepted in this review followed Hagger et al. Health behaviours were further categorised into illness treatment and recovery (ITR), reduced health risks (RHR), and general healthcare (GH). Health behaviours such as injury treatment adherence, reduced health risks, and exercise for patient with heart disease were grouped into ITR. Meanwhile, RHR included various behaviours to reduce threat to health. Other behaviours to maintain good health were categorised in GH.

**Methodology**

Published journals or articles consisting of quantitative studies that used AM and/or CM as antecedents to predict physical health behaviour were included. Journals that were published during the last ten years (2009 to June 2018) were collected from established online journal banks, such as Google Scholar, Ebscohost, Emerald and Science Direct. Conceptual paper, qualitative research, and quantitative research paper that only applied mean comparison (e.g. t-test and ANOVA) or correlation methods of analyses are excluded as these studies did not contain beta coefficient value that required for further comparison. A total 21 journals detected and included in this review.

Beta coefficient value (or standardised regression coefficient) are used for direct comparison of the relative effect of each AM and CM on the dependent variable. Beta coefficient eliminates the problem of dealing with different units of measurement and reflects the relative impact on the dependent variable of a change in one standard deviation in independent variable. The details of relationships between AM and CM with health behaviours (in beta coefficient) are tabulated in Table 1.

The articles included in this review covered various health-related behaviours which were grouped into three categories, ITR, RHR, and GH. There are five studies fall under the ITR, five studies under RHR and the remains in GH category. Although the samples of these studies were mostly healthy population, unhealthy population is also included. The samples in these studies were of different age groups, such as adolescents, young adults and adults. Meanwhile, two studies analysed the data in the population survey. Most articles were applying structural equation modelling (SEM) to analyse the influences of motivation on health behaviour.

**Findings**

Except for few cases, AM was consistently and positively related to various health behaviours in GH (beta=.08~.52; beta mean=.240) and ITR (beta=.13~.72; beta mean=.290) categories. AM negatively influenced unhealthy behaviours under RHR category (beta=-.31~-.57; beta mean=-.214). It was noticed that AM was more strongly related to long-term behaviour than with short-term behaviour in the context of weight-loss and exercise behaviour. Nevertheless, Shaikh et al found that the AM was associated with fruit and vegetable intake stronger in the base time than a year later.
CM was examined in 14 studies and revealed inconsistent results in relation to health behaviours. CM was found to influence health behaviour significantly in eight studies (57.14%). Four of these studies found that CM was negatively associated with health behaviours (beta=-.13~-.26; beta mean=-.185) but two studies found that CM was positively related to health behaviours (beta=.17~.21; beta mean=.193).

While for RHR, CM was also negatively related to unhealthy behaviours, but positively associated with unhealthy eating. Among the three studies compared CM influences in short-term with long-term, only Shaikh et al. social support (SS confirmed that CM was positively related to fruit and vegetable intake in the short-run but insignificant in the long-run.

Discussion

Most studies confirmed that AM was significantly and positively related to the health behaviours, supporting the view that AM had the most pervasive effect on intentions and behaviour across the majority of the health-related behaviours in regardless of sample background, such as gender and age. In line with SDT, when an individual agreed with the values and benefits of health behaviour, he would be motivated to perform the behaviour, leading to positive relationship with health behaviour. In contrarily, CM was inconsistently related to health behaviours with only slightly more than half of the studies found CM significantly associated with the health behaviours tested. The finding was consonant with reviewed done by Teixeira et al which in turn is associated with important health outcomes. Accordingly, research on exercise motivation from the perspective of self-determination theory (SDT for exercise behaviour. CM reflects engaging in behaviours due to external pressures and/or internal pressures and thus required the existence of sure pressures to behave. In the events that these pressures unavailable, CM would not associate with the health behaviours.

AM had a higher beta results than the CM reflecting that the AM had stronger influences than CM on the health behaviour. AM results in ITR category reflected that patients with AM were aware of the benefits of health behaviours and were more determined to engage voluntarily with illness treatment and recovery behaviours. To enhance results of illness treatment and recovery process, medical professionals needed to boost the AM of patients but avoiding CM by reducing external pressures to the patient. The findings provided evidence to warrant used of AM to promote health behaviours in other contexts, supporting Hardy et al.

The analysis revealed that both AM and CM were good at discouraging unhealthy behaviours that could threaten the health of individuals. Promoting abstinence from health-risk behaviours could be more effective if the targeted groups were taught of the value to autonomously demotivate risky behaviour and at the same time, they were made aware of the potential external and internal pressure to refrain from the risky behaviour.

Furthermore, AM was found to associate with health behaviours in both the short-term and long-term, but CM was not able to predict any health behaviours in the long-run. The finding confirmed that AM is more likely to produce long-term, sustained behaviour change than CM. While CM might be suitable to pressurise an individual to start performing a health behaviour, AM would be necessary to sustain health behaviour until habitual health behaviour created.

Conclusion

This review provides a unique and important insight into the consequences of motivation towards health behaviour adoption and maintenance. Academically, this paper supported the inclusion of AM and CM in future research of health behaviours. This paper also presents evidence to health professionals to include motivation, particularly the AM in promoting and maintaining health behaviour. The findings may extend to apply in other health context or to resist unhealthy behaviours in both short-term and long-term. Nevertheless, the influences of social support and environment context on motivation were not examined. Future study could review the impacts of social support and environment context on the motivation quality and level. Future review could attempt to examine the influences of motivation on the emotional and psychological well-being. In conclusion, this research draws attention to the importance of motivation quality (AM) as proposed by SDT in promoting health behaviours and refraining from unhealthy behaviours.

The Effectiveness of Aluminum Potassium Sulfate Micro-Particles Addition into Soft Denture Lining Material on Candida Albicans Adherence

Ali Mohad1, Abdalbseet A Fatalla2
1Master Student, 2Assistant Professor, Department of Prosthodontics, College of Dentistry, University of Baghdad

ABSTRACT

Naturally available products have been used widely for centuries in handling human disease. The present study aimed to determine the antifungal ability of aluminum potassium sulfate against *Candida Albicans* adherence to the soft liner material in scientific way. The antifungal ability of aluminum potassium sulfate evaluated against *Candida Albicans* adherence in two part, first part include incorporation of KAL(SO$_4$)$_2$ in too soft liner monomer in concentration (1%,2%,3% by wt.) while the second part include immersion of soft liner specimens in solution of KAL(SO$_4$)$_2$ in concentration(5%,10%,15% percent) during different time periods (0,10,30,60 minutes). In conclusions, the results of current study encourage use KAL (SO$_4$)$_2$ as antimicrobial material in different ways.

*Keywords*: Aluminum Potassium Sulfate, Micro-Particles, Denture Lining Material, Candida Albicans Adherence

Introduction

Soft denture lining material used in patient suffering from pain or soreness resulting from tissue contact with hard denture base. Addition of soft denture lining material ensuring optimal adaptation of the denture to the underling tissue. (1) Soft denture lining material characterized by high resiliency so acting as shock absorber reducing load transmission to the underling tissue. (2) Common problem associated with soft lining material using lack of antimicrobial properties especially in bad oral hygiene cases. Common microorganism isolated from patient present with denture stomatitis is *C. Albicans*. (3) *C. Albicans* present in oral environment of healthy individual and can become opportunistic but present in greater number in denture wearer because the denture reduce flow of O2 and saliva to the underling tissue. (4)

Aluminum potassium sulfate(alum) having chemical formula KAL(SO$_4$)$_2$.12H$_2$O and generally having no odor, no color sold crystal that return white in color in air that used in food preservation and water purification(5). The alum has been recommended as active ingredient part in mouth wash by the Counter Advisory Panel of U.S. Food and Drug Administration (FDAs)(6).

Material and Method

The study divided into two parts:

1. Incorporation of KAL (SO$_4$)$_2$ into soft liner (0%,1%,2%,3%). In comparison with nystatin (1.4% by wt. Added to the soft liner). Where it mixed with soft liner monomer.

2. Immersion of soft liner specimens in suspension of KAL (SO$_4$)$_2$ (0%, 5%, 10%, 15% during times 0, 10, 30, 60 minutes).

Where5 specimens for each group prepared.

Microbiological part of study

**Specimen preparation:** Plastic pattern disk shaped form (10mm in diameter and 2mm in thickness) used to fabricate soft liner specimens. (7)These plastic disks
placed inside addition silicone, waiting until complete setting of silicone then placed inside lower part of the flask then freshly mixed stone (W/P ratio:25ml/100g) poured on it until lower part of flask completely filled. After complete setting of stone, its surface and surface of silicone with plastic patterns coated with separating medium. After that the upper part placed on the lower part completely filled with stone using vibrator and covered with its lid. After setting of stone, the flask opened and plastic disks removed.

**Proportioning and mixing of heat cure acrylic soft liner:** The liquid mixed with powder according to manufacturer direction (P/L ratio1.2g:1ml) in dry clean glass jar and covered with lid.

**Incorporation of aluminum potassium sulfate into soft liner:** The weighted amount of KAL(SO$_4$)$_2$ added to the soft liner monomer and mixed in clean dry glass jar using probe sonicator until become completely homogenous then soft liner powder added. Keeping in mind to subtract the weight of KAL (SO$_4$)$_2$ from weight of soft liner powder.

**Packing:** When the soft liner reach to dough stage, placed on mold space prepared in silicon and secured with polyethylene sheet then upper part placed on it and transferred to the hydraulic press to expel the excess soft liner. Then the flasks removed from press, opened then remove polyethylene sheet and excess soft liner. Then the flask closed and transferred to hydraulic press for 5 minutes under pressure (100g/cm$^2$) then clamping the flask.$^{(9)}$

**Curing and finishing:** The packed dental flask immersed in digital water path. Curing time according to the manufacturer’s instructions (70°C for 90 minutes then for 30minutes after temperature raising to 100°C) $^{(9)}$When curing cycle completed, the flask removed and allow to cool for 30 minutes then flask opened and specimens removed from their mold. The access soft liner material removed using sharp blade and finished by fine grit polishing silicon bur and fine grit sand paper then sterilized in autoclave.

**Isolation of Candida albicans:** Candida albicans was taken from the oral cavity of twenty patients come to the clinic of prosthodontics in college of dentistry seeking for treatment for their problem which was denture stomatitis with oral thrush.$^{(10)}$The oral lesion scrubbed gently by sterilized cotton swab then cultured in sabouraud dextrose agar medium $^{(11,12)}$ then placed in incubator at 37°C for 48 hrs.$^{(13)}$

**Identification of Candida albicans:**

- **Microscopical examination:** Few numbers of inoculum were taken from colony and placed on glass slide then adding drop of normal saline to form suspension. Then the suspension spread and allows drying on slide at room temperature then fixed by passing it on Bunsen burner flame for few seconds. The glass slide stained according to Gram’s Method$^{(14)}$.

- **Germ tube formation:** Take yeast cells from single colony and suspended in tube containing serum (0.5 ml). These tubes taken to incubator at temperature 37°C for 3hrs. When incubation period completed, a drop of this suspension taken and placed on glass slide. Then the slide examined under low power of magnification to see germ tube$^{(15)}$.

- **Biochemical Identification:** To confirm that the fungal isolated is *C. albicans*, analytical profile index (API) of candida system was utilized. Adding of 1-2 isolated and activated colonies to NaCl (0.85%) with turbidity about 3McFarland standard value(equal to 10$^6$ cell/ml) when candida suspension are prepared. The small tubules filled by this suspension of candida. Where these tubules immediately covered by mineral oil because some of the reactions are anaerobic. Then the API strip system transferred to incubator at 37°C for 24 hrs.

**Evaluating the effect of aluminum potassium sulfate on adherence of *C. albicans* to the soft-liner specimens:**

**Adherence test procedure:** *C. albicans* was diluted using NaCl (0.9), a suspension of 10$^7$ CFU ml (0.5 McFarland standards) was prepared by using a McFarland densitometer $^{(16)}$. Then the sterile soft lining specimens were deposited in sterile bottles containing 10ml of the prepared yeast suspension. Then the specimens incubated at room temperature for 1hour. Then the specimens removed and rinsed two time with phosphate buffered saline solution(PBS) for (1) minute,then the specimens dried by filter paper. The adhered cells fixed through using methanol then staining of specimens by crystal violet for (60) seconds. Then the specimens rinsed again with PBS for(30)seconds. After that drying of the specimens. Then the specimens examined with inverted light microscope $^{(17,18)}$.The adherent yeast cells calculated in three fields of view for each sample and the mean of these three fields was taken for each one specimen. The result expressed as (yeast cells/mm$^3$).
Results

Scanning electron microscope (SEM): SEM results of soft liner before and after the addition of 2% and 3% by wt. KAL(SO$_4$)$_2$ micro particles powder are shown in Figure 1.

Figure 1: Scanning electron microscope results: control group(A,B), 2% group of KAL(SO$_4$)$_2$ (C,D), 3% group of KAL(SO$_4$)$_2$ (E,F).

Test of Homogeneity of Variances: Before starting with ANOVA table multiple comparisons test, the variances of tested groups were analyzed by running the Levene’s test of homogeneity. According to primary analysis of data homogeneity, Games-Howell test was selected for multiple comparisons of incorporation part of candida adherence test while Boneferroni test was selected for multiple comparisons of immersion part of candida adherence test.

Evaluating the adherence ability of C. albicans (incorporation part): Evaluation of specimens’ groups where made by staining the specimens of each group with crystal violet and then examined under the inverted light microscope. The mean value of control group (38.4). The mean value of the first experimental group (incorporation of nystatin (1.4% by wt.) is (8), the mean value of second experimental incorporation group (0.01 of KAI (SO$_4$)$_2$) is (21), the mean value of third experimental incorporation group (0.02 of KAI (SO$_4$)$_2$) is (10) and the mean value of fourth experimental incorporation group(0.03 of KAI (SO$_4$)$_2$) is (8.2).

Comparison of the means of C. albicans adherence test results of the experimental groups using one-way ANOVA was highly significant (table 1).

To compare the mean values among all study groups, Bonferroni multiple comparison test was conducted. There was significant difference between all groups except the difference in control group between 30/0 and 60/0, in 5% immersion group between 0/0.05 and (30/0.05, 60/0.05) and 30/0.05 t/c with 60/0.05, the difference in 10% immersion group between 0/0.10 and 10/0.10 and finally in 15% immersion group between 0/0.15 and 60/0.15 which are non-significant (Table 4).

*: time in min./concentration of aluminum potassium sulphate (g/L)

Discussion

Application of soft lining materials became important for edentulous patients with removable dentures. These soft liners will act as a cushion between the resorbed ridge and the denture to absorb and distribute the applied occlusal forces. (19, 20, 21)

One of the highly important problems associated with the using of soft liners, the colonization of microorganisms on these liners especially C. albicans causing denture stomatitis. (22)

Many studies attempted to prevent colonization of fungi by incorporation of antifungal agents within the soft denture liner material itself and addition of nanoparticles. (23, 24)

In this study an effort was made to develop soft lining material with anti-fungal properties against C. albicans through addition of KAL (SO₄)₂ in to soft liner material.

From the statistical results of this performed study, there was highly significant reduction in the numbers of C. albicans cells that adhered on the soft lining material surface containing KAL(SO₄)₂ in comparison with the other control soft lining specimens.

Aluminum potassium sulfate is natural products have been used for centuries in treating human diseases and they contain components of therapeutic value. Natural products are environmentally safer, easily available, and cheap.

Alum is an effective solution for the removal of the smear layer when used as a final rinse. It does not significantly change the structure of the dentinal tubules. Studies are in progress to determine the efficacy of alum as a root canal irrigant with and without NaOCl for removing the smear layer and completely disinfecting the root canal system. (25)

Aqueous extract of KAL (SO₄)₂ were being good sources for the bioactive compounds that exhibited good antimicrobial properties. It was observed that the bacterial growth inhibition was increase when the alum concentrations increase. Since the body doesn’t absorb aluminum, alum could be considering as a harmless material and has a low toxicity in laboratory animals. (5)

Nurse Feelings When Become a Member of Code Blue Team at Wava Husada Hospital Kepanjen, Malang

Annisa Rahmania¹, Indah Winarni², Septi Dewi Rachmawati²
¹Master of Nursing Student, Department of Emergency, ²Lecturers of Nursing Masters in the Faculty of Medicine, University of Brawijaya

ABSTRACT

Background: Code blue is an emergency management that is used to provide information when patients experience cardiac arrest and respiratory arrest in the hospital. The code blue system consists of a team that is a collection of certified doctors and nurses who are assigned to handle cases of the emergency. But sometimes in the process of implementing the code blue system, the Code Blue team encountered several problems. The aim of this study was to explore the feelings of nurses when joining a member of the Code Blue team.

Method: This study was a qualitative study with an interpretive phenomenology approach. Participants in this study were 8 nurses selected using purposive sampling technique with inclusion criteria are they were nurses who had been members of the code blue team for ± 2 years, had attended ACLS training, were willing to become participants by signing the informed consent. This research was conducted in March 2019 at Wava Husada Hospital. The method used in this study is in-depth interviews supported by a semistructured and open-ended question guide.

Results: The results of this study obtained 4 themes, that were: 1) felt confused when they got a code blue for the first time; 2) faced two choices of tasks; 3) felt useful to others; 4) felt sorry and sad when the patient passed away. Nurses felt confused when getting a code blue call. This is related to those who did not have the experience to work on a team. They not only feel confused but are also faced with two job choices. That sometimes makes them feel like a dilemma. In addition, they also sometimes felt sorry and sad when the patients they helped cannot be saved and continued to stay alive. But behind the confusion and dilemma, they also felt useful because they can help others.

Conclusion: Taking a part as a code blue nurse was not an easy. There was big responsibility that they must embrace besides being a health care provider in their respective service units. This is what caused joy to become a nurse in the code blue team

Keywords: nurses feelings, code blue team

Introduction

Cardiac arrest is a condition when the heart loses its function suddenly, unpredictable time, and can occur in someone with a history of heart disease or not ¹. Cardiac arrest causes 17,668 deaths in the United States². The incidence of cardiac arrest that occurred in the hospital was 209,000 events³,⁴ and most occurred in the ward and not monitored⁵. Cardiac arrest can cause brain death and permanent death when initial treatment is not immediately performed or treatment is delayed＞5 minutes from the occurrence of cardiac arrest⁶. Handling that can be done on someone with cardiac
arrest is to provide basic life assistance in the form of pulmonary heart resuscitation. Resuscitation is the act of putting pressure on the heart and artificial breath to someone who has stopped breathing and cardiac arrest. The hospital emergency code is a code that is used throughout the world that aims to convey information quickly, especially information relating to emergency conditions. This code is often referred to as code blue.

Code blue is emergency management that is used as a means of communication when there are patients who need immediate medical treatment related to breathing and cardiac arrest, such as resuscitation. The code blue system consists of a team formed specifically to handle patients with emergency conditions. This team is called the code blue team which is a collection of several health workers consisting of certified doctors and nurses who are required to be able to provide treatment to patients with emergency conditions, but sometimes in the process of implementing the blue code system, the Code Blue team encountered several problems.

The results of the preliminary study interviews with code blue nurses at Wava Husada Hospital found that nurses who were the code blue team were nurses who also worked in a service unit. When conditions in one service unit are many patients, not all code blue personnel can be present when code blue is activated. This sometimes puts them between two difficult choices. The aim of this research to explore the feeling of nurses in the scope of emergency services in the Code Blue system has not been done much, so further research is needed on this matter.

Method

This research was qualitative with interpretive phenomenology approach. Participants in this study obtained 8 nurses who were selected using a purposive sampling technique with inclusion criteria: nurses who had been members of the code blue team for ± 2 years, had participated in ACLS training, were willing to become participants by signing informed consent. This research was conducted in March 2019 at Wava Husada Hospital. The method used in this study was in-depth interviews supported by a semistructured and open-ended question guide. Data analysis was performed using Interpretative Phenomenology Analysis (IPA), that were: reading and re-reading, initial noting, developing emergent themes, searching for connections across emergent themes, moving the next cases, looking for patterns across cases.

Findings and Discussion

Analysis of the data from the interviews conducted to 8 participants related to their experience as a code blue team, 4 themes were found:

**Theme 1: Feeling confused when they got code blue for the first time**

This theme illustrates that when they got a code blue for the first time, the nurse feels confused to respond to the call. This is in accordance with the following participant statement:

“That thing, that was making me confused, because it takes time so long and there is a lot of simulation, so that how it is. Because it was my first time so I was confused, it was like “what I have to do?” and then which way that I should take to go to that room (laughing) because I was extremely panic (P1)

“When I was the first time doing my “code blue”, it was so nervous, afraid, and panic for real. I have known enough the theory before, but when we exactly do it when the patient is in front of us which is it was my first time I was so panic and confused what else that I could do even though the patient already stable, but finally, we are getting used to it. (P7)”

The participant’s statements show that when they got the first code blue they felt confused and panic. They did not know their roles and duties because they had never been a member of the code blue team even though they knew the theory.

This confusion and panic emerged because they did not have the experience of being on the previous code blue team. The experience intended is the experience of working in a system that is systemized. This made them not aware of their respective roles and duties when there was a code blue call for the first time. This is in accordance with the statement delivered by Patricia Benner which states that “experience-based skills mastery is safer and faster when relying on a strong educational basis”.

This implies that the more the experience of a nurse is supported by a high level of education, the more skilled the nurse will be in carrying out nursing actions. When a nurse is more skilled in carrying out nursing actions, his response will be good in dealing with a condition.
Theme 2: Faced two choices

This theme illustrates that participants are sometimes between two choices of tasks that are just as important when there is a code blue call. This is in accordance with the following participant statement:

“Yes, of course, I was confused because it was still crowded and there is a lot to do around here. When the hospital ward still crowded, there are three of us who in duty and then there is a code blue signal, there is no option except we have to go save someone!” (P2)

“When we have spare time like now, if there is a code blue signal, of course, we will help the others to help and lighten our friend’s burden at the hospital ward. The hectic moment was when there is a patient with cardiac arrest, that will be definitely a very confusing moment, at that moment we really want to help them with pleasure. But sometimes at a code blue moment take some times, 30 minutes maximum. Meanwhile, there are the others patient that have a plan to move to ICU room, the rest of our friends at the ICU have to well prepared, at the other side if we got a lot of patient like this, they have to handle my patient as well. How pity they were... so, if our friends are the type of “yes man/yes woman”, automatically they also handled our patient as well, that’s how the situation is. Then if in one shift there are 3 code blue signal, how long has it been?” (P5)

The participant’s statements above show that when there was a code blue call that coincided with the many patients in the room, they felt confused. In essence, when there is a code blue call, they are happy because they can help friends in the room but it will be a problem when the situation in the service unit is a lot of patients. They feel confused to choose, besides wanting to help nurses’ friends who are in the room, they also feel hard to leave the responsibility in the service unit, therefore they feel they are on two choices that are equally important.

The nurses who were the participants in this study not only served as blue code nurses but also became executive nurses in each of the three different emergency units. Difficulties arise when the code blue call occurs together with the condition of their unit that has many patients. This makes nurses sometimes confused in choosing choices that must be fulfilled. This is consistent with Utkualp’s statement in his study which revealed that nurses working in intensive units faced more ethical dilemmas than nurses who worked in ordinary care units. This relates to the agreement, sharing resources fairly, and deciding responsibilities.

Theme 3: Feel useful for others

This theme illustrates that since becoming a nurse of Code Blue they feel they are useful people. This is in accordance with the following participant statement:

“When I first time joining, it was felt like happy, proud of my self, yeah, as simple as that, because at least we can help our friends at the hospital ward that still have many things to do with their own problems that may still haven’t settled yet” (P2).

“My first feeling was like “oh, at code blue team would be great!”. I felt happy because I can teach to other people about these things, to them at the hospital wards, tell them which one is right and which one is wrong, which one is good and which one is bad. And also we can help to lighten their (nurses) responsibility, right?” (P3)

The participants’ statements above show that participants feel happy because they can be useful for others. They are happy to be able to make easier the duties of other nurses, especially room nurses and feel their own satisfaction when they can help save patients.

The results of research conducted by Sneltvedt & Bondas (2015) reveal that the most important source of pride for a nurse is the relationship with the patient and recognition from the practice community. This is in accordance with the sub-theme feeling useful to others. The blue code nurse feels happy to be able to help others. They feel happy when they can help in the process of saving patients with cardiac arrest, especially if the patient can be saved. This feeling of being happy is not only felt by the patient but also by other nurse friends. They feel happy when they can help ease the work of nurse friends in the ward.

Theme 4: Feeling sorry and sad when the patient dies

This theme illustrates that code blue nurses feel regret and sadness when patients fail to be saved. This is implied in the following participant statement:
“Feeling sad? Yes of course. Because of feeling fail, feels like “why I can’t help, can’t keep the patient alive and become better again” it was like that” (P1)

“Feels very sorry, because everything that we want when we got patient with really bad condition we just wanna be like “come on dude, be alive!” with our big hope that our patient can stay alive. It made me sad and cry at last..... Even though at that moment, it wasn’t us that do the surgery when I help him, I saw that person was really healthy with good condition comparing now, I feel the heavy burden after that. I wish I could have the power to give him a soul and then make him alive again (Participant crying).....” (P7)

“If we did that (CPR) and the patient finally passed away ... I felt like my body was so fatigue or maybe I was the one who was so touched, too, what do you want ... all was a totality, I was so sorry, that was it” (P7)

The participants’ statements above show that participants feel regret when the patient cannot be saved. They hope the patients can survive. One participant likens if the patient’s life can be returned he will get it so that the patient can stay alive.

The feeling of regret that they feel arises because sometimes the expected results do not match the reality. Nurses really hope patients can stay alive after the rescue process but the results are different. Regret is a natural consequence that cannot be avoided in clinical practice. Regret is an emotion experienced by someone when he believes that the situation he is experiencing will be better if someone behaves differently. Although the code blue nurse felt sad and sorry if the patient could not be saved, the feeling of sadness and regret did not affect the psychological condition of the nurses. Nurses can still do their daily tasks smoothly, both as code blue nurses and as nurses in the service unit. This implies that the regret they feel has no effect on their condition. They regret but accept reality.

**Conclusion**

Being a member of code blue team is not an easy eventhough in making emergency handling of cardiac arrest at Wava Husada Hospital is not new thing to them. Many things they experience and feel as long as they become a nurse of a code blue. Starting from the feeling of confusion and panic they feel when there is a code blue call, faced with two choices of tasks, feel useful for others, feel sorry and sad if the patient dies. Things like that that they feel as up and down moment when joining into the code blue team.

Determination of CXCL12 Serum Levels in Breast Cancer Women

Arkan H. Frayyeh¹, Ehab D. Salman¹, Alice K. Melconian¹
¹Biotechnology Department, College of Sciences, University of Baghdad, Iraq

ABSTRACT

Breast cancer is a disease that can be described as malignant cells from the breast tissues. Immune deregulation has been postulated to be one of the mechanisms underlying the pathogenesis of breast cancer. The current study is planned to shed light on the following profiles and identify the relationships serum levels of CXCL12 among obesity postmenopausal, and Breast cancer. This study hypothesized that CXCL12 levels would have a link with breast cancer patients. The serum CXCL12 level was measured by enzyme-linked immunosorbent assay (ELISA) in breast cancer patients (n=60) and healthy controls (n=61). The observations indicate a significant increase (P ≤0.05) in breast cancer patient’s serum level of CXCL12 compared with healthy control. The study also presented a significant difference among age and Body Mass Index (BMI) between patients and control groups. The results supported that the immune disturbance is related to breast cancer patients and might play an important role in the pathophysiology of breast cancer.

Keywords: Breast cancer; Chemokines; obesity; postmenopausal

Introduction

Breast cancer is the most prevalent cancer in women worldwide, and it remains the most common cause of death in females ¹. In Iraq, it ranks as the first among the population accounting for about 19% of all newly diagnosed cancers and 34.4% of the recorded women cancers with an incidence rate approximating 23/100,000 female population ². Risk factors for breast cancer include female sex, older age, genetics, lack of childbearing or lack of breastfeeding, higher levels of estrogens, certain dietary patterns, exposure to radiation, Tobacco smoking, positive family history of breast cancer and obesity ³. Among postmenopausal women, the BMI at diagnosis was positively associated with the risk of breast cancer ⁴. Chemokines play an essential function in the organization of a different cellular, physiological, and developmental processes. Their aberrant expression can lead to a variety of human diseases, including cancer ⁵. Approximately 50 chemokine ligands and 20 chemokine receptors have been recognized in humans ⁶. This system of molecules shows an indistinctive network, in which chemokine receptors interact with various chemokines with inconstant affinities and multiple chemokines link to the same receptor ⁷. The chemokine receptor (CXCL12) is one of two important factors in the cross-talking between tumor cells and their micro-environment regulating diverse processes in cancer including Epithelial Mesenchymal Transition (EMT), invasion, angiogenesis and metastasis ⁸,⁹.

Patients and Method

This study carried out by two groups of subjects that enrolled during the period of March 2017 - June 2018. The first included 60 cases of breast cancer with an age range of 21-72 years. For the purpose of comparison, 61 age and gender matched cases were enrolled as control of healthy individuals. From each participating subject, a venous blood sample (3 ml) was obtained. The serum obtained by putting the blood samples in a clean, dry plain plastic tube and allowed to clot at room temperature (20-25 C) for 15 minutes before centrifugation. The tubes centrifuged at 5000 rpm for
5 minutes; serum was collected and kept in the freezer until used. The laboratory methods included assessment of serum for CXCL12 was determined by enzyme-linked immunosorbent assay (ELISA) method.

**Assessment of Serum Level of CXCL12:** This was prepared according to the company instructions (Elabscience; USA).

The data were calculated for the Body Mass Index is a simple calculation using a person’s height and weight. The formula is BMI = kg/m$^2$ where kg is a person’s weight in kilograms and m$^2$ is their height in meters squared. BMI has 5 classifications as: Underweight: BMI is less than 18.5, Healthy weight: 18.5 to 24.9, Overweight: 25 to 29.9, and Obese: when it is 30 or higher.

**Statistical Analysis:** All data were analysis using SPSS version 21. One-way analysis of variance was used for parametric data while the Kruskal Wallis test was used for non-parametric data.

**Results and Discussion**

For the calculation and comparison of results, the Mean ± SD was used to illustrate the relationship between the control and patient’s groups as in table 1.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

The differences between groups were tested by one-way analysis of variance, and the data shows that there is a significance difference ($P \leq 0.002$) between control and patients groups.

The BMI within patients group was statistically significant compared with the control as in Fig. 1. This is supporting for the investigators who reported a modest, but not statistically significant, increased risk of invasive breast cancer among the overweight and obese postmenopausal women from both trials. These results also are matching the observational evidence showing stronger positive associations of obesity with postmenopausal breast cancer risk (Neuhouser *et al.*, 2015).

![Fig. 1: Means of BMI comparison between patient and control groups](image-url)
The following graphic Fig.2 shows the relationship between BMI categories according to nonparametric calculations. It shows that the increasing in weight is getting increased straight line among patients group compared with the control group, which indicates that the BMI increased in Breast tumors.

![Fig. 2: Mean plot between groups and Body Mass Index](image)

Females who were overweight had an increased incident frequency of breast cancer risk relative to normal weight. Females at middle-aged 40-50 years are undergoing the condition of postmenopausal depressions, which is associated with obesity, lower physical activity, and higher caloric intake. The diagram shows that the obesity scale represents a significant difference (P≤0.05) among patient’s groups and healthy individuals. Obesity is associated both with a higher risk of developing breast cancer, particularly in postmenopausal women and with worse disease outcome for women of all ages. It worth to be noticed that a positive association of BMI with breast cancer risk was seen in postmenopausal women, in which women aged 40-50 and above years (Munsell et al., 2014). In the bone marrow, CXCL12 is mainly produced by osteoblasts lining the bone endosteum (Neiva et al., 2005). The current study aims to shed light on the serum levels of CXCL12 in the samples of patients groups and healthy females. The results revealed that the concentration of CXCL12 has significantly increased in patients group compared with control as mean was 5.09 (Fig. 3).

![Fig. 3: Mean concentration of CXCL12 for patients and control groups](image)
The cross analysis showed that the CXCL12 means reflected significant differences in accordance with obesity indicator of the patient’s group. Distributing the patients into age groups revealed that breast cancer group were clustered at the age group ≥ 50 years (70.0%) for CXCL12; this cluster was observed at the first quarter of the age range 40-49 years (70.0%) if it compared with other groups like 30-39.

The concentration of CXCL12 serum level has recognized also a significant increase with the developing of age for both groups, where it showed high increasing at 50> years old with a confidence interval (CI) of error: 95% as described in Fig. 5.

![Fig. 4: Mean CXCL12 ng/ml concentration with age of patients groups](image)

These results are matching the previous reports stated that CXCL12 is displaying angiogenic properties (Lazennec and Richmond, 2010). Orimo et al. (2005) illustrated that elevated levels of CXCL12 expressed by cancer cells and tumor-associated stromal cells directly stimulated the proliferation and invasiveness of breast cancer cells in an autocrine and paracrine manner (Domanska et al., 2013).

The quantitative data of CXCL12 concentration, mean, and median have been analyzed statistically. Means between groups were compared using Kurskal-Wallis test showed that the Mean Ranks of CXCL12 is significantly increased among patient groups.

The Kruskal-Wallis revealed a significant increase in the Mean of patients group compared with control (table 4). As it matched the results of Saski et al. and Wang et al. as they both shown that CXCL12 might be expressed also in many tumor cells (Sasaki et al., 2009; Wang et al., 2009). Therefore, there was increasing evidence that CXCL12 plays an important role in many steps of tumor progression, such as invasion, migration, and proliferation of malignant cells (Łukaszewicz-Zajac et al., 2016). In the current study, all indicators were analyzed in unified graphics to measure the interactions of CXCL12, age, and obesity on breast cancer women and compare it with the control group.

The following graphic (Fig.6) illustrates that CXCL12 concentrations showed high levels in Breast cancer of patients who have BMI≥ 40 and at the age of 40-50 as postmenopausal females. The mean of CXCL12 in this category was 8.4.

![Fig. 5: The concentrations of CXCL12 ng/ml elevated levels of patients’ serum related to the developing of age and BMI](image)
It is obviously showing that CXCL12 levels in breast cancer were significantly higher in postmenopausal and these findings matched the study of Neuhrbouser et al. (2015) stated that females who were overweight and obese had an increased invasive breast cancer risk compared with normal weight women. The risk was greatest for obesity grades 2+3 (BMI>35.0 kg/m2) (hazard ratio [HR] for invasive breast cancer =1.58, 95% CI 1.40–1.79) (Neuhrbouser et al., 2015). On the other hand, these results do not correspond with the research of Berstad et al. (2011) which indicates that Among women at age 35-64, BMI at age 18 is inversely associated with risk of breast cancer, but association with recent BMI varies by menopause status, race and hormone receptor status (Berstad et al., 2011). Arendt et al. (2013) found that interactions between adipocytes and macrophages via an IL-1β/CCL2/CXCL12 signaling nexus promote breast cancer angiogenesis and progression under obesity (Arendt et al., 2013).

These findings should be interpreted with caution because of the sample size, but it can be justified because the cases were randomly selected. Furthermore, it has been established in most of the regional studies that breast cancer is recorded at the approximation of the age of 50 years. Studies showed that Arab countries, almost half of woman with breast cancer are below the age of 50 years or even below 40 years compared to more than 65 years in developed countries (El-Attar, 2005). Furthermore, large studies conducted both in the US and Europe have demonstrated that obesity and weight gain increase breast cancer risk among postmenopausal women (Dumitrescu and Cotarla, 2005). A recent meta-analysis of 25 studies found that obesity increased the risk of developing breast cancer in a non-linear dose-response in postmenopausal breast cancer (Xia et al., 2014). One possible link between obesity and the increased incidence of ER+ breast cancer in postmenopausal women is the elevated level of circulating estrogens from increased aromatization of androgens in adipose tissue (Lorincz and Sukumar, 2006). Also, some recent studies have indicated that circulating estrogens may protect against the development of breast cancer in obese women (Suba, 2013).

**CXCL12 Signaling:** CXCL12 can improve the multiplication, survival, and infestation of cancer cells. It has been appeared to assume a significant part in the managing of breast’s metastasis and growth to explicit organs. High CXCL12 expression also corresponded to poor clinical results. An elevated level of CXCL12, allowing tumor cells to directionally migrate to attack organs via a CXCL12-CXCR4 chemotactic inclination. CXCL12 binding to CXCR4 initiates various downstream signaling pathways that result in a plethora of responses such as an increase in intracellular calcium, gene transcription, chemotaxis, cell survival, and proliferation. Chemokine receptors are pertussis toxin-sensitive GTP-binding proteins of Gi type. After chemokine binding, the heterotrimeric G protein is activated by the exchange of GDP for GTP and dissociates into the GTP-bound α and the βγ subunits. The CXCL12-CXCR4 signaling pathway has been recognized as having a very critical role in the retention and homing of hematopoietic stem cells in the bone marrow microenvironment and lymphocyte trafficking. It has also been implicated in the maintenance of the secondary lymphoid structure. CXCL12 has been found to be expressed constitutively in several organs, including the lungs, liver, bone marrow, skeletal muscle, kidney, brain…etc. Interestingly, the organs which exhibit an enhanced secretion of CXCL12 are also the most common secondary metastatic sites of breast cancer. This observation has further highlighted the important role played by the CXCL12-CXCR4 signaling axis in breast cancer metastasis.

**Conclusion**

Obesity is associated with increased invasive breast cancer risk in postmenopausal women. These clinically meaningful findings of the increased level of CXCL12 among overweight postmenopausal breast cancer women should motivate programs for obesity prevention.

Relationship of Gestational Age, Folic Acid Intake and Haemoglobin Level of Third-Trimester Pregnancy with Infant Birth Weight in Ende Regency, East Nusa Tenggara Province, Indonesia

Asmulyati Saleh1, Harsono Salimo2, Endang Sutisna Sulaeman3
1Nutrition Postgraduate Student, Sebelas Maret University, Indonesia, 2Paediatrics of Faculty of Medicine, Sebelas Maret University/Dr. Moewardi Public Hospital, Indonesia, 3Faculty of Medicine, Lecturer, Sebelas Maret University, Indonesia

ABSTRACT

LBW (Low Birth Weight) incidence is one of the health problems in Indonesia that still has to be handled properly. This can occur due to several factors, some of which are gestational age, folic acid intake and the Hb level of third-trimester pregnancy. LBW can cause several health problems in infants such as infectious diseases, respiratory problems, central nervous system disorders, and mortality risk. This research is aimed at analysing the relationship of gestational age, folic acid intake and the Hb level of third-trimester pregnancy with infant birth weight in the operational area of Ende Health Centre in East Nusa Tenggara. This research used a cohort design from January to March 2019 with a sample size of 109 respondents selected by using purposive sampling system. The instruments used were the questionnaire sheets about mother and infant characteristics and SQ-FFQ sheets to interview pregnancy consumption patterns. The data were analysed using chi square test. Based on the statistical test, there is a relationship of gestational age (p-value = 0.001), folic acid intake (p-value = 0.000) and haemoglobin level of third-trimester (p-value = 0.000) with infant birth weight in the Ende Health Centre of East Nusa Tenggara. The gestational age classified as not at risk for giving birth to LBW babies is > 38 weeks of gestational age. The folic acid intake considered not at risk for giving birth to LBW babies is > 600 mg. Then, the Hb level of third-trimester pregnancy which are not at risk for giving birth to LBW babies is > 11 g/dl.

Keywords: LBW, gestational age, folic acid, haemoglobin, pregnancy

Introduction

Low birth weight, known as LBW, is one of the health problems that can still be found in Indonesia. LBW is a condition in which a newborn baby has a weight of < 2,500 grams1. LBW incidents can occur due to several factors such as anaemia, nutritional status of pregnant women, and increased body weight during pregnancy2. Another factor that can also affect infant birth weight is the mother’s age when she is pregnant. Infant birth weight can be categorized into three, namely low birth weight weighing < 2,500 grams, normal birth weight weighing 2,500-3,999 grams, and high birth weight weighing ≥ 4,000 grams3.

The prevalence of LBW that could be found in Indonesia in 2013 was 10.2%, where one of the provinces with a high prevalence of LBW was East Nusa Tenggara with a prevalence of 15%1. One of the regencies with a high prevalence of LBW in East Nusa Tenggara in 2017 was Ende Regency of 13.5%. This percentage has increased considerably from the previous year where the percentage of LBW incidence found in the operational area of Ende Health Centre was 12.1%4. The percentage...
of LBW incidence in Ende regency in 2015 was 9.5%, 12.1% in 2016, and 13.5% in 2017.

Low birth weight in infants can cause health problems for them in the future because they have a high risk of mortality and morbidity. LBW is caused by several factors, one of which is lack of nutrition during pregnancy.

Maternal nutritional needs during pregnancy are influenced by the amount of macronutrient and micronutrient intake. There are several micronutrients that have a relationship with the infant birth weight such as folic acid. Pregnant women need the folic acid of 600 µg per day. Folic acid consumption is useful to prevent congenital birth defects.

Nutritional needs during pregnancy will increase by 15% compared to the needs of normal women. The increase in energy and nutrients is needed for fetal growth and development, increase in the content of the uterus, changes in the composition and metabolism of the mother’s body, volume of blood, placenta, and amniotic fluid. Food consumed by pregnant women will be used for fetal growth by 40% and the rest (60%) is used for the metabolism of the mother.

Another factor associated with infant birth weight is gestational age. Gestational age or pregnancy age is the time needed by the mother during conception until giving birth. Another factor also related to infant birth weight is the mother’s haemoglobin level during the third-trimester pregnancy. Anaemia is a condition where the circulation of red blood cells decreases from the normal level where pregnant women classified as anaemia have the Hb level of < 11 g/dl.

This research aimed to analyse the relationship of gestational age, folic acid intake and the haemoglobin level of third-trimester pregnancy with infant birth weight in Ende Regency, East Nusa Tenggara Province.

Material and Method

This research employed an observational analytic quantitative approach with cohort design. It was conducted in Ende Regency from January to March 2019. The research samples were 109 third-trimester pregnant women. The technique was purposive sampling. The inclusion criteria are third-trimester pregnant women who remained permanently in Ende regency area, had MCH books, experienced term and preterm labour, and were willing to be the research subjects. The exclusion criteria are pregnant women who are hospitalized because of congenital diseases before pregnancy and pregnant women with hyperemesis. The independent variables are the folic acid intake and haemoglobin level of third-trimester pregnant women while the dependent variable is the incidence of low-birth weight infants. The data were collected by the interview technique based on the SQ-FFQ, form recall questionnaires, and the scale scale.

The characteristics of mothers and infants taken in this research are maternal age, gestational age, folic acid intake, haemoglobin level, and infant birth weight. The types of data taken in the research are primary data and secondary data. Primary data taken are gestational age, folic acid intake, and infant birth weight while the secondary data are maternal age and haemoglobin level. The data were then analysed using the chi-square test with a significance value of p value < 0.05.

**Discussion**

The results of the distribution of maternal and infant characteristics in this research can be seen in Table 1, which shows that most respondents are 20-35 years old with a total of 82 mothers or 75.2% of the total respondents. 2 respondents are classified as at the risk age of < 20 years and > 35 years and 25 respondents of 1.8% and 23%, respectively. This indicates that most mothers are classified as having a reproductive age that is safe and reduces the risk of abnormal birth weight. Pregnant women aged < 20 years have a greater risk of giving birth to premature and LBW babies, experiencing bleeding during intercourse, and death for both the mother and fetus compared to those aged between 20-35 years10. Pregnant women aged > 35 years are also considered at a risky age because they are more likely to give birth to babies with genetic disorders11.

Based on Table 1, it is known that most of mothers have a relatively full gestational age, ranging from 38-42 weeks with 89 respondents or 81.7%. The second highest number is in mothers with early gestational age of <38 weeks with a total of 20 respondents or 18.3%. This indicates that most mothers give birth at full gestational age and have a lower risk of giving birth to LBW babies. Premature birth or birth with < 38 weeks of gestational age is the birth of a baby that can occur due to one of the factors, namely a growth disorder during the pregnancy12. The distribution of folic acid intake in the third trimester is mostly adequate of > 600 mg similar to the distribution of the haemoglobin level of third-trimester pregnancy of the research respondents, most of whom did not experience anaemia with the Hb level of > 11 mg/dl. The number of respondents who did not experience anaemia is 41 or 68.33%. This indicates that most mothers do not experience anaemia during their pregnancy.

Based on the interview results of consumption patterns during pregnancy, it is known that most mothers consume only a few types of food ingredients as recommended, namely staple foods, vegetable side dishes, milk, and supplements. Most respondents said that they consume animal dishes such as chicken, eggs, and sea fish only 2-3 times a week. Consumption of blood-pressure tablets considered less can occur because most mothers forget to consume and do not understand the use of added blood tablets for pregnant women. Consumption of meat and blood-added tablets is not really able to influence the Hb level during pregnancy due to their association with the anaemia incidence. Most iron sources come from animals such as chicken, beef, and so on13.

Based on Table 2, it is known that there are 59 infants, 54.13% of the total respondents, with normal birth weight and full gestational age. The number of infants with LBW is 30 or 27.5%, all of whom were born with early gestational age. Based on the statistical test, the value of p is 0.001 where the value of p is <α = 0.05, which means that there is a relationship between gestational age and infant birth weight. This is in accordance with the research conducted by Sulityorini where mothers with gestational age less than 38 weeks had a risk of giving birth to LBW babies 2,204 times greater than those with gestational age more than 38 weeks14.
Early gestational age can occur due to maternal age and nutritional status during pregnancy. The age of mothers who are classified as at risk has a problem with pregnancy is the age of less than 20 years and more than 35 years. The research conducted by Mendez et al. in 2015 wrote that mothers of 20 years old and more than 35 years old gave birth to babies at early gestational age far more than those between 20-35 years old. 

Most babies are born with normal birth weight from mothers who do not experience anaemia during pregnancy. The number is 70 or 64.2%. The number of infants that can be found with LBW born to mothers who have anaemia is 26 or 23.8%. Based on the statistical test, the value of \( p \) is 0.00 where \( p < \alpha = 0.05 \), which means there is a relationship between the Hb level of the third-trimester pregnancy and infant birth weight. This is in accordance with the research conducted by Choirunnisa, which an association between the anaemia incidence in pregnant women and infant birth weight. The incidence of anaemia and Hb level during pregnancy has a role in fetal growth, where Hb level of <11 g/dl during pregnancy can cause fetal growth retardation in the womb. 

Most babies are born with normal birth weight from mothers with adequate intake of folic acid. The number is 70 or 64.2%. The number of babies found with LBW from mothers with less folic acid intake is 26 or 23.8%. Based on the statistical test, the value of \( p \) is 0.00 where \( p < \alpha = 0.05 \). It means that there is a relationship between folic acid intake in the third-trimester pregnancy and infant birth weight. This is in accordance with the cross-sectional research that folic acid intake of pregnant women affects the baby’s anthropometry, namely birth weight and birth length. Folate deficiency during pregnancy can be a risk factor for fetal malformations and various placental-related diseases. This result is similar to the research result of the lack of folic acid intake during pregnancy that will affect infant birth weight.

**Conclusion**

There is a relationship between gestational age, folic acid intake, and the haemoglobin level of third-trimester pregnancy in the operational area of Ende Health Enter. The action that can be done to prevent the occurrence of early gestational age, folic acid intake, and anaemia during pregnancy is to improve nutritional status before pregnancy. Premature nutritional status that is classified as abnormal can increase the risk of LBW birth. The action that can be taken is to increase food consumption to be balanced and diverse. Giving education about the age safe for pregnancy also needs to be provided by the health centre midwives to teenagers to avoid pregnancy at the age of mothers who are at risk of giving birth to LBW babies.

Effect of *Lactobacillus* on the Small Intestinal Mucosa Measurement of Healthy Broilers Chicken Under Heat Stress Condition

Balqees H. Ali

*College of Veterinary Medicine, University of Baghdad, Iraq*

**ABSTRACT**

**Objective:** The present study was conducted to investigate the effect of lactobacillus bacteria on the intestinal mucosa morphology in broiler chicks under stressful environmental conditions.

**Materials and Method:** For this study, 180 broiler chicks (day-old) were randomly divided in to 2 rooms (90 chicks for each room were separated to 3 group), each group contains 30 chicks). The first room was exposed to heat stress (38-40°C) on 3 weeks old for a period of 10 days 3 hours daily: first group (G1) received lactobacillus acidophilus $1 \times 10^8$ cfu m$^{-1}$ via crop inoculation one day old; the second group (G2) received the same dose for G1 but at three weeks of age; third group (G3) was consider the control group (without any treatment). The second room also divided into 3 groups (G4, G5 and G6). This room was kept under natural condition; G4 received L. acidophilus $1 \times 10^8$ cfu ml$^{-1}$ via crop inoculation on day old; G5 received the same dose for G4 but at three weeks of age; G6 was consider the control. Collected samples at 42 days old of chicken (duodenum, jejunum and ileum). Histological techniques were applied on each sample and also the ocular micrometers were used to measure the thickness of the intestinal mucosa.

**Results:** Results showed that significantly ($P<0.01$) higher in the crypts of lieberkuhn of duodenum in G4 compared with other groups. Chicks in G6, G2 and G1 respectively have significantly ($P<0.01$) higher in the crypts of lieberkuhn of jejunum. The ileum crypts of lieberkuhn was significantly ($P<0.01$) higher in G2 compared with other groups while chicks in G3, G4, G5 and G6 show significantly ($P<0.01$) higher the villi length of duodenum. So the villi length of jejunum show high significantly ($P<0.01$) was in G2 compared with other groups and chicks in G1 show high significantly ($P<0.01$) in the villi length of ileum.

**Conclusions:** Taken of the lactobacillus acidophilus to the broiler chicks improving the intestinal morphology and integrity of birds subjected to the heat stress and non-heat stressed birds.

**Keywords:** lactobacillus acidophilus, broiler, small intestine and heat stress.

**Introduction**

In healthy chicken, the intestinal microcrobflora remains stable, so this stability may be disrupted by various factors like environmental stress for example poor feeding, overcrowding, high or low temperature, the young chicks under stressfull condition suffer from changes in the composition and activity of the gut microflora. Also, under stress conditions changes in the intestinal microflora have been reported with number of anerobic microorganisms decreasing whilst hat of coliform bacteria increasing some studies writed that disturbance of the intestinal microbiota decrease in growth rate lead to various infectious disease and weakens resistance. Decrease the heat stress in chicken house by using many ways like provision of clean and cool drinking water, feeding during the cooler times of the days decrease the number of birds per cage, addition of electrolyte supplements to their drinking water are being practiced, and feeding during the cooler times of the day. The live microorganisms (probiotics), hat administrated in adequate amounts, confer healthbenefit on the
host through improvements to the intestinal microbial balance. Probiotics are viable microbial additives like lactobacillus acidophilus, staphylococcus faecium and Saccharomyces cerevisiae with the effects of restoring the microbial balance of the gut in the animals they are administrated to, so these microbial additives causing inhibit the growth of pathogenic microorganisms and provide digestive enzymes, adesirable effect for the host, and as a result changes in the intestinal microflora, and synthesis of lactic acid leads to lowering of the intestinal PH, adhesion or colonization to the intestinal mucosa and prevention of ammonium synthesis. In this study, the aim was to detect the effects of heat stress and lactobacillus acidophilus using against heat stress on the villi length and crypts of lieberkuhn of duodenum, jejunum and ileum.

**Materials and Method**

**Poultry House:** done this experiment was in poultry house of pathology and poultry diseases at the college of veterinary medicine-Baghdad university.

**Experimental Animal:** In the study one hundred and eight-day old Rose broiler chicks, from a commercial broiler breed (Rose Jordan origin) were divided randomly in to 6 groups 30 chicks each, and each 3 groups were put in a separate room, the first room contained group one which was given lactobacillus acidophilus bacteria (1×10^8 cfu ml) at one day old by oral inoculation, group two (G2) was Lactobacillus acidophilus bacteria (1×10^8 cfu ml) at three weeks old by oral inoculation and group three (G3) as control group. This room was exposed to heat stress (38-40°C) for three hours continuously in four days at starting from three weeks old. The second room, contained group four (G4) which was inoculated lactobacillus acidophilus bacteria (1×10^6 cfu ml) at one day old by oral inoculation, group five (G5) which was given Lactobacillus acidophilus bacteria (1×10^6 cfu ml) at three weeks old by oral inoculation and group six (G6) as control group, this room was in a normal temperature.

**Histological Test:** At the end of the study the specimens were taken from intestine chicks includes: duodenum, jejunum and ileum from each group after 120 hr. form exposed to heat stress (non-heat and heat stress). The samples were immediately fixed by formalin (10%) for 24 hr. after dehydration with ethyl alcohol increasing concentration (100-70%) of ethylic alcohol and in xylol after that the slides were stained with Hematoxylin and eosin stain. An ocular micrometer were used to measure the thickness of the intestinal wall layer.

**Statistical Analysis:** the data were analyzed by using Spss. To calculated the difference between means Duncan-multiple test was used.

**Results**

Table. (1) showed the average value obtained for the crypts of lieberkuhn under normal conditions and those exposed to heat stress after 120 hr., show significance differences (P<0.01) between groups the high level of the crypts of lieberkuhn in the group receiving lactobacillus acidophilus in one day of chick (G4) non-heat stress compared with other group.

Table (2), show the results of the effect of lactobacillus acidophilus on the crypts of lieberkuhn of the jejunum after 120 hr. from exposed to heat stress, these results showed increase significance differences (P<0.01) in G6, G2 and G1 respectively while G4 and G5 show little increase compared with control group G3 (exposed to the heat stress).

The results presented in table (3) show high significance increase in G2 (P<0.01) compared with other group of the effect of lactobacillus acidophilus on the crypts of lieberkuhn of the ileum after 120 hr. from expose to heat stress while G3 and G4 show significantly decrease (P>0.01) compared with other groups respectively.

The effect of lactobacillus acidophilus on the villi length of duodenum after 120 hr. from exposed to heat stress showed in table (4), the high significant (P<0.01) was in G3, G4, G6 and G5 and the low significant (P<0.01) was in G1 and G2 (exposed to heat stress).

Table (5) shows the results the effect of lactobacillus acidophilus on the villi length of the jejunum after 120 hr. the high significant (P<0.01) was in G2 compared with other groups of experiment the results presented in the table (6) show the high significant (P<0.01) was in G1 compared with other groups also in G2 was show increase in villi length of ileum after 120 hr. from exposed to heat stress compared with G3, G4, G5 and G6 respectively.

Discussion

The present study showed the high significant increase in the crypts of liber Kuhn of the small intestinal parts (duodenum, jejunum, ileum) in the groups that inoculated of lactobacillus acidophilus in the one day or 2 wk – of chick age with or without exposed to heat stress.

Those agree with14 who small intestinal lactobacillus and bifidobacterium, jejunal villus height, protein level of occluding but no temperature and diet interaction was observed in the present study revealing that the supplemented probiotics had the same effect at both temperatures. Also15 referred to that the symbiotic and probiotic resulted in an increased in the crypt depth of intestinal mucosa of broilers and these lead to improve the gut health16. Reported that inclusion of 10^7 cfu/g of bacillus licheniformis in the diet of heat-stressed hens was effective in the gut by increasing the crypt depth and restoring the impaired villus structure. So the increasing in crypts depth lead to more activity in degeneration of absorptive epithelial cells which covered the vilii, and active in releasing the digestive enzymes17,18. 19 showed that the increase to the depth of crypt result from the intestinal formation which more digestible, with improved absorption and protein analysis, in addition to a few equipment of the food components of the intestinal maintenance. Increasing the height of the villus in groups inoculated with lactobacillus acidophilus bacteria (1x10^9 cfu/ml)at one day or at 3 weeks old by oral inoculation with heat stress or non-heat stress groups of small intestine (duodenum, jejunum, ileum) specially in jejunum and ileum of G2 group that inoculated lactobacillus acidophilus bacteria (1x10^9 cfu/ml)in 3 weeks old with heat or non-heat stress that agreement with14 who found supplemental probiotics increased (p< 0.05) jejunal villus height and revealing that the supplemented probiotics had the same effect at both temperatures. Also the different of intestinal wall thickness resulted mainly from different in thickness of mucosal layer because presence of villi and intestinal glands and the increasing of villi length increased the absorptive area20. But, 21 found that the heights of villi in the duodenum jejunum and ileum of quails exposed to head stress decreased with the decreased in the number of goblet cells located in the ileum villi found to be statistically significant compared with duodenum and jejunum that non-significant it was also deterrent that in those treated with yeast against head stress, the height of the villi in the jejunum decreased with group that treat with bacitracin zinc the height of the villi in the jejunum and ileum decreased and the goblet cell count increased. While, 22 reported that the effect of lactobacillus acidophilus and bacitracin zinc causes a higher effect on weight gain and benefit from feet much more that their individual effect probiotics may reverse the impaired villus–crypt structure of head stressed birds23. So, several studies have revealed the potential benefits of probiotics in improving the intestinal morphology and integrity of birds subjected to head stress and as part of the nutritional strategies, inclusion of the impaired physiological condition in poultry due to heat stress24,25,26,27,28,29.

Conflict of Interest: This research is a personal non-profit work and there is no conflict of interest.

Source of Funding: None.

Ethical Clearance: Ethical clearance was obtained from the Faculty Scientific Committee (College of Veterinary Medicine, University of Baghdad, Iraq) to Study the effect of lactobacillus on the small intestinal mucosa measurement of broilers chicken under heat stress condition.

ABSTRACT

Feeds is the common constituents includes vitamins, soya beans, whole cereals and vegetables. For Salmonella and Escherichia successful control, the feed should be exposed to 85.7°C temperature because of spores are heat resistant. Crops of oilseed and grains shows the presence of diverse microflora, and to low moisture content these are highly resistant. As with natural microbial contaminants of feed, the inoculation’s primary vector is soil. Animal feces mixed soil can contaminate the crops which are standing by direct deposition or if used as fertilizer. Lowering the feeds pH (haylage, silage) or feeds which are dry (meat meals, grains) may considerably reduce the activities of spoilage and allows the long time storage of animal feeds. Cl. Perfringens, Cl. Botulinum, Listeria, E.coli, Salmonella and other pathogens are involved in the pathogenesis of the poultry feeds. Cl. Botulinum is an obligate anaerobe, generally associated with silage, haylage, and contaminated carion. Listeria spp. are not possessing spore cycle, but may survive for 10-12 years. Strains of E. coli are normal microflora of human and animal intestine, and hence serves as feeds fecal contaminant. Salmonella is ubiquitous in nature and can spread horizontally and vertically throughout the livestock herd or poultry flock. In grains and feed other pathogens also may be present, though their routes of transmission are not clear. Various methods are used to avoid and treat the contamination of feed like rapid drying, shortening the time of storage, soybean oil supplementation and other chemical treatment methods are also included.

Keywords: Poultry birds, Poultry feeds, Control methods, Livestock, Long time feed storage

Introduction

For a range of microbial contaminants poultry feeds serves as carrier like mycotoxins, bacteria and moulds¹. All the birds domesticated by man are referred to as poultry, it includes geese, duck, turkey, ostriches, pigeons, domestic fowl, guinea fowl². In the environmental contamination of feed material many bacteria are associated from the enterobacteriaceae family. Enterobacteriaceae family consists of many genera involving Salmonella, Enterobacter, Escherichia etc³. Feeds common constituents includes vitamins, soya beans, whole cereals and vegetables such as amaranthus spp, tridax, water leaf. Generally, feed is a major vector for Salmonella and other bacteria’s transmission to the processing plant and farm. With Salmonella, other pathogens also can be introduced from the feed, such as Clostridia, Listeria and Escherichia. Some of these bacteria may be found higher than Salmonella in feed⁴. Extensive contamination of feed and feed ingredients may occurs by antibiotic resistant bacteria i.e. multi-antibiotic resistant strains of Salmonella⁵, Streptococcus⁶. Enterococcus and Escherichia are found in feed. In feed high level of bacteria is generally found to be associated with poultry’s productivity problems⁷⁹.

Salmonella, Escherichia, Cl. Perfringens, Cl. Botulinum, Listeria, E.coli, Salmonella and other pathogens are the major contaminants which should be avoided in the feed. The main target of this study is to determine the control measures of these above contaminants. Ekperigin et al.¹⁰ have described that for Salmonella and Escherichia successful control the feed should be exposed to 85.7°C temperature because

DOI Number: 10.5958/0976-5506.2019.02564.6
of spores heat resistance\textsuperscript{11,12}. Bacteria can be controlled by chemical disinfection and recontamination can be prevented, such as treatment with formaldehyde/organic acid blend, organic salt and organic acid\textsuperscript{13}. Researcher carried out study in Iraq found that Salmonella occurs in various animal feeds\textsuperscript{14} (Table 1).

Muhsin et al\textsuperscript{15} carried out a study on bacterial contamination of imported poultry feed in Iraq found various bacterial contaminants in various quantities as shown in Figure 1.

**Raw feed ingredients of bacterial ecology**

**Bacteria found in feed and their origin:** Crops of oilseed and grains shows presence of diverse microflora, with range of population from $5\times10^3$ to $1.6\times10^8$ CFU/g to low moisture content these are highly resistant\textsuperscript{16,17}. Primary inoculation of plant material is by generated dust during strong wind or rain or while mechanical harvesting when the soil is disturbed. The environment of soil is microhabitats collection consisting of organic matter, aqueous domains and clay particles that are variable in ionic strength, minerals, nutrients, gas composition, redox potential and pH\textsuperscript{18}. This soil microhabitats variability translates to population of diverse microorganisms, both aerobic and anaerobic.
Survival and origin of pathogens in feed: When the human or animal pathogenic bacteria contaminates feed, becomes a disease transmission’s potential route to both the populations, and is of great concern to consumers and producers. As with natural microbial contaminants of feed, the inoculation’s primary vector is soil. Animal feces mixed soil can contaminate the crops which are standing by direct deposition or if used as fertilizer. In the animal intestine the unattached bacteria or sloughed off bacteria leave the environment of soil and mix in bacteria from soil.

Factors influencing pathogens survival in feed: Pathogenic microorganisms variety may live alive in feeds. Lowering the feeds pH or feeds, which are dry may considerably reduce the activities of spoilage and allows the long time storage of animal feeds. Drying and ensiling cannot do complete elimination of population of pathogens. Pathogens may utilize cycles of sporulation (Cl. Perfringens and Cl. botulinum) or acid resistance mechanisms (L. monocytogenes) and/or desiccation (E. coli) to animal feed survival. These resistance mechanisms are bacterial life cycles important natural part. So, as to continue their species they must colonize intestines of animal.

Transition of pathogens from poultry to human: There are several diseases are transmitted from the poultry to humans includes Cl. perfringens, Cl. botulinum, Listeria, E. coli, Salmonella spp etc. Some strains of Salmonellanoticeably predominate in birds. S. galzinarum and S. cubanaaare the most common examples of purely poultry borne agents.

Important bacterial pathogens present in feeds

Clostridia: In feed two species of Clostridia which are anaerobics of major concern: Cl. Botulinum and Cl. Perfringens. Cl. Perfringens is linked to necrotic enteritis in poultry and tin primates to bloat (gastric dilation). Cl. Perfringens is isolated from animal feeds at 3-8000 organisms/g populations. Cl. Perfringens can be isolated from feed which is pelleted due to its high heat resistance in spore state.

Cl. Botulinum is an obligate anaerobe, generally associated with silage, haylage, and contaminated carion or spore contaminated sandy pastures. Cl. Botulinum type B and C can be isolated from hay cubes, mixed poultry feeds, brewers grains, damp alfalfa hay.

Listeria: Species of Listeria are invasive microorganisms which causes septicemia, encephalitis, abortions in ruminants. Listeria spp. Are not possessing spore cycle, but may survive for 10-12 years.

E. coli: Strains of E. coli are normal microflora of human and animal intestine, and hence serves as feeds fecal contamination. E. coli different strains causes variable diseases syndromes involving cellulitis, airsacculitis, swollen head syndrome, septicemia. Some E. coli serotypes, are found to cause avian cellulitis.

Salmonella: It is ubiquitous in nature and can spread horizontally and vertically throughout the livestock herd or poultry flock. Contamination of Salmonella spp. in feeds and their methodologies of detection and measures of control are reviewed extensively elsewhere. The Salmonella spp. physiology lends itself to survival and contamination on feeds wide range and ingredients of feed. The Salmonella spp. survival in bone meal, meat, poultry feeds and dry milk is shown to be inversely proportional to moisture content, having great survivability at 0.43 and 0.52 than at 0.75 water activity.

Other Pathogens: In grains and feed other pathogens also may be present, though their routes of transmission are not clear. Feed thus contains a diverse microflora which originates from soil which is characterized by its survival ability under desiccation conditions and micronutrients wide range. When the storage of animal feed is done under anaerobic moist conditions such haylage or silage, diversity of bacteria is inhibited by low pH.

Control Strategies

Control of Bacterial Contamination: Several methods overview used to control contamination of bacteria in feeds is presented in Table 2.

Conclusions

The inoculation’s primary vector is soil for the natural microbial contaminants of feed. Animal feces mixed soil can contaminate the crops which are standing by direct deposition or if used as fertilizer. Various methods are used to avoid and treat the contamination of feed like rapid drying, shortening the time of storage, soybean oil supplementation and other chemical treatment methods are also included. Several strategies are made like rapid drying, shortening the storage time, addition of zinc bacitracin Mineral acids, short-chain fatty acids, isopropyl alcohol, aldehydes, trisodium phosphate as disinfecting agents, addition of bacteriophages, propionic acid, bacteriocin producing bacteria so as to avoid contamination of poultry feeds.

Recommendation

So as to overcome feed degradation, several strategies are made which includes: shortening the time of storage to prevent the caking and browning of the feed, and soybean oil supplementation so as to overcome losses of fat50. To prevent overgrowth by storage microorganism, method of rapid drying is widely used for grain preservation51. To control growth of gram positive bacteria and hinder sporulation of Clostridium perfringens in feed, zinc and bacitracin can be added52. In order to control pathogens addition of other disinfecting agents is done. Some of which include aldehydes, isopropyl alcohol, trisodium phosphate, short chain fatty acids, mineral acids52. However, these disinfectants microbial activity is inhibited by the organic matters high concentration in feed. From large period, Encilage method is used for preservation of feed.

Ethical Clearance: The present study is a review article. So, it does not need any ethical clearance.

An Exploratory Study on the Roles of Bhutanese Primary Health Care Managers in Responding to Childhood Obesity

Chimi Wangmo¹, Phudit Tejativaddhana², Mary Cruickshank³, David Briggs⁴

¹College of Health Systems Management, Naresuan University, Thailand and Ministry of Health, Royal Government of Bhutan; ²ASEAN Institute for Health Development, Mahidol University (MU), Thailand; ³Professor of Nursing, School of Nursing & Healthcare Professions, Federation University, Australia and Adjunct Professor, CHSM, NU, Thailand; ⁴Adjunct Prof. CHSM, NU, Thailand and University of New England, Australia

ABSTRACT

This is initial research that examines the status of childhood obesity in Bhutan in the context of data that describes global, national, cultural and continental contexts.

The study aims to assess the understanding of health policymakers, health professionals and other stakeholders’ perceptions of the challenges posed by childhood obesity, and to assess their state of readiness to address those challenges.

A qualitative method using in-depth semi-structured interviews of a purposeful sample with primary healthcare managers (PHC), policy makers and school coordinators in one district in Bhutan.

The respondents described the major challenges and barriers, and roles in the management of childhood obesity. PHC managers were not aware or had little awareness of childhood obesity. This result extended to the policy level, to health professionals, school teachers, communities and parents. In other words, the unawareness was extensive and, preparedness was not evident.

Bhutan needs to recognise the challenges an impending emergence of childhood obesity presents and move to establish policy and practices for the health system to implement.

Keywords: Bhutan, primary health care managers, childhood obesity, exploratory

Introduction

The Kingdom of Bhutan is in the Himalayan region with a population of 735,553 and a land area of 38,394 square kilometres¹. PHC is the core policy focusing on health for all². There is free basic public health services delivered through a PHC approach³ with a Ministry of Health (MOH) supporting the district health system⁴ Modern health care in Bhutan began in 1961 with two hospitals, two doctors, and two nurses⁵. Today, healthcare services are delivered throughout 31 hospitals, 178 basic health unit clinics and 654 outreach clinics. Bhutan is confronting an increasing challenge from Non-Communicable Diseases (NCDs)⁶. One of the risk factors for NCD is obesity. Childhood obesity is strongly correlated with obesity as an adult⁷. Worldwide obesity has doubled since 1980⁸. Globally, 1.5 billion adults are either overweight or obese and that number is expected to increase to 3 billion by 2030⁹. The worldwide prevalence of childhood obesity has increased from 4.2% in 1990 to 6.7% in 2010 and is expected to reach 9.1% by 2020¹⁰. In South East Asia, it has increased from 1.2 million to 2.5 million over 20 years. Studies conducted in Asia¹¹ suggest about 48% of obese children under five live in Asia and developing countries¹². Similarly, in the Pacific States obesity is significant¹³. In a US study that

DOI Number: 10.5958/0976-5506.2019.02565.8
reviewed the prevalence of obesity and overweight in some of the Pacific region sees rates set at 10% at age 2 years and 23% at age 8 years14.

The study aims to assess the understanding of health policymakers, health professionals and other stakeholders’ perceptions, of the challenges posed by childhood obesity, and to assess their state of readiness to address those challenges.

Method

A qualitative method using in-depth semi-structured interviews with the PHC managers and others to provide a deep understanding of the roles of the PHC managers and to provide an account that explores and captures the participants’ perceptions, feelings, and meaning15.

The study was conducted in the Mongar District, Bhutan. Among twenty districts, Mongar is one of the fastest developing district with a population of 37,150, has good highways and most of the regional offices are in this district. Health services in this region include the eastern regional referral hospital (ERRH), a Basic Health Unit (BHU) grade I, 22 BHUs grade II, 5 sub-posts, 5 indigenous units and 52 Outreach Clinics (ORC). The Mongar district has 2 District Health Officers, 2 Medical Doctors, 7 Nurses, 1 Clinical officer and 47 Health assistants16.

The participants in this study included the District Health Officer, Head of the regional hospital and PHC Staff from Mother and Child Health unit (MCH), NCD focal person, a Medical officer (1) or BHU grade I in charge, and Health assistants (6) (BHU grade II) who have managerial and supervisory roles and work with PHC services and disease prevention. The BHU included larger medium BHUs and small BHUs; classified as per the area size and population. A further four participants included two school health coordinators (primary and high school) and two from the health policy level. The total number of participants in the purposive sample was fifteen.

*Note: PHC: Primary Health Care; PL: Policy Level; SHC: School Health Coordinator; MBBS: Bachelor in Medicine and Surgery; MPH: Master’s in Public Health; BBA: Bachelor in Business Administration

The data was collected between January and March 2018, utilising semi-structured interviews. The 15 informants were interviewed at their places of work. The duration of interviews was approximately 60 minutes. The record of what was said and done during the interviews was audio recorded, and then transcribed.
prior to data analysis, using content analysis. Themes were finalized and illustrated with quotations from the original text to help communicate meaning. The data and emergent themes were confirmed with the advisor’s guidance and included comparison of the coded concepts by other researchers.

**Results**

The respondents described major challenges and barriers, and roles in the management of childhood obesity. The challenge faced by PHC managers was that they were not aware or had little awareness of childhood obesity. This result extended to the policy level, to health professionals, school teachers, communities and parents.

At the policy level the participants emphasised the current concern about undernutrition:

…I think the major problem is still related to undernutrition in children under 5…1 in 5 children are either undernourished or stunted… obesity in children is about a percent [1%] in the 2015 nutrition survey. (PL 1).

While PHC managers felt that childhood obesity cases are minimal:

From my perspective, we do have childhood obesity in the community, not much but a few cases … (PHC 5).

There are few obese children … especially those children from urban areas not from rural. (PHC 6).

Some PHC managers felt that they do not have any childhood obesity cases:

Under the age of 5 years we don’t have childhood obesity. We have malnutrition… I have been here for four years, but I haven’t encountered obese children. (PHC 7).

A PHC manager who is a medical doctor said they do not have to focus on childhood obesity:

…We are not focusing on childhood obesity … because we are focusing more on stunting and lower weight children…we have not dealt with any children with obesity but that doesn’t mean to say there won’t be children with obesity … (PHC 3).

The school health coordinators stated that:

In school, I don’t think it is a very serious issue. I think health coordinators are informed at this stage. It doesn’t mean it doesn’t exist. I think we have around 2-3 cases. I think it is okay. (SHC1).

PHC managers talked about the unawareness of community and parents. Obesity is considered healthy and treated as normal in the community:

In the village, obesity is considered healthy… it is still considered as healthy and a child is normal and eating well. Maybe some of the population understand it but I see many considering childhood obesity as normal. (PHC 7).

The PHC managers shared their views on the future agreeing that there will be an increased problem of childhood obesity:

Looking into 10 years down the line, there will be childhood obesity because now the living and eating styles of the population have changed… However, now the time has changed, and we get every day. Eating habits have totally changed to refined products from high fibre intake. (PHC 6).

In the future there will be an impact of childhood obesity on health systems with increased NCDs particularly if rural populations migrate:

…if we do not act … now this will shift from the people who are young right now, they will become an adult one day and … their health problems may go up. (PHC 1).

There is a lack of strategic direction and policies to guide PHC managers:

We do not have a policy regarding childhood obesity rather we do have one for the management of underweight children. Whatever, if there are underweight cases, we refer to the child specialist until a child is fine. (PHC 2).

PHC managers mentioned the shortage of human resources for not being able to focus on childhood obesity:

My health centre is in one of the highest populated communities with only two of us. One of us must look after OPD and one attends outside. Especially during heavy patient load, we can’t show concern in this area of childhood obesity. (PHC 8).
Guidelines on the management of childhood obesity are lacking:

…we don’t have such guidelines; hence we are not able to do much. Also, we have our own responsibilities to cover the syllabus. (SHC 2).

…we are focusing more on undernutrition… but I think in the areas of obesity health professionals might need some guidance on what to do. (PL 1).

Two PHC managers serve as fully fledged managers in the district and one in a regional hospital, the others have a dual role as managers and practitioners in their health centres:

We have multi-tasking both clinical as well as administration of the health centre. Therefore, we can’t focus only on one problem such as childhood obesity although we have a bigger responsibility to look after the childhood obesity. (PHC 6).

As there are only two of us, one of us look after the OPD and one attends outside. (PHC 8).

Bhutanese are changing their eating habits:

…Marketing has reached everywhere right after birth… a child has everything to eat …and formula feeding…parents don’t have time and … give the child to a caregiver where the habits of taking junk foods pick up. (PHC 10).

Health literacy about obesity amongst PHC managers is minimal or non-existent:

… I feel health workers are not serious themselves because even their children … are obese…. I feel they are not worried about the obesity. Just forget about other children, health workers themselves have obese children. (PHC 4).

The roles of PHC managers in the management of childhood obesity are ineffective:

I don’t follow up actively, but the obese child often visits the hospital when he is sick with other conditions. Then I take the opportunity to monitor his weight and blood sugar. (PHC 3).

We have recorded overweight children, but action is not taken. (PHC 2).

School health coordinators shared that:

I did not call anyone from the hospital. Usually, we give instruction ourselves related to healthy eating habits and other related matters. (SHC1).

PHC managers and health professionals have not carried out health education related to childhood obesity:

No as of now we have not carried out any mass health education but when we come across a few cases of obese children, we do inform their parents and relatives on risks and the probable future health condition of the children. (PHC 3).

One informant from the policy level informed:

At present, we don’t have a BMI measurement for the children. We are using the same standard as the adult. That is one thing missing in the children’s BMI measurement. (PL 1).

Some PHC managers said that they did not manage obese children because they never came across anyone with such issues:

We haven’t managed an obese child because we did not get any cases yet. (PHC 7).

I haven’t managed childhood obesity because I did not get any of them. (PHC 11).

Discussion

The main objectives of this study were to identify the challenges and barriers, and the roles of Bhutanese PHC managers in the management of childhood obesity at the district level in Bhutan. The perceptions of PHC managers is that childhood obesity is a small problem, but the incidence of obesity is rising. The perception is also reflected in the perspectives of policy managers, school coordinators, parents and communities.

If Bhutan does not recognize childhood obesity as one of the public health concerns and issues at present, then it is highly likely that Bhutan will be like other developed and developing countries with a high incidence of rising childhood obesity. At an individual level, the PHC managers have little control factors which contribute to childhood obesity. At the social level, both parents and health workers were not concerned about the growing incidence of obese children. Some saw a level of obesity as representing being healthy and well.

This study has highlighted the improper or inadequate management of childhood obesity. PHC managers have a limited role in the management of obesity, and the duality of roles requires them to manage the organization as well as to see the patients. Their roles were usually focused
towards curative aspects. The management role in healthcare requires a dual set of skills that requires one to be proficient in leadership, business, and communication, as well as a strong healthcare background. Their roles should include advocacy that includes healthy key messages on obesity and modelling healthy behaviours in the community. The Bhutanese health care system needs to move to a participatory model where there is active participation from the community during the decision-making process.

**Strengths and limitations of the study:** The study adds body of knowledge in strategic directions for the policy makers in preventing childhood obesity. The only limitation of the findings may not be able to generalizable to other PHC managers from other districts and may not be applicable to secondary and tertiary health managers.

Determination of Safe Benzene Concentration at Kebon Jeruk Toll Gate Keeper Jakarta Indonesia

Danang Setia Budi1, Abdul Rohim Tualeka1, Pudji Rahmawati2, Syamsiar S Russeng3, Bambang Wispriyono4

1Department of Occupational Health and Safety, Public Health Faculty, Airlangga University, 60115, Surabaya, East Java, Indonesia; 2Department of Development of Islamic Society, State Islamic University Sunan Ampel, Surabaya, Indonesia; 3Department of Occupational Health and Safety, Public Health Faculty, Hassanudin University, Makassar, Indonesia; 4Department of Environmental Health, Public Health Faculty, University of Indonesia, Makassar, Indonesia

ABSTRACT

Benzene is a liquid aromatic hydrocarbon compound that is clear, colorless, flammable, and volatile. High concentrations of benzene in the body through inhalation can cause health problems. The purpose of this study is to determine the safe concentration of benzene exposure (C6H6) in Jakarta Kebon Jeruk toll gate keeper. Toll gate keepers are vulnerable to exposure to benzene compounds in the air. 20 toll gate keeper who are divided into toll gate 1 and toll gate 2 were population in the study. The sample technique used total population sampling. The present study used quantitative data analysis manually calculated through the calculation of safe concentration in the environmental toxicology concept. Safe concentration data on Jakarta Kebon Jeruk toll gate keeper were based on data from rat experimental animals, experimental body surface, workers’ characteristics of body weight, body height, body surface area, breathing rate and working duration. In addition, data on benzene concentration, animal km, human km, NOAEL and safe limits for toxin doses were also used. The average measurement results of benzene concentration in the air entering the body of workers through inhalation was 0.00167 mg/m3 (0.0052 ppm). This value is lower than benzene threshold according to the Minister of Manpower Regulation Number 5 of 2018 of 0.5 ppm. The safe concentration of benzene calculated was 0.0875 mg/m3 (0.0273 ppm). Based on the calculation of safe concentration, the concentration of benzene in the environment of the Kebon Jeruk toll gate keeper indicated safe.

Keywords: benzene, safe concetration, toll gate keepers

Introduction

The development of the transportation sector makes it easy for people to move and carry out their activities. On the other hand, the development of the transportation sector also has a negative impact towards the community. The negative impacts include congestion and air pollution due to motor vehicle gas emissions. Air pollution can have a negative impact on public health and cause health problems such as respiratory problems, respiratory infections and even systemic diseases such as cancer.

Jakarta is one of the big cities in Indonesia with the highest pollution level. The increasing number of the volume of motor cycle is also one of the causes of increasing environmental pollution. Directorate of Metro Police Traffic Subdistrict Registration and vehicle identification reported that in 2013 the number of vehicles in Jakarta and its surrounding areas reached 16 million units.

One of the air pollutants caused by motorized activities include aromatic hydrocarbon compounds such as benzene, toluene and xylene. According to the Agency for Toxic Substances and Disease Register, chemical compounds that can cause health effects on humans and are found in petroleum content namely benzene,
toluene, xylene, ethylene, Total Petroleum Hydrocarbon and Polycyclic Aromatic Hydrocarbon. Benzene is a clear, colorless, flammable and volatile liquid aromatic hydrocarbon compound. Exposure to benzene in high concentrations that enter the body through inhalation can cause health problems and lead to death.

Toll gate keepers are prone to be exposed to benzene. Most benzene exposure received by toll gate keepers comes from inhalation exposure lines sourced from gasoline and exhaust vehicles. Toll is a state development facility that aims to facilitate traffic, improve distribution services, improve equity in development and justice outcomes.

Researches on benzene risk analysis on human activities is mostly done at gas stations and workshop mechanics. Rusdiyanto stated that workshop workers exposed to chemical substances in the form of gas exhaust motor vehicles inhaled benzene levels that exceed the Threshold Value (NAB) of 0.5 ppm.

A research measured the concentration of benzene at the toll gate 1 and the toll gate 2 of the Jakarta Kebon Jeruk and produced a value of 0.00163 mg m$^{-3}$ and 0.00171 mg m$^{-3}$. The research was conducted on 20 respondents of Kebun Jeruk toll gate keepers who were divided into toll gate 1 keeper and toll gate 2 keeper. Based on previous research, the researchers have not calculated Safe Concentration calculation. Toll gates are one of the work environments with benzene exposure. Therefore, the calculation of safe concentration is important to ensure the health of workers. Safe concentration is calculated by using the Reference Concentration formula with No Observed Adverse Effect Level which is adjusted to the research data so that a safe value can be found on pollutant chemicals to avoid health problems. This study was conducted to calculate safe concentration through the Reference Concentration calculation with No Observed Adverse Effect Level as the safe limit of benzene concentration in the Kebun Jeruk toll gate keepers.

### Material and Method

This study aims to determine the safe concentration of benzene in the work area of the Kebun Jeruk toll gate in Jakarta. The approach used in this study is a cross-sectional approach and is in the form of observational descriptive research. The population in this study was 20 respondents of toll gate keepers who were exposed to benzene chemicals. Population determination was carried out through total working population of Kebun Jeruk toll gate keepers, Jakarta.

The study was conducted in May 2019. It begins with literature study on the analysis of toxicological health risks which included calculation of intake, type of risk and value of dose-response. Secondary data collection was carried out by conducting a literature study of previous research. Supporting research data were also used such as the type of chemical, weight of the experimental animal and results of the measurement of benzene in the air obtained through measurements of NIOSH1501 with activated carbon adsorbing pipe using Chromatography technique.

The variables used in this study were the characteristics of the experimental animals which included weight and surface area, worker characteristics including weight, body surface area, and worker breathing rate. The concentration of benzene in the workplace is also obtained through previous research literature studies. Processing variables by calculating factor Km in animals, No Observed Adverse Effect Level, RfC benzene in workers and calculation of safe concentration on workers is carried out. Data analysis was carried out using the Environmental Health Risk Analysis method.

### Results

**A. Characteristics of Experimental Animals:**

Measuring the level of toxicity of chemical compounds using experimental animals is the process of supporting testing. The experimental animals used were white rats.

### Table 1: Distribution of Characteristics of White Mice

</tbody>
</table>

Where:

- **BSA:** Body Surface Area (m$^2$)
- **W:** Weight (kg)

The body surface area calculated was 0.024165 m$^2$.  

B. Workers’ Characteristics: The characteristics of workers used were body weight, height, and exposure duration. The population of 15 workers Kebon Jeruk toll gate keepers with an average weight of 67.9 kg and an average height of 159 cm. The duration of occupational exposure is 8 hours per day.

1. Workers’ Body Surface Area: This is calculated with the following formula

\[
\text{BSA} = \sqrt{\frac{W \cdot H}{3600}}
\]

Where

BSA: Body Surface Area (m²)
W: Weight (kg)
H: Height (cm)

\[
\text{BSA} = \sqrt{\frac{67.9 \cdot 159}{3600}} = 1.73 \text{ m}^2
\]

2. Workers’ Respiratory Rate: Breathing rate calculations can be done using the following formula

\[
\text{BR} = 5.3 \ln W - 6.9/24
\]

Where

BR : Breathing Rate
W : Weight

\[
\text{BR} = 5.3 \ln 67.9 - 6.9/24 = 0.64 \text{ m}^3/\text{hour}
\]

C. Benzene Concentration: Measurement of benzene concentrations inhaled by workers was carried out at two different toll gate points. The concentration of benzene at the door of Kebon Jeruk toll, Jakarta has an average of 0.00167 mg/m³ (0.00052 ppm).

Table 2: Distribution of Benzene Concentration

<table>
<thead>
<tr>
<th>Location</th>

<td>78.11</td>
<td>0.00054</td>
</tr>
<tr>
<td>Average</td>
<td></td>
<td></td>
<td>0.00052</td>
</tr>
</tbody>
</table>

Based on the results of the above measurements the highest benzene concentration was 0.00171 mg m³ (0.00054 ppm) at toll gate 2, while the lowest concentration was 0.000163 mg/m³ (0.00051 ppm) at toll booth 1. The value of benzene concentration is lower than Threshold Value by 0.5 ppm.

D. Animal Km and Human Km: Determination of safe dosage limits or safe concentration on workers begins with the calculation of Animal km and human km

1. Animal Km

\[
\text{Animal Km} = \frac{W \text{ animal}}{\text{BSA animal}}
\]

Where

Animal Km: Km factor on experimental animal
W: Weight (kg)
BSA: Body Surface Area (m²)

The distribution of Animal Km is as follows:

Table 3: Calculation of Animal Km in White Mice

<table>
<thead>
<tr>
<th>Experimental animal</th>
<th>W (kg)</th>
<th>BSA (M²)</th>
<th>Animal Km</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>Average</td>
<td>0.1407</td>
<td>0.024165</td>
<td>5.82</td>
</tr>
</tbody>
</table>

The calculation results of Animal Km are shown by the table above with an average of 5.82 in white rats.

2. Human Km: Human Km calculations are also needed for workers to support risk analysis

\[
\text{Human Km} = \frac{W \text{ human}}{\text{BSA human}}
\]

Where:

Human Km: Km factor on human
W: Weight (kg)
BSA: Body Surface Area (m²)

Table 4: Human Km calculations for workers

<table>
<thead>
<tr>
<th>Number of worker</th>
<th>W avg (kg)</th>
<th>BSA avg (m²)</th>
<th>Human Km avg</th>
</tr>
</thead>
<tbody>
<tr>
<td>20</td>
<td>67.9</td>
<td>1.73</td>
<td>39.24</td>
</tr>
</tbody>
</table>

Based on the calculation of human km above, the average human km value is 39.24.

E. No Observed Adverse Effect Level (NOAEL): Toxicity test was performed by determining
the highest dose without causing effects on experimental animals or No Observed Adverse Effect Level.

Saridewi and Tualeka stated that the calculation of the highest toxins without causing effects on experimental animals was 3.0 mg/m$^3$ (0.022 mg/kg). NOAEL calculations in this study can be obtained from the following formula:

$$\text{NOAEL benzene} = \frac{3 \times 0.00013 \times 8}{0.1405}$$

$$\text{NOAEL benzene} = 0.022 \text{ mg/kg}$$

**F. Inhalation Reference Concentration (RfC):**

Shaw et al. in a study conducted by Saridewi and Tualeka, show that the calculation of the reference concentration on workers or the Inhalation Reference Concentration can use the following formula.$^8$

$$\text{RfC} = \frac{\text{NOAEL}}{\text{Animal KM}} \times \frac{1}{\text{Human KM}}$$

Where

RfC: Inhalation Reference Concentration

NOAEL: No Observed Adverse Effect Level

Animal Km: Km factor on animal

Human Km: Km factor on human

Based on the calculation of reference concentration on toll gate keepers obtained from the NOAEL value, the average Animal Km and the Human Km average are as follows.

$$\text{RfC} = \frac{\text{Animal KM}}{\text{Human KM}}$$

$$\text{RfC} = 0.022 \frac{5.82}{39.24}$$

$$\text{RfC} = 0.0033 \text{ mg/kg}$$

The reference concentration value of the Jakarta Kebon Jeruk toll gate keepers is 0.0033 mg/kg.

**G. Safe Concentration (C safe) of Benzene:**

In Saridewi and Tualeka, it is shown that the calculation of safe concentration on benzene substances can be calculated using a formula obtained from William, Davis and Soemirat.$^7$ Calculation of safe concentration using the value of Inhalation Reference Concentration, No Observed Adverse Effect Level (NOAEL), average length of work, average body weight and breathing rate of the Kebun Jeruk Jakarta toll gate keepers are as follows.

$$\text{C Safe (mg/m}^3\text{)} = \frac{\text{RfC} \times \text{W} \times \text{BR} \times \text{T}}{\alpha}$$

Where,

C safe: The safe concentration (mg/m$^3$ or ppm)

RfC: Inhalation Reference Concentration (mg/kg)

W: Weight (kg)

$\Delta$: Percentage of substances absorbed by workers’ lungs (%)

BR: Breathing Rate (m$^3$/hour)

T: Time

Calculation of safe Concentration can be seen in the formula as follows.

$$\text{C safe (Mg/m}^3\text{)} = \frac{0.033 \times 67.9}{50\% \times 0.64x8}$$

$$\text{C safe (Mg/m}^3\text{)} = 0.224 \text{ Mg/m}^3$$

$$\text{C safe (Mg/m}^3\text{)} = 0.0875 \text{ Mg/m}^3$$

$$\text{C safe (ppm)} = \frac{\text{Berat Molekul}}{\text{Berat Molekul}}$$

$$\text{C safe (ppm)} = \frac{0.0875 \times 24.45}{78.11}$$

$$\text{C safe (ppm)} = 0.0273 \text{ ppm}$$

**Discussion**

Benzene concentrations in Kebon Jeruk toll gates was 0.00163 mg/m$^3$ (0.00051) on toll gates 1 and 0.00171 mg/m$^3$ (0.00054) on toll gate 2. Benzema concentration at toll gate 2 concentration is higher than benzene concentration at toll gate 1. Based on the regulation of the Minister of Manpower Number 5 of 2018 concerning the Threshold Limit Value, benzene concentration is 0.5 ppm.$^5$ The concentration of benzene in the gate of Jakarta Kebon Jeruk toll was below the threshold value. Calculation of safe concentration at the Jakarta Kebon Jeruk toll gate is based on calculations of Reference
Concentration and No Observed Adverse Effect Level. The result of No Observed Adverse Effect Level is 0.022 mg/kg. This result is comparable with study by Swaen et al. which states that NOAEL benzene compounds are 3.0 mg/m³ or equivalent to 0.022 mg/kg.⁸ According to the Agency of Toxic and Substances, the value of No Observed Adverse Effect Level for exposure through inhalation of 3 ppm through the respiratory system.¹ Thus, the value of No Observed Adverse Effect Level benzene is safe for workers.

Reference Concentration through the inhalation pathway for benzene can be calculated through the value of NOAEL, Animal Km, Human Km for Jakarta Kebon Jeruk toll gate keepers. The results show that the Reference Concentration value through inhalation is 0.0033 mg/kg. These results were considered the same as the study by Kartikasari which had an RfC value of 0.0039 in workers exposed to benzene in the petroleum processing laboratory.⁹ In addition, based on the Reference Concentration value through inhalation based on U.S EPA National Center for Environmental Assessment, RfC value is 0.03 mg/m³. This shows that the value of RfC for Kebon Jeruk toll gate keepers is still smaller than Integrated Risk Information System Chemical Assessment Summary.¹⁰

Reference Concentration through the inhalation pathway for benzene can be calculated through the value of NOAEL, Animal Km, Human Km for Jakarta kebon Jeruk toll gate keepers. The results show that the Reference Concentration value through inhalation is 0.0033 mg/kg. These results reconsidered similar to the study by Kartikasari which had an RfC value of 0.0039 in workers exposed to benzene in the petroleum processing laboratory.⁹ In addition, based on the determination of the Reference Concentration value through inhalation based on U.S EPA National Center for Environmental Assessment, RfC value is 0.03 mg/m³. This shows that the value of RfC for Kebon Jeruk toll gate keeper is still lower than that of Integrated Risk Information System Chemical Assessment Summary.¹⁰

**Conclusion**

Benzene concentration in the air that entering the body of workers through inhalation on average was 0.00167 mg/m³ (0.0052 ppm). This value is still below the Benzene Threshold Value according to the Minister of Manpower Regulation Number 5 of 2018 of 0.5 ppm.⁵ Calculation of safe concentration on workers shows the safe level by 0.0875 mg/m³ (0.0273 ppm). Through the results of the calculation of safe concentration, benzene in the work environment of Kebon Jeruk toll gate keepers is in the safe category.

Control measures and efforts to minimize health effects can be in the form of the use of personal protective equipment for workers and work shift arrangements. Personal protective equipment can be in the form of respiratory masks to protect workers from direct benzene exposure.

**Conflict of Interest:** All authors have no conflicts of interest to declare.

**Source of Funding:** This is an article “Health Risk Assessment of the exposure of Benzene, Toluene, and Xylene in Toll Gate Keeper” of Occupational Safety and Health Department that was supported by Activity Budget Plans 2019, Faculty of Public Health, Universitas Airlangga.

**Ethical Clearance:** The study was approved by the institutional Ethical Board of Health Ministry of Tangerang City

Analysis of Patient Safety Culture and Work Team in Educating the Effect of Leadership Style on Patients Safety Performance

Dike Widyakti Sawfina Maharani¹, Margono Setiawan², Dodi Wirawan Irawanto², Mintarti Rahayu²

¹Doctoral Program in Management Science, ²Departement of Management, Faculty of Economics and Business, University of Brawijaya

ABSTRACT

This research was compiled to test and analyze the influence of patient safety culture, leadership style and team work on patient safety performance at the Ulin Hospital in Banjarmasin. A research concept framework that brings together four variables, namely leadership, teamwork, patient safety culture and safety performance. This study uses a positivist paradigm based on quantitative research. This study aims to examine and analyze analyzing patient safety culture and teamwork in mediating the influence of leadership style on patient safety performance. The results of the research obtained were a culture of patient safety and team work mediating the influence of leadership style on patient safety performance.

Keywords: Leadership, Mediation, Patient Safety Culture, Safety Performance, Team work

Introduction

The results of the patient safety study in the late 1990s found a 3.9% and 2.7% unwanted incidence in hospitalized patients. In 2008, the Ministry of Health and Services of the US Inspector General conducted measurements with the Global Trigger Tool which showed that unwanted events increased 10-fold (to 32%).

In Indonesia, safety law has been made related to patient safety in 2009 which states that hospitals as health care agencies that deal directly with patients must prioritize safe, quality, anti-discriminatory and effective health services by prioritizing patient interests in accordance with standard hospital service.¹

Patient safety is a top priority in health services and is the first critical step to improve service quality and is related to the quality and image of hospitals.² Research in various hospitals in Australia reports that supportive leadership has a positive impact on safety motivation which then improves patient quality and safety. Safety culture is an organizational goal, a top priority, and driven by leadership. Studies conducted by Nieva and Sorra report that poor patient safety culture is an important risk factor that can threaten patient safety.³

Based on Minister of Health Regulation 1691/MENKES/PER/VIII/2011 concerning Hospital Patient Safety that each hospital is required to carry out patient safety management. Ulin Banjarmasin Hospital is a hospital owned by the Provincial Government of South Kalimantan type A with complete classification according to the 2012 Hospital Accreditation Commission assessment Ulin Hospital Banjarmasin has a commitment to maintain and continue to improve the quality of care and patient safety so that excellent continuously for the community.

The culture of reporting an error is hampered because the formation of blaming culture is an event that often occurs, so that solutions sometimes stop by pointing to someone’s mistakes. So that a system is needed where it can be seen how far the patient’s safety performance in the hospital can make continuous and continuous quality improvement efforts and to meet the needs and demands of the community and refer to the law on hospitals.

Method

This study uses a positivist paradigm based on quantitative research. More specifically, this study aims to analyze the effect of exogenous variables on endogenous variables. Exogenous variables include: leadership style, teamwork. Endogenous variable is patient safety performance. In addition to exogenous and endogenous variables, in this study there are also mediating variables, namely the culture of patient safety.

The population in this study were all employees working in all installations in Ulin Hospital Banjarmasin. The need for the number of samples will be calculated using the Slovin formula. Then the number of samples needed is:

\[ N = \frac{N}{Nd^2 + 1} = \frac{1215}{(1215)0.05^2 + 1} = 300.9 \approx 301 \]

In variable measurement techniques, when viewed from the nature of their influence, the research variables can be classified into endogenous variables and exogenous variables. In this study, to be able to measure and study the hypothesized variables, it will use the second order CPA measurement model, where the dimensions reflect the first level latent variables while the hypothesized variables are called the second level latent variables. The measurement scale that will be used in this study on all variables is the ordinal scale in this case the Likert scale.

The data to be collected and analyzed in this study come from primary data and secondary data. Primary data is collected from research instruments, namely questionnaires, which are the main instruments in this study. The secondary data will be collected from internal data from Ulin Banjarmasin Hospital.

In the research instrument test consisted of validity and reliability tests. Data analysis methods used are descriptive statistical methods and inferential statistical methods. The purpose of the descriptive statistical method is to describe the demographic characteristics of respondents such as gender, age, profession, position, length of work as an employee at Ulin Hospital Banjarmasin. While the inferential statistical analysis method that is data analysis used in inferential statistical methods in this study is partial least square (PLS).

Partial Least Square (PLS) analysis is done through two stages, namely evaluating the outer model and inner model. Outer model is a measurement model to assess construct validity and reliability. The second stage in PLS analysis is the evaluation of the inner model to find out the coefficient R² for the dependent construct and the t-statistical value for the construct significance test in the structural model.

The patient safety performance variables of each item have an average value ranging from 2.66-4.79 which can give an idea that patient safety performance is good enough. The highest mean value of 4.79 is in identifying patients before administration of drugs,
blood, or blood products. While the lowest 2.66 is in carrying out the provision of information that is timely, accurate, and relevant in the hospital environment. This study uses six indicators to describe variable patient safety performance, including safe, effective, patient-centered, timely, efficient and equitable indicators.

Based on the results of the descriptive study that based on the average score of the respondents’ answers to the leadership style variables are included in the good category, thus it can be said that actually all indicators are included in the criteria of good. Therefore, all of these indicators should be maintained or reused. This study uses six indicators to describe the variable patient safety performance, including contingent reward indicators, active management by exception, passive management by exception, inspirational motivation, intellectual simulation, and individualized consideration, idealized influence.

The variable value of team work for each item has an average value ranging from 3.51 - 4.24 which can give an idea that the value of the team work is good. The highest average value of 4.24 is in the team members committed to achieving common goals/missions, while the lowest 3.51 is in me giving to other team members in decision making. This study uses three indicators to describe the value of team work variables, including indicators of commitment to shared goals (TW1), decision making (TW2), and conflict management (TW3).

The variable patient safety culture of each item has an average value ranging from 2.26 - 4.31 which can give an illustration that the patient safety culture is quite good. The highest average score of 4.31 is in our mutual support for one another, while the lowest of 2.26 is unpleasant if working with other parts of the hospital. This study uses twelve indicators to describe the variable of patient safety culture, including perception indicators (BK1), frequency of reporting (BK2), supervision (BK3), organizational learning (BK4), intra-sub-departmental collaboration (BK5), openness of communication (BK6), reciprocal errors (BK7), error sanctions (BK8), staff/employees (BK9), management support for patient safety (BK10), collaboration between sections (BK11), and transfer and replacement (BK12).

**Model Confirmatory Factor Analysis:** This section presents the confirmatory factor analysis (CFA) model in the construct of transformational leadership style and construct of transformational leadership style to determine the validity of item-based construct. The item loading factor (Model Transactional Leadership Style) ranges from 0.747-0.854 already has good validity. Reliability on each indicator is well measured, cronbach alpha values range from 0.733-0.792, composite reliability ranges from 0.849-0.873 and average variance extracted (AVE) ranges from 0.652-0.706. The results of the analysis after evaluation, all items meet the requirements. The item loading factor (Model Transformational Leadership Style) ranges from 0.608 to 0.874 has good validity. Reliability on each of the measured indicators is good, cronbach alpha values ranging from 0.625-0.803, composite reliability ranges from 0.830 to 0.871 and average variance extracted (AVE) ranges from 0.553 to 0.733. The results of the analysis after evaluation, all items meet the requirements.

**Testing Linear Assumptions:** Before conducting further evaluation of this analysis, it is necessary to conduct a linear assumption test, namely that the relationship between constructs to be tested has a linear relationship. Linearity results explain that all paths meet linearity assumptions, namely the results of the F test in the linearity section are significant (p <0.05). These results provide the conclusion that linearity requirements have been fulfilled in all paths in the hypothesis model. The results of the linearity test result of the F test are significant (p <0.05).

**Outer Model Testing**

**Discriminant Validity:** Discriminant validity testing in research uses cross loading values and square root of average (AVE) with the aim of checking (testing) whether indicators were valid in explaining or reflecting latent variables. The results show that the discriminat value of the validity of a variable is higher than the correlation value between variables. Thus it can be concluded that the outer model of this study has fulfilled discriminant validity.

**Composite Reliability:** Composite reliability tests the value of reliability between indicators of the construct that forms it. The composite reliability results are said to be good, if the value is above 0.70. Reliability test results show that all constructs have a composite composite coefficient of more than 0.70. Thus, all measurement models used in this study already have high reliability. So that further analysis can be done by examining the goodness of fit model by evaluating the inner model.
Convergent Validity: Convergent validity measures the validity of an indicator as a measure of a construct, can be seen from the outer loading. Indicators are considered valid if the outer loading loading value is 0.5 to 0.6 is considered sufficient, the number of indicators per construct is not large, ranging from 3 to 7 indicators. In the PLS model, the loading factor for the reflexive indicator is outer loading, and for the formative indicator is the outer weight.

Model Compatibility: The model determination coefficient is calculated using all coefficients of determination (R2) in the model.

Table 3: Inter-Variable Correlation Matrix

In the hypothesis model, team work and patient safety culture are mediators in the relationship of leadership style to patient safety performance. The alleged teamwork and patient safety culture as a mediator is quite strong, because the correlation coefficient between leadership styles with these two variables ranges from 0.496 and 0.574.

Inner Model Testing: Inner model testing aims to determine the value of path coefficient, inner T-statistic model, and total effect value that shows the level of variation in changes in the independent variable on the dependent variable.

Table 4: Path Coefficient Test Results in the Inner Model

<table>
<thead>

</tbody>
</table>

Noted: ns = p > 0.05; * = p < 0.05

The second order model of leadership style explains that transactional leadership (loading factor = 0.940) and transformational (loading factor = 0.961) is significant (p <0.05) in explaining leadership style.

Mediation Test Results: In the hypothesis model, the variable teamwork and patient safety culture are mediating variables for the relationship of leadership style to patient safety performance. In the hypothetical model, there are six paths that have a direct influence, and there are four relationships containing indirect effects. In particular the relation to the research hypothesis there are only two indirect effects to be discussed.

</tbody>
</table>

Indirect effects on the path of leadership style on patient safety performance through team work were obtained from the results of the path coefficient of leadership style, team work and patient safety performance which was 0.496 x 0.017 of 0.009 which was not significant (p > 0.05). Indirect influence on the path of leadership style on patient safety performance through a patient safety culture was obtained from the results of the path coefficient of leadership style, patient safety culture and patient safety performance of 0.296 x 0.482 of 0.143 was significant (p < 0.05).

Variance account for (VAF) is 43.2% and 4.6% calculated from the ratio of indirect effects to total influence. Hair et. al. (2014) divided mediation based on VAF values into three, namely not mediating if VAF <20%, partial mediation on VAF between 20% -80%, and complete mediation if VAF was more than 80%. In the results of this analysis the mediating nature of the patient safety culture is partial mediation, whereas in teamwork it is not proven as a mediating variable.

Conclusion

Patient safety culture mediates the influence of leadership style on patient safety performance. In this hypothesis will be related to the coefficient test results indirect influence of leadership style on patient safety performance through a patient safety culture has a coefficient with a positive direction of 0.298 (p <0.05). Maternal Death Model Decreases the Expression of BDNF in Rattus Norvegicus Newborns’ Cerebrum and Cerebellum

Duhita Dyah Apsari¹, Hermanto Tri Joewono², Widjiati³

¹Postgraduate Student of Reproductive Health Sciences, Faculty of Medicine, ²Department of Obstetrics and Gynecology, ³Department of Embryology, Faculty of Veterinary Medicine, Airlangga University, Surabaya, Indonesia

ABSTRACT

Maternal death occurred in the initial pregnancy period up to 42 days after giving birth. Maternal death could cause early life stress in newborns which activated the HPA axis and glucocorticoid secretion as a stress hormone marker. The developing brain was very sensitive to the initial exposure to stressors that would affect the Brain Derived Neurotrophic Factor (BDNF) expression, which was one of the most important endogenous mediators of stress responses in the brain. This study aimed to analyze BDNF expression in the cerebrum and cerebellum of Rattus norvegicus newborn with the maternal death model. The control group (K1) consisted of newborns Rattus norvegicus which were not separated from the mother until 3 days old and the treatment group (K2) is maternal death model consisted of newborns Rattus norvegicus which were separated immediately from the mother after birth until 3 days old and fed with animal milk as a substitute nutrient. After 3 days treatments, 3 newborns with the heaviest, medium, and lowest weights were taken from each mother to sacrifice. BDNF examination was carried out on cerebrum and cerebellum with immunohistochemical method and the results were analyzed with Mann Whitney test. The results showed that the mean BDNF expression in the cerebrum and cerebellum of 3 days old Rattus norvegicus with maternal death model which were separated from the mother lower than the mean BDNF expression of control group.

Keywords: BDNF expression, separation from mother, maternal death model

Introduction

Maternal death is the death of a woman during pregnancy, childbirth, or within 42 days after the end of pregnancy. Maternal death did not depend on the length and location of the pregnancy. This death could be caused by anything related to pregnancy, childbirth, or medical handling. Maternal and infant death rates were a benchmark in assessing the health status of a country.¹⁷,²⁶

Maternal death could affected the children survival, especially in the first 1,000 days of life for children up to 3 years old. The main impact of maternal death was the direct loss of the relationship between the mother and the newborn baby, causing by the absence of bonding and attachment between mother and baby and the immediate cessation of breast milk intake. Mothers also played an important role in giving and responding to communicative signals from babies after birth. The absence of bonding and attachment was one of the causes of neonatal stress. Neonatal stress is an early life stress occurred in neonatal period (birth to 1 month).¹,¹⁰

In early life, babies were prone to experiencing pain and stress. When a baby faced a particular stressor, the hypothalamic-pituitary-adrenal axis would be activated and the paraventricular hypothalamus secretes Corticotropin-releasing hormone (CRH) which then stimulated the secretion of Adrenocorticotropic hormone (ACTH) by the pituitary gland. This hormone would induce the adrenal gland cortex to secrete
glucocorticoids (GC), namely cortisol, which was considered a stress indicator hormone. Neonatal stress in newborns was associated with cortisol hormone responses and baby behavior. Neonatal stress caused glucocorticoid increasing which could had an impact on the baby’s brain development. In addition, the socio-emotional stress reactivity during the early period of neonatal life would affected the brain development.10,11

The part of the brain that had cognitive function was the cerebral cortex, but recent research showed that the cerebellum contained more neurons than the cerebral cortex that allowed it to be involved in cognitive function.2 The cerebrum and cerebellum were interconnected through polysinaptics and form a system associated with cognitive function and interference neuropsychiatry.7

Brain Derived Neurotrophic Factor (BDNF) is a neurotrophic factor that played an important role in brain development because of its ability to protect brain cells from various pathological conditions. BDNF also functioned to maintain neuron survival and regulate synaptic plasticity by increasing the number of dendritic spines and synapse formation. This molecular mechanism underlies cognitive function and brain development which was influenced by BDNF regulation.14 BDNF was also one of the most important endogenous mediators of stress response in the brain. The developing brain was very sensitive to the initial exposure to stressors which would also affected BDNF expression.9 Based on this background, this study was conducted to analyze the differences in BDNF expression in the cerebrum and cerebellum of Rattus norvegicus newborns with maternal death model.

Material and Method

This research was true laboratory experimental with randomized post-test only control group design. The 3-day-old Rattus norvegicus as sample unit. Female rats were pregnant through the superovulation technique by giving a 10 IU injection of the hormone Pregnant mare serum gonadotropin (PMSG). After 48 hours, they were given 10 IU injection of HCG hormone and later continued to monomating. Pregnant rat diagnosis was seen at 17 hours after mating with the presence of a vaginal plug.25 The pregnant rats were cared until aterm and gave birth naturally.

Experimental animal samples were divided randomly into 2 groups, namely the control group (K1) consisting of newborn rats which were not separated from the mother until 3 days old and the treatment group (K2) is maternal death model consisting of newborn rats which were separated from the mother immediately after birth until 3 days old and fed with animal milk as a substitute nutrient. After 3 days treatments, 3 newborns with the heaviest, medium, and lowest weights were taken from each mother to be sacrificed and the head decapitation was performed. The head part was separated and then put into 10% formalin. Imonohistochemical examination of BDNF expression was carried out on histochemical cerebrum and cerebellum preparations.

Findings

Figure 1: Histopathology of BDNF expression in the 3 days old Rattus norvegicus cerebrum between control group and treatment group. BDNF expression represented by brown color chromogen. Yellow arrow indicated the area was the maximum expression. (Immunohistochemical staining, 400x magnification; Miconos microscope MCX50LED; Optilab Plus camera)

The results showed that BDNF expression mean in cerebrum of treatment group was lower than control group (Table 1) and by Mann Whitney test result showed that not significant differences in the BDNF expression in cerebrum between control group and treatment group with a p value = 0.348 (significantly different need p value <0.05) (Table 2) which mean that the decrease of BDNF expression were not happened drastically based on statistical analysis. Similar results also showed in cerebellum that the BDNF expression mean of treatment group was lower than control group (Table 3) with no significant different (p value = 0.392) (Table 4).

Discussion

The novelty of this research is the maternal mortality model which was carried out by separation of newborns from the mother from day 0 to day 3. Some previous research was carried out by separating newborn from the mother a few days after birth or not fully separation which mean separation only done few hours before returned back to the mother. The full separation immediately after birth and examination of BDNF cerebrum and cerebellum expression of 3 days old newborn had never been done before. The separation treatment from day 0 to day 3 early in newborn rats would be the same as the human baby separation immediately after birth from the mother for approximately 1 month. This was included in the criteria for maternal death (42 days after birth).

This research showed that BDNF expression mean of 3 days old Rattus norvegicus cerebrum and cerebellum with maternal death model was lower than control group (Table 1; Table 3). The decrease of BDNF expression could caused by several things.

In early life, babies were prone to experiencing pain and stress. Research by Shi et al (2010) states...
that chronic stress could reduce mRNA expression and BDNF protein expression in hippocampus. The study by Calabrese et al (2015) also showed that the separation of rat’s pups from the mother in the postnatal day 2 to day 14 had reduced BDNF expression in the ventral hippocampus and ventromedial prefrontal cortex. However, the separation in the study was only carried out 3 hours every day then returned to the mother after the treatment. In another study, Binggio et al (2014) showed that a decrease in BDNF expression occurred significantly in the postnatal separation from the third to the 15th day postnatal.4,8,21

Brain-Derived Neurotrophic Factor (BDNF) was a protein that played an important role in the development, maintenance, and synaptic plasticity.16 This protein was expressed in the brain, which included the frontal cortex, parietal, cingulate, temporal, retrosplenial, prirhinai, hippocampal, entorhinal cortex, brain stem, cerebrum, and cerebellum. Each area in the brain had different BDNF concentrations.5 The BDNF gene expression in the brain was influenced by many stimuli, both in physiological and pathological conditions. BDNF regulation was influenced by activation of NMDA receptors (NMDAR), calcium influx (Ca$^{2+}$), and through activation of CREB.10 BDNF was one of the most important endogenous mediators of stress response in the human and mammalian brains. The developing brain was very sensitive to the initial exposure to stressors, especially because of the reprogramming number of stress-sensitive gene pathways.9

Stressor at early of life would cause glucocorticoid to increase. Glucocorticoid played an important role in the BDNF regulation. Glucocorticoid decreased the activity of activator protein-1 (AP-1) and CREB needed in transcription of BDNF genes, influenced the cascade of BDNF signals via TrkB and p75NTR receptors, decreases the infusion of Ca$^{2+}$ ions in postsynapsed membranes, inhibits trkB-mediated signal cascades, and decreases expression phospho-TrkB (pTrkB), and influence the PLC-γ signal cascade regulation by BDNF and inhibit the PI3K-Akt pathway.22,23

With the BDNF presence, the TrkB receptor homodimerizes and initiates several signaling pathways and would support neuron survival, growth, and differentiation. Glucocorticoid(GC) passed through the plasma membrane and entered the cytosol to bind to glucocorticoid receptor (GR), and induces homodimerization (GR-GC complex). The GR-GC complex would target BDNF promoters. Increased glucocorticoid levels caused relocation of nucleus CREB regulated transcription coactivator 2 (CRTC2) to the cytosol. This could decreased the transcription activity of CREB which would caused a decrease in BDNF expression.12

In addition, regulation of BDNF expression by glucocorticoid was also related to DNA methylation and histone modification.BDNF transcripts containing exons I, II, IV, and VI were mostly expressed in transcript neurons so that they display different subcellular localization and could showed that protein was translated by different efficiency in soma or dendritic which would produce local effects. Decreasing BDNF expression was also often associated with increased DNA methylation in BDNF promoters. DNA methylation was one of the contributing factors to long-term epigenetic reprogramming and gene activity in the developing brain. Methylation of BDNF genes was often considered a key mechanism of early life stress and influenced brain function.13,24 Research by Roth et al (2009) and Blaze et al (2013) showed that early life stress in children caused changes in DNA methylation in BDNF accompanied by reduced expression in BDNF.5,18

Stress also could caused the glucocorticoid receptor translocation from the cytoplasm to the nucleus that would result in the imbalance of mitochondria and the production of NADPH oxidase (NOX). Some stress signaling pathways would follow NOX stimulation and would led to cell damage and lower BDNF expression.19

Changes in BDNF expression indicated a dependence on the time period, that was on direct or long-term effects, an acute or chronic. A recent analysis of hippocampal transcriptomies showed that the stress effects on children on BDNF expression were very dependent on age and could vary over the lifetime.24

Some of the above could explained that the maternal death model with separation from the mother could affected the BDNF expression mean, both in the cerebrum and cerebellum of 3 days old Rattus norvegicus.

**Conclusion**

The results showed that the BDNF expression mean of 3 days old Rattus norvegicus cerebrum and
cerebellum with maternal death model which newborns immediately separated from the mother after birth until 3 days was lower than the BDNF expression from control group which not separated from the mother.

Lipid Accumulation Product: A Simple and Useful Surrogate Marker for Glycemic Control in Women with Type 2 Diabetes Mellitus

Ekhlas Khalid Hameed¹, Noor Saadi Hassan², Zina Hassan Abdulqahar²

¹The Clinical Biochemistry Department, Al-Kindy College of Medicine, University of Baghdad, Iraq; ²Clinical Biochemistry Department, College of Medicine, University of Baghdad, Iraq

ABSTRACT

Aim: Lipid accumulation product had developed as a surrogate marker of central fat accumulation. It mirrors the combined anatomical (waist circumference) and biochemical changes (fasting serum triglyceride level) associated with excess lipid accumulation. We aimed to study the association between lipid accumulation product and glycated hemoglobin in type 2 diabetic patients.

Materials and Method: During January 2017 to July 2018 one hundred eighty consecutive type 2 diabetic women (age 25-60 years) were enrolled in this study at Baghdad Medical city. Waist circumference, weight, height and blood pressure was measured. Fasting blood sample was analyzed for blood glucose, glycated hemoglobin and lipid profile. The Lipid accumulation product and Visceral Adiposity Index were calculated based on a published mathematical model. Statistical analysis was done by SPSS version 23.

Result: The glycated hemoglobin was higher across the quartiles of Lipid accumulation product, the number of diabetic patients with poor glycemic control increased with the increase in Lipid accumulation product. Significant positive correlation exists between HbA1C and Lipid accumulation product. In addition, the area under the curve showed that Lipid accumulation product has a good predictive power to identify the state of poor glycemic control.

Conclusion: Lipid accumulation product is significantly associated with glycemic control. As HbA1C evaluation is not available in daily clinical application, it is reasonable to suggest the use of LAP as a simple and indirect assessment of long term glycemic control.

Keywords: lipid accumulation product; type 2 Diabetes Mellitus; Glycated hemoglobin

Introduction

Diabetes Mellitus (DM) is increasing to an alarming global level. It is associated with low quality of life and a devastating micro and macro vascular complications. Strict glycemic control is pivotal in preventing its complications and improves the quality of life (1).

Glycated hemoglobin (HbA1c) is used as a measure of glycemic control in diabetic patients, however, this test is not widely available in every clinical setting especially in the undeveloped countries. In addition, it is relatively expensive making follow up of glycemic control in diabetic patients unsatisfactory (2).

Lipid accumulation product (LAP) is developed as a surrogate marker of central fat accumulation. It combine an anthropometric measure -the waist circumference (WC) and a biochemical measure -the blood triglyceride level (TG). LAP has been suggested as a marker of obesity, metabolic syndrome, insulin resistance and polycystic ovarian syndrome (3, 4, 5).

Many previously published studies confirmed the role of LAP as a simple, inexpensive and accurate index
to estimate cardiovascular risk and all-cause mortality (6). Higher LAP is associated with atherogenic lipid profile, higher level of lipoysis, higher interleukin -6 level, increased plasminogen activator inhibitor, abnormal glucose metabolism, higher oxidative stress and systemic inflammation (7, 8). LAP index was proposed for the first time in 2005 in an epidemiological study with the database of the National Health and Nutrition Examination Survey (NHANES III). In that survey, LAP was superior to body mass index (BMI) in the evaluation of cardiovascular risk in Americans (9).

The aim of this study is to study the utility of LAP as a marker of glycemic control in type 2 diabetic patients.

Material and Method

Study Population: This study was conducted from January 2017 to July 2018. One hundred eighty women, aged 25 to 60 years, with a clinical diagnosis of type 2 diabetes mellitus for at least one year and on oral hypoglycemic medications, were recruited from the Baghdad Medical city.

Patients were excluded from the study if they were pregnant, lactating, smoker, had severe impairment of hepatic, cardiac, or renal function, or if they use insulin. So twenty patients, were excluded from the study and the final participants number was 160 adult women.

Demographics, anthropometric, and clinical measurements: Information on the patients age, medical history and medications, duration of diabetes and antidiabetic medications, was collected.

Anthropometric measurements were assessed by trained personnel. Height was measured using a tape measure to the nearest 0.2 cm, in a standing position without shoes. Weight was measured while the subjects were wearing lightweight clothing without shoes. BMI was calculated as weight (kg), divided by the square of the height (m²). WC was measured to the nearest 0.1 cm, midway between the lower margin of the ribs and the iliac crest using a soft measuring tape, without applying any pressure. Written informed consents were obtained from all participants.

Biochemical Measurement: An overnight 12-hour fasting blood samples were collected into plain tubes and allowed to clot and then centrifuged at 4°C for 10 minutes to separate serum. serum glucose, triglyceride and total cholesterol levels were measured by the enzymatic colorimetric methods. High density lipoprotein cholesterol (HDL-C) was measured by the immunoturbidimetry after precipitation of apo B-containing lipoproteins with phosphotungstic acid. Low density lipoprotein-cholesterol (LDL-C) was calculated from serum total cholesterol, HDL-C and triglycerides, according to the Friedewald equation (10). EDTA tubes was used to obtain plasma sample for HbA1c measurement which was performed with high-performance liquid chromatography.

Definition of Index (7, 11)

LAP and Visceral adiposity index (VAI) in women was calculated as:

\[ \text{LAP} : \left[ \text{WC (cm)} - 58 \right] \times \left[ \text{triglycerides (mmol/L)} \right] \]

\[ \text{VAI} : \left[ \frac{\text{WC}}{36.58 + 1.89 \times \text{BMI}} \right] \times \left( \frac{\text{TG}}{0.81} \right) \times \left( 1.52 / \text{HDL} \right) \]

(The TG and HDL-C concentrations in the indices are measured in mmol/L).

The patients were categories into two category on the basis of HbA1c levels; < 7% good glycemic control, ≥ 7% poor glycemic control. The selection of these cutoff values of HbA1c was based on American Diabetes Association guidelines (12).

Statistical Methods: Statistical analysis was performed with SPSS version 23.0 software. The data are represented as mean and standard deviation (SD). A P value of less than 0.05 was considered statistically significant. The LAP index was categorized into quartiles (<44.98, 44.98 to 57.88, 57.89-82.20, and > 82.20) and the parameters of the patients were compared across the quartile categories.

Comparisons between the groups were performed by analysis of variance (ANOVA) test. The associations between LAP and other parameters assessed using linear Regression and correlation analysis.

Pearson chi-square test was used to examine the difference in frequency between the groups. Receiver-operating characteristic (ROC) analyses were performed to assess and compare the discriminative power of LAP for glycemic control. The area under the receiver operating characteristics curve (AUC) and 95% confidence intervals (CIs) were computed.
Results

The mean age of participants was 55.72 ± 9.4 years. The range of LAP index was < 44.98, 44.98-57.88, 57.89-82.20 and > 82.20 in the 1st, 2nd, 3rd, and 4th quartile categories of LAP, respectively. The clinical, biochemical and anthropometric characteristics of the participants across LAP quartile are presented in table 2. Participants in the highest quartile of LAP had higher HbA1c, FSG, TC, LDL-C, TG, BMI, WC, VAI. Significant increasing trends of all of the measured parameters are observed across increasing LAP quartile except for HDL-C which shows a decreasing trend. Mean levels of HDL-C decreased significantly across increasing LAP quartiles.

Linear regression analysis showed that LAP correlate significantly with HbA1C (r=0.290, P=0.001), FSG (r=0.257, P=0.001), WC (r=0.553, P=0.000), BMI (r=0.530, P=0.000), HDL (r=0.679, p=0.00), TG (r=0.915, P=0.000) and TC (r=0.355, P=0.000).

In ROC analysis, the area under the curve showed that LAP had good predictive power to identify the state of poor glycemic control which was comparable to that of the Visceral adiposity index (VAI) while BMI has the least AUC (table 3).

Discussion

The present study evaluated the ability of the surrogate marker, LAP in identifying glycemic control in type 2 DM patients. The glycated Hb was higher across the LAP quartiles, the number of diabetic patients with poor glycemic control increased with the increase in LAP Index. Significant positive correlation exist between HbA1C and LAP. In addition, the area under the curve showed that LAP has a good predictive power to identify the state of poor glycemic control.

The LAP was developed in an attempt to mirror the combined biochemical and anatomical changes associated with excess lipid accumulation. Measurements of serum TG concentrations and waist circumference are accessible and low-cost procedures, On the other hand, HbA1C measurement is relatively expensive and not routinely available in every clinical setting, at least in most of the undeveloped countries.

It is suggested that lipoprotein particle that have small diameters are linked to diseases risk more than those with large diameters (13, 14) and that the abdominal size correlate inversely with the diameter of lipoprotein particles (15), accordingly, LAP may state disease risk through the relations between its two components (TG and WC).

Excessive lipid accumulation, predominantly in the abdominal region, is characterized by an increased insulin resistance. As the lipid is structured, it is reasonable to assume that LAP is able to mirror both visceral fat mass deposition and an increased lipolytic activity (16, 17). the increased lipolytic activity in the visceral fatty tissue is associated with less suppression by insulin, more free fatty acids released, more free fatty acids delivered to the liver and eventually more hepatic glucose production. Additionally, excess fatty acids slow down the hepatic insulin removal and this add to the insulin resistance (18).

Many previously published studies demonstrated the role of LAP in prediction of disease. LAP levels were independently linked with all-cause, cardiovascular and congestive heart failure mortality in normal weight postmenopausal women (19). Chiang et al (20) investigated the accuracy of LAP in predicting metabolic syndrome in Taiwanese adults in China, and he concluded that LAP is a simple index with higher predictability. Comparable results were found in Iran population (21). Another
population based cohort study suggested that the level of LAP was an independent predictor of cardiovascular events in normal BMI Iranian individuals (22).

In the NHANES III (Third National Health and Nutrition Examination Survey) population LAP level demonstrated a higher association with T2DM than BMI (23).

Another finding of this study was the strong association of LAP with total cholesterol, HDL-C levels - the independent risk factors of cardiovascular disease-. Rui et al [24] found that LAP correlated positively with serum total TG,TC, FPG,WC but negatively with HDL. Similar to the finding of this study, in addition, he found that LAP could be a better parameter than Triglyceride glucose index and VAI for predicting Metabolic syndrome.

The area under the curve showed that LAP had good predictive power to identify the state of poor glycemic control. Although Visceral adiposity index (VAI) has a comparable power, but it require additional measurements (BMI and HDL-C).

Several limitations in this study needed to be pointed out. Firstly, it was a cross-sectional study with a relatively small sample size, Secondly, the lack of information on the use of lipid-lowering drugs may possibly influence the results. Thirdly, the participants in this study were all women.

In conclusion, it is crucial to assess the glycemic control in a convenient and inexpensive way. Our study suggests that LAP is significantly associated with glycemic control. As HbA1C evaluation is not available in daily clinical application, it is reasonable to suggest the use of LAP as a simple and indirect assessment of long term glycemic control.

Conflicting Interest: None

Source of Funding: Self

Ethical Clearance: Ethical approval was obtained from the Ethical Committee of the Al-Kindy college of medicine.

The Safe Concentration Determination for Public Health Problems Due to Inhalation of Air Containing Hydrogen Sulfide Around Industrial Area of Medan Indonesia

Erlinda Rasikhah Hadi Salma¹, Abdul Rohim Tualeka¹, Pudji Rahmawati², Syamsiar S Russeng³, Atjo Wahyu³

¹Department of Occupational Health and Safety, Faculty of Public Health, Airlangga University, 60115 Surabaya, East Java, Indonesia; ²Department of Development of Islamic Society, State Islamic University Sunan Ampel, Surabaya, East Java, Indonesia; ³Department of Occupational Health and Safety, Faculty of Public Health, Hasanuddin University, Makassar; East Java, Indonesia

ABSTRACT

Hydrogen sulfide or H₂S was a chemical compound which is colorless, flammable, explosive, corrosive, dangerous, and poisonous with the smell like rotten eggs. The source of H₂S came from human activities namely industrial activity and waste. The animal feed industry and the seafood processing industry were industries that produced waste containing H₂S gas. This research was done to determine the safe concentration of H₂S which had the potential to disrupt the health of the community around Medan industrial area. This was an observational research, cross sectional and descriptive. The research population was residential community around the industrial area of animal feed and seafood processing at a radius of 300m and 800m. The number of research sample was 104 people. The data analysis used quantitative data analysis manually to decide the safe concentration (C safe) of H₂S for community which were obtained from the data of experimental animal weight that was white mice (Wanimal), body surface area of white mice (BSA animal), worker weight (W), worker height (h), worker respiratory rate (BR), body surface area of worker (BSA), length of working time (t), concentration of H₂S (C), NOAEL, animal Km, human Km, and safe human dose of toxin (SHD).

The results showed measurements of H₂S concentrations in the industrial area of animal feed and seafood processing at 300m was 0.0022 ppm while at 800m was 0.0064 ppm, which means that both were above the Threshold Limit Value (TLV) of 0.0005 ppm according to the ATSDR provisions regarding the Odor TLV H₂S. According to KepMenLH No. KEP-50/MENLH/1996 concerning standard level of odor with TLV of 0.02 ppm, then only for the community around industrial areas at radius 300 m with a concentration of 0.022 ppm which was above the TLV. Akan tetapi konsentrasi hidrogen sulfida pada radius 300 m dan 800 m tersebut berada di bawah Minimal Risk Levels (MRL) tingkat pemaparan inhalasi hidrogen sulfida yang ditetapkan oleh Agency for Toxic Substances and Disease Registry (ATSDR) 2016 untuk efek akut sebesar 0.07 ppm.

Upaya pengendalian yang dilakukan untuk masyarakat berisiko adalah pengkonsumsi enzim sitokrom P450 yang terkandung dalam makanan yang mengandung zat besi seperti kacang-kacangan, sayuran, daging, kuning telur, dan ikan untuk menurunkan tingkat hidrogen sulfida dalam tubuh. Control efforts taken for people at risk were consuming the cytochrome P450 enzyme in iron-containing foods such as nuts, vegetables, meat, egg yolks, and fish to reduce the level of H₂S in the body. TSelain itu adanya gangguan pada enzim sitokrom oksidase menyebabkan suplai energi hasil oksidasi di mitokondria berkurang, untuk itu perlu mengkonsumsi makanan yang mengandung antioksidan seperti alpukat, delima dan anggur (Tualeka, 2013). The interference with the cytochrome oxidase enzyme caused the energy supply from oxidation in the mitochondria to decrease, so it is necessary to consume foods that contain antioxidants such as avocados, pomegranates and grapes (Tualeka, 2013).

Keywords: Hydrogen Sulfide, safe concentration, public, animal feed and seafood processing industries.

DOI Number: 10.5958/0976-5506.2019.02570.1
Introduction

Yong Bai (2019) explains that H₂S is a colorless gas, flammable, poisonous, and has a smell like rotten eggs. (1) Humans can smell hydrogen sulfide at low concentrations in the air, starting at 0.0005 ppm. This can increase the risk of exposure to air levels which can cause serious health effects. H₂S is mainly absorbed through the lungs, digestive tract and skin (ATSDR, 2016). (2)

H₂S inhibits the cytochrome oxidase enzyme that contains iron inside mitochondria as an energy-producer. (3) Mitochondria are susceptible to oxidative stress which requires adequate antioxidants. The interference with the cytochrome oxidase enzyme causes the energy supply from oxidation in the mitochondria to decrease, called hypoxia (Tualeka, 2013). (4)

ACGIH sets the Threshold Limit Value of H₂S is 10 ppm. (5) In Indonesia according to KepMenLH No.KEP-50/MENLH/11/1996, the TLV is set at 0.02 ppm. (6) Sedangkan berdasarkan Agency for Toxic Substances and Disease Registry (ATSDR) Nilai Ambang Batas (NAB) hydrogen sulfida sebesar 0,0005 ppm sesuai ketentuan ATSDR tentang Nilai Ambang Batas Bau Hidrogen Sulfida (H₂S). Based on the ATSDR, the TLV of H₂S is 0,0005ppm in accordance with ATSDR provisions regarding the odor TLV of H₂S. (2)

In Dipa study (2016), the results of measurements of the H₂S concentration in kawasan industri pakan ternak and pengolahan hasil laut radius300 m sebesar 0,03 mg/m³ (0,0022 ppm) sedangkan konsentrasi H₂S pada radius 800 m sebesar 0,009 mg/m³ (0,0064 ppm), yang berarti keduanya berada di atas Nilai Ambang Batas (NAB) hydrogen sulfida sebesar 0,0005 ppm sesuai ketentuan ATSDR tentang Nilai Ambang Batas Bau Hidrogen Sulfida (H₂S). Industrial areas at 300m is 0.0022ppm while the concentration of H₂S at 800m is 0.0064ppm. (7) It means both are above the TLV of 0.0005ppm according to the ATSDR provisions regarding the odor TLV of H₂S. Sedangkan menurut KepMenLH No.KEP-50/MENLH/1996 tentang baku tingkat kebauan dengan Nilai Ambang Batas Bau Hidrogen Sulfida (H₂S), sebesar 0,02 ppm maka hanya pada masyarakat kawasan industri pakan ternak dan pengolahan hasil laut (radius 300 m) dengan konsentrasi sebesar 0,022 ppm yang berada di atas Nilai Ambang Batas (NAB). According to KepMenLH No.KEP-50/MENLH/1996 concerning standard level of odor with TLV is 0.02ppm, then only for the community around industrial areas at 300m with a concentration of 0.022 ppm is above the TLV. Berdasarkan penelitian yang dilakukan tidak menimbulkan efek karsinogenik, namun berdampak pada kesehatan jika terpapar secara kontinyu.

Research in Norway regarding the assessment of exposure H₂S in wastewater treatment workers has shown that 93 workers are above the safe limit of the H₂S concentration which is 0.1 ppm. It can be concluded that the majority of wastewater treatment workers experience respiratory problem. (8)

Based on previous research on H₂S there has been no research on H₂S safe concentrations. The concentration of H₂S should be within safe limits so that it does not cause health problems for the community. Oleh karena itu, berdasarkan penjelasan di atas, penulis akan mengukur batasan konsentrasi aman hydrogen sulfida di pemukiman penduduk sekitar industri pakan ternak dan pengolahan hasil laut. Therefore, the author will measure the limits of the H₂S safe concentration in residential area around Medan industrial area.

Material and Method

This study was an observational, cross sectional and descriptive study. Populasi dalam penelitian ini adalah ibu rumah tangga yang tinggal di sekitar kawasan industri pada Radius 300 m dan radius 800 m. The number of samples in this study were 52 people at a radius of 300 m and 800 m, so the total sample was 104 people.

Data mengenai konsentrasi benzena di udara didapatkan dengan melakukan pengukuran langsung menggunakan atuk Spektrofotometer dan dialisis dengan Iont sulfida bereaksi dengan p-amino-dimethyl anilin dan FeCl₃ membentuk metilen biru, mengacu pada metode SNI 19-7119.7-2005. The direct measurement of H₂S concentration used a spectrophotometer and analyzed with sulfide ions reacting with p-amino-dimethyl aniline and FeCl₃ forming methylene blue, referring to the SNI 19-7119.7-2005 method.

The research variables were H₂S concentrations, housewife weight, height, respiration rate, length of work day, body surface area, weight and body surface of white mice, the highest dose of toxin without effect on experimental animals (NOAEL), Animal Km, Human Km, safe limit of dose (SHD), and H₂S concentration.
The data analysis in this study was done by using quantitative data analysis manually to determine the \( \text{H}_2\text{S} \) safe concentrations.

**Results**

A. Characteristics of Animals and the Surface Area of Experimental Animals (White Mice):
Suatu senyawa dikatakan toksik ketika masuk ke dalam tubuh dan berpotensi menyebabkan gangguan kesehatan tubuh. Pada umumnya, respon manusia terhadap toksikan secara kualitatif memiliki kesamaan dengan respon hewan yaitu sekitar 90% gen hewan ini mirip dengan manusia, sehingga fakta ini menjadi dasar ekstrapolasi dari data hewan ke manusia. In general, the human response to toxicity qualitatively had similarities with the response of animals that was about 90% of the genes of these animals were similar to humans.

Based on the data of white rat body weight, the body surface of mice could be calculated using the following formula:

\[ \text{Animal BSA} = 0.09 \times W^{0.67} \]

B. Community Characteristics, Community Body Surface Area and Community Respiratory Rate:
Based on Table 2, it was known that the average body weight at a 300 m and 800 m was 68 kg. Lama waktu penduduk khususnya ibu rumah tangga yang terpapar gas \( \text{H}_2\text{S} \) pada radius 300 m dalam sehari adalah 18 jam sedangkan lama waktu ibu rumah yang terpapar gas \( \text{H}_2\text{S} \) pada radius 800 m dalam sehari adalah 15 jam. The length of time residents, especially housewives who were exposed to \( \text{H}_2\text{S} \) gas at 300 m in a day was 18 hours while at 800 m in a day was 15 hours. Tinggi badan menggunakan nilai rata-rata tinggi badan wanita dewasa Indonesia yaitu 153 cm. Height used the average value of Indonesian adult women’s height was 153 cm.

Based on this data, the body surface area and the respiration rate of workers could be calculated using the following formula.

1. **Body Surface Rate**

\[ \text{BSA} = \frac{\sqrt{W \times h}}{3600} \]

2. **Respiratory Rate**

\[ \text{BR} = \frac{5.3 \times \ln W - 6.9}{24} \]

</table>
The analysis results of the BSA and BR calculation according to tables 2 and 3 showed that the average BSA of workers was 1.27 m² and the average workers BR was 0.64 m³/hour.

C. Hydrogen Sulfide Concentration (H₂S): The measuring results of H₂S concentration in the industrial area showed different results at a radius of 300 m and 800 m which was equal to 0.03 mg/m³ (0.022 ppm) and 0.009 mg/m³ (0.0064 ppm).

Based on the measurements results, both were above the TLV of 0.0005 ppm according to ATSDR provisions regarding the Odor Limit Value of H₂S. According to KepMenLH No. KEP-50/MENLH/1996 regarding the standard level of odor with the TLV of 0.02 ppm then only for the industrial area community at radius 300 m was above the TLV.

D. Animal Km and Human Km

1. Animal Km

   \[ \text{Animal Km} = \frac{W_{\text{Animal}}}{\text{BSA Animal}} \]

   The results of the Animal Km calculation were shown in table 5, with the average of Animal Km was 5.81.

<table>

E. NOAEL: To determine the safe limit concentration of a chemical begun with the toxicity test determining the highest dose without causing effects on experimental animals or No Observed Adverse Effect Level (NOAEL). Based on US Environmental Protection Agency research stated that H₂S NOAEL was 1 mg/m³ or equivalent to 0.0074 mg/kg obtained from the following calculations.

\[
\text{H₂S NOAEL} = 1 \text{mg/m}^3 = \frac{1 \times 0.00013 \times 8}{0.1405} = 0.0074 \text{mg/kg}
\]

F. Safe Human Dose: The safe limit for the dose of toxins for humans or Safe Human Dose (SHD) was found to be initiated using the following formula from Shaw et al (2007).

\[
\text{SHD} = \text{NOAEL} \times \frac{\text{Animal Km}}{\text{Human Km}}
\]

Information:

SHD: Safe Human Dose (mg/kg)
Animal KM: KM factors in animals
Human KM: KM factors in humans

Based on the formula, the calculation obtained from the NOAEL value, the average animal Km, and the average human Km were:

\[
\text{SHD} = 0.0074 \times \frac{5.81}{39.26} = 0.001 \text{mg/kg}
\]

G. Safe Limits of Hydrogen Sulfide Concentration (H₂S): Determining the safe limits of H₂S concentrations used the following formula (William, 1985; Soemirat, 2003; Davis, 1991).
Caman = \frac{(SHD)(W)}{(\delta)(BR)(t)} \text{ mg/m}^3 \\
To convert units of mg/m\(^3\) to ppm the following formula was used. \(10\)

\[ C\text{aman} = \frac{\#mg/m^3}{(MW)} \times 24.45 \text{ ppm} \]

Information:

C safe: The concentration of toxins in the air which is safe for the community (mg/m\(^3\))

SHD: Safe Human Dose (mg/kg)

W: Weight (kg)

\(\delta\): % of substances absorbed by the lungs

BR: Human respiratory rate (m\(^3\)/hour)

t: Working time (hours)

MW: Molecular Weight

Based on formula above, the calculation of the safe concentration of H\(_2\)S on average in residential areas around industries at radius 300 m and 800 m shown in table 7 and 8 were equal at 0.01 ppm.

\[ C\text{ safe average} = \frac{(SHD)(W)}{(\delta)(BR)(t)} \]
\[ = \frac{(0.0011)(68)}{(50\%)(0.64)(17)} \]
\[ = 0.0137 \text{ mg/m}^3 \]
\[ = 0.01 \text{ ppm (radius 300 m)} \]

\[ C\text{ safe average} = \frac{(SHD)(W)}{(\delta)(BR)(t)} \]
\[ = \frac{(0.0011)(68)}{(50\%)(0.64)(15)} \]
\[ = 0.0155 \text{ mg/m}^3 \]
\[ = 0.01 \text{ ppm (radius 800 m)} \]

The lowest C safe = 0.0113 mg/m\(^3\)

Based on the safe concentration calculation in 52 people who were housewives living around the industrial radius of 800 m, the calculation result of the lowest safe concentration of H\(_2\)S or the safest limit for the community was 0.00113 mg/m\(^3\) (0.0081 ppm).

\[ \text{The lowest C safe} = \frac{\#mg/m^3}{(MW)} \times 24.5 \text{ ppm} \]
\[ = \frac{0.0113}{34.08} \times 24.5 \text{ ppm} \]
\[ = 0.0081 \text{ ppm} \]

The calculation results of safe limits at radius 300 m was of 0.007 ppm and 0.0081 ppm at radius 800 m could be used to predict the concentration of toxins in the air that was safe if there was no determination of TLV and for comparison with TLV which had been set by various institutions both by the National Standardization Agency, ACGIH, NIOSH and OSHA (William, 1985 in Tualeka, 2013).
Discussion

Berdasarkan hasil perhitungan, NOAEL hidrogen sulfida sebesar 1 mg/m³ setara dengan 0,72 ppm. Based on the calculation results, H₂S NOAEL is 1 mg/m³ (0.72ppm). Hasil NOAEL ini lebih kecil dari ATSDR tahun 2016 yaitu 2,5 ppm untuk sistem per napasan dengan paparan menengah. This NOAEL result is smaller than ATSDR in 2016, which was 2.5 ppm for respiratory systems with medium exposure. Selain itu besdasarkan NOAEL hasil perhitungan lebih kecil dari penelitian yang dilakukan Brenneman et al (2000) dalam EPA-IRIS NOAEL H₂S sebesar 14 mg/m³ yang menunjukkan bahwa kisaran paparan menengah dengan tingkat keparahan kontinyu. Based on NOAEL, the calculation results are smaller than the research conducted by Brenneman et al (2000) in EPA NOAEL H₂S of 14mg/m³ which indicates that the range of exposure is medium with continuous severity. (11)

Based on the calculation of the H₂S SHD value hidrogen sulfida didapatkan hasil yaitu 0.001 mg/kg.s obtained at 0.001mg/kg. Hasil SHD ini lebih kecil dari penelitian yang dilakukan Brenneman et al (2000) dalam EPA-IRIS (2009) yaitu 0,0044mg/kg yang menunjukkan bahwa paparan kronis tingkat rendah terhadap H₂S. Dengan demikian hasil perhitungan nilai SHD yang dilakukan lebih aman bagi manusia dengan menggunakan NOAEL sebagai perhitungan RfC. The results of this SHD are smaller than the research conducted by Brenneman et al (2000) in EPA (2009) which was 0.0044mg/kg which indicates the low levels of chronic exposure to H₂S. (12) Thus the calculation of SHD values performed is safer for humans by using NOAEL as SHD calculation.

Based on the results of this study, the safe concentration of H₂S in Medan industrial area is 0.0077ppm (radius 300 m) and 0.0081 ppm (radius 800 m). Hasil penelitian ini lebih lebih kecil dari nilai ambang The results of this study are smaller than the H₂S TLV concentrationmenurut (ACGIH) yaitu 10 ppm., Badan Standarisasi Nasional Indonesia (SNI 19-0232-2005) yaitu 10 ppm. according to ACGIH which is 10ppm. The Indonesian National Standardization Agency (SNI 19-0232-2005) is 10 ppm. Sedangkan untuk kawasan industri radius 800 m berada di bawah batasan konsentrasi aman yaitu 0,022 ppm konsentrasi H₂S > 0,0077 ppm konsentrasi aman H₂S. This was compared to the concentration of H₂S at a radius of 300 m above the safe concentration limit of 0.022 ppm H₂S concentration > 0.0077 ppm H₂S safe concentration. Sedangkan untuk kawasan industri radius 800 m berada di bawah batas konsentrasi aman yang di tentukan yaitu 0,0064 konsentrasi H₂S < 0.0081 ppm konsentrasi aman H₂S. Whereas for the radius of 800 m was below the safe concentration limit, which was determined to be 0.0064 H₂S concentration > 0.0081 ppm H₂S safe concentration.

Recommendation

Recommendations for controllers are people at risk of consuming the cytochrome P450 enzymeyang terkandung dalam makanan yang mengandung zat besi seperti kacang-kacangan, sayuran, daging, kuning telur, 50/MENLH/11/1996 the TLV odor is set at 0.02ppm. Dengan demikian, nilai hasil penelitian dapat dijadikan acuan dalam menentukan nilai ambang batas hydrogen sulfida (H₂S) di lingkungan pemukiman sekitar industri pakan ternak dan pengolahan hasil laut dan juga aman bagi pekerja yang terpapar H₂S. The value of research results can be used as a reference in determining the TLV of H₂S in residential areas around Medan industries so that it is safe for workers exposed to H₂S.

Conclusion

The measurement results of the H₂S concentration of inhaled by the public, especially housewives in industrial area at 300m radius was 0.03 mg/m³ (0.022 ppm), while the measurement results of H₂S concentration at a radius of 800 m is 0.009 mg/m³ (0.0064 ppm) which means that both were above the TLV of 0.0005 ppm according to ATSDR provisions regarding the Odor TLV of H₂S. Whereas according to KepMenLH No.KEP-50/ MENLH/1996 concerning standard level of odor with TLV of 0.02 ppm, it was only in the industrial community radius of 300 m with a concentration of 0.022 ppm which was above the TLV.

Based on manual calculations for the lowest safe concentration limits of H₂S was 0.0077ppm (radius 300m) and 0.0081ppm (radius 800m). Hal ini jika dibandingkan dengan konsentrasi hidrogen sulfida yang ada di kawasan industri pada radius 300 m berada di atas batasan konsentrasi aman yaitu 0,022 ppm konsentrasi H₂S > 0,0077 ppm konsentrasi aman H₂S. This was compared to the concentration of H₂S at a radius of 300 m above the safe concentration limit of 0.022 ppm H₂S concentration > 0.0077 ppm H₂S safe concentration. Sedangkan untuk kawasan industri radius 800 m berada di bawah batas konsentrasi aman yang di tentukan yaitu 0,0064 konsentrasi H₂S < 0.0081 ppm konsentrasi aman H₂S. Whereas for the radius of 800 m was below the safe concentration limit, which was determined to be 0.0064 H₂S concentration > 0.0081 ppm H₂S safe concentration.
Danielikan untuk menurunkan tingkat hidrogen sulfida dalam tubuh. Contained in the iron-containing foods such as beans, vegetables, meat, egg yolks, and fish to lower the H2S levels in the body. Adanya gangguan pada enzim sitokrom oksidase menyebabkan suplai energy hasil oksidasi di mitokondria berkurang, untuk itu perlu mengkonsumsi makanan yang mengandung antioksidan seperti alpukat, delima dan anggur (Tualeka, 2013). The interference with the enzyme cytochrome oxidase causes the supply of energy from oxidation in mitochondria to decrease, so it is necessary to consume foods that contain antioxidants such as avocado, pomegranate and grapes (Tualeka, 2013).

ABSTRACT

Background: Bilih fish (Mystacoleucus padangensis) contains omega-3 fatty acids and has the potential to be included as an ingredient in biscuits for children. Objective this study to develop biscuits formulated with Bilih fish and to analyze the effect of bilih fish-based biscuit treatment in cognitive learning abilities of Sprague Dawley rats.

Method: One biscuit formula was selected based on the best organoleptic test, and then given to 24 growing rats (21 days old Sprague Dawley strain male) for 28 days using a complete randomized design study. Treatments were P1 (standard feed (SF)), P2 (SF + standard biscuits (F0)), P3 (SF + F0) + pure omega-3 oil) and P4 (SF + the best formula biscuit (F20)). Parameters measured on rats were weight, consumption of standard feed, %FCE (food conversion effective) and Y-Maze score.

Result: Organoleptic test showed the best formula biscuit to administration 20 g Bilih fish flour to one formula dough with chocolate flavor. The consumption of standar feed of rat taken from P4 was significantly different from P2 but undifferent with P2 and P3. The highest Y-Maze score were obtained from P4, which was significantly different from P1, P2, and P3 in five days treatment. The highest persen of FCE in P4 was not significantly higher than P1, P2, and P3.

Conclusions: Production of biscuits by adding 20 g of bilih flour to one formula dough with chocolate flavor increased consumption of standar feed and Y-Maze score of growing rats significantly, but %FCE was not significantly.

Keywords: Bilih fish, omega-3 fatty acid, y-maze score.

Introduction

The first 1000 days of life is a golden period for child development. It starts with 270 days during pregnancy and followed by 730 days after birth or two years. The lack of nutrient in 1000 days of life impact stunting and low cognitive. Early age malnutrition, in children aged 3-11 years in all genders and ethnicities, led to a reduction in IQ scores about 15.3 points at the age of 11. The lack of omega-3 consumption may cause a direct problem in children’s growth and development. Bernardi (2012) stated that omega-3 needed for brain growth and development in children aged 0-2 years is very rapid. Thus malnutrition that occurs during this golden period will lead to growth faltering and impaired brain development. Adequate nutrients intake to support growth and increase cognitive aspects in 0 – 2 years age is pivotal. The adequacy of nutrients includes energy, carbohydrates, proteins, fatty acids, especially omega-3, which is a brain fatty acid. Omega-3 plays a role in brain growth and development both in normal and stunting children. It can help the growth in birth weight, body length and help improve the child’s cognitive ability.
Omega 3 is widely present in various types of fish. However, fish products have specific organoleptic properties which are not necessarily favored by children. Thus, research to improve acceptance of fish products amongst children is still a need. Research related to locally processed food products with fresh fish in the form of biscuit has been carried out by Widodo et al. (2015) to improve the nutritional status of children under five through the intervention with Snakehead fish-based biscuits.7

The development of local freshwater fish-based processed products into biscuits has several advantages, namely simple to produce, store, and distribute with relatively low prices with long shelf life. It can also be adjusted to the child’s digestion and shaped in such a way as to increase the children’s acceptance. Thus for the development of local fish-based biscuit products in Solok Regency, West Sumatra the Bilih fish was chosen. The results of the preliminary research showed that Bilih contains a high level of omega-3, about 0.553 g/100g of fresh fish.8

Previous study Cutuli et al (2016) found that the cognitive development and improvement in skill observed in mice using the Y-Maze test was related to the supplementation of omega-3 fatty acids.9 Further, Bernardi (2012) stated that omega-3 fatty acid play an important role in brain development and brain health and the low levels of omega-3 fatty acid in the body of experimental animals would affect dysfunctional brain development and disruption of growth, showing that omega-3 supplementation, DHA is useful for brain development, especially in memory and cognitive aspects in hippocampus.5

Previous studies by Mirza (2012) related to the development and cognitive improvement of the hippocampus in experimental animals were carried out using the Multiple T-Maze methods resulted in significant differences between the rat (given Centella Asiatica leaf extract) and the control. Experimental animals with the Centella Asiatica leaf extract intervention had increased in activity (walking, climbing, and smelling) compared to control experimental animals.10

This study aims to determine the effect of biscuits containing Bilih fish flour on the development of cognitive (the learning ability) of the experimental rat. Animal subjects (male neonatal Sprague-Dawley rats aged 21 days post-weaning) were used as the experimental animal because it is the same with under five years children. Thus it is crucial to study the potential of biscuits enriched with Bilih fish to improve the growth of children which started with animal study before further steps in a human subject is taken.

Materials and Method

This research was conducted from September 2017 until January 2018. The ethical clearance number 72-2017 was issued from the Institute for Research and Community Service of animal ethics commission, IPB University. This study used experimental rats was a completely randomized design.

The material used in this research was Bilih fish that was made into flour and then formulated into biscuits. The location, formula of fish-based biscuit product, rat treatment design and omega-3 fatty acid dose that use to this study refer to Diana et al. (2019).8 For the animal study, the effect of biscuit intervention on cognitive learning abilities Sprague Dawley rats. Purchase of Sprague Dawley rats was from PT. Indoanilab laboratory. The rats were bred and kept in the animal laboratory in PT. Indoanilab Bogor which is a semi-barrier type of facility. These rats are the 6th generation descendants of the female and male Sprague Dawley SPF (Specific Pathogen Free) strain rat, originated from Food and Drug Supervisory Agency (BPOM) Indonesia.

The research subjects were 21 days old male rats (post-weaning) of the Sprague Dawley strain (24 rats). The rats were moved and adapted for 14 days in Animal Veterinary Hospital (RSHP) research laboratory. The rats were given standard daily rations (including water) ad libitum for 14 days as an acclimatization period. Before treatment was given, the rats were placed in cages, weighed, and measured. Next, 24 rats were divided into four treatment groups and fed with standard feed for 14 days (acclimatization). After the acclimatization, all the rats entered the treatment period for 28 days. Every 2-7 days, the white rats were weighed using a digital measurement instrument with the accuracy of 1 gram. The cognitive aspect parameters were tested on rats using the Y-Maze method to measure cognitive abilities and spatial memory.11 The measurement of the Y-Maze score was done twice a week. Y-Spontaneous Maze Alternation is a behavioral test for measuring spatial working memory based on the willingness of rodents to explore new environments. The advantages of Y-Maze are the refinement of T-Maze, and if compared to other methods, Y-Maze is easier to be executed, many parts of the brain including the hippocampus, septum, basal forebrain, and prefrontal cortex--are involved in this task. This test is used to quantify cognitive deficits and evaluate effects on cognitive. Rat typically prefer to investigate a new arm of the maze rather than returning to one that was previously visited.12 The Y-Maze values are expressed in % alternation with a value >50%, which
is considered normal. The parameters were observed to calculate the frequency of recurrent error entering the arm and the frequency of error entering the empty arm at the labyrinth Y. At each labyrinth arm, the rat can develop a cognitive map of spatial relationships on which path the rat has visited. The Y-Maze was performed for 5 minutes in all treatment rats P1, P2, P3, and P4.

Statistical analysis used the ANOVA test procedure in a completely randomized design at 95% confidence level (α = 0.05) as well as further testing of Tukey test to determine the difference in the effects of treatments. Data processing was carried out on the computer using SAS 9.1 software.

**Results**

Table 1. The ANOVA results showed that there was a significant difference in the overall average of rats’ standard feed intake between treatments. The results of Tukey’s test indicated that the overall average amount of standard feed intake of P4 group (10.06 ± 1.81 g) was not different from P3 (9.43 ± 0.41 g) and P1 (9.33 ± 0.56 g) but significantly different from P2 (9.03 ± 1.33 g).

**Table 1: The average standard feed intake of experimental rats during the 28-d treatment period**

The standard feed given was produced by PT Indofeed. Table 1 showed that the high standard feed intake of the P4 group could be caused by the nutrient content in P4 (the administration of 20 g Bilih fish flour to one formula dough with chocolate flavor). The best biscuit in P4 group had complete nutritional content such as carbohydrates, fat, fatty acids (omega-3, EPA, DHA, omega-6, and AA), and protein which were nutrients that played a significant role in the growth and cognitive development. The interaction between nutrients in P4 (F20 (the administration of 20 g Bilih fish flour to one formula dough with chocolate flavor) -- i.e., omega-3 fatty acids, protein, affected the growth and cognitive development. DHA plays a role in myelinization, synaptogenesis, and neuronal membrane structures, thereby increasing the appetite of rats against the standard feed given in the afternoon.

The high intake of standard feed in the P4 group might be caused by the nutrient contents of P4 such as omega-3 fatty acids, EPA, DHA, omega-6, and AA. Omega-3 could increase the rats’ appetite; thereby, the amount of standard feed consumption of the P4 group was higher than P1, P2, and P3 groups.

Table 2 showed that the ANOVA test results of the treatments were not significant in food conversion effective (FCE) of rats despite the differences in the average FCE. The highest increment in FCE was observed in P4 (21.87 ± 2.70%), compared to P3 (20.37 ± 8.03%), P2 (20.32 ± 5.13%) and P1 (17.75 ± 8.63%).

**Description:** Different letters in the same column show *significant differences p<0.05 (ANOVA test), * not significant with p > 0.05 (ANOVA test). P1= SF, P2= SF + F0, P3= SF+F0+ pure omega-3 oil and P4= SF + F20 (administration of 20 g Bilih fish flour to one formula dough with chocolate flavor).
feed given to increase the weight of experimental rats. Although the FCE value of P4 was not significant, it tended to be higher than P1, P2, and P3. The consumption of P4’s standard feed was more efficient in increasing the weight of experimental rats than other treatments (P1, P2, and P3). The results of this study were similar to the results of a study conducted by Fajri et al. (2013) who found that the FCE values were not significantly different between the treatments. 

Table 3 showed that the ANOVA test results of the average Y-Maze rat score in five days treatment were significant differences in Y-Maze score in the treatment group. Tukey test results showed that the highest score Y-Maze (63.34 ± 12.40) in P4, which was significantly different from P1 (20.00 ± 27.39), P2 (52.15 ± 14.16) but insignificant different from P3 (45.84 ± 26.69). This result research confirms that proliferation neuron cell happened 2-3 years old children is the same with 40 days of age rats in this research. The results of this study are supported by the by Cutuli et al. (2016), who stated that the treated rats showed better new recognition skills in Y-Maze tests with objects compared to control rats.

P-value: 0.864 0.035

Description: Different letters in the same column show *significant differences p<0.05 (ANOVA test), * not significant with p > 0.05 (ANOVA test). P1= SF, P2= SF+F0, P3= SF+F0+pure omega-3 oil and P4= SF+F20 (administration of 20 g Bilih fish flour to one formula dough with chocolate flavor).

Tabel 3 the rats in the P4 treatment F20 (20g Bilih fish flour to one formula dough with chocolate flavor) had the greatest Y-Maze score. This is because P4 contains complete nutrients such as energy (518.09 kcal/100g biscuit), fat (27.81 %/100g biscuit), protein (6.60 g/100g biscuit), carbohydrates (60.29 g/100 g biscuit) and omega-3 fatty acids (0.66 %/100 g biscuit), linolenic acid (0.66 g/100g biscuit), DHA (0.01 g/100g biscuit), EPA (0.01 g/100g biscuit), AA (0.01 g/100g biscuit) and omega 6 (3.48 g/100g biscuit). Based on RDA (2013), the nutrient requirement need for children aged 1-3 years is 1125 kcal in energy, 155 g of carbohydrate, 26 g of protein, 44 g of fat and 0.7 g of omega-3 fatty acid. The contribution of energy from biscuits in this study can be considered as a good source of energy and omega-3 fatty acid.

Conclusion and Suggestion

The addition of 20g Bilih fish flour to one formula dough with chocolate flavor significantly increased the consumption standard feed and the Y-Maze score, although it was not significant for weight and %FCE in rats. Therefore Biscuits with enrich with Bilih Fish can be recommended for the government to be used as an alternative to ASI complementary foods in optimizing growth and cognitive in infants.

ABSTRACT

Benzene in the air can be found from emissions of coal and oil combustion, gas stations, and motor vehicle workshops. This research was descriptive, observational, and cross sectional and aimed to determine safe duration of exposure (Safe Dt) to benzene for officers of the public gas stations around the area of Diponegoro University Semarang. The subjects of this research were 28 officers determined by Slovin formula and proportional random sampling and taken by purposive sampling technique according to the inclusion criteria of the researchers. The variables of this research were animals weight, BSA experimental animals, officers weight, Body Surface Area, officers breathing rate, benzene concentration, Animal Km, Human Km, NOAEL, officers RfC, and Safe Dt.

The average concentration was 0.25 ppm and the highest concentration was 2.08 ppm. From the comparison of results and the Threshold Limit Value according to Permenakertrans No.5/MEN/X/2018, there is still a need for efforts to control benzene exposure by companies and governments, such as determining the period of service of officer who refers to the calculation of safe duration of exposure (Safe Dt) to benzene by 2.2 years. In addition, efforts to control benzene exposure can be also performed by providing Personal Protective Equipment (PPE), i.e half mask respirator with an organic vapor cartridge for officers and regular monitoring of benzene exposure in the work environment.

Keywords: Benzene, public gas stations, duration of safe exposure

Introduction

Benzene in the air is resulted from emissions of coal and oil combustion, gas stations, and motor vehicle workshops. Chronic benzene exposure or long term inhalation can cause various circulatory disorders, including reduced red blood cells and aplastic anemia. The Environmental Protection Agency (EPA) classifies carcinogenic benzene for humans through various exposure routes(2).

The level of exposure to benzene at gas stations in low and middle income countries according to Navasumrit et al. (2005) and Bahrami et al. (2007) in IARC
Monographs showed higher concentrations of benzene\(^{(3)}\). Severity of poisoning caused by benzene depends on concentration, route, and duration of exposure, as well as age and medical conditions of the exposed person\(^{(4)}\). Benzene compounds as solvents have the value of the Inhalation Reference Concentration (RfC) and Cancer Slope Factor (CSF) that have been determined by the US Environmental Protection Agency’s Integrated Risk Information System (IRIS U.S. EPA) in 2003. The value of Inhalation Reference Concentration (RfC) for non-effect carcinogenic 3\(\times 10^{-2}\) mg/m\(^3\) converted to 0.0086 mg/kg/day and the Cancer Slope Factor (CSF) value for a carcinogenic effect of 2.2\(\times 10^{-6}\)-7.8\(\times 10^{-6}\) mg/m\(^3\) which is converted to 0.1-0.34 mg/kg/day\(^{(5)}\).

Exposure to benzene which can be tolerated by the European Chemicals Agency (ECHA) is 1 ppm or converted to 3.25 mg/m\(^3\)\(^{(6)}\). The National Institute for Occupational Safety & Health states the Recommended Exposure Level (REL) of benzene which can be tolerated at 0.1 ppm or if converted to 0.32 mg/m\(^3\)\(^{(7)}\). Whereas according to the Committee for Hazardous Substances in Germany, benzene exposure can be tolerated at 1.9 mg/m\(^3\)\(^{(8)}\). Indonesia itself regulates the safe limits of benzene exposure concentrations in Permenakertrans No.5/MEN/X/2018 in 2018. The Threshold Limit Value (TLV) of benzene is 0.5 ppm\(^{(9)}\).

Central Java is a province with the third largest population estimate in Indonesia in 2013\(^{(10)}\). Semarang has the highest population growth rate compared to other cities or districts in 2010-2017 by 1.72% caused by the existence of several universities\(^{(11)}\). In 2013, this affects the number of motorized vehicle use in Banyumanik and Tembalang subdistricts which reached 5,707 and 16,221 units\(^{(12)}\). Ministerial Decree Number 1585/K/32/MPE/1999 concerning the gradual elimination of lead (Pb) and substitution with benzene does not reduce the carcinogenic effects of fuel\(^{(13)}\). Public gas stations officers have a high level risk of benzene exposure because they exposed to hazardous chemicals for years of work.

Based on the results of research by Costantini et al. (2003) and Paci et al. (1989) in Agency for Toxic Substances and Disease Registry (2007), shoe factory workers in Italy showed an increased risk of leukemia along with increased benzene exposure. International Agency for Research on Cancer (IARC) and the Environmental Protection Agency (EPA) Weight of Evidence for Carcinogenicity (WOE) in 2005 under U.S. The Environmental Protection Agency classifies benzene in Category 1 (carcinogenic) and CH (carcinogenic to humans)\(^{(14)}\). The risk of cancer or other health problems due to exposure to benzene to humans is clearly dangerous so it is necessary to calculate the safe duration of exposure to workers exposed to benzene in the work environment.

Previous research has not calculated the safe duration of exposure (Safe Dt) using either RfC formula with No Observed Adverse Effect Level (NOAEL) for workers exposed to benzene when working. Public gas stations officers are one of the jobs with a high risk of benzene exposure so that the calculation of Safe Dt is important to reduce the risk of cancer and other health problems due to benzene exposure\(^{(15)}\). Safe Dt to benzene is best calculated using RfC formula with NOAEL adjusting the research data so as not to cause harmful effects on the body\(^{(16)}\). Therefore, the authors calculated Safe Dt to benzene using RfC formula with NOAEL as the safe limit for the duration of benzene exposure for public gas stations officers.

### Material and Method

This research was a descriptive, observational, and cross sectional which aimed to determine safe duration of exposure (Safe Dt) to benzene. The population of this research was 78 officers of the public gas stations around Diponegoro University Semarang. 28 officers were taken as samples taken by purposive sampling technique according to the inclusion criteria of the researchers.

Data were taken in the form of primary data obtained through filling out questionnaires, weighing the body, and measuring benzene intake officers of the public gas stations with personal dust sampler and coconut shell charcoal as well as secondary data such as the number of officers, years of service, type of fuel, work shift schedules, and weight of experimental animals. The variables of this research includes animals weight, BSA experimental animals, officers weight, officers body surface area, officer breathing rate, benzene concentration, Animal Km, Human Km, NOAEL, reference concentration of benzene on the officer, and safe duration of exposure (Safe Dt) to benzene in the air for officers. Analysis of research data to determine safe duration of exposure to benzene was carried out manually.
Findings

A. Characteristics and Bodies Surface Area of Experimental Animal: The toxicity test using animals as a model aims to see the existence reactions in humans against a test substance. The experimental animals used in this research were white mice (Rattus Norvegicus)\(^{20}\).

The surface area of white mice is calculated by using the following formula.

\[
BSA = 0.09W^{0.67}
\]

Where,

BSA: Body Surface Area (m\(^2\))

W: Weight (kg)

B. Characteristics, Body Surface Area, and Respiratory Rate of Officers: The samples of this research have characteristics with an average body weight of 58.57 kg and an average length of time working 6.5 hours/day. In this research, the average height used was the average Indonesian male height of 159 cm.

1. Body surface area

\[
BSA = \sqrt[3]{W \cdot h/3600}
\]

Where,

BSA: Body Surface Area (m\(^2\))

W: Weight (kg)

h: Height (cm)

\[
BSA = \sqrt[3]{58.57 \cdot 159/3600} = 1.6 \text{ m}^2
\]

2. Breathing rate

\[
BR = \frac{5.3 \ln W - 6.9}{24}
\]

Where,

BR : Breathing Rate (m\(^3\)/hour)

W : Weight (kg)

\[
BR = \frac{5.3 \ln 58.57 - 6.9}{24} = 0.6 \text{ m}^3/\text{jam}
\]

**E. No Observed Adverse Effect Level (NOAEL):**

Swaen et al (2010) stated that the calculation of No Observed Adverse Effect Level (NOAEL) benzene was 3.0 mg/m³ or equivalent to 0.022 mg/kg obtained by using the following formula\(^{(21)}\).

\[
\text{NOAEL benzene} = 3.0 \text{mg/m}^3
\]

\[
\text{NOAEL benzene} = \frac{3 \times 0.00013 \times 8}{0.1405} = 0.022 \text{mg/kg}
\]

**F. Inhalation Reference Concentration (RfC):**

Shaw et al. (2007) in the 2013 Industrial Toxicology & Risk Assessment book stated that the calculation of inhalation RfC can use the following formula\(^{(22)}\).

\[
\text{RfC} = \frac{\text{NOAEL}_{\text{animal Km}}}{\text{human Km}}
\]

Where,

Animal Km : Km factor on animal

Human Km : Km factor on human

Inhalation RfC obtained from the NOAEL value, the average Animal Km, and the average Human Km are as follows.

\[
\text{RfC} = \frac{\text{NOAEL}_{\text{animal Km}}}{\text{human Km}} = \frac{0.022}{36.6} = 0.003\text{mg/kg}
\]

**G. Safe Duration of Exposure (Safe Dt) to Benzene:**

Control of non-carcinogenic and carcinogenic risks can be performed by determining the safe limits of exposure to hazardous chemicals for officers, one of which is by determining the duration of safe exposure associated with the duration of work and working period\(^{(23)}\).

\[
\text{Safe Dt} = \frac{\text{RfC} \times W_{b} \times t_{avg}}{C \times BR \times t_{E} \times f_{E}}
\]

Where,

Safe Dt : Safe duration of exposure for officers (years)

RfC : Inhalation Reference Concentration (mg/kg)

Wb : Weight (kg)

t avg : Average of time (day)

C : Konsentrasi di udara (mg/m³)

BR : Breathing Rate (m³/hour)

tE : Duration (hour/day)

fE : Frequency of Exposure (day/year)

\[
\text{Safe Dt} = \frac{0.0003 \times 58.57 \times 30 \times 65}{0.82 \times 0.6 \times 6.5 \times 267,43} = 2.2\text{years}
\]

The average concentration of benzene in the air exposed to samples was 0.82 mg/m³ (0.25 ppm). From the total measurement of benzene concentration, the highest was 2.08 ppm\(^{(1)}\). The average value of this concentration is lower than the TLV, yet the highest concentration value far exceeds the TLV of 0.5 ppm according to Permenakertrans No.5/MEN/X/2018. Toxicity test was carried out by using NOAEL as the determination of the highest dose of toxin without causing an effect. Based on the results of these studies, the benzene NOAEL value of *Rattus norvegicus* was 0.022 mg/kg. This value is in accordance with the results of a research by Swaen et al. (2010) with NOAEL benzene value of 3.0 mg/m³ or equivalent to 0.022 mg/kg\(^{(21)}\). The NOAEL value obtained was smaller than that of the 2005 Agency for Toxic Substances and Disease Registry (ATSDR) of 3 ppm at medium exposure through inhalation\(^{(1)}\).

Based on the results of RfC calculation, NOAEL value, average Animal Km and Human Km was 0.003 mg/kg. The RfC of this research was smaller than the value set by IRIS U.S The EPA in 2003 of 0.03 mg/m³.
(0.0085 mg/kg/hr)

Apart from being smaller than IRIS U.S. EPA, the result of this research was also smaller than the research conducted by Hayat (2013) by 0.0086 mg/kg/day

and research conducted by Salim (2012) by 0.01 mg/kg/hr. Thus, the result of this research was safer for humans.

Based on the results of the calculations, the value of Safe Dt to benzene at the public gas stations around Diponegoro University Semarang was 2.2 years. This is smaller than the average duration of public gas stations officers exposure of 5.5 years. In addition, the Law of the Republic of Indonesia No. 13 of 2003 concerning Labor states that the maximum time limit for hiring employees is 3 years. This indirectly provides protection so that public gas stations officers are not exposed to benzene for much longer.

**Conclusion**

Measurement of the concentration of benzene at public gas stations around Diponegoro University Semarang resulted in an average concentration of 0.25 ppm and the highest concentration of 2.08 ppm. The average value of the concentration is lower than the Threshold Limit Value, yet the highest concentration value far exceeds the Threshold Limit Value of 0.5 ppm according to Permenakertrans No.5/MEN/X/2018. Therefore, there are still efforts need to be taken to control benzene exposure by companies and governments to keep officers healthy.

One of the efforts to control benzene exposure is determining the working period of officers, which refers to the calculation of benzene safe exposure, reduces the concentration of toxins to the safe limits of toxin concentration for officers, and reduces exposure time per day by < 8 hours/day. Calculation Safe Dt to benzene for non-carcinogenic risks to public gas stations officers around Diponegoro University Semarang resulted in 2.2 years. In addition, efforts to control benzene exposure can be performed by providing Personal Protective Equipment (PPE) in the form of half mask respirators with organic vapor cartridges and periodic monitoring of benzene exposure in the work environment.

**REFERENCES**

ABSTRACT

**Background:** Urinary tract infection (UTI) is the most common urologic disorder. The normal urine pH is average of 6.2. UTIs or bacteriuria are among the causes shifting the urine pH to word alkalinity.

**Objectives:** Isolation and identification of bacterial uropathogens from alkaline urine and to assess their susceptibility to commonly available antimicrobial agents.

**Patients and Method:** This cross-sectional study was conducted in Baquba for the period from September 2016- November 2017. Patients were attending Baquba Teaching Hospital and Al-Batool Teaching Hospital for Maternity and Children complaining of urinary tract infection. A total of 250 patients were included. The age range was 5-50 years. 218 (87.2%) were female and 32 (12.8%) were males. Mid-stream urine samples were collected in sterile containers. General urine examination including measurement of pH was done. All samples were aseptically cultured on blood and MacConkey agar plates which were incubated at 37 °C for overnight. Identification of bacterial growth was based on cultural, microscopical and biochemical criteria. The Kirby-Bauer disk diffusion technique was used to determine the bacterial susceptibility to Amoxacillin, Gentamycin, Doxycycline, Nalidixic acid, Tobramycin, Azithromycin, Ciprofloxacin, Cefotaxim, Trimethprime-sulfamethoxazol and Phosphomycin antimicrobials according to CLSI, version 2012. The MIC of all bacterial isolates against Ciprofloxacin and Azithromycin was determined according to the CLIC, version 2014. Human privacy was respected by taken participant’s oral consent. Statistical analyses were done using the SPSS, Version 21 and P values were considered significant wherever it is less than 0.05.

**Results:** The results found that the rate of alkaline urine among patients with UTI was 11.9%. It was significantly higher in female compared to males (87.5% vs 12.5%, P = 0.0001), and the majority of patients were in the age group < 20 years. All patients had positive bacterial growth and E. coli was the predominant (28%, P < 0.05), and 45.9% of these isolates were urease producers. Except for Amoxacillin (100% efficacy), all bacterial isolates were completely resistant to Tobramycin, Gentamycin, Nalidixic acid, Cefotaxime and Phosphomycin (0% efficacy), and partially resistant to Ciprofloxacin (71.4% efficacy), Azithromycin (85.7% efficacy) and Doxycycline (57.1% efficacy).

**Conclusion:** Although the rate of alkaline urine is low, but unignorable. Bacterial isolates are generally resistant to most antimicrobials. Thus urine pH should be considered while choosing antimicrobials for treatment of patients with UTIs.

**Keywords:** Alkaline urine, Urine PH, Urease producers

---

**Introduction**

Urinary tract infections, with its diverse clinical syndromes and affected host groups, remains one of the most common urologic disorder in both community and hospital patients \(^1, 2, 3\). Factors that affect urine pH include dietary constituents, vomiting, diarrhea, lung disease, hormones, kidney function, and UTIs. It is well
known that UTIs by fastidiously growing urea splitting uropathogens are responsible for the shift of urine pH toward the alkalinity \(^4, 5\). A related consequence is that the formation of various types of kidney stones is strongly influenced by alkaline urinary pH as it enhances the metabolic activity of urease-positive bacteria \(^6, 7\). In this context, it has been documented that when urine pH is greater than 6.5 and the presence of specific aryl metabolites, the siderocalin, a human antimicrobial protein was no longer neutralized the bacterium iron acquisition molecule enterobactin. Instead, enterobactin was able to swipe iron away from siderocalin and promote more bacterial uropathogens growth \(^8\).

In majority of UTIs, empirical antimicrobial treatment is practiced before the laboratory results of urine examination or culture. Several studies had documented that the therapeutic efficacy of antimicrobials was decline or even the cure time (time to negative cultures) was prolonged under alkaline urine \(^9, 10\). It had been reported that the tetracyclines, nitrofurantoin, and many of the \(\beta\)-lactams were exhibited their highest activity under acidic urine pH, conversely, the fluoroquinolones, co-trimoxazole, aminoglycosides, and macrolides all functioned optimally at alkaline pH, while Sulfamethoxazole, oxacillin, amoxicillin and clavulanic acid, vancomycin, imipenem, and clindamycin were largely unaffected by pH, recommending that clinicians should consider the urine pH of their patients when treating UTIs \(^11\). In a similar study, it had been reported that the urine pH values below 6 lead to a reduction of bacterial killing of trimethoprim, fosfomycin, amikacin, colistin and ertapenem against the five bacterial species \(^12\). Although acidification of urine is widely recommended for prevention and treatment of urinary tract infections, it has been found that acidification of urine led to major impairment of antimicrobial activity of fluoroquinolones probably due to reduction of uptake of fluoroquinolones into bacterial cells \(^13\). A further report had documented that in contrast to ciprofloxacin, the potency of delafloxacin was further enhanced in the acidic environment commonly observed in the setting of urinary tract infection \(^14\).

Patients and Method

This cross-sectional study was conducted in Baquba for the period from September 2016- November 2017. Patients were attending Baquba Teaching Hospital and Al-Batool Teaching Hospital for Maternity and Children complaining of signs and symptoms related to urinary tract. The age range of patients was 5-55 years (Mean age ± SD, 21.78 ± 12.39 years). 218 (87.2%) were female and 32 (12.8%) were males. Human privacy was respected by taken participant’s oral consent. Mid-stream urine samples were collected in 20 milliliters sterile containers. General urine examination was done promptly including urine reaction and pH measurement. A total of 2100 urine samples were screened for pH, and of these, 250 had alkaline reaction, all of which were included in this study. The range of pH was 8-11 (Mean ± SD, 8.86 ± 0.50). Thereafter, all samples were aseptically cultured on blood and MacConkey agar plates which were incubated at 37 °C for overnight (18-24 hours). Identification of bacterial growth was based on cultural, microscopic and biochemical criteria. The disk diffusion technique on Mullar-Hinton agar was used to determine the bacterial susceptibility to certain antibiotics and antibacterials according to the CLSI, 2012. The antimicrobial agents include Amoxacillin (25 µg/disc), Gentamycin (10 µg/disc), Ciprofloxacin (5 µg/disc), Tobramycin (10 µg/disc), Azithromycin (30 µg/disc), Cefotaxim (30 µg/disc), Trimethprime-sulfamethoxazol (10 µg/disc) and Phosphomycin (200 µg/disc). The MIC for all bacterial isolates against Ciprofloxacin and Azithromycin was determined on Mullar-Hinton agar according to the CLIC, 2014. Statistical analyses were done using the Statistical Package for Social Science (SPSS), Version 21 and P values were considered significant wherever it is less than 0.05.

Results

The results showed that 11.9% (250/2100) of patients with UTIs had alkaline urine. The age and sex distribution showed that female was significantly higher compared to males (87.5% vs 12.5%). Moreover, the majority of patients were in the age group < 20 years.

Total (%): 118 (45.9) 139 (54.1) 257 (100) 138 (53.7) 119 (46.3) 257 (100)
The antimicrobial susceptibility test revealed that all bacterial isolates were completely resistant (0% efficacy) to Tobramycin, Gentamycin, Nalidixic acid, Cefotaxime and Phosphomycin. All isolates were immediately sensitive to Trimethoprim-Sulfamethoxazole (50% efficacy). On the opposite side, all isolates were completely sensitive to Amoxicillin (100% efficacy). For Ciprofloxacin all isolates are sensitive except those of E. coli and Ps. aeruginosa (71.4% efficacy). Similarly, all isolates were sensitive to Azithromycine except those of S. aureus (85.7% efficacy). For Doxycycline, all isolates were sensitive except those of E. coli, S. aureus and Ps. aeruginosa (57.1% efficacy). The MIC of Azithromycin for all bacterial isolates was ranged between (64-1024) µg/ml, while the MIC of Ciprofloxacin for all bacterial isolates were ranged between (4-28) µg/ml.

Discussion

Globally, urinary tract infection is the most common infection in both community and hospital patients (15, 3). Checking urine pH is part of the routine urinalysis, as normally acidic urine is a natural defense barrier against urinary tract infection, beside that the urine pH reflects acid-base balance in the body (16, 4, 17). In the present study the rate of alkaline urine among patients presented with UTI was 11.9%. Although this rate was significantly lower than that of acidic urine; however, it shouldn’t be ignored.

The results also showed that females with alkaline urine were significantly higher compared to males and the majority of patients were in the age group < 20 years. In the context of sex differences, undoubtedly, most of previous studies affirmed that females were predominant (18). This sex difference is related to a anatomical, physiological, and hormonal causes (19, 15). On the other hand, the predominance of children and young adults is not unusual as UTIs in these ages are very common most probably due to low personal hygiene, urine incontinence in some children and retention of urine in the bladder for long time and low mobility especially during school time increases the recurrence of UTIs among children particularly among girls (5.7 times more than boys) (20, 21). The high bacterial isolation rate in females and the predominance of E. coli are actually other predictable outcomes. Interestingly, almost all studies in this context agree that E. coli and other Gram’s negative enterobacteriaceae are the major output (9, 22). The most acceptable explanation, is that the E. coli forming the bulk of enterobacteriaceae in GIT, which is the prime source of these bacteria in UTIs (23, 2).

The significantly higher rate of bacterial isolation in non-pregnant compared to pregnant women was inconsistent with most of previous studies (24, 25). It is extensively documented that symptomatic or asymptomatic bacteriuria, history of previous UTIs, low socioeconomic status and alkaline urine are risk factors for UTI in pregnancy that may elevates the risk of pyelonephritis, premature delivery, and fetal mortality among pregnant women (26, 27, 13). The current result may be due to unevenly distributed study samples as those below 15 years was predominant (all were non-pregnant), and of note, almost each sample yield one bacterial growth.

It is well documented that UTIs by fastidiously growing urea splitting uropathogens shifted urine pH toward the alkalinity; a medium that is further promote growth of uropathogens (13, 5, 8), as well as urolithiasis (28, 6). Moreover, these types of UTIs may be further complicated to alkaline-encrusted pyelitis which may be life-threatening if it is ignored; thus antibiotic therapy plus urease inhibitors perhaps offer the best preventative treatment (5, 29).

Aerobic and Anaerobic Bacteria in Tonsils of Different Ages with Recurrent Tonsillitis

Gulbahar F. Karim¹, Siham Sh. AL-Salihi², Qanat Mahmood Atya³, Kasim Sakran Abass⁴

¹Department of Basic Nursing Sciences, College of Nursing, University of Kirkuk, Kirkuk, Iraq; ²Medical Laboratory Techniques, Kirkuk Technical College, Foundation of Technical Education, Kirkuk, Iraq; ³Department of Biology, College of Science, University of Tikrit, Tikrit, Iraq; ⁴Department of Pharmacology and Toxicology, College of Pharmacy, University of Kirkuk, Kirkuk, Iraq

ABSTRACT

Background: Tonsillitis is considered one of the most otolaryngological diseases. It might lead to tonsillectomy if not treated properly.

The aims: of the current study is to determine the prevalence of chronic tonsillitis caused by bacterial infection among different age groups of both sexes at Kirkuk City. In addition find out the bacterial load in the tonsillitis cases, as well as their susceptibility pattern to some common antibiotics.

Method: Two hundred and ten throat swabs were taken from patients with signs and symptoms of chronic tonsillitis. The swab samples were cultured on different culture media. The isolates were diagnosed using laboratory methods for identification of bacteria.

The Results: revealed a high prevalence of chronic tonsillitis in Kirkuk city and it was more predominant in female (55.63%). The female to male ratio was 1.2:1. The most affected age group was (1-10) years old, constitute (35%) of all participant. There are 160 samples produce positive bacterial growth. The results showed that Streptococcus pyogenes was the most infectious bacteria associated with chronic tonsillitis which constitute (41.9 %) of bacterial isolates, followed by Staphylococcus aureus (35.6%), Streptococcus parasanginus (7.5%), Streptococcus mitis (6.3%), Streptococcus agalactiae (5.6%), and Streptococcus mutans (3.1%). The results of antibiotic sensitivity test, disc diffusion method revealed that the most isolates under investigation were found to be multidrug resistant. Since all isolates were resistant 100% to Ampicillin, followed by high rate resistant to penicillin (82.58%), with moderate resistance to Erythromycin (59.92%), Amoxicillin-Clavulanic acid (59.68%), and less resistant to Cefotaxime (47.70%), Ceftriaxone (38.08%). However, most of them were highly sensitive to Ciprofloxacin, and Imipenem.

Conclusion: The knowledge about the most likely local infectious microorganisms and their susceptibility to antibiotics can reduce the chance of chronic tonsillitis.

Recommendation: It is recommended to control throat infections and tonsillitis, this required the availability of primary care with adequate dose, and course of appropriate antibiotics treatment, which play important role in the prevention of chronic tonsillitis and its long term squeal.

Keywords: Tonsillitis, Antibiotics, Bacteria, Tonsillectomy, Streptococcus pyogenes.

Introduction

Tonsillitis is the term refer to inflammation of tonsils, which are organs of the immune system, this tissue naturally act as a defense against infection¹. The tonsillitis considers one of the most otolaryngological diseases, which might lead to tonsillectomy operation for many patients². It is usually indicated when there are six
attack or more per year for two successive years. Other indications of tonsillectomy include; obstructive sleep apnea, Quinsy, and suspicion of malignancy. It has the potential when performed for the proper requirement, as infectious indication. The etiological agents of tonsillitis might be viruses, as Epstein-Barr virus, rhinovirus, adenovirus, parainfluenza, influenza type A, and B. Most viruses likely have a role in the development of tonsillitis, crypt obstruction, and secondary bacterial infection. The most prevalent bacteria involved in tonsillitis were *Streptococcus pyogenes* that cause sore throat, *Staphylococcus aureus*, *Haemophilus influenzae*. The less frequent microorganisms encountered were different Staphylococcus species, Streptococcus species, and other oral microflora. Also some species of intestinal bacteria were detected by some investigators which might be attributed to oral fecal contamination. Multidrug resistant emerged among most of these microorganisms, which may be due to injudicious, and over use of antibacterial therapies without following proper antibiotic policy. The aims of the present study is to determine the prevalence of chronic tonsillitis caused by bacterial infection among different age groups of both sexes at Kirkuk City. In addition find out the bacterial species in the tonsillitis cases, as well as their susceptibility pattern to some common antibiotics.

### Patients and Method

Two hundred and ten throat swabs were tacked from patients with signs and symptoms of chronic tonsillitis, who were attending Azadi Teaching Hospital at Kirkuk City during a period of the 1st of January to the end of December, 2017, their genders and ages, were recorded. The tonsillar swab was inserted into tonsils' region for each patient, carefully rotated there, and then withdrawn avoiding contaminated with mouth and transported immediately to laboratory under aseptic condition.

**Bacteriological Study:** The swab samples were cultured on Brain heart infusion broth (transport media), Nutrient agar and MacConkey agar, then incubated at 37°C for 24 hours. Also, they were cultured on chocolate agar then incubated anaerobically in a candle jar at 37°C for 24-48 hours. The growing colonies were further cultured on other media as Mannitol salt agar. The pure colonies were tested with the gram staining, and biochemical tested for identification of bacteria according to Bergey’s manual of determinative bacteriology [8], then the results confirmed by Api, Staph. and Api Strep. System (BioMérieux, France).

**Antibiotic Susceptibility Test:** All the isolated bacterial species were submitted to eight antibiotic discs using the disc diffusion method. The antibiotics including Ampicillin (AM) 30 mg, Penicillin (P) 10mg, Amoxicillin-clavulanic acid (AMC), Cefotaxime (CTX) 30 mg, Ceftriaxone (CRO) mg, Erythromycin (E), 30mg, Ciprofloxacin (CIP) 10mg, and Imipenem (IMP) mg, (Oxoid Company). A single colony was transferred to 5ml nutrient broth then incubated at 37°C for 24hr. The inoculum was adjusted to 0.5 McFarland turbidity standard solution, then spread evenly with sterile swab on the surface of agar. The standard antibiotic discs were placed at some points in the same Petri dishes then they were stand for 45minutes. Later incubated at 37°C for 24hr. The diameter of zones of inhibition were measured and interpreted according to [9].

### The Results and Discussion

Table (1) demonstrates the distribution of tonsillitis according to gender and age groups. It revealed the high rate of chronic tonsillitis in this city. Also it showed that the chronic tonsillitis was more predominant in female with frequency of 89 (55.63%) than male which include only 71(44.38%) of total participants. The male to female ratio was 1: 1.25. Regarding the age, it had been found that the most affected age group was (1-10) years old with the frequency of 56(35%) patients. While the less age group were (41-50) years old.

**Table 1: Distribution of tonsillitis with positive bacterial culture according to gender and age groups**
The result of present study was in agreement with Jamal\(^2\) who found in a study on tonsillitis including 200 patients, in which the percentage of females was higher (56.6%) than the males. Also other investigators\(^3\) in Baghdad reported the children under fifteen years were more susceptible to tonsillitis than other ages.

These results might be attributed to increased activity of children at this age group which enhance the exposure to infection than other ages. In addition to contacting children with each other in kinder garden and school beside, intrafameliac transmission of infectious agents that cause the disease.

Table (2) illustrates the frequency and percentages of bacterial species isolated from infected tonsils. From the two hundred and ten throat samples, 160 samples produce positive bacterial growth. Accordingly only these samples included in the study. Out of 160 samples exhibit positive bacterial growth 67(41.9 %) of isolated bacteria were \textit{S. pyogenes}, followed by \textit{S. aureus} 57(35.6%), \textit{S. parasanginus} 12(7.5%), \textit{S. mitis} 10(6.3%), \textit{S. agalactiae} 9(5.6%), and \textit{S. mutans} 5(3.1%). This finding indicated that Lancefield Group A Beta Hemolytic Streptococcus GABHS (\textit{S. pyogenes}) was the most infectious bacterium associated with tonsillitis. These results were in accordance with that conducted by Al-Mousawi\(^11\) who showed that 43.69% of his total isolates were \textit{S. pyogenes} from throat swabs of 250 cases of tonsillitis in Najaf governorate. While the results of current study was higher than other investigator, who were found 37.3% of their total isolates were \textit{S. pyogenes} from throat infection of patients with tonsillitis in Yemen\(^2\). This result might be due to many virulence factors produced by this bacteria, in addition to climate variation. More over easy transmission of these bacteria by droplet spread, thus close contact between children in school or in large families can increase the risk.

\textit{S. aureus} found to be the second most bacteria isolated in the present study. This result was in accordance with that reported by Bakir and Ali [6] who revealed that this bacteria was the most frequent microorganism, which constitute 37.7% of their total isolates from tonsillitis cases. This finding due to the fact that \textit{S. aureus} were posses many virulence factors that attributed to their invasiveness and pathogenicity as well as their resistant to multiple antibiotic agents.

The percentages of \textit{S. parasanginus} and \textit{S. mitis} were (7.5, and 6.3)% respectively. This finding was less than that reported by [13] who diagnosed (34.3 and 11.9) % of their total isolates from children with tonsillitis in Baghdad was \textit{S. parasanginus} and \textit{S. mitis} respectively. The less frequent bacterial species encountered through present research were \textit{S. agalactiae} and \textit{S. mutans} which constitute (5.6 and 3.1) % respectively of total isolates.

These finding were relatively higher than that dictated by other authors who observed only (4.2 and 0.7)% of their isolates were belong to these two species \textit{S. agalactiae} and \textit{S. mutans} respectively. The finding of varies bacterial species with different frequency in this study may be due to the presence of these microorganisms as normal flora in the upper respiratory tract, moreover most of them were opportunistic and can cause disease especially in immune compromised patients.

Table (3) demonstrates the results of antibiotic sensitivity (disk diffusion method. It showed the most isolates under investigation were found to be multidrug resistant because they were resistant to more than three antibiotics. All isolates were resistant 100% to Ampicillin, followed by high rate resistant to Penicillin with moderate resistant rate to Erythromycin and less resistant to Amoxicillin-Clavulanic acid, Cefotaxime, and Ceftriaxone. Furthermore, there are some resistant isolates were emerged to the other aminopenicillin as Amoxicillin despite its combination with inhibitor agent called clavulanic acid which increase its activity. These results were consistent with previous study conducted by Bakir and Ali\(^6\) who showed that the most Gram positive bacterial isolates from tonsillitis cases were highly resistant to Penicillin, and Ampicillin, more over most of these bacteria were \(\beta\)-lactamase producers. These results revealed the that the bacterial isolates under investigation were confer resistant to \(\beta\)-lactam (\(\beta\)-lactam) antibiotics which include Penicillin, Ampicillin, Amoxicillin, Cefotaxim, and ceftriaxone.
This finding might be due to the production of β-lactamase enzymes which hydrolyze β-lactam ring of β-lactam antibiotics. In contrast, other investigators reported that there were no β-lactamase enzymes had been produced by their isolates which include 67 bacteria belong to β-hemolytic group C and F streptococci from patients with acute pharyngitis at Hilla city. They suggested the resistant of their isolated bacteria to antibiotics attributed to other causes as Alteration of β-lactam target enzymes, especially penicillin binding proteins. Moreover, penicillin less effective in eradicating GABHS which found to be the most frequent bacteria in the current study because Penicillin have the capacity to eradicate the normal oropharyngeal flora, especially α-hemolytic Streptococci which provide an ecological barrier to GABHS infection by producing bacteriocin.

Concerning the moderate resistant of the studied isolates to Erythromycin in the present study, it might be due to irregular and overuse of this drug without performed routine culture and sensitivity of microbes to the drug. This might lead to genetic mutation and acquire resistant gens to antibiotic. Other researchers investigated the molecular screening of erythromycin gene of seven strains of S. pyogenes. They improved all isolates did not contain the resistant genes, so they concluded that the resistant to erythromycin could be due to other causes as structural modification of erythromycin by glycosylation, phosphorelation, or lacton ring cleavage by erythromycin esterase.

There are many mechanisms by which bacteria confer resistance to the antibiotic agents including intrinsic impermeability, as well as acquired resistance as mutations, plasmids, and transposons. Furthermore, the tonsils with chronic inflammation, and adenoid contain more scar tissues following each infection. In turn causing an impairment of antibiotic penetrating into the core and become more resistant to antibiotic therapies.

Regarding the Ciprofloxacin and Imipenem, most isolates were found to be sensitive to these drugs with resistant rate of (2.49 and 2.92) % respectively. This finding was in agreement with other researchers who found the most effective antibiotics, and less resistant against his isolates from tonsillitis cases were Ciprofloxacin and Imipenem with resistant of (14.9 and 17.5) % respectively. Hence they could be used as drugs of choice for treating tonsillitis.

It have been concluded that the disease was predominates among female, and (1-10) years old age group. The major pathogenic bacteria was S. pyogenes. Furthermore Most isolates were multidrug resistant. Most of isolates under investigation were sensitive to Ciprofloxacin and Imipenem. Hence, the knowledge about the most likely local infectious microorganisms and their susceptibility to antibiotics can reduce the chance of recurrent tonsillitis and its complications. It is recommended to control throat infections and tonsillitis, this required the availability of primary care with adequate dose, and course of appropriate antibiotics treatment, which play important role in the prevention of chronic tonsillitis and its long term sequel.

**Conclusion**

The chance of chronic tonsillitis can be reduced by increase the knowledge about the most likely local infectious microorganisms and their susceptibility to antibiotics.

Efficacy of the Health Belief Model in Enhancing the Oral Health of Female Middle School Students

Halah Kamal Ismael1, Aysin Kamal Mohammed Noori2
1MSc (C), 2Instructor, Department of Community Health Nursing, College of Nursing, University of Baghdad

ABSTRACT
This study aimed to (1) examine the effect of the Health Belief Model-based intervention (HBM) in enhancing the oral health of students, identify the association between students’ age, family’s socioeconomic status (SES), and their oral health. A randomized controlled trial (RCT) was used to guide this study. The study included a systematic random sample of 140 female students who were randomly assigned into two groups; 70 students for the study group and 70 students for the control group. These students were recruited from two middle schools for girls in Al-Karkh side in Baghdad City. The study instrument includes the sociodemographic of age, parents’ level of education, household’s occupation, family’s monthly income, and student’s birth order. Also, it includes the oral health belief questionnaire (OHBQ). Students in the study group only received the HBM-based health education. Data were analyzed using the statistical measures of frequency, percent, Mean, standard deviation, repeated measures ANOVA, and Pearson’s correlation.

The study results displayed that the HBM-based intervention positively influenced students’ Perceived Susceptibility of contracting oral disease, Perceived Barriers of adhering to oral health practices, Self-Efficacy of adhering to oral health practices, Perceived Benefits of adhering to oral health practices, and the Perceived Severity of contracting oral disease.

The student researcher concluded that the HBM-intervention significantly made the students perceive a lesser chance of contracting oral disease, enabled the students to overcome the barriers to adhere to oral health practices, enabled them to increase their self-confidence of adhering to oral health practices, made them sensitize the potential benefits of adhering to oral health practices, and made them sensitize the potential seriousness of not adhering to oral health practices.

Keywords: Health Belief Model; Oral Health

Introduction
Dental decay and periodontal inflammation are the most widespread Oral health problem. Quality of life deterioration is the consequences of the oral disease. About 35% of the world are suffering from dental problems. The World Health Organization (WHO) considered oral health as a part of community health in all human life. The WHO suggests that oral disease, if left unsolved, can have a great effect on the quality of life (1). The education about oral health is considered the cornerstone of the dental hygiene. According to the American Dental Hygienists’ Association (ADHA); oral hygienists have “a primary role in promoting the wellbeing of individuals and the public by engaging in health promotion/disease prevention activities” (2).

Causality between oral care and another systematic health problem such as respiratory disease, atherosclerotic vascular disease, diabetes, pregnancy-related complications, renal disease, and osteoporosis still unclear. Diabetes has a true bidirectional relationship with periodontal disease. A strong statistical evidence shows that treating one condition impacts positively on the other (3).
Applying of Health belief model to the oral health condition it is really crucial. It will change the health belief concerning oral cavity and eventually systemic health and lifestyle and oral health in particular. Individual health practices such as oral self-care are based on personal choices. The guiding principles found in the models of healthy behaviors provide useful ways to the oral health care practitioner in enhancing effective individual client behaviors (4).

Health-related behaviors can effectively be modified by the using of health belief model by targeting various model’s key aspects of the constructs (Kallio, 2013). Decreasing perceived barriers while increasing perceived benefits is considered an way for interventions that may alter the health-promoting behavior and cost-benefit analysis by providing data about the efficacy of various behaviors to eliminate the risk of disease, knowing a major perceived barriers, giving engaging incentives to “health-promoting behaviors”, and attending a social support or another resources to enhance health-promoting behaviors (5).

In this study, it is important to determine whether the health belief model is effective to improve the oral health of female middle school students at Al-Karkh Side, so eventually, to applicate the educational program in the health care centers as a primary prevention teaching program. This study aims to determine the effect of the HBM-based health education in enhancing the oral health of students.

Method

Design of the Study: A randomized control trail design was used in the present study with the application of a pretest, posttest I, and posttest II approach for the study group and control group. Study group and control group were pretested on December 3rd, 2018. The posttest I was conducted on January 17th, 2019. The posttest II was conducted on February 12th, 2019.

Study Instrument: The data for this study were collected using questionnaire which consisted of three parts (a) socio-demographic characteristics (father education, mother education, household’s monthly income), birth order, grade, and parents brushing habits.

The Oral Hygiene Beliefs Questionnaire

Perceived Susceptibility Scale: The first construct is perceived susceptibility was used to measure the likelihood of getting oral disease including teeth decay, and periodontal disease. This scale is a 5-point Likert type scale that is composed of three items. These items were measured on a 5-point Likert scale. Responses on this scale range from 1 (Strongly disagree) to 5 (Strongly agree). The total scores range from 3 to 15, with a higher score indicating higher perceived susceptibility of contracting oral disease

Perceived Severity Scale: The perceived severity scale was used to measure one’s belief about the seriousness of contracting oral disease or leaving it untreated. This scale is a 5-point Likert type scale that is composed of four items. These items were measured on a 5-point Likert scale. Responses on this scale range from 1 (strongly disagree) to 5 (strongly agree). The total scores range from 4 to 20, with a higher score indicating higher perceived severity of the oral disease

Perceived Barriers Scale: The perceived barriers scale was used to measure one’s possible obstacles to making oral examination. This scale is a 5-point Likert type scale that is composed of three items. These items were measured on a 5-point Likert scale. Responses on this scale range from 1 (strongly disagree) to 5 (strongly agree). The total scores range from 3 to 15, with a higher score indicating higher perceived barriers to making oral examination.

Perceived Benefits Scale: The perceived benefits scale was used to measure an individual’s assessment of the value or efficacy of oral hygiene. This scale is a 5-point Likert type scale that is composed of three items. These items were measured on a 5-point Likert scale. Responses on this scale range from 1 (strongly disagree) to 5 (strongly agree). The total scores range from 3 to 15, with a higher score indicating higher perceived benefits to making the oral examination.

Self-Efficacy Scale: The Self-Efficacy scale was used to measure an individual’s confidence of performing oral examination. This scale is a 5-point Likert type scale that is composed of six items. These items were measured on a 5-point Likert scale. Responses on this scale range from 1 (strongly disagree) to 5 (strongly agree). The total scores range from 6 to 30, with a higher score indicating higher self-efficacy of performing oral examination.

Data were analyzed using the statistical package for social science (SPSS) for windows Version 24 (Chicago, IL).

The age mean for participants in the study group is 13.25 ± .65; more than a half age 13-years-old (n = 39; 55.7%), followed by those who age 14-years-old (n = 23; 32.9%), those who age 12-years-old (n = 7; 10.0%), and one who age 15-years-old (n = 1; 1.4%). For the control group, the age mean is 14.07 ± .93; two-fifth age 15-years-old (n = 28; 40.0%), followed by those who age 14-years-old (n = 24; 34.3%), those who age 13-years-old (n = 13; 18.6%), and one who ages 15-years-old (n = 5; 7.1%).

Concerning the BMI, the BMI mean for participants in the study group is 23.64 ± 4.16; most are of normal range (n = 46; 65.7%), followed by those who are overweight (n = 9; 12.9%), those who are underweight (n = 8; 11.4%), and those who have class I obesity (n = 7; 10.0%).

For the control group, the BMI mean is 23.82 ± 3.92; more than a half are of normal range (n = 39; 55.7%), followed by those who are overweight (n = 15; 21.4%), those who are underweight (n = 10; 14.3%), and those who have class I obesity (n = 6; 8.6%).

Lastly, a half of families in the study group are of the upper middle socioeconomic class (n = 35; 50.0%), followed by those who are of the lower middle class (n = 23; 32.9%), those who are of the upper lower class (n = 10; 14.3%), one who is each of lower class and upper class (n = 1; 1.4%).

For the control group, more than a half of families are of the upper middle socioeconomic class (n = 38; 54.3%), followed by those who are of the lower middle class (n = 17; 24.3%), those who are of the upper lower class (n = 10; 14.3%), and one those is each of lower class and upper class (n = 5; 7.1%).

</table>

There was a (a priori p = 0.01) significant difference (F (1.615, 111.466) = 75.921, p = 0.01) in the students’ perceived susceptibility over time for participants in the study group. The omnibus effect (measure of association) for this analysis is .524, which indicates that approximately 52% of the total variance in the students’ perceived susceptibility values is accounted for by the variance in the administered intervention.

For the control group, there was no significant difference (F (1.113, 76.803) = .299, p = 0.004) in the students’ perceived susceptibility over time. The omnibus effect (measure of association) for this analysis is .004, which indicates that approximately .04% of the total variance in the students’ perceived susceptibility values is accounted for by the chance.

There was a (a priori p = 0.01) significant difference (F (1.848, 127.508) = 98.947, p = 0.01) in the students’ Perceived Barriers of adhering to oral health practices over time for participants in the study group. The omnibus effect (measure of association) for this analysis is .589, which indicates that approximately 58% of the total variance in the students’ Perceived Barriers of adhering to oral health practices values is accounted for by the variance in the administered intervention.

For the control group, there was no significant difference in the students’ Perceived Barriers over time. The omnibus effect (measure of association) for this analysis is .014, which indicates that approximately 0.1% of the total variance in the students’ Perceived Barriers of adhering to oral health practices values is accounted for by the chance.

There was a (a priori p = 0.01) significant difference (F (1.184, 81.671) = 82.391, p = 0.01) in the Self-Efficacy for adhering to oral health over time for participants in the study group. The omnibus effect (measure of association) for this analysis is .544, which indicates that approximately 54% of the total variance in the Self-Efficacy for adhering to oral health values is accounted for by the variance in the administered intervention.

For the control group, there was a (a priori p = 0.01) significant difference (F (1.020, 70.402) = 4.302, p = 0.05) in the Self-Efficacy for adhering to oral health over time. The omnibus effect for this analysis is .059, which indicates that approximately 5% of the total variance in the Self-Efficacy for adhering to oral health values is accounted for by the chance.
Discussion

This randomized controlled trial aimed to positively change female students’ health beliefs related to oral health using the Health Belief Model.

There was a statistically significant difference in the values of the students’ perceived susceptibility of contracting oral disease over time for participants in the study group.

This indicates the positive effect of the HBM-based intervention in making students recognize the likelihood of their contacting oral disease in case of neglecting their oral health practices.

There was a significant difference in the students’ Perceived Barriers of adhering to oral health practices over time for participants in the study group.

This indicates that the HBM-based intervention positively affected students in overcoming barriers to oral health practices. Students’ Perceived Barriers to adhere to oral health practices in the study group. There was a significant difference in the Self-Efficacy for adhering to oral health over time for participants in the study group.

This reflects that the HBM-based intervention enabled students to consolidate their self-confidence in sticking to a healthy behavior (adhering to oral health practices).

Conclusions

The HBM-intervention significantly made the students perceive a lesser chance of contracting oral disease).

The HBM-intervention significantly enabled the students to overcome the barriers to adhere to oral health practices.

The HBM-intervention significantly enabled the students to increase their self-confidence of adhering to oral health practices.

Recommendations

There is a need to replicate a similar study on impovred community segments.

It is vital to coordinate with the media with the goal of raising the publics’ awareness of the potential seriousness of not adhering to oral health practices and the potential benefits of adhering to oral health practices.

Conflict of Interest: The researchers report no conflict of interest.

Source of Funding: This study did not receive any funding from any agency.

Ethical Clearance: A permission to conduct this study was obtained from the ethical committee in the College of Nursing, University of Baghdad.

The Effect of Selection on Some of the Basic Determinants of Learning Some of the Basic Skills of Football

Hamid Abdul Shaheed Hadi1, Hayder Jaber Mousa1, Ali Hameed Ali1, Hayder Naji Habash Alshawi2
1Directorate General of Najaf Education, Ministry of Education, Iraq; 2Department of Physical Education and Sports Sciences, Faculty of Education for Girls, University of Kufa, Iraq

ABSTRACT

Throughout the selection process to proceed properly, it is necessary to use the tests and measurement because it is the best way to recognize the capabilities of beginners and their potential and predetermine to reach a fundamental point is to improve the learning of some skills to football. Some physical characteristics if these specifications are available, some basic skills can be learned in a better way, that based on the recommendations that emphasize the use of appropriate age, physical specifications and appropriate physical attributes, and make it the basic to answer the following question: Will learning be better? If these physical specifications and physical attributes are available in advance. This research aims to identify some of the basic determinants (physical measurements) of the students of Faculty of Physical Education and Sports Sciences at the University of Kufa for the academic year 2018-2019, and to identify the effect of selection on the basis of some basic determinants in learning some of the basic skills of football, the researchers used the experimental method to suit the nature of the Mash. The students of the second stage in the Faculty of Physical Education and Sports Sciences at the University of Kufa for the academic year (2018 - 2019), the number of (34) students, was based on physical indicators of the analysis of the global study of “Riyadh Khalil” the total length and length of the legs, The chest width and skills were handling, rolling and scoring, and an exploratory experiment was conducted to identify the factors and constraints that researchers could face when carrying out the basic experiment.

Keywords: Selection, Basic Determinants, Basic Skills, Football.

Introduction

For the selection process to proceed properly, it is necessary to use the tests and measurement because it is the best way to recognize the abilities of beginners and their potential and predetermine to reach a fundamental point is to improve the learning of some skills to football. To let the individual gain that access to the optimal performance, this requires the availability of some physical specifications of each game and the availability of some physical qualities and if these specifications can be learned some of the basic skills of football better, and in connection with previous studies, researchers considered the study of this subject. Based on recommendations that confirm the use of appropriate age and physical specifications and appropriate physical attributes promised by the rule to answer the next question? ...

Will learning be better if these physical specifications and physical attributes are available in advance?

The objective of the research is to identify some basic determinants (physical measurements and physical and skill traits) for the students of the Faculty of Physical Education and Sports Sciences at the University of Kufa for the academic year 2018-2019, and to identify the effect of selection on some basic determinants in learning some basic skills of football. The importance of research is to try to establish basic determinants for the selection of youth and to teach them the basic skills of football.

DOI Number: 10.5958/0976-5506.2019.02576.2
Practical Part

Field Research Procedures: The researchers used the experimental method to suit the nature of the problem on the students of the second stage in the Faculty of Physical Education and Sports Sciences at the University of Kufa for the academic year (2018 - 2019), the number of (34) students,

Tests:

First: Identify the physical, physical and skill indicators of the study: After the researchers learned a lot of research and studies that are looking at the identification of physical, physical and skill indicators were based on physical indicators of the analysis of the global study of “Riad Khalil” as these indicators are the most comprehensive factors and got the best predictions and above, as follows:

1. Overall length and length of the two legs.
2. The circumference of the leg.

The researchers chose these indicators based on the recommendation he made at the end of his research to adopt these indicators in the selection of football players.

Then the physical tests were selected which obtained the best predictions in the thesis itself and as follows:

1. Wide jump of stability.
   - Purpose of the test: Measure the explosive force of the two men.
   - Tools: flat ground, tape measure.
2. The test of sitting from immobility during (10 seconds):³
   - Purpose of the test: Measure the speed characteristic of the muscles of the abdomen.
   - Tools: Stopwatch, a colleague to install the two legs.
   - Registration: Records the number of times during (10 seconds).
3. Test side step during (20 seconds):⁴
   - Purpose of the test: Measurement of agility.
   - Tools: volleyball court, stopwatch.
   - Registration: Calculates the number of times that the two lines are touched by hand (20 seconds).
4. Test run 20 m of stand :⁵
   - Purpose of the test: measuring the transition speed.
   - Tools: Stopwatch, straight route, set from start and end to 20m, whistle, tape measure.
   - Registration: records the time when the specified distance was finished.
5. Touching the ground and the wall sequentially during (20 seconds):⁶
   - Purpose of the test: Measurement of dynamic flexibility (bending the spine and the length and rotation).
   - Tools: Stopwatch, smooth wall, chalk.
   - Registration: The number of touches (times) made by the student on the two marks during (20 seconds).

Physical Indicators:

1. Total length:¹
2. Measurement of the length of the man:

3. Leg circumference: Wrap a horizontal measuring tape, so that it is perpendicular to the longitudinal axis of the leg and read the measurement to the nearest cm.

4. Chest width: The two ends of the palometer are placed on the lateral extension of the mid-thoracic point on both sides of the chest and measured to the nearest cm.
Technical Tests

1. Handling test:7 (Handling a small target 12 m).
   - **Objective of the test:** measuring the accuracy of handling.
   - **Tools used:** 5 footballs, a small target of 110 x 63 cm, measuring tape and Burke.
   - **Test procedures:** draw a line for the beginning length (1 m) and a distance of 12 m for the small target, and put balls fixed on the starting line.
   - **Performance description:** The student stands behind the starting line facing the small goal, and begins when giving the signal handling ball bearings towards the goal to enter him, and given to each student five consecutive attempts.
   - **Registration:** The grade is calculated by the total scores obtained by the student from handling the five balls as follows.
     1. Two steps for each correct attempt enter the small target.
     2. One degree if the ball is level-based or the beam has not entered the target.
     3. Zero if the ball is out of the small goal.

2. Rolling test:
   - **Name of test:** rolling the ball in (zigzag).8
   - **Objective of the test:** measuring the ability of the player to control the ball while running between the characters.
   - **Tools used:** (10) Personals, Soccer, Stopwatch.
   - **Characterization of the test:** 10 persons are placed in a straight line, the distance between each person and another (2) m and the distance between the starting line and the first person (2) m.
   - **Method of performance:** The tester person stands 11 meters away from the target and when the start signal is given, then the tester person scoring.
   - **Registration:** The tester person is given 3 attempts for the preferred foot as points are recorded according to the location.

3. Test scoring:9
   - **Name of test:** scoring on a goal divided by squares at (11) m.
   - **Test Objective:** Measure scoring accuracy.
   - **Tools used:** tape measure, football, goal divided by ropes on nine sections, Burke to draw the penalty point.

   **Exploration Experience:** A pilot experiment was conducted on 14/10/2018 on a sample of (20) female students with the basic determinants chosen deliberately. The specific physical measurements were conducted at 9:00 am. Physical tests were conducted on 15/10/2018. On 16/10/2018, the specific tests were conducted to avoid fatigue and boredom and the accompanying negative aspects. The exploratory experiment “is a pilot study carried out by the researcher on a small sample that carries the same sample characteristics in all respects to carry out part of the work with a view to selecting suitable ones And curricula.”

   **The scientific foundations of the tests:** For the purpose of ascertaining the scientific basis of the tests, the credibility and objectivity of these tests were relied on during their application. For the purpose of knowing the stability of the physical and skill tests, 20 students with determinants were selected in a deliberate manner and five days later, And the skill using the simple correlation coefficient (Pearson) as shown in Table (1).

Pre Tests: Pre tests were conducted at 9 am on 28/10/2018 for the variables of the technical study (handling, rolling and scoring). The work required to have a team specialized in football game. The stadium was well prepared with the availability of tools and supplies.

Application of the Curriculum: The curriculum was adopted in the curriculum of the football lesson as a comprehensive containing the basic skills of the whole football, it meets the purpose for the students of the second phase, and was agreed in advance with the Department of the Department, and the curriculum was implemented by the teacher material and the team and the assistant in the presence of researchers on a continuous basis. The teacher used the lesson in a typical way, taking into consideration all the steps of the lesson from the preparatory, main, educational, and practical sections. The lesson time was 60 minutes. The work lasted two months at 3 units per week. The duration of the lesson was 60 minutes divided according to the special division of the lesson.

Posttests: After the completion of the curriculum, the post-tests were conducted on 29/12/2018. All the necessary requirements were prepared, and in the same circumstances as the pre-test, and the students themselves, the technical variables were measured (handling, rolling and scoring)

Statistical Means: The researchers used the Social Science Statistical Courier (SPSS)

Results and Discussion

This axis included displaying the results of the statistics after processing them statistically and in line with the goals.

View, analyze, and discuss the results of the skill tests for the sample of the research.

The researchers attributed this to the effectiveness of the curriculum applied to the members of the research sample where the curriculum contains a set of exercises and selected and selected accurately to suit the skills studied, as well as the process of physical selection and physical measurements have had the greatest impact in speeding up the learning process. And others that "learning does not happen simply by repeating the movements and mathematical skills of the players, but must be based on the training of scientific basis for the advancement of the level of their abilities and skills to the best"11

It is known that the progress and acquisition of skillful performance is achieved through organized practice. This is confirmed by Mohamed Abdul Ghani,“Progress in movement or skill is achieved through practice and repetition and avoid mistakes, and this is through the practical performance of the learner under the guidance of the teacher or teacher and this in itself is one of the main steps Used in the teaching of motor skills «12

In the review of the previous table we find that there is progress in the level of performance of the skills studied and the researchers believe that the good interaction of the sample of research and selection through scientific foundations has contributed significantly to learning these skills and interaction and seriousness and the rush in the application of the curriculum has a significant impact and positive in the learning process that “The process of acquisition and attenuation and the stabilization of mathematical skills during skill numbers This process requires a positive mathematical contribution to the implementation of the specified objectives”13

Conclusions

The researchers concluded that young players could be selected according to basic criteria to help them learn the basic skills of football. In addition, there is a positive
impact of physical measurements in learning some of the basic skills of football, and that there is a clear impact of physical qualities in learning some of the basic skills of football. Students of the College of Physical Education and Sports Science can learn football skills even in the absence of physical and physical characteristics, and that the selection made according to some of the determinants is appropriate for learning the research skills and speed of student learning.

ABSTRACT

The research problem focused on the weakness of learners in the performance of basic skills in dueling, which must be learned by students and suitable for each skill and then move to the other skill, and the reason for not being able to double the learning process that reaches the learner to certain limits of learning skills, Lack of time to address the learning disability, or lack of learning method, so researchers considered the problem by using the learning method to be able to learn to reach the best results and to reach the learner to a certain stage of good performance. The objectives of the research were to classify the students according to the criterion of independence versus dependence on the cognitive field, and to develop a learning method in order to be able to adapt to the cognitive method (independence versus cognitive dependence) in learning some basic skills in student dueling, The Effectiveness of the Learning Method In order to be able to learn according to the cognitive method (independence versus dependence on the cognitive field) to learn some of the basic skills of students’ fencing, K) used in the search rely on the scale (Ola Asaad Aldiri, 2011). The researchers concluded that the measure of independence versus reliance on the cognitive field used by the researcher in the sample of the research sample is capable of classifying the students as independent and dependent on The educational curriculum in the learning method for the sake of mastery is effective in learning the members of the research sample of some basic skills in the dueling of the students. The learning method in the learning method for mastery has had an effect in the group The researchers recommended that the independence scale should be used against dependence when it is necessary to classify the samples into an independent group and others based on the cognitive field, because it is capable of classification, and to emphasize the use of the learning method for students. When learning basic skills in fencing.

Keywords: Learning for mastery, Cognitive Style, Basic Skills, Fencing

Introduction

The research problem focused on the weakness of learners in the performance of basic skills in dueling, which must be learned by students and suitable for each skill and then move to the other skill, and the reason for not being able to double the learning process that reaches the learner to certain limits of learning skills, Lack of time to address the learning disability, or lack of learning method, so researchers considered the problem by using the learning method to be able to learn to reach the best results and to reach the learner to a certain stage of good performance.1

The objectives of the research were to classify the students according to the criterion of independence versus dependence on the cognitive field, and to develop a learning method in order to be able to adapt to the cognitive method (independence versus cognitive dependence) in learning some basic skills in student
dueling. The effectiveness of the learning method in order to be able according to the cognitive method (independence versus dependence on the cognitive field) to learn some basic skills in fencing for students.2

**Practical Part**

**Procedures Research’s Field:** The researchers used the experimental method to suit the nature of the problem on the students of the third stage in the College of Physical Education and Sports Sciences at the University of Kufa for the academic year (2018 - 2019) and the number of students (34).

**The Tests:** Determine the validity of the scale (independence versus dependence on the cognitive field) used in the search:

The researchers examined the sources and previous studies that dealt with the subject of measuring independence versus dependence on the cognitive field. They adopted the (Ola Asaad Aldiri, 2011) scale for independence versus dependence on the cognitive field. This measure deals with the study of the personality of the individual and the knowledge of individual differences among individuals in the field of eating Information and dealing with different situations. In order to identify the validity of the scale, it was presented to a group of experts and specialists (15) experts to show the validity and suitability of the members of the research sample, and after collecting questionnaires distributed to experts and specialists and unloading The value of the square (kai square) was greater than the tabular value of (3.84) at the degree of freedom (1) and the level of significance (0.05). This measure consists of three sections which are as follows:3

**Section I:** It is for training and does not count its degree in the assessment of the examinee, and consists of seven paragraphs easy.

**Section II:** consists of nine paragraphs of gradual difficulty.

**Section III:** It also consists of nine paragraphs of gradual difficulty and this section is equivalent to the second section of the test.

Each paragraph in the three sections is a complex or complex form that contains a simple form. The researcher is asked to discover and set its limits on the last page of the test. The test organization ensures that the examinee cannot see the simple form, in addition to the complex or complex form it contains one for each of the three test sections a specific time, two minutes for the first section, five minutes for the second section, in addition to five minutes for the third section.

**Defining offensive skills in dueling and measuring methods:** The researchers presented a range of offensive skills to the experts in the sport of fencing to determine the most important tests suitable for the variables of the study, and identified the important offensive skills of the game (direct attack, direct attack, change in direction, the circular attack) in the duel, and the method of assessing the performance of offensive skills in duel was done by three arbitrators who evaluate the performance according to the form prepared for this purpose with the division of class by skill sections.

**The scientific foundations of the tests:** For the purpose of identifying the scientific bases of the validity, reliability and consistency of the tests established and their relevance to the individual of the research sample, the researchers sought to adopt these principles in the process of applying the tests.

**Believable Test:** The believable test means that “believable test measures what is being for its measured.”4 In order to obtain the honesty coefficient for the tests used, the authentic honesty (sincerity of the arbitrators) was used by presenting the tests to a group of experts and specialists. The scale and skill tests for the duel were presented to the experts. The validity of the tests and the virtual scale were proven after the experts agreed that they would achieve the purpose for which they were developed and their suitability for the age group under consideration.

**Stability Tests:** The researchers established the stability coefficient of the scale and the technical tests under study in the test method and the re-tests on a sample of (8) students, after (14) days for the scale, and four days for the technical tests were re-tests on the students themselves.

**Preparation of the Curriculum:** The researchers presented a number of scientific references and related researches, including interviews with experts and specialists(Matrod, 1997), 5 and in order to achieve the objectives of the research, they developed a learning method in order to be able to master the experimental groups. The unit is distributed as follows:
First: The preparatory section and duration (15) minutes and includes:

a. Introduction and warm-up: the students are stopped in a uniform format and taking the absence and the preparation of tools for the success of the educational unit and give general exercises for all members of the body and duration (5) minutes.

b. Special warm-up: The exercises are taught with the skills studied and the parts and muscles working to perform this skill and duration (10) minutes.

Second: The main section and duration (25) minutes and divided into two parts:

a. Theoretical section: The skill is explained by the teacher and then the skill is presented to illustrate the correct performance and duration of the skill (10).

b. Application section: The performance of the given skill assigned to each unit is applied and applied according to the number of repetitions assigned to each skill with guidance and correction of errors by the teacher and his duration (15).

Third: Closing section and duration (5) minutes:

In which a small game is given to serve the main section or to give relaxation and relaxation exercises, giving some guidance to the students and then ending the educational unit and performing a greeting and walking quietly.

The material teacher implemented the experimental curriculum under the supervision of the researchers, as the two groups (independent, accredited) studied the method of learning for mastery.

Time and sections of the unit: The program was divided into 15 units per unit (45) minutes, with two units per week. The program took (8) weeks, equivalent to 30 units for the experimental research groups. The total duration of the educational program (1350) Minute (22.5) hours, bringing the time of the educational program for each group (675) minutes.

(15 minutes), the main section (25) minutes (10 minutes) for the theoretical part, (15) minutes for the applied part, and the final section (5) minutes. The total time of the preparatory section was (450) minutes and (33.33%) of the total time of the lesson and the two groups.

The main part of the educational program was (750) minutes and (55.55%), which includes the educational part and the applied part. The total time for the final part of the educational unit was (150) minutes and (11.11%) of the total program time.

Main experience:

Pre-tests: The pre-test of the sample was conducted at 9:00 am, and all the variables in terms of time, tools and devices, as well as the auxiliary team, were set to be applied during the post-test. The tests were conducted on the playground of the College of Physical Education and Sports Sciences. The researchers, with the help of the auxiliary team, applied the tests according to a predetermined sequence. The skills (direct straight attack, phase change, round attack) of the two research groups were tested and after completion the totals were rotated on the three test stations.

Application of the curriculum: The educational curriculum was applied to the members of the research sample by two teaching units per week for each group. The educational curriculum was applied to the skills of direct attack, change of direction, circular attack, and five learning units for each skill. And a test to determine the student learning ratio for the skill. There were three levels of the study sample (good, medium, weak), as in Table (1).

Table 1: Shows the levels of the two groups (independent) and (accredited) according to the method of learning in order to be able to skills (direct straight attack, attack change direction, circular attack)
The researchers (weak and middle-level students) reported that they were making an effort to learn the skill better, and that it was done outside of the teaching unit, using a holistic method of learning for learning (learning through homework). Or additional applications related to concepts or objectives in which they have not reached the appropriate level of competence “.7

The remaining modules were completed. The researchers conducted the end of module (5) test for each skill to determine the skill learning level (Direct attack along, trend change, circular attack). The researchers observed that all the students of the sample reached the percentage of ability of more than (85%) with a difference in grades.

Post-tests: After the completion of the curriculum, the post-test was conducted for the sample of the research. The researchers conducted the post-test on some of the skills of the research duel, namely (direct straight attack, attack change direction, circular attack) in the playground of the College of Physical Education and Sports Science. The experiments were performed with a Canon camera, and the researchers were keen to have the conditions similar to the tribal test in terms of location and conditions, the presence of the same helper team, and the use of the same steps that were applied in the to the pre-test.

Statistical Means: The researchers used the Social Science Statistical Courier (SPSS).

</tbody>
</table>

In Table 2, the results showed that there were significant differences between the pre-test and the post-test and the post-test in the technical variables under study. The researchers attributed this to the effectiveness of the educational curriculum applied to the two samples of the research where the curriculum contains a set of exercises that were selected and selected accurately in order to fit the studied skills as well as the nature of the age group of the sample. Qassem Lazzam and others states that “learning does not happen simply by repeating the movements and skills of athletes by the players, but the training must be based on the basis of scientific codified to advance the level of their abilities and skills towards the Hassan”.

Ghazi Saleh Hamoud believes. These are the ages to play between their peers while relying on the multiplicity of training and practice on the basic skills of the duel and the general rules of the rules of the game. The trainer must make skills training based on the existence of a purpose or goal to be achieved or automatic access by performing the exercises correctly and serious.

Conclusions

Through the results obtained by the researcher concluded the following:

1. The measure of independence versus reliance on the cognitive field used by the researcher on the members of the research sample is capable of classifying the students as independent and dependent on the cognitive field.

2. The educational method of learning in order to be able to be able to be positive in learning the
members of the research sample of some of the basic skills of dueling students.

3. The learning method of learning for empowerment has had an impact on the group of independent individuals rather than on the cognitive group.

The Development of Nursing Intervention Based on Indonesian Nursing Intervention Standard on Infarction Stroke in Hospital

Hani Riska Ariyanti¹, Nursalam Nursalam², Slamet Riyadi Yuwono³
¹Magister Student, ²Professor, Faculty of Nursing, Universitas Airlangga, Surabaya, 60115, Indonesia; ³Lecturer, Politeknik Kesehatan Kemenkes, Surabaya, 60282, Indonesia

ABSTRACT

Introduction: Infarction stroke is the most common stroke affecting millions of people worldwide, most patients die or are permanently disabled, so proper planning is needed. Nursing intervention on the clinical pathway is a planning guideline in giving nursing care to patients.

Objective: This study aimed to develop a nursing intervention based on Indonesian nursing intervention standards on the clinical pathway of infarction stroke.

Method: The design in this study is research and development (R&D) with a descriptive approach. The sampling technique used a purposive sampling technique by setting inclusion and exclusion criteria. The sample in this study was a clinical pathway client for stroke infarction and medical records of clients with stroke infarction with 122 medical records. The research instrument used an observation sheet. The data in this study were analysed using univariate analysis.

Results: The results showed that most nursing interventions based on the Indonesian nursing intervention standard on the clinical pathway of infarction stroke (93%) were mobilization support (I.05173) with nursing actions including monitoring heart frequency and blood pressure before starting mobilization, monitoring the general condition while doing mobilization and encourage simple mobilization.

Conclusion: Nursing interventions developed in infarction stroke client’s clinical pathway instruments are prepared based on the Indonesian nursing intervention standards, including mobilization support, fall prevention, communication promotion: speech deficits and management of increased intracranial pressure. Nursing interventions developed on clinical pathways must be evidence-based so that they can improve the quality of nursing care given to patients.

Keyword: nursing intervention, clinical pathway, infarction stroke.

Introduction

Clinical Pathway is an integrated service planning concept that summarizes each step given to clients based on service standards, nursing care standards and other evidence-based health care service standards with measurable results and within a certain period¹. The clinical pathway is a reflection of the interdisciplinary team including medical staff, nursing staff, and other health personnel in the form of service standards from each of these professions². Hospitals are usually lacking in providing comprehensive and evidence-based services regarding care for clients due to different patient responses³.

Infarction stroke is the most common stroke affecting millions of people worldwide, most patients die or are permanently disabled⁴and most are expensive and restricted in applicability. Lying flat ‘head down’ positioning of AIS patients has been shown to increase by as much as 20%, mean cerebral blood flow velocities (CBFV. Stroke is a large global and public epidemic of concern for health services because mortality rates are known to vary greatly between countries and
geographical regions. Stroke is a disorder of blood flow to the brain which causes cell death. Infarction stroke occurs when the blood supply to the brain decreases significantly or is closed due to the formation of clots in the arteries to cause a decrease or cessation of blood flow to the brain that often occurs in the carotid artery or caused by blood clots that form in an area the body, often forming in the heart and then flowing through the arteries until the clot is trapped in smaller blood vessels causing obstruction of blood flow.

Clinical pathways are most suitable for disease or clinical conditions that require a multidisciplinary approach and predictable clinical course (in at least 70% of cases). The implementation of clinical pathways is multidisciplinary in terms of doctors/dentists, nurses, physiotherapists, nutritionists/dietitians, pharmacists, and others. Nurses must be included in the development, intervention, and evaluation on an ongoing basis and have an important role in all aspects, especially in determining diagnosis and nursing intervention. Enforcement of nursing interventions in care planning is one of the competencies of nurses who are the entry points for formulating nursing care. Nursing interventions must be accurately stated to achieve positive and specific patient outcomes.

The effort that can be done is to develop nursing interventions based on the Indonesian Nursing Intervention Standard on the clinical pathway of infarction stroke clients. The Indonesian Nursing Intervention Standard is a standard of nursing intervention issued by the Indonesian National Nurses Association (INNA) to standardize nursing interventions in Indonesia to create uniformity of terminology to describe the scope of interventions carried out by nurses and increasingly show nursing contributions in health services. The development of nursing interventions based on Indonesian Nursing Intervention Standards on the infarction stroke clinical pathway client is a discovery that has never been studied before.

This study aimed to develop a nursing intervention based on Indonesian nursing intervention standards on the clinical pathway of infarction stroke.

**Method**

The design in this study is research and development (R&D) with a descriptive approach. The sample in this study was a clinical pathway client for infarction stroke and medical records of clients with infarction stroke with 122 medical records. The sampling technique used a purposive sampling technique by setting inclusion and exclusion criteria. The research instrument used an observation sheet. The data in this study were analysed using univariate analysis.

**Results**

The study was conducted from March 28, 2019, to April 31, 2019, at the hospital. During the period of data retrieval, there were 122 medical records and clinical pathway clients for infarction stroke with medical record search results as follows.

<table>

</tbody>
</table>

Table 3 showed that nursing actions for mobilization support nursing interventions (I.05173), namely all respondents (100%) monitored heart frequency and blood pressure before starting mobilization, monitored general conditions during mobilization and recommended simple mobilization. Nursing actions for preventive nursing interventions (I.14540), namely all respondents (100%) taking measures to identify falling risk factors, calculating falling risk assessment scores, installing bed handrails and suggest calling nurses if they need help moving. Nursing actions for communication promotion nursing interventions: speech deficits (I.13492), that is, some respondents (21%) took action using alternative communication methods (e.g writing, blinking eyes, hand signals). Nursing actions for nursing management of intracranial enhancing management (I.06194), namely most respondents (83%) took collaborative actions with the medical team: administration of anti-hypertensive drugs and anti thrombolytics.

**Discussion**

Nursing interventions in clinical pathways for infarction stroke clients include mobilization support (I.05173), fall prevention (I.14540), communication promotion: speech deficits (I.13492) and management of increased intracranial pressure (I.06194). Clinical pathways carried out by nurses lead to increased efficiency and allow for standardization of care, increased utilization of nursing resources, and high stakeholder satisfaction whereas physicians weaned salbutamol frequency for the control group patients as per standard care. The primary outcome was LOS in hours. Secondary outcomes included number of salbutamol treatments administered, ICU transfers, unplanned medical visits postdischarge, and stakeholders’ pathway satisfaction. Research staff, investigators, and statisticians were blinded to group assignment, except for research assistants enrolling participants. Qualitative interviews were done to assess acceptability of intervention by physicians, nurses, residents, and patients. RESULTS We recruited 113 participants (mean age 4.9 years, 62% boys. Nursing interventions are written in the clinical pathway instrument to be used as guidelines in carrying out nursing care so that it requires conformity and accuracy in composing or choosing a diagnosis and nursing intervention. If the nurse chooses a diagnosis
and improper nursing interventions will result in the continuity of nursing care and multi-profession coordination.

Indonesian nursing intervention standard is a nursing intervention standard issued by the Indonesian National Nurses Association (INNA) to standardize nursing interventions in Indonesia to create uniformity of terminology to describe the scope of interventions carried out by nurses and increasingly show nursing contributions in health services.

According to Theofanidis and Gibbon (2016) in an evidence-based clinical review stating that stroke is a condition where the brain part is suddenly badly damaged by a disruption of the blood supply. As a result of this disorder, it will cause loss of function for certain parts of the brain such as hemiplegia, weakness, perceptual dysfunction, visual impairment and or speech. Nursing interventions in stroke patients include continuity management, treatment of pressure areas, swallowing management, and early mobilization. Other important nursing interventions include prevention of pulmonary thromboembolism and early antiplatelet therapy.

Disorders of physical mobility in infarction stroke clients are very common. Assessment of the body’s ability to assess exercise needs. Exercise can improve functional capacity, ability to carry out activities of daily living, and quality of life to reduce cardiovascular risk. Physical mobility support in stroke patients should emphasize low to moderate intensity exercise activities, muscle strengthening activities, reduction of sedentary behavior and risk management for secondary stroke prevention. Some infarction stroke clients experience weakness in the extremities, which inhibits physical mobilization.

The risk of falls is also common in clients with stroke infarction. Systematic reviews have shown that falling risk factors for hospitalization are gait instability, restless confusion, urinary incontinence, history of falls and psychotropic treatment. For older patients in hospital rehabilitation settings, risk factors include floor carpeting, vertigo, confusion, cognitive impairment, stroke, sleep disorders, anticonvulsants, tranquilizers, antihypertensive drugs, falls before and need transfer assistance. Nurses are important professionals who help minimize complications arising from falls by identifying risks early on, planning and implementing prevention strategies. The implementation of a continuous fall assessment on fall prevention is an early nursing intervention to avoid falling events and complications.

Effective communication between health care staff and patients is an important aspect of maintaining patient safety. In the context of stroke rehabilitation specifically, staff must be competent to enable people with verbal communication disorders to convey their daily needs and desires and support them to understand and participate in decision making, which aims to enhance the participation of aphasic patients, has been shown to improve conversation partner knowledge and skills. However, there is a lack of evidence for transfer of SC training to practice in post-acute rehabilitation settings. Aims: We aim to develop an understanding of causal mechanisms implicated in the transfer of SC training by examining the nature of the setting, staff perspectives, and the situated character of the action. Methods and Procedures: Twenty-eight staff from a multidisciplinary team were trained in SC. We collected detailed and varied data, including staff experiences of SC training and implementation, and video data of routine practice. Using a critical realist approach, we develop explanatory mechanisms for barriers to and enablers of transfer. Eleven team members (nursing, therapy, and assistant staff).

During the acute stroke phase, the prevention of increased intracranial pressure is very important. Increased post stroke intracranial pressure in patients with infarction stroke is an important part of acute stroke therapy and can save lives. Intracranial pressure can usually be observed for the first four days after infarction. Nursing care in the management of increased intracranial pressure includes perspective assessment and data integration, ventilation monitoring and hemodynamic functions, and appropriate patient position. Nursing interventions include neurological monitoring, ventilator support, fluid, and electrolyte maintenance, appropriate temperature management and surgical intervention if needed. Nurses must collaborate with inter professional teams to carry out actions based on evidence-based guidelines.

The clinical pathway aims to improve the organization and efficient patient services based on evidence and guidelines. A clinical pathway is an integrated multi-profession planning guideline including nurses. Nursing interventions are written in the clinical pathway instrument to be used as guidelines in carrying...
out nursing care so that it requires conformity and accuracy in preparing or choosing nursing interventions. If the nurse chooses improper nursing interventions, it will result in the continuity of nursing care and multi-profession coordination.

Conclusion

Nursing interventions developed must be evidence-based so that they can be used as standard nursing care and improve the quality of care given to patients. Nursing interventions developed in infarction stroke client’s clinical pathway instruments are prepared based on the Indonesian Nursing Intervention Standards, including mobilization support, fall prevention, communication promotion; speech deficits and management of increased intracranial pressure Nursing actions from each nursing intervention are included in the infarction stroke client’s clinical pathway instrument so that continuity of nursing care can run well.

Relationship between Mental Workload and Fatigue of Motorcycle Rider among East Java Student

Hendrati LY¹, Martini S¹, Lestari K. S.²
¹Department of Epidemiology, ²Department of Environment Health, Public Health Faculty, Universitas Airlangga, Indonesia

ABSTRACT

Fatigue is a decreased body condition due to physical and psychological burden. Fatigue affects the ability to ride a motorcycle. One of them is affected by workload. Aims of this study to analysis correlation between fatigue state and workload on senior high school students that use motorcycle. A cross-sectional study was conducted. Data collected from population in east java Island Indonesia. Population of study are student from senior high school. Sample size of this study was 453 student who ride motorcycle. Questioner to measurement of fatigue use Subjective Self Rating Test from Industrial Fatigue Research Comittee (IFRC). Questionare to assess mental workload used National Agency and Space Administration Task Load Index (NASA-TLX). The results showed that the characteristics of respondents in this study were mostly female (57.6%) and aged 17-19 years old. Most of respondents had mental workload were middle (52.5%). Overall, Effort, Mental Demand, Temporal Demand acquired the highest workload scores while physical demand recovered lowest workload score. The overall fatigue level showed that 62.9% of students who ride motorcycle felt fatigue as middle and 32% as high. Subjectively activity fatigue felt by most respondents (99.8%). Frequency of fatigue that felt respondents is rare. Mental demand has a negative correlation with fatigue. Physical Demand has a negative correlation with activity and mental fatigue. Temporal Demand has a negative relationship with activity fatigue. Own Performance has a negative relationship with fatigue. Effort has a negative relationship with fatigue. Frustration on level and fatigue obtained a significant positive correlation. Schools consider conditions that cause frustration to students so that the risk of fatigue can be reduced.

Keywords: Workload, frustration on level, Sex, prevalence of fatigue

Introduction

Fatigues are condition. Fatigue is a condition of decreased energy so that it does not have the will and ability to do activities. Fatigue is one of the indicators of physical quality. Analysis by Armstrong et al (1) in his study found a phenomenon of 66% of people driving vehicles tired or sleepy and 2.4% of participants who experienced fatigue having a history of traffic accidents.

The study of Engberg, et al found that the proportion of fatigue in the population of women aged 25-45 years is 10.8 % while in men in the same age group is 9.7% (2). Women have a higher incidence of fatigue than men. Fatigue that occurs in motorcycle riders can cause loss of concentration while driving. Motorcycle riders who experience sleepiness 5.9 times experience traffic accidents (3). Fatigue is a risk for a significant incidence of motorcycle accidents Fatigue is a condition that can be physical fatigue and mental fatigue that can be triggered by stress, medication, overwork, or mental and physical illness. Sleep quality, decreased quality of life, stress are significantly associated with fatigue and residual fatigue. Short sleep, depressed mood, length of work associated with residual fatigue (4).

Muscle fatigue is a loss of muscle strength (muscle contractility) reversibly during work. Fatigue is a condition that can be caused due to neurological and
non-neurological factors. Neurolgic factors that cause fatigue include central fatigue (mental fatigue), mental disorders (mental disorder), disorders of the central nervous system (organic Central Nervous System). Non-neurological factors include heart problems, pulmonary disorders, blood disorders, metabolic diseases and chronic fatigue syndrome (CFS).

Material and Method

Design of this study is crosssectional. Method of data collection to get information was obtained through a survey. Participants of this study was student of senior high school that chosen considering with criteria was motorcycle driver. The sample selection is based on multistage random sampling. The first stage is the determination of the location of the school based on the selection of the city with the highest accident rate. The second step is to determine the school based on cluster random. The third step is to determine students through simple random sampling. Questioner instrument that use this study. Questioner distributed to student after obtaining head of school to conduct the study. Before the participant answers the questionnaire, the overall project goals and objectives of the survey were explained to student and head of school. Four hundred fifty three of six hundred eleven copy were filled. Collected data at 2017. The level of workload of students who drive two-wheeled vehicles based on the calculation of the NASA TLX method. Fatigue measurement of respondents in this research used Subjective Self Rating Test from Industrial Fatigue Research Commite (IFRC). The sample of the study were student who used motorbikes aged 17-19 years. The mental workload data was analyzed by summing all mental workloads value divided by fifteen before being grouped. Data on mental workload are grouped into three. High group if the value of mental workload is more than 75%, medium if 50% -75% and mild if less 50%. Severe group if the value of fatigue is more than 90%, medium if 61% -90%, mild if 31-60% and no fatigue if less 30%. Descriptive statistics was Correlation analysis was performed using spearman non parametric analysis. A significance level of 0.05 was used for all statistical analysis.

Result and Discussion

Characteristic of Respondents: Respondents in this study were senior high school. The range age was 17-19 years old and average was 17 (± 0.32) years old. Most of the gender of the respondents are female (57.6%). Respondent experience workload are middle (52.5%). The results of the research conducted by Barret (2018) show that women’s feedback fatigue is higher in prevalence than men.

Fatigue Status: Most respondents experience fatigue. The prevalence of fatigue obtained from the results of the study was 99.8%. The proportion of students who experienced severe fatigue found in the study was 4.2%. Fatigue item include are activity, mental and physical fatigue. Most fatigue that felt responden is actifity fatigue. Activity fatigue felt by respondents 99.8%, as for other, mental fatigue (99.3%), physical fatigue (98.9%). The frequency of activity, mental and physical fatigue experienced by respondents is rare. Descriptif analysis showed in table 1.

According to Tien’s study, academic stress has an effect on the severity of fatigue. An education system that requires students to interact with the internet so students use time to seek knowledge for academic demands through the internet. The study by Chatharine and Lamyae said that internet-addicted students experience higher fatigue than students without internet addiction. An education system that requires students to interact with the internet so students use time to seek knowledge for academic demands through the internet. The study by Chatharine and Lamyae said that internet-addicted students experience higher fatigue than students without internet addiction.
Activity Fatigue Status: There were ten item to measure activity fatigue in the Subjective Self Rating Test questionare. Sleepy, want to lie down and tired of the whole body aimed the highest activity fatigue scores while standing unstable obtained the lowest activity fatigue scores. Respondents that felt Heavy feeling on the head (92.8%) that most of frequency headache was rare (55.6%). Respondents that felt tired of talking (96.2%) that most frequency were rare (57.8%). Respondents that felt weight on feet (86.0%) that most frequency felt weight on feet were rare (48.3%). Yawning felt by respondent (95.5%) that most frequency felt yawning were often (41.9%). Respondents felt distracted mind (92.3%) that most frequency o sense distracted mind were rare (46.6%). Sleepy symptons felt by respondents (98.9%) that most frequency were often (44.6%). Respondents (88.1%) felt burden on the eyes that most frequency felt burden on the eyes were rare (41.7%). Awkward and rigid movements felt by respondents (81.1%) that most frequency were rare (37.5%). Most frequency of respondents (69.4%) felt standing unstable that most frequency were always never (36.4%). Want to lie down symptom felt by respondents (96.8%) that most frequency were rare (39.5%). Presentation of each item shown in table 2.

Mental Fatigue Status: Mental fatigue included in the Subjective Self Rating Test questionare are ten item. Presentation of each item shown in table 3. Trust condition, not concentrating and feeling anxious accessed highest mental fatigue scores while not diligent in work received the lowest mental fatigue scores. Hard to think Tired of talking felt by respondents that most of frequency were rare (45%). Nervous was felt by 85.4% of respondents that the highest frequency is rare (52.3%) Not concentrating felt by most respondent were rare (65.3%). Most frequency of the respondents that sense difficult to focus were rare (57.2%). Easy to forget symptoms felt by respondents that most frequency were rare (51.9%). Most of respondents that felt not trust were rare (44.2%). Feeling anxious felt by most of respondents were rare (56.3%). Difficult to control attitude felt by respondents (85.6%) that Most frequency of respondents that felt difficult to control attitude were always never (46.8%). Not diligent in work symptom felt by respondents (82.9%) that most frequency were rare (46.6%).

Physical Fatigue Status: Physical fatigue experienced by respondents is explained in 10 questions. Tables 4 express the various conditions that describe physical fatigue. Physical symptoms of fatigue felt by most students were dyspnea (99.1%). Respondents that felt headache were 94.8% that most of frequency headache was rare (48.8%). Stiff on the shoulder felt most frequency was rare (39.1%). Most frequency respondents that felt back pain were rare (47.2%). Dyspnea felt by most of respondents were never (39.7%). Most frequency of the respondents that sense thirsty were often (44.6%). Hoarseness symptoms felt by respondents that most frequency were rare (43.7%). Most of respondents that felt dizziness were rare (43.9%). Eyelid spasme felt by most of respondents were rare (42.2%). Most frequency of respondents that felt tremor on the limbs were always never (32.9%). Unhealthy symptom felt by most respondents were rare (56.3%).

MD: Mental Demand; PD: Physical Demand; TD: Temporal Demand; OP: Own Performance; E: Effort; FL: Frustation on Level

*Correlation is significant with α =0.05 level (2 tailed)

**Correlation is significant with α =0.01 level (2 tailed)

Student activities include learning that requires remembering, counting and looking for subject matter. Student activities include learning that requires remembering, counting and looking for subject matter. This activity is getting easier, so the activity fatigue gets lower.

Students in this survey felt that the more satisfied the completion of school assignments, the lower activity fatigue. Low performing students are students who experience more fatigue (16). Low performing students are students who experience more fatigue.

School assignments given to students include group and individual assignments, if students have succeeded in working will give satisfaction to the students themselves.

Efforts that have been made in completing the tasks that lead to good performance, According to the results of this study indicate that significantly increasing efforts will decrease the activity fatigue.

This study show that between frustation on level and mental fatigue have corelltion. According to Williamson et al, mental health is associated with fatigue (9). Study in University of Montreal shows that 72.7% stress caused by workload (8). Stress is part of a condition that determines a person’s level of frustration related to fatigue. The study conducted by Annupama et al stated that there is a correlation between stress and fatigue in students (7). Feel safety is a part of determining the level of frustration. There is a relationship of feel safety with mental workload. Mental burden is related to the process of attention and effort (15). Social interaction is related to feel safety that related to the level of frustration. The study conducted by Michiyo et al showed that students with low social interactions tended to increase depression scores (19). Studies in Pakistan which are the results of a survey show financial responsibility is a cause of frustration (13).

Conclusion

The mental workload is related to fatigue. Mental demand has a negative correlation with fatigue. Physical Demand has a negative correlation with activity and mental fatigue. Temporal Demand has a negative relationship with activity fatigue. Own Performance has a negative relationship with fatigue. Effort has a negative relationship with fatigue. Frustation on level and fatigue obtained a significant positive correlation.

Conflict of Interest: In carrying out this research, researchers do not have conflict of interest with research informants and between participants

Source of Funding: This research was conducted with self funds

Ethical Clearance: This research was conducted on the awareness of respondents as volunteers in filling out the questionnaire. Before the study, respondents were given an explanation and signed informed consent.

Single Nucleotide Polymorphisms in IL-10-1082 A\G Gene and Association with HCMV Infection in Abortion

Hiba A. Hatem Mayyada F. Darweesh

Department of Biology, Faculty of Sciences, University of Kufa, Iraq.

ABSTRACT

Recurrent spontaneous abortion (RSA) affects approximately 1-5% of pregnancies, about third of cases were unknown cause. The production of cytokines can be influenced by genetic polymorphisms and lead to high or low levels of cytokines that subsequently play an important role in establishing a successful pregnancy. So, the present study aimed to determine whether polymorphism in IL-10-1082A/G is associated with the incidence of abortion in AL-Najaf city. Case-control study was performed to 80 patients and 40 healthy individual as control, 30 patients infected with Cytomegalovirus. Blood samples were collected from all participant. Blood used in detection IL-10-1082A/G polymorphism by amplification refractory mutation system (ARMS-PCR) Technique. IL-10 serum level were measured by enzyme-linked immunosorbent assay test(ELISA). The result explain that the age group (20-29) and at three time of recurrent abortion was more infected with CMV.SNP in IL-10-1082A/G were AA (60%), AG (27.5%) and GG (12.5%) in patients as compared to control (15%), (30%) and (55%) respectively. AA genotype associated with low serum level of IL10 (2.5 pg/ml) while GA and GG genotype associated with high serum level (5pg/ml and 12. 3 pg/ml) respectively. This result shown that IL-10 level is significantly decrease in aborted patients than control, and AA genotype is risk factor for abortion. Conclusion: The polymorphism in IL-10 at position (1082A/G) has association with abortion at AA genotype, GG consider as protective factor. decrease IL-10 levels in aborted women if CMV infected or non-infected.

Keyword: IL-10, polymorphism, ARMS, abortion, HCMV.

Introduction

Recurrent pregnancy loss(RPL), meaning as two or more consecutive pregnancy losses before the 20th week of gestation from the last menstrual period, represent one of the most distressing problem in obstetrics occurs in approximately 1-5% of women at reproductive age. Many factors may be consider a causes for RPL as genetic error, anatomic abnormalities, hormonal abnormalities, infection such as HCMV, immunologic factors or systemic disease, and about 40% of the cause is unknown. SNP is a variation in a single nucleotide that occurs at a specific position in the genome in less than 1% of the population. Several cytokine gene polymorphisms have been reported to affect gene transcription and influence serum cytokine production and play key roles in the susceptibility, development, and severity of diseases such as thalassemia, Asthma and abortion. Interleukin-10 is an important immune suppressive and anti-inflammatory molecule that inhibits T cell proliferation and suppresses selectively Th1-mediated cellular responses. In the pregnancy women IL-10 levels increase markedly in placenta tissue during early pregnancy and remain elevated well into the third trimester, decreased production of IL-10 contributes to poor placental development process, blocking angiogenesis and impairing vascular development, ultimately resulting in abortion. IL -10 gene polymorphisms have been reported to influence the level of cytokine production and implicated in abortion pathogenesis. Human cytomegalovirus is the most common pathogen in uterus during pregnancy, which may lead to some serious results such as miscarriage, stillbirth, fetus developmental retardation.
Materials and Method

Patients and Control Group: This study was in agreement with declaration of Helsinki guidelines which approved by Al-Zahra Teaching Hospital and Health ministry of Iraq Ethical committee and verbal acceptance was obtained from all participants before taken sample.

Case control study was conducted on 80 aborted women attending to Al- Zahra Teaching Hospital in AL- Najaf province during period from august till December 2018. The patients were divided into two groups according to their infected with Human Cytomegalovirus and non-infected, in addition to 40 apparently healthy women as control group,. clinical examinations were done for each subjects and the information was recorded in a data sheet. Blood samples were collected for estimation CMV (IgG, IgMbysight–USA kit) and detection IL-10 serum level (Elabscience- USA kit) by sandwich ELISA system (Biotech-USA)and PCR amplification for IL10A/G polymorphism as following.

DNAisolation and PCR: Genomic DNA was extracted from fresh peripheral blood using a commercially available kit applying Genomic DNA kit System (Favogen- china) then stored at -20°C till use. SNPs IL-10-1082G/A amplification refractory mutation system (ARMS-PCR)in two reaction employing one common forward and two reverse primers F-5’-AGCAACACTCCTCGTCGCAAC-3’, R1 5’-CCTATCCCTACTTCCCCC-3 and R2 5’-CCTATCCCTACTTCCCCT3’ with an amplicon size of 179 bp. The reaction mix was done in 20µl volumes include 5µl of template DNA, PCR Premix kit (i-Taq) 5 µl, Primers (foreword2.5 µland reverse2.5µl) and Nuclease free water 5µl (Applied PCR system, USA). and PCR conditions were initial denaturation at 94°C for 5 min, followed by denaturation at 94°C for 30s,while annealing applied (58,60,62,64°C)to obtain most clear picture which were at 62°C for 1 min and 1 min of extension at 72°C, with a final extension of 7 min at 72°C. The result of PCR products were resolved by electrophoresis on agarose gel stained with 3.5µl (0.5% concentration) from ethidium bromide,therun lasted for 65 volt for 75 minute. The gel was then photographed on UV light (320nm) and scored for the presence or absence of an alleles specific band.

Statistical Analysis: Data were expressed as mean and standard deviation. The significantly of IL10 serum levels in patients and controls using student t-test. Allele frequencies were estimated using the gene-counting method. Differences of genotype and allele frequencies between aborted and control groups were also analyzed using the 2 test. Pearson coefficient and odds ratios (ORs) for the risk of abortion and their 95% condense intervals (CIs) were calculated using logistic regression analysis. All statistical analyses were performed by Microsoft excel and the Graph Pad software (prism version 6). The difference was considered significant, if p < 0.05.

Results

1. Family history on abortion women: The current study showed that the percentage of aborted ladies had a positive family history of abortion was appeared 54 % of patients as fig (1-A).

2. Cytomegalovirus (CMV) in aborted women: Out of 80 aborted patients there were 30 (37.5%) sera confirmed positive for anti- HCMV-antibodies. The remaining 50 (62.5%) were sero-negative. From 30 seropositive patients only 20 (66.7 %) were positive toward IgG and 2 (6.6%) positive for IgM and 8 (26.7) were positive for both IgG and IgM as in fig (1-B).

3. Molecular study

Distribution of IL-101082G/A genepolymorphism in aborted patients and healthy control: The results revealed that AA homozygous genotype was 60% in the abortion women and 15% in the controls that was statically significant whereas homozygous genotype GG represent 12.5% in aborted and 55%in controls as shown in Fig. 2 and Table 1.

The result revealed that “A” allele have higher prevalent in the abortion women with percentage (73.75%) in compared to controls (30%) Fig 3.

Fig. 2: Ethidium bromide-stained agarose gel of PCR amplified 179 bp of IL10-1082G/A gene. Show: DNA molecular size marker (100bp Ladder), bands 1,3,5,7,9,11 and 13 for A allele, while 2,4,6,8,10 and 12 for G allele, so bands 1,2 represent AA genotype while 7,8 for AG genotype, finally 9,10 for GG genotype.

Fig. 3: Case-Control comparison in relative frequency of three genotype IL-10 1082G/A gene

4. Immunological study

a. Concentration of IL-10 in serum: The present study indicated that a significant decrease in serum level of IL-10 in patients, mean was 6.48pg/ml in compares to control group (13.32pg/ml) Fig.4.
b. Correlation between IL-10 polymorphisms and its production in abortion women: The results showed that IL-10 serum levels were significantly lower ($p < 0.05$) in the abortion women with genotype AA about 2.5 pg/mL while, the GA and GG mean levels were (5 and 12.3) pg/mL, respectively (Fig. 5).

c. IL-10 serum level in CMV infected and non-infected patients: It is clear that IL-10 has been decreased in both abortion infected with CMV or non-infected patients in compared with healthy, as show in fig (6).
Discussion

Family History on Abortion Women: Many of the recent studies of abortion confirmed that abortion associated with mother family history and regarded as one of risk factor. Generally, large percentage of women having a family history in their mother threatening them in risk of pregnancy loss. Among females, experience of an abortion within a current relationship was associated with increased risk for various forms of sexual dysfunction, and found that abortion history from mother a great risk. The important risk factor for having adverse effects on pregnancy, as the chronic disease, social, and the mother history of abortion.

Cytomegalovirus (CMV) in Aborted Women: Human cytomegalovirus is an important etiological agent of intrauterine infection, which may lead to some serious results in pregnant women such as miscarriage, cerebellar malformation and fetus development retardation. In Karbala/Iraq, Abbas revealed that the main cause of infectious agent (TORCH) that caused abortion in pregnant women was CMV, high prevalence of CMV IgG among aborted women 96% while IgM was 7%. Al-musawi indicated the presence of CMV IgG (93.9%) and IgM (5.29%) antibodies in high rate among pregnant women in the Baghdad city and is likely to be transmitted from mother to fetus in the uterus through the umbilical act as source of infection and cause spontaneous abortion. CMV had wide spread in pregnant women and cause abortion to them.

Distribution of IL-10-1082G/A genotypes and alleles among patients and control groups: The present study revealed that the A allele and AA genotype in aborted patients significantly associated with abortion. In contrast, the “G” allele, GG genotype has a rather preventive role. This indicate that the “G” allele may be protective factor. The research shown a possible association with spontaneous abortions and IL-10 polymorphism and explain that genotype AA and allele increased frequencies in abortion. In North Indian, Parveen showed a significant association of A allele women with recurrent pregnancy loss. Ameta-analysis study in 635 women with spontaneous abortions, revealed a statistically significant association of A allele with spontaneous abortions. Bohiltea demonstrated a strong association for -1082G/A IL-10 polymorphism in 69 women of the Romanian population with recurrent spontaneous abortion. The substitution of A allele in place of G allele at -1082 position reduced the production of IL-10, thereby dampening the maternal immune response, enhancing fetal tissue damage and thus resulting in spontaneous abortion.

IL-10 concentration in serum of aborted women: IL-10 production was significantly lower in patients with recurrent miscarriage as compared with normal pregnancy. Abdulgany and Bakir shown that decrease serum level of IL-10 in patients of RSA in contrast with healthy control. IL-10 has its role in the preservation of pregnancy until the completion of gestation. A higher levels of IL-10 production in human placental tissue during early pregnancy play important role in maintenance of normal pregnancy. Women with decreased production of IL-10 contributes to poor placental developmental process with an increased rate of spontaneous abortions.

IL-10 serum level in aborted women infected and non-infected with CMV compared with control: Interleukin IL-10 plays an important role in the prevention of spontaneous abortion. Serum levels of IL-10 were significantly lower in the aborted CMV patient groups compared to controls. Interleukin10 producing CD3+/CD8+ T-cell counts against infection of CMV were significantly lower in women with RSA. In spontaneous aborted women due to CMV and according to Mosman the level of IL-10 was lower in patients than in control. A significant lower in IL-10 expression in activated peripheral blood cells in recurrent abortion women due to infectious agents as compared with control group.

Conflict of Interest: There are no conflict interest.

Source of Funding: The authors declare that they have no competing interests.

Ethical Clearance: All authors are in accordance with the ethical standards of the responsible committee on human experimentation (institutional and national) and with the Helsinki Declaration of 1975, as revised in 2000 (5).

Molecular Study of *Echinococcus Granulosus* in Misan Province, South of Iraq

Hussain A. Mhouse Alsaady¹, Hussein Ali Naeem Al-Quzweeni²

¹Biology Department, College of science, University of Misan, Maysan, Iraq

ABSTRACT

Cystic Echinococcosis (CE) has serious impacts on human health and his animals. It is leading to a significant public health and socio-economic problems in different parts of the world. This study includes a molecular characterization of *Echinococcus granulosus* in definitive and intermediate hosts including humans in Misan province, south of Iraq. The present study includes survey for CE during the period from December 2017 to October 2018. A 3287 cases were examined 922 sheep, 405 buffalo, 2 camel, 983 cow, and 150 goats from central slaughterhouse of Al-Amarah city (capital of Misan province) and 819 human from Al-Sader Teaching Hospital and Al-Zahrawi Surgical Hospital, the adult worms were obtained from 2 stray dogs. The genetic characterization of the *E. granulosus* complex in human and livestock population was described for the first time in Misan province by using polymerase chain reaction (PCR) and DNA sequencing technology of mitochondrial gene Cox1. The results showed a high prevalence 72.72% of the sheep strain (G1) had been infected all hosts, where 13.63% was recorded as buffalo strain (G3) in sheep and cow hydatid cyst and 4.54% as SB041 strain was recorded in sheep, also 9.09% G1BC genotype was recorded in sheep and buffalo. These records are the first data for the genetic diversity of *Echinococcus granulosus* in Misan province, south of Iraq.

Keywords: Molecular Study, Cox1, Echinococcus granulosus, Misan, Iraq.

Introduction

Cystic Echinococcosis (CE) or hydatidosis caused by the larval stage of a zoonotic tapeworm *Echinococcus granulosus* which is endemic in the most regions of the world[1][2][3]. The adult worm is living in the small intestine of canids members as definitive host, mostly dogs and wolves[3][4][5]. The herbivores are infected with *E. granulosus* when grazing the contaminated herbage with the canids feces contains *E. granulosus* eggs[6]. However, humans can be accidentally infected by swallowing eggs with contaminated food, water and directly when contacted with infected dog[7]. In livestock, the infection with *E. granulosus* caused a considerable economic loss in milk and meat production, edible organs and decreased in fecundity[8][9]. The high infection rates and the global distribution of (CE) is return to the wide range species of infected intermediate hosts[1][8]. However, the infection rate of human is related with the infection rate of domestic animals specially dogs and sheep[10][11]. More than one global study reported that *E. granulosus* had variable strains in different regions of the world[12][13], which had different routes in epidemiology, pathology, control, and prevention[14][17].

Today, there are ten distinct strains or genotypes identification as G1 - G10. These genotypes are associated with distinct intermediate hosts like sheep, Buffalo, horses, cattle, camels, pigs, cervids, goats, and others[15][12][16]. In Iraq, hydatid cyst is one of the most endemic diseases in both humans and animals, which caused some significant human problems in health and economic activities[17][18][7].

Materials and Method

Sample Collection: The HC specimens were collected during the period from December 2017 to October 2018; from slaughtered livestock animals (sheep, buffalo and
cow) from central slaughterhouse of Amara city in Misan province (31°51'49.0”N 47°08'51.1”E) where human’s HC obtained from patients whom underwent to surgery in Al-sader Teaching Hospital and Al-Zahrawi Surgical Hospital. While the adult worms were obtained from stray dogs. The Protoscoleces and the germinal layers were isolated from each cyst then washed with PBS in prepared to DNA extraction. The specimens were preserved in labeled tubes with 70% ethanol and stored in deep freeze (-20°C) until used for DNA extraction.

**DNA extraction:** The DNA were extracted according manufacturer’s instructions of DNA extraction kit (gSYNC™ DNA Extraction Kit, geneaid, Korea). The purified DNA samples were frozen at -20°C until used in the polymerase chain reaction (PCR) technique.

**PCR amplification and gel electrophoresis:** The mitochondrial DNA target sequences for Cox1 gene were amplified by PCR with using the following protocol: PCR was carried out for the purified DNA samples with PCR preMix (BioNeer, Korea) in a 50μl final volume of reaction. Two conserved primers, JB3 (Forward): '5- TTT TTT TTT CAT CCT GAG GTT TAT-3' and JB4.5 (Reverse): '5-TAA AGA AAG AAC ATA ATG AAA ATG-3' [19], were used for amplify the mtDNA region consistent to partial Cox1 gene. The Cox1amplification began with an initial denaturation at 94°C for 5 minutes, 40 cycles of 94°C for 45 seconds, 51°C for 35 seconds, and 72°C for 45 seconds, followed by a final extension at 72°C for 10 minutes. The amplification products were resolved by electrophoresis in a 1% agarose gel using TBE buffer 1X (at 65 V for 1 h.) A 100bp ladder (Bioneer, Korea) was included as molecular size marker. Gels were visualized by staining with ethidium bromide solution (0.5 µg/ml) and banding patterns were photographed over UV light using Gel documentation [28].

**Sequencing:** The PCR amplified Cox1 gene specimens were automatically sequenced with using Applied Biosystem (genide, Korea) then compared with retrievable reference sequences of E. granulosus strains of GenBank in order to infer the micro variants. Homologue sequences were retrieved from GenBank representative of genetic variability circulating in the E. granulosus complex were included with all specimens and analyzed to obtain the phylogenetic tree by using MEGA X software.

**Results**

The results of PCR Amplicons electrophoresis with 1% agarose gel which visualized by ethidium bromide stain showed that PCR products sizes were 446bp (Figure 1).

![Figure 1: Electrophoreses pattern of PCR product for Cox1 gene 446bp, 1% Agarose, 65 V, 60min, M: DNA marker ladder 100bp.](image)

The results of Cox1 gene sequences for 29 isolates of E. granulosus were analyzed for detecting sequence variations with Cox1 reference sequences in GenBank databases and by using molecular analysis programs like MEGA the current study detected that E. granulosus had variant strains like sheep strain (G1), buffalo strain (G3), G1BC genotype and SB041 strain (Table, 1). Sheep strain (G1) consisted about 72.72% (16/22) of sequenced isolates, buffalo strain (G3) was recorded in 13.63% (3/22) of isolates, G1BC genotype was showed in about 9.09% (2/22) in sheep and buffalo isolates and only 4.45% (1/22) of isolates was matched with strain SB041 as showed by phylogenetic tree (Figure 2).

**Table 1: The distribution of E. granulosus strains**

</table>
Hence the results showed that the sheep strain (G1) is the predominant strain among other strains of *E. granulosus*.

**Figure 2: The Evolutionary relationships of *E. granulosus***

The evolutionary history was inferred using the UPGMA method. The optimal tree with the sum of branch length = 0.46113100 is shown. The tree is drawn to scale, with branch lengths in the same units as those of the evolutionary distances used to infer the phylogenetic tree. The evolutionary distances were computed using the Maximum Composite Likelihood method and are in the units of the number of base substitutions per site. This analysis involved 32 nucleotide sequences. Codon positions included were 1st+2nd+3rd+Noncoding. All ambiguous positions were removed for each sequence pair (pairwise deletion option). There were a total of 380 positions in the final dataset. Evolutionary analyses were conducted in MEGA X.

**Discussion**

In Iraq few studies were conducted in molecular field, some studies agreed with our findings in different species host, like Hama *et al.* (2015); Hassan *et al.* (2016) and Hassan *et al.* (2017)[21][22][23]. PCR and gene sequencing techniques were applied for investigating of some isolate of *E. granulosus* collected from human and some livestock animals this technique are used for the first time for *E. granulosus* strain identification in Misan province, for that the current study considered as the first databases of molecular characterization for *E. granulosus* in Misan.

The present study showed that sheep strain (G1) is the dominant strain (72.72%) of *E. granulosus*, this finding was agreement with some previous studies from different regions of the world that mentioned the (G1) was cosmopolitan strain[24][7]. G1 strain was distributed as: sheep (66.66%), buffalo (75%), cow (75%), human (100%) and Dog (100%), this results agreement with relatively high infection rate 2.16% and high fertility 65.00% of sheep hydatid cysts.

This domination of G1 was reported by other studies in some areas of Iraq such as: Baraak (2014) in human from different provinces of Iraq[25], the sheep strain (G1) reported as the most prevalent strain in Kirkuk, Iraqi Kurdistan and Kirkuk - Sulaimania respectively [22][23][7]. The results confirm previous evidences from molecular
genotyping surveys described high prevalence for sheep strain (G1) in Iraq.

The buffalo strain G3 was recorded in this study with low frequency 13.63% since it has been observed in E. granulosus specimens distributed between sheep (22.22%) and cow (25%) of hydatid cysts, this genotype was detected previously in some regions of Iraq like in Al-Qadisiyah province it recorded by Fadhil and A’aiz (2016) also G3 recorded in Kirkuk province and Sulaimania province by Hammad et al. (2018). The G1BC was recorded in 9.09% of E. granulosus specimens, this genotype recorded in sheep (11.11%) and buffalo (25%) of hydatid cysts. This genotype was identified according to EURLP method. The morphological parameters of G1BC was significantly different with other genotypes. The buffalo hydatid cyst with this genotype was the only fertile buffalo’s HC sample, where buffalo HC with G1 was sterile this may indicate that buffalo of Misan region is not suitable host for G1. This is the first record for G1BC genotype in Iraq. Only one (4.54%) of E. granulosus specimens was recorded as SB041 strain recorded by Beato et al. (2013) this genotype recorded in sheep (11.11%) hydatid cyst. The variations of morphological features of SB041 when compared with G1 and bosting with gene sequencing results and result of analysis with phylogetic tree (Figure 2) exhibited that our isolate (S.17) is likely to be SB041.

The phylogenetic analysis for mitochondrial Cox1 by the evolutionary history (Neighbor-Joining method) (Figure 2) showed that the majority of E. granulosus samples in various hosts aligned with G1 genotype. It also showed the origin similarity of some E. granulosus samples and strains (s.14-s.46, s.17-SB041) and (G2-G3-s.59, G6-G7).

Conclusion

Genotypes of E. granulosus circulating in Iraqi intermediated and definitive hosts were here updated: G1 was found to be the most dominant genotype in all examined hosts, G3 was also recorded for first time in Misan province.

The Human Arthropathy Inflammatory and Immune Herd Plots

Ibrahim M S Shnawa¹, Baha H H Alamidie²

¹Department of Biotechnology, College of Biotechnology, University of Qasim, Qasim, Babylon, Iraq;
²College of Dentistry, University of Babylon, Babylon, Iraq

ABSTRACT

The herd responses [HR] of human arthropathy patients were being assessed. Arthropathies can broadly be subdivided into; immune mediated and non-immune mediated. The immune mediated were of rheumatic and rheumatoid types. HR responses were of three main basic fractions. The low, the moderate and the high responders for the inflammatory, natural cellular immune and rheumatic herd responses. The nature of the inflammatory herd plot [Erythrocyte sedimentation rates] was of skewed plot type. While the natural cellular immune and the rheumatic response plots were of normal Gaussian distribution plot types. It is to be noted that these immune herd plots are being a novel finding in arthropathy patients.

Keywords: Arthropathy, Cellular, herd, immune, Rheumatic, Rheumatoid.

Introduction

A joint is an area of human body where two different bones meet. It functions to move the body parts connected its bones. Arthropathies are a group of human joint disorders featured by inflammatory, normal or overreacted immune responses. There are over-hundred types of human arthropathies. The main manifestation of these disease conditions are; joint pain, stiffness, swelling and tenderness. Their most common types are; osteoarthritis, rheumatic, rheumatoid and septic [1-5]. The aim of the present work was to report on the inflammatory and herd immunity plots for the arthropathy patients.

Materials and Method

Blood samples were collected [6] from the brachial vein of 60 arthropathy patients referred by the rheumatologists to microbiology laboratory, Department of basic sciences, College of dentistry, University of Babylon and microbiology laboratory, Department of Biotechnology, College of Biotechnology, University of Qassim as a test group and 10 apparently normal subjects as a control during the year 2018. The collected samples were divided into two portions one with anticoagulant for erythrocyte sedimentation rate [7], total leukocyte counts [7] and the other portion without anticoagulant for saving sera to investigate; acute Protein [6], ASOT, Rheumatoid factor [6] and serum uric acid [8]. Raw data were made in continuous class intervals to build up herd plots [9].

Results

I. Herd Responses: The nature of the human herd responses for the human arthropathy patients were found to be of three main responder types, as low medium and high. These herd response fraction types were noted in the inflammatory, the immune and the rheumatic responses, Table 1.

II. Herd Immunity: These arthropathy test patients were broadly divided into immune mediated and non-immune mediated types groups I to V, Table 2. The dual use of total leukocyte count, acute phase protein, rheumatoid factor and the anti-streptolysin O as a diagnostic battery and as herd immunity probes in arthropathy patients was proved to be valid for the immune mediated types group III and IV, Table 2.

III. Herd Inflammatory Plots: The outstanding sign of the inflammatory responses is ESR. The ESR values of the test patients were ranging from 20 to 140. The herd plot of these inflammatory responses was of skewed plot type, Figure 1. While the uric acid herd serum values were ranging from 5 to 9, and the herd plot was of normal Gaussian distribution curve, Figure 2.

IV. Herd Immunity Plots

*Natural Cellular Immune herd Plot*: The nonspecific cellular immune responses of the herd is represented by the total leukocyte counts of the arthropathy patients was ranging between 8000-14,500 cell/ml. for both sexes. The herd plot was of normal Gaussian distribution curve type, Figure 3.

*Rheumatic herd Plot*: The ASO titre represents the rheumatic response in arthropathy patient herd. The ASO titer was ranged from 300-1600 Todd U/ml. The herd plot type was of normal Gaussian distribution curve type, Figure 4.

Figure 4: Herd plot of rheumatic response in arthropathy patients
Discussion

Herd is a group of human individuals live at certain ecologic niche and showing mutual interplay with its biotic a abiotic components. Herd immunity is a collective rather than confined term to the common sense of immunity\(^\text{[10,11]}\). In the mere immunologic sense; carriers, past -infected, past -vaccinee and pre-immunity are the major elements of herd immunity\(^\text{[12]}\). The individuals forming the human herd expressed three responder types towards infection, vaccine and inflammation. Herd responses and herd immune probes, Table 3, have been found operative in; Typhoid, tonsillitis, periodontitis\(^\text{[10,13-15]}\).

</tbody>
</table>

In the present communication herd immunity plots are being reported in arthropathy patients using leukocyte counts, and ASOT as well as erythrocyte sedimentation and serum uric acid as probes. They were proved to be valid probes for herd immunity of arthropathy patients, Tables 1-3.

Molecular mimicry between Streptococcus pyogenes antigens and synovial antigens induce an autoimmune rheumatic arthropathy \(^\text{[16]}\). Positive acute phase protein response, positive rheumatoid factor, high erythrocyte sedimentation rates and high total leukocyte counts may indicate acute rheumatoid arthropathy\(^\text{[17,18]}\).

Conclusion

Three herd responder types were evident among arthropathy patients. Three Gaussian distribution and one skewed plot types were determined. Leukocyte count and antistreptolysin O and rheumatoid factor were found good probes for the immune mediate arthropathy. The adopted diagnostic battery seemed to be valid for the test patients. Herd immunity plots seemed to be a novel finding in arthropathy patients.

Acknowledgment

The authors wish to express their gratitude to the consultant rheumatologists at Merjan Teaching and at Hillah Surgical Teaching Hospitals for case referral.

Conflict of Interest: Non-conflict

Source of Funding: Self

Ethical Clearance: The research project is formally registered in both affiliated departments. Clinical samples were taken from the patients with complete their own satisfaction.

Congenital Lobar Emphysema—A Case Series for 2 Years

Ibrahim Shuker Mahmood1, Fawzi Salih Shihab2, Ahmad Mahmood Mohammed1

1Tikrit Teaching Hospital, Tikrit City; 2Tikrit College of Medicine, Tikrit University

Abstract

Background: Congenital lobar emphysema (CLE), a rare variety of congenital malformation of lung characterized by over distension of a lobe of a lung due to partial obstruction of the bronchus, can be a diagnostic and therapeutic challenge for the treating pediatrician.

Aim: To study the way of presentation, diagnosis, management and prognosis of CLE and comparing our results with other studies done in other centers.

Method: A case series of ten patients with CLE. All of our patients were managed in the department of pediatric surgery center at AL-KHANSAA hospital in Mosul city between January 2016 to January 2018.

Results: We have found that the right upper lobe is more affected than the left upper lobe and more than one lobe can be affected. The surgical treatment lobectomy of the affected lobe. The mortality rate was high in patients having congenital heart diseases and those with late presentation and complication. Ten patients, five male and five females, their ages ranged from 7 days to 6 months.

Conclusion: CLE is a rare congenital anomaly, most of our patients are infant less than 6 months old and most of them presented with respiratory distress, recurrent chest infection and some of them presented with pneumothorax.

Keywords: congenital lobar emphysema, respiratory distress, lobectomy, pneumothorax.

Introduction

CLE is a respiratory disorder of varying degree of severity which allows air to enter the lungs but not escape. (1) CLE is a rare condition, which is found in the neonatal period. (2)

Normally male babies are affected more often than females. CLE is usually unilateral affecting the left upper lobe followed by the right middle and right upper lobes. (3-6) Involvement of more than one lobe is rare. Similarly involvement of lower lobe is also extremely rare. (2) The current theory, which suggests inadequate cartilaginous support of the bronchus was first proposed by Gross and Lewis (7), and is most favored. (8) Polyalveolar lobe (an estimated three to five fold increase in number of alveoli for the whole lobe), is described by Hislop and Ried, in one of the recently described pathological entities that can give rise to CLE. (2, 7)

Aim of the Study: Prospective study on the way of presentation, diagnosis, management and prognosis of CLE and comparing our results with other studies done in other centers.

Patients and Method

From January 2016 to January 2018, ten cases with CLE admitted to the pediatric surgery center in AL-Khanssa teaching hospital. The cases were managed by different surgeons in the center. The medical records of these patients were registrated for age at presentation, sex, presenting symptoms, investigations, treatment and outcome. Most patients discharged from hospital in 7-8 post-operative days. We follow up the patient each 2 week for 3 months and then each month for other 3 month by physical examination and chest x-ray if indicated. Only two patients came regularly for follow up, the other four seen irregularly.

Results

Ten patients (5 males and 5 females) were included in this study. The age distribution of our patients range from 7 days to 6 months three patients at the neonatal age group and seven patients at infantile age group. Four (40%) patients were presented with RUL only while two (20%) patients lobe affect are RUL with RML. Two
(20%) patients lobe affect is LUL. One (10%) patient presented with RML and one (10%) patient presented RLL. The body weight ranged between 3Kg for the youngest 7 days female and 5.5 Kg for the oldest 6 months male. Two patients have associated congenital heart disease (ventricular septal defect).

All patients have dyspnoea, tachypnoea, and intercostals recession, some have attacks of cyanosis and wheezing. Deviation of the trachea, and mediastinum away from the affected side, hyperresonance on percussion and severely diminished air entry on the affected side were found in all patients.

In eight patients, the chest radiographs demonstrate over distention of the affected lobe. Within radiolucent zone, there are faint bronchovascular markings. (Figure 1 & 2)

CT scan in those five patients shows a hyperlucent, hyper expanded lobe with middle substernal lobe herniation and compression of the remaining lung. Mediastinum is significantly shifted away from the side of the abnormal lobe.
All the six patients have excellent prognosis and full expansion in affect side, except one patient died post-operative from heart failure due to congenital heart disease (VSD).

Surgical emphysema presented in one patient treated conservatively and the patient became well. Pulmonary edema in patient with congenital heart disease (VSD) and with heart failure. The patient died in the third postoperative day. Fever and atelectasis in two patients and treated conservatively.

In our study (3) patients died, (2) patients died pre-operatively, in intensive care unit, one of them with (VSD) and other one with late presented with pneumothorax. The third patients, have (VSD) operated upon but the patient died post-operatively due to the development of pulmonary edema and heart failure.

Discussion

In our study we reported ten cases of CLE from January 2003-January 2006 in Mosul province. Nuchtern and Harberg during a 10-year-period performed 1051 thoracic surgical operations, 22 (2.1 %) of them were for congenital lung cysts, and of these only 6 (0.6%) were for CLE. (10) Wesley et al over a 10-year-period reviewed 22 patients with congenital lung cysts, (3) of them were for CLE. (11)

Over period of ten years from 1990-2000, 12 children with congenital cystic disease of the lung were treated at Al-Qatif Center Hospital, Al-Qatif, kingdom of Saudi Arabia (KSA). Six of them had CLE. (12) In our study, all patients are full term infant and premature infant is not recorded as the same as in the other study show the CLE is characteristically found in the term infant, but acquired lobar emphysema is common among preterm. (13-15)

In our study we have three patients in the neonatal age group (30%) and seven patients in the infantile age group (70%). But in other study show: 33% of cases of CLE presented at birth and 50% are diagnosed at the age of one month. Presentation after 6 months is uncommon only 5% of the cases. (16, 17)

The age in our patients range from 7 days to 6 months (mean = 2.9 months). This may be due to progressive over distention of lobe after which birth is the main pathogenesis of CLE. (18, 19)

Histological examination showed large markedly over distended alveolar spaces without tissue destruction consistent with CLE. (12) The causes of CLE often cannot be identified, the airway may be obstructed or the infant’s lung may not have developed properly. (20) In our study, we reported only one case with positive family history which might reflect underlying genetic etiology. CLE has also been described in association with maternal chorioamnionitis and CMV pneumonitis. (21, 22)

Our study, is differ from other studies regarding the lobes affected.

The most common lobe affected is RUL about 40%, while in other study over period of ten years, from 1990 to the 2000 at AL-Qatif Central Hospital in Saudi Arabia six patients had CLE all of them the lobe affected is LUL. (12) CLE is usually unilateral disease affecting the left upper lobe followed by the right middle and right upper lobe and rarely lower lobes. (3-6) while in our study the lobe affected is RUL followed by (RUL & RML) and LUL, then RML and RLL. Involvement of more than one lobe is rare. Similarly involvement of lower lobes is also extremely rare. (2, 4) But in our study more than one lobe are affected 20% and lower lobe infected is 10%. Most babies with CLE presented with repeated attacks of cough, breathlessness, failure to thrive and refused feeding. (23) But in our study, most our patients with normal body weight as shown in table no.3 because most of our patients are very young and have early presentation and management.

CLE is frequently associated with congenital heart disease which should be looked for during the evaluation.
of these patients. In our study there are two patients 20% with congenital heart disease (VSD) diagnosis by echo-cardiogram. In other studies approximately 10%-12% of patients with CLE have congenital heart disease. In our study, the patients presented with acute respiratory distress soon after birth are four patients (40%), patients presented with recurrent attacks of chest infection are also four patients (40%) and patients presented with recurrent attacks of chest infection complicated by pneumothorax (complicated CLE) are two patients (20%). This finding is nearly similar to the other studies. The majority of patients with CLE presented early with acute neonatal respiratory distress, a small group of them may be asymptomatic or presented at a later age with recurrent chest infection. 

In all our patients on examination show ipsilateral hyperresonance on percussion and diminished or absent breathing sound in the affected side. The maximal cardiac dullness is shifted away from the side of the lesion. A proximately half of infant with CLE have varying degree of respiratory distress, and other have minimal symptoms until they develop an intercurrent respiratory tract infection. Most patients not diagnosed until they developed sever dyspnea when they are between 1 and 4 months of age, even though they had some respiratory difficulty earlier. 

In our study all our patients chest radiogram was done. The chest radiogram was diagnostic and five from our 10 patients CT scan was done to confirm diagnosis and excluded others causes of lobar emphysema. CT scan of the chest may be valuable in locating extrinsic etiological factors such as bronchogenic cyst, which must be considered whenever CLE is diagnosed.

The surgical treatment of CLE is total lobectomy which must be performed early, overcome the potentially life threatening acute respiratory distress and reduce the possibility of subsequent complication. AL-Bassam et al managed five children out of 37 with CLE conservatively and all did well with no surgical intervention.

We found surgical resection to be both safe and effective in the management of CLE. Total lobectomy is well tolerated in infants and children as growth and expansion of the remaining lung tissue is known to occur in children up to the age 5 years with subsequent total lung volume and function ultimately returning to normal.

In our study six patients have lobectomy of the affected lobe and all six patients became well and with excellent result post-operatively except one patient, died post operatively because the patient have congenital heart disease (VSD) and developed pulmonary edema and heart failure, the patient died in the third post-operative day. So the surgical treatment (total lobectomy) is the best treatment of CLE. In our study five patients from six patients lobectomy were done with excellent prognosis, but from four patients who were not operated two of them died preoperative and the other two have history of recurrent attacks of chest infection and failure to thrive.

In our study, the mortality rate high in patient with CHD, late presentation with complicated CLE (pneumothorax) and when more than one lobe is affected.

Conclusion

CLE typically affects young infant less than 6 months of age. The most common lobe affected with CLE are RUL then LUL. High mortality rate most commonly occurs in those with late in presentation, patients with congenital heart disease and when more than one lobe is affected. Treatment of CLE is surgical resection (total lobectomy). CLE has good prognosis after lobectomy in patient without other condition.

The Carotid Intima-Media Thickness in Workers with High and Low Exposure to Air Pollution

Isabella Laleno1, Muhammad Aminuddin1
1Department of Cardiology and Vascular Medicine, Faculty of Medicine Universitas Airlangga, Dr. Soetomo Teaching Hospital, Surabaya 60285, Indonesia

ABSTRACT

Background: The exposure to chronic air pollution is associated with cardiovascular morbidity and mortality through atherosclerosis acceleration and progression. Carotid intima-media thickness (CIMT) is an important subclinical sign of atherosclerosis.

Objective: To analyze the difference of CIMT between chemical industry workers with high and low exposure to air pollution.

Method: There were 66 male subjects who consisted of 33 chemical industry workers in the production division and other 33 non-industry workers who have worked for more than 1 year. The subjects underwent the examination of CIMT in left and right carotid artery.

Results: The mean of left CIMT test was 0.97 ± 0.08 mm in industry workers and 0.75 ± 0.15 mm in office workers. The mean of left CIMT test was 1.01 ± 0.09 mm in industry workers and 0.72 ± 0.10 mm in office workers. On the other hand, the mean of left and right CIMT test was 0.99 ± 0.07 mm in industry workers and 0.74 ± 0.11 mm in office workers. The difference analysis of left CIMT between two groups was examined by using unpaired t-test. There was no significant difference of CIMT value between subjects who worked in industry and office (p < 0.05; 9% CI 0.16 – 0.28). On the other hand, the difference analysis between left CIMT and the mean of left and right CIMT was measured by Mann-Whitney test. The results showed that there was a significant difference between two groups (p < 0.05).

Conclusion: There was no significant difference between subjects with high and low exposure to air pollution (p < 0.05).

Keywords: air pollution, subclinical atherosclerosis, carotid intima-media thickness (CIMT), cardiovascular

Introduction

Air pollution can cause human health problems (1). The association between the high level of air pollution and human health have been known since more than a decade ago. Several epidemiological studies support this association and indicate significant increased morbidity and mortality because of air pollution worldwide (2).

Air pollution consists of heterogeneous mixtures of various substances such as ozone (O3), carbon monoxide (CO), sulfur dioxide (SO2), nitrogen oxides (NOx), liquids, and particulate matter (PM). Various epidemiological data suggest that air pollution, especially PM, as the main risk factor causing serious health problems in humans. The PM consists of solid and liquid components from combustion of motor vehicles, road dust, forest burning, wind-borne soil, and volcanic emissions (3). PM which has aerodynamic diameter of <10 μm (or known as PM10) can enter directly into the lungs. On the other hand, PM with aerodynamic size of <2.5 μm (PM2.5) and <0.1 μm (PM0.1) can be inhaled to
the deepest part of the lungs, deposited in the alveoli, into the pulmonary circulation and possibly into the circulation systemic. The harmful effects of PM on the cardiovascular system have been established by various epidemiological and observational studies (4).

The rapid development of industrialization and urbanization in the last three decades has resulted in various adverse impacts on the environment, both in developing and developed countries in the world. In the world, especially in the United States and European countries, industrial environmental pollution is a controversial topic (5). Emissions to the atmosphere from various chemical industries, such as ammonia industry, urea industry and nitric acid industry including sulfur dioxide (SOx), nitrogen oxides (NOx), carbon oxides (COx), hydrogen sulfide, hydrogen cyanide, volatile organic compounds (VOC), NH3 and suspended particulate matter (SPM) which are the sources of air pollution (6).

Cardiovascular disease, until recently, has been a major cause of morbidity and mortality in developed and developing countries, and atherosclerosis is the underlying primary pathological mechanism. Atherosclerosis is a long-term process involving various mechanisms in it including lipid peroxidation and inflammation affecting the coronary vessel wall. Air pollution can contribute to an increased risk of cardiovascular events through initiation and promotion of atherosclerotic progression (1). Air pollution can trigger atherosclerosis in peripheral blood vessels, coronary arteries, and aorta. The mechanism by which PM causes atherosclerosis can not be determined. However, there are two hypotheses that have been proposed and have been tested experimentally. The first hypothesis is that the inhaled particles can trigger an inflammatory response in the lungs, which then releases various inflammatory and protrombotic cytokines into the systemic circulation (3). The other hypothesis stated that rapidly inhaled PM that can translocation into circulation, with potential effects directly on homeostasis and cardiovascular integrity. The data of experimental study showed that the mechanism of air pollution role on various cardiovascular cases including ischemia, endothelial dysfunction, activation of fibrinolysis system, and possible effects on destabilization of atherosclerotic plaque (7).

Carotid Intima-Media Thickness (CIMT) is a technique of measuring subclinical atherosclerosis progression that has been validated through various clinical trials. CIMT can assess non-invasive atherosclerosis by using ultrasound imaging directly, with high resolution, and with an automated data processing system (8). The quantitative measurement of CIMT correlates with all major risk factors of atherosclerosis and cardiovascular clinical cases. In the last two decades, CIMT has been widely used to estimate the risk of cardiovascular cases, such as acute myocardial infarction, stroke, and sudden cardiac death. The relationship between air pollution and CIMT as a sub-clinical atherosclerotic marker was first reported by Kunzli, et al. in 2005. Two cross sectional population-based studies that were Nixdorf Recall Study in German and Multi Ethnic Study of Atherosclerosis in United States also reported the association between air pollution exposure and CIMT change (7).

The researchers are intended to evaluate the carotid intima-media thickness in chemical industry workers in East Java that were highly exposed to air pollution compared to the workers with low exposure to air pollution.

**Method**

**Sample:** There were 66 male subjects that consisted of 33 chemical industry workers and the other 33 office workers. The subjects fulfilled the inclusion criteria including chemical industry workers and office workers who worked for more than 1 year, willing to join the research, and signed informed consent. The data was collected by using consecutive sampling method. The research was conducted on October-December 2013 in private hospital that manages safety and health at particular chemical industry in East Java (9).

This study was observational analytic study with cross sectional approach. The study protocol was approved by the Ethical Commission in Dr. Soetomo General Hospital Surabaya. The data analysis was examined by using unpaired t-test and Mann-Whitney test. The difference was considered significant if the value of \( p < 0.05 \). All the data analysis was processed by using SPSS software version 20 (10).

**Result**

The result of CIMT measurement used in this research is the measurement of thickness of intima - the posterior wall media (far wall) of right and left carotid artery, and the right and left combined mean
Table 1: The characteristics of carotid intima-media thickness of the research subjects

</table>

Note: SD = Standard Deviation; CIMT = Carotid Intima-Media Thickness; mm = milimeter

After the normality test performed in the left CIMT, it was found that the value had normal data distribution; therefore, the left CIMT difference analysis between the two groups used unpaired T test (Independent T test). There was a significant difference between industry workers (0.97 ± 0.08 mm) and office workers (0.75 ± 0.15 mm) with the significance value of \( p < 0.05 \); 95% CI 0.16 – 0.28

The results of right carotid artery measurements obtained mean CIMT of 1.01 ± 0.09 mm in industry workers, and 0.72 ± 0.10 mm in office workers. After the normality test, it obtained abnormal value distribution. The analysis of differences in the right carotid intima media thickness between the two groups was performed using non parametric test of Mann Whitney. Mann Whitney test results showed a significant difference between industry workers and office workers with a significance value of \( p < 0.05 \).

Discussion

A cohort study of young adults without cardiovascular disease showed that individuals exposed to higher pollutant exposure experienced faster progression of carotid intima-media thickness (CIMT). Air quality improvements are also associated with changes in CIMT progression in which decreased PM\(_{2.5}\) levels also indicates a slower CIMT progression. These findings suggest that long-term exposure to higher pollutants can accelerate the pathology of blood vessels \(^{(1)}\).

This study shows that the average intima-media thickness in industry workers was 1.01 ± 0.09 mm for right carotid artery, 0.97 ± 0.08 mm for left carotid artery, and 0.99 ± 0.07 mm for the combined average of both carotid arteries. It can be concluded that industry workers had abnormal CIMT value (normal value of 0.9 mm). On the other hand, the average intima-media thickness in industry workers was 0.72 ± 0.10 mm for right carotid artery, 0.75 ± 0.15 mm for left carotid artery, and 0.74 ± 0.11 mm for the combined average of both carotid arteries. It can be concluded that office workers had normal CIMT value (normal value of 0.9 mm). It means there was a significant difference in average value \( p < 0.05 \).

Industry workers experience direct contact with chemicals, and are in production sites where chemical pollutants are formed, whereas office workers never experience direct contact with polluting chemicals, and are located at a distance of 2 km from the production site \(^{(5)}\). These results are in accordance with with previous cross sectional and cohort studies indicating that the
closer the distance to high pollutant levels will lead to significant increases in CIMT values (11).

The relationship between air pollution and CIMT as a sub-clinical atherosclerotic marker was first reported by Mitchell, et al. (2019). The study observed the association between air pollution and atherosclerotic progression in humans. This study shows that closer distance to congestion sources and higher PM2.5 levels were associated with higher IMT progression in 1,483 adults in Los Angeles, USA. A cross-sectional analysis in adults showed that long-term PM2.5 concentrations greater than 10 mg/m3 were associated with a larger CIMT of 1% - 10%. Adar et al., investigated the progression of carotid intima media thickness and long-term PM exposure (12). Among the 5362 participants involved in the MESA (Multi-Ethnic Study of Atherosclerosis) with an average annual CIMT progression of 14 mm/year, increased PM2.5 levels of 2.5 mg/m3 during the follow-up period (2.5 years), it was associated with CIMT progression of 5.0 mm/year (95% CI, 2.6 - 7.4 mm/year) higher than those living in the same metropolitan area. This study reported that the association between exposure to air pollution and atherosclerosis in human was signed by CIMT changes (13).

Moreover, the association between long-term carbon black exposure in people living close to the main road with CIMT in elderly showed increased black carbon levels of 0.26 μg/m3 in a year was associated with increased CIMT of 1.1% (95% CI: 0.4, 1.7%). Rivera, et al. conducted a cross-sectional study using 2780 REGICOR participants, showing the long-term exposure of NOx for the 5th and 95th percentiles (25 μg/m3), traffic intensity (15,000 vehicles/day), and traffic loads at 100 m (7.2 million vehicles/m/day) corresponds to a CIMT difference of 0.56%, 2.32%, and 1.91% respectively (14).

The data have not been able to show the association between exposure to pollutants and the carotid intima-media thickness. Nevertheless, with statistically significant differences of the results, it can be assumed that workers who are in long-term direct contact with and exposed to highly concentrated pollutants have significantly abnormal and higher CIMT values than office workers (15). The limitation of this study is that the total of the sample was small; thus, it can not reflect the group population exposed to high and low air pollution levels overall. The researchers also can not directly measure the levels and types of pollutants existed in the workplaces of each group; thus, the high levels of pollutants are only based on the assumption that those who work in factories are exposed to pollutants are chronically higher, otherwise those working in the office are less exposed (4). This does not allow the researchers to be able to determine the association between the pollutant level and the carotid intima-media thickness(15).

In addition, there has been no research that can be used as reference for the carotid artery intima-media thickness in Indonesian who have various ethnics. It is still required better design and research methods as well as larger sample quantities to be able to determine the association between exposure to pollution and the carotid intima-media thickness. Another limitation is that blind was not performed in this study, and CIMT measurements are performed by one person and one measurement only; therefore, they can not be assessed for inter and intra-observer variations (7).

Conclusion

There was a significant difference between subjects with high (industry workers) and low (office workers) exposure to air pollution (p < 0.05). The subjects who were exposed to chronically high air pollution level had higher CIMT value than the subjects exposed to low air pollution level.

Ethical Clearance: This study involves participants in the process using a questionnaire that was accordant with the ethical research principle based on the regulation of research ethic committee. The present study is carried out in accordance with the research principles. This study implemented the basic principle ethics of respect, beneficence, non-maleficence, and justice.

Conflict of Interest: There is no report about conflict of interest since this study has been conducted until now.

Source of Funding: All of the research processes is funded by the authors only.

Using Species-Specific Polymerase Chain Reaction Technique for Detection of Cows, Buffallos, Seeps and Goats Milk and Cheeses in Basra City

Jalal Yaseen Mustafa

College of Veterinary Medicine, University of Basra

ABSTRACT

A polymerase chain reaction (PCR) was applied to identify cows’ sheep’s, goats’ and buffalo’s milk and cheese’s in Basra city by using specific primers targeting to identify the species of animals to detect the cheating in local and imported cheeses and in crude milk as a comparative point to detect accuracy of result come from amplified gene of cheeses. The present study aimed to develop a rapid PCR-based method for the detection of cows’, sheep’s, goats’ and buffalo’ cheese. The current study revealed that there was no cheating in imported cheeses, whereas, reported some cheating in the local cheeses compared with the crude milk as a standard to limited the accuracy of result.

Keywords: Species specific PCR; Cheese promoter, cows, buffalos, milk

Introduction

Cheese is a substance produced from the milk after transmitted from the liquid ship to gelatin or solid by curd the milk and separated the whey then maturation the result to contain the cheese. It is one of the oldest types of processed foods. Cheeses are considered to be food products made from the milk, because they are highly nutritious, tasteful, high-yielding, and high-growth. Species identification in animal products has received great attention in recent years. Particularly, species identification of dairy products has a remarkable importance for several reasons, including frequent human adverse reactions toward some species milk proteins and government regulations.

Some cheeses are manufactured from defined amounts of each type of milk. Thus, authenticity issues in cheese analyses are challenged not only by milk species identification but also by the need for quantitative determination of bovine milk in ovine or other animal cheeses manufactured from raw or processed milk.

However, as the estimated percentage of bovine milk in mixed cheese is strongly affected by the casein content of milks used for cheese manufacture, the results were approximate. On the other hand, methods for milk species quantification based on the whey protein fraction suffer from a shortcoming, as that fraction is more sensitive to heating than the casein fraction. Excessive proteolysis during cheese ripening can also be disadvantageous for quantification.

In recent years, significant attention has been turning towards DNA-based approaches. DNA-based approaches have proven to be reliable, sensitive and fast for many aspects of food authentication, for that the polymerase chain reaction is one of the most common genetic technique used for limited the species origin in food.

Milk from the ruminant healthy mammary glands has a large number of somatic cells, which contain genomic DNA acceptable for PCR amplification. Although it is known that somatic cells found in milk insist during cheese manufacturing and ripeness processes, protocols reporting the isolating of genomic DNA after cheese-laboring and use as a template for PCR amplification are more rare compared with other food model such as meat or fish. For instance, a multiplex PCR have been used to recognize the milk of bovine, caprine and ovine species in cheese products. In addition, convey

an affective PCR-based method for the limited of 1% level of undeclared bovine milk in water buffalo milk, mozzarella cheeses. Maudet, and Teberlet\textsuperscript{14} progressed a PCR-based technique for the detection of bovine milk in caprine cheeses\textsuperscript{15,16,17,18}.

**Materials and Method**

**Selection and Preparation of the Samples:** In the present study, one hundred twenty cheese sample were collected from the marketing cheese as follow. 20 sample from craft (cheddar cheese), 20 sample from Almarai (cream cheese), 20 sample from Kiri, 20 sample from Anchor, and 40 sample from local Basra cheese (20 from Curls cheese/Thefair cheese and 20 from bulk cheese/Arab cheese). Milk sample from four type of animals (Cow, sheep, goat and buffalo) was also collected as a comparative point with cheese. Samples were transported to the laboratory under refrigeration and processed immediately or stored at until used.

**DNA Extraction:** Genomic DNA was extracted from milk or cheese producer not more than two weeks from the prepared by using a Wizard DNA clean up kit (Promega, Madison, WI). Samples (2 ml from the milk) or (2 g from the cheese) were digested in 8.6 ml of extraction buffer, pH 8.0 (10 mM Tris, 150 mM NaCl, 2 mM EDTA, and 1 % SDS), 1 ml of 5 M guanidine hydrochloride and 200 µL of 20 mg ml proteinase K (Boehringer mannheim GmbH, mannheim, Germany). Then, the samples were incubated overnight at 55°C with shaking at 60 rpm and stand to cool at room temperature. Five hundred microliters of chloroform (Sigma-Aldrich) were then added to the lysate. The samples were then centrifuged at 13,000 rpm for 10 min. The clear aqueous supernatant (500 µL) was used to purify the DNA using the Wizard DNA cleanup system kit (Promega) with a vacuum manifold, according to the manufacturer’s instructions. Finally, the DNA was eluted in100 µL of sterile deionized water to know the amount of DNA in sample after extraction making Nano drop and recorded the concentrate of DNA by spectrophotometry at 260 nm and 280 nm.

Results and Discussion

In the current study, 120 cheese sample are tested for detection the cheating of the cheese either from cow sources or other type of animal. The concentration of DNA in the sample after extraction, limited by Nano drop, the result around (1.8-1.9), its normal and very good concentration of DNA between (1.7-2)\(^{19}\).

The result revealed high sensitivity of PCR technic to limited the accuracy of sources of milk type. This finding is in agreement with previous studied\(^{16,20}\). This procedure, followed by a DNA extraction protocol based on a commercial kit, proved to be highly efficient, yielding good quality DNA even when milk samples were submitted to severe heat treatments. The specificity of primer set chosen, greatly influences accurate species identification of PCR\(^{21}\).

The most extended techniques involve PCR amplification of a conserved gene fragment from a group of species by using universal primers, or amplification of DNA with specific primers for identification of a defined target organism\(^{22,23}\).

Figure (1) showing the result of PCR amplified for the cheese samples. This figure showing 300 bp band, this size for cow sources for cheese and milk, this sample for Kiri, Craft, Almari, Anchor and control point (milk from cow), the same sample we cannot see any amplified for primers for sheep, goat and buffalo in figure (2). This result mean the purity of milk used in preparing of cheese in these company. As well as, for a comparative unit, in the figure (1) showing amplification for GoaD primer for the sample from goat milk, the size of band (444 bp), M/INV primer for the sample from sheep milk, the size of band (371 bp) and for milk of buffalo, the PCR amplification band are (520 bp).

Fig. 1: Results of PCR amplification, lanes 1,10 is the ladders, lane 2 for BosD primer for Kiri, lane 3 for BosD primer for Craft, lane 4 BosD primer for Almari, lane 5 BosD primer for Anchor, lanes 6 for BosD primer from cow, lane 7 for GoaD primer from goat, lane 8 for M/INV primer from sheep, lane 9 for primer from buffalo

Fig. 2: Results of PCR amplification, lane 1 is the ladder, lanes 2, 3, 4 for GoaD primers from goat, lanes 5, 6, 7 for M/INV primer from sheep, lane 8, 9, 10 M/INV primer from sheep
Figure (3) showing the result of PCR amplified for the local cheese samples (both Curls cheese/Thefair cheese and bulk cheese/Arab cheese), in this figure showing 300 bp band, and sometime 444 bp, 300 bp for cow sources for cheese, while 444 bp for buffalo, this mean some of this sample are prepared from both cow and buffalo milk, but we cannot see amplified by sheep and goat primers.

This result reported some cheating in the local cheeses when we compared with the crude milk as a standard to limited the accuracy of result.

This result showed some cheating in the local cheeses when we compared with the crude milk as a standard to limited the accuracy of result.

Fig. 3: Results of PCR amplification, lane 1 is the ladder, lane 2 for BosD primer for cow, lane 3 for BosD primer from Curls cheese/Thefair cheese, lane 4 BosD primer from bulk cheese/Arab cheese, lane 5 buffalo primer from Curls cheese/Thefair cheese, lane 6 buffalo primer from bulk cheese/Arab cheese, lanes 7,8 GoaD primers from goat, lanes 9,10 M/INV primer from sheep

The result showing all the sample from Craft cheese, Kiri Cheese, Almarai cheese and Anchor cheese are the sources is cow. This finding showing in the figure (1) which revealed the size of PCR amplification gene (300 bp) and absent any amplify by other primers (sheep, goat and buffalo) in figure (2), this size of PCR amplification in our study is in agreement with previous study24 which used the same primer for detection cow sources of milk cheese compared with goat sources19.

The result showed the sample from local cheese sources is cow some time, whereas, sometime cow and buffalo. This finding showed in the picture (2) which revealed the size of PCR amplification gene some time just (300 bp) and sometime (300 bp and 520 bp), but we cannot see any amplify by other primers (sheep and goat). This size of PCR amplification in present study is in agreement with previous study24, which used the same primer for detection cow sources of milk cheese compared with goat sources19.

This result showed a huge problem because revealed the cheating in the milk which used for prepare the cheese because the absent of censorship which committed the animal breeder to use only one type of milk sources as well as the animal breeder talk about this type of chees are just from cow. The cheating because the high concentration of buffalo milk especially for lipid and the customer wanted cow cheese, for that the animal breeder mixing cow and buffalo milk to decrease the cost of milk preparing, as well as, many of the places of north Basra they have much of buffalo to used sources of milk to prepare the cheese. Bottero3 uses a set of 3 specific primers pairs allowing the detection of cow, goat, and ewe DNA in a single tube. Its advantage over the methods utilizes a single primer pair is the elimination of false negative results.

Once upon a time, tested a pair of primers designed by12 originally progressing for the identification of meat admixture of multiple species. It has been found that high specificity of the detection of bovine milk mixed with the milk of goat could be accomplished only when specific conditions of the test, including the accurate number of PCR cycles3.

In conclusion, the PCR method described hither is a beneficial and straight forward approach to detection low levels of cows’ milk replacement (0.1%) in milks of a higher commercial value. Furthermore, the style offers high sensitivity and specificity, with the best advantage that it can also be utilize in thermally or otherwise processed milk products with prolonged protein denaturation. Therefore, the PCR technique may demonstrate useful method for food inspection services to trace the species origin of milk mixtures or cheese.
products, thereby conserve the traditional manufacturers and consumers against food product adulteration and misrepresentation.

The Effectiveness of Chelating Property of Chitosan Nanoparticles on Dentin

Jamal A. Abu Al-timan¹, Hussain F. Al-Huwaizi², Hayder H. Abed³

¹Department of Esthetic and Conservative Dentistry, College of Dentistry, Almustansyria University, Baghdad, Iraq; ²Department of Esthetic and Conservative Dentistry, College of Dentistry, University of Baghdad, Baghdad, Iraq; ³Department of Basic Science, College of Dentistry, Almustansyria University, Baghdad, Iraq

ABSTRAcT

The use of chitosan nanoparticles (CNPs) will improve anti-microbial efficacy, mechanical integrity of diseased dentin matrix and tissue regeneration. Mechanical preparation in root canal treatment leads to the formation of smear layer. The aim of this study was to evaluate the effectiveness of chitosan nanoparticles in combination with Glyde gel in removing of smear layer. Twenty-five extracted maxillary single-rooted premolars were selected, and divided into five groups according to irrigation material used, (GI=Glyde gel, GII=2:1 (Glyde-CNPs) gel, GIII=NaOCl gel 5.25%, GIV=NaOCl gel 2%, GV=Saline only). The teeth were instrumented using ProTaper Next System (X1-X4) when one of five irrigant materials used as a lubricant during instrumentation. A scoring system was used to conduct the SEM assessment in coronal, middle and apical part. The statistical analysis was done with Chi square test at (P<0.05). The smear layer was significantly reduced in all groups except the control and NaOCl groups (P>0.05). Chitosan nanoparticles could enhance the activity of Glyde gel in removing the smear layer.

Keywords: Chitosan, Nanoparticles, SEM, smear layer, chelation.

Introduction

The chemomechanical preparation was the effective procedure to disinfect the root canal system. Bacteria are communities of cells adhered to an organic surface of dentin. The high density of bacterial cells are resistant to antimicrobials and was the main factor responsible for most persistent and chronic bacterial infection. Mechanical preparation leads to formation of smear layer. Which can be removed by using NaOCl and EDTA. NaOCl was one of the most recommended irrigant because of its ability to dissolve tissue and antibacterial activity. However, NaOCl can cause denaturation and dissolution of dentin collagen especially when using in high concentration and for a long periods of time, this may cause damage to ultra structural of dentin. In addition, NaOCl cannot debride root canal biofilm completely alone. It has been shown that irrigation with 17% EDTA has an effect on cleaning canal walls. Moreover, The using of NaOCl and EDTA in combination for effective cleaning and antimicrobial actions are more appreciable than being used alone.

Chelating agent mostly used as a final rinse in root canals, because it well remove the smear layer from root dentin. The smear layer may be solubilized in acids because its composed of very small particles. EDTA reacts with the calcium ions in dentin and forms soluble calcium chelates. However, the structural characteristic of the dentin could be altered by chelating agents which result in a compromised mechanical integrity and a increased potential for bacterial adherence on the collagen. Chitosan nanoparticles (CNPs) are one of the commonly investigated polymeric nanoparticles in endodontics.

Chitosan is a natural polysaccharide that is obtained by deacetylation of chitin, one of the most abundant polysaccharides in nature that forms most of the external skeleton of arthropods such as crabs and shrimps. Chitosan has a covalent immobilization of exposed dentin by its functional phosphate group which could be bind to calcium ions to form surface for crystal nucleation, resulting in the formation of a calcium phosphate layer. The resistance of the dentinal surface could be improved by chitosan treatment against the degradation by collagenase. Furthermore, chitosan has a chelating capacity, biocompatible, and antimicrobial effects against Gr+ve and Gr-ve bacteria as well as fungi.
The current study aims to investigate the ability of CNPs to enhance the ability of EDTA in Glyde gel to remove the smear layer from a root-dentin surface or not.

Materials and Method

Twenty-five extracted single-rooted maxillary premolar teeth were choose in this study. The teeth were cleaned from tissue and debris and stored in saline solution at room temperature. The radiograph from buccolingual and from mesiodistal was taken to verify that the root has a straight, single canal. The teeth, which had a wide or calcified canal, were discarded. The teeth were decoronated of 14mm from the apex. The patency of the canal was obtained by K-file #10 (Dentsply-Sirona, Switzerland). The apices were sealed with light cure flowable composite after inserting #10 inside the canal to prevent the materials from entering the canal. Polyvinylsiloxane (PVS) impression material were used for mounting the roots so that the entire root surface was covered by the impression material. The roots were randomly divided for five group, four experimental (n=5) and one control group. The instrumentation procedures were done by ProTaper Next system (X1-X4) (Dentsply-Sirona, Switzerland). Each group has a different irrigation material (Glyde gel, 2:1 (Glyde: CNPs) gel, NaOCl gel 5.25%, NaOCl gel 2% respectively, and normal saline for control group).

The experimental gel was obtained by adding chitosan nanoparticles to Glyde gel. The chitosan nanoparticles (80-100nm) obtained from Sisco Research Laboratories (SRL, India). This powder was dissolved in 1 V/V% acetic acid solution at a concentration of 0.1 W/V % in stirring machine for 8hs at 55°C. The pH of solution was raised to 5 with 1 mol/L NaOH. The concentration of CNPs was 10mg/ml was used in the experiment. The Glyde gel (Dentsply-Sirona, Switzerland) was used as a base material in this experiment. The chitosan solution (10mg/ml) was added to Glyde gel in concentration of 2:1 (Glyde-chitosan) to not change the flowability of the Glyde gel.

Fourier transform infra red Spectroscopy is a form of vibrational spectroscopy and reflects both molecular structure and molecular environment. FTIR spectroscopy (Alpha A. Bruker) was used to detect that CNP's still active in concentration 2:1 formula in the range from 4000-500 cm⁻¹. (Fig.1) The root canals were enlarged to size 20 with K-file, and the roots were filled with gel material during instrumentation. Instrumentation file (X1) was used to enlarge and shape the canal to working length, and when the file became loss, remove the file and irrigate the canal with 1ml distilled water to wash out the canal.

This procedure was repeated for X2, X3 till the end with X4. At the end of instrumentation, the distilled water inside the canal was suctioned out by the Micro Cannula (Coltene, Switzerland). In Group I, Glyde gel was used as the irrigant with an intermittent wash of distilled water. In Group II, The experimental gel was used while in group III, NaOCl gel 5.25% was used as an irrigant. In Group IV, NaOCl gel 2% was used as an irrigant and lastly in group V, Saline was used as an irrigant at the same procedure mentioned before. A scanning electron microscope (SEM) was used to evaluate the cleanliness of dentin on the instrumented canal wall surface. The roots were removed from impression material and prepared for SEM observation.

Two opposing grooves were done along the lingual and buccal root surface without penetration into the root canals using a diamond disc under water cooling to facilitate the splitting of the roots into halves. The splitting was done by a chisel, rinsed with distilled water and fixed in 4% formalin for 24h. For each tooth the half containing the most visible part of the apex was selected. The dehydration of the specimens was done by 80% alcohol for 15min, 90% alcohol for 15min, and 100% alcohol for 20min. All the specimens were mounted on aluminum stubs, sputter-coated with platinum and observed using a SEM. The images showing the canal wall surface at x5000 magnification was token from the apical, middle, and coronal portion.

The images were examined by two endodontic specialists who assessed the amount of area in each part was covered by a smear layer. The values obtained by one examiner that showed concordance with that from the other examiners and had the lowest amount of discrepancy between these observations were chosen for the statistical analysis. A scores of one to three were ascribed to each sample according to Torabinejad et al., 2003. No smear layer on the surface of the root canal; all tubules were clean and open was scored as one, no smear layer on the surface of root canal but tubules contained debris was scored as two, having smear layer covered the root canal surface and the tubules was scored as three. The statistical differences was done by Chi square test.
Results

FTIR Spectra of chitosan has characteristic band. The spectra showing a peak at 3347Cm⁻¹ indicate symmetric stretching vibration of OH and amine adsorption peak at 3024.51 Cm⁻¹ indicate presence of CH stretch (Fig. 1). The coronal third presented least amount of smear layer (most cleaner area) especially in GI and GII, followed by the middle third and the most amount of smear layer found in the apical part. This mostly seen in all the groups except in GV that used saline, all the three-thirds showed least amount of cleanness.

Figure 1: FTIR test for Chitosan nanoparticles combined with Glyde gel

However, GI and GII presented the least amount of smear layer and debris on the walls of dentin while GIII and GIV (NaOCl 5.25% and NaOCl 2%) presented a smear layer and debris on the walls (especially score II and score III) in all three thirds. In GV, a smear layer mud was seen on the walls of dentin in all thirds because of using saline for irrigation. (Fig. 2)
Discussion

The thickness of smear layer to be in the range of 1-2µm.\(^{(27)}\) The smear layer was more in volume in rotary preparation than in hand instrumentation.\(^{(28)}\) The smear layer may vary from one canal to another depending on the type and nature of dentin, and also the sharpness and geometry of cutting instruments.\(^{(25)}\) The smear layer may prevent the penetration at intra canal irrigants into dentinal tubules harboring microorganisms. However, the smear layer can be colonized by bacteria and protect the biofilms which adhered to dentin walls.

The adaptation of root canal filling materials could be effected by the presence of smear layer and lead to microleakage.\(^{(5,6)}\) On the other hand, if the canals contaminated by bacteria after preparation, the presence of smear layer might be able to prevent bacteria from entering into dentinal tubules.\(^{(29)}\) Nevertheless, smear layer itself contain bacteria and this will be always the primary concern in endodontic treatment. The removal of smear layer was effectively in the coronal and middle part of the canal, but its more difficult in the apical third, because of the size of the canal, taper and diameter, ramifications, deltas, isthmuses and permeability of dentin.\(^{(30)}\) Group II (chitosan plus the Glyde gel) experimental group, presented the least amounts of smear layer among all other groups at all three thirds (coronal, middle and apical) and there was no significant difference between the experimental group and the Glyde gel group. The coronal third presented the most clearness area from smear layer followed by the middle third, and the most amount of smear layer was in the apical part of the canals.

Chitosan nanoparticles are soluble in weak acid solutions and could be also soluble in water. The functional phosphate groups of the chitosan molecule bind to calcium ions on the dentinal surface and this lead to formation of crystal nucleation on the surface.\(^{(31)}\) Chitosan has a very good antibacterial effect against Gram +ve and Gram -ve organisms and fungi, because of its poly cationic nature. The cell wall of the microorganisms was altered by chitosan and subsequent leakage of intracellular constituents. The bacterial adhesion mechanisms also altered by using of chitosan, thereby preventing biofilm formation.\(^{(31)}\) Glyde root canal conditioner is a combination of EDTA
(15%) and carbamide peroxide (10%) used in a calcified areas within the root canal to facilitate the use of file. EDTA has the ability to clean the canal by removing the inorganic material, also has the ability to detach the biofilms adhering to root canal walls.\(^{(32)}\)

The chelation mechanism of chitosan to dentinal structure had a various theories. The first one stated that two or more amino groups of a chain of chitosan bind to the same metal ion, which is called the bridge model theory. The second theory said that only one amino group bind to the metal ion.\(^{(33)}\) Ionic interaction between the metal and the chelating agent occur because the chitosan polymer is composed of chitin which has got nitrogen atoms with free pairs of electrons. The process of formation of complexes between chitosan and metal ions occurs because of ion exchange, adsorption, and chelation. The chemical structure of chitosan, and the type of ions determine the type of interaction which take place.\(^{(34)}\) The negotiation of narrow and curved canals could be facilitated clinically by reduction in the micro hardness of dentin. The reduction in micro hardness facilitates the instrumentation techniques. Micro hardness of dentin will reduced when using the chitosan as an irrigating materials and its effects greater in higher concentration.\(^{(35)}\)

**Conclusion**

The mixture of chitosan nanoparticles and Glyde gel would be beneficial in improving the smear clearing efficacy. The mixture appears promising according to the evaluation as an irrigant material in the apical, middle, and coronal thirds of the root canal.

ABSTRACT

Background: An annual estimate of 4 million newborns were die in the first week of life worldwide. The high rate of newborn death is showing that the health development has not accomplished (WHO, 2012). According to Health Department in (Saputri, 2013), stated that about 57% newborn death were mainly caused by perinatal disorder and low birth weight. WHO and Unicef (2004) estimated among 20 million newborns, 15.5% baby in the world were born with low birth weight, and 95.6% among them were in developing country. The rate of low birth weight in Indonesia 2013 remained high. East Nusa Tenggara province had more low birth weight (15.6%) than national average (10.2%). Kupang denotes benchmark of East Nusa Tenggara province, had 337 cases of low birth weight, with the highest case came from the area of Manupaten Health Center with 35 cases (12.5%), and the lowest came from Oepoi, 13 cases (1.1%). One of main factors is the collaboration of health worker in integrated Ante Natal Care (ANC).

Aim: This research aimed to describe the collaboration of health worker in integrated ANC in health center.

Method: This research used qualitative method with phenomenon approach. The samples were health worker in Oepoi health center, chosen by means of purposive sampling (7 peoples). Result: There was a good collaboration among health workers in conducting integrated ANC in Oepoi Health Center, Kupang, involving doctor, dentist, midwife, nurse, nutritionist and laboratorian.

Conclusion: The health worker collaboration in integrated ANC has been done well.

Keywords: Health worker collaboration, low birth weight, health center

Introduction

The rate of baby death denotes one of indicator that affecting the aim of government sustainable millennium development program. Annual estimate of 4 million newborn deaths in the first week of life. The high rate of newborn death signifies that the development program in health is not accomplished yet (1). About 57% of newborn death occurred in less than a month old baby, and mainly caused by perinatal disorder and low birth weight (2). A newborn considered low birth weight if the birth weight is less than 2500 gram, disregarding the gestation period. Birth weight denotes the weight of the baby an hour after the labor (3).

Low birth weight remains a certain health problem in some countries, since it is considered as the cause of baby death. According to WHO, approximately 20million babies were born with low birth weight, and 19 million among them were from developing country, with incidence number of 11-31% (4). In developing countries, this condition is worsened by low nutrition intake during pregnancy, which causing micro-nutrients deficiency such as anemia, giving undesirable effect.

toward the expectant and the newborn (4). WHO and UNICEF (2004) estimated about 20 million babies in worldwide, 15.5% were born with low birth weight, and 95.6% of low birth weight newborn came from the developing countries. The rate of low birth weight in developing countries were 16.5%, double of developed countries, 7% (5).

The comparative of low birth weight cases, according to basic health survey (RISKESDAS) among provinces in Indonesia 2013, remained showing a high trend. Nationally, some provinces had a high cases of low birth weight, compared to the national average (10.2%); namely East Nusa Tenggara (15.5%), Middle Sulawesi (16.8%) and Papua (15.6%). Based on the district report 2011, it was noted that the number of low birth weight were 3484, increased in 2012 (3911), and further increased to 4457 in 2013 (6).

Kupang, denotes a benchmark for East Nusa Tenggara province, had 337 babies with low birth weight. Area of health center with the highest number of low birth weight cases was Manupaten Health Center, with 35 cases (12.5%) and the lowest number of low birth weight cases was Oepoi Health Center, with 13 cases (1.1%). One of main factor that correlated to low birth weight is the health service. An exquisite health service in preventing low birth weight case is necessary, especially in Ante Natal Care (ANC). Health service as the front line in giving health service, have an important role in giving health care toward society (7).

Previous research by Sakai (2016) also stated the effectivity of inter-profession collaboration, with good attitude and assurance of the health workers. Moreover, a favorable team management capability, building a good teamwork to fulfill the goal with well-organized action, that also will motivate to give a health service with more care toward the patient. Furthermore, a good attitude and behavior can build a strong teamwork to fulfill the requirement to give a professional health service, with a better quality (8). A good collaboration between health workers is expected to improve the quality of integrated ANC, that may prevent baby with low birth weight.

Against the foregoing situation, it is necessary to observe the collaborations between health workers in conducting integrated ANC in Oepoi Health Service in Kupang, as the health service with the least cases of low birth weight in East Nusa Tenggara. This study aimed to describe the collaboration between health workers in conducting integrated ANC in Oepoi Health Service in Kupang, East Nusa Tenggara.

Material and Method

This was a qualitative study with phenomenon approach. This study took place in Oepoi Health Center, Kupang, by means of guided interview. The examination of ANC can be evaluated from K4 report, pregnant women register and also direct observation. This study was conducted in March – June 2018, involving all the health workers in Oepoi Health Center as much as 37 peoples (4 general practitioners, 1 dentist, 9 nurses, 9 midwives, 3 pharmacists, 2 public health scholars, 3 nutritionists, 3 sanitarians, and 3 laboratorian). After applied the inclusion criterias which were the health workers who have been working since January 2017; the health workers who are handling ANC in health center; agreed to be the respondents the samples reduced to 7 respondents.

Findings

Geographically, Oepoi belongs to the area of Oebufu District, Sub-district Oebobo, Kupang with an area of 3.5 km². The working area of Oepoi Health Service included 4 sub-district, namely Oebufu, Kayu Putih, Tuak Daun Merah, and Liliba. Meanwhile, the human resources in each work unit in Oepoi Health Service in 2017 are 4 doctors, 1 dentist, 9 nurses, 9 midwives, 3 pharmacists, 2 public health scholars, 3 nutritionists and 3 medical analysts.

Table 1: Health workers distribution based on age

<table>

</tr>
<tr>
<td>36-45 y.o.</td>
<td>5</td>
<td>70</td>
</tr>
<tr>
<td>Total</td>
<td>7</td>
<td>100</td>
</tr>
</tbody>
</table>

Table 1 is showing the distribution of health workers based on the age group. Most of the respondents were belong to 36-45 years old group (70%) and the least belong to 26-35 years old group (30%).

The evaluation of integrated ANC by the health workers of Oepoi Health Service Kupang is tabulated.
in Table 2. It was recorded that integrated ANC had been well-conducted, which mean that it was conducted according to the standard operational procedure.

Table 2: Evaluation of health workers collaboration in doing Integrated ANC

<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Total</td>
<td>7</td>
<td>100</td>
</tr>
</tbody>
</table>

Table 2 is showing that the evaluation of collaboration in integrated ANC showing that all the respondents were doing a good collaboration. The result shows that the collaboration has been done well, thus, the case of low birth weight in Oepoi Health Service is less compared to the other Health Services in Kupang.

Discussion

Collaboration between health worker in conducting integrated ANC: The description of collaboration that was done by the health workers, including doctors, dentist, midwives, nurses, nutritionists, public health scholars and laboratorian will be explained as follows:

1. Doctors’ Collaboration: General practitioners give an excellent service toward the patients, and have a good faith toward the ongoing collaboration. This can be concluded based on the doctors’ statements as follows:

   “I belief that all my colleagues involved in integrated ANC are able to collaborate and cooperate. All of them are giving the best according to their competence, and I belief in that. Therefore, I have no worries regarding other trivial matters.”

   “I give health service not restricted to pregnant women only, but also the family. I also remind them to regularly visit health center for checkup. As the head of this health center, I also acknowledge that health workers in health center have important role in preventing low birth weight.”

   The result of the current evaluation is in accordance to previous study by Agus (2015) which stated that a good quality of health service is necessary, particularly in preventing low birth weight, by giving ANC. Health center, as the front line in giving health services to the society have an important role, including giving ANC to the pregnant women (7).

2. Dentists’ Collaboration: Dentist is also reported giving a good health service. There are two dominant aspects that correspond to the general practitioner did, namely have faith in collaboration and give a full care of treatment to the patients. These are the dentist’s statement:

   “It’s an honor to be able to cooperate with other profession.”

   “We always discuss all the things that we don’t understand”

   “Our duty is to communicate to other team members, so that we can work together, caring the pregnant women. We do our best to prevent oral and dental problems in pregnant women, and immediately treat those who have oral and dental problems.”

   Those statements is correspond to the theory of collaboration, which stated that a collaboration is based on principles of togetherness, equality, responsibility and accountability (9).

3. Midwives’ Collaboration: Midwives also have contributions in this collaboration. The result of observation also proved that midwives gave services better than the others. Their statements as follows:

   “This is a sacred profession, and of course, I belief that inter-profession teamwork may make better integrated ANC, thus, preventing low birth weight.”

   “We cannot work all alone, there are team from the other profession that give us so much help. Without them, I don’t think we can make it happen.”

   This result is in accordance to the statement that a goal can be accomplished faster and better if done in teamwork. In a good teamwork, the team member should be able to cooperate and collaborate to reach the set goal (10).

4. Nurse Collaboration: The observation revealed that the nurses in health center were able to build
a good collaboration. A good attitude and belief as a professional, is an important factor to build a good teamwork. These are the nurses’ statements:

“I have faith in our colleagues, that they are able to complete the task well.”

“In every meeting, I always give my best to keep this team solid.”

According to Smith (2017), collaboration is a process where the doctors, nurses, and other health workers create a plan and work together as colleagues, with each other competencies limitation and give respect to each other involved in giving services toward individual, family, and society (11).

5. Nutritionists’ Collaboration: Nutritionists in health service also doing a good collaboration, by giving deep care toward the patient and also the team, which help make the team become solid. These are the statements of the nutritionists:

“I give support and my best to our colleagues in other profession. When there is pregnant women with nutrition deficiency, I will give food supplement, health education and regular nutrition counseling immediately, until they recovered.”

“We will also educate the family, so that they can help pregnant women in home.”

To build a good collaboration, giving each other support is necessary. Each profession occasionally doing their work separately, this may be an obstacle in collaboration. The willing to share, depend and help each other will eventually improve the collaboration (11).

6. Public Health Scholars’ Collaboration: Public health scholars also did a good job in collaboration, better than the other profession. Public health workers have a good team management, which may encourage the society in health service work area to build a collaboration to prevent any pregnancy disorder, and especially, prevent baby birth with low birth weight. These are the statements of public health workers:

“Aside from this team, we also try to reach ward office to work together in facing public health problem, especially regarding pregnant women.”

“Actually, the key role lays in communication among team member. The more we have intense group discussion and good communication, the less weight we bring, as all of the team member are there to give a hand.”

In collaboration, a good communication is necessary to make the work and message relay ease. Each member should be able to receive and give advices to others. Communication is a key in a collaboration (12).

7. Laboratorian Collaboration: Laboratorian did a good job in collaboration, by giving a better service and care toward the patient. This may be due to their focus more on laboratory.

“Our duties, indeed, in laboratory. All the pregnant women who did check-up will get a good service, and we also discuss with our other-profession colleagues.”

“We convey and discuss the lab test result of the pregnant women, so that we can give the best explanation and advice to prevent painful labor and baby with low birth weight.”

The knowledge from each individual, should be shared to help the others. Therefore, it may help to find a better solution to face a problem together (12).

Conclusions

Based on the observation, it can be concluded that integrated ANC by the health workers in Oepoi Health Center is well-conducted with a good coordination, which make the low number of low birth weight cases in Oepoi Health Center. In order to maintain the good achievement, it is advised to distribute the necessary tools of ANC to the health workers in health center. This collaboration model can be adopted by other health service, although a further research remains

Conflict of Interest: There is no conflict of interest for every author.

Source of Funding: This research funded by self-funded

Ethical Clearance: There are no human participants involved in this research. However the procedure of this research had already gotten ethical approval of Health Research Ethics Committee, Faculty of Public Health, Univeritas Airlangga.

ABSTRACT

Background: The role of Zinc as an anti-oxidant and anti-inflammatory has been proven and this substance is relatively cheap and easily obtained by the community. This research aims at analyzing the effect of 40 mg/day of Zinc sulfate for 12 weeks on zinc and pro-inflammatory cytokines TNF-α, IL-1β and IL-6 in MB-type leprosy patients.

Method: The study design used randomized pretest-posttest control group design, the study subjects were MB patients with 121 patients who did not experience leprosy reactions, 31 subjects were analyzed as a supplementation group, and 31 patients as a control group. Measuring serum zinc levels using method Atomic Absorption Spectrophotometer (AAS), the levels of TNF-α, IL-1β and IL-6 using method of ELISA, statistical analysis using independent t-test, paired test, Mann Whitney and Wilcoxon sign rank test.

Results: Zinc sulfate supplementation of 40 mg/day for 12 weeks in MB-type leprosy patients controlling the decrease in zinc levels of 1.22 pg/dL was higher than leprosy patients who did not receive Zinc sulfate supplementation, significantly reducing IL-1β cytokine levels (p: 0.032), but significantly reduced cytokine levels, TNF-α (p: 0.063) and IL-6 (p: 0.389).

Conclusion: Zinc sulfate supplementation of 40 mg/day for 12 weeks in MB type leprosy patients controlled the decrease in serum Zinc levels, and reduced levels of pro-inflammatory cytokines IL-1β.

Keyword: Zinc supplementation, TNF-α, IL-1β, IL-6, MB, leprosy

Introduction

Leprosy is a chronic disease caused by an infection of the bacterium Mycobacterium leprae. This disease is a major cause of deformity and disability among other infectious diseases that cause stigma, psychosocial and economic disorders (¹).

Leprosy is a public health problem in developing countries and is often associated with poverty and often associated with malnutrition. Poor nutritional status can be caused by inadequate food intake both in quantity and quality of food (²). Individuals with leprosy eat vegetables more often and rarely consume animal protein. Most vegetables are not a good source of zinc because of phytate. This substance will bind zinc so that zinc cannot be absorbed by the gastrointestinal tract. Low-protein and rich diets phytate- play a role in the high prevalence of zinc deficiency in developing countries. Zinc deficiency leads to decreased immunity in the form of macrophage cell failure in the process of phagocytosis and decreased T-cell ability for differentiation and proliferation (³).

Several studies on animal experiments and clinical observations in humans, the state of nutrition plays a role in the journey and development of leprosy and among these nutritional elements, zinc is the most important trace element for the growth of thymus organs and lymphoid tissues, which act as organs in differentiation and maturation of cells which is involved in cellular immunity (⁴).

Decreasing the immune system and increasing leprosy infection can be caused by low levels of zinc in the body. Zinc is able to play a role in increasing immune
response nonspecifically and specifically. Macrophage cells that play a role in immune response systems will experience problems in killing intracellular infectious agents, decreasing cytokine production and obstacles in the process of phagocytosis (4).

This research is expected to be useful for programs to improve nutritional status, especially the levels of leprosy patients’ zinc and as an evaluation program for the prevention and management of leprosy reactions.

Method

This research is an experimental study using randomized pre and post test control group design. The study began from grouping leprosy patients based on the diagnosis: leprosy with reaction and leprosy without reaction as the research subject. This study was conducted in 11 Health Center areas in Tegal Regency in January-May 2018. The inclusion criteria for the sample in this study were male and female patients, age 15-60 years, leprosy type MB in MDT treatment, without reaction, and willing to participate in research. The research subjects were randomly selected, the treatment group was a type of leprosy with MB clinical signs of reaction and the control group was MB leprosy without reaction. Data collection using questionnaires through history, interview, clinical examination, and blood serum examination in case subjects and controls. The number of samples of 72 people consisting of treatment groups 36 people and a control group of 36 people. The case group was given Zinc sulfate supplementation with a dose of 40 mg/day for 12 weeks while in the control group only MDT was given. Data analysis using program SPSS for windows with Correlation test Chi-Square and test t.

Results

At the beginning of data collection, the subject of the study amounted to 72 participants, until the end of Zinc sulfate supplementation the number of subjects who met the criteria for analysis amounted to 62 people (Treatment group 31; control group 31). The characteristics of the research subjects in both the treatment and control groups can be seen in Table 1.

Table 2 shows that reaction risk factors in the subjects of the study were co-infection, food intake, anemia status (Hb level), and daily food intake, both in the treatment and control groups, statistically get results there are no significant differences. Differences exist in mean levels of Hb, Zinc, TNF-α cytokines, IL-1β, and IL-6 before and after Zinc sulfate supplementation at a dose of 40 mg/day in MB type leprosy.

Discussion

Leprosy infection in host is associated with the quality of the immune response (6). The main defense mechanism in M. leprae infection involves immune cells, especially macrophages, lymphocytes and cytokines that regulate the production, release and modulation of cellular immunity reactions (5).

Macrophages are the main defense system against M. leprae infection. Phagocyte cells such as macrophages, neutrophils, eosinophils and T and B lymphocytes have the enzyme NADPH oxidase which is responsible for the production of ROS when stimulating the immune response. Macrophages will recognize M. leprosy or its cell wall components through TLR, this bond will activate the nuclear factor kappa B (NF-κB) pathway which will induce the release of cytokines such as TNF-α, IL-1, IL-6 and IL-12. These cytokines will cause inflammation and stimulate adaptive immunity. Interleukin-12 will activate T cells and induce the release of IFN γ which in turn activates the enzyme phagocyte oxidase (NADPH oxidase) so that ROS releases such as superoxide, hydroxyl radicals and hydrogen peroxide occur (7).

The distribution of the characteristics of the research subjects showed that there were more male subjects than women. These results are in accordance with a previous study by in Brazil showing that the number of male leprosy patients was more than that of women (8). Leprosy is more common in men with a ratio of 2: 1, whereas according to age the incidence increases at the age of 10-14 years, then decreases followed by another increase at the age of 30-50 years.

Regarding nutritional status, Singh reported that 40.5% of patients who experienced a decrease in hemoglobin levels had a body mass index (BMI)> 18.5 and 59.5% less than that. BMI> 18.5 shows normal nutritional status, while BMI <18.5 indicates malnutrition. Several previous studies have found that micronutrient intake affects the immunological response in leprosy (9). In this study most BMI subjects between leprosy groups and healthy (non-leprosy) groups had normal BMI. This is contrary to previous research which found a significant difference in BMI and Zinc status in leprosy patients with a control group (not leprosy). Most of the research subjects in the leprosy group worked as laborers who were fed food for enough energy when on the move. But if it is observed from a recall of 1x24 hours of food intake consumed, most groups of leprosy consume vegetables more often and consume a little food intake sourced from animal protein. The mean BMI in the case group was 21.09 and in the control group (10).

Based on statistical tests, there is a relationship between energy adequacy rates and protein adequacy rates with the incidence of leprosy reactions. According to previous research, respondents who lack intake of nutrients, especially energy and protein, have underweight nutritional status. Theoretically, lepers will have a thin nutritional status due to increased protein catabolism (11). If this is not supported by providing.
enough protein food, subjects living side by side with leprosy sufferers noted that high protein intake is needed for sufferers and even people around them to increase endurance. Patients with less weight do not have sufficient immunological responses due to low levels of energy and protein consumption will cause abnormalities in immunity as indicated by a decrease in the number of T lymphocytes, decreased cell activity natural killer, and decreased function of interleukin production (12).

The average Hb level in the case group 11.5 and the control group 12.1 were both below the normal Hb level. According to WHO the normal male Hb level was 13 g/dl and adult women 12 g/dl, was declared anemia if the Hb level was lower than normal limits. Anemia in leprosy is caused by a chronic disease, usually me is iron deficiency anemia because of the destruction of iron and iron binding proteins by macrophages, disruption of iron metabolism and release of cytokines which suppress erythropoetin production (13).

In this study the results of the zinc serum levels of the study subjects (± 95 µg/dL) were below the average level of healthy human Zinc (± 104 µg/dL), when seen the average level of Zinc in the treatment group after receiving Zinc sulfate supplementation 40 mg/day for 12 weeks there was a decrease in zinc levels of 1.8 µg/dL, while in the control group it decreased at 3:02 mg/dL, and the statistical test results prove there is a significant difference between serum zinc levels before and after supplementation (p: 0.003). Zinc levels in patients with leprosy can cause bacterial multiplication M.leprae because of decreased cellular immunity which plays a role in eliminating micro bacteria. Zinc supplementation in patients will provide a good influence on increasing levels of Zinc serum which is important for the development of cellular immunity (14).

The daily intake of male zinc intake in a day is 11 mg and adult women is 8 mg, and the mean zinc level of leprosy patients who have previously reacted is lower than patients who have never reacted in the control group, but not significantly different. Based on the results of this study there was a significant difference between the levels of Zinc which received 40 mg/day Zinc supplement intervention and the control group, according to the results of previous study, after 8 weeks supplementation of the intervention group significantly had a higher Zinc concentration than control group (13).

The results of this study also showed increased levels of zinc serum and decreased levels of TNF-α and IL-6 after Zinc supplementation, this is consistent with previous studies that plasma Zinc concentrations rapidly decrease during acute phase responses to different stimulation, pressure, infection, and trauma. (14)

Pro-inflammatory cytokines, including TNF-α, IFN-γ, and IL-1β and IL-6 have been reported to play a role in the mechanism of leprosy reactions both type I reactions (reversal reactions) and type 2 reactions (including ENL).

Chronic inflammation is characterized by an increased level of production of inflammatory cytokines. Some conditions are associated with chronic inflammation such as obesity, where patients with lower zinc food intake present with lower plasma and intracellular zinc concentrations together with IL-1α, IL-1β, and IL-6 gene expression that are regulated compared with patients with Higher zinc intake (16).

In addition to TNF-α inhibiting agents, ENL treatment is corticosteroids, because in addition to having anti-inflammatory and immunosuppressant effects, corticosteroids also have a barrier effect on the activity of various cytokines such as IFN-γ, TNF-α, IL-6, IL-1 and IL-2 receptor expression. Oral corticosteroids recommended by WHO are prednisolone, starting with a dose of 0.5–1 mg/kg/day (40–60 mg) until clinical improvement occurs, then lowering 5-10 mg every week for 6-8 weeks. The treatment dose of 5–10 mg/day can be given several weeks to prevent recurrence of ENL (13).

Production of cytokines can also be decreased by administration of MDT, even cytokines can drop to the same level as healthy patients if all M. leprae antigens can be eliminated. Decreased levels of TNF-α were also found in patients after receiving MDT, which showed a decrease in the number of bacteria due to therapy. Klofazimin has anti-inflammatory effects and can inhibit mitogen stimulated by peripheral blood cells. Together with dapsone, clofazimin can reduce the production of cytokines, especially pro-inflammatory cytokines. Therefore, MDT must still be given when ENL occurs, because MDT can also control ENL episodes (13).

**Conclusion**

Zinc sulfate supplementation of 40 mg/day for 12 weeks can maintain a decrease in serum Zinc levels, and
reduce IL-1β levels, however statistically there is not
enough evidence to reduce levels of TNF-α and IL-6.
Lepers need to pay more attention to the frequency and
quality of daily food intake by fulfilling sufficient energy
and protein needs and need to consume Zinc Sulphate
tablets during treatment.

The Status of Her2 Expression in a Group of Iraqi Women with Cervical Carcinoma

Kawakeb N Abdulla¹, Basim M. Khashman¹, Saba Jassim Alheshimi², Ameer A. Oudah³
¹Iraqi National Cancer Research Center, University of Baghdad; ²Lecturer of Gynecology and Obstetrics, College of Medicine, Misan University, Iraq; ³Department of Clinical Pharmacy, Baghdad Medical City, Baghdad, Iraq

ABSTRACT

Background: Cervical cancer is the third most common cancer and fourth leading cause of death in women worldwide. HER belongs to family of receptors plays a central role in the pathogenesis of several human cancers. They regulate cell growth, survival, and differentiation via multiple signal transduction pathways and participate in cellular proliferation and differentiation. HER2 expression in cervical cancer has been reported to be present in recurrent tumors and its expression is related to poor prognosis in locally advanced cervical cancer.

Objective: study Her2 expression and its correlation with the development of cervical carcinoma.

Method: a retrospective study was designed to involve about 30 formalin fixed paraffin embedded tissues blocks from Iraqi women with cervical carcinoma. The immunohistochemical staining was performed using anti-Her2 to evaluate the expression of this marker.

Results: From the 30 formalin fixed paraffin embedded tissues blocks, 5 were positive for Her2 and 25 were negative. All the 15 normal cervical tissue blocks were negative for Her2.

Conclusion: A significant correlation between Her 2 and cervical cancer.

Keywords: Her 2, cervix, cancer, Iraqi women, immunohistochemistry

Introduction

Cervical cancer is the most common form of cancer in women in developing countries and the third most common form of cancer in women in the world as a whole. The major risk factor for the development of pre-invasive and invasive carcinoma of the cervix is human papillomavirus infection. Cervical screening programs have dramatically improved cervical cancer incidence and reduced deaths, but cervical cancer still a health burden. The biomarker discovery for detection and diagnosis of cervical carcinoma represents one of the current challenges in clinical medicine and cytopathology. HPV infection causes changes in expression of host cervical cell cycle regulatory proteins. These host proteins may have a role as ‘biomarker’ of dysplastic cells. One of these biomarkers is HER2 (human epidermal growth factor 2) is a protein and is a member of the human epidermal growth factor receptor family. HER receptors belong to family of Tyrosine kinase. Over-expression of HER 2 has been shown to play an important role in the development and progression of certain aggressive types of breast cancer. In recent years the protein has become an important biomarker and target of therapy for approximately 30% of breast cancer patients. It is strongly associated with increased disease recurrence and a poor prognosis of some cancers. Over-expression is also known to occur in ovarian, aggressive forms of uterine cancer, such as uterine serous endometrial carcinoma. HER2 testing is performed in breast cancer patients to assess prognosis and to determine suitability for certain therapy. In cervical cancer, HER2 receptor expression has been reported to be upregulated, but its prognostic and therapeutic value remains unclear.
The signaling pathway of EGFR may be dysregulated in cancer and is associated with carcinogenesis and tumor growth. In cervical cancer, EGFR is a potential prognostic biomarker, since the co-expression of EGFR is associated with a poor response to chemo-radiation.

HER2 expression can be identified in various cancers other than breast; its incidence ranges from 1% to 12% in cervical cancers. HER2 expression in cervical cancer has been reported to be present in recurrent tumors and that its expression is related to poor prognosis in locally advanced cervical cancer.

**Material and Method**

A retrospective study was designed to involve 30 formalin fixed paraffin embedded tissues blocks from Iraqi women with cervical carcinoma and 15 normal tissue blocks. The immunohistochemical staining was performed using anti-Her2 to evaluate the expression of the marker.

Analysis of the results was done using Easy Fisher Exact Test Calculator.

**Results**

The immunohistochemical expression of HER2 was evaluated. From the 30 formalin fixed paraffin embedded tissues blocks with cervical cancer, 5 were positive for expression of Her2 and 25 were negative. All the remaining 25 cervical cancer tissues blocks were negative for Her2. All the 15 normal cervical tissue blocks were negative for Her2, there was no significant difference between both groups. As shown in table 1.

Discussion

Cervical cancer is a major women health problem worldwide. It ranks high among the causes of female cancer mortalities and is an important disease in developing and developed countries.

The tumor markers is conventionally used for screening, but recent studies have revealed the mechanisms of carcinogenesis and the factors associated with a poor prognosis in cervical cancer. Utilization of biomarkers may facilitate personalized treatment and improved outcomes in cervical cancer, biomarkers for predicting prognosis have emerged from recent studies. The human epidermal growth factor 2 (HER2) is a transmembrane receptor tyrosine kinase located on chromosome 17q21. In normal cells, activation of HER2 mediates cell signaling pathways including the phophotidylinositol 3- kinase/protein kinase B and others which regulate cellular processes of proliferation, motility and survival. HER2 overexpression resulting in several reactions which leads to uncontrolled cell proliferation, angiogenesis and invasion leading to tumor growth and invasion.

In the present study, Her2 expression was found in 5 of the 30 tissues blocks of cervical carcinoma which was studied through immunohistochemical staining. All the 15 normal cervical tissue were negative for Her2. This result was in agreement with a study done by Iida et al were they found significant amplification of the EGFR locus in six of 59 cases of cervical SCC, but in none of 52 cases of adeno/adenosquamous cell carcinoma, with EGFR amplification significantly correlated with shorter overall survival rates.

A study on cervical cancer samples by immunohistochemistry also revealed that HER2 was frequently expressed in (53.5%) of the studied samples. The overexpression of Her2 may be behind the abnormal growth of the stimulus to cells to become abnormal or cancerous cells. As in some studies were they found that HER2 overexpression is related to a worse prognosis in cervical cancer.

On the other hand the overexpression of HER2 may have no relation to the changes that stimulate the cervical normal cells to change into cancerous cells but there are other factors that play this role as shown by a study done by Alma Chaves et al were they found low frequency of HER overexpression in the studied samples of cervical cancer.

Conclusion

This study showed the importance of HER2 expression in the pathogenesis of cervical cancer which may have an importance in the diagnosis. We recommend to perform a study on large number of tissue blocks in the future to clarify the relation between HER2 and cervical cancer.

The Immunohistochemical Evaluation of BRCA2 Expression with HPV Infection in a Group of Iraqi Women with Cervical Carcinoma

Kawakeb N Abdulla1, Basim M. Khashman1, Saba Jassim Alheshimi2
1Iraqi National Cancer Research Center, University of Baghdad; 2Lecturer of Gynecology and Obstetrics, College of Medicine, Misan University, Iraq

ABSTRACT

Background: Cervical cancer is the third most common cancer and fourth leading cause of death in women worldwide. There is an increased evidence of correlation between BRCA with HPV onco-proteins. Some researchers found that the E7 and E6 onco-proteins interact directly with BRCA1 in vitro and associate with BRCA1 in vivo in cultured cells.

Objective: study BRCA2 expression and its correlation with the oncogenic HPV16 in Iraqi women with cervical carcinoma.

Method: A retrospective study involve 30 formalin fixed paraffin embedded tissues blocks from Iraqi women with cervical carcinoma previously diagnosed for HPV infection. The immunohistochemical staining performed using anti-BRCA to evaluate the expression of both markers.

Results: From the 30 formalin fixed paraffin embedded cervical carcinoma tissues blocks, 8 blocks were positive for BRCA expression and 22 were negative. All the normal cervical tissue blocks were negative for BRCA.

Conclusion: immunohistochemical evaluation of BRCA2 expression with HPV infection in a group of Iraqi women with Cervical Carcinoma was significant.

Keywords: BRCA2, HPV17 infection, oncogene, cervix, cancer, Iraqi women, immunohistochemistry

Introduction

Cancer of the uterine cervix is the third most common gynecologic cancer diagnosis and cause of death among gynecologic cancers in the United States 1. Cervical cancer has lower incidence and mortality rates than uterine corpus and ovarian cancer, as well as many other cancer sites. These rankings are similar to global estimates for other developed countries. Unfortunately, in countries that do not have access to cervical cancer screening and prevention programs, cervical cancer remains the second most common type of cancer (17.8 per 100,000 women) and cause of cancer deaths (9.8 per 100,000) among all types of cancer in women 2.

Human papillomavirus (HPV) is central to the development of cervical neoplasia and can be detected in 99.7 percent of cervical cancers 3. The most common histologic types of cervical cancer are squamous cell (69 percent of cervical cancers) and adenocarcinoma (25 percent) 4. HPV is a group of more than 150 related viruses. Two HPV types (16 and 18) cause 70% of cervical cancers and precancerous cervical lesions 5.

Mutations in the BRCA (which normally produce tumor suppressor proteins that help repair damaged DNA and, therefore, ensure the stability of each cell’s genetic material), mutations in these genes predispose an individual to malignancy 6. People who have inherited mutations in BRCA1 and BRCA2 tend to develop breast and ovarian cancers at younger ages than people who do not have these mutations 7. A large study of cancer

DOI Number: 10.5958/0976-5506.2019.02590.7
risk in BRCA1 cancer families in Europe and North America revealed that BRCA1 mutation carriers are also at significantly increased risk for the development of several other cancer types, including pancreatic cancer, uterine cancer, and cervical cancer. The evaluation of biomarker status in cancers yields information about prognosis and treatment response. The aim of this study was to identify BRCA expression in Iraqi women with cervical cancer.

**Material and Method**

This retrospective study was designed to involve 30 formalin fixed paraffin embedded tissues blocks from Iraqi women with cervical carcinoma previously diagnosed for HPV infection and 15 with normal cervical tissue. The immunohistochemical staining performed using anti-BRCA and anti-HPV to evaluate the expression of the both markers. Analysis of the results was done using Easy Fisher Exact Test.

**Results**

Table (1) shows that from the 30 formalin fixed paraffin embedded cervical carcinoma tissues blocks, 8 blocks were positive for BRCA2 expression and 22 were negative. From the 15 formalin fixed paraffin embedded normal cervical tissues blocks, all were found to be negative for BRCA2 expression.

**Discussion**

Advances in molecular techniques have allowed for the identification of biomarkers in tumor cells like BRCA. Mutations in BRCA can lead the cells that are more likely to develop genetic alterations change into cancer cells. Studies have found that BRCA mutation carriers have increased risk of cancer at other sites than breast or ovary such as the cervix.

The current study showed that BRCA expression was significantly present in patients with cervical cancer, from the 30 cervical carcinoma tissues blocks that studied through immunohistochemical evaluation, 8 samples were positive for BRCA expression. This result was in agreement with several studies, in which for women carrying a BRCA mutation, the estimated risk of developing a cancer other than breast or ovarian cancer by the age of 70 years was roughly twofold that of the general population (i.e., 1 in 5 versus 1 in 10). In another study they found that tumor cells carrying BRCA1 promoter hypermethylation are hypersensitive to DNA-damaging drugs and may result in pronounced tumor death because of their underlying defect in BRCA pathway. A large study of cancer risk in BRCA1 cancer families in Europe and North America revealed that BRCA1 mutation carriers are at significantly increased risk for the development of pancreatic cancer, uterine cancer, and cervical cancer.
The high BRCA expression could be the induced factor that cause the normal cells to change into cancerous cells, which was reported by K. Rhein et al where they found an increased risk of cervical cancer for women with BRCA1 and BRCA2 13.

Interaction of E6 and E7 onco-proteins with BRCA could reflect a mechanism through which these HPV onco-proteins disturb the cellular transcriptional mechanism. A study demonstrated that interaction between BRCA and oncogenic HPV-E6 and E7 proteins that results in the antagonism of several different functional activities of BRCA1 14.

BRCA expression in the other hand may be not related directly in changing normal cells into cancerous cells but it is due to presence of HPV or other risk factors which may be present that increase a person susceptibility for cervical cancer 6. A study done by O. Johannsson et al suggest that apart from breast and ovarian cancer, the incidence of other cancer types like cervical cancer do not appear to be greatly increased in BRCA1- and BRCA2- associated families and does not warrant specific clinical follow-up in carriers 15.

**Conclusion**

The present study showed the importance of BRCA expression in cervical cancer pathogenesis which may be of value in the diagnosis, treatment and prognosis. We recommend a further study that includes large number of samples to give more clear view on the relation of BRCA expression and cervical cancer.

Prognosis Within 24 Hours Using Nursing Early Warning Scoring System (Newss) Method On Left Heart Failure Patients At Mitra Delima Hospital, Malang

Luluk Nur Aini¹, Lilik Supriati², Titin Andri Wihastuti²
¹Nursing Master Program, Faculty of Medicine, ²Lecturer in Medical Faculty, University of Brawijaya, Malang Indonesia

ABSTRACT

Assessment in emergency department determines the accuracy of diagnosis and administration of therapy at left heart failure patients. NEWSS is a fast scoring method in assessment. This research has purpose to analyze prognosis within 24 hours using NEWSS method with left heart failure patients. Observational analytical research method was used with a prospective cohort design. Research location at Mitra Delima Hospital, Malang. The respondents were 48 patients which selected by consecutive sampling. Data analysis used univariate tests and ROC diagnostic tests. The results shown that statistical analysis of univariate tests obtained prognosis results in 24 hours on 39 patients (81.3%) with left heart failure who did not experience cardiac arrest, and 9 patients (18%) experienced cardiac arrest. The diagnostic test shown the AuROC results were 0.967 (95% CI 91.2%-100%), sensitivity of 0.889 and specificity of 0.872. In conclusion, sensitivity value of NEWSS was 0.889, which means clinically, the ability to produce positive cardiac arrest rate was 88.9%. Clinical specificity value was 0.872 to produce a negative value of no cardiac arrest by 87% and AuROC value of 0.967 which included into category of very good in predicting prognosis within 24 hours on left heart failure patients.

Keywords: Prognosis in 24 hours, Left Heart Failure, NEWSS

Introduction

The prevalence of heart failure in all most country and abroad continues to increase year by year, but the prognosis is always bad. Data from hospitals in the United Kingdom from 2000 to 2017 heart failure mortality rates were 30,906 from 55,959 patients \(^1\) While in Indonesia the incidence of cardiac arrest in patients with heart failure also shows a high prevalence with the most cases in east Java \(^2\). Which is 54,826 patients from 226,698.

The treatment in patients with heart failure requires high costs, especially for health care including pharmacological and rehabilitative. Early detection and rapid assessment can increase patient life expectancy.

The NEWSS is a new method applied in Indonesia since 2015 as a way to predict the deterioration rate of patients based on their clinical conditions.

The accuracy prediction to know prognosis of cardiac arrest in the short term has been investigated with the AuROC NEWSS results of 0.89 \(^3\). This is in accordance with a study that independent predictor of mortality in patients with cardiovascular disorders were RR, SpO₂, temperature, pulse, blood pressure, and mental status with an AuROC value of 0.90 \(^4\). The NEWSS method has not been implemented in all of hospitals in Malang region, certainly with various considerations. One of them is because of the need for a high level of accuracy from nurses who do scoring like the one which states that the output of NEWSS is influenced by the involvement of practitioners in scoring because it determines accurate results \(^5\).

Thus, the researcher interested to know how the value of sensitivity and specificity of NEWSS in scoring patients with left heart failure at Mitra Delima Hospital, Malang in Indonesia.
Methodology of Research

This study used an observational analytic method with a prospective cohort design. The samples were 48 patients with left heart failure which selected based on consecutive sampling. Data retrieval was conducted from March 25 to April 20, 2019 at Mitra Delima Hospital in Malang Indonesia. Analysis of univariate data based on age, educational level and gender were categorical data, thus the presentation was in the form of frequency distribution while the numerical data was presented with mean and standard deviation.

Table 3 explained that was mostly no cardiac arrest with 39 people (81.3%).

4. Analysis of Diagnostic Test

Figure 1: ROC Curve
Based on the figure 1 and table 4, obtained cut off point score was at point 6, which meant the detection of cardiac arrest at a score of 5.50 with a sensitivity value of 0.889 and a specificity of 0.872.

**Discussion**

NEWSS scoring method consisted of 6 components of assessment including, respiratory rate (RR), systolic blood pressure, temperature, pulse frequency, level of consciousness and oxygen saturation. Table 2 shown that the average respiratory rate was 25x/min. Increasing the frequency of breath was influenced by a decrease in cardiac output, this was an effort to compensate the mechanism because of the increased need for oxygenation in the heart muscle cells. Every person had several phases of development, when entering the phase of the elderly the function of organs would progressively decrease, especially at the age of more than >65 years. The researcher stated that at the age of the elderly, their blood vessels were no longer elastic and inflexible, causing plaque or fat that accumulate more easily and blocking the blood flow until atherosclerosis occurred which was one of the causes of coronary heart disease and could become heart failure with the initial symptom was having difficulty breathing. This sign could be caused by the presence of a murmur, atrial fibrillation and dysfunction in the left ventricle. Thus, the patient should be followed by a blood test to find out the exact cause that tightness was not caused by anemia but by the underlying disease of left heart failure.

Table 2 also shown that the average pulse frequency of heart failure patients was 93x/min. Pulse could show changes in the cardiovascular system. The pulse could be felt where the arteries passed. In the normal human heart, the pulse originated from the SA node (normal sinus rhythm). The greater the metabolism in an organ, the greater the blood flow. The next heart compensation was to accelerate the heart rate and increase the flow of blood pumped from the heart throughout the body. According to sympathetic and parasympathetic nerve activity in the heart and blood vessels was influenced by the activity of the hormones epinephrine and norepinephrine (adrenaline). Increased secretion of both would induce and excite the sympathetic nerve to carry out vasoconstriction resulting in an increase in heart rate frequency followed by an increase in blood pressure.

The average blood pressure in the study results was 140mmHg. Blood pressure was referred to as mean arterial pressure when arterial pressure was averaged over one heart cycle. Mean Arterial Pressure (MAP) or blood pressure was a reflection of peripheral resistance and average volume in the arteries. MAP values should be maintained at a minimum limit of 60mmHg and preferably above 60mmHg, because if it was less than 60mmHg, perfusion to the brain of the coronary arteries and kidneys would experience metabolic disorders. The category of MAP values which was above 100 made a situation that was not good because it indicated blood pressure in the blood vessels to be high and then had an effect on increasing capillary vascular and rupture damage. In patients with left heart failure, the high blood pressure raised the weight of the heart while low blood pressure indicated a failed heart work.

Based on table 1, the majority of left heart failure patients were female. Generally, left heart failure occurred in groups of women because most of women experienced menopause, where at that time LDL cholesterol increased and estrogen decreased which caused women to suffer more from left heart failure. Researcher before also agreed with the theory which stated that women were at small risk of heart failure because a woman’s blood vessels were protected by estrogen before a woman entered the menopause process. The estrogen hormone increased the production of Highdensity lipoprotein (HDL) which could prevent the process of atherosclerosis.

The average body temperature of the patient was at 36.48°C. Increased temperature could dramatically increase the workload of a patient’s body organs. Humans basically always tried to maintain the normal state of the body with a very perfect body system in order to adjust to changes that occurred through the process of convection, radiation and evaporation. Temperature was also influenced by air temperature, if the air temperature was higher then the body responded with the onset of body fatigue and hypertermia, but if the air temperature was under 35°C it would cause hypothermia at the

---

**Source:** Primary Data 2019
patient’s body temperature. If the level of heat produced was the same as the level of heat lost, body temperature would be stable in body temperature (10).

The average of SpO₂ was 94.73%. Oxygen saturation was the presentation of hemoglobin that bound to oxygen in the arteries. The condition of hypoxemia indicated that patients needing oxygenation therapy. To determine the administration of oxygen there were several categories that should be observed, among others: scores of <4 was light respiratory distress using the nasal canule, a score of 4-5 was moderate respiratory distress while using nasal CPAP, a score > 6 was severe respiratory distress using intubation and ventilator. Heart failure patients could experience a decrease in oxygen saturation due to a decrease in the diffusion of oxygen in the blood, thus in clinical conditions there would be a decrease in oxygen saturation. Patients would experience shortness of breath, rapid and superficial pulse, and decreased consciousness (11).

Patients with left heart failure could experience decreased consciousness or called syncope. This was because the level of oxygen in the brain decreased and then the manifestation was that the brain was unable to maintain consciousness and it could even occurred even harder, coma. Syncope was transient loss of consciousness due to transient global cerebral hypoperfusion characterized by rapid onset, short duration and spontaneous recovery. The researcher explained that this loss of consciousness was caused by a decrease in blood flow to the reticular activation system located in the brain stem which occured limiting cerebral blood flow for 10 seconds.

The research data shown that many patient categories were elderly, elderly people easily experienced orthostatic hypotension. They had decreased oxygenation less than 3.0-3.5mlO₂/100 gram tissue/minute, thus the effect of this decrease in oxygen supply was a decrease in consciousness of patients with left heart failure. If you see the results of the pulse examination, there were also patients who had a tachycardia of 160x/min. Tachycardia was a manifestation of the condition of the long pause phase of the pacemaker to start an impulse so that if the hemodynamics were still inadequate due to this phase, the patient become unconscious and could even become cardiac arrest.

The medical team and nurses should be aware that if a decrease in consciousness occurs then this was a sign of danger before the occurrence of Sudden Cardiac Death. Hospitals also often accepted patients with left heart failure who were re-hospitalized due to low levels of education (12). This was in line with the research of explaining that there were factors in the social structure of education that affected individuals to know about the utilization of health services. The higher the education status, the individual would access health service and could reduce the risk of high prevalence, but if they were low, they would move away. This was called self-efficacy, it is belief in the ability of an individual to move motivation.

The AuROC value in this research was statistically very strong, cut off point value 5.50 with a sensitivity value of 0.889 and a specificity of 0.872. The results of this study were in line with study that predicted value of NEWSS AuROC was 0.93 while APACHE II was only 0.79 and the difference was statistically significant (Z=4.348 P <0.01)(13). Other researchers also in line with stated that the value of NEWSS could predict the incidence of cardiac arrest for 2-6 hours faster (13, 14). This study was conducted in 433 patients with acute heart failure. Data analyzed by binary logistic regression showed P <0.05 with area under curve 0.911 and 0.662 (p <0.05).

However, NEWSS also had weaknesses, the success of NEWSS was determined by the ability of practitioners to do scoring. Experienced practitioners were more reliable in applying this method, thus the results could be trusted. But on the contrary, if the practitioner was an inexperienced person there would be many obstacles faced so that the scoring obtained was not right, the decision of the intervention chosen was ultimately not suitable, thus the algorithm of the left heart failure patient could not be continued.

**Conclusion**

The prognosis in 24 hours with the NEWSS method on patients with left heart failure in the hospital obtained 39 from 48 patients (81.3%). The NEWSS method had a sensitivity value of 0.889 and a specificity of 0.872 including into a strong category. In similar studies could consider the research sample group specified to one age group of the elderly with a certain age limit to minimize the presence of confounding factors.

Descriptive Mapping of Needs among Diabetes Mellitus Patients

Made Kurnia Widiastuti Giri¹, Adnyana Putra¹, I Made Kusuma Wijaya¹, Komang Hendra Setiawan¹, Ni Putu Dewi Sri Wahyuni¹

¹Faculty of Medicine, Universitas Pendidikan Ganesha Bali, Indonesia

ABSTRACT

There are some kinds of therapeutic guidelines that have been created for diabetes mellitus patients. However, it cannot be denied that it has a part of nonpharmacologic therapy. Theoretically, nonpharmacological therapy is dietetic and exercise. Related to the statement, this study aimed at describing statements of what diabetic patient need for pharmacological and nonpharmacological therapy. Twenty-five diabetic patients (13 females and 12 males) were invited to join a month-small-group discussion for 4 months in Chronic Disease Forum, Buleleng- Bali, Indonesia. They were asked to discuss what they face in therapeutical and what they need based on (1) comfort, (2) aesthetics, and (3) safety aspects on pharmacological and nonpharmacological therapy. From the depth interview, patients state that they need doctors and nurses services in a better communication. As the result from small group discussion, it has been known that patients need exercise model and booklet of 2 weeks diet menu. Furthermore, they need the certainty of an exercise model developed in future research which will be validated by the expert.

Keywords: yoga, diabetes mellitus, therapy, mapping needs

Introduction

Diabetes mellitus (DM) is the condition in which the level of blood sugar is increasing due to the insulin malfunctions [¹]. Clinically, the increased level of blood sugar stimulates the serious complication in blood vessels (angiopathy) and nerves (neuropathy) thus DM potentials to disrupt almost all of the organs [²]. Statistically, DM has quite high morbidity and mortality, it is estimated that at 2030 Indonesia will have the highest number of diabetes in the world. This phenomenon increase Indonesian burden of diseases [³].

Exercise is one of the integral parts of DM management along with education, diet, and pharmacology therapy [⁴]. Unfortunately, many DM patients do not conduct appropriate exercise based on the latest research finding.

As illustrated, the model of the diabetes exercise that was developed in Indonesia in the period in the 1990s took the form of Senam Diabetes Indonesia only incorporate aerobic technique. Meanwhile, several recent types of research show that the use of the technique aerobic is not sufficient in controlling the level of blood sugar. The technique should be combined with the strengthening exercise (resistant training) that stimulated the skeletal muscle. The muscle subsequently will produce cytokines (IL 3 and IL 6) that play roles in the increase in the sensitivity of insulin [⁴].

Furthermore, the strengthening exercise increases the muscle mass, therefore, increase the capacity of glycogen savings which helps to regulate blood sugar. Another problem in conducting the exercise in DM is that the exercise should be conducted regularly. Therefore the exercise model should interest the subjects and yields a high exercise adherence.

Yoga is the practice of the physical activity that came from India since 4000 years ago [⁵]. Several kinds of yoga are practiced to increased wellbeing. Among them are asanas (postural), pranayama (control of the breath), Dharana (concentration), and mudras (finger gesture) [⁶]. Asanas yoga provides combined aerobic, resistant and balances training therefore potential to control the level of blood sugar [⁷]. Pranayamas and mudras are also potential to improve neural and vascular health of DM patients [⁸]. Yoga also provides relaxation which potentials to increase exercise adherence. This research aims to develop a yoga exercise model which potential to control blood sugar and yield on the high exercise adherence among the DM patients.
Method

The methods of the current research comprised three main stages which were Designing, Validating, and Reception Test.

1. Designing
   a. Based on a literature review based on DM pathophysiology and exercise physiology.
   b. Based on social-psychology aspects which aims to increase exercise adherence
   c. Based on the safety aspect to minimize adverse effects. The designing was based on Perkeni (Perhimpunan Endrokinologi Indonesia) recommendation which requires exercise to employ CRIPE principles (continue, rhythmic, interval, progressive and endurance)

2. Validation (Expert Judgment): The yoga prototype was validated by three experts on exercise therapy, endocrinologist and exercise trainer.

3. Reception Test (Secondary Validation): The validated yoga model was tested to 25 DM subjects (13 female and 12 males). During this stage, the subjects were invited to attend once a week (supervised) and advised to conduct twice a week (unsupervised) for eight weeks. The percentage of attendance (supervised session) and compliance (unsupervised session) in 8 weeks represent absolute unsatisfactory while 10 represent absolute satisfactory. At weeks 8, the dropout rate was also calculated by calculating the percentage of subjects who were not attended to the last session.

Results

a. Development Phase

   (i) Literature Review: Based on the literature review several standing, seated and combined poses were identified as the main asanas. Those poses were selected due to their characteristics and potential to provide aerobic, resistant and balance exercise which are needed in diabetes mellitus patients. The main asanas were combined with pranayamas (breathing exercise) to stimulate autonomous nerves.

   The pranayamas were selected since there is plenty of evidence suggest that pranayama exercise increased parasympathetic and decreased sympathetic activity. With this regards, it is assumed that pranayama may decrease glucagon and epinephrine release before exercise as anticipation responses and during exercises which can cause blood sugar elevation. In addition to asanas and pranayamas, several mudras were identified to increase peripheral blood flow so that prevent neuropathy and microangiopathy.

   b. Socio-Psychological Aspects: To increase exercise adherence, the prototype should stimulate addictive effect” so that it will attract the subject to do the exercise regularly. Pranayama components were intended to increase relaxation which stimulates comfort to the diabetes mellitus patients. Another aspect which needed to be considered was the difficulty level of the poses. The poses which were difficult to be conducted were less likely to attract subjects to regularly do the exercise.

   Therefore, everyone poses selected in this developmental phase was tested to inexperience subjects. Their response to the difficulty level of each pose was rated. The poses which were selected were fell into category very easy and easy, while the poses which fell into difficult and very difficult were omitted.
c. Safety Aspects: The majority of diabetes mellitus patients are old and have already suffered from health complication such as high blood pressure and neuropathy. They also have a relatively low aerobic capacity and stiff joint. Therefore, several poses which require high physical capability were not selected. One the examples of those poses are the pose which requires a large range of movement. Other reasons were the pose which gives a high impact on a certain part of the body, for instance, standing in one leg for a long time or balancing upon small muscle groups such as hand and arm.

(ii) Prototype Development: Based on progression and esthetics, the following prototype was modeled.

a. Warming Up: The basic asana pose in warming up was standing poses. It was started with mountain pose (tadasana) which was combined with pranayama (breathing exercise) which included three-part breath (dirgha pranayama). This incorporated (i) prolonged and fine inhalation, (ii) exhalation and (iii) retention.

Mountain pose (tadasana) was combined with arm movement to increase heart rate and neck movements to increase flexibility. Meanwhile, the poses also incorporated mudras to increase peripheral blood flow and to enhance the pranayama effect. Several mudras which were selected in the prototype includes gyan, rudra, pritvi, shanka, vayu, linga, surabhi, and surahi mudras.

Mountain pose was followed by five-pointed star pose, goddess pose, crescent moon pose, chair pose, stork pose, and dancer pose so that more muscle groups were involved to increase heart rate. The poses were modified with arm and hand movements. The final pose in the warming up was mountain pose which was the initial movement in the main exercise.

b. The Main Exercise: The main exercise incorporated surya namaskara especially turiya yoga branches which includes (i) invoke, (ii) intent/inhale, (iii) surrender/exhale, (iv) assume/inhale, (v) allign/exhale,(vi) awareness/inhale, (vii) surge upward/exhale, (viii) expand as space/exhale, (ix) ignite/inhale, (x) void/exhale, (xi) fullness/inhale and (xii) third eye/exhale.

Surya namaskara was selected because it provides resistant and balance exercises which were needed by diabetes mellitus patients. The aerobic metabolism can be stimulated with the modulation of intensity and repetition of the Surya Namaskar cycles.

For the first time yoga learners, Generally, it is suggested to them to complete one cycle in 5 to 10 minutes. After the physical condition allowed the subjects to increase the exercise dosage, it can be conducted more than once. The Surya namaskara was finished with a mountain position which was followed with surrender as the transition pose to obtain easy pose (sukhasana).

c. Colling Down: The basic pose in the cooling down was seated positions. It was started with an easy pose (sukhasana) as the basic pose. It is followed with bound angle pose (buddha kanasana), half lotus pose (Arda padmasana), lotus phase (padmasana), cow face pose (gemukhasana, simple twist (parsva sukhasana), seated half spinal twist and (ardya matsyendrasana). The seated position was followed with the last pose which is child pose.

d. Validation and Revision: The validation was conducted by three experts on each exercise therapy, endocrinology, and exercise training. The prototypes were approved by the experts so that it can be used in the reception test to evaluate the exercise adherence related to the prototype and the perception of the subjects upon the comfort, aesthetics and the safety aspects of the models.

e. The Reception Test

(i) Exercise Adherence and Drop Out Rate: The first analysis was based on the percentage of subject attendance once a week yoga session. The average of the percentage of subjects attendance during the invited session for both sexes was 95.5 % (female and male were 95.1 % and 95.8% respectively). The detail percentage of attendances from first to eight weeks were illustrated in Figure 2.
It can be observed from the graph that the drop out rate was 0. The percentage of attendance during the first to eight weeks was between 90 to 100%.

As the subjects were advised to do two more yoga exercise unsupervised at home. During the meeting, they were asked to report how many yoga session they did unsupervised. The percentage of the subject did unsupervised yoga exercise during first to eight weeks were 82.0% in total and 69.79 % and 93.0% for male and female respectively. The detail percentages of unsupervised exercised from first to eight weeks were illustrated in Figure 3.

(i) Subjects Perception Upon Yoga Exercise: In the final week, the subjects were asked to rate the yoga model they have done for eight weeks upon esthetics, comfort, and safety.
The scale was 0 to 10 which 0 represent unsatisfaction and 10 was the maximum satisfaction. The average satisfaction for esthetic, comfort and satisfactory were 7.44; 8.90 and 7.52. The detail responses for both sexes were provided in Figure 4.

![The Perception of Subjects toward The Yoga Model](image)

**Figure 4: The Perception of Subjects toward the Yoga Model**

**Discussion**

In recent years, yoga has been an exercise basis which is closely related to the improvement of several ailments including diabetes [8]. This research attempt to model yoga exercise which benefits diabetic patients based on the literature review and socially accepted by the subjects.

Based on the literature review, several aspects need to be considered. Firstly the exercise should accommodate aerobic, balance and resistant training and secondly the exercise should apply CRIPE (continue, rhythmic, interval, progressive and endurance) concept [8]. The yoga model develops in this research includes several standing and seated poses and also utilize sun salutation (surya namaskara) poses as those has the potential to benefit diabetic patients [9]. The asanas were combined with pranayamas to stimulate autonomic nerves so that the balance between sympathetic and parasympathetic can be achieved. The mudras were utilized to increase peripheral blood flow to manage and prevent neuropathy [10].

In order to be accepted and increase patients’ motivation to conduct the exercise, the exercise models should incorporate the easy but challenging exercise which allows patients to improve in line with their ability. The level of difficulty of the poses should be arranged to stimulates the feeling of success so that motivates them to continue the practice [11].

They should enjoy the exercise and look forward to continuing to practice them supervised or unsupervised. Those concepts were applied in this research to increase exercise adherence.

The prototype of the yoga model in this research was validated by the experts of exercise therapy, endrocynologist, and exercise trainer to ensure that the models were conceptualize based on diabetes mellitus pathophysiology, exercise physiology, and aesthetics. The experts control the models so that the models will have the maximum benefits in controlling blood sugar level, preventing and managing DM complication and have optimal exercise adherence.

The reception test which was conducted for three weeks on 25 of diabetes mellitus patients (13 females and 12 males) revealed that the average of the percentage of subjects attendance during the invited session for both sexes was 95.5 % (female and male were 95.1 % and 95.8 % respectively). This implied that the model yielded a quite high exercise adherence.

It is also found that the dropout rate of the program was 0%. However as the exercise should be conducted more than once a week to obtain maximum benefits, therefore the subjects were advised to conduct unsupervised exercises at home at least twice a week.

The percentage of unsupervised exercised (the number of sessions divided by two) was 82% on average
and 69.79% and 93% for male and female respectively. From Figure 3, it can be seen that more female conducted unsupervised exercises each week. In addition, during the last weeks, there were several females subjects which conducted exercises more than twice a week. It might imply that females subjects were more independent in memorizing the poses and have more motivation to conduct the exercise.

On average, the rating provided by the subjects in esthetics, comfort, and safety were 7.44; 8.9 and 7.52 respectively. This means that the prominent features which were valued the greatest by the subject were a comfort. Meanwhile for esthetics and safety were aspects which needed to be addressed.

Conclusion

Yoga prototype for diabetes mellitus patients was successfully modeled. The model contains (i) several standing, seated and combined asanas, (ii) basic pranayamas and (iii) mudras for controlling blood glucose, balancing autonomic nerve responses and increasing peripheral blood flow. The model has been validated by exercise therapist, endocrinologist and exercise training experts. Upon the reception test, it is revealed that the model yielded quite a high exercise adherence and receive a relatively high rating for esthetics, comfort, and safety.

Evaluation of Malaria Surveillance Based on Attribute in Health Office of East Sumba District

Margaretha Domingga¹, Atik Choirul Hidajah²

¹Master Study of Epidemiology, ²Department of Epidemiology, Faculty of Public Health, Airlangga University, Surabaya, Indonesia

ABSTRACT

Malaria is infectious disease caused by malaria mosquitoes. East Sumba District in 2017, API is 30.9/1000 population and SPR is 17.95%. One of the important factors that influence the high of malaria cases is the performance of malaria surveillance because it has a role in preventing disease, it is necessary to evaluate malaria based on approach system and evaluation surveillance attribute. This study was qualitative research with an evaluation study design. Identification of problems in the input, namely there are no analyst staff, laboratory facilities are lacking limited funds. The process of data entering from the PHC to the district is not timely, namely 68.18% and incomplete at 77.27%. At the output, information dissemination has been carried out at regular meetings. The result of evaluation attributes where simplicity are not simple. Flexibility is inflexibility. Data quality, acceptability, sensitivity, representative, timeliness are low, PPV and stability is high. The alternative solution is to increase the capacity of malaria surveillance managers and health analysts.

Keywords: API, Surveillance Attribute, e-SISMAL, Malaria

Introduction

Malaria is an infectious disease caused by plasmodium parasites which are transmitted by malaria mosquitoes, can cause death especially babies, toddlers, pregnant women. It is realized that the spread of malaria knows no administrative boundaries, therefore malaria control efforts require national, regional, and even international commitments. Diagnostic malaria will be examined using RDT or giemsa blood test to confirm the presence of parasites in the blood. World data shows that since 2000 deaths from malaria globally have fallen by around 60%, of which 65% occur in children under five. Around 3.2 billion people live in areas at risk malaria. In 2015, an estimated 214 million cases of malaria, of which 400 thousand cases of them died.

This disease is still endemic in Indonesia. Economic losses due to malaria for one year in Indonesia reached Rp 366,576,403,496. In Indonesian, 247 districts have received malaria elimination certificates. Profile Health East Nusa Tenggara Province illustrate that API in 2017 is 3.77/1000 population.

Source: East Sumba District Health Office, 2017

The Report Profil Health East Sumba District in 2017 illustrates that from 158 villages with low API
were identified as many as 18 villages (11.39%), moderate as many as 35 villages (22.15%), and high as many as 105 villages (66.46%) (9). The pattern minimum maximum pattern serves to determine the peak period of transmission and the right time to carry out malaria control activities (10), looking at the lowest and highest cases then graphed and compare with the malaria pattern in the following year (11).

![Pattern of Malaria Transmission in East Sumba District](source: East Sumba District Health Office, 2017)

The above conditions illustrate that the peak of malaria cases occurred in December and March and decreased in July and August.

One of the important factors that influence the high incidence of malaria is the performance of malaria surveillance (12), because surveillance is a series of continuous observation processes in the collection of data, analysis, and interpretation of data to detecting trends in disease (13).

The purpose of this study is to describe the implementation of malaria surveillance based on a system approach and evaluate surveillance attributes, identify solutions for consideration in determining the policy for making malaria control, prevention and eradication programs.

**Material and Method**

Evaluation of the malaria surveillance system was carried out in the East Sumba District Health Office from July-August 2018. The design of this research is qualitative research with an evaluation study design. The subjects in this study were evaluation components of the malaria surveillance and attributes.surveillance. Research informants were managers Malaria program in

the Health Office and program managers in 22 Public Health Centers (PHC).

Primary data collection techniques through interviews with respondents using questionnaires and observation. While secondary data collection was obtained through the study documents of malaria surveillance data in the East Sumba District Health Office and PHC. Data analysis was carried out descriptively with technical instructions related to malaria published by the Indonesian Ministry of Health and Guideliness for Evaluating Surveillance Systems from CDC and Prevention in 2001 (14).

**Findings**

**A. Surveillance System**

1. Input

   a. Man: The human resources in the malaria program are doctors/midwives in the Public Health Sub-Center (PHsC), the analytical staff, the pharmacist, malaria program manager and Head of PHC. From 22 PHC that only 6 analyst (27.27%) of PHC while other that work are employees who are trained and do not have competence in the laboratory.
b. **Machine**: The implementation of surveillance system has been supported by adequate media such forms, computer, and transportation (100%). e-SISMAL application at the national level which facilitated the recording and reporting system\(^{(15)}\), but this application had not been tested in East Sumba.

c. **Money**: Funding for surveillance comes from Center Fund and District Government. East Sumba District has received assistance and grants from the Global Fund (GF) but has now been stopped, while the allocation from Government has not been sufficient for the program activities.

d. **Method**: Surveillance system was supported by malaria prevention guidebook, including Regulation of the Health Minister Number: 042/Menkes/SK/1/2007\(^{(16)}\), Decree of Director General of P2P Number: HK.02.02/IV/1813/2017\(^{(17)}\), Technical Guidelines for Investigating Epidemiological Malaria\(^{(18)}\), and several other guidebooks.

e. **Market**: Disseminated information through periodic reports to the district level to the central level, was also conveyed at a meeting forum involving cross-sectors. The Regional Governments is still lacking supports Malaria program where absence of a Regional Regulation.

2. **Process**: Malaria data is the results of malaria program services, entered to the malaria register and recapitulated by PHsC, collecting reports to PHC and sent to District Health Office at the latest every 5 months. Data that entered was not on time, namely only 15 PHC (68.18%) and completed report only 18 PHC (77.27%). Records in the malaria are the processed and presented in the form of tables, graphs. Data validation will be conducted once every 3 months. Descriptive data analysis using indicators API, SPR and ABER. Data interpretation is giving a description on a results so that the data becomes meaningful and produces epidemiological information.

3. **Output**: The achievement of the Malaria program performance to be disseminated in the form of report from District to a higher level and feedback to the PHC. The result of the scope of indicators are also disseminated at program evaluation meetings but not yet made in the form of bulletins, scientific publication or writing on the website.

B. **Surveillance Attribute**

1. **Simplicity**: According to respondents the current flow of malaria surveillance reporting is simple (72.73%) but the rest (27.27%) states difficulties because the diagnosis of malaria through a laboratory examination. RDT supplies are insufficient. From 22 PHC that only 6 analyst (27.27%). It can be concluded that the program are not simple because laboratory tests is needed for diagnosis.

2. **Flexibility**: Malaria surveillance which is region with high endemicity, namely early discovery, appropriate treatment and complications, expansions of services with survey, active and passive case detection. It can be concluded that surveillance is inflexible because laboratory examination are not equipped with adequate equipment.

3. **Data Quality**: Almost all PHC filled out incomplete 77.27% in malaria program reports. PHC rarely conducts data validation with PHsC officers. It can be said that the quality of data is low.

4. **Acceptability**: The local government had not optimally contributed to malaria prevention and the accuracy of the PHC reports was still 68.18%. It can be concluded that the acceptability is still low.

5. **Sensitivity**: Almost all respondents stated that the malaria surveillance system was able to analyze malaria events (90.91%), was able to analyze the API, SPR and ABER trends every year (86.36%), but because the collected data was invalid, it could be concluded that sensitivity was not sensitive.

6. **Positive Predictive Value (PPV)**: From slide shipments from January to June 2018 from 9 existing PHC, there were 482 positive slides examined from total of 1226 slides. And people who are found to be positive malaria (100%) are truly experiencing malaria.

7. **Representativeness**: Case analysis based on the variables of person, place and time
(90.91%), and the presentation was carried out during the quarterly mini workshop and presented on the wall data but if validity of the data 72.73% it can be concluded that system were not representative.

8. Timeliness: Respondents stated that 68.18% of PHC had not sent reports to the Health Office on time, so it could be concluded that the timeline were not timely.

9. Stability: Respondents had used computers and report files to do processing and storage (86.36%). For the nature of equipment, respondents stated that it was easy to obtain and operate computers as much as 95.45% and operate a computer properly so it could be concluded that the stability was high.

Discussion

The discovery of malaria as indicated by the API in 2017 was 30.9/1000 population and placing as a malaria endemic area with the aim of reducing malaria transmission with findings and management patient, prevention of risk factors, epidemiological surveillance, improving human resources\(^{(19)}\).

Enforcement of malaria diagnoses still a problem because use clinical diagnosis, 266 people in 2015, 54 people in 2016 and 2 people in 2017. Determination of the diagnosis of malaria by microscopic examination to improve the validity of the diagnosis, so that it can reduce the incidence of anti-malarial drug resistance and prevent transmission\(^{(20)}\).

SPR was 17.95%, shows the magnitude of infection rates in population. Calculation of SPR should be done every month, not only at the end of the year because it can help identify local transmission of malaria compared to the number of cases of raw malaria\(^{(21)}\).

Maximum and minimum patterns of an illness describe the pattern of disease over a period of time. In chart 2, it is known that peak malaria cases occur in the rainy season, so that the peak of mosquito density can be predicted around November and February and decreases during the dry season. This is due to high rainfall and a breeding ground for mosquitoes in stagnant pools and ponds. Joseph \textit{et al} (2014) said that the maximum and minimum patterns, it can be seen that the effective time for malaria vector control activities can be carried out in October and January.

According to CDC (2001) simplicity means simple and easy to operate structures, but can still reach the goal. The diagnosis malaria with the laboratory, but RDT are insufficient and it can be concluded that are not simple. A system can be said to be simple where the case definition is easily applied\(^{(22)}\). Decree of Indonesia Health Minister number 1116/Menkes/SK/VIII/2003, states that epidemiological surveillance resources consist of epidemiologists, functional positions including laboratory\(^{(23)}\), but the lack of analysts in PHC made the surveillance not simple.

Flexibility means a system that is able to adapt to changes in information or field conditions with limited time, budget and easily integrated with other systems (CDC, 2001). East Sumba District is a region with high endemcity and find patients with surveys, active and passive case detection but become inflexible because the discovery of patients must go through laboratory tests.

According to CDC (2001) data quality describes the completeness and validity of the data recorded; acceptability can be seen from the desires of organizations to participate, completeness of reports; and timeliness of reporting means the rate of speed to find out trends, and outbreaks. PHC rarely conduct data validation, the report completeness was 77.27% smaller than the target >90% and timeliness reporting was only 68.18% of target 80% in accordance with Regulation of the Minister of Health Number: 1479/Menkes/ SK/ X/2003. To get good data quality, it is necessary to have periodic malaria monev meetings, training in malaria, strengthen the information system with e-SISMAL application. Supported by Research who conducted Nicola (2016) some countries have built electronic-based reporting systems and achieved success such as Sri Lanka, because with electronic-based reporting, shortening time and reducing the level of miscalculations. With high data quality, timely information, can detect disease early and accelerate health service responses\(^{(24)}\). The need for rewards for PHC with a good surveillance system, because attributes are highly subjective, including the personal willingness of those responsible for implementing system to provide data accurate, complete and timely\(^{(25)}\).

Sensitivity is ability to capture accurate information data, through level of reporting and the level of ability to detect outbreaks; Representation means being able to describe health incidents according to time and place (CDC, 2001). The interviews revealed that was able to
analyze malaria incidence based on person, place and time variables (90.91%), but because the collected data was incomplete (77.27%) it was concluded that program is insensitive and irrepresentative. According to CDC (2001), PPV is the proportion of people identified as actual cases, relating to the clarity and accuracy of case definitions. No errors were found indicating PPV was high.

Stability is related to the reliability is the ability to collect and provide data precisely without errors and availability is the ability to operate when needed (CDC, 2001). Respondents stated that they had used computers and report files to do processing and storage so it could be concluded that the stability was high.

**Conclusion**

Malaria is an infectious disease caused by malaria mosquitoes. Surveillance performance affected the high number of malaria cases because have a role to preventing disease, it is necessary to do an evaluation based on the system approach and surveillance attributes. The evaluation surveillance attributes where simplicity are not simple, flexibility is inflexibility, data quality, acceptability, sensitivity, representation, timeliness are low. PPV and stability is high.

Problems in conducting surveillance at the PHC are lack of cross-sector cooperation, lack of labor and laboratory facilities, and alternative solutions that can be carried out are increased cross-sector cooperation, increasing the capacity of malaria surveillance managers.

**Suggestion**

The need for policies from Central Government to using e-SISMAL applications, legal regulations from the regional government, cooperation with the private sector to find out, treat patients and prevent malaria. There needs to be additional analysis staff, procurement of infrastructure, malaria training and additional operational costs for implementing malaria surveillance at the PHC and East Sumba District Health Office.

Low Level Laser Therapy on Postoperative Trismus and Swelling after Surgical Removal of Impacted Lower Third Molar

Marwah Safaa Ali¹, Sahar Shakir Al-Adili²
¹Department of Oral and Maxillofacial Surgery, College of Dentistry, University of Kufa, Iraq; ²Department of Oral and Maxillofacial Surgery, College of Dentistry, University of Baghdad, Iraq

ABSTRACT

Background: Low-Level Laser Therapy (LLLT) offer many benefits in controlling the inflammatory process, so it is used in reducing postoperative sequelae following extraction of third molar. The exact biological mechanism behind its action still unclear. There is evidence to suggest that it may have significant neuropharmacological effects in the synthesis, release, and metabolism of a series of biochemical substances.

Objective: This study aimed to demonstrate the effect of intraoral and extraoral low level laser therapy after surgical removal of lower third molar.

Material and Method: forty patients who were in need for surgical removal of lower third molar were studied. Patients were randomly assigned into two groups, LLLT and placebo. Patients in the LLLT group received low level irradiation intraorally (at three point occlusal, buccal and lingual to operation site at 1cm away from the target tissues) and three point extra orally at the masseter muscle including origin and insertion. The total energy was 18 J. While in the placebo group the handpiece was inserted intraorally at proximity to the operation site and then was touched extrorally to the masseter muscle for 180 s total, but the laser was not activated. Assessment of trismus and swelling was done before surgery as a baseline record as well as at the second and seventh postoperative days.

Results: there was no significant difference in trismus between the two groups, while the swelling in the LLLT group was significantly less than in the placebo group in the 2nd and 7th postoperative days.

Conclusion: this study showed that low level laser application have beneficial effect in swelling reduction after third molar surgery, but the trismus did not reach statistically significant level.

Keywords: low level laser therapy, impacted lower third molar, trismus, facial swelling.

Introduction

Third molar eruption occur between the age of 17-21 although there is wide variation in eruption dates. Sometimes third molars may stays impacted in the jaw as a result of many causes like adjacent teeth conditions and soft and hard tissue barrier, the prevalence is about 20%-30% of the population, so that surgical removal of impacted wisdom teeth is one of the most common procedures performed by oral surgeon (¹,²).

Complex factors lead to swelling and trismus after extraction of impacted third molar, however they originat from inflammatory process that is caused by surgical trauma (³).

Different methods are being used to reduce or inhibit trismus, and swelling after third molar surgeries (⁴) (⁵) (⁶) (⁷).

Some of these treatment modalities have side effect or possible limitations, this lead to find out other method like the use of low level laser therapy which shows promising possibilities.
The biological effects of laser first were studied in 1976 for the first time \(^{(8)}\) then the concept of laser treatment started to take shape in 1971 \(^{(9)}\) and from that time it has been used in treatment of several disorders like rheumatoid arthritis, carpel tunnel syndrome, non-healing ulcer and so on. \(^{(10)}\)

Low-level laser therapy (LLLT) is a technique that is effective in modulation of inflammatory response and as a result reduction of swelling and pain and speed up healing \(^{(11)}\).

The anti-inflammatory effect of the LLLT could be due to inhibition of IL-6, MCP-1, IL-10, and TNF-\(\alpha\) in a dose-dependent manner which lead to increase of phagocytic activity, reduction of blood vessel permeability, and restoration of micro capillary circulation \(^{(10,12)}\).

Although the applications of LLLT are numerous, the results about thier efficacy are controversial \(^{(13)}\). This may be caused by different methodology used by various studies, different types of laser device and handpiece, different irradiation parameters and variation or difficulties in measuring the variables related to postoperative sequelae \(^{(14)}\).

This study aimed to evaluate the effectiveness of using low level diode laser, 980 nm in the management of postoperative trismus and edema after surgical removal of impacted third molar.

**Patients and Method**

This study was carried out as double blind placebo controlled randomized prospective clinical study. It was performed during period from December 2018 until the end of April 2019.

A total of 40 patients participated in the study, 18(45%) male and 22(55%) female, age range was between 18-35 years, with a single impacted mandibular third molar in similar positions (Class I-II-III and position B, Pell and Gregory’s classification) \(^{(15)}\). They were randomly assigned into two groups, 20 patients LLLT group, received LLLT immediately after surgery; and 20 patients placebo group; received sham LLLT.

All patients had mandibular third molar, totally or partially impacted in the bone in need of surgical extraction. Exclusion criteria were medical illnesses like diabetes, corticosteroid and anti-inflammatory therapy, patients with history of head and neck radiotherapy, pregnant and nursing women, patients with acute infection in relation to third molar especially pericoronitis.

All participants were informed about the risks of oral surgery and treatment hazards, and a written consent was obtained from all. This study was approved by the Ethical approval Committee in the Collage of Dentistry/ University of Baghdad.

Surgical procedures for all patients were done by the same surgeon who used a standardized technique. The patients were operated under local anesthesia that had been obtained by inferior alveolar, lingual and long buccal nerve block injection using the same agent Lidocaine hydrochloride 2% with Adrenaline 1:80,000 in 1.8 mL glass cartridge (Septodent®, France). A proper two sided mucoperiosteal flap was reflected. The bone removal and/or tooth sectioning was done. Bone removal was performed with fissure or round bur in a surgical straight handpiece under copious saline irrigation.

The tooth was removed and the edges of the wound were sutured with a black silk suture 3/0 with simple interrupted suturing technique.

After surgery, all patients received 625 mg Amoxicillin with Clavulanic acid. A single dose of oral Azithromycin 500mg was given for patients with history of allergy to Penicillin (one patient). Paracetamol (500 mg) with caffeine PO q12hr, and a Chlorhexidine digluconate 0.12% mouth rinse for 10 days except on the day of surgery.

A gallium-aluminum-arsenide (Ga-Al-As) diode laser device (Pioneer®, china) with a continuous wavelength of 980 nm was used as source of laser light. Both patient and operator were wearing safety goggles for eye protection.

Immediately after the operation, patients in the LLLT group had been received low-level laser therapy at six points 3 extra oral at the masseter muscle, including origin and insertion, and 3 intraoral, placed at 1 cm from operation site administered on occlusal, buccal and lingual sides. Laser energy was applied to treatment groups at 100 mw (0.1 w) for a total of 180s (30 s for each point), 0.1W x180s=18 J.
In the placebo group the handpiece was inserted intraorally at proximity to the operation site and then was touched extraorally to the masseter muscle for 180 s total, but the laser was not activated.

Post operatively, assessment of the mouth opening was done by asking the patients to open their mouth as much as possible and the inter-incisal opening was measured with a caliper in millimeter between the incisal edges of the right maxillary and right mandibular central incisors, the outer contour of the check was assessed by measuring the distance between the lateral corner of the eye and the angle of the mandible(Line A), tragus and the outer corner of the mouth (Line B) and tragus and soft tissue pogonion (Line C), using measuring tape. These measurement were done on three occasions, before surgery, at the 2nd, and 7th postoperative days using the same method and by the same examiner who was different from the operator and in double blind way. The time of operation was also recorded using stopping watch and compared between the groups.

**Result**

The mean operation time for LLLT Group was 35.95 min. and for placebo group was 35.75 min. There was no statistically significant difference between the two groups in terms of mean duration of surgical operation (p-value = 0.910). Table 1.

Discussion

Topical sign of inflammation, like swelling, and severe discomfort commonly related to surgical removal of impacted lower third molar \(16\). Previously suggested that there may be a close association between time of operation and postoperative morbidities \(17\). However in this study, there was no significant difference in time of surgical operations between LLLT group and placebo group.

Different preventive method have been used to manage these postoperative sequelae, one of them is the use of LLLT that has been shown to prevent or reduce trismus and facial swelling following surgical extraction of impacted mandibular third molar without any side effect, however some studies didn’t report any positive effect.

This controversy may be a result of variations in study designs and absence of uniform reporting of physical variable like type of laser device, wave length, time of application, and distance between the source and tissue in addition to lack of standardization in measuring variables related to postoperative morbidities after third molar surgery, like trismus and facial swelling \(18\).

In some studies LLLT was applied only extraorally \(19\) or only intraorally \(14\) while other authors performed both extraoral and intraoral application \(20\).

Trauma of surgery during mandibular third molar removal may lead to muscles spasm, particularly masseter muscle which lead to difficulty in mouth opening known as trismus. For evaluation of trismus manual caliper is used to measure maximum oral aperture. The present study concluded that the difference in trismus scores between the LLLT group and placebo group was statistically not significant, this finding agreed with study conducted by López-Ramírez et al. \(14\) and Røynesdal et al. \(21\), while Carrillo et al. \(22\) and Aras and Güngörmüş \(20\) reported that LLLT reduced trismus and has positive effect.

Postoperative facial swelling is an expected sequel after removal of impacted third molar. The probable cause is tissue response to surgical trauma in oral cavity. Swelling is gradually increased and reaches its peak value during 48 hrs postoperatively and regress by the 4th day and it is fully resolved in one week \(23\).

According to the result of this study LLLT have positive effect on swelling and there was statistically significant difference in swelling between the two groups in the 2\(^{nd}\) and 7\(^{th}\) postoperative days this result is similar to that obtained by Ferrante et al. \(24\), Kazancioglu et al. \(19\), and Aras and Güngörmüş \(25\) who reported in their studies that reduction of facial swelling can occur by the use of LLLT. However, the current findings are not consistent with those of Carrillo et al. \(22\) who found no statistical significant effect of helium-neon laser on studied patients.

The difference in methodology and results of the different studies are too varied to find the ideal parameters for use of the laser therapy and to estimate its clinical effectiveness.

This study revealed that LLLT is useful for decreasing trismus and swelling after impacted lower third molar removal. The effects of LLLT may depend on the method of its application.

Conclusion

1. Facial swelling was significantly less in LLLT group compared to placebo group after third molar surgery.
2. Trismus was less in LLLT group compared to placebo group, although statistically not significant.

Role of Betatrophin and Irisin on Diabetes Mellitus Type 1 Management (Experimental Study)

Maysaa J. Majeed1, Zainab A. Razak Al-Sharifi1, Shifaa Jameel Ibrahim1

1Department of Biochemistry, College of Medicine, University of Baghdad, Baghdad, Iraq

ABSTRACT

Background: Type 1 diabetes occurred when immune system destroys cells of pancreas called beta cells, usually treated with insulin and was advised to get regular physical activity.

Aim of Study: Evaluate irisin hormone as represented the exercise hormone in the treatment of diabetes type 1 rats in comparison with betatrophin hormone.

Material and Method: Twenty three rats were included in this study, five of them was considered as control group, while the rest injected with a single dose of alloxan 0.1mg/g, in order to develop diabetes type 1, six of them were dead. Six of inducible diabetes type 1 rats were treated with betatrophin. The other six rats were treated with irisin. Spss version 18 was used in the expiations of statistical methods of the research.

Results: After diabetes type 1 induction, diabetic rats type 1 groups showed higher blood sugar and serum irisin and lower serum insulin and betatrophin level than control group with p<0.05. Diabetic rats’ type 1 with Betatrophin injection showed significant lower blood sugar and significant higher serum insulin level with when compared with Diabetic rats type 1 after irisin injection treatment.

Conclusion: Betatrophin can hold a hope for diabetes type 1 control more than irisin

Keywords: diabetes mellitus, irisin, betatrophin and rats.

Introduction

Regular exercise assists everybody health, for diabetes, it plays a major role in keeping health, regardless of the type of diabetes it is important for the overall health and wellness. With type 1 diabetes the key of treatment is keeping the balance between insulin doses with the food eaten and the activity has been done (1). Novel hormones discovered by different studies can improve the diabetes status. On one hand, betatrophin (2) can hold the best treatment for both types of diabetes (type 1 and 2) by regenerate the pancreatic β-mice cell mass. On the other many researches documented that irisin exercise hormone generated by endurance exercise training in both mice and humans, which act on the cells of white adipose tissue thus increasing total energy expenditure and mitigating diet-induced insulin resistance in certain animal models (3). Circulating irisin is also significantly lower in individuals with T2D compared with non-diabetic controls, whereas recombinant irisin administration to fat mice significantly improves glucose tolerance (4, 5).

Material and Method

Seventeen rats involved in this study, their age range was 2-3 months-old, and the study was done at animal house, College of Medicine-University of Baghdad. The animal protocols were approved by the Use and Care of Experimental Animals Committee of the Jichi Medical University Guide for Laboratory Animals (6).

Study Design: Twenty three rats were induced type 1 diabetes by subcutaneously injection of a single dose of alloxan 0.1mg/g, six of them were dead then the rats were divided into two groups:

Group 1: Involve six DMI rats, after a day from diabetes inducible, they were treated with 0.2 mg betatrophin/g body weight.
Group 2: Six DMI rats, after a day from diabetes inducible, they were treated with 100ng/ml of recombinant protein (lyophilized irisin Fc-Fusion).

Group 3: Five rats represented control non-diabetic rats.

All rats were not significantly differing in their body weight and age.

Method

Fasting serum glucose was measured by colorimetric methods, serum insulin concentration were measured using an enzyme-linked immunosorbent assay. Rats’ weight was measured by weight meter. Glucose and insulin and recombinant proteins (betatrophin and irisin) were provided by Phoenix pharmaceuticals, INC, GERMANY.

Results

To confirm the matching between studied rats groups, The statistical a nova- test was done and all studied parameters showed no significant difference with p>0.05.

Irsin showed positive significant correlation with blood sugar and insulin in diabetic rats type 1 before irisin injection treatment with r= +0.45, p <0.05. Same results was obtained in Diabetic rats type 1 after irisin injection treatment r= +0.34, p <0.05. While Betatrophin showed negative significant correlation with insulin.
Discussion

Irisin has discussed by many previous studies as a messengers molecules released by skeleton and heart in response to exercise \(^{(7,8)}\) acting on various tissue including skeleton, heart, liver, fat and the brain \(^{(9,10)}\). Researchers suggest that irisin can be used as therapeutic potential in insulin resistance and type2 diabetes mellitus by browning of white adipose tissue, facilitating glucose uptake in skeletal muscle and heart, improving hepatic glucose and lipid metabolism, and pancreatic β cell function \(^{(11-15)}\). Most studies talk about the role of irisin in diabetes type 2 but only few focus on its role in diabetes type 1.

As well as most studies documented the role of irisin in diabetes type2, the researchers documented the role of betatrophin in the proliferation of pancreatic cells consequently increasing insulin secretion \(^{(16)}\) and improving diabetes type1 statues, which the current research undergo this explanation. but this betatrophin don’t have this role in diabetes type2 that may not control pancreatic β-cell expansion or its function \(^{(17)}\).

Diabetic type1 rats treated with irisin showed no improvement in their blood sugar suggested that irisin have no role in glucose metabolism in diabetic type1 rats, although plurality studies \(^{(18)}\) suggest that that irisin is insulin-rebuilding hormone, and can specifically accelerate the generation of mouse beta cells and regenerating mouse beta cells \(^{(19-23)}\). In general experimental studies proved that irisin has anti-apoptotic effect on pancreatic beta-cells and stimulates beta-cell proliferation, irisin fails to regulate blood glucose that may be related to the damage severity of beta cells and glucose toxicity.

Different studies suggest that people with long-standing type 1 diabetes may be treated only when beta cell destruction can be inhibited. That the apoptosis of beta cell and new beta cell formation must be occurring that concomitant must be occurring even after long-standing type 1 diabetes \(^{(24)}\).

Conclusion

Betatrophin can hold a hope for diabetes type1 treatment, but the role of irisin in the diabetes type1 treatment need for further research controlling the way and severity of destruction of beta cell.

Correlation between LDL, HDL, LDL/HDL Ratio and Preeclampsia Incidence at RSUD Pamekasan, Indonesia

Mazdalina Rahmawandari Nurhani¹, Kusworini², Bambang Rahardjo²
¹Student of Master Program, ²Lecturer of Master Program, Midwifery Faculty of Medicine Universitas Brawijaya Malang

ABSTRACT

Besides bleeding and infection, preeclampsia is the leading cause of maternal mortality in Indonesia. Preeclampsia may cause multi organ dysfunction which may result in death. Although the exact causes of preeclampsia are not known, one of the widely accepted theories is oxidative stress. Oxidative stress may be triggered by high LDL-c, low HDL-c and high LDL/HDL ratio. The study aimed at investigating the correlation between LDL-c level, HDL-c level, LDL/HDL ratio and preeclampsia incidences at dr. H. Slamet Martodirdjo Regional General Hospital (RSUD) Pamekasan. The study used analytical observational method and case control design. The subjects were 64 pregnant women consisting of 32 preeclamptic and 32 non-preeclamptic women. The subjects were selected using consecutive sampling method. Data were collected from physical examination and laboratory tests. Data were analyzed using eta and logistic regression test. Result showed that there was a significant correlation at α < 0.05 between LDL-c level (ρ=0.000), HDL-c level (ρ=0.000), LDL/HDL ratio (ρ=0.000) and preeclampsia incidence. LDL-c level, HDL-c level, LDL/HDL ratio were risk factors for preeclampsia. These factors should be targetted by health care professionals when conducting routine prenatal checkups.

Keyword: LDL-c, HDL-c, rasio LDL/HDL, Preeclampsia

Introduction

Today, preeclampsia is still a leading cause of maternal mortality in the world, accounting for 15 % to 20% of maternal mortality. This is also the leading cause of infant mortality and morbidity. This condition occurs after 20 weeks of gestation and is marked by increased blood pressure of more than 140/90 MmHg and proteinuria of more than 0.3 mg/day. Without immediate intervention, preeclampsia may result in multi organ dysfunction which causes death.

In Indonesia, preeclampsia is the second leading cause of maternal mortality after bleeding, while in East Java Province it is the first leading cause of maternal mortality in 5 consecutive years.

The exact causes of preeclampsia are not yet known, although ED occurring in placental blood vessels has been widely accepted as a theory that explains the etiology and pathophysiology of preeclampsia. One theory that develops in pathogenesis preeclampsia is oxidative stress theory.

Oxidative stress is induced by reactive oxygen species (ROS). This includes superoxide anion (O2-), hydroxyl anion (OH) and peroxide hydrogen (H2O2) which may damage cell structure including lipid, protein and DNA. Some studies showed that excessive production of ROS may be caused by high LDL-c level and low HDL-c level which may result in increased production of lipid and oxidized protein which lead to vascular endothelial damage which is the main pathogenesis of preeclampsia.

Normally, lipid profile level, including LDL-c and HDL-c level, increases during pregnancy, particularly during the second and third trimester. This is due to an increase in steroid sex hormones as well as a change in hepatic metabolism and adipose. Such changes contribute to an increase in LDL level. It has been...
reported that during pregnancy LDL becomes smaller lipoprotein and is, consequently, more atherogenic (10). Meanwhile, HDL stays at recommended level and is at its highest in the second trimester. The combination between elevated LDL and decreased HDL in the blood increases the risk of atherosclerosis (11). This places pregnant women at higher risk of atherosclerosis which has similar characteristics with preeclampsia (12).

Although some studies have investigated the relationship among an increase in LDL-c concentration, a decrease in HDL-c concentration, an increase in LDL/HDL-c ratio and increased risk of preeclampsia, the results have not always been consistent (13)(14)(15). Considering the high prevalence of preeclampsia in Indonesia, as well as its exorbitant health care cost and considerable impact, establishing the exact relationship among the variables seems urgent. Up to now, eventhough pregnant women with preeclampsia characteristically show atherogenic lipid profile and oxidized lipoprotein, routine measurement of lipid and lipoprotein have not become a standard procedure during pregnancy checkups (16). Cholesterol test as preeclampsia screening is easy and cheap, thus can be performed by all health-care facilities in Indonesia. Therefore, the study aimed at finding out the correlation among LDL-c level, HDL-c level, LDL/HDL ratio and incidence of preeclampsia at RSUD Pamekasan.

**Materials and Method**

The study used analytical observational method and case control design to investigate the correlation among LDL-c level, HDL-c level, LDL/HDL ratio and preeclampsia. The study was conducted at RSUD Pamekasan from Februari to April 2019. The subjects were 64 pregnant women who were divided into two groups; preeclamptic and non-preeclamptic group.

The inclusive criteria were: Age between 20-40, gestational age of more than 34 weeks, no previous preeclampsia and eclampsia history.

The exclusive criteria were: Chronic hypertension, Diabetes Mellitus, heart diseases, thyroid diseases, kidney and liver dysfunction deseases, Cushing syndrome, Trombofili, Lupus Erythematosus, consumption of lipid profile management drugs (estrogen, corticosteroid, lipid decreasing drugs, anti-epileptic drugs) alchohol consumption and cigarette smoking, and gemellus.

Every preeclamptic subject and non-preeclamptic subject were matched on the basis of their age, BMI and parity.

**Blood Pressure Measurement:** Blood pressure was measured using digital blood pressure monitor. The measurement was done while subject was supine, on her left lateral position. The head was elevated 30 degrees. Before measurement, the subject was allowed 5 minutes to relax and blood pressure was read. The reading was repeated 2 times with 5 minutes interval and the mean of these two readings was recorded as the result of the reading.

**Proteinuria Test:** Proteinuria is tested using dipstick method with Combostik 10M strip test and the result was read using ComboStik R300 automatic machine.

**Blood Sample Collection:** LDL-c and HDL-c level. LDL-c and HDL-c was measured using enzymatic colorimetric method with Selectra Pro M Chemistry Analizer machine and Cholestest LDL and HDL SL 2G reagent by Elitech.

**Statistical Analysis:** Data were analyzed using SPSS for Windows version 25. Data were presented descriptively to indicate means and standard deviations. Independent Sampel t test was used to analyse the difference between LDL-c and HDL-c level and LDL/HDL ratio. Eta test was used to find out the correlation between LDL-c level, HDL-c level, LDL/HDL ratio and preeclampsia. Multivariate analysis was performed using Logistic Regression test.

</table>
Result presented in table 1 indicates that there was no difference in age, parity, BMI, and gestational age between case sample (preeclamptic women) and control sample (non-preeclamptic pregnant women) ($\rho$>0.05). Blood pressure of both preeclamptic and non-preeclamptic women was also presented in table 1. The average systolic blood pressure of preeclamptic group was 169.8 MmHg and the average of diastolic blood pressure of the group was 124.3 MmHg. Meanwhile, the average systolic blood pressure of non-preeclamptic group was 110.3 MmHg and its average diastolic blood pressure was 79.4 MmHg. The table also indicates that there was a significant difference in blood pressure between preeclamptic pregnant women and non-preeclamptic pregnant women ($\rho$ = 0.000).

<td>.000</td>
<td>28.636</td>
<td>5.744-142.776</td>
</tr>
</tbody>
</table>

Table 4 indicates that the odd ratio of LDL-c was 11.880. This means that pregnant women with high LDL-c (>190 mg/dl) had 11-fold higher risk of preeclampsia, compared to pregnant women with LDL-c <190 mg/dl. The odd ratio of HDL cholesterol and LDL-c/HDL-c ratio were 4.564 and 28.63 respectively. This means that pregnant women with low HDL-c and high LDL-c/HDL-c ratio had 4-fold and 28-fold higher risk of preeclampsia respectively.

Discussion

The result of the study indicates that LDL-c level and LDL/HDL ratio was higher in preeclamptic women than in non-preeclamptic women, while HDL-c level was lower in preeclamptic women than in non-preeclamptic women. This is in line with a study conducted by Salhood dan Anjum which stated that there was higher LDL-c level and higher LDL/HDL ratio in
preeclamptic pregnant women than in non-preeclamptic pregnant women, while HDL-c level was lower among preeclamptic pregnant women than in non-preeclamptic pregnant women (17)(18)(19).

Endothelial dysfunction plays a vital role in the pathogenesis of preeclampsia (18). In the last three decades, LDLox and NO have been intensively studied and regarded as important mechanism which contributes to endothelial dysfunction (ED). LDLox and NO exert contradictory actions in protecting endothelium microenvironment which influence key events in ED (20). NO is the most important vasodilating molecule which is synthesized by nitric oxide synthase (eNOS dan NOS III) (21). Besides its vasodilatation function, NO also has pleiotropic vasoprotective, cardioprotective and anti-atherogenic effects. These functions have been summarized from numerous article reviews (21)(22)(23). NO and OxLDL are significant biological mediators which promote protective effect vs pathogenic effect in blood vessels simultaneously. As production of NO and its bioavailability decrease, OxLDL breaks the balance of vascular walls which leads to ED (20). The level of circulating OxLDL depends on the level of oxidative stress and the number of LDL particles. Some studies have revealed a strong positive correlation between OxLDL and LDL-c. One particular study involving 624 respondents came up with strong positive correlation between the two parameters (r = 0.67, P < 0.001) as well as a conclusion that LDL-c was one of the key determining factors in OxLDL concentration. The study also indicated a negative correlation between OxLDL concentration and HDL level (24).

Low HDL-c level was also negatively correlated with preeclampsia and this study showed that a decrease of HDL-c may lead to 4-fold higher risk of preeclampsia. This may be due to the fact that the main function of HDL-c is protecting the function and integrity of endothelium (25). A decrease in HDL concentration is related to ED. HDL tends to increase the number of progenitor cells in serum compartment and in the area of endothelial injury, thus may stimulate direct endothelial repair. One very important aspect is the ability of HDL to promote vasodilatation (26). HDL binds apo A-I from SR-BI receptor and this activates eNOS in endothelial tissue. The presence of apo A-I allows eNOS to pair with SR-BI receptor. Moreover, HDL-c also contributes to vasodilatation when SR-BI induces the expression of cyclooxygenase 2 and the production of prostacyclin (PGI2) by endothelial cells. Besides its vasodilatation function, PGI2 also inhibits trombocyte aggregation. HDL-c may inhibit endothelial cells apoptosis that is induced by LDLox and TNF-α (25). Some writers maintain that HDL-c particles are susceptible to oxidized lipids and proteins, both of which transform these particles into “disfunctional HDL” particles. Disfunctional HDL loses its vasoprotective effect which results in impairment of the function of endothelial tissue (27). Dysfunctional HDL does not stimulate NO release. In fact, it inhibits NO release by inhibiting eNOS activation. Dysfunctional HDL loses its anti-apoptotic effect in endothelial cells which causes ED (28).

High LDL-c/HDL-c ratio is associated with the development of coronary plaque (29). Individuals with high total cholesterol/HDL ratio or high LDL/HDL ratio have higher cardiovascular risk which is caused by an imbalance between atherogenic LDL-c and HDL-c as protective lipoprotein. This imbalance may be due to high LDL-c level may decrease the anti-atherosclerosis properties of HDL-c (30).

**Conclusion**

There was a strong correlation between LDL cholesterol level, HDL cholesterol level, LDL/HDL and preeclampsia.

**Recommendation**

The study may be used as a reference in conducting cheap and easy screening for preeclampsia risk.

Evaluation of the Antibacterial Activity of Iraqi Garlic Derivatives to Escherichia Coli

Minen Al-Kafajy
Lecturer, (PhD), Department of Microbiology, College of Medicine, Thi-qar University

ABSTRACT

Objectives: As a foodborne pathogen, Escherichia coli (E. coli) encounters many barriers to invade and disseminate in the human body, but it might cause disease. Although Fresh garlic juice (GJ) and Garlic oil (GO) were reported to possess antibacterial activity, the mechanism that underlay the garlic antimicrobial activity still obscure.

Method: The hypothesis of my study is to examine the antimicrobial activities of GJ and GO and the combination of either GJ or GO with Amp and CF, respectively.

Results: In my current project, the antibacterial activity of GJ was found to be significant in reducing the bacterial protein synthesis against E.coli, while GO negatively correlated; but, unfortunately, did not reach the significant level. Moreover, GJ and GO were correlated with improvement of the sensitivity of bacteria to antibiotics.

Conclusion: further investigation of the potency of GJ and GO in treating the infections is highly needed.

Keywords: E. coli, antibacterial activity, garlic juice, garlic oil

Introduction

Historically, Garlic (Allium sativum) has considered as customary dietary and medicinal supplements as an anti-infective agent 1. In vitro, it has been proofed the antimicrobial action of fresh and freeze-dried garlic extract against numerous microorganisms such as viruses 2 Bacteria 1 and fungi 3. It has been reported in several papers that allicin (diallyl thiosulfinate) is the primary inhibitory component of garlic that possess antimicrobial activity 4.

Several papers have reported that the main inhibitory component of garlic is the allicin (diallyl thiosulfinate) that produced when garlic cloves are compressed. The concerning issue in the allicin is unstable, and this could be the reason in the differences in reporting garlic bioactivity in multiple publications 5. Interestingly, Cavallito and his workers were discovered that removing allicin from the garlic juice will demolish its biological activity 6.

On the other hand, E.coli is one of the few microorganisms that considered versatile discovered for the first time by Theodor Escherich in 1885. It is one of the harmless bacteria residing in the intestinal area of the human and mammals. As a healthy flora, it inhabits in a mutually beneficial relationship with the host and seldom causes illness. In the industry, E. coli has been widely used in recombinant DNA technology to clone various types of plasmid, produce proteins, nucleic acids, etc 7.

Despite the harmlessness of E.coli, it could cause a severe infection that may affect humans and feeding mammals. E.coli rod-shaped belongs to a gram-negative facultative aerobic bacterium Enterobacteriaceae family historically discovered in the soil and rotting vegetation. Some of the E.coli strains obtaining virulence factors throughout plasmids, transposons, bacteriophages, and pathogenicity islands. Although only seven serotypes of E.coli are recognized as pathogenic, thirteen serotypes of E.coli have been discovered, but only seven of them causing most dangerous cases of human disease such as

University of Sumer, Thi-qar, Iraq
Email: minen2006@gmail.com

dysentery, diarrhea, and infections in the area other than the intestine such as the urinary system and meninges 7.

Studies that focused on using a fecal carriage estimated that most people will consume E. coli contaminated foods between 10 and 15 times a year in middle east countries. E. coli is a common pollutant of a raw diet, nuts, and dairy, and is yearly blamable for many universal recalls of both human and animal food. The USA Centers for Disease Control and Prevention (CDC) has estimated that the epidemic cases were associated with consumption of food products, 73,000 illnesses, 2,200 hospitalizations, and 60 deaths annually in the United States. Complete genome sequencing of bacteria isolated from the product confirmed the genetic presence of the E. coli in the isolated bacteria. In recent years, E. coli accounted for a stunning 50% of the total amount of food recalled by the USDA, the liability in large part to contamination of frozen vegetable products manufactured by food companies. 8

For the majority of humans who ingest E. coli, the only symptoms that happen will be self-limiting gastroenteritis or flu-like symptoms. In the senior people, however, or in patients with low immunity level such as HIV, cancer, diabetes mellitus, and those on immunosuppressive medicine, the disease may proceed to invasive enteric illness, described by septicemia, meningitis, and encephalitis, before analysis is made. The latest study ranked E. coli infection as the fifth most costly foodborne pathogen in the US because the invasive enterobacteria generally result in admission to intensive care 9

The minimum inhibitory concentration (MIC): MIC method was employed to find out the minimum concentration of an anti-microbial agent able to successfully inhibit the observable growth of a microorganism for 24 h incubated at 37°C. MIC has been determined using the method developed by Caldwell and Danzer 10 with minor modification.

Disc Diffusion Method: Whatman No.1 filter paper discs (6 mm in diameter) was impregnated in Fresh GJ solutions, the paper dried and has been cut into discs. 50 l of sterile distilled water (SDW) was added to discs to serve as a control. Discs were placed on Molar Hinton plate completely streaked with the bacteria. The plates were kept for 24 h at 37°C. Next day the inhibition zones were measured. Positive control 10 g Nitrofurantoin (Nit) and erythromycin (Ery) where used as a positive and negative control for E.coli, respectively 11. 0.5 McFarland standard suspension was used to adjust the concentration of the suspension that has been made of the isolated strains.

Material and Method

Garlic Juice (GJ) extraction: Fresh garlic bulbs (Iraqi white-yellowish species) were purchased from the south of Iraq farm. 200 g garlic bulbs were blended in 100 ml sterile distilled water (SDW). The juicer was used to produce a fine garlic juice. The supernatant was collected after centrifugation at 3000 rpm for 30 min and directly filtered (0.4 mM pore size, Millipore). Finally, I obtained 50% w/v, and the extract was Freeze at -20°C for the future experiments.

Garlic oil (GO): The Garlic oil was purchased from a farm. Chemical composition has been determined by HPLC to ensure having the primary component that could possess the antibacterial effect, data not shown.

Microbial Strains: Three hundred clinical isolates were cultured (on blood agar and MacConkey) from clinical specimens of patients at the private internal medicine center (south of Iraq). The isolated bacteria were obtained from the urine of cancer patients that suffer systemic infections and also from pregnant women. The isolates were identified as E.coli would be selected for the present study. The total of E.coli (n=75) was chosen for the present study. Bacterial identification using API 20 E (BioMerieux company, marry Eliote, France) was used for identifying E.coli. Bacterial staining standard microbiology methods were used to examine the purity of the isolated strains. Finally, Nutrient agar slants were used to store the isolated bacteria at 8°C until further consideration.
The suspension was cultured on Mueller Hinton agar (Sigma Aldrich). The agar was incubated for 15 min at 37 °C to ensure that the agar will absorb the bacterial suspension. Finally, the disks containing the Amp, CF, FDG, and GO were placed on the agar using sterile forceps. A total of 5 replicates have been used in my study. After incubation for 1 days at 37 °C, the plates were observed, and the diameters of the zones of inhibitions were measured using a ruler, table (1).

**Protein Synthesis Assays:** 150 ml liquid growth cultured aerobically at 37°C with the presence of unlabeled-DL-Leucine, then, the level of bacterial protein synthesis was detected via adding 10 µCi of L-(5.5-3H) leucine (Sigma Aldrich) to the bacteria. The 150 ml divided into three cylinders, 50ml had supplemented with 10ml GJ (1:5) dilution, the other supplemented with 10ml GO (1:5) dilution while the third left as a control. 2ml of the growth has been taken from each of the 3 cylinders divided into two tubes placed on ice, and each of them was received 0.1 ml of 5% perchloric acid. After 2 hours, all the samples were provided with 5ml of 5% cold perchloric acid and incubated on ice for half an hour. The liquid growth then filtered by 0.4 µm filter. Radioactive counter was used to measure the activity.

**Statistical Analysis:** SPSS software version 18.0 (SPSS Inc. Chicago, IL) was used to determine the significant correlation of the data. One-way ANOVA was employed to detect the correlation between the parameters, while the factorial experiment was performed to evaluate the relationship between the Garlic extracts and the bacterial growth with or without the antibiotics that have been used in my study. Finally, two-way ANOVA was used to determine the significant interaction as P≥ 0.05 was identified as a significant correlation.

**Results and Discussion**

**Clinical Strains:** From all the clinical samples that have been tested in the study, I isolated many strains. However, I chose 75 E.coli to do the further experiment.

**Determine the Garlic derivatives of anti E.coli activities using discs diffusion methods:** By measuring the diameter of the antibiotics, NIT was reflected resistant when the ZOI exactly ≤14, intermediate when it 15-16 and sensitive if it 17mm according to the manufacture instructions. Finally, Ery 15 µg was measured resistant when the ZOI is ≤13, intermediate if it 14-16 and sensitive when it 18mm.

The results that shows that NIT is highly toxic to E.coli which is scientifically expected according to 11. While most of the E.coli strains were resistant to Ery and this results come a long previous data reported by 12. GJ has shown an interesting result by successfully inhibiting 40 strain out of 75. The results comes along the data that suggested GJ can be toxic to variety of bacteria including MRSA 13. Unfortunately, GO has shown toxicity to only 10 strains which is unexpected, since GO has reported to have high anti-bacterial activities 14.

My hypothesis stated that the garlic derivatives would post the antibiotic activity; therefore, I used a combination of the antibiotics with either the GJ or GO. As I expected, the GJ significantly enhance the NIT activity and reduce the number of resistant and intermediate bacteria producing more sensitive bacteria. GO had enhanced the NIT activity. However, the difference did not reach essential effect. The combination of Ery and GJ have significantly increased the sensitivity of the bacteria; However, I am not exactly sure whether the reduction was due to the combination or it is solely from the Garlic derivatives (table 1). Therefore, further investigation is needed for exploring Garlic products effects. My project aims to eliminate the infecting organisms or to prevent the onset of E.coli diseases. The results explain that the GO and GJ exhibit selective toxicity as it demonstrates more significant toxicity to the infecting pathogens than to the host. The next step in the future research will focus on testing the antibiotics and the garlic derivatives on cell lines and animals.

**Table 1:** Test the antibiotics and the Garlic derivatives ability to reduce E.coli growth on the agar plates

Protein Synthesis Assays: A significant negative effect has been detected when measuring the bacterial growth that has supplemented with GJ as compared to the control group, $p=0.02$ (figure 1). The GO protein synthesis showed decreased in the protein synthesis, but the results did not reach a significant level, $p=0.08$ (figure 2). This data suggests that the GJ as it fresh could have a more antimicrobial effect than GO. Another possible explanation is that the GJ could have components that are a potent antimicrobial structure such as allicin in higher concentration than GO. This could be due to the oil extracting mechanism that might be harsh and caused unintentionally distraction and loss in the amount of allicin.

Effect of Using Zirconia and Metallic Bar Attachment Overdentures on the Supporting Structures of Mandibular Edentulous Ridge Area (Randomized Control Trial)

Mohamed Z. Debi1, Amr I. Badr2, Emad M. Agamy3, Gehan F. Mohamed3
1Lecturer, Removable Prosthodontics, Faculty of Dentistry, Pharos University, Alex, Egypt; 2Associate Professor, 3Professor, Prosthodontics, Faculty of Dentistry, Minia University, Minia, Egypt

ABSTRACT

Statement of Problem: Mandibular conventional denture is no longer the most appropriate first choice of treatment, nowadays implant retained overdentures proved to be a predictable and effective method as compared to complete dentures.

Purpose: The aim of the present study was to evaluate the effect of using zirconia and metallic bar attachment overdentures on peri-implant supporting tissue clinically for implant-supported overdentures in the mandible during a year period.

Materials and Method: Twelve completely edentulous patients had two inter-foraminal implants. The patients divided randomly into two equal groups. Six patients received zirconium bar attachment system and the other group received metallic (Cr-co) bar attachment, modified plaque index was obtained for both groups.

Results: No implants were lost from baseline to a year registration. Metallic bar attachments showed significant plaque accumulation than zirconium bar attachments.

Conclusion: There was better modified plaque index for zirconium bar attachment.

Keywords: mandibular overdenture, two implants, zirconium bar, metallic bar

Introduction

After tooth loss, the alveolar ridge resorbs occurs resulting in diminishing of stability and retention of the lower denture, this leads to reduction of comfort, chewing ability, biting force and facial esthetics, this in turn leads general dissatisfaction with the mandibular prosthesis and finally patient seeks replacement of his conventional denture [1,2].

The implant supported bar overdenture is preferred as less expensive alternative, can be removed at night, offers retention and stability similar to those of implant supported fixed-prosthetic.[3,4].

Zirconia has been used to manufacture primary and secondary copings [5, 6,7] due to its good biocompatible and mechanical properties including high wear resistance, esthetics, and low both thermal and electrical conductivity as compared to Cobalt Chromium (CoCr) or Gold copings [8,9].

In the lower jaw two individual zirconium bars was fabricated using the CAD/CAM technology, each zirconium bar was supported by two implants. He found that there was no galvanism due to the metal freedom, good esthetic and good patient psychological acceptance also there was good hygienic ability due to the smooth ceramic surface [10].

Overdenture with two implants would be considered the treatment of choice in completely edentulous patients. Combining the advantages of bar attachment
overdenture and zirconia as a biocompatible strong bar material, made with high precision and fit by the CAD/CAM system, a satisfactory worthwhile prosthesis will be provided.

Materials and Method

Study Design: A Randomized control trial was conducted on 12 completely edentulous healthy patients. For each patient an implant retained mandibular bar overdenture was fabricated using minimally invasive flapless surgical technique.

The study was performed after gaining the approval of the research ethics committee. Patients were informed about the research procedures and follow-up examinations. Informed consent was filled out by each patient in accordance with the regulation of the Ethics Committee in Faculty of Dentistry, Minia University.

Patient’s selection criteria and allocation: The participating subjects in this study were selected according to the following criteria:

Inclusion Criteria: Patients age (45-65 years), sufficient residual alveolar bone quantity and quality, healthy mucosa covering the residual alveolar ridges, Angle’s class I maxilla-mandibular relation, U-shaped lower ridge, Sufficient interarch space greater, Proper oral hygiene, Non smoker patients.

Exclusion Criteria: History of radiotherapy, uncooperative patients, patients with TMD or neuromuscular disorders, abnormal habits, e.g. bruxism, clenching, smoking and alcoholism, diseases that affects bone metabolism e.g. Diabetes, contraindicated patients for any surgical procedures.

All patients who participated in the study received:

- Complete dentures before surgeries.
- Received two implants inserted at the canine region bilaterally. All implants were of the same length and the same diameter (Oxy implant. Via Nazonale Nord, 21A, 23823Colico LC, Italy). The twelve edentulous patients were randomly divided into two equal groups (six patients each).
- Maxillary complete denture and an implant retained mandibular bar overdenture.

Methodology

1. Pre-operative cone-beam computed tomography (CBCT) (SORDEX 3DX. Nahkelantin 160, Tuusula. P.O. Box 148, FI-04301 Tuusula. Finland) to check the quality and quantity of the bone at the planned implant site.

Every patient received complete set of upper and lower complete denture. Bilateral balanced occlusion was

2. utilized for arrangement of artificial posterior teeth and was verified inside the patient’s mouth.

3. Also every patient received surgical guide fabricated using CAD/CAM technology. (Figure 1)

Surgical Stage: To allow repeated placement of the surgical guide intra-orally, an interocclusal index was fabricated after remounting the complete dentures.

1. Infiltration anesthesia was injected to the planned implant sites.

2. Three holes were drilled into the mandible, through the lateral cylinders of the guides, to allow for the insertion of the anchor pins for fixation of the guide throughout the drilling steps.

3. After fixation of the guide, drilling started with the pilot drill and ended with the final drill.

4. After complete osteotomy preparations, surgical guide was removed then implant placement was started first manually till resistance was felt then complete implant placement was done using the wrench system (Oxy implant. Via Nazonale Nord, 21A, 23823Colico LC, Italy). All implants were of the same length and the same diameter.

Figure 1: Surgical guide with fixation lateral pins
5. Two Cover screws were used to cover the implants till delayed loading after 3 to 4 months.

6. Denture Modification:

- The fitting surface of the denture was prepared opposite to the implant sites to accommodate the implant heads
- A tissue conditioning material (Alpha dent products Co., subsidiary of Wallace A. Erickson &Co. 1920N. Clybourn Ave., Chicago, IL 60614, USA) was used to reline the mandibular denture to avoid tissue irritation or implant overloading.

Stage 3: Bar Attachment Fabrication:

- The patients were randomly divided into 2 groups: 
  - group 1 received Co-Cr bar joint attachment while 
  - group 2 received Zirconium bar joint attachment.
- For group 1:
  - Two plastic castable abutments were attached to the implant (fig 2).
  - A plastic castable bar (bar joint design) was used to determine the length of the bar that was going to be used, and then marking the length and the excess was cut.
  - Two retaining slots were made in the mesial aspect of each plastic abutment. These two slots facilitated bar fixation to the abutments and facilitates occlusogingival positioning of the bar pattern. (fig 2)

- Then complete fixation of the bar to the two plastic abutments was done using burn-out self-cured acrylic resin (Duralay, Reliance Dental Manufacturing Co., Chicago, USA.) (fig3)

- Figure 2: Bar placed in the notches

- Figure 3: Bar attached to the plastic abutments with Duralay

For group B:

- The same procedures were made as group A except that:
- After the removal of the assembly of the plastic bar and the two plastic abutments it was sprayed with 3D laser scanning spray to be allowed to be scanned then it was suspended on a tray fo the 3D extra-oral scanner (Zirconzan, scanner SG00, ART, Worldwide, An Der Ahr 7, 39030 Gais/South Tyrol,
Italy) then the 3D image of the scanned bar was checked for accuracy and was milled with the milling machine (Zirconzan, Milling unit M1 Worldwide, An Der Ahr 7, 39030 Gais/South Tyrol, Italy).

- The milled bar was larger than its actual size by approximately 25% so after milling it was placed in a sintering Zirkonofen Furnace (Zirconzan 600/v2. Worldwide, An Der Ahr 7, 39030 Gais/South Tyrol, Italy) at 1600 degree for 12 hours, this allows for the shrinkage of the milled zirconium.

- Then the bar was checked for passive fit and accuracy intraorally. (fig 5)

Figure 5: Zirconium bar intra-orally

Stage 3: (pick up of the plastic clip):

- The clinical pick-up procedure was the same for both groups. The aim was to attach the sleeve to the fitting surface of the existing mandibular overdenture under maximum biting force.

- The nylon clip was fixed on the top of the bar. (fig 6)

Figure 6: Plastic clip on the bar

- A window was opened in the lingual flange of the lower existing denture to accommodate the bar with no interference.

- Any undercuts beneath the bar and copings was blocked out using smooth casting wax (Glattes Gusswachs, smooth casting wax 0.3mm., Ref. no. 40092, BEGO, Germany)

- With using Methyl metha acrylate free self-curing rebase material (Tokuyama Rebase II Fast, Tokuyama Dental Corporation, Japan) was applied in the fitting surface of the mandibular overdenture.

- The denture was seatead in the patient mouth and the patient was asked to close in centric relation and maintain maximum biting for consequently this small window was closed and hence picking up the plastic clip with the fitting surface of the existing denture after setting of the picking up material.

- After setting of the rebase material; the lower overdenture was removed slowly then finished and polished and tried into the patient for any occlusal adjustments.

- The patient was instructed about the oral hygiene procedures and denture care.

Evaluation Phase: Modified plaque index was recorded for every patient at the time of final prosthesis insertion (base line), 3, 6, 9 and 12 months after insertion.

Data was collected, tabulated, and statistically analyzed.

P comparison between group I and II at the same time

* Significant at level 0.05
At the time of implants loading, Paired t-test showed no statistical significant difference between the two groups.

After 3 months of implants loading, Paired t-test showed statistical significant difference between the two groups with (p) value of 0.011.

After 6 months of implants loading, Paired t-test showed statistical significant difference between the two groups with (p) value of 0.023.

After 9 months of implants loading, Paired t-test showed statistical significant difference between the two groups with (p) value of 0.017.

After 12 months of implants loading, Paired t-test showed statistical significant difference between the two groups with (p) value of 0.008 indicating more plaque accumulation around the implants of group II.

Discussion

Two implants connected with bar were used in this study (zirconium bar in the first group and metallic bar in the second group).

In the present study, modified plaque index was recorded according to (Lobene et al; 1986), [11] there was a slight increase in plaque and gingival indices scores in both groups, but it was higher around metal than zirconia bar attachments. It was concluded that zirconia has lower affinity for plaque adherence, and it is more biocompatible. It is well known that plaque induces gingivitis, and hence zirconia has lower plaque index, lower gingival index was predictable. These findings agreed with other studies that have examined removable dentures retained on teeth or implants using zirconia for the fabrication of copings, concluded that zirconia copings can help stabilize soft tissue against inflammation[12,13] (Busscher et al; 2010, Egawa et al; 2013). Also this was in agreements with other in vivo and in vitro studies for bacterial colonization on zirconia ceramic surfaces [14,15] (Rimondini et al; 2002, Scarano et al; 2004)

Elsayed et al; 2012, found that zirconia copings are much better for oral hygiene maintenance than metal cobalt chromium copings; and explained that by the lower bacterial adherence affinity of zirconia [16] CoCr has greater surface roughness, hydrophobicity, and greater electric conductivity and galvanic action, so the surface charge on CoCr can attract the microorganisms to be adhered to the charged surface. Kanerva et al; 2001, stated that regarding biocompatibility; Metallic ions, such as nickel Ni, Co, and Cr are known to cause adverse tissue reactions and allergy; although in our study, there was no observed allergic reactions or patient’s complain from metallic bar attachments. [17]

Degidi et al; 2006, Örtorp et al; 2009, found that Zirconia was found to create less phlogistic reactions in tissue than other restorative materials. [18,19] The level of bacterial products was higher on titanium than on zirconium oxide. Zirconia also could be regarded as a self-regulatory material that can modify turnover of the extracellular matrix, as they can regulate expressions of some genes (Warashina et al; 2003). [20]

Conclusions

Zirconium bar attachment is associated with superior clinical parameters than metallic bar attachment. It has lower plaque adherence affinity and better gingival index which stabilizes peri-implant soft tissue.

ABSTRACT

The research aims to construct, acquire the validity and reliability of Mental Health Inventory (MHI). The MHI’s questionnaire aims to measure the level of Mental Health for the subscales of positive and negative thoughts, positive and negative feelings and positive and negative behaviors of individuals aged 13 to 19. The construction of MHI is based on Cognitive Behavioral Therapy theoretical basis pioneered by Aaron Beck (1967). This inventory contains 60 items that measure 3 subscales. Subscale 1: Positive and negative thoughts, subscale 2: Positive and negative, subscale 3: Positive and negative behavior. Each subscale has 20 positive items and 10 negative items. In order to achieve the reliability, MHI was evaluated by eight expertise consisting of 4 academicians and 4 specialists in psychology, counseling and education. 146 students were chosen to be the respondents from schools in the state of Perak to achieve the reliability. The overall validity of MHI is acceptable which at 0.7864 (78.64%). The value of reliability indicates the acceptable value of 0.731. Hence, this research has successfully developed a questionnaire of MHI which has the value of validity and reliability and it also accepted for Malaysian education usage.

Keywords: Mental Health Inventory, Validity, Reliability.

Introduction

In the era of globalization, the social community nowadays have improving the issues of health problems and psychological disorders such as marriage problems, family, work stress, alcohol abuse, drug abuse and so on. This condition can lead to depression, anxiety, stress and various psychological disorders that give an impact to the quality and well-being of a holistic life.

Mental health is often associated with mental illness but it is not accurate. Mental health is closely related to our lives. It encompasses feelings, thoughts and behaviors within oneself, the ability to interact properly with others, groups and surroundings. It is also about how the person handles the responsibilities, challenges and pressures that happen in everyday life. Individuals who are mentally healthy are able to participate in community activities.

Lately, global awareness of mental health is increasing and we recognized that many mental health issues exist at adolescents (4).

Now, drug abuse is one of the public health issues that are significantly addressed and linked to various mental and behavioral problems (8,7,5).

When the issues of mental health problems in adolescents are not addressed, it can lead to severe mental and physical illness and it will affect the environment including increases the risk of suicide.

The inability to deal with mental problems among adolescents between the ages of 10 to 24 is also the largest contributor to adult mental health disorders (2).

Research on Mental Health: This Mental Health Inventory (MHI) is developed by researchers as an instrument to measure mental health among students aged 13 to 19 years. Based on Behavioral Cognition
theory, this theory aims to change the mindset to an orientation of action that assumes the wrong thoughts leads to wrong behavior and negative emotions. It is a form of psychotherapy that aims to change the pattern of human thought (cognitive) to an action, in order to make people feel better and effective. Model based Cognitive Behavioral Therapy (CBT), the assumption that our feelings and actions are influenced by a person’s thoughts, rather than an uncontrollable external factor. CBT focuses on changing the form of thoughts and negative behavior with new forms of thoughts and behavior.

Basic Theoretical of Mhi’s Construction: The researchers of Mental Health Inventory (MHI) construction states that there are three major subscales of individuals interacting and affecting his mental health, which are subscale of thoughts, feeling and behavior. Nevertheless, these three subscales are not considered separate as they overlap each other. The researchers have been using the MHI Concept Model’s Theory as the basis of theoretical approach to building MHI inventories to test the validity and reliability of this inventory. This theory is used as a guide to coincide with the construction of these inventory items.

Individuals whose mentally healthy can express their emotions and be able to successfully adapt to various stressful situations (1).

The Mental Health Inventory has been developed for a special mental health assessment. Analytical reliability and validity analysis were conducted to provide psychometric information (3,6). A normal individual may not have good mental health at all times, but still be able to do daily activities as usual.

The summary, though these three subscales can be measured separately, but basically it relates to each other as in figure. 1.

A. Subscale 1: Positive and negative Thoughts: Thought is a process of thinking, building knowledge and understanding that involves mental activity in the human brain. Therefore, this subscale is intended to measure thinking as a mental activity in life as well as the process of solving the problems faced. There are two types of thinking which are positive and negative thoughts.

B. Subscale 2: Positive and negative Feelings: Feelings are generally regarded as state or the sense that exists in the individual at a time. This means that feelings are characterized as a psychological state of the individual as a result of events or perceptions experienced by the individual. As such, the MHI is also aimed at testing the level of feeling and how the individual can deal with something, event or problem. There are two types of feelings which are positive and negative.

C. Subscale 3: Positive and negative Behavior: Behavior refers to the action or response of a person. The behavior is usually closely related to the environment. Behavior is also conscious or subconscious, real or obscure, willing or not and naturally or learned. Human behavior can be usual or unusual, acceptable, or unacceptable. Humans assess the acceptability of behavior based on social norms to control it through social control. This Mental Health Questionnaire also aims to measure the extent to which the individual responds or behaves in response to a change in the environment or the problem. There are two types of behavior which are positive and negative behavior.

Purpose of the Research

The main purpose of the research is to construct and measure the validity and reliability of Mental Health Inventory which includes thoughts, feeling and behavior among students in Malaysia. Hence, this research also aims to:

a. Constructing a Mental Health Inventory (MHI) based on literature review
b. Determine the validity value of the MHI questionnaire content.
c. Determines the validity value of the subscale of the MHIs questionnaire

Figure 1: Mental Health Inventory Subscale (MHI)
d. Determine the reliability of the questionnaire.

e. Determine the reliability of the subscale of the questionnaire.

**Administration, Scoring and MHI’s Interpretation:**
Mental Health Inventory (MHI) is an inventory that can measure the mental health of students. MHI contains 60 items to measure three major subscales namely positive and negative thoughts, positive and negative feelings and positive and negative behavior. MHI has 60 items in total and 20 items per subscale. These subscales are divided into subscale 1: Thought: Positive Thoughts and Negative Thoughts, while subscale 2: Feelings: Positive Feelings and Negative Feelings and subscale 3: Behavior: Positive Behavior and Negative Behavior.

Mental Health Inventory (MHI) is easily administered as it takes 20 to 30 minutes to answer. MHI is suitable for group or individual administration. The administration of this MHI is suitable to be administered in a conducive environment without any interruption to the respondent. For the scoring method, the questionnaire of this MHI uses the scale of agreement between 1 to 5 which are strongly disagree (1), disagree (2), half agree (3), agree (4) and strongly agree (5).

**Research Method**

The design of this research is a descriptive study. Descriptive study was used to obtain the validity of the content and the reliability value of MHI which was developed through questionnaire. This research involved three phases: Phase 1: Construction of MHI, Phase 2: Obtaining Content Validity, and Phase 3: Analysis of reliability value.

**Phase 1: Construction of MHI:** The construction of MHI is based on a thorough literature review. Based on previous studies, an approach to the MHI Model would be the foundation of MHI construction. This Mental Health Questionnaire aims to measure the extents of a person’s mental health. MHI contains 60 items to measure three major subscales namely Positive and negative thoughts, Positive and negative feelings and positive and negative behavior.

**Phase 2: Obtaining the validity of the face and the validity of the content:** Face validity is to test accuracy in terms of language, grammatical accuracy and understanding to respondents. Face validity is derived from three language experts who comments and construct the proposals for MHI’s improvement. For the purpose of obtaining the validity of the content, the researchers have stated that the validity of the content refers to the extent to which the test tool is able to collect data that includes the objectives of a field or survey instrument surveyed. Therefore, this questionnaire should be tested on the validity of the content. Hence, once the MHI items are built, the content validity questionnaire is given to 16 expert panel comprising eight academicians and eight counseling and education psychologists to check the accuracy of the contents of MHI items. The review made by the expert panel is to obtain the value of the legal validity of MHI.

**Phase 3: Reliability Analysis:** Next, the third phase is aimed to obtain the value of MHI’s reliability. After MHI gained the value of content, MHI tested the reliability of 146 secondary school students in Malaysia. Data were analyzed using computer program *Statistical Package for the Social Sciences* (SPSS) to obtain value *Cronbach’s Alpha* to determine the reliability of the major scale and subscale of MHIs.

**Results and Discussion**

**Findings of Phase 1: Construction of Scale and Subscale of MHI:** The construction of MHI is based on thorough literature review through the source of books, articles and various journals from local and international. This literary research examines the definitions, concepts, factors, implications and mental health levels of various perspectives. Furthermore, the theoretical foundation for the construction of the MHI’s subscales is the Mental Health Model based on Cognitive Behavior Therapy (CBT). Based on the theoretical basis of CBT, MHI is constructed of 60 items that divide mental health levels into three subscales (20 items for each subscale) namely subscale 1: positive and negative thoughts, subscale 2: positive and negative feeling and subscale 3: positive and negative behavior.

**Phase 2 of research findings: The Face and MHI’s Content Validation:** The expert assessment results have been collected and analyzed to obtain the validity value of the content. Table 1 shows the overall validity and subscale values of MHI.
Table 1: The overall validation and subscale’s value of MHI (n = 8)

<table>

</tr>
<tr>
<td>Positive and negative behavior</td>
<td>20</td>
<td>0.7750 (77.50%)</td>
<td>Accepted</td>
</tr>
</tbody>
</table>

Based on Table 1, the value of the overall validity of MHI is 0.7864 (78.64%). While the validity of the content for subscale Positive and negative subscale is 0.7888 (78.88%), subscale Feeling healthy and unwell is 0.7966 (79.66%) and Positive and negative behavior is 0.7750 (77.50%). Overall the value of content validity is acceptable.

Findings of Phase 3: Reliability of MHI: Furthermore, reliability analysis to obtain coefficient value Cronbach’s Alpha MHI is as follows:

Table 2: Overall reliability and subscale value of MHI (n = 146)

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Interpretation of reliability value Cronbach’s Alpha for the whole item and each subscale is based on the theoretical presented by Sekaran (1992) which states that the reliability value less than 0.60 is considered low and unacceptable. Meanwhile, the value of Cronbach’s Alpha between 0.60 and 0.80 are accepted and values greater than 0.80 are considered to be good. Therefore, overall reliability analysis for MHI shows the coefficient value of Cronbach’s Alpha is 731, which means good and acceptable. This shows that MHI has good reliability and proves that MHI can measure the level of mental health among respondents through the subscale of positive and negative thoughts, positive and negative feeling and positive and negative behavior.

Discussion and Proposal

Through the results obtained, the construction of MHI has a strong theoretical basis based on the in-detail literature on definitions, concepts, factors, implications and mental health levels of theoretical variety. Hence, a theoretical foundation is used as the main framework for the construction of major scale and subscale of MHI which is Mental Health Model based of theoretical Cognitive Behavior Therapy. Additionally, based on the analysis done, MHI has a high value of content validity and good overall reliability. High values of content validity indicate that there is an expert panel agreement that the items in MHI are able to measure the definition of scale and each subscale in the MHI. This is supported in the findings of reliability testing that demonstrates that MHI is able to measure mental health levels divided into three major subscales. While there is a subscale that achieves a low reliability value of 0.321 which is subscale of positive and negative thoughts, the overall value of MHI reliability is good at 0.731 and so is the value of each item. This makes MHI still acceptable and applies in actual studies to measure the mental health level among high school students.

MHI is able to provide a basis for identifying mental health among high school students. In addition, MHI can also assist in implementing mental health improvement programs. It is believed that a good level of mental health among school children is very important in ensuring that they enjoy the healthy nature of adolescents. Based on the findings of the research which gained a high degree of validity and moderate reliability for MHI, researchers suggested that MHI be implemented more comprehensively and widely, especially throughout the secondary schools in Malaysia. It is proposed that further research be carried out to make more statistical analysis of items in the MHI. It is really important in making improvements to scale, subscale and MHI items built to be more standard and quality. The number respondents should be increase to produce better quality of MHI.

Closing

Overall, this research has succeeded in establishing a Mental Health Inventory (MHI) which has a good...
value of good content and moderate reliability. Thus, MHI is able to measure the level of mental health of a person acquired through three major subscales namely subscale of positive and negative thoughts, positive and negative feelings and positive and negative behavior. The analysis of each item contained in MHI also has high reliability value and shows that MHI can measure the mental health level of respondents.

Effect of Immersion Time in 2,5% Sargassum Polycystum Effervescent Granule Denture Cleansing Agent on the Stability Acrylic Resin Plate Colour

Mohammad Dharma Utama1, Harun Achmad2, Ikhriahni3, Andi Adytha M.I.R.3, Anissa F4
1Department of Prosthodontic, 2Department of Pedodontic, 3Postgraduate Program Student, 4Dentistry Study Program, Faculty of Dentistry, Hasanuddin University, Makassar South Sulawesi, Indonesia

ABSTRACT

Sargassum Polycystum is one type of brown seaweed (Phaeopychae) which contains various pigment content such as beta carotene, chlorophyll a and b, and fucoxanthin. Acrylic resin has the porosity and the ability to absorb liquids that can cause discoloration. The purpose of this study was to investigate the colour stability of heat cured acrylic resin plate after immersed in Sargassum Polycystum effervescent granule. This is a laboratory experimental research with a pretest-post test with control group design. The samples are 27 pieces of 20 mm x 10 mm x 2 mm acrylic bars. Samples were divided into 9 groups containing three negative control groups mineral water, three positive control groups Sodium perborate (polident), and three groups of Sargassum Polycystum 2,5% filtrate groups. The immersions were performed in the room temperature for 5, 10, and 15 minutes for every control group. Discolorations of each group were measured using a colorimeter. Statistical tests for this research were independent t-test. Colour change of the acrylic resin plate after immersed in dental prosthesis cleansing agent made from effervescent granule of Sargassum Polycystum 2,5% occurred because of the increase of microporosity on the surface of the rough plate which made pigment micromolecules more attached so that the color of acrylic plate became brown (p<0.05). Acrylic resin plate color changed after immersed in 2,5% Sargassum Polycystum granules at 10 and 15 minutes.

Keywords: acrylic resin, denture cleanser, discoloration, Sargassum Polycystum, effervescent granule.

Introduction

The loss of teeth can result in anatomical and functional changes. As people get older, the susceptibility of losing teeth is increased. This situation also has an impact on the increasing need for dentures. One of the basic material of denture base is the polymethyl methacrylate heat cured acrylic resin. Acrylic resin is commonly used as a denture base due to some properties, such as non-toxic nature, non-irritating to tissues, good in esthetic, inexpensive, and easy to manipulate.1 This acrylic resin also has disadvantages such as the occurrence of porosity, microcracks, absorbing liquid (water and chemicals), residual monomers and discoloration.2 The color stability is a very important clinical characteristic of dental-restoration materials and denture base plate materials. The color changes in the acrylic resin can be caused by two factors: internal and external factors. The internal factors include changes in the matrix that occur due to some physical and chemical changes, while the Denture cleaning can be done with both mechanical and chemical techniques. Mechanical cleaning is a technique using a toothbrush and ultrasonic. While cleaning with chemical techniques is cleansing by immersing dentures in disinfectant solutions such as alkali peroxide, alkali hypochlorite, chlorhexidine, sodium hypochlorite, enzymes, and herbs. This method of denture cleaning has the advantage of being easy to use and it is easily reaching the undercut on the denture base.3,4,5,6 Along with the development of science, the use and utilization of herbal ingredients in Indonesia has
progressed rapidly. Herbal disinfectants are used by the community as an alternative material for cleaning the dentures, in addition to the basic ingredients for denture cleansers in the form of chemicals that develop on the market. The effectiveness of disinfectant ingredients from herbs has been widely researched and proven to prevent the growth of microorganisms found in the denture bases.7

Sargassum sp. Brown algae is one of the herbal ingredients that are antifungal and antibacterial. It can be used as a denture cleaning material.8 from the study conducted tests on methanol extracts that of the three classes of seaweed class Chlorophyta (green algae), Phaeophyta (brown algae), Rhodophyta (red algae), Phaeophyta (brown algae) had the highest antibacterial activity.

Sargassumpolysyctum brown algae has some active compounds such as flavonoids, alkoloid, saponin, phenol, and trapezoid as antibacterial, antiviral, and antifungal agent.9 The research conducted by Rina et al. (2014) stated that Sargassumpolysyctum extracts have an inhibitory effect on the activity of Candida albicans. Several studies have suggested that the pigment content identified in Sargassumpolysycystum (C.Agardh) brown algae extract, named β-carotene, xanthofil, chlorophyll a and chlorophyll c, have been shown to provide antibacterial effects.10,11 Acrylic bases have physical properties which tend to absorb water. Immersion slowly over a period of time causes absorption to pass through the diffusion mechanism (Philips 1991). The occurrence of absorption of liquid dyes in acrylic resin is one of the factors causing color changes in acrylic resin.12 Pigment contained in Sargassumpolycystum could be expected to cause a color change as one of the external factors to the denture. However, information about the effect of immersion of acrylic resin denture plate in granule solution of Sargassumpolycystum on color changes is still limited to this time. Therefore, it is necessary to conduct research to determine the effect of immersion time of acrylic resin plate in granule solution of Sargassumpolycystum as a natural disinfectant on color stability on the denture plate.

Material and Method

Specimen Preparation: Type of heat-polymerized PMMA resin was used for the fabrication of specimens (n=27 per resin). All denture base specimens were prepared according to the manufacturers’ instructions. persegi wax pattern diwidth dimensions of with 20 mm lenght, 10 mm width, and 2 mm thickness. Wax discs were invested in denture flasks followed by a compression moulding technique for conventional heat-polymerized acrylic resin (Q-type) (QC-20, Dentsply) and afterwards melted with boiling water. The heat-polymerized acrylic resins were then packed into the mould, and the metal flasks were placed in a boiler unit for polymerization. All flasks were allowed to cool down for 2 h. All specimens were immersed in distilled water for 24 h for residual monomer release.

Test Immersion Dental Cleanser: Denture cleanser Polident 3 min™ from obtained from the manufacturers. Sargassumpolycystum brown algae is obtained from the coastal waters of Punaga, Takalar district, South Sulawesi, then Sargassum polycystum is made into an effervescent granule which before the effectiveness test has been carried out at a concentration of 2.5%. The sample was divided into 3 groups (Polident 3 min™, granule effervescent Sargassumpolycystum 2.5%, and Aquades. Each group was further divided into 3 small groups according to the immersion time of 5, 10, and 15 minutes for each sample group with 3 plates each. Before being soaked, the glass is cleaned thoroughly. The granule effervescent Sargassumpolycystum 2.5%, Polident 3 min™ Polident andaquades were poured into a jar, the plate was inserted afterward. The 100 ml mineral water then be added slowly. The immersion last for 5, 10, and 15 minutes at the room temperature.

Color Measurement: The Color stability measurement was done using a colorimeter CS-10 (China). The colorimeter was calibrated before being used for sample measurement. The sample placed on a table with a white base and the colorimeter placed perpendicular to the sample with the sensor in the middle of the samples.

Data Analysis: All data were presented as the average ± standard deviation of replicate measurements (n = 3). Statistical analyses of data were carried out with SPSS 21.0 software package. Significance of results was tested by an analysis of t-test. Significance of differences was defined at p < 0.05.

Results and Discussion

This study used colorimeter CS-10 (Chinese) for color measurement. Colorimeter is a device that is sensitive to light and measures the color intensity of an object or the color of a sample in relation to components of red, blue and green light reflected from an object or sample.

![Figure 1: The results of the color change examination on acrylic plates before and after immersion](image-url)
This research was done by immersing the acrylic resin plates in the three ingredients. Observation of color changes was done in three different time intervals, for 5, 10, and 15 minutes. This time interval was based on the study conducted by13 which stated that several variations disinfectants showed susceptible antimicrobial effectiveness of 5-8 minutes. also stated that 5 minutes of immersing of acrylic resin plates in hydrogen peroxide effervescent solution was as effective as a 30-minute bath conducted a study with chlorhexidine and solutions effervescent (alkaline peroxide) with intervals of 5 to 15 minutes. Based on the above argument, the researcher took an interval of about 5, 10 and 15 minutes. Discoloration of denture elements is influenced by some internal and external factors. The internal factors include formulation (polymerization), material properties, chemical structure, and monomer composition used. External factors include the duration of exposure and the type of stain agents such as tea, coffee, and denture cleaning agents. The longer duration of immersion of the denture in the disinfectant solution, the greater color changes of the denture elements that occur.15,16 In this study, acrylic resin denture plate which was soaked in 2.5% granule effervescent Sargassumpolicystum solution for 5 minutes showed that there was no color change between the control group and the study group (Table 1), while soaking in granule solution of 2.5% Sargassumpolicystum effervescent for 10 and 15 minutes showed that there was a discoloration in the study group while the control group did not experience discoloration (Tables 2 & 3). The control group did not show any changes in color because the disinfectant material had not diffused into the resin plate due to time immersion and because of the absence of external factors, the dyestuff. Which stated that 10 minutes immersion of sodium perborate with effervescent denture cleaning materials did not cause discoloration but intrinsic discoloration of the acrylic resin plate after soaking during 40 minutes, 120 minutes, 240 minutes, and 360 minutes.

Color changes in the immersion process of 2.5% Sargassumpolicystum effervescent granule solution for 10 and 15 minutes occurred due to the presence of dye entering and absorbed through the pores on the denture resin plate. It is similar to an opinion that one of the factors that can cause color changes in acrylic resin is the presence of natural and artificial dyes.17 The content of natural dyes in Sargassumpolicystum β-carotene, xanthofil, chlorophyll a and chlorophyll c diffuse into acrylic and causing the discoloration. It is caused by an increase in the amount of microporosities on a rough surface which make it more micromolecules attached so that the color of the acrylic plate become brownish. This research is similar with the research conducted17 which stated that there was a change in the color of the acrylic base after the use of denture cleaning paste due to exposure to rosetta dyes, anthocyanins entered the pores due to the microporosity properties of acrylic. The porosity in acrylic resin resulted in being able to absorb water or liquids and food and chemicals slowly over a period of time. According to19 the water absorption process in heat cured acrylic resin occurred due to diffusion of a water molecule by penetrating a mass of polymetal methacrylate and occupying a position between the polymer chains. As a result, the disturbed polymer chain was forced to separate.20

Several other studies stated that the longer the immersion of acrylic resin in drinks or foods containing dyes such as tea, coffee, and chocolate, the greater the color changes that occur in acrylic resin denture elements.16,21 Changes in color when immersing acrylic resin plates can also occur due to the presence of a compound in sargassumsp, named tannin compounds which are known to contain acidic polyphenols which can disrupt the hydrolysis reaction between phenol and polymethyl methacrylate esters on the acrylic resin plates so that many cavities resulted on it. This condition is similar to study which stated that the presence of coffee liquid diffusion which enters the acrylic resin plate as a result of changes in the volume of coffee solution can result in changes in the color of the acrylic resin plate due to an increase in absorption of tannin substances.22,23

Conclusions

There was a change in the color of the acrylic resin plate soaked in the 2.5% Sargassumpolicystum granules effervescent denture cleaning agent for 10 minutes and 15 minutes.

ABSTRACT

Vascular endothelial growth factor (VEGF) is an important in the formation of new blood vessels which is also known as angiogenesis. It is important in restoring oxygen supply to tissues in case of tissue hypoxic a condition which is normally occurs in the cancer/tumor cells. The aim of the study was to evaluate the correlation between the serum VEGF and angiogenesis in the ovarian cancer patients. This study included 20 ovarian cancer patients enrolled to the Al Hussain medical city hospital in January 2018 to January 2019. The ovarian cancer was detected by the ultrasonography. The enrolled patients are between the age group between 40-50years. The patients with the diabetes, cardiovascular disease were excluded from this study. The fasting blood was collected after getting participant oral consent. The samples were subjected to serum isolation and it was used to evaluate the serum VEGF level by commercially available kits. In the present study, the malignant tumor patients showed significant high levels of serum VEGF in the pre-surgery stage than the benign tumor patients in the same stage. VEGF can be one of the factors which promote the malignancy in the tumor.

Keywords: Vascular endothelial growth factor, Angiogenesis, Surgery, Malignant tumor

Introduction

Vascular endothelial growth factor (VEGF) is an important in the formation of new blood vessels. It is important in restoring oxygen supply to tissues in case of tissue hypoxic a condition which is normally occurs in the cancer/tumor cells. It is also involved in creating new blood vessels in embryonic development, injury, and exercise and in the case of collateral circulation. It is mainly produced by tumor cells, macrophages, platelets, keratinocytes and renal mesangial cells.

Angiogenesis is the formation and maintenance of blood vessels. This is important for physiologic functions and but results in the progression of diseases like cancer and inflammation. VEGF, ephrin-Eph receptors, angiopoietin and the Delta-Notch system play important role in angiogenesis. VEGF-C and VEGF-D and their receptor mainly are responsible for embryogenesis and are regulators of lymphangiogenesis. VEGF executes many functions like vascular permeability, pro-angiogenic activity, stimulation of cell migration in macrophage and endothelial cells. Angiogenesis by means of capillary sprouting causes new vessel formation. Thus, once original blood supply is depleted, it causes hypoxic conditions and depletion of nutrients. Thus, tumor fails to proliferate and apoptosis is induced. Angiogenesis is difficult to measure and often indirect measures are adopted. Hypoxia is the main trigger for VEGF upregulation acting through HIF-1. In case of Hyperglycemia and proinflammatory cytokines are stimulating factors that increases VEGF production.

Disorders in vasculature are results in many human diseases. In cancer, angiogenesis is a major contributor to tumor growth and metastasis. Many VEGFs have already entered clinical use which is also characterized in human diseases. The family members VEGF namely VEGF-B, placental growth factor (PlGF), VEGF-C and VEGF-D
which probably binds their cognate receptors VEGFR-1, 2 and 3 present on vascular endothelium. Signal transduction by VEGF-C and VEGF-D may be useful in lymphatic metastasis in cancer, whereas if this pathway is stimulated. It is beneficial in treating lymphedema.

Numbers of evidence are available about the over-expression of VEGF in tumors but it was poorly correlated with the outcome. Although, there was substantiation evidence that VEGF is associated with growth, infiltration and metastasis of malignant ovarian tumors, the clinical significance of VEGF expression in ovarian tumors remains unclear. So, it is very important to know the relation between the angiogenesis and serum VEGF levels in the ovarian cancer patients in the Iraqi women.

**Material and Method**

This study included 20 ovarian cancer patients enrolled in the Al Hussain medical city hospital in January 2018 to January 2019. The ovarian cancer was detected by the ultrasonography. In the present study, ovarian cancer patients were screened for their further complications.

Fasting blood (n=20) was collected by a single puncture form the cancer patients, after obtaining informed consent. The enrolled patients are between the age group between 40-50years. The patients with the diabetes, cardiovascular disease were excluded from this study.

The fasting blood was collected in the plain vacutainers from the vein after getting participant oral consent. The samples were kept at room temperature for 30min. Followed by the centrifugation at 3000rpm for 15min. The serum was separated and kept at 20°C for further study. Serum sample was used to evaluate the serum VEGF level by commercially available kits (Sigma, USA).

**Statistical Analysis:** The data were subjected to statistical analysis using GraphPad Instat (3.0, Trial Version). Results were presented as Mean ± Standard Error (SE). Dunnett Multiple Comparison Test and one way Analysis of Variance (ANOVA) was done to estimate the statistical significance.

**Results**

In the present study, we evaluate the serum VEGF levels in ovarian cancer patients enrolled in the Al Hussain medical city hospital.

The serum VEGF levels were significantly higher in patients with malignant ovarian tumors as compared to the patients with benign ovarian tumors. We also measured significantly higher levels of serum VEGF in patients with ovarian cancer before therapy than after therapy (p<0.001).

</table>

Results are represented as mean ± standard error. Pre-surgery VEGF levels showed ***p<0.001 as compared to post-surgery VEGF level (unpaired two-tailed test)

The tumor size for the benign and malignant cancer was found to be 1.97 ± 0.18cm and 3.18 ± 0.28cm, respectively. About 45% of the women showed ovarian cancer metastasis. While, about 55% women showed benign tumor (Table 2).

<td>11 (55%)</td>
</tr>
</tbody>
</table>

The serum VEGF levels were lower (p<0.001) in the patients with residual tumor sizes ≤2 cm then the residual tumor sizes >2 cm after surgical therapy. In addition, we found that the serum VEGF levels were significantly higher in the ovarian cancer patients with metastasis to omentum or lymph nodes than in the ovarian cancer patients without metastasis (p<0.001).

![Figure 1: Serum VEGF levels in the enrolled patients](image-url)
The malignant tumor showed positive correlation with the higher VEGF levels in patient with malignant tumors. After tumor removal, the serum VEGF levels were decreased and it was comparable to the benign tumor. The VEGF levels in the benign levels were found to be lower before surgery than the post surgery. Surprisingly, it levels were lower than the pre-surgery malignant tumor patients levels. So, angiogenesis is positively correlated with serum VEGF level.

**Discussion**

Enzyme-linked immunosorbent assay (ELISA) was used to detect the serum VEGF levels in about 74% studies related to the cancer patients14-20. Remaining studies are reported with five other types of assays, including enzyme immunoassay, quantitative sandwich enzyme immunoassay, human VEGF immunoassay quantigo kit, chemiluminescence immunosorbent assay and immunofluorometric assay. Hence, in the present study, we used ELISA assay for detection of serum VEGF level. Since VEGF were also reported to promote angiogenesis in the diabetic conditions. Hence, in the present study, patients with diabetes are excluded.

Plasmin mediated proteolysis in carboxy terminal domains regulated VEGF bioavailability. VEGF-A during embryogenesis can be detected in the trophoblast surrounding the embryo and in the embryonic myocardium, gut endoderm, embryonic mesenchyme and amniotic ectoderm21-22. But in adult organs it declines but is present in vascular beds and in heart21-22. During certain physiological processes such as development of the endocrine corpus luteum during pregnancy, wound healing and tissue repair, formation of new vessels VEGF is upregulated. VEGF is produced by diverse cell types like aortic vascular smooth muscle cells, keratinocytes, macrophages and many tumor cells etc.

Recently in has been demonstrated that Forkhead box P3 (FOXP3) can suppress VEGF at transcriptional level. It has proved by *in vitro* and *in vivo* that via FOXP3 pathway angiogenesis can also be suppressed in breast cancer23. Studies have demonstrated that solid tumors require lymphatic and blood vessels for growth. VEGF is the growth factor facilitating angiogenesis via VEGF receptor (VEGFR)-2 pathways. Thus, modern treatment methods have targeted this endothelial growth factor as a antiangiogenic and antilymphangiogenic therapies24. Oncogenes have an important role in triggering angiogenesis. For eg. H-Ras oncogene in rat cell line (IEC-18) has led in upregulation of VEGF and also increase in vascularization. Tumor suppressor gene p53 is involved in the downregulation of VEGF. In case of mutations in p53, activity of VEGF increases25.

Various animal studies have demonstrated anti-tumour effects of anti-VEGF compounds and anti-VEGF agents. But, in case of human clinical studies the effects of these agents are diverse26. Previously monoclonal antibodies against VEGF receptor 3 have been studied. Study by Valtola et al.27 studied the expression of VEGFR-3 and its ligand VEGF-C in breast tissue. The results suggest that VEGF-3 in upregulated in breast cancer patients and particularly acts as angiogenic growth factor for blood vessels. It is hypothesized that there may paracrine signaling present between cancer cells and that of endothelium. The study also suggested that there may be change in permeability of blood and lymphatic vessels that results in metastasis. Later monoclonal antibodies against VEGF were also tested for its effect on tumour suppression. Development of drug (anticancer agent) named bevacizumab (Avastin; Genentech), which was a humanized variant of anti-VEGF antibody28. It was approved by the US food and drug administration (FDA) as a first line of therapy to treat colorectal cancer patients. This confirmed that VEGF is the main mediator in angioinvasion. However, later Phase 3 trials of bevacizumab showed that when combined with chemotherapy it increased survival rate of cancer patients. But this drug failed to increase the survival of patients who were previously treated with refractory metastatic breast cancer. Also, adding kinase inhibitor, vatalanib to chemotherapy did not show improvement as compared to those in colorectal cancer patients29. How knowledge on angiogenesis and antiangiogenic therapy has made treatment and survival of cancer patients possible. Many markers needs to identified to understand the exact mode of action of these anti-angiogenic drugs30. In the present study, the malignant tumor patients showed significant high levels of serum VEGF in the pre-surgery stage than the benign tumor patients in the same stage. VEGF can be one of the factor which promote the malignancy in the tumor.

The vascular normalization in which VEGF-A is caused transiently normalized vascular structure and permeability of vascular structure is altered. This also results in low tissue pressure so that anticancer drugs
can diffuse within tumors. In the recent era, anti-VEGF-VEGFR drugs such as neutralizing and multikinase inhibitors have been introduced to treat solid tumors. However to develop more efficient anti-angiogenic therapies more research is needed as currently they do not provide a complete cure. Also, the molecular basis of this is not fully elucidated. On the other hand the possible side effects and its clinical implications must be restudied.

**Conclusion**

In the present study, the malignant tumor patients showed significant high levels of serum VEGF in the pre-surgery stage than the benign tumor patients in the same stage. VEGF can be one of the factors which promote the malignancy in the tumor.

**Ethical Clearance:** The blood was collected from the Hussain medical city hospital after their investigation. Oral consent was taken before enrolled the patients in the study.

ABSTRACT

The application of LLLT has become popular in the promotion of wound healing and reduction of pain following nonsurgical and surgical procedures. The aim of this article was to evaluate the efficiency of an SBX putty nano-bone graft with and without applying LLLT in accelerating the bone formation of the intra-bony defects through apical curettage without apicoectomy. In this study a total of 30 upper anterior maxillary teeth with periapical lesions. Patients were divided into two equal groups: Group I: apical curettage without apicoectomy and applying SBX putty nano-bone graft inside the intra-bony defects (n=15). Group II: apical curettage without apicoectomy, applying SBX putty nano-bone graft inside the intra-bony defects and then treating the defect with LLLT (n=15). CBCT was taken to determine the approximate size of periapical radioluencies, All patients were followed up using CBCT for 1 year for evaluation of the size of the radiolucent area and bone density. Results showed that the differences in bone density measured on the panoramic as well as the cross-sectional views at all time intervals were non-significant (p<0.05) Conclusion: The Use of both SBX nano-bone graft and LLLT is considered an optimum choice for accelerating the healing of intra-bony defects.

Keywords: LLLT, Apical curettage, putty nano-bone graft.

Introduction

After the failure of non-surgical RCT, periapical surgery is the last available resort to resolve inflammatory processes in the periapical area(18).

Many materials were used to accelerate bone tissues formation after periapical surgery(9,15). However, the use of bone substitution materials to fill the space created after removal of periapical pathological lesions, speed up the healing process(20,26).

However, one of the drawbacks of traditional apical surgery is affecting tooth integrity (Crown-root ratio) and slow intra-bony formation. So, an Alternative to preserve teeth integrity was to perform periapical curettage without apicectomy(21).

Development of Osteoconductive and Osteoinductive materials in a gel or putty form can allow easy delivery of the material into the bony defect with a syringe. One of these biomaterials is the NanoBone, consisting of ncHA embedded in a silica gel matrix (10,22).

Low level laser therapy which is used in biomodulation, stimulation of healing, decreasing inflammation and pain relief.
The beneficial effect of LLLT on bony healing was proven by many authors.\textsuperscript{(4,27)}.

CBCT allowed for 3D measurements which solved many problems done with the old 2D images and also low radiation dose in comparison with CT\textsuperscript{(8)}, So the main objective of this article was to evaluate the efficiency of an SBX putty nano-bone graft with and without applying LLLT in accelerating the bone formation of the intra-bony defect through apical curettage without apicoectomy.

Materials & Method

30 affected maxillary anterior teeth with necrotic long-standing chronic periapical lesions were selected with no history of previous root canal treatment. The patients were divided randomly into two equal groups: Group I (SBX nano-bone graft), Group II (LLLT + SBX Nano-bone graft).

LLLT (Optodan, Labtajm LTD Kiev, Ukraine) and putty SBX nano bone graft (syringe)(ARTOSS (GmbH), Rostock, Germany) were used in this study.

LLLT Parameters:

- Gallium Aluminum Arsenide(diode).
- Power: 13mw. (0.013w).
- Mode: CW & Pulsed.
- Wavelength: 980nm.
- Noncontact mode at 0.5-1 cm distance from the oral mucosa, in circular motion.

A. Inclusion Criteria:

1. Patients were free from any systemic diseases that may impair healing.
2. All patients came regularly for follow-up visits.
3. The size of the periapical radiolucencies related to the upper anterior teeth were ranging from 6-9mm.
4. Teeth had no history of root canal treatment.
5. All patients included in this study had no history of taking analgesics or other drugs in the 12 hours prior to the intervention.
6. All patients that participated in this study were informed in details about the procedure and its advantage and consequences.
7. All patients were asked to sign a written consent form.
8. The Faculty of Research Ethics Committee reviewed the proposal and the data were kept confidential.

B. Exclusion Criteria:

1. Shouldn’t be taking chemotherapy or radiotherapy to the head and neck region in the 12-month period prior to the treatment.
2. Shouldn’t be taking any drugs which may affect the healing process e.g. systemic steroids or anticoagulant therapy.
3. Patients having periodontal diseases have been excluded from this study.

Patients were evaluated by Cone beam computed tomography in order to estimate the approximate size of the periapical lesions(measurements were taken from Sagittal, Coronal, and Cross-Sectional views) it’s approximate and not definite, as the measurements were taken from three different dimensions, views, angulations and the mean of the three measurements were taken, in order to give us the approximate size of the defect.

An access cavity was taken, clamp, rubber dam and frame were applied on the treated teeth then an apex locator(J-MortiaII) were used to determine the working length and shaping of the canals done using ProTaper Gold Rotary Files(Dentsply) mounted on J-Mortia endomotor. In asymptomatic teeth, Root canals were cleaned or irrigated by Sodium hypochlorite while in Symptomatic teeth, initially with saline and then finally with Sodium hypochlorite. Then root canals were dried and filled with Di-antibiotic paste(Metronidazole and Ciprofloxacin) using lentulo-spiral and plugged apically with a plugger according to the size of the MAF then access was closed By(Fuji2) for a period of 15 days, after 15 days patients were examined to ensure that there are no symptoms, if the patients were asymptomatic, then patients were recommended to rinse with 0.2%CHX one day before filling the root canal and periapical surgery, if the patients were symptomatic, then the same protocol was used again(usually this protocol continuous until the symptoms subside depending on patients immunity, the virulence factor of the bacteria and also giving a chance for the intercanal medication to show it’s effect and most cases took from 3 to 5 weeks to subside. The next step, the canals were filled by pro taper gold gutta Percha depending upon the prepared sizes of the canal and
Resin-based root canal sealer then surgical operation were followed the same day.

**Group I:** A Total of 15 maxillary anterior teeth were selected to this group, a modified Rectangular Flap were considered, followed by apical curettage and then the osteo-conductive and osteo-inductive material was applied (putty SBX-Nano bone graft).

**Group II:** A Total of 15 maxillary anterior teeth were selected to this group, a modified Rectangular Flap were considered, followed by apical curettage and then the osteo-conductive and osteo-inductive material (putty SBX-Nano bone graft) were applied with the low-intensity laser treatment for six sessions, two sessions was applied on the same day, the first session was applied immediately after periapical surgery, the second session after 45 minutes, the third session and the fourth session was at day four and the fifth and sixth sessions were taken at day six. The duration for each session was five minutes.

One week after periapical surgery, all patients were instructed for cone beam as a baseline and followed up for three, six and twelve months respectively for evaluation of the bone acceleration, at following settings: 90 KVP, 8 Ma. 6.1 seconds exposure time, 125 um resolution, 5x5 cm field of view (FOV) and image slice thickness 1.5 mm.

Evaluating the bone acceleration, is done by measuring the bone density, it was calculated using the Hounsfield Unit through the measuring the ROI (Region Of Interest) within the software (On-demand software, OnDemand3D Technology Inc, Irvine, California.), where the region of interest was determined in square area selected depending upon the size and dimension of each lesion. Fig. (1), on the other hand, the mean pixel grayscale values of serial ROIs can be analyzed to determine whether changes in radio densities have occurred or not.\(^{(24, 25, 11)}\)

![Figure 1: a,b.Snapshot of the On Demand software showing Panorama(a) and Cross-Sectional(b) In Panoramic view, shows the Baseline of the periapical radiolucent area related to upper right Central Incisors, the ROI was fixed at 24x14 and the Average of the grey value was -11.9. While in the Cross-Sectional View the ROI was fixed at 74x51 and the Average of the grey value was 197.9.](image-url)
Statistical Analysis: Numerical data were explored for normality by checking the data distribution and using Kolmogorov-Smirnov and Shapiro-Wilk tests. All data showed non-normal (non-parametric) distribution.

Data were represented by mean and standard deviation (SD) values. Kruskal-Wallis test was used to compare between the three groups. Friedman’s test was used to study the changes by time within each group. Dunn’s test was used for pair-wise comparisons.

The significance level was set at P ≤ 0.05. Statistical analysis was performed with IBM® SPSS® Statistics Version 20 for Windows.

Results

Mean and standard deviation values for measurements of bone density recorded for the groups were tabulated and statistically analyzed. Results showed that the differences in bone density measured on the panoramic as well as the cross-sectional views at all time intervals were non-significant (p<0.05).

Discussion

According to some researches (12,16,3) there was a high osteoconductivity of n HA. As well as the presence of silicate ions appears to promote the process of bone formation and remodeling at the bone nHA interface, as well as induction of angiogenesis, as the adequate blood supply is a prerequisite for cellular activity.

LLLT is a treatment that utilizes specific wavelengths of light to interact with tissue and is thought to help accelerate the healing. Studies reported (19,30,17) that laser irradiation of bone stimulates the proliferation of fibroblastic, osteoblastic and mesenchymal cells in their early phase. Immediately after injury, the bone repair process starts in the vascularized regions in tissue anoxia and is accelerated by the stimulatory effect of laser on bone matrix.

Cone beam has been used in many clinical investigations. In the periapical region, the bone density can be measured in (HUs) by using CBCT, studies reported (11,6,29) that the results of these studies support the use of Cone beam to measure bone density before and after periapical surgery.

In this study results showed that the differences in bone density measured on the panoramic as well as the cross-sectional views at all time intervals were non-significant (p<0.05). On the other hand, The highest mean value was found in (Group I), while the least mean value was found in (Group II). Although that, after 12 months, Some cases in both groups had shown full bone formation of the defect as it became indistinguishable from the surrounding bone, this may be attributed to the action of nanoparticles of the nano-bone, effect of LLLT or the combination of both the LLLT and Putty SBX nano-bone graft, this comes in accordance with the result (13,14,25) that reported that Nanobone accelerate bone healing and improved the quality and quantity of regenerated bone. Also, the effect of LLLT comes in accordance with studies (7,4) that reported that the laser improved the acceleration the bone regeneration process. While in effect of time, In both views within each group, there was a statistically significant increase in mean Greyscale values from baseline to 3 months, 3 months to 6 months as well as from 6 months to 12 months, which showed an increase of bone formation. This comes in agreement with results of Vinod et al (32) and Tobon (31).

Conclusion

The use of SBX putty nano-bone graft and LLLT technique in endodontic periapical surgery is considered an optimum choice, as they both accelerate bony healing.

The Effect of Polyamide Micro-Particles Addition on Some Mechanical Properties of Heat Cured Poly Methyl Methacrylate Denture Base Material

Mithaq R. Mohammed
Ministry of Higher Education and Scientific Research, Al-Iraqia University, College of Dentistry, Baghdad Province, Iraq

ABSTRACT

Aim: The aim of this study is to evaluate the effect of addition of different weight concentration of polyamide (nylon 6) PA-6 micro powder on impact strength, transverse strength, surface hardness, surface roughness of heat cured acrylic resin denture base material (PMMA).

Materials and Method: Polyamide - nylon 6 (PA-6) micro powder with average particle size of 15-20 micron (Good fellow Cambridge limited, England) will be added to heat –curing denture base material in a concentration of (0%, 1%, 3%,5%). (160) specimen will be fabricated, (40) for the control group and (120) specimens for different polyamide powder percentage groups.

The mechanical test examined in the Pilot study are (transverse strength, impact strength, surface roughness and surface hardness).

Results: By using Polyamide - nylon 6 (PA-6) micro powder with average particle size of 15-20 micron added to heat –curing denture base material in a concentration of (0%, 1%, 3%,5%).

The mean value of tear and tensile strength of 1% PA-6 reinforcement group increased significantly when compared to control group on the contrast to the same values of 3% and 5% PA-6 reinforcement groups which were decreased significantly.

Conclusion: polyamide denture material produce high resistance to breakage, its modulus is not yet high in a sufficient manner to become equal to the standard of materials of PMMA Laboratory effects, Polyamide gets certain Exciting benefits, but it needs to have their properties improved better than the present PMMA materials properties.

Clinical Significance: The patient wearing the denture suffering from fracture of denture due to several causes. So, adding the (Nylon6) with PMMA to produce denture base with high resistance to breakage.

Keywords: Denture base materials, mechanical properties, polyamide, Poly methyl methacrylate.

Introduction

The most popular material used for denture fabrication is Poly methyl methacrylate (PMMA) since its production in1937, this material has many advantages as an excellent aesthetic characteristics, solubility and low water sorption, convenient strength, low toxicity, easy to reparaie and a simplified technique for the processing of molding. Nevertheless it shows certain disadvantages like polymarizing shrinkage, weak flexural and influence strength with resistant of low fatigue that causes failure of denture.

The Polyamides that are called ‘nylon’ are the thermoplastic polymers that are generated by combination on certain condense between a di amine and
a dibasic acid. Many studies in the field of polyamide are prepared to be as a denture base polymer between 1950 & 1952. These Studies demonstrated the fact that nylon is not fabricated to be used in a good way for denture construction due to the tendency of discoloration and high level of water absorption. therefore, nylon denture is not fit for common use. It is used in exceptional cases such as denture fracture repeatedly and is given to patients who has tissue allergies against fractures of denture or acrylic denture base.

Therefore, This study aims at evaluating the influence of adding various weight concentration of polyamide (nylon 6) PA-6 micro powder on the strength impact, strength of transverse, hardness of surface, roughness of the surface of heat cured acrylic resin denture base material (PMMA).

**Materials and Method**

Polyamide - nylon 6 (PA- 6) micro powder with average particle size of 15-20 micron (Good fellow Cambridge limited, England) will be added to heat –curing denture base material (supplied by Ivoclar Vivadent) in a concentration of (0%, 1%, 3%,5%). (160) specimen will be fabricated, (40) for the control group and (120) specimens for different polyamide powder percentage groups.

The mechanical test examined in the Pilot study are, (impact strength, transverse strength, surface hardness, and surface roughness).

**A. Test of Impact Strength:** (40) Bar shaped specimen with dimensions of (80 mm x10 mm x 4 mm) length, width and thickness respectively will be fabricated according to ISO.179-1, 2000 specification number

The impact strength is to be calculated according to the equation below after testing as in fig. (1).

\[
\text{Impact Strength} = \frac{E}{BD} \times 10^3
\]

Where:
- E is the impact absorbed energy measured in joules.
- B is the specimen width measured in millimeter.
- D is the specimen thickness measured in millimeter.

**B. Test of Transverse flexural strength:** A specimen in (40)Bar shaped with dimensions of length of (65mm x 10 mm x 2.5 ± 0.1 mm) width, thickness will be respectively fabricated according to ADA specification number 12, 1999.

The transverse strength will be calculated according to the formula below after testing:

\[
\text{Transverse Strength} = \frac{3PI}{2bd^2}
\]

Where :
- P is the load peak (N).
- I is the span length that is measured in millimeter.
- b is the sample width that is measured in millimeter.
- d is the sample thickness that is measured in millimeter.

**C. Test of surface hardness (shore D):** (40)Bar shaped specimen with dimensions of (65mm x 10 mm x 2.5 ± 0.1 mm) length, width, thickness will be respectively fabricated according to ADA specification number 12, 1999.

Test will be conducted using digital udometer hardness tester (Shore D).5 readings for each specimen will be then the mean value is calculated.

**D. Surface Roughness Test:** (40)Bar shaped specimen with dimensions of (65mm x 10 mm x 2.5 ± 0.1 mm) length, width, thickness will be respectively fabricated according to ADA specification number 12, 1999. As shown in figure (2).
Test will be conducted by the use of using a portable surface roughness tester (profilometer). 3 measurements at 3 positions for each specimen will be measured then the mean value is calculated.

The Data from quantitative studies of the experimental groups will be collected and compared to the control group using a statistical software SPSS. one-way analysis of different (ANOVA) will be used to compare the mean values of the group samples and a POST-HOC and LSD test is to be applied to compare the distinguished differences among the specified groups. A P values < 0.05 will be statistically considered significant while those > 0.05 will statistically considered of no significance and the values < 0.01 will considered as distinguished.

**Results**

(160) specimen will be fabricated, (40) for the control group and (120) specimens for different polyamide powder percentage groups. using Polyamide - nylon 6 (PA- 6) micro powder with average particle size of 15-20 micron added to heat –curing denture base material in a concentration of (0%, 1%, 3%,5%).

The mean value of tear and tensile strength of 1% PA-6 reinforcement group increased significantly when compared to control group on the contrast to the same values of 3% and 5% PA-6 reinforcement groups which were decreased significantly.

**Discussion**

Polyamide 6 (PA6) which is called nylon 6, is a crystalline designing thermoplastic that has the properties of being intense, solid, and with high melting temperature. Its utilization in certain applications is restricted due to high cost, low dimensional stability because of water absorption and low viscosity of melting. Nowadays, due to the advancement of the dental industry, there is demanding require for more created materials with high constrain for the reason of creation of more complex materials.

The Poly methyl methacrylate (PMMA) resin, as it is broadly utilized in denture base is because it has many advantageous properties such as the fact that its application and utilization are simple and its reparation is doable; In addition, its application is easy, and it is satisfactory for the patients; when it is used in the oral cavity. At the same time its mechanical property, is not perfect since it has weak quality of affect and its resistance to fatigue is limited. These highlights cause denture failure in the event of chewing or on the occasion that the denture is dropped (1-4). There are more researches about increasing the PMMA weariness and quality resistance.

These researches are about how to

1. reinforce the materials of denture when adding filling materials.
2. modulate the PMMA resin materials chemistry.
3. manufacturing substitution denture base materials.

Researches have brought reaches the fact that the leading alternative is the Fiber-reinforced resin. Materials such as rayon, aramid, carbon, extending from, E-glass in addition to the nylon filaments are considered the most excellent strengtheners. There are numerous endeavors that concentrate on the glass fiber influence on the PMMA resin mechanical characteristic. The support of the resin is done in research facility tests with considerable results concerning the quality. Glass fibers are considered exceptionally valuable. Still, there is continuous look for certain resin materials with more satisfactory mechanical quality than PMMA to be the elective ones. PMMA elective polymer laboratory tests. Knowing that the base fabric of wanted denture is not yet created, however.

The increment in surface harshness and hardness when included to PMMA with rate 3% and 5% since the Polyamide 6 (PA6), that is moreover known as nylon 6, is a crystalline designing thermoplastic that is solid, intense, and abrasion resistant and its melting temperature is high because of water absorption and low viscosity of melting, its usage is limited in certain applications. Blend of polyamide 6 by anionic ring-opening polymerization offers ideal mechanical properties (stiffness/toughness adjustment).

The clarification of diminish in the affect and transverse quality with increment of the rate of polyamide-nylon 6 to 3% and 5% for the handle capacity total denture prosthesis failure made from poly methyl methacrylate, (PMMA) The break ordinarily happens from chewing or toothache.
stretch around the small scale breaks shaped in the fabric since of the applications of fracture of dentures by affect strengths, in addition to, when applying a sudden drive to the denture happen fracture result due to the coincidental dropping of dentures on surfaces, such sorts of breaks are more likely due.

PMMA is among the hardest t thermoplastics and enjoys having a high mechanical power, high Young’s modulus and restricted prolongation at the point of break. On rapture, it does not smash. It is moreover exceedingly scratch resistant. It shows low moisture and capacity of water retaining, which all gather to give dimensional solidness to the products made of them. These two characteristics increase as temperature gets higher. The absconds includes frailness and the relative high shrinkage in the amid the handling of polymerization.

### Conclusion

While polyamide denture material produce high resistance to breakage, its modulus is not yet high in a sufficient manner to become equal to the standard of materials of PMMA Laboratory effects, Polyamide gets certain Exciting benefits, but it needs to have their properties improved better than the present PMMA materials properties.

In the table (1) surface roughness shown the mean of group I in which the percentage of polyamide- nylon 6 micro powder 1% nearly similar to the mean of control group while in the group π and group υ the mean of them shown increase in the surface roughness with increase the percentage of polyamide-nylon 6 micro particles as shown in graph(1).

Effects of the Use of Self-Directed Video on Knowledge of Malang City’s Volunteer Communities in Conducting CPR Actions

Apriyani1, Retty Ratnawati2, Ika Setyo Rini2

1Master Program of Nursing, Faculty of Medicine, 2Lecturer in Medical Faculty, University of Brawijaya

ABSTRACT

Cardiac arrest is a cardiovascular emergency which is the highest cause of death in the world, both in developing and developed countries. The occurrence of Out-of-Hospital Cardiac Arrest (OHCA) is commonly encountered by lay people. Therefore, everyone actually has an important role in increasing the survival rate of cardiac arrest patients, especially in the implementation of CPR. One way to improve the ability of lay people to do CPR is to use the learning method of self-directed video. However, several studies have suggested that the self-directed video media is less effective than ordinary knowledge improvement methods. In this regard, the researcher conducted this study with the aim to identify the effects of self-directed video on volunteer knowledge in conducting CPR. This study used a quasi-experiment design with a pretest-posttest approach. Knowledge was measured at pre-intervention, immediate post-intervention, 1-week post-intervention, and 2-week post-intervention using questionnaires. Data were analyzed using Friedman and Wilcoxon tests. The results showed a change in knowledge between pre-intervention and immediate post-intervention, between pre-intervention and 1-week post-intervention, and between pre-intervention and 2-week post-intervention (p=0.001). Thus, self-directed videos are considered able to improve volunteer knowledge in conducting CPR.

Introduction

Cardiac Arrest is the most common emergency condition of heart disease1. Cardiac arrest is a very crucial global health issue, where quick initial assessment, as well as immediate and appropriate responses, can prevent death2. The incidence of cardiac arrest occurs not only in old ages but also young ages1. Cardiac arrest can occur anywhere, either those that can be anticipated (during intensive care) or cannot be anticipated (outside the hospital)3. The most often-occurred cardiac arrest is Out-of-Hospital Cardiac Arrest (OHCA).

OHCA is an incidence of cardiac arrest occurring outside hospitals4. Out-of-Hospital Cardiac Arrest (OHCA) is one of the focus of world health issues due to its fairly high rate of incidence5. Patients with OHCA generally have a lethal ECG picture characterized by Ventricular Tachycardia (VT), Pulseless Electrical Activity (PEA), Ventricular Fibrillation (VF), and Asystole6.

World Health Organization (WHO) states that the incidence of cardiac arrest is the highest cause of death in the world, reaching 60% of the world’s total population7. WHO also suggests that the world’s first-rank cause of the world’s highest rate of death is ischemic heart disease8. Ischemic heart disease is one of the causes of cardiac arrest9. In Indonesia, the number of cardiac arrest cases reaches 10/10,000 Indonesians with age of < 35 years10.

The high rate of OHCA incidence is not in harmony with the treatment given at the time of its occurrence. The treatment in OHCA patients solely covered 40.1% of the victims where the survival rate of patients only reached 9.5%11. That is why the treatment or aid from lay people play an important role in increasing the survival rate of cardiac arrest victims12.
The cardiac arrest victims’ ability to survive will decrease by 7-10% every minute while waiting for the help and arrival of medical members mostly takes longer time. Cardiac arrest victims must be given quick treatment by the lay people by taking first aid measures. CPR actions immediately given will increase 2 to 3 times the survival possibility or chance of cardiac arrest victims. Conversely, delays in carrying out CPR actions will reduce the survival chance. Therefore, CPR actions are the main focus in improving the CPR ability of lay people. One of the efforts to improve the CPR ability of rescuers is through training because knowledge can significantly increase the survival rate in cardiac arrest cases through the provision of qualified CPR.

In reality, CPR training is not always followed by individual good memory ability. Some other studies also reveal that the ability to do CPR actions will continue to decline over time. This is because patients with cardiac arrest cases who highly need CPR actions are exposure-lacking. One of the training methods in improving the respondents’ knowledge related CPR is through self-directed videos. By using the video learning method, participants are more independent with free time (unattached) and consistent with the directions conveyed in the video. The video learning method can be a more innovative way to increase knowledge independently than the simulation learning method. However, several studies have indicated differences between the demonstration learning method and video playback learning method. According to Wibawa (2007), the group using the demonstration method reached a knowledge level of 58.97%, higher than the knowledge level of the group using the learning method of video playback which reached 24.19%. In other words, the demonstration method is more effective in improving knowledge than the video playing method.

Considering the contradictory results of several previous studies and the absence of research stating that the learning method of self-directed videos is able to increase the retention in knowledge and skills, studies using self-directed videos are necessarily conducted to see the knowledge level of volunteers in performing CPR.

Method and Material

This research was experimental research using a queasy experiment design with a pretest-posttest approach. The research respondents were 15 volunteers. The self-directed video used by the researcher was adjusted to the 2015 AHA guidelines and given to the respondents was about 7 minutes long. The criteria inclusion were who had never participated in CPR training, had cellphones, and were willing to be respondents of this research. The knowledge instrument was made based on AHA 2015 and tested for its validity and reliability with an alpha Cronbach value of 0.889. Measurements were made at pre-intervention, immediate post-intervention, 1-week post-intervention, and 2-week post-intervention. Bivariate analysis was done using Friedman and Wilcoxon tests. This research was conducted after obtaining ethical clearance from the ethics committee of the Medical Faculty of Brawijaya University, Malang.

Based on Table 1, the youngest respondent was 18 years old and the oldest respondent was 65 years old with an average age of 36.2. Before being given the intervention (pre-intervention), the highest knowledge score was 4 and the lowest was 1 with an average score of 2.13. Meanwhile, right after being given the intervention (immediate post-intervention), the highest knowledge score was 7 and the lowest was 5 with an average score of 5.73. At 1-week post-intervention, the highest knowledge score was 7 and the lowest was 5 with an average score of 5.73. Meanwhile, at 2-week post-intervention, the highest knowledge score was 7 and the lowest was 5 with an average score of 5.8. At 1-week post-intervention, the highest frequency of video playback was 3 times and the lowest was only once with an average of 2.07 times of playback. Meanwhile, at 2-week post-intervention, the highest frequency of video playback was 4 times and the lowest was twice with an average of 2.53 times of playback.

</tbody>
</table>

Description: P1 = Pre, P2 = Immediate Post, P3 = 1-Week Post-intervention, P4 = 2-Week Post-intervention

As seen in Table 4, all the comparisons of knowledge obtained p-values of 0.001, 0.001, 0.001, 1.000, 0.564, and 0.317 respectively. Therefore, it can be said that there was a change in knowledge between pre-intervention and immediate post-intervention (3.6), between pre-intervention and 1-week post-intervention (3.6), and between pre-intervention and 2-week post-intervention (3.67). In contrast, a change in knowledge did not significantly occur between post-intervention and 1-week post-intervention, between post-intervention and 2-week post-intervention, and between 1-week and 2-weeks post-interventions based on the p-values and mean delta.

Discussion

The results of this study showed that the CPR knowledge between pre-intervention and post interventions (including immediate post-intervention, 1-week post-intervention, and 2-week post-intervention) increased with a p-value of 0.001.

These results are consistent with Hernández-Padilla, Suthers, Granero-Molina, & Fernández-Sola (2015) finding that there is a more significant increase in knowledge of a student-directed group using technological learning media compared to instructor-focused learning. Respondents can find out more knowledge about basic life support by using technology¹⁹.
The increase in the value of respondents’ knowledge regarding basic life support based on the self-directed video can be explained by an approach of technology use that affects the human brain. Self-directed video is one of the innovative media using technology that supports learning. The self-directed video contains active images and sounds that provide audio imaginary effects on the human brain. The audio imaginary effects lead to an increased ability of long-term memory in the brain and make it easier for someone to remember the things learned from the video. Long-term memory enhancement is influenced by the prefrontal cortex activation in the human brain due to the audio imaginary effects of the video. The increased activation will trigger cognitive stimulation and strengthen the memory of someone who has studied the material.

Learning by using technology provides a learning process centered on individuals (learner-centered learning) and improves cognitive abilities as desired accordingly to the content studied. This learning process is carried out independently through learning supporting devices that can play videos.

However, in this study, the assessments of knowledge at post-intervention (immediate post-intervention, 1-week post-intervention, and 2-week post-intervention) did not indicate changes with a p-value of > 0.05 (P2 vs P3 = 1.000, P2 vs P4 = 0.564, P3 vs P4 = 0.317).

The results of this study are in line with Hernández-Padilla, Suthers, Granero-Molina, & Fernández-Sola (2015) finding a change or retention in knowledge between post-intervention and 3-month post intervention.

Knowledge retention after the provision of the self-directed video relates to the respondents’ memory ability. The respondents’ memory of learning is influenced by the selection of learning strategies or models. Based on the results of the study conducted Lubis, Ridayani, Manurung, and Binari (2010), there is a significant difference in the memory ability between students who go through contextual learning and those who experience direct learning. The average memory of students taught using the contextual learning model reached 77.69%, greater than the average memory of those taught using the direct learning model which was equal to 74.44%.

Another study states that the learning strategy or model of mind mapping using multimedia is proven to be able to improve memory. The mind mapping strategy encourages students to interact with other groups of friends about problems faced and improve thinking activities for obtaining understanding. This can be proven from the result of the re-test conducted within 2 weeks. The re-test result of mind mapping strategy showed a memory score of 59.85%, higher than the direct learning method through lectures and discussions which only obtained a memory score of 35.54%.

Furthermore, the learning process using this self-directed video makes it easier for the respondents to review the learned content anywhere and anytime as long as they use supporting technology that can play the video. By reviewing the content of the video, the respondents will be easier to memorize or recall the materials that have been previously studied. Besides, the ability to memorize or recall is also influenced by age. In this study, the average age of the respondents was 36 years. According to Nusantari (2015), most people experience a change of memory as they grow older. Active memory in older adults tends to decrease due to the weakening front lobe. That is why older people tend to easily forget something they already know. This tendency grows by 12% at the age of 70-74 years and significantly increases to be 40% at the age of 85-89.

Based on the findings above, the respondents involved in this study are still considered to fall within the age range with a good memory ability.

Conclusion

In conclusion, there is an increase in the CPR knowledge of Malang City’s volunteer communities on the assessments between pre-intervention and post-intervention of self-directed video (including immediate post-intervention, 1-week post-intervention, and 2-week post-intervention). In contrast, no change or retention in the CPR knowledge of Malang City’s volunteer communities is shown on the assessments between post interventions (including immediate post-intervention, 1-week post-intervention, and 2-week post-intervention).

ABSTRACT

Hydrogen sulfide ($H_2S$) is a colorless, highly toxic, flammable and rotten egg smelled gas. This gas can cause adverse effects on health, especially in the respiratory tract. Low concentrations of $H_2S$ for long periods of time can cause permanent effects such as respiratory problems, headaches and chronic cough. Hydrogen sulfide can be formed naturally and from the process of human activity. One of these human activities is the process of processing animal food and marine products in Medan Industrial Area which produces exhaust gas in the form of $H_2S$ gas.

The aim of the study was to calculate the value of RfC from $H_2S$ exposure in communities in Industrial Area in Medan, Indonesia. This is an observational cross-sectional study with quantitative manual data analysis method. The study sample was 52 residents of industrial estates at a radius of 300m and 52 residents at radius of 800m. Research variables included $H_2S$ concentrations in Medan Industrial Area, body weight, height, respiratory rate, length of day exposure time, body surface area, weight of white mice, body surface of white mice, highest dose of toxin without effect on experimental animals (NOAEL), factor Km in animal (Animal Km), factor Km in human (Human Km) and Reference of Concentration si (RfC).

The result showed that $H_2S$ concentrations at a radius of 300 m was 0.022 ppm and at an radius of 800 m is 0.0064 ppm. This value is above the Threshold Limit Value according to ATSDR provision of 0.0005 ppm. Concentration of $H_2S$ RfC in this study was 0.001 mg/kg; which is smaller than that of released by EPA 2003. The results of the RfC in this study is safe for humans. However, $H_2S$ gas around residential areas was close to NAB. This can increase at any time and can have a negative influence on public health. Therefore, control measures need to be carried out, including by installing additional air monitoring devices in several locations by waste management agencies. In addition, recording is also needed for all complaints of odor felt by the community, including nature, location, time and frequency of complaints. With these measures, air quality, exposure level, and health effects can be controlled.

**Keywords:** RfC, Hydrogen sulfide, Industrial area

**Introduction**

Hydrogen Sulfide ($H_2S$) is a colorless, highly toxic, flammable gas that has the characteristic odor of rotten eggs. The main absorption of $H_2S$ is through the inhalation pathway. When air containing Hydrogen Sulfide is inhaled, it will be absorbed into the bloodstream and distributed throughout the body. Humans can usually smell $H_2S$ at low concentrations in the air, between 0.0005 and 0.3 ppm.
Hydrogen sulfide can be formed naturally like gas from volcano, sulfur springs, swamp, in crude oil and natural gas or as a result of human activities such as gas from sewage treatment plants, manure fertilizer handling operations, petroleum refinery industry, and petrochemical plants. At low concentrations, H$_2$S can cause dizziness, nausea, feeling of drifting, coughing, anxiety, drowsiness, dryness, pain in the nose, throat and chest and olfactory sensory paralysis.

In determining the safe limits of toxin concentrations in the work environment, determining the Reference of Concentration (RfC) toxin in the human body is one of the important steps. Analysis of the risk of toxins in the work environment in Indonesia often uses RfC issued by researchers or institutions abroad, such as America and Europe. In fact, environmental conditions (air pressure and temperature) and human physical conditions (body surface area) differ between Europe and America and Indonesia. It is advisable to determine the risk analysis of toxins using RfC based on research results in Indonesia.

Based on previous research on the Analysis of the Risk of Hydrogen Sulfide Exposure in Communities around Industrial Areas in Medan, the risk level of exposure to Mercury (Hg) through consumption of fish and drinking water in the community has not been performed. In this study, RfC was obtained based on the principle of dose response and toxicity test for determining the highest dose without causing effects on experimental animals or also called No Observed Adverse Effect Level (NOAEL).

The purpose of this study is to determine the RfC of H$_2$S in the communities around Medan Industrial areas that the results can be used as a reference to estimate the amount of exposure each day that can be accepted by the community without causing harmful effects during their lifetime.

**Material and Method**

This research was conducted around an industrial area in Medan, Medan Labuhan sub-district, Indonesia. This study was an observational cross-sectional. The population in this study was housewives who lived around industrial estates at a radius of 300 m and a radius of 800 m. The sampling technique used cluster techniques. The number of samples needed for the subject group was 52 people for each radius so the total sample was 104 people.

The data used are primary data including the measurement results of H$_2$S concentration, intake rate, duration of exposure, and body weight. H$_2$S concentration measurements used the SNI 19-7119.7-2005 method with a photometer spectrometer.

The variables in this study included the highest dose of toxin without causing effects (NOAEL) on H$_2$S experimental animals, weight of experimental animals (W animals), body surface of experimental animals (BSA experimental animals), community weight (W), human height (h), respiratory rate (BR), length of day exposure time (t), community body surface area (BSA), and reference concentration (RfC) of toxins in the human body. Data analysis in this study was carried out by using manual quantitative analysis to determine Rfc in the community.

**Result**

A. Characteristics and Body Surface Area of Experimental Animals (White Mice): Toxicity test was carried out using experimental animals of white mice. In general, human response to toxicity is qualitatively similar to that of animals. This fact is the basis of extrapolation from animal data to humans.

Based on data from table 1, the body surface area of white mice is calculated using the following formula.

$$\text{BSA} = 0.09 \times W^{0.67}$$

Where

BSA: Body Surface Area (m$^2$)
W: Weight (kg)
B. Characteristics, Surface Area and Respiratory Rate of the Residence: The community characteristics in this study included the weight and exposure time of 104 respondents around Medan Industrial Areas at a radius of 300 m and 800 m. Based on Tables 2 and 3, the highest body weight is 79 kg with an average of 68 kg. The duration of the exposure, especially housewives who are exposed to H₂S gas at a radius of 300 m in a day was 18 hours and 15 hours at a radius of 800 m in a day. The height used was the average height of Indonesian adult women’s height of 153 cm.

Based on data on body weight and height, BSA and respiratory rate were calculated using the following formula:

1. The surface area of a community’s body

\[
BSA = \sqrt{\frac{W \cdot h}{3600}}
\]

Where:

- BSA: Body Surface Area (m²)
- W: Weight (kg)
- h: Height (cm)
- Breathing Rate

\[
BR = \frac{5.3 \ln W - 6.9}{24}
\]

Where:

- BR: Breathing Rate (m/jam)
- W: Weight (kg)

</table>

The average body surface area and community respiratory rate according to tables 2 and 3 are 1.71 m² at a radius of 300 m and 1.69 m² at 800 m. The average community respiratory rate is 0.6 m³/hour.

C. Hydrogen Sulfide Concentration (H₂S): The measurement results of H₂S concentrations in the Industry Medan Area are different at 6 measurement locations in 2 radius, both in the industrial area (300 m) and outside the industrial area (800 m) which is 0.03 mg/m³ and 0.0093 mg/m³, each.

Based on the results of measurements, the concentration of hydrogen sulfide around Medan Industrial Area (radius 300 m) was 0.022 ppm with the highest concentration of 0.4 mg/m³ (0.029 ppm) and the lowest of 0.2 mg/m³ (0.01 ppm). H₂S concentration outside Medan Industrial Area (radius 800 m) was 0.0064 ppm, with the highest concentration of 0.2 mg/m³ and the lowest 0.002 of mg/m³ (0.001 ppm).

D. Animal KM and Human KM: Calculation of Animal KM and Human KM is the first step in determining the safe limits of toxin doses for the community.

1. Animal KM

\[
\text{Animal Km} = \frac{W_{\text{animal}}}{\text{BSA}_{\text{animal}}}
\]

Where:

- Animal km: Km factor on animal
- W : Weight of experimental animal
- BSA : Body Surface Area of experimental animal
Table 4: Animal Km in White Mice

E. NOAEL: Determination of safe limit of the concentration of a chemical begins with toxicity test determining the highest dose without causing effects on experimental animals or No Observed Adverse Effect Level (NOAEL). According to U.S. Environmental Protection Agency (EPA), NOAEL from H₂S is 1 mg/m³ (0.0074 mg/kg). Calculation of the conversion from mg/m³ to mg/kg is as follows:

\[ \text{NOAEL} \text{ H}_2\text{S} = \frac{1 \times 0.00138}{0.1405} = 0.0074 \text{ mg/kg} \]

F. Reference of Concentration (RfC): According to Saridewi and Tualeka (2017) the calculation of RfC is done using a formula from Shaw et al.⁷

\[ \text{RfC} = \frac{\text{NOAEL}}{\text{Animal KM} \times \text{Human KM}} \]

Where:

- RfC: Reference of Concentration (mg/kg)
- Animal Km: Km factor on experimental animal
- Human Km: Km factor on human

Results of Reference of Concentration (RfC) obtained from NOAEL, Animal km averages, and Human Km averages are as follows:

1. Radius 300 m

\[ \text{RfC} = 0.0074 \times \frac{5.821035}{39.496} = 0.001090627 \text{ mg/kg} \]

2. Radius 800 m

\[ \text{RfC} = 0.0074 \times \frac{5.821035}{39.198} = 0.001098926 \text{ mg/kg} \]

Discussion

Based on the measurement results, the concentration of H₂S around the industrial area (radius 300 m) is 0.022 ppm, while the concentration of hydrogen sulfide outside the industrial area (radius 800 m) is 0.0064 ppm. At a radius of 300 m and 800 m H₂S concentrations are above the Threshold Value (NAB) of 0.0005 ppm according to ATSDR provisions regarding the Odor Threshold.
Value of Hydrogen Sulfide. According to KepMenLH No.KEP-50/MENLH/1996 regarding the standard level of smell the value of the Threshold Limit Value (NAB) is 0.02 ppm. At a radius of 300 m with a concentration of 0.02 ppm above the Threshold Limit Value (NAB). The concentration of air at a radius of 300m is greater than the concentration of air at a radius of 800m, this is due to differences in the distance from the source of pollutants. The closer the location of the study to the source of pollutants the greater the H2S concentration received by the body.

The results of this study indicate that the average value of the respondent’s body weight is 68 kg, with the lowest weight of the respondent is 54 kg and the highest body weight is 79 kg. In this study, the respondent’s body weight greatly influenced the intake rate where the greater the respondent’s weight, the greater the intake rate of the respondent himself. This is in accordance with the theory which states that the greater a person’s weight, the greater the volume capacity of a person’s lung, which allows more air to enter the body. The finding of the Laila’s study (2018) showed that respondents with the greatest weight had lung volume capacity that big also that allows more air into the body, thereby increasing the potential for breathing air containing pollutant gases such as H2S so that it impacts on health.

According to EPA, NOAEL (No Observe Adverse Effect Level) or the highest dose without effect on animals is an experiment in determining doses that do not show an indication of a statistically significant effect on toxic effects or biological functions. Based on the results of calculations, NOAEL hydrogen sulfide of 1 mg/m3 is equivalent to 0.72 ppm. This NOAEL result is smaller than the 2016 ATSDR of 2.5 ppm for medium exposure respiratory systems.

After the NOAEL value of H2S is determined, the calculation of RfC on H2S exposure in the Medan Industrial Area area was carried out. The RfC value was sought from the risk agent of gas, which uses the reference dose of the chemical species inhalation pathway. The calculation of Inhalation Reference Concentration (RfC) used NOAEL from the U.S. Protection Agency (EPA) by 0.00109 mg/kg (radius 300m) and 0.00109 mg/kg (radius 800m). This value is greater than the H2S RfC found in the previous study on Risk Analysis of Hydrogen Sulfide Gas Levels (H2S) in the Community Around the Bioethanol Plant by 0.000571 mg/kg.

According to IRIS US-EPA the value of hydrogen sulfide RfC gas is 0.000571 mg/kg/day. Although the results of this study indicate that H2S levels is still safe in accordance with the exposure limits of hydrogen sulfide in the air established by the EPA, the effects of low level exposure or long-term hydrogen sulfide at levels of less than 1 ppm in the air are more difficult to predict because the mechanism of chronic toxicity is has not been further studied.

Preventive measures to avoid the chronic effects of H2S gas exposure include routine waste management and air quality monitoring to see air quality conditions due to the production process. The relevant party needs to inform the people living around the Medan and surrounding Industrial Estates regarding H2S concentrations. Installation of additional air monitoring equipment in several locations by the waste management agency is also needed to record all odor complaints that are felt by the community, namely the nature, location, and frequency of complaints so that air quality, exposure level, and health effects can be controlled.

Conclusion

1. NOAEL of H2S around Medan Industrial Area is 0.0074 mg/kg.
2. The average value of Human KM at a radius of 300 m is 40.3 and in a radius of 800 m is 39.9.
3. The value of RfC of H2S in Medan Industrial Area at a radius of 300 m is 0.001090627 mg/kg and at a radius of 800 m is 0.001098926 mg/kg.

Conflict of Interest: All authors have no conflicts of interest to declare.

Source of Funding: This is an article “determination of reference of concentration (RfC) from hydrogen sulfide (H2S) exposure in the community based on weight in industrial area in Medan Indonesia” of Occupational Health and Safety Department that was supported by Faculty of Public Health, Airlangga University.

Ethical Clearance: The study was approved by the institutional Ethical Board of the Public Health, North Sumatera.

Sexual Risk Behaviour of Men Who Have Sex with Men (MSM) in an Urban Society of West Sumatera Province of Indonesia

Hardisman Dasman1, Firda Firdawati1, Yantri Maputra2, Ilma Nuria Sulrieni3, Faiz Nur Hanum3
1Department of Public Health and Community Medicine, Andalas University, Indonesia, 2Department of Psychology, 3Commission of HIV/AIDS Prevention of West Sumatera, Indonesia

ABSTRACT

Background and Aim: The cases of HIV/AIDS have increased in Indonesia in the last decade, especially in Padang Municipality of West Sumatera Province. The cases are consistency higher in high risk population groups, including men who have sex with men (MSM). The study examines sexual behaviour of MSM, which becomes a potential risk of HIV transmission.

Method: We have conducted a qualitative research by interviewing 44 MSM and three HIV/AIDS prevention commissioners and two health workers. The data was analyzed using content thematic analysis approach, which presented narratively and semi-quantitative features.

Result: The result shows that most of MSM are very sexual active and have multi sex partners. On the contrary, most of the sexual contacts are unprotected with low consistenency of condom use. They also have limited knowledge of HIV/AIDS and lack of awareness of its transmission. Voluntary of HIV testing is very low due to personal and access barrier, such as feeling shameful to be recognized by other people and perceive healthy and free from HIV/AIDS risk.

Conclusion: The sexual behavior of MSM becomes a potential risk of HIV transmission. Our findings indicate that there is a need of improvement of health promotion to decrease the risk of HIV transmission, including health education and special access to HIV testing to reach this community.

Keywords: Sexual behavior, MSM, HIV/AIDS

Introduction

The cases of HIV/AIDS have increased significantly in Indonesia over the last two decades.1 In Province of West Sumatera especially, the cases have also increased within the last five years.2 Even, the cases rate was higher in the province than a national rate, which was 24.04 compare to 19.1 per 100,000 inhabitants in 2015. Among districts and municipalities in the province, Padang municipality, the capital city of the province has the highest number of the cases, which consisted more about 50% of the HIV cases in the province were in Padang.

National Comission of HIV/AIDS Prevention of Indonesia also reported that HIV/AIDS cases consistently higher in high risk population groups, such as sex wokers, MSM and injecting drug users (IDU). The data show that the cases of HIV/AIDS more than 5% in those group.3 Specifically, the Comprehensive Surveillance Biological Behaviors in Indonesia reported that the HIV/AIDS cases increased in the MSM groups by 7% within five years, which was 5% in 2007 became 12% in 2011.4 Many studies suggested that MSM is a potential risk of HIV transmission.5-10

Province of West Sumatera is well-known as a religious society in the country, which predominantly belong to Moslem faith and Minangkabau ethnic. Superficially, the society strictly prohibits MSM practice. On the contrary, the Comission of HIV/AIDS Prevention and Department...
of Health of Padang Municipality reported that there was significantly increase of MSM in the area,\textsuperscript{11,12} which was recorded less than 300 in 2012 and more than 1,500 in 2017.\textsuperscript{12} This study aimed to explore the behavior of MSM that became risk of HIV transmission. The study also explored how the MSM perceive on their social norm and values towards their behavior.

\textbf{Method}

The study has been conducted in Padang Municipality, the capital city of West Sumatera Province of Indonesia. The data was collected between June and September 2018. We used a qualitative study design by interviewing 44 MSM, three HIV/AIDS prevention commissioners and two health workers. We obtained MSM from the information of HIV/AIDS prevention commissioners and as well as snow ball from the previous participant. These participants were chosen base on appropriateness and adequacy principles by using data sources triangulation approach.

A qualitative inquiry was very relevant with the problem being investigated and the objectives of the study because the problem is hidden and taboo in the society. Also, the phenomena of the problem being studied was not clearly understood previously. A thematic framework analysis was used to analyze the data and to draw the conclusion.

\textbf{Result}

The main participants of the study, MSM distribute across all occupation and level of education, with the youngest 16 years and the oldest 46 years. Interestingly, about half of them have high education, who has graduated or currently a student at a university. Their occupations vary from laborer, driver, students, and employee.

In average, our participants admitted that they have been as MSM for about 4.77 years, with 13 years as the longest. Most of them is relatively sexual active with the frequency of sexual contact 2.7 times a week. They also tend to have multi sex partner with 2.05 in average (see table 1), with nearly half of them admitted having two or more sex partners concurrently.

\begin{table}[h]
\centering
\begin{tabular}{|c|c|c|c|}
\hline
\textbf{Variables} & \textbf{Min.} & \textbf{Maks.} & \textbf{Mean (±SD)} \\
\hline
Length as MSM (year) & 0.7 & 13 & 4.77 (2.70) \\
\hline
Number of partner (people) & 1 & 5 & 2.05 (1.49) \\
\hline
Weekly Sexual Contact (times) & 0.5 & 15 & 2.75 (3.05) \\
\hline
\end{tabular}
\caption{Descriptive features of MSM sexual behavior}
\end{table}

However, most of the sexual contact is unprotected, with only on third of them use condom consistently. Even, about 6.82\% of them never use it (table 2). Information from participants reveals that there are various reasons that they don’t use condom. They do not use condom because of sexual pleasure reasons and access to condom [P9, 11, 12, 17, 26, 29, 31]. As mentioned by the participants:

“I don’t use condom sometimes, ...what we are lookin for in sexual contact is a pleasure, ... if we use condom, in some extend will minimize the aim” [P11].

“We don’t always use condom, because we don’t always have it. Sometimes I can buy it, sometimes I get it from HIV prevention volunteer. If want to by it I feel ashame...” [P12].

Additionally, some of them do not use condom because they believe that they are free from any risk of diseases transmission if they see that their partner is healthy and do ot have any symptoms of any diseases, such as HIV/AIDS or genital diseases [P11, 18, 26, 29, 33, 41].

“I think we don’t always need to use condom, because I trust my partner, he is only with me... and I see him doesn’t have any diseases. I am safe” [11].

“Ya... we use condom, but not always... you know..., we know our body, we wknow our partner, we don’t have a disease that can transmit to each other” [P29].

\begin{table}[h]
\centering
\begin{tabular}{|c|c|c|}
\hline
\textbf{Variable} & \textbf{f (n-44)} & \textbf{\%} \\
\hline
Condom Use & & \\
Consistent (Always) & 17 & 38.64 \\
Inconsistent (Sometimes) & 24 & 54.54 \\
Never & 3 & 6.82 \\
\hline
\end{tabular}
\caption{Condom use and HIV testing among MSM}
\end{table}
Despite they say that they and their partner healthy and free from diseases transmission including HIV, majority of them (79.55%) do not really know their HIV status because they never been done a HIV test. The participants explained that there are various factors hinder them to do HIV test. Although they know that they can have a test in health centers and hospitals in Padang municipality, they are reluctant to do so. Similar reason for not using condom, they do not have a test because they perceive that they are healthy and nothing to worry about because they do not feel any symptoms of the diseases.

Few of them, also explain that do not have a test because feeling shameful to be recognized by other people. They perceive that the stigma from public is very strong, which will undervalue them [P17, 18, 24, 31, 35]. As mentioned by the participant:

“I cannot do a test in health centers... people will recognize us, you know there is a stigma, that people think that a man who does HIV test is a prostitute customors or MSM. I am afraid my identitity to be revealed” [P24].

**Discussion**

Most of MSM in Padang Municipality of West Sumatera Province do not aware of the HIV risk, in which they do not eager to have the test. Voluntary of HIV testing is very low due to personal and access barrier, such as feeling shameful to be recognized by other people and perceive healthy and free from HIV/AIDS risk.

Our study also reveals that there are two factors that become risks of HIV/AIDS transmission, namely multi sex partners and inconsistence condom used.

**Multi Sex Partners:** Our study indicates that MSM tend to have multi-sex partner, which indicates that they are very sexual active. Our study is similar to Cempaka and Kardiwinata (2012)\(^{13}\) ini Bali, that reported about 77.8% of MSM had multi sexual partner. The study by Nugroho (2012)\(^{14}\) in Jakarta Timur even reported that multi-sex partner within MSM as high as 78.1%.

Our study reveals that MSM is relatively very sexual active, which also related to their young age. In average, they have sexual contact 2-3 times weekly (43.2%). The study indicates that same sex partner is mostly intended for having sexual contact instead of intimate personal psychological relationship.

**Inconsistence of Condom Used:** Despite the MSM are very sexual active and had multi-sex partner, the consistent condom used was very low (38.6%). Our finding is also similar to study in Bali, which was only 37.8%, as reported by Cempaka and Kardiwinata.\(^{15}\) The rate of condom used is not very much different to National Report of Commission of HIV/AIDS of Indonesia, which mentioned about 36%.\(^{11}\) Even, in Dominica,\(^{6}\) where anti HIV/AIDS campaign was slightly better, the consistency of condom used among MSM only reached 43%.

This finding indicates that with most of HIV status of our participants are unknown (79.55%) that could be positive, may lead to a substantial risk of HIV/AIDS transmission among MSM community, in addition to low consistent used of condom.

Lack of Knowledge and their perception of HIV/AIDS influence them to use condom with their intimate partner. They perceive that they are healthy and free from the risk of the diseases when they do not have any symptoms. They are very reluctant to use condom because their main desire to have MSM relationship are mostly for sexual pleasure. They explained that using condom are very unppleasant and will hinder them to gain their aim. The study is also confirmed by Rokhmah dan Khoiron study\(^{15}\) on MSM community in Jember of East Java Province, where the consistency used of condom is very low due to similar reason. Herlani et al\(^{5}\) also reported the condom use by MSM was not a priority, because the same sex behavior is as a sexual adventure for gaining sexual pleasure for them.

Both sexual risk behaviors, multi sex partners and inconsistence condom used have been also a global concern as HIV/AIDS transmission.\(^{8,9,16}\) In China, for example, there has been a growing trends of HIV epidemic among MSM in all Chinese provinces, municipalities, and autonomous regions. The MSM
were also very sexual active, which approximately 90% of them had anal and oral sex within the past six months of the research time. They also had low condom used due to the preference of better sexual sensation, which was only 19.9% with their regular intimate partner and 30.4% with noncommercial casual partners.17

Conclusion

The study reveals that MSM sexual behavior become risks of HIV/AIDS transmission, which lack of knowledge and awareness of the disease. Most of their HIV status is unknown, whe they are reluctant to do a voluntary testing. The consistency of condom used is alo very low due to their perception of the disesease and their sexual willingness. On the contrary, the MSM are very sexual active with their regular and casual sex partners, in which they tend to have multi sex partners.

Conflict of Interest: The authors declare that there is no conflict of interest.

Ethical Clearance: Formal permission was obtained from the Board of Nation and Public Protection of Padang Municipality. The participants (MSM) were voluntary invited to participate in the study, and they were informed that their participation would remain anonymous.

Source of Funding: The research is funded by Faculty of Medicine of Andalas University Grant under Ministry of Research and Higher Education of Indonesia.

An Exploration of Health Beliefs Related to Fluid-Restricted in Patients Undergoing Hemodialysis

Inda Rian P1, Nursalam2, Ninuk Dian Kurniawati3
1Master Nursing Student, 2Professor, 3Lecturer, Faculty of Nursing, Universitas Airlangga, Surabaya

ABSTRACT

Background: Adherence to the therapeutic regimen is important for patients undergoing hemodialysis. The problem of non-compliance with fluid management is still a major problem for patients undergoing hemodialysis. Health-related beliefs on patients undergoing hemodialysis are one of the factors that influence their adherence to the diet, but how is the confidence level of hemodialysis patients in Indonesia especially regarding fluid restriction still unclear. The aimed of this study was to explore the adherence of fluid restriction and health-beliefs related to fluid restriction in patients undergoing hemodialysis.

Method: A cross-sectional study was conducted among 115 patients undergoing hemodialysis with a simple random sampling technique. Data were collected through an information form, the belief about fluid adherence scale including four subscales: perceived threat (susceptibility & seriousness), perceived benefit, perceived barrier, and self-efficacy. Descriptive statistic was used for data analysis.

Result: The result showed that the majority of patients were less adherence to fluid restrictions (53.9%). The prevalence of patients who have perceived barrier was higher (53%) than the result of belief in the perceived benefits (51%). Most patients have negative self-efficacy values against fluid restrictions.

Conclusion: Non-adherence with fluid restriction was a problem among hemodialysis patient. High levels of non-adherence are associated with greater ‘perceived barriers’. A better understanding of health beliefs related to fluid restriction is needed by patients and to facilitate the implementation of tailored interventions.

Keywords: Health belief, Hemodialysis, Fluid restriction, Adherence, End-stage renal disease.

Introduction

Chronic kidney disease is increasing globally. Therapy to replace kidney function in patients with end-stage renal failure includes hemodialysis, peritoneal dialysis and kidney transplantation 1, currently, hemodialysis is the main choice for patients who experience end-stage chronic renal failure. Patient compliance with treatment regimens, including restrictions on fluid intake, diet, treatment, and control schedules are factors that influence the success of hemodialysis. Studies report that many patients undergoing hemodialysis do not adhere to restrictions on fluid intake 2. Nurses use various methods of providing health education, one of which is by speaking directly to patients, but it has not been able to improve compliance with fluid restrictions in patients undergoing hemodialysis. The study reported a high rate of non-compliance of hemodialysis patients, especially against restrictions on fluid intake and dietary restrictions, namely between 30-81.4% 3. According to 4 the prevalence of noncompliance with fluid restriction in patients undergoing hemodialysis is between 3.4-74%. Chronic kidney disease (CKD) was the 27th cause of death in the world in 1990 and increased to 18th in 2010. Based on the Indonesian Renal Registry (IRR) in 2016, 98% of patients with kidney failure undergo hemodialysis therapy 5. Based on monthly report data obtained at Sidoarjo Hospital, Indonesia, it was found that in August to October 2018 the average number of patients with CKD who underwent hemodialysis was 192 patients, with 52% of patients have problem with excess fluid volume.
Non-adherence of patients to fluid restrictions can cause chronic excess fluid which leads to serious consequences for hemodialysis patients, including excessive circulation burden, edema to severe cardiovascular disorders, impaired cognitive function, increased risk of hospitalization, and even death threats (2). Hemodialysis patients are patients with special chronic conditions, who need effective education for their self-care; several issues associated with the process raise barriers that make learning difficult. Computer-based education can reduce these problems and improve the quality of education. This study aims to develop and validate a theory-based multimedia application to educate Persian patients on hemodialysis. The study consisted of five phases: (1) and hemodialysis nurses have an important role to play in it. Development of effective methods is needed to help patients manage fluids. This study uses the theory of the Health Belief Model (HBM) approach as a theoretical framework. HBM was a theory that focuses on individual attitudes and beliefs in explaining and predicting health behavior. The main construction of HBM has perceived susceptibility and perceived severity that is a perceived threat, perceived benefit, and perceived barrier as well as other constructions that have been added namely modification factors, cues to action, and self-efficacy. HBM focuses on the perception of threats and evaluating health-related behaviors as the primary aspect of understanding how a person presents healthy actions.

Health belief of patients undergoing hemodialysis was one of the factors that influence patient adherence to diet (3-9). The method of patient education and self-monitoring effectively improves compliance with hemodialysis patients with restrictions on fluids and diet (10). Therefore, this study wants to assess health belief related to fluid restriction in patients undergoing hemodialysis in Sidoarjo, Indonesia. The objective of this study was to describe the patient’s characteristic of hemodialysis patients which included; age, gender, marital status, and to examine health-belief related to fluid restriction in Sidoarjo, Indonesia patients on hemodialysis.

Method

This research uses descriptive explorative with a cross-sectional approach. The subjects in this study were 115 hemodialysis patients selected with simple random sampling. The inclusion criteria in this study were: patients undergoing regular hemodialysis twice a week; patients over the age of 21 years; patients who had undergone hemodialysis for at least 3 months; were able to communicate in Indonesian. Patients who have severe cognitive impairment and critical conditions were the exclusion criteria of this study. Information obtained from 115 patients who met the inclusion criteria, for the participation rate was 100%.

Individual beliefs are measured through a health belief questionnaire conceptualized based on HBM (perceived threat, benefit, barrier, self-efficacy), questions are modified from previous assessments of themes in the HBM construct (11). The questions in this questionnaire are 21 items. Patient responses were assessed with a 4-point Likert scale starting from “1” (strongly disagree) and “4” (strongly agree). The questionnaire was tested for validity and reliability and declared valid and reliable with Cronbach’s alpha value of 0.808 and the validity level of 21 questions was 0.505-0.886 (> 0.444 with N = 20), so all questions were valid and reliable. fluid restriction measures were assessed using a questionnaire that had been tested for validity and reliability and declared valid and reliable.

Result

Data collection was conducted in February-April 2019 in the hemodialysis installation of Sidoarjo hospital, Indonesia. One hundred fifty people underwent hemodialysis at the time of data collection. Based on the inclusion and exclusion criteria a sample of 115 people completed the questionnaire until the end of the study. The results of the research shown in table 1 represent the characteristics of respondents in terms of gender, age, marital status, recent education, employment status and length of time undergoing hemodialysis.

Based on table 1, out of 115 patients, male patients (n=70) and female patients (n=45), it can be seen that most patients undergoing hemodialysis (61%) are male. Most of the patients (34%) in the group of aged 36-45 years. Most respondents were unemployed (73%) due to their dialysis condition, and more than half of the respondents (52%) had senior high school education.

</table>

Based on table 2 above, it can be seen that in the evaluation of beliefs, some respondents had positive beliefs related to perceptions of susceptibility and severity/perceived threat (53%). From the perceived benefit variable, half respondents showed positive beliefs about the benefits of adhering to fluid restrictions (51%), and on the perceived barrier, most of the respondents (53%) showed confidence in the barrier of fluid restriction. Most respondents have negative self-efficacy (56%), self-efficacy is about belief in self that individuals are able to limit fluids. From the table above, it was found that the adherence of most respondents to fluid restrictions was still lacking (54%).

Discussion

This study sought to investigate adherence to fluid restriction in patients undergoing hemodialysis and patient confidence in fluid restriction measures. This study has added evidence that non-adherence of patients undergoing hemodialysis is still a problem. Overall the high levels of non-adherence were reported in this study. This is probably due to the possibility of subjective estimates of patients, measurements of the level of adherence were carried out with a questionnaire without clinical measurements such as weight. Most of the patients undergoing hemodialysis are male and married. In this study, most of the HD patients were in the age group of 36-45 years (33.8%), this result is in contrast to the study conducted 12 where the most age of group were 60-69 years. this shows a finding that all ages are at risk for developing the end-stage renal disease (ESRD). In this study most of the patients had a high school education, this was different from the study conduct to 13 that most patients have a bachelor’s degree.

The belief of respondents in this study there is 4 main components based on health belief model construction, namely perceived threat (susceptibility & seriousness), perceived benefit, perceived barrier, and self-efficacy. The participants in this study were most knowledgeable about the benefits associated with the recommended fluid restrictions. This can be caused by health education about the benefits of fluid restriction is effective. Patients know about certain benefits obtained from following fluid restriction recommendations, for example recognizing that limiting fluid can keep them from swelling and shortness of breath.

The results of this study also highlight the belief in barriers to high fluid restriction. More than half of patients reported difficulties in following fluid restriction recommendations. This was in accordance with 8 which also reported similar issues regarding salt restriction.
It is important for patients undergoing hemodialysis to know the general obstacles that are felt because they can have adverse consequences for patients. In this study, researchers examined perceptions of benefits and barriers following fluid restriction as factors that might be related to the compliance of patients undergoing hemodialysis. It found a positive and significant relationship between adherence to sodium restrictions and perceived benefits thus indicating an increase in the level of adherence associated with an increase in perceived benefits. While a weak negative relationship was found between adherence to sodium restriction and perceived benefit. In this study, the level of confidence in barriers is higher than the level of confidence in the benefits, this shows that the higher the confidence in the obstacles, the lower the action in limiting fluid.

Most of the respondents had confidence in positive susceptibility and seriousness, although there were still some respondents who had negative beliefs. Individual belief in the susceptibility of the disease is related to symptoms that occur due to excess fluid volume. Individual beliefs about the seriousness of the disease, especially the risk of complications that occur can be shown by the patient’s knowledge of the disease. The patient’s knowledge of the disease will help the patient understand the prognosis of the disease including recommendations for action by health workers to prevent the prognosis of the disease towards a worse. In the belief in benefits, the majority of respondents had positive beliefs, but the level of confidence in the perceived barrier was higher. This shows that respondents’ beliefs/ perceptions of the barrier are greater than the benefits that will be obtained from fluid management behavior. Most of the respondents in this study had negative self-efficacy. Self-efficacy is an individual’s trust in himself that he is able to carry out an appropriate behavior to achieve the desired results of natural individuals facing their conditions.

Based on the evaluation of adherence behavior, it was obtained partly in the low adherence category. Behavior adherence here was defined as the actions taken by respondents in managing fluids. Indicators in adherence include monitoring input and discharging fluid, as well as fluid consumption as recommended. Most patients do not pay attention to urine output or input fluids every day, because urine production is low or even many experience anuria. Input and output of fluid should be considered as a basis for determining the amount of fluid intake every day. Previous studies have shown that individuals who see higher barriers have greater interdialytic weight gain, this indicates low compliance. A lack of motivation is observed by the patients as a barrier to adherence because the patients think that this restriction was not necessary to maintain their condition while having dialysis. Having a sense of self-confidence allows a person to be involved in health-promoting behavior, avoiding health-threatening behavior, and affecting all aspects of life. It takes a high degree of confidence to be able to change lifestyles before being made possible through change.

**Conclusion**

The results of this study corroborate previous studies which showed that rates of non-compliance with fluid restriction were clearly seen in the ESRD population. In addition, the results of this study indicate that participants in this study had a positive perception of the benefits felt in following fluid restrictions, but also reported feeling a number of high barriers. On the other hand, compliance in fluid restriction measures is in a low category. This association shows that increasing patient perceptions about the benefits of fluid restriction compliance, and reducing barriers increases the likelihood that the patient will perform the desired behavior. The perceived benefits and perceived barriers contribute to the increased understanding of compliance behavior in this study. This indicates by increasing patient perceptions of the benefits of fluid restriction compliance, while at the same time reducing barriers will allow patients to carry out the desired behavior, in this case adhering to fluid limitation recommendations.

ABSTRACT

Mercury (Hydrargyrum/Hg) is one of the metals that are hazardous and toxic (B3), liquid, silver white-colored, and easily evaporate at room temperature. In Indonesia, mercury is one of the environmental contaminants caused by illegal gold mining or Unlicensed Gold Mining (PETI). This study aims to determine the reference dose (RfD) of mercury in accordance with the characteristics of workers in Indonesia in order to be able to calculate and predict the risks to their health. This is an observational research by using a dose response approach and NOAEL in experimental animal of white mice (Rattus norvegicus). The subjects in this study were the illegal mining workers in Kayeli Village. The sample used was 67 workers, while the object of this research was the concentration of mercury in wells water and Polymesoda eros shells which are frequently consumed by workers.

Mercury concentration in drinking water in the area of illegal Gold Mining (PETI) was still within safe limits for consumption of 0,0005 mg/l, while the mercury concentration in Polymesoda eros shells was not safe for consumption by 0.756 mg/kg. Safe daily exposure dose of mercury in Kayeli Village Gold illegal mining area is 0,033 mg/kg with a NOAEL value of mercury of 0.23 mg/kg. The RfD value can be used as a reference in predicting the risks to the health of workers in the area of Illegal Gold Mining (PETI) in Maluku Province of Indonesia.

Keywords: Mercury (Hg), Gold Mining, Reference of Doses (RfD), Workers

Introduction

According to WHO, mercury is a metal element that is formed naturally and is classified into 3 main groups of liquid and gas, inorganic mercury (Hg⁺) such as mercury chloride, mercury acetate, mercury sulfide, and organic mercury (Hg²⁺).¹ In Indonesia, mercury is one of the environment contaminants caused by illegal gold mining (PETI). One of the provinces in Indonesia with an increase in mobility and population migration due to gold mining activities is Maluku Province, Kayeli Village, Buru Regency.² Contaminants mercury in the area is caused by the amalgamation method used by workers in an effort to bin gold metal from ore and tailings waste results.³ Without prevention and control, exposure to mercury can cause health impacts. In general, elemental and methylmercury mercury is very toxic and can affect central and peripheral nervous system, whereas organic

mercury has an impact on kidney disorders and irritation of the eyes, skin and digestive tract. Health problems due to exposure to mercury can occur after various forms of mercury are inhaled, swallowed, or even absorbed by the body. Based on research conducted by Hasyimi et al (2014), gold mining in Kayeli Village has a negative impact on public health in the form of diseases that have never previously reported.

Reference of dose (RfD) is a safe concentration of mercury recommended for humans. In several studies, Indonesia still uses the reference results of RfD in America and Europe, thus, it cannot be used as a reference in determining and predicting safe risks for the health of Indonesian workers. Health risk analysis in the Kayeli Village Gold Permit (PETI) area has been carried out in Lain et al. (2016) and the dose reference value (RfD) of mercury was 0.042 mg/kg/day, which is the US EPA reference dose. In addition, the determination of the mercury dose reference in Pahruddin’s (2017) study also uses RfD as determined by USEPA (1997) of 0.0003 mg/kg. In this study, RfD was obtained based on the principle of dose response and toxicity test for determining the highest dose without causing effects on experimental animals or NOAEL. Toxicity test carried out by using experimental characteristics of Indonesian white mice (Rattus norvegicus) and workers in the illegal mining area (PETI) of Kayeli Village.

The research to be carried out in this article is to determine RfD of mercury by using the characteristics of experimental animals and workers in the area of illegal Gold Mining (PETI) Maluku Province Indonesia. The purpose of this article is to calculate and predict the risks to the health of the right gold mining workers. The risk estimates for the health of the right workers in Kayeli Village can determine appropriate control and prevention efforts to overcome the effects of existing mercury pollution and can be used as material for decision-making by the parties concerned, both the regional government and the environment and health in Indonesia.

Material and Method

This study aims to determine the value of RfD as the determination of safe limits of toxin dosage for workers with non reactive research using the dose response approach and NOAEL. The subject of this study is the population of Kayeli Village as many as 558 people with a sample of 67 people. The object of this study consisted of samples of dug well water and samples of shellfish that were often consumed by the people of Kayeli Village. Data analysis was performed by using descriptive analysis on each research variable to describe the characteristics of each sample and quantitative analysis in determining RfD of toxins for workers. Determination of RfD for workers is determined by calculation by formula:

\[
\text{RfD} = \frac{\text{NOAEL}}{\text{Animal Km} / \text{Human Km}}
\]

Result

A. Characteristics of Experimental Animals, Surface Area of Experimental Animal, and Surface Area of Experimental Animal Bodies: Toxicity tests on experimental animals are based on the theory of extrapolation from animal testing data to humans. The following is the formula used in calculating the surface area of the tested animal body:

\[
\text{Animal BSA} = 0.09 \times W^{0.67}
\]

Where:

- BSA : Body Surface Area (m²)
- W : Weight (kg)

Table 1: Characteristics of Experimental Animals, Surface Area of Experimental Animals, and Surface Area of Experimental Animal Bodies

<table>

B. Characteristics, Surface Area, and Body Surface Area of Experimental Animal: The characteristics of workers’ body weight and body surface area of the worker are used in the analysis. Based on Table 2, workers’ body weight ranged from 52 kg to 89 kg with an average weight of 70 kg and a median value of 71 kg, the average height was 159 cm.

The calculation of the average surface area of the worker’s body is performed by using the following formula:

\[
\text{BSA} = 0.09 \times W^{0.67}
\]
Human BSA = \( \sqrt{\frac{W \times h}{3600}} \)

\[ = \sqrt{\frac{71 \times 159}{3600}} = 1.77 \text{ (m}^2) \]

Where:

- BSA : Body Surface Area (m²)
- W : Weight (kg)
- h : Height (cm)

**Table 2: Workers’ Characteristics and Body Surface Area**

Based on the distribution of Table 2, the average body surface area of workers in Illegal mining of Kayeli Village is 1.77 m².

**C. Mercury Concentration**

1. **Concentration of Mercury in Drinking Water**: Measurement of mercury concentrations in drinking water was carried out in 3 excavated wells consumed by the community who live closer to the amalgamation process. Based on the distribution of Table 3, the result of laboratory measurements at 3 points of the dug wells of Kayeli Village shows an average mercury concentration of 0.0005 mg/l.

**Table 3: Concentration of Mercury in Drinking Water of Kayeli Village**

2. **Concentration of Mercury in Polymesoda erosa shells**: Measurement of mercury concentration in Polymesoda erosa shells was carried out at 3 tailings disposal sites directly to the beach and each location was measured 3 points, so that the total sample of shells measured was 9 points. In gold mining, the tailings resulting from gold mining contain inert minerals (inactive) and one or more toxic hazardous materials including mercury.³

**Table 4: Mercury Concentration in Polymesoda erosa Shells**

</table>

Based on Table 4, the result of laboratory test of mercury concentration in the lowest shells at 1.1 was 0.3438 mg/kg, while the highest mercury concentration in shells at location 3.3 was 2.7406 mg/kg. The average value of mercury concentration in Polymesoda erosa shell was 0.756 mg/kg.

**D. Animal Km and Human Km**

1. **Animal Km**: Calculation of Animal Km is one of the first steps prior to determining the safe dose limit for toxins for workers.⁹ Animal Km can be calculated by using the formula below:

\[ \text{Animal Km} = \frac{W_{\text{animal}}}{\text{BSA}_{\text{animal}}} \]

Where:

- Animal Km : Km factor
- W : Weight (kg)
- BSA Animal : Body surface area (m²)

**Table 5: Results of Calculation of Animal Km in Experimental Animals (White Mice)**

<table>
<thead>
<tr>
<th>Experimental animal (white mice)</th>

<tr>
<td>3</td>
<td>0.1410</td>
<td>0.024223</td>
<td>5.820914007</td>
</tr>
<tr>
<td>4</td>
<td>0.1410</td>
<td>0.024223</td>
<td>5.820914007</td>
</tr>
<tr>
<td>5</td>
<td>0.1395</td>
<td>0.024050</td>
<td>5.8004158</td>
</tr>
<tr>
<td>6</td>
<td>0.1415</td>
<td>0.024165</td>
<td>5.855576247</td>
</tr>
<tr>
<td>Average</td>
<td>0.1407</td>
<td>0.024165</td>
<td>5.82</td>
</tr>
</tbody>
</table>
Based on Table 5, the calculation of the average value of Animal Km in white mice is 5.82.

2. Human Km: The Human Km calculation is the next calculation that must be done before determining the safe dose limit for toxins for workers.9 Human Km can be calculated using the formula below:

$$\text{Human Km} = \frac{W_{\text{human}}}{\text{BSA}_{\text{human}}}$$

Where:

- Human Km : Km factor
- W : Weight (kg)
- BSA Animal : Workers’ body surface area (m$^2$)

Table 6: Average Human Km Calculation Results

<table>
<thead>
<tr>
<th>Number of sample</th>
<th>W (kg)</th>
<th>BSA (m$^2$)</th>
<th>Human Km (W/BSA)</th>
</tr>
</thead>
<tbody>
<tr>
<td>67</td>
<td>71</td>
<td>1.77</td>
<td>40.11</td>
</tr>
</tbody>
</table>

Based on Table 6, the results of calculating the average Human Km value of workers in the area of Unlicensed Gold Mining (PETI) is 40.11.

E. NOAEL (No Observed Adverse Effect Level): NOAEL is one of the information that can be used to estimate the safety/risk of chemicals for the human body and also become one of the environmental quality criteria main indicators.9 According to EPA10 and WHO1, NOAEL value of mercury is 0.23 mg/kg.

F. Reference of Dose (RfD): Mercury exposure through the ingestion pathway, the type of safe dose determination for toxins for the body of the worker uses RfD.11 Determination of RfD can be calculated using the formula below:

$$\text{RfD} = \frac{\text{NOAEL}_{\text{Animal}}}{\text{Human Km}}$$

Where:

- RfD : Reference of Dose (mg/kg)
- NOAEL : No Observed Adverse Effect Level
- Km factor (Rattus norvegicus)

Based on the formula, mercury exposure RfD is 0.033 mg/kg through the following calculations:

$$\text{RfD} = \frac{0.23}{40.11} = 0.033 \text{ mg/kg}$$

Discussion

Mercury exposure to workers in the illegal Gold Mining Area in Kayeli Village occurs through ingestion pathways. Based on observations, the average mercury concentration in drinking water in the area of Unlicensed Gold Mining (PETI) is 0.0005 mg/l and is still below the maximum value of mercury permitted and determined by Minister of Health Regulation No.492 of 201012 concerning Drinking Water Quality Requirements and WHO13 of 0.001 mg/l in The Guidelines for Drinking-water Quality. The average mercury concentration in Polymesoda erosa shells in is 0.756 mg/kg and exceeds the maximum limit value of 0.01 mg/kg4 and the minimum risk level value is 0.002 mg/kg determined by Agency for Toxic Substances and Disease Register.14

The value of NOAEL is toxicity test for determining the highest dose without causing any effects on experimental animals and is based on the theory of extrapolation of doses from experimental animals to humans.15 By determining the characteristics of workers in the area of Kayeli Illegal Mining (PETI), the average body weight is 71 kg and height is 159 cm, NOAEL value of mercury is 0.23 mg/kg.10 This value is lower than the NOAEL value of mercury obtained in the Branco study in 2017 is 10 mg/kg in a mother’s hair.16 From the various NOAEL values obtained from several predetermined references, NOAEL is an experimentally determined dose and there is no statistically or biologically significant indication of the toxic effect in question.15

RfD is a non-carcinogenic quantitative toxicity in the form of estimates of daily exposure doses that are not expected to cause adverse health effects even though the exposure lasts for life.5 The mercury RfD value in the area of Unlicensed Gold Mining (PETI) in Kayeli Village is 0.033 mg/kg. Mercury RfD value is bigger than the mercury RfD value set by USEPA (1997)8 and has been used in Pahruddin’s research (2017)7 at 0.0003 mg/kg. In addition, according to the Agency for Toxic Substances and Disease Register the value of mercury RfD in Kayeli Village is also bigger than the ATSDR RfD value of 0.0004 mg/kg.14 RfD values obtained through NOAEL calculations and experimental toxicity tests are inversely proportional to Km factors in humans/workers. This is supported by Safitri’s research (2015) which states that the greater a person’s weight, the less likely the risk is to experience health problems because human
body weight reflects a person’s nutritional status. If a person’s nutritional status is bad it can affect the decline in endurance.\textsuperscript{17} When the immune response decreases, there has been an effect or effect of a chemical/dangerous heavy metal in the body. The integrity of the immune system is needed to defend against microorganisms and toxic products produced.\textsuperscript{18}

**Conclusion**

The concentration of mercury in drinking water contained in the wells digging in the area of Unlicensed Gold Mining (PETI) is still within safe limits for consumption by workers with an average mercury concentration of 0.0005 mg/l, while the average value of mercury concentrations in Polymesoda erosa area shells Unlicensed Gold Mining (PETI) of 0.756 mg/kg is not safe for consumption by workers. If there is no attempt to control mercury concentrations in the shell intake per day, adverse health effects on workers in the Gmining area area of Kayeli Village can emerge. In addition, the daily exposure dose of mercury that is not expected to have a detrimental effect on health in the Kayeli Village Gold Permit area of 0.033 mg/kg with NOAEL value of mercury of 0.23 mg/kg.\textsuperscript{10}

**Recommendation**

Recommended control related to mercury exposure in the Kayeli Village Ilegal Gold Mining Area (PETI) is administrative controls in the form of actions to develop policies related to licensing gold mining activities in the area by the Kayeli Village government. If the policy is enforced and can be implemented properly, it can reduce mining activities that pollute the waters of the Kayeli Village. In addition, technical control in the form of handling mercury pollution can be carried out using the role of microorganisms or bioaccumulation, bioremediation and bioremoval processes.

**Conflict of Interest:** All authors have no conflicts of interest to declare

**Source of Funding:** This is an article about “Determination of Dosage Reference (RfD) of Mercury based NOAEL and Characteristics of Workers in Unlicensed Gold Mining Areas (PETI) Maluku Province, Indonesia” of Occupational Health and Safety Departement thas was supported by Faculty of Public Health, Airlangga University

Using of Blended Learning in Improving Collaboration Skill of Nursing Students

Musrifatul Uliyah¹, Luthfiyah Nurlaela², Mustaji³, Abdul Aziz Alimul Hidayat⁴
¹,²,³Universitas Negeri Surabaya, 60231, Indonesia; ⁴University of Muhammadiyah Surabaya, 60113, Indonesia, Jl. Sutorejo No. 59 Surabaya, (031) 3813096

ABSTRACT

Background: An issue of collaboration between nurses and doctors can be caused by the lack of learning process which contains the element of collaboration in nursing education. Therefore culture and attitude to collaborate are lacking among nursing students.

Aim: This research is aimed to analyze the use of blended learning in enhancing the skill of collaboration of nursing students.

Method: The research is conducted by way of non-systematic type of literature review. Data in the form of articles were collected from several databases which includes PROQUEST, Science Direct, Elsevier, BMJ, Google Scholar and PubMed by searching several keywords search namely “e-learning”, “blended learning”, “Nursing Education”, “collaborative nursing”, “IPE”, “IPC”, “Professional Collaboration”, “Interprofessional Education” using boolean “AND”. In addition to keywords search, the researcher also used inclusion and exclusion criteria in filtering the articles reviewed confining to articles published in 2013-2018.

Results: Blended learning can improve nursing students’ collaboration skills through increasing the elements of cooperation, assertiveness, responsibility, communication, autonomy, coordination, understanding of general goals, mutual respect and trust.

Conclusion: Blended learning can be adopted in nursing education. Blended learning can increase motivation, improve learning outcomes, instill good character values, encourage critical thinking and enhance the collaboration skills of the students.

Keywords: Blended learning, Nursing Education, Collaboration

Introduction

Nursing is professional service which forms an integral part of the health services in the form of comprehensive biopscosocial and spiritual services aiming at individuals, families and communities. Nursing is a service-oriented profession by helping patients to overcome their health problems. One of the characteristics of this profession is to have the skills of collaboration namely establishing cooperation among various health professions in diagnosing health problems and helping to resolve them.

The skill in collaborating is currently considered to be lacking in the nursing profession. According to the research finding of Rumanti, it was stated that the practice of collaboration between nurses and doctors was lacking and most of them were still in the stage of negotiating. Likewise, Reni’s research finding stated that the collaborative implementation between nurses and doctors in one of the Sumedang district hospitals was still not effective. This shows that the spirit of collegiality among the nurses and the doctors has not been formed. The hierarchical interaction between nurses and doctors can still be seen in the interdisciplinary...
relationship among physician nurses. Collaboration problems were also experienced by nurses in Turkey according to Durmus’ research and collaboration. It also happens to nurses in China where the level of collaboration between nurses and doctors was in the medium category in respect of effective communication, perceived respect and willingness to collaborate.

The problems of collaboration between nurses and doctors were caused by various factors including a less positive attitude. According to Tang’s research which stated that doctors view that the collaboration of nurses is less important but assess the quality of collaboration to be higher as compared to the nurses. Besides that, it is also influenced by other factors including communication, respect, trust, unequal strength, understanding professional roles and assigning priority tasks.

The collaboration problem between nurses and doctors can be attributable to the problem of learning process in nursing education and lacking of the application of learning methods that contain element of collaboration which resulted the lacking of culture and attitude to collaborate among the nursing students. The skill of interprofessional cooperation is not easy but yet it can be honed by all nurses provided that they must be trained in the early stage through the process of collaborative learning in interprofessional education. Likewise Foote’s research stated that interprofessional education with collaborative learning approaches can enhance the collaboration skill of interprofessional team, defining roles and responsibilities and increasing trust in nursing skills.

However, various efforts can be made to the learning process in order to resolve the problems of collaboration of nursing students such as the use of clinical instructors to improve the learning experience of the nursing students. Other than that, preceptorship programs can also improve the learning outcomes of nursing students. Besides that, learning with concept maps and blended learning is also able to enhance collaboration. The purpose of this research is to study the utilization of blended learning in improving the collaboration skills of nursing students.

Method

This research is conducted by way of non-schematic type of literature review. Data in the form of articles were collected from several databases which include PROQUEST, Science Direct, Elsevier, BMJ, Google Scholar and PubMed. Data by searching several key words namely “e-learning”, “blended learning”, “Nursing Education”, “collaborative nursing”, “IPE”, “IPC”, “Professional Collaboration”, “Interprofessional Education” using boolean “AND”. In addition to keywords search, the researcher also used inclusion and exclusion criteria in filtering the articles reviewed confining to articles published in 2013 - 2018 in Indonesian as well as English with realiable sources.

Results and Discussion

There are two reasons for adopting blended learning model especially in universities where there are for students and lecturers or referred to as differentiated instruction and the presence of comfort and presence list or referred to as pacing and attendance.

Differentiated instruction means that lecturers can determine the contents of the curriculum, environment, online learning activities, face-to-face depending on the level of difficulty, interest, learning style and are able to determine the time of the students working in groups and to provide additional materials that are not available in online module. Meanwhile, pacing and attendance means that students can independently determine when they want to study. As such, there will be no issue even if the students do not not present during the lecture, they are still able to access the learning materials online so that they will not be left behind.

In addition to the above reasons, blended learning has validity, practicality and effectiveness in learning. Validity can be seen from the elements in blended learning, namely there were elements of application and tutorial had a role in improving the procedural abilities needed by the learning process. Collaboration skill can be honed from the e-learning process of blended learning as there is element of collaboration among the students in solving problems in a given case.

The practicality and effectiveness in blended learning can be seen from planning and implementation. Planning using e-learning facilities of blended learning consists of ease of obtaining subject identity, learning outcomes, learning objectives, materials, time allocation, learning methods, learning activities, assessment of learning outcomes, learning resources, completeness.
of learning tools, presence of face-to-face learning, independent learning, collaboration, assessment and learning material support.

In the implementation of blended learning model, it is practical and effective in orientation, organization, investigation, presentation, analysis and evaluation such as learning preparation, delivery of learning objectives, introduction of materials, introduction of problems related to materials, assigning tasks, related problems to be studied by students, independent and group investigations, gathering information related to the problem to be studied, solution to the problem studied, developing work and presentation of works and evaluating learning outcomes. Likewise, the effectiveness of blended learning is able to make students to be more active and increasing the interest of students in learning as it is not boring.

Some research findings have proven the advantages of blended learning. For example, Ali’s research stated that the implementation of blended learning could increase the motivation of the students and improve learning outcomes15. Susana’s research also stated that blended learning is able to instill good character values in learning among the students16. Likewise in Fitriani Research and Ikhsan, it was stated that blended learning is able to improve students’ critical thinking17.

In nursing education, the application of blended learning also has an impact in improving the learning skills of nursing students in which the Mean et.al study stated that blended leaning is more effective than face-to-face learning in the ability of meta-analysis18. Likewise, Campbell et al.’s research stated the application of discussion in blended learning has better results as compared to face-to-face discussions19.

In the development of blended learning model, it had been carried out by using various approaches such as the development of moodle-based blended learning in microbiology courses20. Development of blended learning design by using assure approach21. Development of blended learning in aspects of learning design by using online social media platforms as supporting lectures 22 and the integration of collaborative problem based learning with blended learning 23.

Blended learning as a learning method has several criteria where Rosenberg has identified the three basic criteria in e-learning:

1. e-learning is a network that can make, improve quickly, save or reappear, distribute and share learning materials and information;
2. e-learning is accessible by all users who have access to internet;
3. e-learning focuses on broader learning where learning solutions can be superior to the training paradigm. 24, 25.

Collaboration according to Orchard (2005) is a joint communication and decision-making process with the aim of meeting health care needs or it can also be defined as a partnership between a team of health professionals with a participatory, collaborative and coordinated approach to share decision making communication about health issues. 26. Collaboration is needed by nurses as there are various elements associated with collaboration which include cooperation, assertiveness, responsibility, communication, autonomy, coordination, general purpose, mutual respect and trust 27.

Collaboration is the first element in building collaboration. Through collaboration one will respect the opinions of others, willing to trust and to accept other opinions. Assertiveness is the second element in building collaboration. Assertiveness means the skill of collaborative team members to offer information, appreciate the scientific approach and share experience they have, and to ensure the opinions of each team are accepted and that consensus can be achieved. Responsibility is the third element in building collaboration which means that each team member must take responsibility based on the consensus, both as a member of the team and the profession. Communication is the fourth element in collaboration which means that each member of the team must share important information about patient care or various information related to clinical decisions. Autonomy is the fifth element in collaboration which means that each team member would have scientific independence or autonomy within the limits of his competence and the freedom to apply knowledge and manage patients in accordance with their fields or professional competencies. Coordination is the sixth element in collaboration which means that each joint decision-making is decided through coordination among team members and at the same time to reduce duplication of decisions making for organizational efficiency. General goals is the seventh element in collaboration which means that collaboration is based on
general-purpose concepts, emphasizing mutual respect and a professional approach to solving problems. Mutual respect and trust are the eighth element in collaboration which means that relationships are dynamic to achieve mutual satisfaction or a relationship that facilitates a dynamic process characterized by a desire to advance and achieve satisfaction for collaborative team members while trust could determine success in collaboration goals. Therefore the element of collaboration could be developed through blended learning.

**Conclusion**

Blended learning is one of the learning models that can be used as an alternative learning model in nursing education in the era of information technology. Blended learning is easy to use and it can increase motivation, improve learning outcomes, instill good character values, encourage critical thinking and enhance the collaboration skills of the students through increasing of the elements of collaboration, assertiveness, responsibility, communication, autonomy, coordination, understanding of general goals, mutual respect and trust

Maternal and Fetal Determinants of Stillbirth among Women Who Attending Maternity Departments of Basra Central Hospitals

Nadeem R Shiaa¹, Sajjad S. Issa², bd AL Kareem H Subber³

¹Department of Medical Operations and Emergency, Basra Health Office, Iraq; ²Department of Fundamental of Nursing, College of Nursing, University of Basra, Basra, Iraq; ³Department of Gynecology and Obstetric, Delivery and Children Hospital, Basra Health Office, Iraq

ABSTRACT

The cross-sectional case control study was carried out in the Basra over a period of six months. The aim of the study is to assess maternal and fetal determinants, incidence of stillbirth in Basra. We also evaluate the prevalence of stillbirth in Basra during previous five years. The women (n=114) who delivered stillbirths whether fresh or macerated at 28 weeks gestation or more were considered in this study. In the control group, women (n=228) who delivered a live baby were considered. In the study period, 26211 numbers of deliveries were reported, out of which about 346 were stillbirths. While, around 410,733 births was reported in last five years and 5,456(1.33%) were found to be stillbirths. The incidence of stillbirths were 13.2 per 1000 births during the period of the study, most of them were males, preterm and macerated stillbirths. The study concluded that woman with these maternal and fetal determinants were more liable to develop stillbirth, and encourage public health education regarding these determinants.

Keywords: Stillbirth, Cross-sectional case control study, Birth weight, Fetus, Iraq

Introduction

Loss of a child is a very difficult life experience to the parents which can often cause complicated grief for them[1-2]. It is a hurtful event even when the parents have not make a relationship with their infant[3-4]. It is always associated with post-traumatic stress, shame, feeling of guilt, depression, anxiety, sleeping disorders, etc.[5-8]. Improving health system makes prevention of most stillbirths possible[7-8]. Women with a history of previous stillbirths are 2-10 time more likely to have another one in subsequent pregnancies[9-10]. However, not all women show this problem[11].

Stillbirth is a death of a fetus that has reached a birth weight of 500g, or if birth weight is unavailable, gestational age of 22 weeks or crown-to heel length of 25cm[12-13]. According to United States stillbirths a birth of a baby, which shows no sign of life like breathing, heartbeats, pulsation of the umbilical cord, or definite movements of voluntary muscles[14, 15]. The Iraqi ministry of health defines stillbirth as the fetal death that occurs after 28 weeks of gestation, which shows no sign of life[16].

From 2000 to 2015 stillbirths rate had declined by 19.4% with several interventions, this means a yearly decline of 2%[19] and 98% of these deaths recorded in the developing countries[20,12]. Half of the stillbirths in developing countries happened during labor, because of a lack of skilled birth assistants and facilities for delivery[21].

The rate of stillbirth in Iraq according to WHO estimates in the year of 2009 was 8.6/1000 total deliveries[22]. The stillbirth rate in Basra Al Zubair was 5.5/1000, while in Basra Abu Al Qaseeb was 15.3 according to the survey done by the ministry of health of Iraq in May 2012, highest stillbirth rate recorded in Halabja (Sulaimanyha) 27.1/1000[23]. While the incidence of stillbirth was 20.4/1000 total births as reported by the study done by Shahlaa AbdAlrahman in Maternity Teaching Hospital in Erbil city, Kurdistan region, Iraq at 2011[24].

There are two types of stillbirth viz. Fresh (death occurs within 12hr of birth) and macerated (death occurred more than 12-24hr)[25-26]. Pre-existing HT, GHT, and PE are a common cause of stillbirth, these hypertensive disorders cause placental insufficiency, fetal growth restriction, and stillbirth[27]. Women with
pre-existing diabetes mellitus (DM) have an increased risk of second and third-trimester stillbirth compared to women without diabetes\cite{28,29}.

The fetal causes of the stillbirth were congenital anomalies\cite{34}, fetal growth restriction\cite{32,33}, chromosomal and genetic abnormalities\cite{34-35}, multiple gestation\cite{36,37}, placental disorders\cite{27} and unexplained stillbirth\cite{38-40}. Risk factors are race and socioeconomic factors\cite{41}, advanced maternal age\cite{42}, obesity\cite{43} and multiple gestations\cite{44-45}.

**Method**

**Study Design:** A cross-sectional study aimed to determine prevalence of stillbirths in Basra central hospitals during the period of study, and case control study was used to determine maternal and fetal determinants of stillbirth. The study was carried out in the city center of Basra governorate over the period of six months started from January to June 2017. The studied sample included 342 women. Women who delivered stillbirths had been taken as cases and women who delivered a live birth were taken as controls.

**Study Tools:** The data were collected from cases and controls by direct interview using special designed close ended questionnaire (Supplementary Data 1). The investigator collected the data regarding the total number of live births and stillbirths of previous five years from (2012-2016). This data was obtained from the biostatistics section of the Basra health department.

**Statistical Analysis:** Statistical analysis of the data was carried out using SPSS program (version 20), Chi-square test of association was used to compare between proportions and to show the significance of the association between the disease (stillbirth) and different factors.

**Results**

The reported deliveries during the study period was 26,211, out of which 346 were stillbirth. So, the incidence of stillbirth in the study center was 13.2/1000. In past five years (2010-2016), about 410,733 births occurred and about 5,456 was found to be stillbirths (13.1 cases per 1000 births).

**Study of different variables in the studied group:** According to Sociodemographic characteristics, the number of mothers reported to age above 19, 20-29, 30-39 and below 40 were 37, 207, 82, 16, respectively. The enrolled urban and rural resident subjects were 210 (61.4) and 132 (38.6%), respectively. Out of 342 cases, active and passive smokers were reported to be 22 (6.4%) and 122 (35.7%), respectively. While, reported educational level as illiterate (45), primary school, secondary school and higher education were 45 (13.2), 32 (38.6), 114 (33.3) and 51 (14.9), respectively. The parity was categorized as 0 (125), 1-4 (160) and ≥5 (57).

About (n=298, 87%) of mothers had no chronic medical illness before pregnancy. The number of cases with pre-existing HT and DM was around 12 (3.6%) and 7 (2%), respectively. Around 13 cases (3.8%) had sickle cell disease. The cases for epilepsy (1.8%), cardiac disease (0.9%), diabetes mellitus with hypertension (0.6%) and Systemic lupus erythematos were found to be 6, 3, 2 and 1, respectively.

About 212 cases (62.1%) had no maternal morbidities during pregnancy. While, GDM, fever and rash history, GHT, PE, antepartum hemorrhage, anemia, PE with GDM, antepartum hemorrhage with anemia, Antepartum hemorrhage with PE was reported to about 12 (3.5%), 10 (10), 11 (3.2%), 20 (5.8%), 14 (4.1%), 51 (14.9%), 4 (1.2%), 7 (2.0%) and 1 (0.3%), respectively.

Around 55 (16.1%) child showed congenital malformation. The number of male and female child birth was reported to be 161 (47.1%) and 181 (52.9%), respectively. Around 294 (72.8%) participant was on folic acid-Iron supplementation. The fetal parameter is depicted in the Table 1.

| Table 1: The fetal parameter among study group |
| Parameter | Variables | No. |
| Gestational age at delivery | ≥37 | 201 (58.8) |
| | 32-36 | 82 (24.0) |
| | 28-31 | 59 (17.2) |
| Singleton/multiple | Singleton | 313 (91.5) |
| | Multiple | 29 (8.5) |
| Birth weight (gm) | ≥2500gm | 184 (56.6) |
| | 1500-2499gm | 51 (15.7) |
| | 1000-1499gm | 38 (11.7) |
| | <1000gm | 52 (16.0) |
| | Missing | 17 |
| Antenatal care | No | 28 (8.2) |
| | Inadequate | 102 (29.8) |
| | Adequate | 212 (62.0) |

Most of the fetuses delivered by normal vaginal delivery (56.7%). While, induction of labor and
cesarean section mode of delivery was found to be about 92(26.9%) and 56(16.4), respectively. Around fresh and macerated types of stillbirth was reported to about 28(24.6%) and 86 (75.4%), respectively. The data for blood group was missing for 13 cases. Antenatal care visit as primary health care, private clinic and both were reported to be 79(25.2), 148(47.1) and 87(27.7), respectively. The blood group of enrolled participants were given in the Table 2.

**Associations between stillbirth and different variables:** There was an association between advanced maternal age and stillbirth, about (33.3%) of cases were in age groups (30-39) years as compared to (19.3%) of controls. About 60%(n=69) of cases lived in rural areas compared to 27.6%(n=63) of controls, while 72.4%(n=165) of controls lived in urban areas compared to 40%(n=45) of cases (p<0.05).

The obstetric determinants such as past obstetric history, antenatal care visit and their type, folic acid-Iron supplementation, gestational age (week) is depicted in the Table 3.

</table>

Higher percentage of cases (47.4%) and controls (61.4%) were delivered by normal vaginal delivery, while induction of labor was higher among cases (41.2%) versus to controls (19.7%) and the difference was statistically significant so induction of labor considered as risk factor. About 13(11.4%) were reported to have cesarean section as compared to control (43, 18.9%). C/S rate was higher among controls so it was protective factor. The statistical significance between the cases and control was 0.0001.

**Conclusions**

The incidence of stillbirths in central hospitals of Basra were 13.2/1000 births. From this study we concluded that elderly women with poor ANC, visiting primary health care, of low educational level, lived in rural area, being AB+ blood group, being active or passive smoker, had history of medical disease and pregnancy with some disease like hypertension, diabetes mellitus, cardiac disease, sickle cell disease, PE, anti partum hemorrhage, febrile illness or infection, not taking folic acid iron-supplementation during pregnancy, had multiple gestation, and past history of pregnancy loss inform of miscarriage or stillbirth, carrying male baby, with congenital anomalies, were more liable to have stillbirth.

**Ethical Clearance:** Ethical clearance were taken from Basra central hospitals.

About 20.2% of cases had a chronic medical illness compared to 9.2% of controls. The pre-existing hypertension, diabetes mellitus, cardiac disease, sickle cell anemia, epilepsy, diabetes mellitus with hypertension and systemic lupus erythromatous condition were 5(4.4%), 3(2.6%), 3(2.6%), 6(5.3%), 4(3.5%), 1(0.9%) and 1(0.9%) in the cases as compared to control i.e. 7(3.1%), 4(1.8%), 0(0.0%), 7(3.1%), 2(0.9%), 1(0.4%) and 0(0.0%), respectively. The increase in the cases was significant (p=0.027) as compared to control group. The recorded blood group of the participants was given in the Table 5.

SPIRITUAL-BASED FAMILY CARE MODELS TO IMPROVEMENT FAMILY HEALTH WITH LEPROSY AT JOMBANG REGENCY OF EAST JAVA INDONESIA

Nasrudin1, Ah Yusuf2, Rachmat Hargono1, Tjipto Suwandi1

1School of Public Health, Airlangga University, Surabaya, Indonesia; 2School of Nursing, Airlangga University, Surabaya, Indonesia

ABSTRACT

Leprosy contributes to the occurrence of stress in the family, demand of the role for caring, and maintaining the health of the family. In this case the strengthening of family spiritual value will impact on the strength and the ability of the family in overcoming the leprosy. The purpose of this research was to make caring model of family spiritual based to enhance the health of the family of lepers’ patient.

Design used in this study was analytical observational. The population was 174 leprosy families in 21 endemic Leprosy public health centers or Puskesmas in Jombang regency of East Java. Total sample used was 120 families with lepers. Data were collected by questionnaire and it was analyzed by using Smart PLS 3.0.

The result shows that: 1. Family factor gives the family with lepers spiritual based family nursing model of care and improving the strength of the family to overcome the stress and their health as well. 2) Individual and environmental factors gave contribution to the occurrence of family stigma, but they did not directly impact on family stress. 3) Family stigma (separation) impact on family stress. 4) Family stress contributed to the use of caring spiritual based. 4) There has been influence or impact of caring spiritual based on the improving the health of the family.

The conclusion is that Family caring model in nursing practice spiritual based impact on the health of the family with lepers.

Keywords: Nursing model of care, Spiritual nursing, Health of the family, Leprosy

Introduction

The family of leprosy patients has the important role for the treatment of leprosy patients and which has the greatest impact due to family members suffering from leprosy, resulting in a situation full of stress and family health problems.

The results of the previous research conducted in 2017 shows that in 39 leprosy patients in Jombang Regency, East Java, 10% of patients experienced physical disability, 30% psychological disorders and 60% experienced psychosocial. Family support for lepers in treatment was found to be 75% low, concealment of 47% patients, families experiencing 80% stress. This condition was influenced by the family’s ability to carry out the function of caring for and enduring the family in overcoming stressful conditions.

Family needs a resource, support and strengthening family resilience in carrying out the family functions of caring for family members who suffer from leprosy and keeping the family for a healthy condition. Furthermore, strengthening family resilience includes three major components, namely: strengthening the family belief systems, strengthening the structure and function of the family, strengthening communication patterns and family power systems in overcoming problems. Spiritual family is the basis of of family values and beliefs.
Individual and family spiritual and religious beliefs are at the core of all family coping and adaptation. The family’s spiritual concept consists of family religious coping, family interdependence, family togetherness and personal spiritual \(^{(1,2)}\).

Family nursing care models in *Family Centered Nursing (FCN)* which is in line with family problems with leprosy sufferers are used for a family approach to caring for and strengthening families as a system. However, they have not got into the strengthening of family values and beliefs as the main resource for strengthening family health. Spiritual-based family nursing models with approaches family centered nursing (Friedman, 2003) are expected to illustrate family care models in improving family health of leprosy patients. This model was developed based family centered nursing theory \(^{(3)}\), spiritual family theory \(^{(1,2,4)}\), stress-coping theory \(^{(5)}\), ABC-X model \(^{(6)}\).

### Material and Method

This cross-sectional design research was conducted on 2018 – 2019. The study population was a leprosy family in 21 endemic leprosy community health services in Jombang regency of East Java, consisted of 174 families of leprosy patients and they had been diagnosed with leprosy and recorded in a public health center or puskesmas data registration. The sample was 120 families taken by using Multi-Stage Random Sampling. Data was collected by questionnaires. Respondent from each family was represented by a family member who cares directly for lepers in the family. The questionnaire was used to measure family factor, individual factor, family stigma environment factor, family stress, spirituality-based care and the family health of leprosy patients. Meanwhile, *Smart PLS 3.0.* was used for analyzing inferential data.

### Findings

The result of path analysis is presented in table 1 of outer weight test shows that all indicators were statistically significant. They have a correlation to used as a measurement tool for the model. Indicators of family factors, individual factors, environmental factors, family stigma, family stress, spiritual family-based family care have a value of loading factors > 0.5 and values composite reliability > 0.6.

Based on value inner weight in table 2, indicators have a correlation coefficient > 0.05 and T values statistic > 1.96. Hence it can be concluded that there is a significant relationship between latent variables. Family factors have the strongest relationship in improving family health.

From the results of path analysis, a spiritual-based family care model in improving the family health of leprosy patients can be seen in Figure 1.

![Figure 1: Family-based family nursing model in improving the health of families of leprosy patients](image-url)

From Figure 1 shows the value of T statistic > 1.96. : 1) There are influences of family factors (perception, support, socio-economic, and family burden) on family-based spiritual care and family stress resistance. 2) There
are influences of individual factors (duration of leprosy, disability, self-concept, self-stigma, and quality of life) to the family stigma. 3) There is an influence of environmental factors (community stigma) on the family stigma. 4) There is a stigma effect of family (separation) to stress the family. 5) There is an influence of family stress on spiritual-based care. 6) There is an influence of spiritual-based care on family health. 7) There is an influence of a spiritual-based family care model on family health.

Discussion

The effect of family factors on family stress: The results showed that t value of 13,778. This means: there is an influence of family factors (perception, burden, support and family socio-economic) on family stress. Meanwhile, family stress is influenced by the ability of the family to understand problems due to leprosy (perception of problems), assessment of family burden due to leprosy. The success of the family in the primary assessment will increase family confidence and family resilience in facing stressful situations due to leprosy. The second assessment by the family of family resources including family support and socio-economic benefits in determining the choice of coping strategies based on existing resources.

The results of family factor research on indicators of family perceptions of leprosy family members found that perceptions were good at only 25%, lack of knowledge. This wrong perception can have an effect on family coping, the emergence of family stigma and impact on the process of care for leprosy patients and family health as a system. Effect of family factors on spiritual-based family care: The results showed that t value of 7.248, this means: there is an influence of family factors (perception, burden, support and family socio-economic) on spiritual-based family care. The existence of leprosy patients in the family affects the family as a system and the family as a collection of family members and creates its own stressors for the family. The biggest problem of leprosy is the social and psychological problem of the impact of stigma for individuals, families and society.

Strengthening families in facing stressful conditions through Walsh’s three basic components of family reinforcement, namely: strengthening the system of family beliefs and (systemfamily belief systems), strengthening the structure and function of the family as an organization, strengthening communication patterns and family power system in overcoming problems (communication/problem-solving) is expected to improve the health of families of people affected by leprosy. The family’s ability to carry out family duties in spiritual-based care is to make the family spiritual as the basis for carrying out the role of family nursing in caring for family members suffering from leprosy.

Effect of leprosy patient factors on family stigma: The results showed that the individual factors included the duration of leprosy. Most of the respondents were found to suffer from 6-12 months of leprosy, a small proportion of respondents had a good self-concept (positive), and even though there was a change in ADL ability only a small number of respondents (20.8%) Independent in ADL, more than half of respondents did not experience disability, for the occurrence of severe self-stigma in a small proportion of respondents (23.3%) the rest experienced moderate and mild self-stigma, and the quality of life of patients who were good and moderate. Stigma also affects family life, both psychologically or emotionally, socially, interpersonally, family functions and structures result in loss of family support in leprosy patients and reduce the quality of life for patients and all family members. The effects of this internal stigma are disruption of self-concept, fear, and mental disorders and a decrease in interest in treatment and activities with social groups. The inability of individuals to adapt physically, socially and spiritually psychologically will reduce the quality of life of leprosy patients. and add to the negative family assessment which results in the stigma of the family.

Effect of environmental factors on family stigma: The results showed that influence of environmental factors on the family stigma (t = 0.974). Stigma in society occurs because of the factors of knowledge and perception that are wrong, social factors, values and beliefs, and factors of values (norms, values and spiritual-religious beliefs) towards leprosy patients and families. Health policy factors can lead to stigmatizing situations, which can be in the form of service procedures, service providers, service regulations or services that distinguish between recipients of stigma and general social groups. The activeness of leprosy
officers in the discovery of leprosy cases, in the treatment and counseling of family and patient counseling, collaboration with leprosy cadres, coordination with community leaders, government and health service health policy holders caused families to still make leprosy officers in health centers as the best social support resources family.

Effects of family stigma on family stress: The results showed that t value of 3.559. This means that there is an influence of family stigma against family stress. The results also showed a separating incidence of 70 (58.3%) moderate. Discrimination obtained by patients from families is still 30 (25%) heavy and labeling families 73 (60.8%) are moderate.

Negative assessments of leprosy patients and their families in the community have an impact on the inability of families to choose a good coping method so that they stand on the behavior of isolating patients, and inhibiting treatment. The family is the entry point in the provision of health services in the community, the potential and involvement of the family becomes even greater, when one member of his family needs continuous assistance because his health problems are chronic, such as in leprosy patients (3).

Effects of family stress on spiritual-based family nursing: The results showed that t value of 2.738. This means that there is an influence of family stress on spiritual-based family nursing. Family resistance to stress is very influential on family resilience. Family resilience is a capacity to recover from difficulties. This is an active process of family resilience to stressors, self-righting, and growth in responding to crises and challenges (2).

Primary appraisal is very influential on the ability of the family to consider whether this is considered a threat, whether the family is able to overcome stress, if the family’s resistance to stress is good then the family will be able to choose coping strategies that focus on the problem rather than focusing on emotions (5,13). Secondary (appraisal) family assessment of family resources will show individual and family self-confidence in overcoming situations and stressors as a result of family members suffering from leprosy. The ability of families to conduct primary appraisal (primary assessment) and secondary appraisal (secondary assessment) to conditions that are full of stress due to leprosy will be very effective in determining coping strategies due to individual changes and changes in social environment (5,13).

Effect of family-based spiritual nursing on improving family health: The results showed that t value of 5.646. It means that there is a family spiritual based nursing influence on family health improvement. In other words, spiritual can be a significant resource in the resilience of individuals and families and it is able also to increase endurance and the recovery process. Therefore, we have to understand the important process and its effects on individuals and families.

The result data of the study reveals that adaptation ability 46 (38.6%) lack, partnership ability 38 (31.7%) lack, mutually reinforcing capabilities and growth (36), 46.7%) lack, ability to care for each other and affection (Affection) 67 (55.8%) lacking, and resolving abilities less 37 (30.8%). Above result of the study was obtained by using APGAR family scores. Friedman (2003) defines healthy families as strong families, a balance of relationships between family members and adaptability which is shown by good communication among family members (3).

ABSTRACT

Mercury is one of the metals in the environment which naturally occurs and is classified as a hazardous material. Mercury is a silver white heavy metal and has persistent properties. It is liquid, volatile, bioaccumulation and harmful to health and the environment. This study aimed to determine the safe concentration of mercury exposure in the community in the area of unlicensed gold mining areas (PETI) in Kayeli Village, Buru Regency, Maluku Province, Indonesia. This study was an observational study with an environmental health risk analysis approach. The sample of this study was 67 people and the object of this study was Polymesoda erosa shells. The variables were the No Observed Adverse Effect Level (NOAEL), Reference Dose (RfD), mercury concentrations in the shells, body weight, shell consumption rate and safe concentrations of mercury in the shells. The result showed mercury concentration in Polymesoda erosa in 9 different sample locations was 0.756 mg/kg and the safe concentration of mercury exposure was 0.71 mg/kg. It was less than the Indonesian National Standard of the maximum limit of heavy metal contamination in food. It can be concluded that the safe concentration of mercury in the shells of illegal gold mining areas in Maluku province of Indonesia is safe and can be used as a reference for the community.

Keywords: mercury, gold mining, safe concentration, community

Introduction

Mercury is one of the metals in the environment which is naturally formed and is classified as a hazardous material. Mercury is a silver white heavy metal and has persistent properties. It is liquid, volatile, bioaccumulation and harmful to health and the environment.¹ Mercury is formed naturally and consists of three forms, namely elemental, inorganic and organic.² Some people are exposed to mercury in daily basis through activities like inhalation, consumption of contaminated food and beverages and skin contact.³

Most of the mercury in the environment comes from human activities, one of which is gold mining.³ Gold mining in Indonesia is mostly unlicensed gold mining (PETI). This kind of gold mining process is a traditional one as it uses mercury in the amalgamation process.

The gold beans obtained from this mining will be milled with a jumble tool and added with mercury to make it into sand powder. After that, the powder will be mixed with mercury for one more time. The mercury waste from this process will contaminate the soil. This process
also produces waste in the form of tailings which will be discharged into the river and pollute the environment.  

According to the Agency for Toxic Substances and Disease Registry, mercury can bring negative effect to human health. It can damage brain and kidney function. Inhaling mercury vapor in the form of methyl mercury causes mercury to go to the brain and affect the nervous system, while consuming mercury-contaminated foods will cause accumulation of mercury in the kidneys which later can harm the kidneys.

Broussard (2002) stated that the digestive tract is the main route of methyl mercury into the body. However, methyl mercury can also be absorbed through the lungs and skin. More than 90% of methyl mercury absorbed by the body enters erythrocytes and binds to hemoglobin, while the rest of 10% is found in the brain and slowly undergoes demethylation which causes neuronal necrosis and becomes toxic to the cerebral cortex.

Mercury not only affects adult health, but also children’s health. Mercury exposure, which can be in the form of contaminated food such as fish and shellfish, can affect children development process. Children who are exposed to mercury can experience decreasing brain ability, mental retardation and inability to move. Mercury is also dangerous for pregnant women. Women who are exposed to mercury during pregnancy have a risk of blindness, seizures and inability to speak.

The safe concentration of mercury exposure through inhalation is 0.1 mg/m³. In Indonesia, it has been set that the safe concentration of mercury exposure is 0.001 mg/L for drinking water and 1 mg/kg for shellfish. There are in approximate 85.57% of workers in the area of Unlicensed Gold Mining (PETI) who consume mercury-contaminated shellfish in a daily basis. Yet, the mercury concentration in the shellfish is still unknown.

A previous study analyzed the health risk of mercury exposure in the community of unlicensed gold mining areas (PETI) in Maluku Province of Indonesia. However, it only calculated consumption intake and estimated risk quotient (RQ) and didn’t calculate the Reference Dose (RfD) and safe concentration of mercury exposure in shellfish. Therefore, this study is aimed to calculate the Reference Dose (RfD) and safe concentration of mercury exposure in the shells using No Observed Adverse Effect Level (NOAEL).

### Material and Method

This study was an observational study using an environmental health risk analysis approach. The context of this research was the community of illegal gold mining areas. They were people living in Kayeli Village, Teluk Kayeli Subdistrict, Buru District, Maluku Province, Indonesia.

The sample was 67 out of 588 people living in the area. The object of this research is *Polymesoda erosa* shells which were taken from three different locations of tailing discharge around the beach. Three shells were taken as the sample for every location, with total of 9 sample shells.

The variables of this study were No Observed Adverse Effect Level (NOAEL), Reference Dose (RfD), mercury concentration in shells, body weight, shellfish consumption rate and safe concentration of mercury in the shellfish.

The measurement result analysis was conducted at the Makassar Health Laboratory Center. To determine the safe concentration of mercury exposure, quantitative data analysis was carried out manually.

The research was started by determining the NOEAL in the experimental animal and followed by calculating the Reference Dose (RfD) and safe concentration of mercury in the shellfish. The calculation using the following formula (Tualeka, 2019).

\[
c_{safe} = \frac{\text{RfD} \times \text{D} \times \text{Wb}}{\alpha \times \text{R}}
\]

Annotation:
- \(c_{safe}\): safe concentration (mg/kg)
- \(\text{RfD}\): reference dose (mg/kg)
- \(\alpha\): % substance absorbed by lung
- \(R\): consumption rate (kg/day)

### Findings

#### A. Characteristics and Body Surface Area of Experimental Body:
The toxicity test was carried out using experimental animals, namely white rats. This was due to the similarity of biochemical systems of experimental animals to the mechanism of the human biology system, so that white rats have qualitatively a similar response to humans.
Table 1 shows the characteristics of experimental animals, its body weight and body surface area.

### Table 1: Distribution of Experimental Animal Characteristic (White Rats)

<table>

</tbody>
</table>

To calculate the body surface area of the experimental animal, the following formula is used:

\[
BSA = 0.09 W^{0.67}
\]

Annotation:

BSA : Body Surface Area (m²)
W : Weight (kg)

### B. Characteristic of Workers and Shellfish Consumption Rate:

The characteristics of 67 samples of workers in communities in the gold mining area without permission from Kayeli Village, Buru Regency, Maluku Province, Indonesia are shown in table 2. It was found that the average body weight was 71 kg, the average height used was Indonesian average of 159 cm, the consumption rate of shellfish was 0.284 kg/day and the average working time is 7 hours/day.

Body surface area and consumption rate was calculated using the body weight and height.

1. **Workers Body Surface Area:** Body surface area was calculated using the formula of Tualeka and Saridewi as shown below:

\[
BSA = \sqrt{W \cdot h / 3600}
\]

\[
= \sqrt{71.159 / 3600}
\]

\[
= 1.77 \text{ m}^2
\]

Annotation:

BSA : Body Surface Area (m²)
W : Weight (kg)
h : Height (cm)

2. **Laju Konsumsi:** According to Tualeka (2013), the consumption rate is 0.284 kg/day.¹⁰

</tr>
</tbody>
</table>

The measurement results of the safe concentration of mercury exposure in shells in the unlicensed gold mining area in Kayeli Village, Buru Regency, Maluku Province, Indonesia was to 0.756 mg/kg, below the limit of the Indonesia National Standard of 1 mg/kg.

### D. NOAEL (No Observed Adverse Effect Level):

The purpose of researches in the field of industrial toxicology is to be able to evaluate the safety of a substance. No Observed Adverse Effect Level (NOAEL) is the highest dose without causing effects on experimental animals, which later is used to determine the safe limits of a chemical. World Health Organization (2005) stated that NOAEL from mercury is 0.23 mg/kg.¹¹

### E. Reference Dose:

Tualeka (2013) stated that the Reference Dose is calculated using the following formula.¹⁰
\[ \text{RfD} = \frac{\text{NOAEL}}{100} = \frac{0.23}{100} = 0.0023 \text{mg/kg} \]

Annotation:
- **RfD**: Reference Dose (mg/kg)
- **NOAEL**: No Observed Adverse Effect Level (mg/kg)

Using the formula above, the reference dose of mercury in the shellfish is 0.0023 mg/kg.

**F. Safe Concentration of Mercury**: The calculation of mercury concentration in the illegal gold mining area in Kayeli Village, Buru Regency, Maluku Province, Indonesia used the formula (Tualeka, 2013) as follows.\(^6\)

\[ C_{\text{safe}} = \frac{(RfD)(Wb)}{(\alpha)(R)} = \frac{(0.0023)(71)}{(81\%)(0.284)} = 0.71 \text{ mg/kg} \]

Annotation:
- **C safe**: safe concentration (mg/kg)
- **RfD**: reference dose (mg/kg)
- **\(\alpha\)**: % substance absorbed by the lung (percentage of mercury is 80%)\(^{13}\)
- **R**: consumption rate (kg/day)

Based on the above calculations, it can be seen that the safe concentration of mercury exposure to shellfish in the illegal gold mining area of Kayeli Village, Buru Regency, Maluku Province, Indonesia is 0.71 mg/kg.

**Discussion**

The measurement of mercury on concentration of *Polymesoda erosa* shells in Kayeli Village, Buru Regency, Maluku Province were carried out from three different locations of tailing discharge around the beach. Three shells were taken as the sample for each location, so the total was 9 sample shells.

The result of NOAEL calculation is 0.23 mg/kg. This result is in line with the limit value set by the World Health Organization and the Agency for Toxic Substances and Disease Registry which stated the NOAEL of mercury to be 0.23 mg/kg. Then, it can be said that the value of No Observed Adverse Effect Level (NOAEL) is safe for the community.

Reference Dose (RfD) in the illegal gold mining area of Kayeli Village, Buru Regency, Maluku Province, Indonesia was 0.0023 mg/kg/day. It is below the RfD of the Environmental Protection Agency in Broussard (2002) of 0.3 mg/kg/day.\(^6\) It can be said that the reference dose (RfD) of mercury in the illegal gold mining area in Kayeli Village, Buru Regency, Maluku Province, Indonesia is safe for the community.

The measurement result of safe concentration of mercury exposure in shellfish in the illegal gold mining area of Kayeli Village, Buru Regency, Maluku Province, Indonesia was 0.71 mg/kg. It is below the standard of regulations set by other bodies. According to the Food and Drug Administration in Broussard (2002) the safe concentration of mercury is 1 mg/kg.\(^6\) Regulation of the Head of the Republic of Indonesia Drug and Food Control Agency Number HK.00.06.1.52.4011.3 concerning Determination of the Maximum Limit of Microbial and Chemical Contaminants in Foods also mentioned that the safe limit of mercury in shellfish is 1 mg/kg.\(^12\) In addition, the Indonesian National Standard regarding the maximum limit of heavy metal contamination in food also mentioned that the safe concentration of mercury exposure to shellfish is 1 mg/kg.\(^13\) Therefore, it can be said that the safe concentration of mercury in shells in the unlicensed gold mining area in Kayeli Village, Buru Regency, Maluku Province, Indonesia is safe and can be used as a reference for the community.

**Conclusion**

The concentration of mercury in shellfish measured at 9 points in the illegal gold mining area in Kayeli Village, Buru Regency, Maluku Province, Indonesia was 0.756 mg/kg. The calculation results of safe concentration of mercury exposure to shellfish using No Observed Adverse Effect Level (NOAEL) and Dose Reference (RfD) was 0.71 mg/kg. So, it can be concluded that the safe concentration of shellfish in the illegal gold mining area in Kayeli Village, Buru Regency, Maluku Province, Indonesia is safe for the community because it is less than 1 mg/kg.
To control mercury exposure to shellfish consumed by the community in the area of gold mining without permission in Kayeli Village, Buru Regency, Maluku Province, Indonesia, some efforts can be taken. We recommend mapping the mercury-contaminated areas, providing information for public about the concentration and types of shellfish that are safe for consumption and periodic health checks from local health services.

Synapsin-I Expression in the *Rattus norvegicus* Pup’s Brain from Rat’s Maternal Death Model

Nur Maziyah Hurin’in,1 Hermanto Tri Joewono2, Widjiati3

1Postgraduate Student of Reproductive Health Science, Faculty of Medicine, 2Department of Obstetric and Gynecology, Faculty of Medicine, 3Department of Embryology, Faculty of Veterinary Medicine, Airlangga University, Surabaya, Indonesia

ABSTRACT

Maternal mortality could be a neonatal stressor that activated the HPA axis to secret glucocorticoids as a marker of stress. Brain development took place rapidly in the first 1,000 days of life. Synapsin-I was involved in the early development of the brain’s nervous system. The purpose of this study was to analyze the impact of separation of Rat’s pup and mothers as a maternal death model on the expression of synapsin-I in the cerebrum and cerebellum of 3 days old *Rattus norvegicus* pups. The control group (K1) consisted of newborn *Rattus norvegicus* which remained with the mother, while the treatment group (K2) consisted of newborn *Rattus norvegicus* which was separated from the mother. After 3 days of observation, *Rattus norvegicus* pups from each parent were taken with the heaviest, medium, and lowest weights to be sacrificed and examined by immunohistochemical of synapsin-I expression. Analysis of the Mann Whitney test for synapsin-I expression in *Rattus norvegicus* cerebrum showed a significant difference between the control group and the treatment group with a value of *p*=0.000 (*p*<0.05). Independent T test analysis of synapsin-I expression in *Rattus norvegicus* cerebellum also showed a significant difference between the control group and the treatment group with a value of *p*=0.000 (*p*<0.05). Synapsin-I expressions in the cerebrum and cerebellum of *Rattus norvegicus* pups that separated from the mothers were lower than those that not separated from the mothers.

Keywords: maternal death model, synapsin-I, cerebrum, cerebellum

Introduction

Maternal Mortality Rate (MMR) was an indicator of assessment of maternal health programs. The case of maternal mortality, also called maternal death, occurs in pregnant women on a number of certain days starting during pregnancy until after the termination of pregnancy or 42 days after delivery. This could be due to causes that were related or exacerbated by pregnancy, handling pregnancy, and/or handling labor. Accidents or incidental events were not the cause of maternal death. Many maternal deaths occur during labor and postpartum.1,2

In 1990-2015, the Maternal Mortality Rate (MMR) globally decreased by 44%, from 385 cases to 206 cases per 100,000 live birth rates. The decline was still far from the Millennium Development Goal 5 a target. This number also did not meet the objectives of the 2030 Sustainable Development Goals (SDG’S) program which targeted maternal mortality rates are 70 of 100,000 live births.3 Since 1991 to 2007, Based on the Indonesian Health Profile (2016), the number of MMR in Indonesia has decreased, from 390 to 228 from 1991 to 2007. According to the Bureau of Communication and Community Services of the Health Ministry of Republic Indonesia, the maternal mortality rate in Indonesia was 4,999 in 2015 to 4,912 in 2016 and 2017 (first semester) decreased to 1,712 cases. Based on the East Java Health Office, the maternal mortality rate in East Java Province on 2015 reached 89.6 of 100,000 live births and on 2016 it increased to 91 of 100,000 live births.

Maternal mortality at the beginning of a child’s life could result in loss of contact between mother and
baby and disruption of breastfeeding which would affect the child survival. Interaction between mother and baby could occur through touch, skin contact, and eye contact which provided a calm effect. Reduced or even lost contact between mother and baby due to maternal death could result in babies having higher cortisol levels than babies who were directly treated by their mothers. Therefore, this might be a cause of neonatal stress at the beginning of a child’s life.

Child’s brain growth and development took place quickly starting in the womb, which was on the first 1,000 days of the children life up to 3 years old. Some important developmental processes include neuron proliferation, synaptic formation, myelination, and axons and dendrites growth. A good brain development and growth would affect cognitive, social, and emotional abilities as the foundation and the development of future generations. The brain consisted of the cerebrum which plays a role in cognitive and affective functions as well and the cerebellum which played a role in motor, cognitive, emotional, and behavioral development. Synapsin-I was the main isoform in neurons which were phosphoproteins that bound to synaptic vesicles. Synapsin-I played a role in synaptogenesis and neuronal plasticity, including synapses development, terminal nerve formation, and neurotransmitter expenditure. Reduced Synapsin-I would result in disruption of axon differentiation, neurit growth, inhibition of formation and synapses, and allowed nerve disorders in the brain.

Neonatal stress could occur due to maternal death which caused the hypothalamus-pituitary-adrenal (HPA) activation to secrete glucocorticoids which were the initial sign of stress. Synapsin-I was involved in the critical development initial process of the nervous system. The stress impact on early neuronal development in the brain could reduce cognitive function with symptoms of dendritic atrophy and loss of synapses. The thought of the maternal deaths impact should not only be on ways to reduce maternal mortality. Maternal health was also an important thing to note, not just for the mother survival, but it was also important for the continuity of brain growth during the golden age in the first 1,000 days of the child’s life as a preparation to face the future changes challenges. Based on this background, this study was conducted to the impact of maternal separation as a maternal death model on the cerebrum and cerebellum synapsin-I expression of 3 days old Rattus norvegicus.

Material and Method

This study was true laboratory experimental designs with randomized post test only control group design. The study was conducted from February to May 2019 at the Laboratory of the Veterinary Medicine Faculty, Airlangga University. The samples of this study were Rattus norvegicus mother and the unit samples were 3 days old Rattus norvegicus. All animals try to be acclimatized before being pregnant. Superovulation of female rats was done by injecting 10 IU of PMSG (Folligon™, Intervet Boxmeer, Holland), 48 hours later, the injection 10 IU of HCG (Chorulon™, Intervet Boxmeer, Holland) was carried out and the mother was immediately mated monomating. 17 hours after monomating, a vaginal plug examination was performed to ensure pregnancy. Pregnant female Rat was taken randomly into 2 groups, each group consisting 18 pregnant female Rat.

The maternal mortality model study group was divided into 2 groups, the control group (K1) consisting of newborn Rattus norvegicus which remained with the mother until the 3 days old and the treatment group (K2) consisting of newborn Rattus norvegicus separated from mother to 3 days old that were given animal milk formula (Esbilac® Powder, Pet-Ag Inc, Hampshire). From each parent, Rattus norvegicus pups were taken with the heaviest, medium and lowest weights.

Imonohistochemical examination with synapsin-I antibodies was assessed semi-quantitatively on the scale of Rammelen-Stegner using the Immuno Reactive Score (IRS). Statistical analysis uses IBM SPSS Statistic 20. Data with normal distribution was tested by Independent T test. If the data was not normally distributed, the data was tested by the Mann Whitney test. This study uses a significance level of 0.05 with a confidence level of 95%.

**Discussion**

The results of this research indicate the mean expression of cerebrum and cerebellum Synapsin-I 3 days old *Rattus norvegicus* with maternal separation was lower than without maternal separation. The results of the examination used microarray analysis for stress at the beginning of life was carried out by maternal separation on day 14-21, while still providing water and feed nutrients, indicating that separation from the parent reduced synapsin-I mRNA gene expression in the Rat pup’s amygdale. Maternal separation in animals shows an increase in high expression of corticotrophin-releasing-hormone (CRH) and glucocorticoid receptors. Glucocorticoids could directly reduce the expression of synapsin-I and EGR-1 transcription in the hippocampus. The results of examination on 9-months-old babies who separated from their mothers for 30 minutes showed an increase in glucocorticoids levels compared to 30 minutes when babies interacted and played with mothers. Maternal separation increases glucocorticoids and ACTH in animals. 9 and 12-days-old rodent show high ACTH and corticosterone. Therefore, the timing and quality of interaction with mother plays a role in the development of the Axis HPA. If there was a maternal death, the contact interaction between the parent and child would be lost then causing early life stress.

The most rapid brain neuron development in the first 1,000 days of life. Synapsin-I is a protein that plays a role in synaptic transmission and plasticity in the presynaptic mechanism. The combined action of synapses that work in different areas of the brain eventually forms brain functions such as learning and memory. Synapsin-I was associated with axon growth and regulation of synaptic vesicles kinetics fusion. Both synapsin-I isoforms function in synapse formation and minimize depletion of neurotransmitters in synapse inhibition by contributing to the retention of synaptic vesicles. Synapsin-I also plays a role in synaptogenesis and modulates the release of neurotransmitters. Changes in synaptic vesicles in the presynaptic terminal could result in reduced release of neurotransmitters and delayed recovery of synaptic transmission after depletion of neurotransmitters.

Immunoreactivity examination of synapsin-I was performed as a direct marker of the synapses presence in the central nervous system. Cerebrum acted in cognitive and affective function. Synapsin-I in the cerebrum was expressed in neurophil, whereas in neurons and dendrites there was little synapsin-I expression. Cerebellum played a role in motor, cognitive, emotional, and behavioral development. In the cerebellum, synapsin-I could be expressed in the molecular layer of the cerebellum cortex, i.e. in the nucleus and cytoplasm of the granular and granular layers of the synaptic complex.

Early life stress which was induced by glucocorticoids caused a decrease in cognitive abilities, including damage to work and nonverbal memory, mental flexibility, and information processing. Symptoms included dendritic atrophy and loss of synapses in neurons. Glucocorticoids mediated cellular or molecular effects on synapses and dendrites through glucocorticoid receptor (GR) and mineralocorticoid receptor (MR). In the brain, GR which had been activated by GC could directly bound to BDNF/CREB in response to stress and would reduced BDNF expression. BDNF bound to TrkB (Tropomyosin related kinase B) in postsynaps and presynaps which caused activation involving 2 pathways, namely phospholipase (PLC)-Ca²⁺-CaMKII and Ras-Raf-MAPK for regulation of synapsin-I expression. When stress and glucocorticoid increase occured, the MAPK activation stimulated CAMKII to reduce transcription of EGR-1 and lower synapsin-I expression. Synapsin-I regulation could also pass IGF-1, IGF-1 pathway (Insulin like growth factor-1) which would bound to IGF1R and activated two signaling pathways similar to BDNF to regulate the regulation of synapsin-I expression directly. If there was an increase in GC and activation of GR, IGF-1 inhibition would resulted in a lower expression of synapsin-I.

Early life stress in the brain was also related to oxidative stress due to an imbalance between ROS and antioxidants. ROS results in GC receptor translocation from the cytoplasm to the nucleus which disrupted the receptor function. Imbalance in mitochondria produces NADPH oxidase (NOX). ROS in the brain was caused by NOX enzymes according to cellular stressors. In addition, many stress signaling pathways such as ERK1, p38 MAPK were activated following NOX stimulation which would affected cell damage which might directly result in lower synapsin-I expression. Apart from this pathway, synapsin-I expression could be directly affected by glucocorticoids via EGR-1. Decreases synapsin-I expression which included several pathways, namely EGR-1, BDNF, IGF-1, and could also be affected by oxidative stress.
Conclusion

Cerebrum and cerebellum Synapsin-I expression of 3 days old *Rattus norvegicus* with maternal separation as maternal death model was lower than 3 days old *Rattus norvegicus* without maternal separation as maternal death model.

ABSTRACT

Toluene is one of the BTX compounds with a strong and distinctive aroma. When inhaled, this can affect the nervous system and body coordination and cause headaches. At constant exposure, toluene compounds can cause more serious health risks that can cause death. This study aims to determine the safe concentration of toluene in Kebun Jeruk toll gate officers, Jakarta. The population in this study were all 20 Kebun Jeruk toll gate keepers divided into two area points of toll gate 1 and toll gate 2. This study used manually calculated quantitative data analysis through safe concentration calculation in environmental toxicology concepts. Safe concentration data in Jakarta Kebon Jeruk toll gate keepers were obtained from experimental animals’ body weight (W animals), body area (BSA animals), workers’ characteristics including body weight (W), height (h), body surface area (BSA), breathing rate (BR) and working duration (t). In addition, data on the concentration of benzene (C), animal km, human km, NOAEL and the safe dose of toxin were also used.

The concentration of toluene in air that enters the workers body through inhalation measured at two average points was 0.00125 mg/m³ (0.00033 ppm). The value obtained is still far below the toluene threshold value determined by the Minister of Manpower and Transmigration Regulation Number Per.13/Men/X/2011 of 2011. The calculated safe concentration of toluene shows a result of 0.0922 mg/m³ (0.0245 ppm) which is still in the safe category. This level must be maintained to assure its level does not increase.

Keywords: toluene, safe concentration, toll officer

Introduction

Toluene is one of the BTX compounds that has a strong and distinctive aroma. When inhaled, this can affect nervous system and body coordination and cause headaches. At constant exposure, toluene compounds can cause more serious health risks that can cause death.¹,²

Safe toluene concentration is not a reference in determining toluene threshold value that it often has an effect on workers even though the concentration is below the Threshold Limit Value. Based on the previous research, exposure of 50 ppm toluene can significantly increase lipopolisakardic (LPS-induced) induction of mouse cell proliferation (Fujimaki, 2010), decrease in antioxidant enzyme activity significantly, and increase fat peroxidation and protein damage both in vivo and in vitro (Karabulut, 2009).³ A previous study found that toluene concentrations below the NAB had an effect on workers. Thus the revision of the Threshold Limit Value is needed regarding the safe limits of toluene concentration in the work environment.

DKI Jakarta is the capital of Indonesia. The pollution level in this city is the highest among other cities in Indonesia. The Directorate of Traffic of the Metro Jaya

DOI Number: 10.5958/0976-5506.2019.02614.7
Police Sub-Directorate of Vehicle Registration and Identification noted that the number of vehicles in Jakarta reached 16 million units in 2013. Air pollutants produced by motorized vehicles include carbon monoxide (CO), methane (CH4), nitrogen oxide (NO2), sulfur dioxide (SO2), and aromatic hydrocarbon compounds such as BTX (benzene, toluene, and xylene).4

Risk analysis research of Toluene on human activities have been mostly carried out at gas stations (Tunsaringkarn, 2012) and in urban areas (Singh, 2012).5 The researches were mostly carried out for researchers aimed to examine effects of toluene chemicals in humans’ health through inhalation. The level of pollution on highways, especially in big city toll roads such as in Jakarta and the length of exposure experienced by toll road officers makes the toll road officers have a greater risk of exposure to chemicals, especially toluene. In Eko Handoyo’s (2015) study, the results of measurements of toluene concentrations at toll gate 1 and 2 of Kebun Jeruk Jakarta were 0.00121 mg/m³ and 0.00128 mg/m³, respectively.6 The study was conducted on 20 toll gate guards. In the previous research, the researchers did not calculate the safe concentration of toluene.

This study aims to determine the toluene threshold value – initiated by the determination of NOAEL toluene in white rats and RfC. Calculation of safe concentration is important to ensure the health of workers.7 The present research is beneficial as a reference in determining the toluene safe (NAB) limit in the work environment in Indonesia and the improvement of existing Threshold Value. Safe concentration was calculated using the Reference Concentration (RfC) formula with No Observed Adverse Effect Level (NOAEL) which is adjusted to the research data.

**Material and Method**

This study aims to determine the safe concentration of air toluene chemicals in the work area of Kebun Jeruk toll gate officers, Jakarta. The approach used was a cross sectional approach with observational descriptive research. The population in this study were 20 respondents. Population determination was carried out through total population of Kebun Jeruk toll officers, Jakarta.

The study was conducted in May 2019, initiated with the study of literature on the analysis of toxicological health risks which included calculation of intake, type of risk and value of dose response. Furthermore, secondary data from the literature study of the previous research was conducted to obtain anthropometric data of the officers of Kebun Jeruk toll gate, Jakarta. Data of supporting research was also taken which included the types of chemicals, the weight of the experimental animals, and the results of measurements of benzene in the air obtained through measurements of NIOSH 1501 (NIOSH, 2003) with activated carbon adsorbing pipes using the gas Chromatography (GC) technique.

The variables used in this study include the characteristics of the experimental animals in the form of weight and surface area of the experimental animals (BSA experimental animals), worker characteristics including weight (W), body surface area (BSA), and worker breathing rate (BR). In addition, toluene concentration in the workplace was also obtained from previous research literature studies. Furthermore, variables were processed by calculating factor Km in animals (Human Km), No Observed Adverse Effect Level, RfC benzene in workers and calculation of safe concentration on workers is carried out.

**Result**

**A. Characteristics and Surface Area of Experimental Animal Bodies:** Toxicity testing of compounds requires animal testing as support. This is because animal response to a toxic substance resembles a human response. The experimental animals used in this study were white mice (*Rattus norvegicus*).8

</tbody>
</table>

Where:

BSA : Body Surface Area (m²)
W : Weight (kg)

Body Surface Area on experimental animal was 0,024165 m².
B. Characteristics, Body Surface Area, and Worker’s Respiratory Rate: The characteristics of workers in this study include body weight, height and length of exposure in working hours per day. The total working population is 20 workers with an average body weight of 67.9 kg and height of 159 cm according to the average height of Indonesian adults. The duration of exposure is 8 hours per day according to the working hours of toll gate keepers. The body surface area and the respiratory rate of workers were calculated using the following formula.

1. Body surface area (BSA): The body surface area of workers was calculated by using the following formula

$$BSA = \sqrt{\frac{W \cdot h}{3600}}$$

Where

- $BSA$ : Body Surface Area (m$^2$)
- $W$ : Weight (kg)
- $h$ : height (cm)

$$BSA = \sqrt{\frac{67.9 \cdot 159}{3600}} = 1.73 \text{ m}^2$$

2. Breathing Rate: The breathing rate of workers is calculated using the following formula

$$BR = 5.3 \ln W - 6.9/24$$

where

- $BR$ : Breathing Rate
- $W$ : Weight (kg)

$$BR = 5.3 \ln 67.9 - 6.9/24 = 0.64 \text{ m}^3/\text{hour}$$

C. Toluene Concentration: Measurement of toluene concentration is carried out in two points, i.e. toll gate 1 and toll gate 2 Kebon Jeruk Jakarta. The average concentration was 0.00125 mg/m$^3$ (0.00033 ppm).

Based on the measurements carried out, the highest toluene concentration at toll gate 2 was 0.00128 mg/m$^3$ (0.00034 ppm) while the lowest was at toll gate 1 at 0.00121 mg/m$^3$ (0.00032 ppm). The toluene concentration value is still far below the threshold value set by the Minister of Manpower and Transmigration Regulation Number Per.13/MEN/X/2011 in 2011 concerning the threshold value of physical and chemical factors in the workplace of 188 mg/m$^3$.

D. Animal Km and Human Km: Determination of safe limits for toxic doses on Kebon Jeruk Jakarta toll door officers began with the calculation of Animal Km and Human Km.

1. Animal Km

$$\text{Animal Km} = \frac{W_{\text{animal}}}{BSA_{\text{animal}}}$$

where:

- $W_{\text{animal}}$ : Km factor on animal
- $BSA_{\text{animal}}$ : Body Surface Area (m$^2$)

Based on the Animal Km calculation, the Animal Km distribution is as follows.

Table 3: Calculation result of Animal Km on White Mice

The average calculation results of Human Km on Kebun Jeruk toll gate keepers is 39.42

E. No Observed Adverse Effect Level (NOAEL):
To determine the safe limit of the concentration or dose of a chemical for human safety, the No Observed Adverse Effect Level (NOAEL) toxicity test was carried out. This is the determination of the highest dose of toxin without causing effects on experimental animals.

Schäper et al. 2003, 2004, 2008; Seeber et al. 2004, 2005; Zupanic et al. 2002 states that the No Observed Adverse Effect Level (NOAEL) toluene calculation is 3.8 mg/m³ (0.0281 mg/kg). The calculation of NOAEL in the present study can be obtained using the following formula.

NOAEL toluene = 3.8 mg/m³

NOAEL toluene = \[ \frac{3.8 \times 0.0013 \times 8}{0.1405} = 0.0281 \text{ mg/kg} \]

F. Inhalation Reference Concentration (RfC):
Shaw et al. (2007) in Saridewi and Tualeka’s study (2017) states that the calculation of the reference concentration on workers or the Inhalation Reference Concentration (RfC) can use the following formula:

\[
\text{RfC} = \frac{\text{NOAEL}}{\text{Animal KM \over Human KM}}
\]

Where

RfC : Inhalation Reference Concentration
NOAEL : No Observed Adverse Effect Level
Animal Km : Factor Km on experimental animal
Human Km : Factor Km on human

The calculation of RfC for Kebon Jeruk toll gate keepers in Jakarta is as follows:

\[
\text{RfC} = \frac{\text{NOAEL}}{\text{Animal KM \over Human KM}}
\]

\[
\text{RfC} = 0.0281 \frac{5.82}{39.24} = 0.00417 \text{ mg/kg}
\]

Based on the above calculation, the reference concentration or RfC in the Kebun Jeruk Jakarta toll gate officer is 0.00417 mg/kg.

G. Toluene Safe Concentration: In a study conducted by Saridewi and Tualeka (2017), the calculation of safe (C safe) concentration is calculated using a formula obtained from William (1985), Davis (1991) and Soemirat (2003). The value of Inhalation Reference Concentration (RfC), No Observed Adverse Effect Level (NOAEL), average duration of work, average body weight and breathing rate of workers were calculated by the following formula:

\[
\text{C safe} = \frac{\text{RfC} \times W}{a \times BR \times T} \text{ mg/m}^3
\]

Where.

C safe : The safe concentration of ctoxin in the air to workers (mg/m³ or ppm)
RfC : Inhalation Reference Concentration (mg/kg)
W : Workers’ weight (kg)
a : Percentage of substances absorbed by workers’ lungs (%)
BR : Breathing Rate (m³/jam)
T : Time (hour)

Calculation of toluene safe C for Kebun Jeruk toll officers is calculated by the following formula.

\[
\text{C safe (mg/m}^3) = \frac{\text{RfC} \times W}{a \times BR \times T} \text{ mg/m}^3
\]

\[
\text{C safe (mg/m}^3) = \frac{0.0281 \times 67.9}{5.82 \times 0.64 \times 8} = 0.283143 \text{ mg/m}^3
\]

\[
\text{C safe (mg/m}^3) = 0.0922 \text{ mg/m}^3
\]

Concentration (ppm) = \[ \frac{\text{C \times 24.45}}{\text{W Molekul}} \]

\[
\text{Concentration (ppm)} = \frac{0.0922 \times 24.45}{92.14} = 0.0245 \text{ ppm}
\]
Discussion

The toluene concentration at Kebon Jeruk toll gate is divided into 2 points, i.e. toll gate 1 at 0.00121 mg/m³ and toll gate point 2 at 0.00128 mg/m³. According to the Minister of Manpower and Transmigration Regulation Number Per.13/Men/X/2011 of 2011 concerning the Threshold Value of Physical Factors and Chemical Factors at Work, Threshold value of toluene concentration is 188 mg/m³. This shows that toluene concentration at Jakarta Kebon Jeruk toll gate is still far below the Threshold Value. Calculation of safe concentration at the Kebon Jeruk Jakarta toll gate is based on the calculation of Reference Concentration (RfC), and No Observed Adverse Effect Level (NOAEL). Test of experimental animals is used to calculate No Observed Adverse Level (NOAEL) or the highest dose of toxin without causing an effect. The No Observed Adverse Effect Level (NOAEL) is 0.0281 mg/kg. According to the Agency of Toxic and Substances, the NOAEL for exposure through inhalation is 3 ppm. Therefore, the value of toluene NOAEL is safe for workers.

Reference Concentration (RfC) of toluene through inhalation can be calculated through NOAEL, Animal Km, and Human Km values. The calculation results of Reference Concentration (RfC) value through inhalation on Kebon Jeruk toll gate keepers is 0.00417 mg/kg. Toluene Reference Concentration (RfC) value limit through inhalation based on U.S Environmental Protection Agency National Center for Environmental Assessment (2003) is 0.03 mg/m³. This shows that the value of RfC for Kebon Jeruk toll keepers is lower than that of Integrated Risk Information System Chemical Assessment Summary (2003).

The toluene safe concentration of officers of the Kebon Jeruk toll is to 0.0922 mg/m³ (0.0245 ppm). According to Minister of Manpower and Transmigration Regulation No. Per.13/Men/X/2011 of 2011 concerning the Threshold Value of Physical Factors and Chemical Factors in the Workplace, NAB from toluene concentration is 188 mg/m³. This shows that safe concentration is still below the NAB and is safe. In conclusion, the value of toluene safe concentration in Jakarta Kebun Jeruk toll gate keepers is considered safe and can be maintained.

Conclusion

Measurement of toluene concentration entering the body through inhalation at toll gate keepers at Kebun Jeruk is 0.00125 mg/m³ (0.00033 ppm). This level is safe and far from the Threshold Value set by the Minister of Manpower and Transmigration Regulation Number Per.13/Men/X/2011 in 2011 by 188 mg/m³.

The safe concentration of toluene of workers is 0.0922 mg/m³ (0.0245 ppm), meaning that air condition of Kebon Jeruk Jakarta toll gate is in a safe category. This condition must be maintained that the level of toluene in the air around the workplace does not increase. The control effort that must be carried out in addition to maintaining the environment is by using Personal Protective Equipment (PPE) on toll gate keepers that workers are not directly exposed to hazardous toluene substances.

The Effect of Fermentation of Oyster Mushrooms on Millet Grain of Healthy Japanese Quail Diets on Some Productive and Physiological Traits

Ola H. Abdul Ameer¹, Yasser J. Jameel², Mahdi A. Ali²
¹Al-Zahrawi University College, ²Faculty of Veterinary Medicine, University of Karbala

ABSTRACT

The study was included two experiments. The first experiment is a laboratory stage of oyster mushroom pleurotus ostreatus was cultured on millet seeds. The analysis of the chemical components of the fermented millet grains showed an increase in the ratio of %CP, %fat and %Ash. While a ratio of fiber and carbohydrates were decreased. This experiment was carried out in the poultry farm of the Department of Animal Production/ Faculty of Agriculture/University of Kufa for the period from 13/11 to 25/12/2017. A 240 unsexed Japanese quail chicks were used; them raised in cages and subjected to the experiment treatments from age of 7 days to age of 42 days. Chicks were divided into five experimental treatments to is standard feed (control treatment). While T1, T2, T3 and T4 are feed contained mushroom fermented millet at percentage of 25, 50, 75 and 100%.

The results showed that the addition of fermented millet of P. ostreatus to the diet significantly or morally improved the percentage of percentage dissolution and internal organs consumed and the relative weight of the main and secondary carcass characteristics of all the treatments compared with the control treatment.

Keywords: Japanese quail, oyster mushrooms, millet.

Introduction

The quail of fast-flying birds is used as a test animal and as a result of improving its productivity through the use of modern methods of breeding, it occupies a good position in some countries of the world as well as other poultry species, especially chickens, as a source of meat and eggs. The wild quail lives in different regions of the world and there are many species. The most important of these is the Japanese quail. The Japanese quail is the smallest species of domestic poultry used in biological and genetic studies because of its small body size and resistance to diseases and rapid growth and handling easily and the possibility of using a large number of birds in a limited area. The female body is larger than males, unlike the other domestic birds. Male males weigh between 100 to 140 g, while adult females weigh 120 to 160 g for female body weight gain at 21, 28, 35 and 42 days compared to males. There was a significant increase in the percentage of the decay with the progress of life, noting that the proportion of The result was 69.84% for the European quail and 70.38% for the Japanese quail. The sex had a significant effect on the weight of the liver, noting that there was a significant increase in the liver in females compared with males. The aim was to improve the productive performance of poultry and raise their efficiency in the conversion of feed to meat and eggs, including the use of plants that contain effective compounds in their nutrition because of the effective compounds that improve the quality and productive qualities such as mushrooms. The fungus (pleurotus ostreatus) is more cultured than any other type of fungus. Mushroom is particularly important because of its high nutritional value and the medicinal properties of its compounds. As well as rich in vitamin B and C and oyster mushroom can grow at temperatures of 20-30 °C and humidity 50-70%. Millet is also considered one of the cereal crops used as concentrated feed stocks for poultry and waterfowl for its high nutritional value compared to barley and maize in its energy level, as well as the shortening of the plant’s
maturity\(^{11}\). In addition, millet grains are higher in protein content compared to other grains\(^{12}\).

### Materials and Method

The millet was obtained from the local markets. It was moistened with water up to 60\%. It was then filled in transparent plastic bags. 1 kg of millet was placed in each bag. The fungal vaccine was added by 5\%. The incubation bags were transferred to the incubation room. This room is equipped with a Split heating and cooling unit in the Plant Protection Department, Faculty of Agriculture, University of Kufa. The temperature was set at 25 ± 2 °C. The fungus was left to grow on the millet for 28 days. Complete the growth of the fungus on it was dried and mixed well and grinded using an electric mill and spread on a dry and clean ground for 24 hours with flipping between one time and another and use in the bush at 25\%, 50\%, 75\% and 100\%. This experiment was conducted in the field of the Animal Production Department, Faculty of Agriculture - University of Kufa for the period from 13 November 2017 to 25/in 2017, using 240 Japanese quail chickens brought from the Abu Ghraib Agricultural Research Center and raised in laboratory-sized cages of 60 x 70 x 60 cm with a plastic feeder.

* According to recommendations [13]

The dietary conversion factor was calculated each week as indicated by\(^{14}\) using the following equation:

\[
\text{Food conversion coefficient} = \frac{\text{quantity of feed consumed during week}}{\text{weekly increase}}.
\]

Hemocytometer is used to count red blood cells. This method is a special glass slide for counting purposes after dilution with dilute solution\(^{15}\).

The percentage of the size of the blood cells was measured using a capillary tube containing a coagulation block, which was filled with blood to about one-third, then the tube was closed with artificial clay and the tubes were placed horizontally in the centrifuge for 15 minutes. The size of the blood cells was measured using a special ruler\(^{17}\). Authors contribution, both of Ola H. Abdul Ameer and Mahdi A. Ali are responsible for animal work and samples collection. Yasser J. Jameel is responsible for data analysis, writing correction and proof reading.

The data was statistically analyzed according to complete randomized desing to study the effect of different parameters in the studied traits and compared the averages using the test and the SAS statistical program using the following mathematical model\(^{18}\).

\[
\text{Yij} = \mu + \text{Ti} + \epsilon_{ij}
\]

where: \(\text{Yij} = \text{View value in transaction.} \ \mu = \text{the general mean of the studied character.} \ \text{Ti} = \text{transaction effect.} \ \epsilon_{ij} = \text{The experimental error effect of the transaction.}\)

### Results and Discussion

The results of the statistical analysis showed that there were no significant differences between the second, third, and fifth week, while there were significant differences at (P <0.01) for the fourth week between the coefficients and the control treatment, but they were not significantly different from each other. Food conversion coefficient 4.73, 3.13, 2.90, 2.76 and 2.80 g feed/g respectively, respectively. There were also significant differences (P <0.05) between the third treatment and the rest of the treatments for the sixth week with values 4.76,
4.66, 4.30, 4.73 and 4.53 g/fed respectively. There were also significant differences between the coefficients and the control treatment for the cumulative food conversion coefficient. The values were 3.4, 3.03, 2.93, 3.00 and 2.9, respectively, but the first, second, third, and fourth transactions did not differ significantly. Overall, the results showed that the cumulative food conversion coefficient in the cumulative values improved significantly numerically in favor of all the treatments compared with the control treatment. These results were consistent with the indicated, noting significant differences in the use of A. Niger fermented soybean powder by 0.5%. Moral improvement in the food conversion coefficient was due to the higher rate of increase of the experimental chicks relative to the control treatment. The improvement of the food conversion factor was due to the increase in the number of beneficial bacteria that act as the Probiotic, which in turn promotes the health of the birds. But did not agree with the results of the results, noting that there were no significant differences between the coefficients in the feed conversion coefficient when adding S. cerevisiae yeast to the paste of date nuclei and use in broiler diets.

Table 3 indicates that there were no significant differences in the number of red blood cells and the number of white blood cells. The values of the parameters were 4.40, 4.34, 4.46, 4.50 and 4.53 (million cells/mm³) 24.23, 24.3, 24.36, 24.33, and 24.33 (1000 cells/mm³), respectively. For PCV, the statistical analysis showed significant differences (P <0.05) for the second, third, and fourth treatment compared with control treatment. The first treatment did not differ significantly from the control treatment. This is due to the secretions and leachates of this fungus may increase the readiness of important elements, especially in the form of blood such as iron, rare metal elements, and some vitamins. The effect of fermented millet in the concentration of hemoglobin indicates significant differences (P <0.05) for all the first, second, third and fourth experiment coefficients compared with control treatment, with values 13.4, 13.50, 13.73, 13.70 and 13.73 (g/mm³) Take over. These results corresponded to the results obtained by the addition of the Aspergillus niger and Taraxacum officinale, as they showed a significant improvement in the volume of blood cells attached to the chicks. However, these results did not correspond with when fermented wheat bran was added to SC as they observed a significant reduction in the size of the blood cells and a decrease in hemoglobin concentration. There were no significant differences between the hemoglobin concentrations.

The characteristic content of folic acid (Folic acid) may be a catalyst for increasing the number of red blood cells (RBC) for the addition of oyster mushrooms to the diet. The increase in the number of red blood cells has led to an increase in the volume of blood cells (PCV) because there is a positive correlation between them. Table 3: Effect of fermented millet with oyster mushrooms (P.ostreatus) on blood cell characteristics (mean ± standard error)

ABSTRACT

The impact of acylation, esterification, and deamidations on foaming, solubility, and emulsifying traits of camel milk caseins were studied. At pH above than 8, a solubility of control, acylated and deamided camel milk caseins were high. The solubility of esterified camel caseins was different. The solubility was high in acidic pH values and decreased with the increment of pH. Compared with control camel milk caseins, acylated and deamided camel milk caseins solutions produced more foam immediately after sparging, while esterification did not improve foaming properties of caseins. The highest EAI for control camel milk caseins was at pH 3, while the highest EAI for acylated camel milk caseins was at pH 4-5. Modification of camel milk caseins with esterification and deamination changed the highest EAI to 8 and 9 respectively.

Keywords: Acylation, Esterification, Deamidation, Camel Milk, Caseins

Introduction

The contents of Camel milk was 4.40% lactose, 3.50% fat, 3.40% protein, 0.79% ash, and 87.0% water. Milk proteins have high nutritional value, high sensory characteristics, and excellent surface properties [1]. Whey proteins and caseins were considered the main classes of milk proteins. Caseins was phosphoproteins condensed from raw milk and at 20°C and pH 4.6. They included around 80.0% of the whole proteid content in cow’s milk. Within caseins the fourth parts κ – CN, β – CN, αs 1 – CN and α2 – CN were distinguished based on the homology of the main composition. Casein was precipitated easily from milk mostly by renneting or at low pH 4.6 at 20 °C. Caseins content in the cow’s milk was almost 80.0% of the proteins. It was around 26.0 g/litre of milk. Casein was divided into 4 small content αs1-, αs2-, β-, and κ-casein [2].

The κ – casein, β – casein, α1 – casein and α2 – casein vary in the sequence, and number of amino acids. They contained 199.0, 207.0, 209.0, and 169.0 of amino acids, respectively. The αs and β- caseins are extensively phosphorylated and lack to organize secondary structure due to their high proline contents. Hence these proteins are capable of binding high values of calcium ions, which can drive to their precipitations [2]. The average whey and casein protein content in milk of camel changes from 0-7 and 1-0% and 2-3 and 1-9%, respectively. The amounts of casein N, wheys protein N, and noon-protein N (NPN) were stated as a ratio of the whole milk protein N. It was located in the ranges 71.0-76.0 %, 17.0-23.0 % and 5.0-8.0-4.0-6.0%, respectively. The food proteins resulted from chemical derivations were commonly used to increase the utilitarian characteristics and nutritional.

The reaction of the chemical which takes place on the groups of amino can be decreased the positive charge of a protein. It was as a result from substituting the positive charged of amino groups by negatively charged or neutral ones. Thus, a lower pl of the protein was achieved. Deamination was represented as a chemical reactions in which an amide utilitarian groups in the side chain of the amino acids asparagine or glutamine was removed or changed to aspartic acid and glutamic acid respectively. Reactions like esterification in which negatively credited carboxyl group of protein were stopped transfer the pl of protein across the alkaline region[3].

The aim of this paper for examining the influence of acylation, esterification and deamidation on functionalities characteristics of camel milk casein.

Material and Method

Camel Milks Source: Milk was collected from thirteen animals from Al-Najef desert -Iraq. Bulk camel were skimmed by centrifugation on 2400 g for 15 min at 4°C.

Preparation of camel milk casein: The skim milk of camel were acidified to pH 4.6 with HCL 1M through constant stirring at the heating degree 20ºC. The mix were re-solubilized and dried by the freeze-dried process was repeated again. Also, the resulting caseinate of NaOH until the pH attained 6.80. The precipitation was postponed in the cold methanol to provide a 1.0 % esters of camel milk casein were used. Camel acid casein was modified the procedure for esters of camel milk casein were used. Camel acid casein was used. 10% suspension of casein into distilled water was instant and, the pH was modified 8.5, utilising a 2 M sodium hydroxide. Acetic anhydride (0.9 g/mL protein) was combined to the solution and the pH were kept at 8.5 for 60 minutes. Acetylated casein solution was dialyzed versus distilled water for 24h, and freeze-dried.

Modification of camel casein

Acetylation: [5] the methods for the acetylation of camel milk casein was used. 10% suspension of casein into distilled water was instant and, the pH was modified 8.5, utilising a 2 M sodium hydroxide. Acetic anhydride (0.9 g/mL protein) was combined to the solution and the pH were kept at 8.5 for 60 minutes. Acetylated casein solution was dialyzed versus distilled water for 24h, and freeze-dried.

Esterification: [6] it was modified the procedure for esters of camel milk casein were used. Camel acid casein was postponed in the cold methanol to provide a 1.0 % suspension. However, the suspension of protein-alcohol was whiskered, then concentrated HCl was gently added to create the suspension 0.070 M into HCl. The mix was whiskered on the heat degree of 4.0 ºC for 24 hours. Then, the mixture was dialyzed using cold deionized water with ratio of 1:1. Also, it was dialyzed against 0.0010 M of HCl and freeze-dried.

Deamidation: Deamination of the camel casein was achieved following a modified version method which was defined by [7]. It was prepared 0.50 N of a dispersion casein with HCl ratio of 1:20. It was hydrolysed by heating process at the degree of 70 ºC for two hours using a water bath method. The cooling specimen rapidly in an ice was used to terminate the reaction. Also, it was adjusted a pH value to reach pH 4.6 then centrifuging on 3000.0g for 15.0 minutes. The pellet was neutralized (pH 6.7–7) with (1 N) of NaOH then freeze-dried.

Electrophoresis: Electrophoresis in decreasing conditions for samples were done using [8].

Functional properties of protein camel milk

Solubility: Stock solutions of 0.10% from 0.150 M NaCl and pH 7.0 of casein were modified to the suitable pH values ranged between 3.0 – 10.0 using 0.1 N of NaOH or 0.10 N of HCl. Then, centrifuging on 12000 g to 15.0 min on 25°C. The absorbance at 280.0 nm was specified the concentration protein of the conducting supernatant. Solubility were stated as the percentage of protein in solution. Minimum of three runs were used to measure the means [4].

Foaming: Foaming properties of casein were investigated and studied consuming the gas-sparging method which was proposed by [9]. Fifteen millilitres of specimens were put in the column size of 1.6 cm ×70 cm and it had 0.1% of 0.15 M from NaCl with equaled seven pH 7. In the flow rate 30.0 ml/min, Nitrogen gas were sparged from the bottom of the column for 2.0 minutes. The height of foam was calculated directly after stopping the flow of gas. Three observations were made of each sample.

The activity emulsifying: The method was defined the activity of emulsifying. The emulsion was triplicated for each specimen which contained as follow: (a) 0.10% in 0.150 M from NaCl and (b) modified pH to be in the range from 3.00 to 10.00 using (0.1 N) HCl or (0.1 N) NaOH[11]. It were arranged by utilizing 0.6 mL of corn oil and 10.0 mL of specimen. The emulsion preparation was finalized by mixing these constituents to 1.0 min at the temperature room using blinder. The emulsion process was as below:

1. “A 0.20-mL aliquot of emulsion was diluted using the ratio of 1/250 of the final dilution by applying 0.10% of sodium dodecyl sulphate (SDS) solution.

2. The emulsions turbidity were recognized spectrophotometrically to 500 nm.

3. The action or the activity of emulsion index (EAI) can measure the interface stabilized area for each unit weight of protein (m²/g). It was measured utilizing the equation as below:

$$EAI = \frac{(2.303)(2)(A_{500}(\text{dilution factor}))}{(c)(1\text{-oil volume})(10000)}$$

Where $A_{500}$ refers to the absorbance at 500 nm. Dilution factor is equal 250.0 and c equals g protein/mL of aqueous solution before the process of emulsion. The results were considered the means of three runs [9].
Results and Discussion

Effect of chemical modification on SDS-PAGE of camel milk caseins: Electrophoretic patterns of acylated, esterificated, deamidated and control camel milk caseins are presented in figure 1. The three main caseins of camel milk, α_s-CN, β-CN and κ-CN are shown as major dark-staining components in the control gel(1).

These components did not change substantially upon treatment with esterification acylation, and deamidation but the density of bands was changed. The higher change in bands density was noticed upon treatment with deamidation followed by esterification, while treatment with acylation cause less decrease in bands density.

Deamidated and esterified samples bands were faint. However, in SDS-PAGE, there were no evident molecular mass changes between modified samples and native protein. This is as a result of replacing ammonium cations by neutral acetyl groups through acetylation action, whereas esterification was converted carboxylic acid groups to ester derivative.

Solubility of camel milk caseins: The characteristics of solubility can be served as an index for optimizing the influences of adjustments on proteins. Also, it was indicated the possible disadvantages and advantages of utilizing the protein in question in specific foods. Moreover, assess the significance of free amino and, carboxyl groups in the solubility of camel milk caseins, acylation, esterification and deamidation were conducted for caseins.

At pH values higher than 8, the solubility of control, acylated and deamidated camel milk caseins was high refer to (Figure 2). A maximum protein solubility was observed on high pH values because in this condition, the protein’s positive and negative net charged molecules interact more with water[12]. At pH values lower than 5 the solubility of control camel milk caseins was higher than the solubility of acylated and deamidated camel milk caseins and this can be related to the fact that at low pH value the amino groups in proteins play the major role in their solubility and since that the modification in the case of acylated and deamidated targeted the amino groups in proteins the solubility became less [12]. In pH values between 5-to-7 the solubility of deamidated casein was the highest. This result was related to the fact which deamidation induced casein micelles dissociation that caused by increasing in the electrostatic repulsions between caseins and also it was due to breaking of salt bridges[13]. Also, figure 2 shown the solubility of esterified camel caseins was different. The solubility was high in acidic pH values and decreased with the increment of pH until it reached to 29% at pH 10 and this can explained by the role of esterification in modification of carboxyl group responsible of protein solubility at high pH values. The negative charges of carboxylate moieties in proteins during the Esterification can be neutralized by addition ester groups. The alcoholic groups can be attacked nucleophilic to the free carboxyl groups of a protein persuades significant changes in the net charge of protein. Thus, in its conformation, and hence in its functional characteristics[3].
lamellar phase. As a result of its large interfacial area of liquid-gas, the producing foam was required energy and it was essentially unstable \cite{14}. The foam was generally air and was categorized by low density, high surface area, high viscosity, and high surface energy. Compared with control camel milk caseins, acylated and deamided camel milk caseins solutions created more foam directly after sparging; see figure 3, while esterification did not improve foaming properties of caseins.

Control and esterified camel milk caseins foam volume immediately after sparging was 0.5 mL, while this volume increased to 5.5 and 5 mL after deamidation and acylation, respectively.

This variance may also be correlated to the chemical modification treatments, which changed hydrophobicity surface of proteins \cite{15}. Deamidation was induced dissociation of casein micelles as a result of increasing in the repulsions of electrostatic between caseins and breaking salt bridges. The analysis of observations size particles through transmission of electron microscopy approved that the de-structuration of casein micelles through viewing small size of the particles in highly deamidated of camel milk skim \cite{13}. A result of these physico-chemical changes, the improvement deamidation foaming properties of camel milk caseins was achieved.

Figure 3: Foam volume (mL) of 0.1% control, esterified, acylated and deamided camel milk caseins in 0.15 M NaCl

This result have a good agreement with the results of \cite{14}, who noticed that acylation developed the water-holding, oil-holding, and foam properties of glandless cottonseed flour.

Camel milk caseins emulsion activity: The characteristics of emulsification rely on the protein ability to spread to the interface of the water-oil, orient, and unfold in the fashion which the hydrophobic sets assistant by the oil. However, groups of hydrophilic were associated with the phase of water\cite{17}. Caseins readily form stable protein films and are used extensively in the food industry, particularly in frozen desserts, baked products, and meat emulsions. Caseins, because of their flexible structure and many hydrophobic and hydrophilic regions, spread out on the phase interface and interact with all phases to form stable film. Removal of some or most of the negatively and positive charges from casein by chemical modification alters its net protein charge and changes the flexibility of the modified protein structure. Therefore, the ability of a modified casein to form stable protein films in an emulsion or foam is a very important functional consideration\cite{17}.

The impact of pH in the (EAI) of camel milk caseins presents in figure 4. The highest EAI for control camel milk caseins was at pH 3.0, while the highest EAI for acylated camel milk caseins was at pH 4-5. Modification of camel milk caseins with esterification and deamination changed the highest EAI to 8.0 and 9.0 respectively. The enhanced emulsifying properties of modified camel milk caseins at different pH values can be indorsed to the modification process applied to produce it. It was resulted that, the previously hidden exposure of hydrophobic fields on the protein backbone\cite{18,19}.

Figure 4: pH effect on the (EAI) of 0.1% control (■), esterified (■), acylated (■) and deamided (■) camel milk caseins in 0.15 M NaCl

Conflict of Interest: None of the authors have any conflicts of interest to declare.

Source of Funding: The research was performed independently, there is no funding, influence over study design, analyses, manuscript preparation, or scientific publication.
Ethical Clearance: The project was approved by the local ethical committee in Al-Qasim Green University.

Implementation Program of Child Under 5 Years’ Growth and Development Problems in Bangkalan, Madura

Qurnia Andayani¹, Toetik Koesbardiati², Windhu Purnomo³

¹Doctoral Student of Public Health, Faculty of Public Health, ²Lecturer of Social Science and Political Science Faculty, ³Lecturer of Public Health Faculty, Universitas Airlangga, Surabaya, Indonesia

ABSTRACT

There are high cases of child growth and development problems (CGDPs) and Bangkalan Regency as the highest rate of severe wasting and high stunted cases from Indonesian health survey in East Java Province (2013), but CGDPs early detection and intervention coverage are very low even though there are few programmes that have been made to tackle it. It’s aimed to assess the implementation of CGDPs programs to overcome it. This qualitative study is conducted with informants that’s consisted of head of health care, child nutrition coordinators and child growth development coordinators in each level (Regency and Subregency), Child growth development nurse in Hospital, 3 Midwives in village maternal health center, 3 Posyandu cadre and 25 mothers of child under 5 years. Data were collected by observation, in-depth interview and validated by the triangulation method. The result shows that there are prohibitions from all community-based program such as low participation of the community, lack competency of midwives to do early detection of CGDPs, lack participation of cadre. Besides that, if health provider finally tracks cases, unfortunately almost half of the mothers refuse to be referred. It’s happened because they feel ashamed of that condition and accepted it as a natural process. In the other side, there is no integrated CGDPs referred system means there is no strong commitment and coordination among stakeholders. There is a need for collaboration between practitioners and academic also multisectoral support for program planning until evaluation.

Keywords: child, child growth and development, intervention program

Introduction

The first years of life is an important period for the basis of further child growth and development. It is an important stage because there are many aspects that are growing rapidly and it’s the milestone of individual behavior¹. The age of the first 5 years is very sensitive to the environment and lasts so short, so that, it is called a critical period that wouldn’t happen again². Because of that, early detection for child growth and development problems (CGDPs) is a must for every child based on Indonesia Health Role Number 25 the Year 2014 section 21 point j and become the responsibility of government and community³.

CGDPs is a condition of a child under five years with malnutrition and developmental delay. It’s a source to the increasing of child morbidity and mortality rates, beside that it also gives impact for the quality of future generation.

In 2013, Bangkalan is a regency of the highest rate for severe wasting and the 8th highest stunting rate in East Java Province - Indonesia⁴. Growth delay such as severe wasting and stunted conditions have significance influence on development delay⁵. So, growth delay can be a warning to global growth and development delay.

Source Nutrition section 2012-2016⁶,⁷,⁸,⁹,¹⁰

Graph 1: The Coverage of Exclusive Breastfeeding in Bangkalan Regency
Graph 1 showed that there is low coverage of exclusive breastfeeding. The conventional nurturing belief about colostrum as bad milk that isn’t needed by baby still become one of breastfeeding practice in Bangkalan, the other things are babyborn feeding by honey, soft banana, young coconut, and many others.

Material and Method

A qualitative study conducted in Bangkalan Regency, Madura Island, East Java Province, Indonesia. The informants were consisted of head of PHC, nutrition coordinator and child growth development coordinator in each level (Regency and Subregency), Child growth development nurse in Hospital, 3 Midwives in Polindes (village maternal health center), 3 Posyandu cadre and 25 mothers of child under 5 years use list of question sheet.

Data collection technique of this study was aimed to collect primary and secondary data. Primary data were collected through in-depth interview uses the guideline to all informants. Bernard states there are four steps in the preparation of field notes. 1) Small notes or field jotting in a small notepad, 2) Diary recording, 3) Log for reference daily research activities, 4) The notes through descriptive recording through the recording obtained by researchers in the field. Secondary data were collected from Bangkalan health office profile, PHC profile, medical record, hospital and posyandu documents, then it’s triangulated.

Problem priority determination using Hanlon method, there are 4 criteria:
1. Magnitude of problem
2. Gravity or seriousness of problem
3. Ease of overcoming the problem
4. PEARL (appropriateness, economic feasibility, acceptability, availability, legality)

Findings

Bangkalan is one of four regencies for 1260.14 km² in Madura island where is lived Madura tribe as the majority. In terms of geographic location, Bangkalan Regency located on Madura Island, or to be exact is located on the west of Madura Island and the nearest regency to reach Surabaya as Metropolitan city that is connected by Suramadu bridge. In contrast, Bangkalan is still underdevelop regency based on Ministry of Village, Development, Transmigration publication Year 2016. Bangkalan Regency has few healthy facilities that still can’t fulfill all of the people need.

Source: Bangkalan Health Office, 2016

Table 1 showed that the health facility quantity still couldn’t fulfill all the need of Bangkalan residents.

There are 876 midwives, 618 nurses, 11 nutritionists, 9 sanitarians, 12 pharmacists, 4 public health specialists, 49 doctors, 16 specialists. It showed that there are several lacks of specific health resources in Bangkalan regencys can lead to lower quality of services.

Program: There are programs that focus on child growth and development in Bangkalan Regency and still ongoing to be implemented. Such as:

1. **Posyandu**: Posyandu is one of community-based health effort by utilizing the potential and resources available in the community. There is total 1091 posyandu in Bangkalan. Problems of Posyandu activities in Bangkalan Regency as community empowerment effort are less active cadre to do 5 desk posyandu standard. The situation made less quality of health care because the health staff especially midwife has no time for providing health education about child nurturing & child growth development early detection and intervention in this event.

The participation of mother toddlers to attend posyandu is influenced by weather, season or trade and agricultural so that the parent’s presence becomes very low.
2. **Nutrition Post:** Nutrition Post is an activity for mothers of under 5 years old malnutrition group gathering. The objective of the programme is giving group intervention & promotive – preventive activities. Unfortunately, the programme doesn’t focus on whole problems of child growth and development but only the nutrition aspect.

Activities of nutrition post are health education about balanced nutrition, environmental health, family health planning. The second activity is cooking for 6 days in a row to develop recipes from local products and preventing nutrition loss while cooking conducted by PHC nutritionist. Then, eat together with their child after weighting and the last is giving substitute food (milk or biscuit) and multivitamin.

The problem is there are few of all mother don’t finish 6 days programme. It’s caused by mother’s working hours. Few of mothers are also the main worker for family. So, if the mothers don’t work, they can’t provide food. Beside of that, Health staff should be the one who provides food so the health staff needs to wait for the programme’s fee or use their own expense.

3. **Healthy Child Trip:** Healthy child trip is a fun trip. Every toddler from 6 Early Education Institution that has MoU with PHC come to visit Bangkalan subregency PHC and follow the route as the guide gave and lead them together with their teacher. They will go to nutritionist room to get nutrition assessment for their nutrition status based on their age in KMS (a kind of child growth graph in Indonesia), they got anthropometric measurement by Dacin as standard weighing tool, microtome to measure the height and also Lila meter to measure lipid mass and measuring tape to measure brain development. The next route, child continue their trip to visit midwife to get child growth and development early detection used questioner of child’s development pra screening (KPSP).

In 2017, Bangkalan Subregency as the only one PHC that held this programme has assisted 476 children 3-7 years old. The problems are no health staff that qualified to assess CGDP of early detection and intervention by certification improvement.

4. **Safari Posyandu:** Motivation and sharing activities by inviting all mothers in the remote area that is low participation for the *posyandu* activities (4 times per year in each random village). Coordination between health sector and farming department also National Family Planning department (NFPD). At first, leader of PHC will give motivation session about the importance of posyandu for maternal and child health, then, farming department share about how to make a productive small land near house and family planning information especially about contraception from NFPD.

5. **Severe Malnutrition Tracking:** Health Staff tried to track the severe malnutrition child under 5 years old that never contact to health services because of many factors. The problems are about parents’ work hour and health staff work hour that don’t match each other could make the loss of target tracking.

![Graph 2: Direct Causes of CGDPs in Bangkalan Regency 2013](image)

**Graph 2:** Direct Causes of CGDPs in Bangkalan Regency 2013

**Source:** Nutrition Section, 2013

Graph 2 showed that there are many factors which Bangkalan department has observed from the field as the main causes of CGDPs such as poverty as the highest (31.6%), low knowledge about nurturing (18.4%), nurturing practices (18.4%), also another sick (16.4%) and low birth weight (4.4%).

**Sources:** Bangkalan Health Department, 2016
Table 2 showed that there are few of program indicators that can’t fulfill the target especially exclusive breastfeeding as one nurturing practices in society that still in the point of 28.3%.

“Mon lastarennah laher langsung eberri’ maddhu, ro’ merro’ ma’le sehat bhaji’eng -------- mon nanges langsung edhuleng pas omor 4 areh otabah 7 are ma’le ebo’eng olle lakoh”. (Ny.S)

This problem is increasing because mothers give food such as honey, young coconut to their babyborn beside of soft banana that they believe can be fast solution to keep baby calm when baby (0-6 months) is crying and then they can continue to work.

Problem Identification

1. Identification of problem based on primary data
   a. Identification of CGDPs intervention programme based on interview with programme coordinators in regency, subregency & village level: Mothers who have CGDPs won’t referre their child to intensive health care because of poverty aspect (not work means no income means no food), the belief that their child is healthy, mother feels shame if her child get intensive treatment in the health center because of neighbor who visit her child assume what’s her child disease. There is no health staff that has child developmental early detection instruments & trained to do it (including assessing nutrition status), midwives have overload tasks to do that also make low motivation situation.

   b. Identification of CGDPs intervention programme based on interview with posyandu cadre & mothers: Mother knows that their child never get development early detection/intervention by health staff, mother’s perception of CGDPs is healthy child that don’t need to referre to PHC can cause delay in intervention effort, Low knowledge and education about how to do nurturing based on child growth and development guidance (KMS) book. Economic problems to supply food including how to serve balance nutrition, stimulation and health services (only 56,67% have national health insurance). It supports the data about poor people number is 205,71 in Bangkalan or 21,41% while 2016 also the Human Development Index (HDI) in Bangkalan as number 2 lowest in East Java 2017 is 69.77%. Oleen as a condition of malnutrition and/or developmental delay that is most of people in the rural area believe as condition that people knew can be happened to Madurese child as natural process and only oleen shamans can cure it by specific massage, jamu or herbal drink, and amulet. Even some of oleen child’s mother try to find treatment from both of them (doctor and shamans). This phenomenon is only known by Madurese.

2. Identification of Problem based on secondary data: The situation of low coverage of CGDPs early detection can delay the intensive intervention effort, also low percentage of midwives with child growth and development certification and last certification workshop of child growth and development of health staff is 11 years ago but there is no refreshing material, programme that has been developed is only focused on growth problems.

Priority Problems and Identification of Problem causes: Mother’s perception of CGDPs is a healthy child that doesn’t need to be referred to PHC cause delay in an intervention effort. It’s caused by the perception of the susceptibility of CGDPs’ mother who feels her child is healthy, perception of CGDPs who referred to PHC is a shame thing, few mothers and family believe that the condition is only oleen and shaman will cure child by jamu and massage.

Alternative Problem Solving: Alternative problem solving for this situation is health education for mother of CGDPs to improve their knowledge about healthy child and child nurturing that consider cultural approachment and local wisdom, increasing the health promotion and improving health care facilities, community empowerment by involving cadre, religious and community leader to push up the issue & community awareness for CGDPs, assisting of CGDPs’ mother and family uses family approaches collaborated with Health Academy in Bangkalan.

Plan of Action: The general purpose of this plan of action is reduced the CGDPs under 5 years old to 50% in 2019 by early detection and intervention assistance by collaboration with Health Academy. The specific
purposes, such as the increased of cadre, religious and community leaders participation to find the CGDPs and persuade to seek health care, the increased of Posyandu participation, the increased of skillful health staff to do early detection and intervention for CGDPs, the increased of CGDPs early detection & intervention by health staff, the increased of mother and families about child-nurturing practices and concept of healthy child.

**Implementation:** There are few implementations, such as:

a. Collaboration with all sectors to do mapping of CGDPs in Bangkalan Regency.

b. Assisting healthy child under five years old family by Health Academy students collaboration

c. Early detection of child under five years using standard KPSP questionnaire

d. CGDPs intensive intervention by health staff by assessing growth and development then focus on specific problems of each child.

e. Mother seeks for health care to her CGDPs.

**Evaluation:** The evaluation process based on the aspect of continuing collaboration with all sectors, the record of child health increases better each year, the absence of CGDPs with a delay intervention because of cultural factor. All child under 5 years old, especially in rural area got assisted by Health Academy Students. Mother of a child under 5 years old know how to do nurturing practice better and there is a significant improvement of knowledge, attitude, and practice to do child nurturing.

**Conclusion**

CGDPs is the problem for Nation because it can reduce the quality of future generation. So, there is a need for collaboration between academics and practitioners also multisectoral stakeholders for CGDPs programme planning until evaluation especially implementation and also by involving the cultural approachment in each programme.

Effect of Exercises Using Devices to Develop Some of the Motor Qualities and Offensive Basketball Skills

Rasha Talib dheyab¹, Omar Saad Ahmed¹

¹College of Physics Education and Sports Science, University of Diyala, Diyala, Iraq

ABSTRACT

Basketball has a great care and interest in being one of the most popular and exciting games in the world and wants to be seen by young people and adults and different levels of social and cultural. The basketball game is characterized by multiple skills and cohesion and the ability to control well all the skills of the game as well as the need for the ability to behave properly. During the game, you need dynamic abilities such as agility and motor compatibility of the game’s skills. The research problem seeks to achieve the maximum victories in the game of basketball through participation in various tournaments and so it is noticeable that it changes material efforts with or with In order to achieve this, the researcher can clarify his problem with the following question: The researcher chose the research sample in a deliberate manner to conduct the research and reached (14) players from the specialized basketball school in Diyala governorate. The researcher concluded that the exercises used positive effect in the development of fitness and motor compatibility, as well as the existence of differences of significant significance between agility and motor compatibility in the tests of tribal and remote.

Keywords: Basketball, Exercises, Kinetic qualities.

Introduction

The start of the trend of countries to take care of sport in terms of scientific progress in the formation of society and generations, whether physical, mental, psychological or social, as this trend came in various fields to show the level of development in the field of sports, which serves the achievement of sports in general and recording the best results.¹ And achieve the highest levels in international forums that draw the civilization of those countries participating, and the training process is the most important and fundamental aspects, which have been subjected to continuous efforts and large as a result of the use of new and innovative means and modern methods and interest in age groups began to take G by large stakeholders in the scientific reference and planning, which is based on sound scientific foundations on how to deal with these young lions and young.²

The researcher conducted different surveys for the trainers of the game and the teachers. He has found a weakness in some of the offensive skills that are the basis in achieving the goal in all the team members, including the skill of passing, dribbling and scoring as well as some of the kinetic qualities such as compatibility and agility, which is the gate or the basis for the development of the skills mentioned above.³ The most critical points noted by the researcher at Diagnosis of the problem is the occurrence of many mistakes in passing, scoring and dribbling skills that lead to a lack of appropriate exercises to develop skills and qualities also the lack of not using modern devices in training the players.⁴

The Research Goal: Identify the effect of exercise devices in the development of fitness, motor compatibility and some basketball offensive skills on the and pre and post tests.

Research Hypotheses: There are significant differences between the pre-test and post-test of the research sample in the development of fitness, compatibility and some offensive skills in basketball.
Research Methodology And Field Procedures:

Research Methodology: The researcher used the one-trial experimental approach to suit the nature of the research.

Community Sample Search: The selection of the sample is one of the most important and fundamental matters in the work process of the research. Therefore, the sample of the research should be representative of the primary community. It should be true. So the researcher pre-test the research community which was the specialized school in basketball in Diyala city, they were (20) members chosen carefully either the sample search conducted research and amounted to (10) players.

Research tools and means of collecting information: The search tools are how the researcher can collect data and solve the problem to achieve the objectives of the search, regardless of those tools of data, samples, and devices.

Machines and tools used in research: The mobile device for the developing fitness, Compatibility and some skills.

Movable character training device for the development of fitness and compatibility and some basic skills: This device is used to exercise and improve the motor qualities without the help of the coach or other players so the chances are equal for all players.

Measurements: Height 3 m, base 1.5 m, the characters each one 3 m long folded from the middle is made of plastic material and is foldable and harmless when collided by players and there are three speed in the device.

![Figure 1: Mobile Surface Propeller](image)
Mobile Surface Propeller: This device works at a near-ground-level and contains low barriers. The height can be controlled at a different speed, during which the difficulty of the exercise can be increased, and the safety conditions for the players are also available. The arms are made of plastic material and covered with sponge material.\(^{(7)}\)

Tests used in research:

Fitness and compatibility tests: The first test ran between the stands characters:

**Test Name:** jogging between stable characters 20 m.  
**The objective of the test:** measuring agility.  
**Tools used:** tape measure, license number (10), stopwatch, whistle.

**Performance:** When the whistle is heard, the player will run between the stable characters on two sides for a distance of 20 meters.

**Second:** The test of motor compatibility:  
**Test name:** Test numbered circuits.  
**The objective of the test:** Measuring the compatibility of both legs and eyes.  
**Tools used:** Stopwatch, drawing (8) circles on the ground each circle with a 60 cm circumstances, whistle.  
**Performance:** The player stands in circuit no. (1). When the signal is heard, the player jumps on both feet together into circle number (2) and turns to the second circuit until no. (8) as quickly as possible. The registry records the time it takes to move through the numbered circuits.

Skills Tests:

**First:** correction: Purpose of the test: Measure the accuracy of correct scoring.  
**Gadgets:** basketball court - basketball goal - whistle.  
**The number of attempts:** Allow each player ten attempts.

**Second:** the chest - passing test. (1)  
**Test Name:** Handling the wall from a distance of 3 m in 3 sec.

**Objective**

To measure the movement of lactic oxygen to the skill of chest passing.

**Measurement:** Calculate the number of times the ball touches the wall for 30 seconds.

**Third:** the high dribbling: (1): The name of the test starts from the high start point and of a high-speed dribbling for a distance of 20 m in the dominant arm.

**Purpose of the test:** Measuring the high speed dribbling for each player.

**Procedures:** Draw two parallel lines; the distance between them is 20 m. make a start and end lines.  
**Test performance:** The registrar calls the names to give the start signal first and record the results. Secured Timing as well as standing at the finish line b.

**Calculation of Degrees:** A score for each player is the time it takes to perform the test from the moment the starting signal is at line A until the finish line B.

**Exploration Experiment:** The time needed to implement the proposed vocabulary. Create an idea of how players receive training and testing. Overcoming mistakes and obstacles that may arise when implementing the main experiment. Find out the size of the assistant team and the primary team and confirm the validity of the tools used.. Ensuring the proper performance and implementation of tests. Provide special exercises (proposed).

The first exploratory experiment was conducted on Friday 10/8/2018 at 10:00 am on a sample of (5) samples from outside the main sample to determine the validity of the equipment and the prepared exercises.

The second exploratory experiment was conducted on Saturday, 11/8/2018, which coincides with the sample of the first experiment at ten o’clock in order to determine the validity of the tests used.

**Test Stability:** The method of stability through the test and repeated- test. The test was applied to a sample of (5) players on Saturday, 11/8/2018 at 10 am and then the tests were returned after a week and the members of the
first test themselves on Saturday, 18/8/2018 and under 
The same conditions, time and place. After processing 
the results using the simple correlation coefficient, all 
calculated values were less than (0.05).

Objective of the test: It is meant to be free from bias 
and not to issue self-orders. Since the tests are based on 
conclusive evidence, i.e., numbers as a result of the main 
experiment results, the objectivity is high.

Exercise: The researcher prepared special exercises 
that performed on devices, and these exercises include 
the ability to motor as well as some offensive skills in 
basketball.

Pre-Tests: The researcher conducted the standard tests 
of the research sample on Friday, 24/8/2018 at ten 
o’clock in the morning at Diyala Sports Club room for 
the variables of the research and the researcher confirmed 
all the conditions.

The main experience: Exercises were prepared to 
develop motor skills and some offensive skills in basketball.

These exercises were applied in the main section of 
the training module (the physical-skill part) in a 
picular preparation.

The training time was 90 minutes, and the number of 
training units was 16 units. The total time of the 
training units was 80 minutes and 30-40 minutes in the 
main section of the unit.

The researcher adopted the method of high-intensity 
periodical training ranged from 80-90% as well as through 
the times the exercise performed and how many times the 
exercise repeated or implemented and the training curve 
within the training unit in partial intensity (2).

The researcher took care of the gradual speed of the 
deVICES that used and the regular exercise in terms of 
difficulty, performance and the level of difficulties that 
caused by increasing the speed of the training devices.

Remote Tests: After performing all repetitions and all 
exercises by the sample of the researcher, the researcher 
conducted the tests of the dimension on Saturday 
20/10/2018 at ten o’clock in the morning and observed 
the same conditions of pre- testing as much as possible.

Statistical Means: Statistical data were processed using 
SPSS.

Discussion of Results

The researcher attributed the evolution in 
compatibility to the use of exercises devices, which had 
a positive impact in the development of this attribute; 
the researcher used the training devices in the training 
the players, which added competition between players 
and a development in the compatibility of motor. The 
player uses the ball on the device and the player was in 
contrast to the movement of the training device and with 
the ball. The researcher also attributed the effectiveness 
of the mobile surface propeller used in the search, where
the players were trained by jumping and gradient with the right and the left legs and backward. This device is working to develop the dynamic compatibility of the basketball player. Graduation of the development of this capacity by training from the public to the private, and this is what he pointed out (3) to develop the compatibility of the athlete occurs by training this level of mobility (compatibility) General and simple and easy and then compound in the start-up phase or establishment phase, As well as the gradual training of this kinetic ability (special compatibility during the two specialized training stages).

The repetition of the exercise and giving it sufficient time in explanation and performance helps the player to fully understand the details of the whole movement. This is confirmed by that sensations play an important role in the motor coordination of skill and coordination between the musculoskeletal system, The performance of the skill and the recognition of the treatment contributes to the ease and flow of motor performance of the skill.

Discussions of Offensive Basketball Skills

The researcher attributes the evolution and the significance of the differences in the tests of the technical variables to the use of exercises in the devices as the mobile movable characters device has had a significant impact in the development of skills through facing the player the different speeds and put in conditions similar to the conditions of real players and skill as well as the element of excitement and competition, which the device is adding for the players during the training and it has a significant impact in the players skills development. The treatment and correction of errors in according to a correct scientific and educational methods and allow players to perform the most number of correct repetitions and direct them towards the exact performance, which plays a prominent role in achieving the training goal. The training was natural and challenging in the course of the training units until you reach the compound exercises, which is confirmed by that the development of the level of technical performance of players by providing the opportunity to increase the number of repetitions as well as giving feedback to address errors during the performance and the teaching of motor skills lead to correct the player’s responses and guide his behavior towards the correct form that raises the level and accuracy of the performance of learning For skill.

The exercises in the devices within the curriculum of the training modules were the level of these exercises, where the skills performed on the movable character training device which consists of tow combined devices working on clockwise and anti clockwise. The player revolves around and can perform skills in several exercises positions on the device where it can perform, and the device is stopped and can also perform, and the device works As well as the principle of gradualism in the exercises where the player plays skills. The skill of the dribbling is not a skill alone, but collapsed skill that combines several things including speed, agility, deception and control of the ball, so not to unleash any choice of exercises that achieve the goal of training delays the arrival of the player to the level of performance required during the time period specified for training, which is also confirmed by that the gradual access to the best level of performance has become an essential rule in training and that hierarchy means achieving the training plan. The time of the intensity of the exercise, the gradualist of exercises from simple to composite to the most difficult of the devices under multiple circumstances. The central role contributing to the development of the level of skill performance where the complex exercise between the skills that used in the research a prominent role in the development of the skill of correction, The existence of a positive relationship between the types of skills as each skill performed by the player is the correction, and this is confirmed by both that carrying performance “is the ability of the player to bear the repetition of the performance of psychological skills for long periods without feeling tired”.

Conclusion

The results showed that the use of the two mobile devices and ground fans in training has developed agility and motor compatibility and some basic skills of basketball, that the use of devices have a definite effect in the development of variables for the sample of the research, and through the findings of the research recommends that the use of suggested devices Modern in the development of fitness and compatibility and some of the offensive skills basketball, as well as the use of other devices to develop other skills and skills, and the use of the player to the advanced devices during training, especially in the games to improve performance and add fun to train and stay away from boredom and Traditional exercises, experiments and studies on different age groups.

Implementation of Speech Therapy and Social Stories Increasing Social Interaction in Children with Autism

Retno Twistiandayani¹, Khoiroh Umah¹, Dede Nasrullah²
¹Lecturer in Bachelor Degree of Gresik University, Indonesia; ²Lecture Faculty Health of Science University Muhammadiyah of Surabaya, Indonesia

ABSTRACT

Autism is defined as developmental disorders with the main characteristics i.e. social interaction disorders, communication disorder and restricted imagination interest and ability whose symptoms begin to appear before a three-year-old child (Amanda, 2017). Social Skill Training, one of them is social stories therapy become important to be owned by children with ASD (Autism Spectrum Disorder) so that they can behave in accordance to the social rule. The study aimed to analyze the differences between the influence of speech therapy and social stories in increasing social interaction on children with autism. The research method was a pre-experimental study with a pre and post-test with control group design. This study was divided into two groups and observed in two stages. After the data was fulfilled then an analytical test was used paired t-test and independent t-test. The results found that the influence of speech therapy in increasing social interaction \( p=0.004, \rho<\alpha=0.005 \). It was obtained the influence of social stories therapy as well in increasing social interaction \( p=0.004, \rho<\alpha=0.005 \). There was a significant difference between obtaining speech therapy and social stories in increasing social interaction on children with autism. The speech therapy and social stories were necessary to improve their social interaction that it could increase children’s with autism ability to interact with their surrounding social environment.

Keywords: Speech Therapy, Social Stories Therapy, Social Interaction, Children with Autism

Introduction

According to Baron S and Cohen (2009), autism is a state of person since he/she had been born or toddler made him/her could not form social relation or normal communication, in addition, he/she overcomes trouble to understand anything from other people’s point of view ¹. As a result, they are isolated from others and go into repetitive world, activity, and obsessive desire as well as difficult to develop their ability to create interaction and relation ². There are some therapy methods used to overcome social interaction disorder on children with autism either by medical or non-medical therapy ³. One of medical therapy often used in resource center is speech therapy to improve their social interaction. The speech therapy is applied to train the speaking ability of children’s with autism ⁴.

Gresham and Kern (2004) in Raymond (2008) stated that in order to create effective social skills training, students who observe must be able to pay attention to whom as models of behavior, able to remember what they had been observed, be able to imitate what they have seen, and have the motivation to engage in new behavior ⁵. Based on the latest theory, social skills training has become one of the most efficient therapies for autistic healing, especially in the treatment of social stories focusing on methods of giving examples of social life through a story, so that it indirectly stimulates children to follow the main character’s behavior ⁶. Social therapy stories are a new therapeutic technique for autistic children, where therapists provide an overview of stories about people’s culture that aim to help students who experience impaired social interaction of which aims at understanding social rules of the culture ⁷.

DOI Number: 10.5958/0976-5506.2019.02619.6
In some developing countries like Indonesia, children with autism can reach 66,000,805 people. According to data from the East Java Education Office in 2011 there were 388 SLBs of 13,159 students. In addition, there are 93 inclusive schools with students with special needs 1,476 children and 15% (221) of them are autistic children. Based on preliminary data from researchers at the Gresik District Resource Center in October 2016, there were 48 autistic children and 45% experiencing impaired social interaction. Based on the research results of Achmad C (2009) in the “Kasih Mama” therapy center, it was found that play and storytelling therapy could improve the abilities and social skills of children with autistic disorders.

From the 50 children with autism who experienced social interactions disorder, 35 children had mild social interactions (70%). Social interaction on children with autism who were left on an ongoing basis could have a negative impact on their life such as being isolated from the environment because they were happy with their own world but ignoring others around him.

Methodology

This research method was a pre-experimental study by designing pre- and post-test with the control group design. The sample was taken by purposive sampling technique that matches it according to specified inclusion criteria. The independent variable was speech therapy and social stories, while the dependent variable was the social interaction of children with autism. This study was divided into two groups and observed in two glasses. After the data was fulfilled, then the analytical test was carried out using the paired t-test and independent t-test.

Research Result

Effect of Speech Therapy in Improving Social Interaction on Children with Autism

*The statistic result showed that independent test of p-value = 0.022 dan α = 0.005 depicted that p value < α or p value < 0.05 which meant Ho was rejected so that there was a significant difference in social interaction between experimental and control groups. The result of social Interaction on the experimental group after and before carrying out speech therapy treatment showed higher than social stories group.*

**Discussion**

**Effect of Speech Therapy in Improving Social Interaction on Children with Autism:** The statistical test resulted in the effect of speech therapy in increasing social interaction on children with autism. The results of the analysis obtained the minimum-maximum value in the experimental group experienced an increase in social interaction after speech therapy. There were several therapeutic methods that could be used in dealing with social interaction disorder on children with autism both through medical therapy and non-medical therapy. One of non-medical therapy commonly used in resource centers was speech therapy to increase social interaction on children with autism. Speech therapy aimed to train the speaking ability of children with autism. Social interaction was influenced by several factors, i.e. motivation, gender, environment, value, background, and age.

Before speech therapy, the level of social interaction ability of children with autism reached a minimum of 5 and a maximum of 9, because the characteristics of respondents were 5-12 years old. The phase of school children aged 5-12 years experienced various patterns of development such as intellectual, language, emotional, social, moral, motoric, and religious appreciation. At point no. 2 (to care if friends fall), 4 (to be able to greet others), 6 (to want to budge), 9 (to want cooperating and not challenging), 13 (be able to share), 15 (be sensitive to the feelings of others) and 18 (gestures directed/focused), all respondents did not have those abilities. After carrying out speech therapy, it increased their social interaction of children with autism that was a minimum score of 12 and a maximum of 15. This state could be seen from their achievement of social interaction values in points 4, 8 and 20, which were most children with autism could afford to greet others, to show good care and to provide care when parents left. The provision of speech therapy was carried out in 8x meetings using teaching aids so that it could stimulate the children to show and to tell things related to the picture in question. This speech therapy would train children with autism to communicate and speak. Moreover, their parents must be patient and should not give up in training them as it is not like training normal children.

**Effect of Social Stories Therapy In Improving Social Interaction On Children with Autism:** The results of statistical tests showed that social stories therapy increased social interaction on children with autism. The results of the analysis obtained the minimum-maximum value in the control group got an increase in social interaction after the therapy, yet it was not too significant. The social therapy stories are a new therapeutic technique for children with autism done by therapists who provides a description of stories about community culture that aims to help students who experience social interaction disorder. It aimed to understand the social rules of the culture of society. And it could be given once a week.

Before implementing social stories therapy, the level of social interaction ability of children with autism reached a minimum score of 4 and a maximum score of 9. At point no. 2 (to care if friends fall), 4 (to be able to greet others), 6 (to want to budge), 9 (to want cooperating and not challenging), 13 (be able to share), 15 (be sensitive to the feelings of others) and 18 (gestures directed/focused), all respondents did not have the ability in that matter. After therapy social stories experienced improvement, the social interaction of children with autism reached a
minimum of 9 and a maximum of 14. It could be seen in the achievement of social interaction scores in point no. 4, 6, 9, 13 and 18, most of them were able to greet others, want to give in, work same and not challenging could share and gesture directed/focused.

Social therapy stories aim to increase social interaction on children with autism so that those who initially don’t budge refuse to work together and challenge them eventually to budge and cooperate with friends13.

Different Between Implementation of Speech Therapy and Social Stories in Improving Social Interaction on Children with Autism: The results of the statistical analysis showed that there were significant differences in social interactions between experimental and control groups. The social interaction in the experimental group after speech therapy was higher than the control group.

Social interaction was a dynamic relationship, involving relationships between individuals, between groups and between individuals and groups. Two conditions for the occurrence of social interaction according to Gillin (2010) were the existence of social contact (social context) and social communication 14. In the experimental group after speech therapy, most of the respondents were already at the stage of social communication which item no.5 indicated that all respondents had contact with other people and most children who experienced autism worked together and were not challenging. According to Pamoedji G (2007) The level of success in handling autism in children was not only dependent on the therapy process, but there were factors that could influence it, including role and involvement of parents in the treatment of children with autism, Teaching and education processes on them, their health conditions, their level of intelligence, their level of abnormalities (mild, moderate, severe) and their ages when first handled 15 16.

Conclusion

The results showed that speech therapy had an effect on increasing the social interaction of children with autism as well as social stories therapy and there were differences in speech therapy and social stories on social interactions in children with autism. The speech therapy and social stories were one alternative therapy that has many known benefits in the field of health. However, responding to speech had more influence in increasing the social interaction of children with autism. For this reason, therapists at the Gresik Resource Center were advised to more optimally apply speech therapy in their implementation, especially on children with autism who experience social interaction disorder.

Determination of Safe Sulfur Dioxide (SO₂) Concentration among Street Vendors of Ampera Bus Station, Palembang, Indonesia

Rizqy Kartika Sari¹, Abdul Rohim Tualeka¹, Pudji Rahmawati², Syamsiar S Russeng¹, Atjo Wahyu³
¹Department of Occupational Health and Safety, Faculty of Public Health, Universitas Airlangga, 60115 Surabaya, East Java, Indonesia; ²Department of Development of Islamic Society, State Islamic University Sunan Ampel, Surabaya, Indonesia; ³Department of Occupational Health and Safety, Faculty of Public Health, Hassamuddin University, Makassar, Indonesia

ABSTRACT

Sulfur dioxide is a corrosive substance harmful to humans. In the form of gas this substance has a pale color, nearly invisible and has a strong odor. Transportation activities in the bus station produces SO₂ exhaust gas which is dangerous for street vendors. The purpose of this study was to determine the safe concentration of sulfur dioxide at street vendors at Palembang’s Ampera Terminal, Indonesia. This is an observational, cross sectional and descriptive study. The study population was street vendors at Ampera Terminal Palembang, Indonesia. The sampling technique used a total population of 84. Data analysis was conducted manually quantitative to determine the safe concentration (C safe) of sulfur dioxide for workers obtained from the data of experimental white mice (W animals) weight, body surface area of white mice (BSA animals), workers’ body weight (W), workers’ height (h), workers’ body surface area (BSA), workers’ respiratory rate (BR), working time (t), concentration of sulfur dioxide (C), animal km, human km, NOAEL and reference of concentration (RfC).

From data processing, the concentration of sulfur dioxide in Ampera bus station, Palembang was 0.2298 mg/m³ (0.08771 ppm). This value is under (SNI) 19-0232-2005 of 5.2 mg/m³ (1.98 ppm). Based on the manual calculation, the safe limit of sulfur dioxide concentration in Ampera bus station, Palembang is 0.395 ppm. This value exceeds the value set by Permenaker No. 5 of 2018 of 0.25 mg/m³ (0.09542 ppm). From these findings, control from the adverse effects of sulfur dioxide on workers’ health is needed. Control recommendations include routine inspection of vehicle exhaust emissions and improvement efforts to reduce SO₂ emission levels to reduce health risks. In addition, health consultation facilities need to be provided for street vendor workers in Ampera Palembang.

Keywords: sulfur dioxide, bus station, safe concentration, street vendor

Introduction

SO₂ is the most common toxic substance in large cities and is a very strong pollutant in relation to respiratory diseases (Farisi, 2018)¹. Effects of exposure to sulfur dioxide in adults include problems in breathing, changes in breathing ability, as well as burning sensation in the nose and throat (ATSDR, 2010)².

One of the vehicle exhaust gases produced from activities is SO₂ gas. Emission of vehicles in the bus station when engine is running but the vehicle stops (idling) is twice higher than that of the emissions of exhaust gases when the vehicle is running normally (EPA, 2011)³. Transportation in large coal-fueled cities contributes 32.5% SO₂ in national pollutants (Rao V et al, 2013)⁴.

According to (SNI) 19-0232-2005 the permissible TLV of sulfur dioxide is 5.2 mg/m³ (1.98 ppm)⁵.
According to Permenaker No. 5 of 2018 Threshold Limit Value (TLV) of sulfur dioxide is 0.25 mg/m³ (0.09542 ppm). ACGIH in 2005 set a threshold limit value (TLV) of sulfur dioxide of 2 ppm.

The safe concentration of sulfur dioxide is not a reference in determining the threshold value of sulfur dioxide that it often has an effect on workers even though the concentration is below the threshold. A study found that lung cancer incidence was 1.3% higher in areas of high concentration of sulfur dioxide (≥0.008 ppm) than in areas with low concentration of sulfur dioxide (<0.005 ppm) (ATSDR, 2010). Changes in lung function were found in workers exposed to 0.4-3.0 ppm sulfur dioxide in 20 years or more. Sensitive breathing such as asthma can result from exposure to low concentrations (0.25 ppm) of sulfur dioxide (ATSDR, 2010). Based on the results of the research, the concentration of sulfur dioxide below the specified TLV (ATSDR, 2010 of 3 ppm) has had a health effect on workers. Thus TLV needs to be improved based on the results of research on the safe limits of sulfur dioxide concentrations in the work environment. The average weight, height, temperature and air pressure conditions in a place are the reasons for safe concentration and TLV of a different chemical. Based on calculations, the concentration is safely influenced by body weight, respiratory rate, and length of work time.

The research was carried out by determining the safe limits of sulfur dioxide concentration in the work environment based on workers’ body weight, respiration rate and duration of daily work. Respiration rate is influenced by workers’ body weight.

This research aims to determine the safe concentration of sulfur dioxide at street vendors in Palembang’s Ampera bus station, Indonesia. This study began with the determination of NOAEL in white rats and RfC. The benefit of the research is as a reference in determining sulfur dioxide TLV in the work environment in Indonesia, i.e the Ampera Palembang bus station as an improvement from the existing TLV.

**Material and Method**

This study was an observational, cross sectional and descriptive study. The population of this study is street vendors around the Ampera Terminal Palembang.

The sampling technique was a total population of 84 people. The study began with the collection of primary data including concentrations of sulfur dioxide in the air, length of work, and workers’ body weight. Primary data of experimental animals is the weight of white mice. Data on the concentration of sulfur dioxide in the air obtained by direct measurement at the Ampera bus station in Palembang, Indonesia refers to SNI 19-7119.2-2005. Measurements were made using the midget impinger and Griess Saltzman method and spectrophotometer analysis technique.

The research variables include the concentration of sulfur dioxide in the workplace, workers’ weight, height, respiration rate, length of work daily, body surface area, weight of white rats, body surface of white rats, highest dose of toxin without effect on experimental animals (NOAEL), Km factor in animals (Animal Km), Km factor in workers (Human Km), safe limit of toxin dose for workers (RfC), and benzene concentration safe for workers (C safe).

NOAEL of sulfur dioxide from μg/m³ to mg/kg, where 1 mg/kg equivalent to 1 ppm obtained from calculations using the following formula:

\[
\text{NOAEL} = \frac{n \times \text{BeratMoleckul}}{24,45} \times 1000
\]

Determination of safe dosage of toxin for workers (RfC) is calculated using the following formula (Shaw et al, 2017 in Tualeka, 2013):

\[
\text{RfC} = \frac{\text{Animal Km}}{\text{Human Km}} \times \text{NOAEL}
\]

Where:

RfC : References of concentration (mg/kg)

Animal Km : Km factor on animal

Human Km : Km factor on human

Determination of safe concentration using the following formula (William et al, 1985 in Tualeka, 2013):

\[
\text{C safe} = \frac{(RfC)(Wb)}{\delta(BR)(t)} \text{mg/m}^3
\]

Conversion of units of mg/m³ to ppm was performed by using the following formula (Tualeka, 2013) (9):
C safe (ppm) = \( \frac{mg}{m^3} \) (MV) 24,5

Where :

C safe : concentration of toxin in the air safe for workers (mg/m³)

RfC : Inhalation Reference Concentration (mg/kg)

W : Weight (kg)

\( \delta \) : % substances absorbed by the lungs

BR : Human respiratory rate (m³/hour)

t : Working duration (hours/day)

MW : Molecular Weight

Data analysis was performed by using quantitative data analysis manually to determine safe sulfur dioxide concentrations for street vendors at Ampera bus station, Palembang, Indonesia.

Findings

A. Characteristics and the Surface Area of Try Animals (White Mice):

Human response to toxicity is generally similar to animal responses qualitatively, thus, test on animal becomes the basis for extrapolating animal to human data (Tualeka et al, 2019). Toxicity test is carried out by using white rats.

</table>

Based on white rat body weight data, the body surface area (BSA) was calculated using the following formula:

Animal \( BSA = 0,09 W^{0,67} \)

where:

BSA : Body Surface Area (m²)

W : Weight (kg)

B. Workers’ Characteristics, Body Surface Area and Breathing Rate:

The characteristics of the workers in this study include weight and duration of work from 84 street vendors at Palenbang’s Ampera bus station, Indonesia. Based on Table 2, the highest body weight was 100 Kg, the lowest weight was 37 Kg, and the average body weight was 65.57 Kg. The average working duration in a day is 8 hours, the shortest duration of work in a day was 5 hours/day and the longest duration of working in a day was 12 hours/day. The height used in the research was the average value of Indonesian adult height of 159 cm.

Based on data on body weight and height of workers, body surface area and worker respiratory rate were calculated using the following formula:

1. Workers’ Body Surface Area

\[ BSA = \sqrt{W.h/3600} \]

\[ = \sqrt{65,57 \times 159/3600} \]

\[ = 1,448 \text{ m}^2 \]

where:

BSA : Body Surface Area (m²)

W : Weight (kg)

h : Height (cm)

2. Workers’ Breathing Rate

\[ BR = 5,3 \ln W - 6,9/24 \]

\[ = 5,3 \ln 65,57 - 6,9/24 \]

\[ = 0,63627 \text{ m}^3/\text{hour} \]

where:

BR : Breathing Rate (m³/hour)

W : Weight (kg)

Table 2: Average Distribution of Workers, Breathing Rate and Working Duration of Street Vendors of Ampera Bus Station, Palembang, Indonesia

<table>
<thead>
<tr>
<th>Number of workers</th>

<tr>
<td>84</td>
<td>65,57</td>
<td>159</td>
<td>1,448</td>
<td>8</td>
<td>0,63627</td>
</tr>
</tbody>
</table>
The results of the calculation of body surface area and worker respiratory rate were 1,448 m² and 0.63627 m³/hour, respectively.

**C. Sulfur Dioxide (SO₂):** Measurement of the concentration of Sulfur Dioxide was obtained through measurements at 4 predetermined points (Arista et al, 2015). The average value of SO₂ concentration in Ampera Terminal Palembang was 229.8μg/Nm³ or equivalent to 0.2298 mg/m³ (0.08771 ppm). The concentration of sulfur dioxide is under (SNI) 19-0232-2005 of 5.2 mg/m³ (1.98 ppm). The concentration of sulfur dioxide is below the threshold (TLV) value of sulfur dioxide according to ACGIH in 2005 of 2 ppm. However, the average concentration of sulfur dioxide is very close to the highest level allowed by Permenaker No. 5 of 2018 of 0.25 mg/m³ (0.09542 ppm).

**D. Animal Km and Human Km**

1. **Animal Km**

   \[ \text{Animal Km} = \frac{W \text{ animal}}{\text{BSA animal}} \]

   where:
   - Animal Km : Km factor on animal
   - W : Weight (white rats)
   - BSA : Body Surface Area (white rats)

   Table 3 shows the calculation result of Animal Km in white rats of 5.81.

2. **Human Km**

   \[ \text{Human Km} = \frac{W \text{ human}}{\text{BSA human}} \]

   where:
   - Human Km : Km factor on human
   - W : Weight (Kg)
   - BSA : Body Surface Area (m²)

   The average Human Km of street vendors in Palembang’s Ampera terminal is shown in the table of 45,283.

**Table 4: Workers’ Average Human Km Calculation**

<table>
<thead>
<tr>

<tbody>
<tr>
<td>84</td>
<td>65,57</td>
<td>1,448</td>
<td>45,283</td>
</tr>
</tbody>
</table>

**E. No Observed Adverse Effect Level (NOAEL):**

Toxicity test is used to evaluate the safety of a substance. The safe limit of the concentration of a chemical can be determined by the toxicity test for determining the highest dose without causing effects on experimental animals or No Observed Adverse Effect Level (NOAEL). NOAEL of sulfur dioxide was 660 μg/m³ (OEHHA, 2016) or equal to 0.25 mg/kg (0.25 ppm) obtained from the following calculation:

\[ \text{NOAEL} = \frac{n \times \text{Berat Molekul}}{24,45} \times 1000 \]

\[ 660 \mu g/m^3 = \frac{n \times 64,06}{24,45} \times 1000 \]

\[ n = 0,25 \text{ mg/kg} \]

**F. Reference of Concentration (RfC):** Calculation of Inhalation Reference Concentration for street vendors in Ampera Palembang, Indonesia based on NOAEL values, on average Animal Km, the average Human Km is as follows.

\[ \text{RfC} = \frac{\text{NOAEL} \times \text{Animal Km}}{\text{Human Km}} \]

\[ = 0,25 \times \frac{5,81}{45,283} \]

\[ = 0,032 \text{ mg/kg} \]

Where:

- RfC : References of concentration or Inhalation Reference Concentration (mg/kg)
- Animal Km : Km factor on animal
- Human Km : Km factor on human
From the calculation of the formula, the RfC calculation result is 0.032 mg/kg.

G. Safe Concentration of Sulfur Dioxide (C safe):

The results of the calculation of safe concentration of sulfur dioxide in street vendors of Ampera Palembang bus station based on RfC values, average workers’ weight, percentage of substance absorption, average workers’ breathing rate and average duration of work are as follows:

\[
C_{safe} = \frac{RfC(Wb)}{(\delta)(BR)(t)}
\]

\[
= \frac{(0,032)(65,57)}{(40\%)(0,63)(8)}
\]

\[
= 1,034134 \text{mg/m}^3
\]

\[
C_{safe} \text{ (ppm)} = \frac{mg/m^3}{(MV)}^{24,5}
\]

\[
= \frac{1,034mg/m^3}{(64,06)}^{24,5}
\]

\[
= 0,395 \text{ ppm}
\]

Where:

- C safe: Toxin concentration in the air safe for worker (mg/m³)
- RfC: Inhalation Reference Concentration (mg/kg)
- W: Weight (kg)
- \(\delta\): % substances absorbed by the lungs
- BR: Human Breathing Rate (m³/hour)
- t: Working duration (hour/day)
- MW: Molecular Weight

The result of the calculation of the reference dose (RfC) exposure to sulfur dioxide was 0.032 mg/kg. RfC in the present study is smaller than the RfC determination at studies of human exposure controls in a population of 0.067 mg/kg. At this rate, human health including populations that have sensitive breathing such as asthmatics still protected. Thus, the RfC of the present study is safe for humans.

Based on the results of this study, the safe concentration of sulfur dioxide in the street vendors of Ampera bus station, Palembang was 0.395 ppm. This value is lower than sulfur dioxide threshold value according to (SNI) 19-0232-2005 of 5.2 mg/m³ (1.98 ppm) and ACGIH in 2005 of 2 ppm. Thus, the value of the result of this study can be used as a reference in determining the threshold value of Sulfur Dioxide in the Ampera bus station, Palembang and is safe for those who were exposed to it.

Conclusion

The measurement result of the average concentration of sulfur dioxide in street vendors around the Ampera bus station in Palembang, Indonesia was 0.2298 mg/m³ (0.08771 ppm), which means below the threshold according to the Indonesian National Standard (SNI) 19-0232-2005 about the Threshold Limit Value (TLV) in the workplace air of 5.2 mg/m³ (1.98 ppm). However, the average concentration approached the highest level permitted according to Permenaker No. 5 of 2018 of 0.25 mg/m³ (0.09542 ppm). In contrast to the predetermined threshold value of 0.095 ppm, the concentration of sulfur dioxide in the present study was 0.395 ppm. This value is lower than that of specified in the 2005 ACGIH Threshold Value of 2 ppm. Therefore, control efforts are needed that the communities are protected from the adverse effects of sulfur dioxide on health.

Control recommendations include routine inspection of vehicle exhaust emissions and improvement efforts to reduce \(SO_2\) emission levels so as to reduce health risks. In addition, health consultation facilities need to be provided for street vendors in Ampera bus station, Palembang.

Conflict of Interest: All authors have no conflicts of interest to declare.

Source of Funding: This is an article “Determination of Safe Sulfur Dioxide (SO₂) Concentration among Street
Vendors of Ampera Bus Station, Palembang, Indonesia” of Occupational Health and Safety Department that was supported by Faculty of Public Health, Universitas Airlangga.

The Influence of Training Handover based SBAR Communication for Improving Patients Safety

Roymond H. Simamora¹, Achmad Fathi¹

¹Faculty of Nurses Universitas Sumatera Utara., Jl. Prof. T Ma’as No.3 Medan. Sumatera Utara Indonesia

ABSTRACT

Background: Nurses in patient safety have promoted the use of standard communication at the time of handoff as a means to reduce margins for errors during the transfer of important information. One way to standardization is to use the effectiveness of SBAR communication. The purpose of this study was to determine the effect of training on the implementation of nursing handover based on SBAR communication.

Method: used quasi-experimental, with intervention and control groups. The Statistical test used Wilcoxon and Mann Whitney test. Result: z value is -2.093 and p> 0.05. This shows that there is an effect of training on the leadership of the standard implementation of the head of the room on the commitment of nurses in implementing SBAR Communication Based Handover nursing.

Discussion: there is a difference in the level of commitment of nurses in implementing nursing handover based on SBAR communication in the control group. intervention group in terms of implementing SBAR communication-based Nursing Hand Over.

Recomendation: This study shows the value of utilizing educational programs for nursing in handoff communication settings. Such standard training programs must be considered to train nurses to communicate effectively at handoff.

Keywords: Nurses Commitment, Nursing Hand Over, Patient Safety, SBAR Communication

Introduction

Ineffective handoffs can contribute to gaps in patient care and violations of patient safety including medication errors, and patient death(1). In his seminary report, Crossing the Quality Chas(2) revealed that inadequate reports were among the main causes for errors in patient safety. This is a Joint Commission joint-to-joint analysis of more than 3,000 events that resulted in death or serious injury. Communication failure was cited as the root cause of 65% of these events with at least half of the failures that occurred during the handoff (3).

The health system of more than one person with various levels of education and maintenance of continuity between turns is very important for safety. Researchers from this industry have studied errors in long communication handoffs before patient safety culture becomes clear in today’s health systems (4). In particular, the literature that examines strategies to improve the security of the handoff report process is a means of combating barriers to effective communication (6). The results of the study by (5) describe a marked decrease in adverse events in patients after applying the standard communication process during handoff, which was found to assist in the arrangement and standardization of communication between caregivers. communication SBAR, This technique was originally developed by the military and is associated with inaccurate and incomplete information transmission (7).

SBAR is a standard oral communication method, but it has been used as a template to guide the development of written forms and checklists that accompany patients during handoff times. This framework assists nurses in presenting their patient’s thoughts and data; situation, background,
and judgment, in a logical order that encourages critical thinking; recommendations about what needs to happen next in a patient care situation. The authors conducted an evidence-based literature review on the effectiveness of repair interventions in clinical handoffs. Their evaluation is related that although they often mention the role of education and training literature in handoffs, detailed studies of their structure, implementation or evaluation are still limited. Traditionally, communicating handoff reports from nurses to nurses on shift changes has been stated in the literature by (8).

According to Wolf (8), nurses are critical of the ability of new graduates to collect data, provide sufficient information, and articulate diagnoses, treatments and treatment plans. Wolf (8) observed in his study that the performance of novice nurses during the shift report serves as evidence of their competence. According to nurses graduates are “ashamed when their reports are long and there is confusion about important facts for the well-being of their patients”. The author also makes it difficult for nursing students to understand and promote confusion between them. Therefore, nursing instructors and primary care nurses often spend extra time interpreting shift reports to students. The authors expressed concern that nurses were not routinely exposed to standard communication techniques such as those currently applied in important team communication such as the shift hand-offs (10). The authors have limited opportunities for evidence-based communication skills during their educational experience. Because the health care system continues to be documented (2) in their executive summary, the American Association of Colleges of Nursing Specifically addresses the need to teach communication practices that enable the delivery of high-quality and safe patient care (11). Institute of Medicine Reports for Nursing Education, argue that the IOM report must be at the core of all nursing development programs (12).

The Quality and Safety Development Project for Nurses consists of nursing faculty members who have adopted an approach to integrating quality and safety content into a continuing nursing education curriculum (13). In terms of teamwork and collaboration, the project recommends that nurses learn skills that will enable them to follow communication practices that minimize the risks associated with handoffs between providers and all transitions in care (14). Beginner nurses and expert nurses feel the situation from different sets that can change how the situation is communicated (15). Standardization of communication during handoffs between nurses has the potential to equalize the differences between beginner nurses and experts when trying to communicate the clinical situation. In conclusion, literature scanning reveals the relationship between the quality of information shared during handoff and adverse patient outcome problems. Teaching nurses how to conduct a quality handoff report using a standardized communication technique such as SBAR has the potential to empower and enable them to communicate handoff report in a manner that enhances patient safety immediately upon entering into practice. Suggested components of a quality handoff using SBAR in a published handoff form that can be used between nurses at shift change (5). Introduction of standardized communication for handoff at the academic level will help to address identified evidence gaps in education and training in clinical handoff. This research aims to address the quality of novice nurses handoff reports and its’ significance to a culture of patient safety. The purpose of this study was to determine the effect of an SBAR developed education program on the quality and organization of nurses handoff reports.

**Method**

This research design is quasi-experimental. 2 groups namely intervention and control groups, The sample is 94 nurses from 6 rooms, 47 people as the control group and 47 intervention groups. The instrument uses Self Reports Instrument analyzed by non-parametric statistical tests because the results of normality test and homogeneity test data are not normal to the test used Wilcoxon and Mann Whitney test.

**Result and Discussion**

The results of the research are shown in the table:

Shown in table 6. The z value was obtained -2.093 and p>0.05. Thus the average level of commitment of nurses in implementing nursing hand over after training in the control group and intervention group was significant.

Discussion

In table 6. shows the average level of commitment of nurses in implementing weighing (Nursing Handover) after training in the control group and intervention groups there are significant differences. with z value is -2.093 and p>0.05. This shows that there is an effect of training on the leadership of the standard implementation of the head of the room on the commitment of nurses in implementing weighing in Medan city hospitals. The relationship between SBAR communication and patient safety and handoff is well reported throughout the literature. Lack or ineffective verbal communication when handoffs have emerged as a common theme around side effects and the situation almost fails in nursing. With this attitude the nurse will work professionally in providing appropriate nursing care standards and in an effort to improve the quality of nursing services, so as to provide satisfaction to patients and nurses themselves, where employees who have a high commitment will show an attentive and responsible work attitude answer to his duties and show loyalty to his organization (16).

Subjects from both groups communicated “tests/treatments” under the recommendation domain. However, “goals” compared to the control group. Subjects in the control group were negligent in handling the “falling protocol” compared with 2 subjects in the intervention group who discussed it in the recorded audio handoff. The similarity between cohorts is closed every day for 2 hours “part of the recommendation component in the handoff report. This may be due to the nursing system to address skin damage problems. With the exception of one subject from the intervention group, subjects from both groups were ignored to mention the need before removing pneumococcal vaccine Combined Commission includes screening for these vaccines in the Indonesian National Patient Safety Goals, and they consider them to be an important component in the recommendations section of the SBAR handoff, the opportunity to practice SBAR techniques in simulation, clinical awareness and quality improvement reports and improve positive outcomes for patients.

The commitment attitude with high motivation is needed by a nurse in providing health services to patients. With this attitude the nurse will work professionally in providing appropriate nursing care standards and as an effort to improve the quality of nursing services, so as to provide satisfaction to patients and nurses themselves, where employees who have a high commitment will show an attentive work attitude and is responsible for his duties and shows loyalty to his organization.

Because the commitment contained belief, binding, which will generate energy to do the best. Significantly the commitment has an impact on the work performance of human resources which ultimately affects the
performance of a company in realizing the company’s vision and mission goals. With the training approach we take into account based on SBAR communication, the weighing of the thank you in the treatment room will be good so as to enable professional nurses to arrange the provision of nursing care and to regulate the environment to support the implementation of patient safety. The implementation of weighing in a good patient safety effort is influenced by various factors.

The factors that influence success include support from the hospital leadership and the head of the room, knowledge and commitment of all nurses and other staff, as well as collaboration between nurses, with doctors, or another health team. Commitment from all hospital components to carry out patient safety is the basic capital of achieving quality service delivery. Implementation of weighing and implementation of patient safety in hospitals is a commitment of hospital management to be able to provide professional health services.

**Conclusion**

The main conclusion that was realized was that the training provided nurses in the intervention group with a framework, structure and guidelines that allowed them to include more important data points about patients than nurses from the control group. After receiving training presentations and case study examples of SBAR principles, nurses in the intervention group showed evidence of being able to differentiate prominent patient data. The training program provided to nurses assisted them in carrying out handoff reports. This study provides insight and guidance efforts that can help overcome the problem of side effects associated with ineffective handoffs.

**Recommendation**

For Managerial nurses must consider embracing the SBAR patient safety initiative to teach handoffs. Important to educate nurses in the most effective way to do handoffs. Overcoming barriers to effective nurse-to-nurse communication by standardizing and supervising and selecting appropriate handoff methods can be one way to reduce errors. Supporting the practice with SBAR in simulation laboratories to allow nurses to feel confident about transferring these skills to the clinical arena. By introducing SBAR to nurses, this will prepare them for the type of ongoing involvement in quality improvement and error reduction.

Effects of *Nigella Sativa* Oil on Biochemical Parameters of White Male Rats Exposed to Diazinon

Rusul M. Alhilo¹, Hussain J. Kadhim¹, Mohammed T. Abbas²

¹Collage of Veterinary Medicine, University of Kerbala, Iraq; ²College of Pharmacy, University of Kerbala, Iraq

**ABSTRACT**

Many research showed the negative effects of diazinon (DZN) by inducing hepatorenal dysfunction. Therefore, this study was aimed to investigate the prophylactic and protective effects of *Nigella sativa* oil (NSO) against diazinon induced physiological and biochemical alterations in white male rats by biochemical tests (aspartate aminotransferase (AST), alanine aminotransferase (ALT), alkaline phosphatase (ALP), total bilirubin (TOT.BIL), and total protein). 45 white male albino rats weighing (220–240 g) were used, rats were arbitrarily divided into five groups, (9 rats for every group). Group 1 rats fed on traditional diet without treated as a control (CON). Rats in group 2 were treated with DZN via gavage in a dose of (10 mg/kg/daily) received was started at 15 days to the stop relating to the experiment. Rats in groups 3 were treated with NSO via gavage in a dose of (2 mg/kg/daily) received was started at 15 days to the stop relating to the experiment. Rats in group 4 were treated with DZN plus NSO via gavage and received was started at 15 days to the stop relating to the experiment. Rats in group 5 (prophylactic group) were treated with 2 ml/kg/every other day via gavage NSO in start from the first day for 14 days of the experiment and then DZN received at the above mentioned dose at 15 days to the end of the experiment. The consequences revealed to that a significant increased (P≤0.05) in AST, ALT, ALP, TOT.BIL activity of male rats treated with DZN compared with other groups and such an increase refers to hepatic dysfunction. And a significant increased (P≤0.05) in TP of CON group, (NSO)-treated group, (DZN+NSO)-treated group, and (NSO+DZN)-treated group, compared with (DZN)-treated group. Also, there were a significant increased (P≤0.05) in creatinine and urea in(DZN)-treated group compared with the other groups, which refers to kidney injury. Our Study concluded that *N. sativa* oil pretreatment significantly reduced the diazinon induced hepatotoxicity, and nephrotoxicity.

**Keywords:** *Nigella sativa* oil, diazinon, biochemical, histopathological, rats.

**Introduction**

Therapeutic plants have been utilized for treating diseases for several centuries in dissimilar domestic systems of medicine as like well as popular medicines. Between a variety of therapeutic flora, *Nigella sativa* (*N.sativa*) (Family: Ranunculaceae) is rising as like a marvel herb with a fashionable historic and religious backdrop, several research seeing that exposed its extensive range regarding medicine possible⁴. *Nigella sativa* has been appreciably studied because of its biological actions and medicine potent and shown to possess widish range of actions viz. as diuretic, anti-hypertensive, anti-diabetic, anti-cancer and immunomodulatory activity, painkiller, anti-microbial, anthelmintics, analgesics and anti-inflammatory, spasmolytic, bronchodilator, gastroprotective, hepato protective, renal protective and anti-oxidant characteristics. The seeds regarding *N. sativa* are broadly utilized in therapy of numerous illnesses such as bronchitis, asthma, diarrhea, rheumatism and skin disorder. It is furthermore utilized as liver stimulant, digestive, antidiarrheal, appetite tonic, emmenagogue, to raise milk product in nursing mothers to resist parasitic contagions, and to backing immune system⁵. Diazinon (diethoxy [ (2 – isopropyl – 6 – methyl – 4 – pyrimidinyl) oxy ] - thioxophosphorane) is an artificial alchemical material with wide-ranging insecticide action⁶. It has been broadly utilized throughout the world with enforcements in cultivation and horticulture.
for controlling insect in crop. Several reports have been published with respect to DZN and its effects on biochemical parameters of rats, rabbits, and mice.

This study was aimed to show the efficacy of *Nigella sativa* oil in alleviating the deleterious of diazinon in liver and kidney of rats with respect to biochemical parameters.

**Materials and Method**

**Animals and Management:** Forty-five male albino rats weighted (220-240 g) were utilized in this research. The animals were reserved beneath good ventilation system and received a neutral pattern of eating and water during the experimental time. The experimental was carried out at University of Kerbala-Colleage of Pharmacy: animal were reared in plastic cages under suitable environment conditions at temperature 23 ± 2 °C for two weeks from 2/1/2017 to 12/2/2017, they kept before experimental beginning for acclimation.

**Experimental Design:** The animals were randomly divided into five groups. Each group consisted of nine animals. The first group included CON group: they were fed with only standard rat diet and tap water. The second group included DZN group: in this group rats were gavaged with (10 mg/kg/daily) of DZN as orally and received was started at 15 day to the end of the experiment. The third group included NSO group: rats were treated with (2 ml/kg) every other day dose NSO via gavage, and received was started at 15 day to the end of the experiment. The forth group included DZN + NSO: rats were treated with DZN plus NSO 2 ml/kg every other day via gavage and received was started at 15 days to the end of the experiment. The five group included NSO + DZN group: rats were treated with 2 ml/kg/every other day via gavage start from the first day for 14 days of the experiment and then diazinon received at the above mentioned dose at 15 days to the end of the experiment.

**Data Collection and Biochemical Parameters:** At the end of the experiment, rats were anesthetized with ethanol and sacrificed 24h after the last DZN and NSO. About 5ml of blood was drawn in a disposable syringe by cardiac puncture. Blood samples were gathered in centrifuge tubes. Serum was separated from coagulant blood by centrifugation at 860Xg for 20 min, and then serum was quickly frozen at-20°C for one day for serum biochemical analysis (AST, ALT, ALP, total bilirubin, total protein, urea, creatinine).

**Statistical Analyses:** The data was analyzed using the Statistical Package for Social Science program (SPSS 12). For comparison between dissimilar experimental rat groups, one-way analysis of variance (ANOVA) was utilize pursued by Tukey's test. The results were expressed as means ± SD and (P<0.05) was considered to be statistically significant.

**Results and Discussion**

There are asignificant increased (P ≤ 0.05) in AST, ALT, ALP, TOT.BIL activity of male rats treated with DZN while therewere nosignificant variation among other groups in table (1).

Also theresults ofthis table showed a significant increased (P≤0.05) in TP of CON group, (NSO)-treatedgroup, (DZN+NSO)-treatedgroup, and (NSO+DZN)-treatedgroup, compared with (DZN)-treatedgroup.

Table (1) also shows that therewere asignificant increased (P ≤ 0.05) in creatinine and urea in(DZN)-treatedgroup comparedwith theother groups. (Mean ± SD).

Different letters in the same raw represent a significant difference at (P≤0.05).
Data are represented as mean ± SD, N = 9, DZN= diazinon, NSO= Nigella sativa Oil. AST= aspartate aminotransferase, ALT= alanine aminotransferase, ALP= alkaline phosphatase, TOT.BIL= total bilirubin, TP= total protein.

According to our study concluded that DZN was managed at a dosage of10 mg/kg/daily which resulted in a significant increased (P ≤0.05) in serum levels of liver function markers consisting of AST, ALT, ALP, TOT.BIL activity of male rats while there were no significant differences between other groups in table (1), that evidence of hepatic dysfunction. These dysfunction is also thanks to the manufacturing of free radicals and participation of oxidative stress to internal organ toxicity prompted through DZN treatment. Transaminases (AST and ALT) were considered to be a more sensitive measure in evaluating liver function and damage. Aspartate transaminase (AST) and alanine transaminase (ALT) are the enzymes which is involved in the transformation of amino acids to keto acids. They are pathophysiological marker enzymes utilize to measure tissue harm. Increases in AST and ALT serum levels have been attributed to damage to the structural integrity of the liver. This height could potentially be referring to the discharge of these enzymes from the cytoplasm into the blood circulation following split of the plasma membrane and cellular damage. Serum AST, ALT and ALP are biomarkers in the diagnosis of hepatic damage for the reason that they are freed into the circulation following cellular harm. The raised levels of the ALT and AST enzymes in the serum indicated cellular leakage and loss of functional integrity of the liver cell membrane. In addition, elevated contents of ALP may reflect impaired biliary tract function. The level of serum ALP might be raised due to the presence of increased biliary pressure and cholestasis. The liver is the main location of xenobiotic metabolism and initial pass metabolism for most drugs and chemicals, therefore, hepatotoxicity would be central to any poison chiefly as soon as eaten into the body. The hepatic function check is important in any toxicity diagnosis. The actions of ALT, AST and ALP enzymes are often considered sentient biomarkers which may straight demonstrate the range to which hepatic damage may have take place and or scale of it toxicity. The preceding studies hold talked about comparable conclusion where they observed raised hepatic function with tremendous discharge of these hepatic function enzymes into circulation. According to levels of serum ALT, AST, ALP, and total bilirubin were significantly higher in DZN treated rats, since necrosis or membrane injure discharge these enzymes into circulation, which have the same opinion with the earlier reported consequence. In the other hand, we found there were no significant differentiation among other groups in table (1). CON rats, rats treated with NSO at dose of 2 mg/kg/day, rats treated with (DZN+NSO), and rats treated with (NSO+DZN). The reason is due to a bigger amount of these flora have shown advantageous curative effects, including anti-oxidant, anti-inflammatory, anti-cancer, anti-microbial, and immune modulatory effects. The hepato protective effects of nigella sativa oil in this research can be stand appreciably ascribed in accordance with thymoquinone ingredient. The anti-inflammatory, anti-viral and anti-neoplastic actions of N. sativa have been earlier documented in different in vitro and in vivo study researches. The anti-oxidant effects of N. sativa have been earlier elaborated in animal models of liver ischemia, in which it improved the anti oxidant amplitude and decreased oxidative stress. Our findings in table (1) showed that a significant raise in serum levels of TP, in control rats, rats treated with NSO at dose of 2 mg/kg/day, rats treated with (DZN+NSO), and rats treated with (NSO+DZN) compared with (DZN)-treated group, where there were a significant decreased (P≤0.05), investigated the elevated concentration of total protein and their crumbs may be accredited to raise action of hepatic functions when N. sativa seeds were nourished according to. While we showed that a significant decrease in serum levels of TP in rats treated with diazinon, in agreement with who found that total protein level was significantly decreased after exposure to DZN for three weeks and indicated that the contact to DZN reasoned a harsh disorder of carbohydrates, lipids and proteins metabolism. Our study coincided with many earlier researches recorded significant height in serum urea and creatinine concentration in pesticide uncovered workers and such rising was indicate to renal injure and disorder of kidney action. Serum levels of urea and creatinine were shown to be of clinical assessment that indicate renal injury in pesticide exposed farmers. Creatinine is an off all product that is usually filtered from the blood and secreted with urine. Raise in creatinine level in response to pesticide contact indication renal disorder and maybe a result of damage glomerular role. In the same context, numerous authors referred the altitude of urea and creatinine in pesticide uncovered persons on the base of tubular renal failure,
damage glomerular filtration, urinary tract impediment and kidney injury. Urea is created by deamination of amino acids in the liver, and then it is imparted by blood to the kidneys wherever its release with urine. Height of serum urea observed in the present research in reaction to pesticides exposition may be explained by: 1) failure in its composition as a result of decline hepatic function, 2) disorder in protein metabolism as in the present results and 3) reduction in the filtering rate of the kidney. In this context, undue exposition to pesticides reasoned cytotoxic alteration in the hepatic and renal biochemical markings.

**Conclusion**

Through our serum liver enzymes biochemical tests studies we concluded that (N.sativa oil 2mg/kg) be able to Improvement of liver and kidney status through reduction of diazinon toxicity in male white rats.

**Conflict of Interest:** This research is a personal non-profit work and there is no conflict of interest.

Role of Serum Activin A and Granulocyte Macrophage-Colony Stimulating Factor in the Prediction of Pregnancy Outcome in PCOS and Non-PCOS Women Following ICSI

Saad S. Al-Dujaily¹, Nagham T. Shukry²

¹Biotechnology Research Center; ²High Institute of Infertility Diagnosis and ART, Al-Nahrain University, Baghdad, Iraq

ABSTRACT

Granulocyte macrophage-colony stimulating factor (GM-CSF) are a groups of glycoprotein growth factors, which are involved in the embryonic development and implantation process.

This study aimed to found out the role of serum activin A and G-CSF on the positive implantation leading to pregnancy outcome, in the PCOS and non-PCOS women following intra-cytoplasmic sperm injection.

In this study, eighty-eight women were enrolled and divided according to the cause of infertility, into 50 PCOS women, and 38 women diagnosed as non-PCOS, the selected women were undergoing ICSI. The activin A was measured in serum at the day of oocyte retrieval, and the GM-CSF was measured in the serum at the day of embryo transfer. All women participating in this study had the β-HCG test, 12-14 days after embryo transfer.

This study concluded that, serum activin A and GM-CSF levels are valuable in predicting pregnancy outcome in infertile PCOS women than non-PCOS women.

Keywords: Serum activin A, Granulocyte macrophage, Colony stimulating factor, Prediction of pregnancy outcome, PCOS, non-PCOS women, ICSI.

Introduction

Studies on the female reproductive tract show that the complicated physiological processes, like the menstrual cycle, ovulation, parturition, and implantation, are the hallmark of inflammation(1). The reproductive events lead to the up-regulation of the mediators (inflammatory), which includes the cytokines, growth factors, and lipid mediators inside the host. They act through direct effects on oocyte, embryo, and immune cells in the ovarian and uterine tissues, or an indirect effect through the immunological environment of oocytes production, implantation and embryo development(2). Activins have a wide range of action, which includes: Embryogenesis and its regulation, reproductive system development, healing of the wound, differentiation of the stem cell with the regulation of immune response(3). The activins directly stimulate follicular development in two manners: 1-Extra-ovarian effects, by FSH synthesis at the hypothesis. 2-Intra-ovarian autocrine signals by granulosa cells self-enhancing proliferation, with the up-regulation of aromatase enzyme and FSH receptors expressions in the cells within the dominant follicle(4,5). Activin A are playing a role in endometrial decidualization and in the priming of the endometrium, to prepare for implantation and enhance endometrial repair after menstruation(6).

Granulocyte macrophage-colony stimulating factor production and its receptors were confirmed in the reproductive tract of the females (7), and it has been studied frequently at the feto-maternal interface(8). GM-CSF is involved in the embryonic developmental process, by enhancing the growth and viability, through exerting positive effects on the various genetic paths, for example, cell proliferation, development to blastocyst, hatching of zona pellucida and embryonic implantation.

On the other hand, polycystic ovarian syndrome (PCOS), is one of the common causes of subfertility(9). It was first discovered by Stein and Leventhal in 1935(10). The main cause of PCOS remains unclear(11,12) and the prevalence of PCOS can be assessed, based on the
criteria used and population analysis between 6% and 25%(13,14). PCOS causes start with chronic inflammation of the ovary, which leads to changes in the endocrine and metabolism(15). The current study is designed to found out the role of serum activin A hormone and GM-CSF that correlate with successful embryonic implantation and pregnancy in PCOS women following ICSI outcome.

**Patients, Materials and Method**

The present study was performed on the randomized eighty-eight infertile women, who attended the High Institute of Infertility Diagnosis and Assisted Reproductive Technologies, Al-Nahrain University in Baghdad-Iraq through the period from November 2016 till April 2018. The women age that included in the study was ranged between (20-40) years old who complaining from primary and secondary subfertility for a period (1-17) years. Exclusion criteria were included: Endocrine abnormalities, congenital malformation, women with high FSH levels more than 12mIU/ml. The tubal blockage was excluded by hysterosalpingography (HSG). In addition to the examination of all women by pelvic ultrasound. Male partner was evaluated by the specialist in urology.

The 88 women were divided, according to the cause of infertility, into non-PCOS group, which included 38 normal women, and the cause of their subfertility is due to male factors. Second group was included 50 women with PCOS and their diagnosis depends on the at least two of three Rotterdam criteria (Rotterdam ESHRE/ASRMS sponsored PCOS consensus workshop group) (9). The ICSI procedure was done by the clinical embryologist as described by Neri, et al(16).

Embryo transfer usually was done by flexible catheter (Cook-Ireland Ltd) with the guide of abdominal ultrasound. The luteal phase was supported by using progesterone in the form of Actavis (Cyclogest, Barnstable, UK)* 200- 400 mg twice/day, which was given to all women from the day of ova pick up till β-HCG test (performed 12- 14 days post embryo transfer). Serum activin A was measured in both groups at the day of ova pick up and serum GM-CSF was measured at the day of embryo transfer. The obtained serum used to measure the levels of activin A and GM-CSF, by using Enzyme-Linked Immunosorbent Assay (ELISA) technique (Biotek, USA), by using diagnostic kit (Kono Biotech), which provides a quantitative determination of the human activin A and GM-CSF concentration in the serum.

**Statistical Analysis:** The statistical analysis system-IBM-SPSS version 24. The numeric variables expressed as the mean ± standard error (SE), and the nominal variables expressed as numbers and percentages. Comparison between variables was done by using the unpaired t-test and Fisher exact test. The differences between values were considered statistically significant at the level of (P<0.05), and a highly significant at the level of (P<0.001)(17).

**Results**

In the PCOS women the mean age was (31.58 ± 0.65) years old, their age were between 20 and 40 years, while for the non-PCOS group the mean age was (33.23 ± 0.91) years old, ranging between 21 and 40 years. The statistical analysis showed that there was no significant (P=0.134) difference in the mean age between PCOS group and non-PCOS group, as shown in table (1). Women were divided into those having primary infertility and secondary infertility. It was found that the number and percentage of women with primary infertility in the control group was 23 (61%) i.e. more than those of secondary 15(39%). On the other hand, the number and percentage in the PCOS women with primary infertility was 38 (76 %), i.e. more than the number and percentage of PCOS patients with secondary infertility 12(24 %). Thus, there was no significant (P=0.162) difference in the type of infertility between two groups. According to duration of infertility in this study the mean duration of infertility in PCOS group (6.97 ± 0.57) years, and the mean duration of infertility in non-PCOS group (6.23 ± 0.74)years. There was a no significant (P=0.428) difference between the two women groups

PCOS: Polycystic ovary syndrome; E2: estradiol; FSH: Follicular stimulating hormone, LH: Luteinizing hormone, *: Unpaired t-test
No significant (P=0.846) difference was encountered between non-PCOS and PCOS groups regarding the total mean of basal E2 for control (44.92 ± 2.08 pg/mL), and for PCOS group (44.34 ± 2.06 pg/mL). Furthermore, the total mean of basal FSH for non-PCOS group (6.41 ± 0.45 mIU/L), and (6.28 ± 0.30 mIU/L) for PCOS group, was shown no significant (P=0.807) difference between the two groups. There was a highly significant (P<0.001) differences in the level of basal LH and in the LH/FSH ratio, between the two groups, (Table 2).

In figure (1), the mean of the estradiol level on the day of hCG injection of non-PCOS group (1381.89 ± 106.26 pg/mL) was significantly (P=0.009) lower than that of E2 level in the PCOS group (1827.79 ± 121.87 pg/mL).

PCOS: polycystic ovary syndrome, GM-CSF: Granulocyte macrophage colony stimulating factor, *: Unpaired t-test
The biochemical pregnancy was positive in 27 (31%) out of 88 women participating in the present study. The number of pregnancy and the percentage was higher in PCOS than that of non-PCOS groups, 17 (34%) versus 10 (26%). However, there was no statistically significant (P=0.439) difference between the two groups as shown in figure (2).

Figure 2: Distribution of non-PCOS and PCOS women into pregnant and non-pregnant

Table (5), illustrates that the level of basal E2 and FSH was non-significantly (P>0.05) higher in pregnant women of the non-PCOS group compared to PCOS pregnant women. On the other hand, there was higher basal LH level and LH/FSH ratio in PCOS pregnant women, than pregnant women from non-PCOS group, and there was a significant (P<0.05) difference between two groups. The statistical analysis show no significant (P>0.05) differences between the level of serum activin A and GM-CSF in PCOS pregnant women compared to non-PCOS pregnant women.

Discussion

In the current study, the mean age of the whole females participating in the present study was (32.29 ± 0.55) years, and the mean age of the non-PCOS and PCOS women tends to be comparable to other studies which were done earlier (18,19). This may have resulted from the early marriage in Iraq (5). The result of present work noticed that the rate of primary infertility was more than the rate of secondary infertility in the females with or without PCOS. This finding may comparable to other studies which was dealing with the prevalence of the primary and the secondary infertility (12). The explanation is that the couples with the secondary subfertility have lower tendency toward having another child, probably because they have satisfied and economically stable, so the women with secondary subfertility, asking for the ART’s, will be much lesser than those women with primary subfertility fertility (17).
The current study revealed that the E2 level in the serum, at the day of hCG injection was more in the women with PCOS than in the non-PCOS women. Because in the PCOS females, there was a high degree of ovarian vascularization through the ovarian stimulation associated with vascular endothelial growth factor (VEGF) levels in the serum and in the FF. Moreover, the VEGF, causes enhancement of the proliferation and the function of granulosa cells. The granulosa cells of the women with PCOS were active functionally, with exaggeration of the estrogen hormone responses, to the stimulation by the FSH, when compared to the normal women, and it may be responsible for the increased risk of ovarian hyperstimulation syndrome in the PCOS women, stimulated by gonadotropin. The concentration of the estradiol was a good indicator of the follicular maturation.

The studies show conflicting results, in some of them consistent with the finding of this study, in that the serum E2 is significantly higher in the women with PCOS than in the control females. On the contrary to the results of the present study, several researches were demonstrating lower serum estradiol significantly in the PCOS females when compared to control females. Furthermore, other authors stated that there was no significant difference in mean serum estradiol E2 level between women with PCOS, and control women.

Regarding basal LH level and LH/FSH ratio, the present study shows that the women with PCOS have higher levels than that of non-PCOS, with a highly significant difference between them. In fact, in the PCOS women, there was a consistent elevation in the GnRH pulse frequency which causes an elevation in the LH pulse frequency and amplitude associated with normal or low secretion of the FSH which leads to an elevation in LH/FSH ratio. These results agreed with results obtained by Yins et al., who found that women with PCOS had significantly elevated LH, estradiol, and LH/FSH ratio compared with that in the control group.

Interestingly, some studies they found that the LH/FSH ratio did not significantly different between women with PCOS and normal women, thus they concluded that the LH/FSH ratio was a valuable test but not for PCOS diagnosis.

Influence of Perception about their Partners and Marital Status on Prevention of HIV AIDS Transmission among Papuan Women in Sorong City

Sariana Pangaribuan1, Chatarina Umbul Wahyuni2, Hari Basuki2, Ari Probandari3

1Student of Doctoral Program, 2Lecturer of Doctoral Program, Faculty of Public Health Universitas Airlangga, Surabaya, Indonesia; 3Lecturer of Doctoral Program, Faculty of Medicine Universitas Sebelas Maret, Surakarta, Indonesia

ABSTRACT

Introduction: HIV AIDS transmission among women continues to increase. Women’s vulnerability could be driven by gender inequality that leads to women are not able to control sex behavior of their partner and ensure that the practices are safe from HIV transmission. It aimed to analyze influence of marital status, perception about their partner and partner status on prevention of HIV AIDS transmission among Papuan women in Sorong city.

Method: It was analytical observational study with cross-sectional study design. Study population included Papuan women which had spouse, 350 women were involved as samples. Data were collected using questionnaire, analyzed with regression analysis and Chi-Square test.

Results: Majority (50.3%) of respondents lived with their spouse, 14.9% of respondents whose partner had other partner. Most of perceptions about partner were found at moderate levels (70.9%, respectively). Majority (67.4%) of respondents did not use any prevention of HIV AIDS transmission. Marital status ($p$ value = 0.001), partner status ($p$ value = 0.019), Perception about partner ($p$ value = 0.000).

Conclusions: Perception about partner, marital status and partner status had influence on prevention of HIV AIDS transmission among Papuan Women in Sorong city.

Keywords: Marital status, Perception, HIV and AIDS prevention

Introduction

HIV and AIDS transmission among women continues to increase from year to year. According to data from the World Health Organization (WHO), in 2015, 47.5% of people living with HIV and AIDS (PLWHA) were female.1 In addition, data from Ministry of the Health Republic of Indonesia has shown that in 2016, occupation, as a housewife ranked first in people with HIV and AIDS.2 Prevalence of HIV and AIDS in Papua based on behavior survey results in 2013, was 2.3% of general population.3 Besides, according to data from Sorong City Health Office in 2015, 40% of PLWA in Sorong city were housewife.4

Women’s vulnerability to HIV is mainly driven by gender inequality that leads to the inability of women to control the sexual behavior of their partner.5 Condom use as prevention of HIV transmission in Papua is low as only 26%.6 In sexual relation with their partner, women have lower bargaining power to negotiate safe sex practices, even though their partner is at very high risk of HIV transmission.7 The objective of this study was to analyze the influence of marital status, perception about partner and partner status on prevention of HIV and AIDS transmission among Papuan women in Sorong city.

Material and Method

This was an analytical observational study with a cross-sectional study design. The study population included Papuan women which had the spouse, with a total of 350 women were involved as samples. Multistage random sampling was used as a sampling technique, with inclusion criteria included woman aged 20-40 years and willing to study subject. Data were collected from January to April 2018 and analyzed using regression analysis and Chi-Square test.

Findings

Table 1 shows that majority (50.3%) of respondents lived together without any institutional bond by custom, religion, or civil. In addition, a majority (85.1%) of respondents had no other partner (single partner), but there were remaining 14.9% of respondents whose partner had another partner (multiple partners). Most of the perceptions about partner were found at moderate levels (70.9%, respectively). The majority (67.4%) of respondents did not use any prevention of HIV and AIDS transmission.

Bivariate analysis was used to analyze the correlation between marital status, partner status, perception about partner and prevention of HIV and AIDS transmission as presented in Table 2. Marital status, partner status, and perception about partner had a significant influence on the prevention of HIV and AIDS transmission. Preventive measure against HIV and AIDS transmission was done among 62.3% of cohabiting respondents. Over 78.9% of them had no other partner (single partner), and perception about partner were found at moderate levels (62.3%, respectively).

Discussion

In this present study, the majority of respondents did not do any preventive measure against HIV and AIDS transmission even though they were in cohabitation without any institutional bond, and thus there was still a chance of their partner easily leaving them and looking for another partner. It may be caused by lack of knowledge and awareness of the risk of contracting HIV and AIDS from their partner. Marital status significantly influenced preventive measure against HIV and AIDS transmission. Marital status plays a crucial role in the prevention of HIV and AIDS transmission, for without marriage bond between man and woman the household will be more fragile and vulnerable to separation.

Partner status significantly influenced preventive measure against HIV and AIDS transmission. Respondents whose partner had multiple partners were likely to do preventive measure against HIV and AIDS transmission compared to those with a single partner.

The women who are in relation with their partner will generate perceptions about their partner. These
perceptions are a complex process result from the relation with the partner. Perception about the partner is fundamental in building the relationship. Care and the trust-based relationship will shape a good perception. If a man recommends condom use in sexual relation with his partner, possibly he is unfaithful or he has been feeling suspicious of his partner being unfaithful. Condom use as prevention of HIV and AIDS transmission on women was found inconsistent, and women who use a condom were those who have thought that their partner was untrustworthy. Condom use of couple with a single sexual partner was found inconsistent because the perception that their sexual partner was at low risk of contracting HIV. Perceptions have the influence on preventive measures by using the condom and performing HIV/AIDS Voluntary Counselling and Testing (VCT).

Conclusion

Marital status had an influence on the prevention of HIV and AIDS transmission among Papuan women. Partner status had an influence on the prevention of HIV and AIDS transmission. Perception about partner had an influence on the prevention of HIV and AIDS transmission.

Using Random Amplified Polymorphic DNA (RAPD) Fingerprinting Technique to Analyze Genetic Variation in Staphylococcus Aureus Isolated from Different Sources in Babylon Province Hospitals

Shaima R. Banoon¹, Zahraa Kamil Kadhim², Zahid S. Aziz¹, Zahraa Isam Jameel¹, Ruqaya M.J. EWadh⁴

¹Biology Department, College of Science, University of Misan, Maysan, Iraq; ²Biology Department, College of Science, University of Kufa, Najaf, Iraq; ³The Islamic University, Babylon, Iraq; ⁴College of Pharmacy, University of Babylon, Babylon, Iraq

ABSTRACT

Genetic fingerprinting of 19 different isolates of Staphylococcus aureus from wounds, skin, nails and urinary tract infection taken from patients who admitted at AL-Hilla General Teaching Hospital and Babylon Hospital for Maternity and Pediatric, using random amplified polymorphic DNA (RAPD) was carried out. Two (OPY-07 and OPX-20) primers showed polymorphism among the isolates tested generating 12 bands, 8 of which were polymorphic with sizes ranging between 250 and 1 kb. All the isolates were classified completely into one major group with nineteen different subgroups. The nineteen different subgroups suggest adaptation of S. aureus in the different host cells. This indicates possible relationship between host origin and genetic variation among S. aureus isolates. The DNA fingerprint defined for each strain of S. aureus could be useful in epidemiological studies, medical diagnosis and the identification of new strains and their origins.

Keywords: Staphylococcus aureus, RAPD, PCR, Fingerprinting Technique, OPY-07 and OPX-20

Introduction

The major sources of S. aureus in hospitals are septic lesions and carriage sites of patients and personnel. Carriage often precedes infection. The principal mode of transmission is via transiently contaminated hands of hospital personnel. Airborne transmission seems important in the acquisition of nasal carriage [1]. S. aureus are Gram positive cocci in clusters belonging to Micrococaceae family. Staphylococcus aureus is an important agent of healthcare-associated and community-acquired infections; they cause a variety of superficial and deep infections [7]. They are frequently found as contaminants in clinical specimens taken from the body surfaces, for example, swab from skin, nose, throat, wounds, burns and bed-sores. Sometimes, acts as opportunistic pathogens and cause infections. The pathogenicity of S. aureus include, abscesses, boils, conjunctivitis especially in newborn, cross-infections in hospitals septicemia and food poisoning [2 & 17].

Staphylococcus pathogenic versatility is compounded by its ability to develop resistance to new antibiotics almost as fast as they are introduced and this consider a serious setback in many hospitals causing various hospital outbreaks has been reported in many studies[3]. However, nosocomial infections caused by S. aureus are clinically serious and control of such infections requires strain typing to identify degree of virulence, the source of contamination, and resistance to commonly used antibiotics. It is important in epidemiology and ecology to be able to identify bacterial species and strains accurately[18].

Rapid identification and classification of bacteria is normally carried out by morphology, nutritional requirements, antibiotic resistance, isoenzyme comparisons, phage sensitivity[19] and more recently by
DNA based methods, particularly rRNA sequences or rDNA \textsuperscript{[20]}, strain-specific fluorescent oligonucleotides \textsuperscript{[16]} and the polymerase chain reaction (PCR)\textsuperscript{[15]}. Each of these methods has specific applications and advantages. However, closely related isolates are difficult to identify and differentiate using the biochemical methods. For effective chemotherapeutic treatments of infections or disease caused by this organism, the degree of virulence of different strains needed to be determined\textsuperscript{[2]}.

The aim of this study is to carry out a genetic characterization of different isolates of \textit{S. aureus} from different sources in Babylon Province hospitals using random amplified polymorphic DNA polymerase chain reaction (RAPD-PCR). This RAPD procedure works with anonymous genomic markers requires only small amounts of DNA and when compared with the biochemical methods, are simpler, very sensitive, cheaper, faster and less labour intensive than other DNA maker methodologies.

Material and Method

Specimen Collection and the Identification of \textit{S. aureus}: Forty clinical samples were collected from wounds, skin, nails and urinary tract infection taken from patients who admitted to AL-Hilla General Teaching Hospital and Babylon Hospital for Maternity and Pediatric, during the period from October 2017 to the May 2018. Collected samples were serially diluted and spread on sterile Mannitol Salt Agar medium and incubated at 37\textdegree C for 24 hrs. Yellow color colonies obtained were screened for the conformation of \textit{S. aureus} by Gram staining, and biochemical (Mannitol fermentation and catalase) tests\textsuperscript{[14]}.

Isolates Propagation: About 200 µl \textit{S. aureus} isolate was transferred into 75 ml of nutrient broth (pH 7.5) in a 250 ml conical flask and kept under constant shaking at 37\textdegree C for 24 h. The bacterial cell was removed by centrifugation, washed with 0.1 mM Tris-EDTA and kept at -20\textdegree C for DNA extraction\textsuperscript{[13]}.

Genomic DNA Extraction: DNA of \textit{staphylococcus aureus} isolates was extracted and purified according to Geneaid protocol of presto™ Mini gDNA Bacteria Kit, Taiwan. Concentration of DNA was determined spectrophotometrically (NanoDrop) by measuring its optical density at 260 nm the purity of DNA solution is indicated by ratio of OD260/OD280 which is in the range of 1.8 ± 0.2 for pure DNA\textsuperscript{[11]}. Gel electrophoresis was used for detection of DNA by UV transilluminator (Cleaver, UK)\textsuperscript{[9]}.

RAPD-PCR amplification: RAPD analysis was according \textsuperscript{[9]}, each isolate was tested with Two arbitrary or random primers as described in [Table -1]\textsuperscript{[18]} were primers synthesized by BioNEER, Korea. The DNA amplification reaction was carried out in a 25\textmu l volume containing 5\textmu l DNA, 12.5\textmu l GoTaq® Green Master Mix (Promega), 2.5\textmu l of primer (10 pMol), and 10\textmu l of nuclease free water; A single primer was used in each reaction. Amplification was carried out in thermal cycler (Eppendorf) which was conducted as in [Table-2]\textsuperscript{[18]} with a little modification.

The amplification products were resolved by electrophoresis in a 1.2% agarose gel using TBE buffer 1X (at 70 V for 2 h.) A 1 kb ladder (Promega, USA) was included as molecular size marker. Gels were visualized by staining...
with ethidium bromide solution (0.5 µg/ml) and banding patterns were photographed over UV light using Gel documentation [9].

**Phylogenetic Analysis:** Positions of unequivocally scorable RAPD bands were transformed into a binary character matrix (“1” for the presence and “0” for the absence of a band at a particular position). Phylogenetic tree was created by the unweighted pair-group method arithmetic (UPGMA) average cluster analysis [6].

---

**Results and Discussion**

**Identification of S. aureus:** A total 40 clinical samples were collected from patients who admitted at AL-Hilla General Teaching and Babylon Hospital for Maternity and Pediatric hospitals. The result has been show 19 isolates as *S. aureus*.

**RAPD analysis of staphylococcus aureus:** Polymorphism assay for *Staphylococcus aureus* isolates was carried out using two primers (OPY-07 and OPX-20); as shown in (figure 1 and 2) respectively.

---

**Figure 1:** RAPD-PCR using the primer OPY-07. [M Line (Marker), (1-19) the isolates numbered]

**Figure 2:** RAPD-PCR using the primer OPX-20[M Line (Marker), the (1-19) isolates numbered]

---

**Genetic characterization of S. aureus isolates by RAPD analysis:** Two primers (OPY-07, OPX-20) showed polymorphisms among individuals; The amplification reactions with the 2 primers generated 12 bands, 8 of them being polymorphic (Table 1) with ranging between 250bp and 1 Kb detected among the 19 *S. aureus* isolates and each of primer give different genetic profiles (figure 1 and 2).

Using 8 RAPD markers to construct phylogenetic relationship among 19 *S. aureus* isolates with OPY-07 led to classification into one major group while thirteen different subgroups were obtained at 100% similarity coefficient; in these subgroups strain with closed related and divergence as shown (Figure 3).
Figure 3: Dendogram analysis showing phylogenetic diversity of 19 Staphylococcus isolates identified by RAPD markers

As with OPX-20 led to classification into one major group while ten different subgroups were obtained at 100% similarity coefficient; in these subgroups strain with closed related and divergence as shown (Figure 4).

Figure 4: Dendogram analysis showing phylogenetic diversity of 19 Staphylococcus isolates identified by RAPD markers

While phylogenetic relationship among 19 S. aureus isolates with (OPY-07, OPX-20) led to classification into one major group while nineteen different subgroups were obtained at 100% similarity coefficient (Figure 5). This level of clustering was based on the origin of S. aureus strains.

Figure 5: Dendogram analysis showing phylogenetic diversity of 19 Staphylococcus isolates identified by RAPD markers using OPX-20, OPY-07.
Genetic fingerprinting and phylogenetic diversity between different S. aureus isolates were determined by converting RAPD data into a Jaccard similarity matrix and analyzed by UPGMA to produce a phylogenetic tree. The DNA band pattern obtained is similar to a bar code, allowing the identification of each individual. For instance, isolate Staph14 and Staph15 presents unique bands when its DNA amplified with OPX-20 primer tested (Figure 2). In the same way isolate Staph1 and 9 with OPY-07 primer (Figure. 1). These bands could be used to characterize and identify it. All the isolates were classified completely into one major group with nineteen subgroups. However, the nineteen different subgroups obtained in this study suggests possible and frequent occurrence of mutants in S. aureus in different host cells. Previously, S. aureus has been described as a variable bacterium with many pathogenic and antibiotic resistance variants [17]. The restricted number of cultural and morphological characters of S. aureus, and the lack of standardization of cultural conditions and virulence tests among different investigator have led to confusion in the characterization of this pathogen, special phenotypes usually consist of isolates that are genetically less related and such identification of isolates using biochemical, cultural and morphological techniques often lack consistency and accuracy [5]. In the current study, we have found that identification of genetic diversity in S. aureus depends on sources of isolates, different host cells and occurrence of mutants and that agree other studies [10].

Beside, the possible and frequent occurrence of mutants in S. aureus constitutes the broad genetic variation that exists within Staph1 to Staph19 genotypes (figure 5). RAPD markers exposed possible relationship between host origin, mutation and genetic variation among S. aureus isolates, and this proved its fingerprinting and diagnostic potential. Obviously, for these DNA bands patterns to have a practical meaning in the areas of medicine, population biology and epidemiology, specific DNA bands must be related to host origins, mutation and virulence genes [4].

This could be by a systematic comparison of DNA band patterns among bacteria comparing for the different host origins, mutation and virulence genes present. The DNA fingerprint defined for each strain of S. aureus should be useful for epidemiological surveys, medical diagnoses, and in the identification of new virulent strains and their origin. Furthermore, RAPD-PCR could be used to track the paths of transmission, which could be used in controlling the spread of strains within hospital, and between the hospitals, and especially preventing the nosocomial infections caused by the multi-drug resistant MRSA [12].

**Conclusion**

Random amplification of the DNA of S. aureus isolates reveals the efficacy of these selected nucleotides sequences in determination the similarity or variations among all isolates.

Effect of Using Distal Extension Bar on the Posterior Ridge Area in Implant Supported Mandibular Overdentures

Sherif M. Abdel Hamid, Ahmed G. Hamzawi, Emad M. Agamy, Gehan F. Mohamed

1Lecturer, Prosthodontics, Faculty of Dentistry, Pharos University, Alex, Egypt; 2Associate Professor, Prosthodontics, Faculty of Dentistry, Minia University, Minia, Egypt

ABSTRACT

Bone resorption of the posterior ridge area considered as a major problem due to overdenture rotation during function.

The aim of this study was to compare the effect of using a distal extension bar in two implant supported mandibular overdentures on the posterior ridge area in two groups of completely edentulous patients receiving two implants in the mandibular canine region.

Twelve completely edentulous patients were assigned randomly into two equal groups, group I patients received an implant supported overdenture with metallic bar attachment with bilateral posterior extension, in group II patients received an implant supported overdenture with metallic bar attachment with no posterior extension. Posterior ridge resorption was measured radiographically.

Results showed non-significant decrease in the posterior ridge resorption between the two groups.

Conclusion bars with distal extensions showed non-significant decrease in the posterior ridge resorption than bars with no distal extension.

Keywords: implant overdenture, distal extension bar, overdenture rotation.

Introduction

Today, restoring the edentulous patient with an overdenture on 2 splinted or un-splinted implants may be considered the state of the art (1,2)

Overtures considered as an ideal treatment option for edentulous patients as they are simple, cost effective, viable, and less invasive, however, controversies toward the design of attachment systems exist (3-5).

The design of attachments used with implant supported overdentures should provide equal implant-tissue support and optimum distribution of the forces around the implants to allow loading within physiologic levels of the bone (6, 7).

Bar retained implant overdentures exhibit high survival rates and low incidence of technical complication for both implant and prosthesis, so they are considered as an adequate treatment option for edentulism (6).

Splinting of implants together was an ideal option to reduce the risk of overload to implant supported overdentures due to obtaining a greater surface area and sharing the load between them (9, 10). However the overdenture rotation during function leads to bone resorption in the posterior ridge areas (11-14).

The use of long-bar overdentures supported by interforaminal implants have been suggested to provide effective support for implant overdentures and minimize their rotation during function (15).

Connecting implants with distal extension bar may decrease the overdenture rotation during function, enhance the denture support, improve chewing, and reduce loading of denture-bearing areas (16-18). Distal extension design increase prosthesis rigidity, retention, improves denture stability, and affords a more conservative surgical and economic treatment. Moreover,
the supporting area of bars with distal extension was found to be larger than those without distal extensions (6).

**Aim of the Study:** The aim of this study was to compare the effect of using a distal extension bar in two implant supported mandibular overdentures on the posterior ridge area in two groups of completely edentulous patients receiving two implants in the mandibular canine region.

In the first group patients received an implant supported and retained overdenture with metallic bar attachment with bilateral posterior extension, in the second group patients received an implant supported and retained overdenture with metallic bar attachment with no posterior extension.

**Materials and Method**

**Patient Selection:** For the present study twelve healthy completely edentulous patients were selected from the outpatient clinic of the prosthodontics department, Faculty of Dentistry, Minia University, with their ages ranged from 50-70 years.

Patients were included in this study provided that they had the subsequent inclusion criteria: Adequate residual alveolar bone quantity and quality anterior to the mental foramen, U-shaped lower ridge to evade the lingual placement of the bar that arises with v-shaped ridges, appropriate Interarch distance to receive overdentures and attachments, Angle’s class I maxilla-mandibular relationship.

Patients were omitted if they had one of the following TMJ or neuromuscular complaints, Abnormal habits, (e.g. bruxism, clenching, smoking and alcoholism). Bone metabolic disorders (e.g. Diabetes), Past radiation therapy in the head and neck region

**Surgical and prosthetic procedure:** A new set of upper and lower complete dentures had been constructed for each patient using the conventional methods.

The denture of each patient was marked by guttapurcha then scanned by the CBCT machine.

Patients were scanned by the CBCT machine (SOREDEX 3DX, Nahkelantie 160, Tuusula. P.O. Box 148, FI-04301 Tuusula. Finland) while they wearing their dentures.

A customized surgical guide was fabricated for each patient, via CAD/CAM technology through the data attained from the cone-beam CT (CBCT).

Taken images by CBCT were introduced into a viewing software then sent for fabrication of the guide as follows

The patients’ scans were opened in blue sky bio software. Blue Sky Bio opens DICOM data directly from the CBCT machine, The Denture scan and patient’s CBCT were superimposed over each other by placing exact dots on the gutta percha markers, to ensure that both scans are accurately superimposed over each other.
lateral cylinders were obtained in each guide to allow the placement of anchor pins for guide fixation.

![Fig. 4: fabricated surgical guide](image)

Two root-form endosseous implants were placed at the canine areas in the mandibular of each patient as follows

Three holes were prepared in the mandible, through the available lateral cylinders of the guides to receive anchor pins for guide fixation.

Osteotomy preparations were prepared at the planned implants sites bilaterally using serial drills to the appropriate depth of the drills. Drills were operated via specific removable sleeves designed to match the drills sizes (OXY implant. Via Nazionale Nord, 21A, 23823 Colico LC, Italy).

After completing the osteotomy preparations and removal of the guide, implants were placed as decided. All implants were of the same length (13 mm) and the same diameter (3.5 mm). (Oxy implant. Via Nazionale Nord, 21A, 23823 Colico LC, Italy)

The fitting surface of the denture was adjusted opposite to the implant positions to accommodate the implant heads, a tissue conditioning material (Alpha dental products Co., subsidiary of Wallace A. Erickson&Co. 1920N. Clybourn Ave., Chicago, IL 60614, USA) was used to reline the denture fitting surface to avoid tissue irritation or implant overloading.

Patients were assigned randomly into two groups: 

**group 1** received Co-Cr metallic bar joint with bilateral distal extensions 7mm **group 2** received Co-Cr metallic bar joint with no distal extensions

After 3 months of implant placement, healing abutments were positioned for two weeks, then two plastic bar abutments were attached to the implant heads with fixation screws, A plastic bar (bar joint design) was positioned between the two copings and its required length was adjusted, leaving 2-mm clearance space beneath the bar for oral hygiene measures.

A prefabricated plastic pattern of the bar was lute to the plastic extensions of the bar abutments using a self-cured acrylic resin (Duralay, Reliance Dental Manufacturing Co., Chicago, USA.). For **group 1**, two plastic distal extensions (7 mm in length) were luted to the plastic bar abutments and oriented along the crest of the ridge. In **group 2**, no distal extensions were used.

![Fig. 5: bar with distal extension](image)

![Fig. 6: bar with no distal extension](image)

Both plastic patterns were cast as one piece into cobalt chromium alloy (Niadure, DFS Diamon, Germany) according to the commonly used casting technique. The bar was then finished, tried in the patient mouth and then polished

The bar copings complex over the implants was checked for passive fitness by the tactile sense when tightening the screws in place without any resistance.

The clinical pick-up procedure was done in the same manner for both groups, nylon clip was secured in place on top of the bar, no clips were placed over the cantilever, The undercuts beneath the bar and copings was blocked out using smooth casting wax (Glattes Gusswaches, Smooth casting wax 0.3mm.,Ref. no.40092,BEGO,Germany).
The fitting surface of the denture's opposing to the bar was modified to allow complete seating without interference. By creating a small window at the lingual flange opposite to the bar and sleeve attachment to escape the excess pick-up material.

The denture placed in the patient mouth and the patient was asked to close in centric relation and maintain maximum biting for the period of setting of the rebase material (Tokuyama Rebase II fast, Tokuyama Dental Corporation, Japan).

**Assessment of Posterior Ridge Area:** The assessment was based on the panoramic radiographs that are routinely taken at intervals during treatment. Radiographs used in this study were those taken shortly after 6 months and the most 12 months. This method is similar to that used by Wright et al. 2002\(^{(19)}\) using proportions that minimize errors related to magnification and distortion.

The anatomical landmarks: M (lower border of mental foramen), S (sigmoid notch), and G (gonion). These 3 landmarks were used to construct the triangles on the right side (M-S-G) and left side (M”-S”-G”) of the mandible. Point (N) is the center of the triangle if line was drawn from each corner (or vertex) of a triangle to the midpoint of the opposite sides, then those 3 lines meet at a center of the triangle.

Boundaries were constructed by the following lines: The boundary line M-G, the boundary line A-L: A line from the crest of residual ridge (point A) to the lower border of the mandible (point L) through M perpendicular on M-G, the boundary line M-N, and the boundary line G-P: the line G-N extended to the crest of the residual ridge through point P. The experimental bone area was eventually outlined by the area PAMG and the reference area by the triangle MGN (Fig 5).

![Fig. 7: assessment of posterior ridge resorption on panoramic radiograph](image)

The posterior ridge ratio was calculated by dividing the bone area over the reference area. Moreover, the ratios for the right and left part in each patient were averaged to get the mean. The change in posterior mandibular ridge ratio was calculated in the 1st interval by subtracting (the ridge ratio at 6 months - the ratio at the loading time) and the 2nd interval by subtracting (the ridge ratio at 12 months - the ratio at the loading time).

### Results

For both groups, the posterior alveolar ridge resorption was recorded at the right and left sides of each patient radiographically using panoramic X-ray, at different follow-up intervals, the first interval from implant insertion-implant loading, the second interval from implant insertion-6 months, the last interval from implant insertion-12 months.

### Discussion

Results of posterior ridge areas showed posterior mandibular bone resorption in both groups, this may be due to the built-in possibility of rotation of two-implant-retained overdentures which cause unfavorable distribution of occlusal load to the posterior mandibular ridge\(^{(13)}\).
When the mucosa beneath the denture base is compacted, the blood flow that delivers nutrients and removes metabolites from the bone can be affected, potentially leading to resorption \(^{20}\).

Statistical analysis showed non-significant decrease in posterior mandibular bone resorption between group I (Bar with no distal extension) and group II (Bar with no distal extension). This was in agreement with the results of several studies \(^{14,21,22}\).

The reduced resorption rates in group I (Bar with distal extension) could be due to the direct denture base acrylic contact with the healing abutments, which provides effective support and prevents denture base rotation. The posterior ridge may be protected from excessive loading, with most of the load being transmitted vertically to the implants \(^{23}\).

The reduced posterior ridge resorption when age increases is in agreement with the results of other studies \(^{11,21}\) and may be attributed to the fact that, by increase of age, the quantity of the alveolar bone decreases due to continuous resorption and most of the remaining bone is compact and resistant to resorption. Each 1 mm increase in the initial height of the mandible caused a 1.1% increase in posterior ridge resorption. This may be due to the presence of alveolar bone, which is more liable to resorption \(^{14}\).

**Conclusion**

Within the limitation of this study, it could be concluded that in two implant support mandibular overdentures bars with distal extensions showed non-significant decrease in the posterior ridge resorption than bars with no distal extension.

Salivary and Seral Sex Hormones in Relation with Periodontal Problems

Sulafa Khair Al-Deen Banoosh¹

¹B.D.S. M.S.c Lecturer, Department of Basic Sciences, College of Dentistry, University of Tirit, Iraq

ABSTRAcT

The aim of this study to find any differences in the level of sex hormones in saliva and serum and any relations of these hormones with the periodontal tissues status.

Material and Method: This study consist of (40 female and 40 males), blood and salivary samples were taken from young healthy students, their ages(18-24) years. The salivary samples collected according to special constructions, the blood and salivary samples were collected at the same time from the same subjects in the morning at 8:00-10:00AM. The samples were dated and freeze until the time of analysis, the samples were collected from all females during the follicular phase of the menstrual cycles. Oral examinations done by using plane dental mirror and explorer. Any signs and symptoms for gingivitis or periodontitis recorded as study cases.

Results: The results of this study shown that there were appositive correlation between the serum and salivary sex hormones levels. Also there was a significant differences in the levels of the testosterone hormones for female in study group (periodontal problems) when compared with control group.

Conclusion: Periodontal problems could be caused by many factors some are locally others are systemically or could be genetic, in this study no hormonal effects noted and any increased could be due to the treated effects of the hormone for treat the inflammatory conditions. These facts need more researches to be improved.

Keywords: sex hormones, periodontal problems, gingivitis, periodontitis, saliva

Introduction

Hormones are definite as regulatory molecules that adjust reproduction, growth and development, continuance of the inner environment, in addition to energy production, operation, and storage[1], the hormonal effects be a sign of physiological/pathological changes just about every types of tissues in the body. Targets for many hormones like androgens, estrogen, and progesterone have also been found in periodontal [2], as a result, systemic endocrines imbalances might had a significant impact in periodontal pathogenesis.

Periodontal diseases (gingivitis and periodontitis), are two most important types of inflammatory disease attack the periodontium [3]. Gingivitis can be defined as an inflammation of gingival tissues that not caused clinical attachment loss [4]. The homeostasis of the periodontium include compound factors interaction, in which the endocrine system acting significant function [5]. Researchers have shown that any changes in the periodontal situation may be related to variations in the levels of sex hormones. This relations is clear in the recent periodontal diseases categories [6], which includes the follow hormone -related diseases categories: puberty- linked gingivitis, menstrual cycle-related gingivitis and pregnancy – related gingivitis [7]. Estrogen and progesterone are responsible for physiological changes in ladies at particular periods of their life. The two hormones have important natural activities that can influence many organs systems as well as the oral cavity. Estrogen receptors find in osteoblast-
like cells give a mechanism for the activity on bone, these receptors were additionally situated in periosteal fibroblasts, scattered fibroblasts of the lamina propria and periodontal ligament fibroblasts, demonstrating the activity of sex hormones on various periodontal tissues. Progesterone epidemiologic, experimentally, and clinically information have established that its activity in the bone metabolism and can be important in the role of combination of the bone resorption and bone formation \(^8\). Androgens hormones are responsible for normal spermatogenesis and are concerned for the improvement the secondary sexual characters in male puberty, testosterone receptors are find in the periodontal tissues and the count of these receptors on the fibroblasts tends to increase the inflammation or overgrowth of the gingival, the testosterone have an effect on periodontal tissues by increase the matrix synthesis \(^9\). The aim of this study to find any differences in the level of sex hormones in saliva and serum and any relations of these hormones with the periodontal tissue’s status.

Materials and Method

This study started from December 2017-february 2018 which consist of (40 female and 40 males), their ages (18-24) years. Blood and salivary samples were taken from young healthy students who normally looked with no personal or family history for any diseases. Oral examinations done by using plane dental mirror and explorer. Any signs and symptoms for gingivitis or periodontitis recorded as study cases. The salivary samples collected by asking the subjects to spit the saliva in the graduated tube according to the construction of Tenvuo and Lagerlof\(^9\), the blood and salivary samples were collected at the same time from the same subjects in the morning at 8:00-10:00AM and dated, freeze until the time of analysis, the samples were collected from all females during the follicular phase of the menstrual cycles. Serum and salivary sex hormones (testosterone, progesterone, and estrogen) were determined by using AccuBind ELISA Microwells (competitive enzyme immunoassay kit) (Monobind Inc., USA). The statistical tests that were used in this study was paired t-test for comparison, the level of significance was accepted at P< 0.05, and highly significance when P< 0.001.

Results

Table (1) Shows the means and standard deviation of the sex hormones (testosterone, estrogen, and progesterone) in serum for control and study groups and the (t) test and p-value between them. statistically no significant differences between them.

**Discussion**

In this study there were appositive correlation between the concentration of sex hormones in saliva and serum for both groups (control and study) these results make saliva more acceptable for monitor the biomarkers than that done by other biological fluids like serum or urine because the sample of saliva is non-invasive, and can collected from special peoples (infants, children) and many other conditions in which the blood or the urine samples is not viable [10]. this results similar to the results found by (Zahim, jameel 2014) [11]. Also in this study there were no clear results about the concentration
of the sex hormones in the study group when compared with control group only a significant differences in the concentration of the testosterone hormone in the female in study group this could be due to the effect of testosterone in periodontal tissues which are:

1. Inhibit prostaglandin secretion[11]
2. Enhance osteoblast proliferation and differentiation[12]
3. Reduce IL-6 production during inflammation[13]
4. Enhance matrix synthesis by periodontal ligament fibroblasts and osteoblasts [3].

That could make the concentration of the hormone increase to overcome the inflammation in these tissues. This results similar to the result by (Eleni, et al) [14] who conclude that the androgen hormone may alter periodontal tissues responses to microbial plaque and thus indirectly contribute to periodontal disease, and (Elizabeth, et al.) [2] who found that testosterone hormone act as immunosuppressor that decrease the immunity therefore male more expected to infection than female. It’s important to understand that female have periodontal problems due to the fluctuations of sex hormones in various decades of life. One must remember the differences in the outcome among studies could be attributed to contrasts in symptomatic criteria used, size of the samples, contrasts in biochemical systems procedures, even differences in statistical methods and difference in the method for salivation collections (stimulated or un stimulated), in additions to contrasts in inclusion criteria used for choice of ladies.

Conclusion

Sex hormones consider a serious part in influencing periodontal problems development. These properties are varied depending upon the gender and in addition the life time periods. It is additionally that not all patients and their periodontal tissues react similarly to similar amounts of sexual hormones. also, the sex hormones can be limited its effect by plaque control and maintains good oral hygiene.

Effectiveness of Soursop Leaf Extracts on Decreasing Blood Sugar for Type-2 Diabetes Mellitus Patients

Ta’adi¹, Mardi Hartono¹, Sunarto¹, Choiroel Anwar²

¹Lecturer of Nursing Study Program, Ministry of Health Polytechnic Semarang, Indonesia; ²Lecturer of Ministry of Health Polytechnic Semarang, Indonesia

ABSTRACT

Background: Lately, the treatment of diabetes mellitus, which is often carried out by the community is eating herbal plants, one of which is soursop leaves, which are believed to be able to reduce blood sugar levels. The objective of this research is to determine the effectiveness of soursop leaf extract in reducing blood sugar levels in type-2 diabetes mellitus patients.

Method: This study is quasi-experiment randomized with pre-test - post-test control group design in 32 types two patients treated in Pekalongan city health center area. The blood sugar level of the treatment group was measured after administration of 500 mg soursop leaf extract, three times a day within one week (65 mg extract of soursop leaves in 500 mg).

Results: There was an effect of soursop leaf extract on blood sugar although not statistically significant (p = 0.957). Also there was the effect of soursop leaf extract on fasting blood sugar, although it was not statistically significant (p = 0.770) and there was an effect of soursop leaf extract on postprandial blood sugar although it was not statistically significant (p = 952).

Conclusion: There was the effect of soursop leaf extract on reducing blood sugar levels (fasting and postprandial) even though it was not statistically significant.

Keywords: Soursop leaf extract, Blood sugar, Type-2 diabetes mellitus

Introduction

The increasing number of patients with diabetes mellitus (DM) mostly types two diabetes mellitus with several risk factors, including risk factors that cannot be changed and risk factors that can be changed. Unchangeable risk factors include a family history of diabetes mellitus: over 45 years of age, ethnicity, childbirth with birth weight above 4 kg and less than 2.5 kg. The risk factors that can be changed include obesity, physical activity, hypertension, dyslipidemia, and unhealthy (1).

Management with insulin (especially injection) is still quite expensive and with some side effects of oral hypoglycemic drugs. This experience makes the control of diabetes Mellitus switch to herbal treatments, namely soursop leaves (Annona muricata). This relates to the ease of these materials to find as well as the secondary metabolic content of soursop leaves which is useful in decreasing blood sugar levels, such as flavonoids and tannins. Compounds flavonoids and tannin have hypoglycemic effects by several mechanisms, namely by inhibiting glucose absorption, stimulating insulin release, increasing glucose uptake by peripheral tissues, and regulating enzymes that play a role in carbohydrate metabolism.

All parts of the soursop tree can be used as traditional medicines against various human diseases. The fruit can be used as a natural remedy for rheumatic pain, neuralgia, arthritis, diarrhea, dysentery, fever, malaria, parasites, rheumatism, and rushing skin as well as to increase the production of breast milk after childbirth. The leaves are used to treat cystitis, diabetes, headaches,
and insomnia. Also, soursop leaf extract (Annona muricata) has the potential as an agent for the treatment of hyperglycemia.

The leaf decoction is believed to show anti-rheumatic and neuralgic effects, while topically cooked leaves are used to treat abscesses and rheumatism. In a previous study, soursop leaves with a given dose of hypoglycemic impact were thought to be caused by flavonoids, which stimulated insulin secretion, increased repair or proliferation of β-cells and increased effects of insulin.

**Method**

This study used a quasi-experimental design randomized with pre and post-test control group design. Several samples fulfilling the requirements were randomly allocated with the proportion half of the samples was treatment group and another half as control group.

Descriptive data analysis was indicated by the mean or proportion and standard deviation of blood sugar levels, occupation, gender, age, genetic history. To prove the effect of soursop leaf extract on blood sugar levels in patients with type 2 diabetes mellitus, repeated measure of ANOVA at α = 0.05 was applied.

**Results**

This study was conducted in 4 (four) medical center areas in Pekalongan city. As stated in the following table - each medical center area was taken 4 samples into treatments and 4 samples as controls. Respondent characters describe on the table below.

**Discussion**

The effect of soursop leaf extract on blood sugar when, after being controlled by sex, age, genetic history of diabetes mellitus, and work status, shows that in the treatment group initially had an average blood sugar at 254.6 which was slightly higher than in the control group i.e. 253.97 after being given soursop leaf extract with a
dose of 3 x 500 mg/day for 6 days, in the treatment group experienced a decrease in sugar blood when lowered to 234.99 compared to the control group only dropped to 239.51. A reduction in blood sugar when lower in the treatment group showed that soursop leaf extract drinks affected lowering blood sugar while even though it was not statistically significant (p = 0.957). The small influence is influenced by various factors, including those related to the type of food (carbohydrate intake) of the respondents who in this study were not rigidly regulated; time of taking blood samples with the distance between meals, and activities of respondents after eating.

The effect of soursop leaves on fasting blood sugar, after being controlled by sex, age, genetic history of diabetes mellitus, and work status; shows that in the treatment group initially had an average fasting blood sugar 179.48 which was slightly higher than in the control group ie 175.52, after being given soursop leaf extract with a dose of 3 x 500 mg/day for 6 days, the treatment group decreased fasting blood sugar becomes 155.95, while in the control group it drops to 145.11. The decrease in fasting blood sugar in the treatment group showed that soursop leaf extract affected reducing fasting blood sugar even though it was not statistically significant (p = 0.770). The small influence is influenced by various factors, including the type of food intake consumed at dawn and the activities of spatial respondents.

The effect of soursop leaf extract on blood sugar 2 hours after meals, after being controlled by gender, age, genetic history of diabetes mellitus, and work status; shows that in the treatment group that initially had an average fasting blood sugar 251.11. The lowering of blood sugar when more economical in the treatment group showed that soursop leaf extract affected reducing blood sugar while even though it was not statistically significant (p = 0.0001). The small influence is influenced by various factors, one of which is the primary type of carbohydrate intake consumed.

The content of lactose additives 25% affects blood sugar levels, although this lactose additive cannot be avoided because it is an absolute requirement to make extracts in capsule form with a function to minimize unpleasant odors and prevent the solids from becoming sticky. Even in establishing several other extracts, the levels of lactose can reach 65%, meaning that the lactose additives in the soursop leaf extract are the minimum limits (3).

The results of the previous study showed that high glucose levels in diabetes mellitus triggered oxidative stress characterized by an imbalance between the amount of free radicals and antioxidants. Previous research on effective soursop and moringa extract in its single form were able to reduce blood sugar levels accompanied by the ability to reduce the impact of oxidative stress. 36 animals were divided into 6 groups: normal group (aquades), negative control (cmc na 0.5%), positive control (glibenclamide dose 1.26 mg/kg bw), soursop extract 100 mg/kg bw, moringa extract dose 200 mg/kg bb and combination i (75:25), ii (50:50) and iii (25:75) in percent. All groups of test animals, except the normal group, were induced by alloxan at a dose of 160mg/kgbb on day 0, followed by treatment of test animals from day 1 to day 14. On the last day, the test animals were sacrificed to take the liver organs and measured oxidative stress levels, including lipid peroxidase and glutathione. The use of single and combination moringa and soursop leaf extracts was able to reduce oxidative stress, which was marked by the decrease in LPO levels and significantly increased gsh levels. (p<0.05). Optimal activity on 50:50 moringa soursop combination. This combination gives better results than the single form (4).

Based on the results of the study with the theme of blood glucose levels before and after administration of extract of starfruit leaves and soursop leaves in patients with diabetes mellitus, obtained and analyzed by paired t-test with confidence interval of the difference 95%obtained a significant value = 0.000 means p <0.05, then h1 was accepted which showed a significant difference between blood glucose levels in patients with diabetes mellitus before and after administration of soursop leaf extract (5).

In a study entitled the effect of soursop leaf extract (Annona muricata), On decreasing blood glucose levels, it was explained that flavonoid is having a hypoglycemic impact with several mechanisms namely by inhibiting glucose absorption, increasing glucose tolerance, stimulates insulin release or acts like insulin, increases glucose uptake by peripheral tissue and regulates
enzymes that play a role in carbohydrate metabolism\(^{(4)}\). Other studies more specifically mention that quercetin compounds, one type of flavonoid from subclass flavonol, have the potential as a hypoglycemic agent through a mechanism inhibition of the alpha-amylase enzyme that plays a role in the breakdown of carbohydrates. In vitro research also shows that quercetin has the potential as an inhibitor of glucose transport by intestinal glut2 and glut5, which is responsible for glucose absorption in the small intestine. This is what causes quercetin to reduce glucose levels in the blood\(^{(6)}\). Tanin can lower blood glucose levels by increasing glucose uptake through activation of MAPK (Mitogen-Activated Protein Kinase) and PI3K (phosphoinositide 3-kinase). The hydrolyzed tannin is divided into gallotannic and ellagitannin. Gallatin can increase glucose uptake while inhibiting adipogenesis. Ellagitannin derivatives, on the other hand, namely lagerstroemin, flosin b, and reginin have properties similar to the hormone insulin (insulin-like compound). These three compounds can increase glucose transport activity in adipose cells in vitro\(^{(7)}\).

On blood sugar levels of alloxan-induced Wistar (Rattus norvegicus) rats, it was concluded that soursop leaf extract at a dose of 5000 mg/kg bb rats had the effect of lowering blood sugar levels in wistar rats higher than soursop leaf extract dose of 1000 mg/kg bb rats and 2000 mg/kg bb rats measured at 30, 60, 90 and 120 minute minutes. Further research with variations in dosage and determination of the active ingredients contained in soursop leaves need to be done\(^{(8)}\).

As with the study of the effect of ethanol extract of soursop leaves (Annona muricata) On blood glucose levels and liver histology in alloxan-induced diabetic mice (Mus musculus) Using a completely randomized design with five treatments and five replications. The treatment consisted of negative controls (without treatment), positive controls (injected with alloxan as much as 100 mg/kg bw), and treatment of soursop leaf extract with a multilevel dose of 50 mg/kg, 100 mg/kg bw, 150 mg/kg every day for 21 days. The results showed that administration of soursop leaf ethanol extract was able to increase the body weight of mice (p <0.05) at a dose of 50 mg/kg bw per day. Ethanol extract of soursop leaves caused a decrease in blood sugar levels (p <0.05) and improvement in liver histology\(^{(9)}\).

Experiments in the study treated the concentrated extract of soursop leaves for two weeks in hyperglycemic Wistar rats, decreased glucose levels, 8-ohdg levels, and ages levels. 2. The lowest levels of glucose, 8-ohdg and ages occurred in treatment p3 (dose of 150 mg/bb/day) with levels of 137 mg/dl, 1.664ng/l and 0.033 mol/dl respectively. The finding is another alternative of treatment besides natural treatment like walking\(^{(10)}\).

**Conclusion**

There is an influence of the administration of soursop leaf extract on decreasing blood sugar levels, fasting blood sugar, postprandial blood sugar, which is controlled by gender, age, occupation, and genetic history even though it is not statistically significant.

**Ethical Clearance:** Ethical clearance was obtained from the Semarang Ministry of Health Polytechnic. We also wish to thank all the participants who contributed to this study.

Effectiveness of Mini Long Protocol in Patients with Previous IVF Failure Due to Poor Response

Thuraya Hussamuldeen Abdull1, Sumaya Taher Sayhood2, Alaa Mohammad AlKhawaz3
1Consultant Obstetrics & Gynecology, Fellowship of Infertility & Reproductive Medicine; 2Proff. In Obstetrics & Gynecology, Tikrit Medical College, University of Tikrit, Tikrit city, Iraq; 3Consultant Uro-surgery, Director of High Institute for Infertility Diagnosis and ART

ABSTRACT

Background: If pregnancy is not achieved after several cycles of in vitro fertilization, it is important to know the causes of implantation failure to design the appropriate strategy to increase the chances of pregnancy.

Objective: To evaluate the effectiveness of mini long protocol in patients with previous IVF failure due to poor response in group of Iraqi patients.

Patients and Method: A clinical trial study was carried out during the period from the first of October 2018 to the end of May 2019. The data was conducted in High institute of Infertility diagnosis and assisted reproductive technologies/Al-Nahrain University- Baghdad center for infertility and In-Vitro fertilization, when the convenient samples were taken. 30 convenient samples of infertile women suitable for ICSI within the ages between 27-43 years with previous IVF failure were included.

Results: Positive PT were found in 18/30(60%) of the infertile women after the IVF and stimulation procedures, Significant associations were found between all variables in the table 4 with the PT success (when there is highly significant association were found between AMH, E2 at pick up, embryo of transfer, Lt ovary, embryo day and number of embryo transfer) with the success pregnancy. While significant association were found between; female age, male age, FSH, AFC, endometrium thickness, dose of stimulation, right ovary, and number of oocyte with success pregnancy.

Conclusion: Mini-long protocol can help to improve the patient experience, egg yields and clinical pregnancy rate.

Keyword: Smooth down regulation, in vitro-fertilization, endometrium thickness, Embryo.

Introduction

Fertility is the capacity to produce offspring and it was defined as: failure to achieve a pregnancy in a 12 month period for patients under 35 years of age and failure to conceive in a 6 month period for the over 35 years. (1)

The Global prevalence of the infertility is expected to be one in seven to one in five (14-20%) couples in their reproductive age. (2) In the High institute of Infertility diagnosis and assisted reproductive technologies/Al-Nahrain University- Baghdad center for infertility and In-Vitro fertilization the infertility rate was (30%). (3)

The causes of infertility can be divided into: male cause, female cause or a combination of both and include ovulatory disorders, tubal disease, endometriosis, chromosomal abnormalities, sperm factors and unexplained infertility. (4) The majority of infertility cases, both male and female factors, are overcome through surgical and medical infertility treatment. Medical treatment options include assisted reproductive techniques (ART) such as in vitro fertilization (IVF), intracytoplasmic sperm injection (ICSI), and intrauterine insemination (IUI). (5)
Recurrent implantation failure: Implantation failure is a term used to describe both patients who have never shown quantifiable signs of implantation such as increased levels of hCG, and those who have increased hCG production without later ultrasound evidence of a gestational sac. (6)

**Objective**

To evaluate the effectiveness of mini long protocol in patients with previous IVF failure due to poor response in group of Iraqi patients.

**Patients and Method**

A clinical trial study was carried out in the period from the first of October 2018 to the end of May 2019. The data was conducted in High institute of Infertility diagnosis and assisted reproductive technologies/Al-Nahrain University- Baghdad center for infertility and In-Vitro fertilization, when the convenient samples were taken.

**Ethical consideration:** The study protocol was approved by the Arabic Board of Medical Health Specialization for Obstetrics and Gynecology in Iraq and the High Institute for Infertility diagnosis and Assistance Reproductive Technologies- Al Najrain University.

**Sample size:** 30 convenient samples of infertile women suitable for ICSI within the ages between 27-43 years with previous IVF failure were included. Women with basal FSH levels under 15 IU/L, TSH, and prolactin (PRL) levels within normal limits (2-29 ng/ml)

**Exclusion Criteria:**

1. Women with history of IVF and become a pregnant (no matter if the abortion or labor were happened)
2. Women with premature ovarian failure.
3. Husband with Azo-spermia cases confirmed by testicular biopsy were excluded

Full history from the patients were taken (women age, Husband age, type &duration of infertility) and BMI were measured.

The end points studied included the number of oocytes recovered, number of mature (MII) oocytes, fertilization, cleavage, morphology based embryo quality, pregnancy rate.

**Method**

On the 2<sup>nd</sup> day of menstruation, venous blood were drop from the patients to measure AMH, estrogen, Progesterone, LH, FSH, TH function, prolactin and thrombophilia screening

On the 5<sup>th</sup> day of menstruation the patients receive oral contraceptive pills for 2 weeks duration (14 days) and on the day 12<sup>th</sup> when patients take pills number 12 the progesterone tab (5 mg) two times daily were giving to the patients for three days duration.

Then patients were assessed and after the day 14<sup>th</sup> of taking the OCP and progesterone the Decapiptyle injection were given to the patients, in which each ampoule contain 0.1 ml of Tripetorelin and daily injection of one unit (0.01) of the Tripetorelin for 6 days. The patients will follow up by vaginal U/S and E2 every 3 days

Then after these six days of Tripetorelin injections the patients came either in the first day of menstrual cycle or without cycle but the endometrium size was (≤3mm) and the follicles were symmetrical in both ovaries and their sizes were (<5 mm), all patients were received androgen gel during the days of decapiptyle injection 0.01 unit vaginally

On the days 7<sup>th</sup> the stimulation protocol were begin which is either by FSH (alone or with LH) with Decapeptyl in a dose of 0.1 IU full dose ampoule (long agonist protocol).

During the stimulation period we follow up of the patients by vaginal U/s and E2 level measurement according to the response of each patients, we can use one ampoule of Decapeptyl, then follow up of the patients until the follicule reach size 17,18,19, and 20 mm.

Pregnyl trigger the detection of serum progesterone were done, then Pregnyl trigger in a dose of 5000 IU or 10000 IU and after 35 hours the ovum were pickup and then return it.

**Results**

A total of 30 women with history of infertility and previous IVF failure were included in this study, the main age group of the patients were in age between 31-40 years in which 19(60.0%) patients in this group, 15 (50.0%) of the male were found in this group. 21(70.0%)
of the patients were with primary infertility and 9(30.0%) is 2ndary. The main cause of the infertility was ovulatory 14(46.7%), then male infertile 11(36.7%) then unexplained 3(10.0%) and 1(3.3%) for each tubal and blocked tube.

As shown in figure 1, the positive PT were found in 18/30(60%) of the infertile women after the IVF and stimulation procedures and 12/30(40%) were not become pregnant after the study procedures.

![Figure 1: Response of pregnancy rate according to the number of patients (n = 30)](image)

Significant association were found between cause of infertility especially ovulatory and male fertility with primary infertility (p=0.03), while no association were found between women age and pregnancy test with the type of infertility (p>0.05) (table 1)

**Discussion**

The current study revealed that there is an important role of the maternal age in the quality of the embryo, Zeyneloglu HB et al, found that when the maternal age increases so the frequency of aneuploidy does. (8)

Pregnancy rates also have been found to be decreased as maternal age increases. (9) Which is same that found in the current study which is found that there is a significant decrease of the mother age <35 years old with increase pregnancy rate.

Endometrium thickness in the current study was significantly increased in positive pregnancy rate than in negative pregnancy rate. Miwa et al. study conducted a trans-vaginal Doppler ultrasonography study that found that uterine radial artery resistance index was significantly higher in patients with thin endometrium < 8 mm than with normal thickness endometrium > 8 mm, the thickness of the endometrium has been determined to have an effect on implantation rates. (10) It was suggested that about 8 mm is the lower limit for which ART can still usually be successful. From a thickness of 9 mm to 16 mm chance of pregnancy increases from 53 to 77% showing that a significant difference does exist in implantation rates. (11)

The principal aim of treatment with in vitro fertilization is to realize a live birth term. On the other hand, as the number of eggs retrieved is considered to be an essential prognostic variable, treatment protocols of the IVF is aim to improve this outcome. The current study revealed that blastocysts in grade one with more embryo were with pregnancy rate more than others. This is in agreement with Sunkara SK et al, study that mentioned there is a strong association between the number of eggs and live birth rate. (12)

**Conclusion**

Mini-long protocol can help to improve the patient experience, egg yields and clinical pregnancy rate.

ABSTRACT

Sulfur dioxide (SO$_2$) is a sharp and non-flammable gas from coal combustion activities, fuel oil power plants, copper smelting, and volcanic eruptions. The accumulation of SO$_2$ exposure can detriment to lung function, respiratory tract, irritation, asthma, and even causes death. This study aimed to calculate the value of RfC from SO$_2$ exposure in communities in residential settlements around the area of Palembang’s fertilizer industry, Indonesia by using NOAEL SO$_2$ in white rats and the weight and height of Indonesian exposed to SO$_2$. This was an observational cross-sectional study. To analyze the data, manual quantitative analysis was made. The samples were adults and adolescents, seventeen years old or above, who had settled for more than 2 years. The variable of this research were the concentration of SO$_2$ in the settlements around the fertilizer industry, residents’ body weight, height, respiratory rate, exposure time per day, and body surface area, weight and body surface of white rats, No Observed Adverse Effect Level (NOAEL), Animal Km, Human Km and Reference of Concentration (RfC).

The results showed that the average SO$_2$ concentration was 0.248 mg/m$^3$ (0.0946 ppm). This meant that it is below the threshold limit value according to PP RI No. 41 of 1999 namely 900 µg/Nm$^3$ (0.34 ppm). However, it is approaching the highest limit permitted by Permenaker No. 5 of 2018 which stated the limit to be equal to 0.25 mg/m$^3$ (0.095 ppm). The average SO$_2$ RfC obtained in this study was 0.04 mg/kg. It is less than the one issued by EPA/NAAQS 2010, that is equal to 0.21 mg/kg and it means that the RfC result of this study is safer for humans than of the others. Nevertheless, the presence of SO$_2$ around residential areas, which is almost close to TLV and can increase at any time, can bring a negative effect to public health. Therefore, continuous controlling is highly needed. It includes reducing SO$_2$ concentration, controlling SO$_2$ emissions and evaluating industrial activities periodically in order to maintain air quality and level of exposure so health effects can be well-controlled.

Keywords: Sulfur dioxide, RfC, community, fertilizer industri

Introduction

SO$_2$ is a gas that smells sharply and is non-flammable.$^1$ SO$_2$ in air comes from coal combustion activities, fuel oil power plants, copper smelting, and volcanic eruptions.$^2$ In urban areas, the main source of SO$_2$ in the air are from electricity generation activities, especially those that use coal or diesel oil as fuel, gases discharged from diesel-using vehicles and industries that use coal and crude oil fuels.
During the process of making the urea fertilizer, the fertilizer industry in Palembang disposes waste which contains impurities in the form of gases, a by-product of SO₂ which is produced by boilers and electric power chimneys in the factory areas, which is the biggest contributor of SO₂ emissions in the world.

In his study, Solichin (2016)³ measured that the concentration of SO₂ in residential areas around the Palembang fertilizer industry is 0.248 mg/m³ (0.0946 ppm). His result is below the threshold value limit set by Indonesian government in PP RI No. 41 of 1999 limit to be 900 µg/Nm³.⁴ However, his result is approaching the highest limit permitted by Permenaker No. 5 of 2018, which is equal to 0.25 mg/m³.⁵ Even though it does not cause a carcinogenic effect, it can bring negative impact to public health if the community are continuously exposed to it.

The accumulation of SO₂ exposure can detriment to lung function, respiratory tract, irritation, asthma, bronchitis, emphysema, and even causes death.⁶ Daud and Sedionoto study (2010) showed that residents who lived for a long time with a radius of less than 300 m from the SO₂ industrial area had a risk of decrease of pulmonary capacity by 1.37 times and pulmonary function by 1.62 times.⁷ Moreover, according to Kurniawati and Azizah (2006), there were numbers of people living within 300 metres from the industry who suffer from throat irritation, chronic cough, and eye irritation.⁸

There is still no research that calculates the reference concentration (RfC) for SO₂ in communities in the residential area of the Palembang fertilizer industry using anthropometric data of Indonesian people. RfC for SO₂ recommended for the people of Indonesia still uses references from American and European research, so that it cannot fully be used as a reference in determining risk for Indonesian people for its less accuracy. It is like the study conducted by Ani (2018)⁹ which used the RfC of SO₂ issued by EPA/NAAQS 1990, namely 0.026 mg/kg.

In this study, the calculation of RfC will be derived from experimental doses of NOAEL using the characteristics of the experimental animals of white rats (rattus novergicus) from Indonesia and anthropometric factors from the community in the area settlement of the Palembang fertilizer industry. The values used in this study are NOAEL SO₂ of 0.25 mg/kg, average body weight of 57.65 kg and average height of 159 cm.

Therefore, this article was aimed to determine SO₂ reference of concentration (RfC) in the community around the Palembang fertilizer industry, so that the results can be used as a reference to estimate the safe limit of SO₂ exposure each day for the community without causing harmful effects during their lifetime using the characteristics of Indonesian people.

Material and Method

This study was conducted in the residential settlements in Palembang’s fertilizer industry. This was an observational cross-sectional study. The population in this study was residents living in the area around the fertilizer industry exposed to SO₂, with a sample of adults and adolescents aged 17 years and older who had settled for more than 2 years. Cluster sampling technique was employed, resulting in 297 respondents.

The primary data of this study were SO₂ concentration, breathing rate, duration of exposure, and body weight. The measurements of SO₂ concentration were carried at 10 air sample points in 3 different locations (radius of 800 meters, 1050 meters, and 1300 meters).

The variable of this research were the concentration of SO₂, residents’ body weight, breathing rate, exposure time per day, body surface area, weight and body surface of white rats, NOAEL of SO₂, Animal Km, Human Km and RfC. To analyze the data and determine RfC of SO₂, manual quantitative analysis was made.

Findings

A. Characteristics and Body Surface Area of Experimental Animal: The experimental animals used in this study were white rats (Rattus novergicus). In general, the human response to toxicity is qualitatively similar to the response of these animals, so that the results of this study test can be used as a basis for extrapolation from animal to human data.¹⁰

</tbody>
</table>
Using the data of white rats in Table 1, body surface area of white rats can be calculated using the following formula:

\[
\text{BSA} = 0.09 \times W^{0.67}
\]

Annotation:
BSA : Body Surface Area (m²)
W : Weight (kg)

B. Characteristics, Body Surface Area and Respiratory Rate of Residents: The residents’ characteristics in this study included body weight and exposure time. The average body weight was 57.65 kg and the average exposure time was 21 hours. For the height, the average height of Indonesian people, 159 cm, was used. Using this data, body surface area and breathing rate can be calculated using the following formula:

1. Body Surface Area of Residents

\[
\text{BSA} = \sqrt{\frac{W \times h}{3600}}
\]

Annotation:
BSA : Body Surface Area (m²)
W : Weight (kg)
H : Height (cm)

\[
\text{BSA} = \sqrt{\frac{57.65 \times 159}{3600}} = 1.59 \text{ m}^2
\]

2. Breathing Rate

\[
\text{BR} = \frac{53 \ln W}{69} \times \frac{24}{24} = \frac{53 \ln 5765}{69} = 0.6 \text{ m}^3/\text{hour}
\]

The measurement results showed that the average body surface area of residents is 1.59 m² and their breathing rate is 0.6 m³/hour.

<td>0.244</td>
</tr>
<tr>
<td>Average</td>
<td>0.248</td>
</tr>
</tbody>
</table>

Based on the measurement results, it is known that the average \( \text{SO}_2 \) concentration in the residential areas around the fertilizer industry is 0.248 mg/m³ (0.0946 ppm) with the highest concentration of 0.254 mg/m³ (0.097 ppm) and the lowest concentration is 0.245 mg/m³ (0.0943 ppm).

D. Animal Km and Human Km: To determine the RfC for the community, Animal Km and Human Km need to be carefully calculated.

1. Animal Km

\[
\text{Animal Km} = \frac{W_{\text{animal}}}{\text{BSA}_{\text{animal}}}
\]

Annotation:
Animal Km : Animal Km factor
W : Weight (kg)
BSA : Body Surface Area (m²)

<td>1.59</td>
<td>35.9685</td>
</tr>
</tbody>
</table>

Table 5 shows that the average of Human Km is 35.96.

E. No Observed Adverse Effect Level (NOAEL):

NOAEL can determine doses experimentally where there is no statistically significant indication of toxic effects or biological problems. The Office of Environmental Health Hazard Assessment in 2016 stated that NOAEL sulfur dioxide is 660 µg/m³ or equal to 0.25 mg/kg. It was obtained from the calculation using the following formula:\(^{11}\)

\[
\text{NOAEL SO}_2 = \frac{n \times \text{molecul weight}}{24,45,1000}
\]

\[
n = 0.25 \text{ mg/kg}
\]

F. Reference of Concentration (RfC): Saridewi dan Tualeka (2019) stated that the calculation of RfC used the formula from Shaw et a. (2007).\(^{12}\)

\[
\text{RfC} = \frac{\text{NOAEL \ Animal Km}}{\text{Human Km}}
\]

Annotation:
- RfC : Reference of concentration (mg/kg)
- Animal Km : animal km factor
- Human Km : human Km factor

The result of RfC calculations obtained from NOAEL, the average of animal Km, and the average of human Km are shown below.

\[
\text{RfC} = \frac{\text{NOAEL \ Animal Km}}{\text{Human Km}} = 0.25 \times \frac{5.81}{35.96} = 0.04 \text{ mg/kg}
\]

The results above shows the RfC for SO₂ in the community living in the vicinity of the Fertilizer Industry, Palembang is 0.04 mg/kg

Discussion

Based on the results of measurements made, the average value of SO₂ concentration in residential areas around the fertilizer industry is 0.248 mg/m³. The value of SO₂ concentration obtained from this study is higher than the results of research conducted by Nukman et al (2005) who studied the SO₂ in 9 major cities and found the average SO₂ value of 0.033 mg/m³.\(^{13}\) A risk assessment has been ldakassar by characterizing risk quotient (RQ) The significant different concentration between this study and other studies is caused by differences in the sources of SO₂ pollution itself. SO₂ source for the study by Nukman et al (2005) was the source line, namely the highway, while SO₂ sources for this study were the power plant chimney and fertilizer industry boiler. Those are among the main sources of sulfur, the activities of industries that use coal and crude oil fuels.

The RfC result showed 0.04 mg/kg. This indicates that the calculation of RfC SO₂ in this study is smaller than
the calculation of SO₂ RfC issued by EPA/NAAQS 2010 in Rahman (2007) which is equal to 0.21 mg/kg. Thus, it can be said that the results of this research are safer for humans. Although it is still relatively safe, exposure to SO₂ continuously could bring a negative impact. Thus, control efforts need to be carried out including overcoming the reduction of SO₂ which can be done through two processes, absorption and electron beam.

Effort in reducing and controlling SO₂ emissions can be carried out with several ways, using low sulfur fuel, replacing other energy sources for fuel, processing sulfur before combustion, and processing SO₂ from exhaust gases. In addition, it is necessary to evaluate activities in the fertilizer industry by taking samples of SO₂ regularly, preparing health consultations for the community, installing additional air monitoring devices in several locations by waste management institutions, recording all odor complaints by the community, namely nature, location, time, and frequency of complaints, so that health effects can be well-controlled.

**Conclusion**

The average result of SO₂ concentration in residential areas around the fertilizer industry is 0.248 mg/m³, which one of the results of SO₂ measurements in this study passed the quality standard of government regulations (PP RI No.41 of 1999). However, the average SO₂ concentration is very close to the highest level permitted by Permenaker No. 5 of 2018 concerning Occupational Safety and Health of the Work Environment which set the limit to be equal to 0.25 mg/m³ (0.095 ppm).

The RfC for SO₂ result showed 0.04 mg/kg. This indicates that the calculation of RfC for SO₂ in communities in the residential area of the Palembang fertilizer industry is smaller than the calculation of RfC for SO₂ issued by EPA/NAAQS 2010 which is equal to 0.21 mg/kg. Thus, it can be concluded that the results of this research are safer for humans. However, the fact that it is very close to TLV and can increase at any time can bring a negative effect to public health. Therefore, serious prevention action is highly needed.

Comparative Study for Preemptive Administration of Intravenous Infusion of Nefopam Versus Paracetamol in Providing Postoperative Analgesia for Patients Undergoing Anterior and Posterior Vaginal Wall Repairs Under Spinal Anesthesia

Yasir Fadil Muhammad Ali Alkhazraji1, Sahar Swadi Raheem2, Qatar Al-Nada Adnan Abood3

ABSTRACT

Background: The aim of the current study was to evaluate and compare the postoperative analgesic effects of preemptive intravenous (IV) paracetamol and nefopam versus and their effect on the total requested dose of tramadol postoperatively.

Materials and Method: 60 adult female patients, aged 20-55 years, ASA physical status I and II were scheduled for anterior and posterior vaginal wall repair (APR) and assigned in a randomized manner into three groups after spinal anesthesia. In control group, 50 ml of normal saline had been infused intravenously over 15 minutes. In group (P), an intravenous infusion of 1 g paracetamol had been given over 15 minutes. In group (N), an intravenous infusion of 20 mg nefopam in 50 ml normal saline had been given over 15 minutes. Visual analogue scale (VAS) were taken at a constant times postoperatively and the total requested postoperative dose of tramadol had been calculated.

Results: Both paracetamol and nefopam groups are associated with a significant longer time to first request of postoperative analgesic treatment (group N > P > C) (P < 0.05) with a significant reduction in the total required postoperative analgesics. VAS revealed a significantly lower score in Group N and P, compared to group C.

Conclusion: Preemptive i.v. paracetamol and nefopam is a good plan to provide an effective postoperative analgesia following spinal anesthesia in patients undergoing vaginal APR.

Keywords: Anterior and posterior vaginal wall repair; Intra venous paracetamol, nefopam, preemptive, tramadol

Introduction

Pelvic organs prolapse is a common gynecological problem and mostly need to be corrected surgically by anterior and posterior vaginal wall repair (APR). Postoperative pain (POP) is a major psychological burden and responsible for the triggering a series of physiological changes that increases the rate of morbidity and mortality. Early and adequate treatment of POP enhances early mobilization and reduces the rate of complications and hence cost of hospitalization. Preemptive analgesia immediately before the surgical procedure is an effective measure in the prevention of POP. Paracetamol is an analgesic agent used for mild to moderate pain. It has minimal side effects and it does not interfere with blood clotting. Intraoperative administration of paracetamol before the end of surgery is an effective measure in the management of POP. Nefopam is a centrally-acting non-opioid analgesic. It

DOI Number: 10.5958/0976-5506.2019.02630.5
does not affect COX but it interrupts the reuptake of serotonin, dopamine, and norepinephrine. Plasma peak concentrations are reached after 30 min of continuous intravenous infusion and its effect lasts for 6 hours. The potency of a 15–30 mg dose is equivalent to 50–100 mg of pethidine administration and considered as a safer, well-tolerable agent with fewer side effects. The aim of this study was to evaluate and compare the efficacy and safety of paracetamol and nefopam infusion as a preemptive analgesia and to assess their effects on the total daily requirement of postoperative analgesic drugs.

**Materials and Method**

This study was conducted from 1st of November 2018 to 1st of May 2019 when 60 adult patients, aged 20-55 years, ASA physical status I and II were scheduled for APR and involved in this study.

Exclusion criteria from this study include: Patients with ASA physical status > II, patients receiving analgesics, allergy to local anesthetics, refusal of the patient, Patients who receive enzyme inducers (carbamazepine, phenytoin, barbiturates, rifampicin) or have a history of alcohol abuse, history of liver or renal diseases, history of bleeding tendency, neuropathies, diabetes mellitus, hypertension, pregnant and lactating women, infection at the site of infection and immune compromised patients.

A clear approval was taken from all the patients who were divided randomly into two equal groups. Non-invasive blood pressure, oxygen saturation and lead II electrocardiogram were monitored. After receiving an intravenous infusion of 10 ml/kg normal saline, spinal anesthesia was done using gauge 25 spinal needle at L3-L4 interspace and administration of 2.5 ml bupivacaine 0.5%. Immediately before starting the surgical procedure (APR), patients were divided randomly into three equal groups. In control group (C), 50 ml of normal saline had been infused intravenously over 15 minutes. In group (P), an intravenous infusion of 1 g paracetamol had been given over 15 minutes. In group (N), an intravenous infusion of 20 mg nefopam in 50 ml normal saline had been given over 15 minutes. POP was assessed by using the visual analogue score (VAS) which is measured every 3 hours during the first 24 hours postoperatively. I.V. administration of 50 mg tramadol was given as a rescue analgesic agent. Time of first rescue analgesic and the total analgesic dose/24 hours were recorded.

**Statistical Analysis**

Statistic with the SPSS program, version 24. The qualitative data had been analysed by using of Chi - square. The quantitative data had been analysed by using student’s paired t-test was used. VAS were analysed by the Friedman test.

**Results**

Demographic parameters (age and body weight) showed that there was no obvious significant difference in N and P groups in comparison with control group. Regarding the duration of surgery, there was a significant difference in group C which is clinically of no applicable importance (79.13 ± 20.58 in control group in comparison with 109.13 ± 36.33 in nefopam group and 97.25 ± 30.60 in paracetamol group) (table 1).

Regarding the onset of pain, was much earlier in Group C. Mean of VAS was higher in group C > P and N groups. VAS revealed a significantly lower score in Group N and P, compared to group C. There was no significant difference between all groups regarding VAS at 3rd postoperative hour. The maximum mean of VAS score occur at 6th postoperative hour in control group, while it occurs at 9th postoperative hour in Paracetamol and at 12th postoperative hour Nefopam group. There was significant difference between the groups regarding VAS at 6th, 9th and 12th postoperative hours while there was no significant difference thereafter. Nefopam group has a lower VAS score than Paracetamol group (which is only significant at 9th postoperative hour) (table 3). Total dose of analgesic (tramadol in mgs in 24 hours) was very significantly lower in groups P and N than group C (N < P < C) (table 4).

Discussion

Adequate postoperative analgesia is very important for the accurate care of the patients and considered as an essential human right. This study is focused on the impact of the administration of an intravenous infusion of Paracetamol and Nefopam on the outcome of pain control after APR surgeries. There was significant difference between these groups regarding VAS at 6th, 9th and 12th postoperative hours with prolonged duration of postoperative analgesia and reduced total analgesic dose in Paracetamol and Nefopam groups than control group. Paracetamol is widely used for controlling moderate postoperative pain. It has an anti - prostaglandins (PGs) effect with some cyclooxygenase inhibitory effects. Nefopam produces its analgesic effect through a non-opioid centrally acting mechanism. This study is in agreement with the study of S. Zhang and his colleagues which revealed that Nefopam can provide a safer analgesic effect than tramadol and can reduce the total consuming dose of postoperative tramadol. V. Martinez and his colleagues concluded that nefopam was superior to most analgesics used alone in terms of reducing morphine consumption with patient control analgesia which is run in parallel with the result of the current study. Regarding the effect of preemptive administration of i.v. paracetamol, A. W. H. Barazanchi and his colleagues found that Preoperative use of paracetamol is recommended for providing postoperative analgesia.

Conclusion

Preemptive i.v. paracetamol and nefopam is a good plan to provide an effective postoperative analgesia following spinal anesthesia in patients undergoing vaginal APR.

Impact of Thyroid Dysfunction on Control of Diabetes Mellitus

Zahraa Abdulaali Al-Mudhafar¹, Israa Nihad Ahmed², Mohammed Sami Turki², Safaa Ali Khudhair³

¹Department of Physiology, Faculty of Medicine, University of Kufa, Iraq; ²Najaf Health Directorate, Ministry of Health, Iraq; ³Department of Medicine, Faculty of Medicine, University of Kufa, Iraq

ABSTRACT

Background: Diabetes mellitus (DM) refers to a group of common metabolic disorders that share the phenotype of hyperglycemia. There are two broad categories of DM, designated type 1 and type 2. Thyroid hormones affect glucose metabolism via several mechanisms. Thyroid disorders and DM are the two most common endocrine diseases reported in clinical practice and each can influence the other. During hyperthyroidism, the half-life of insulin is reduced together with increase hepatic glucose production and increase in glucose gut absorption. In hypothyroidism, reduced glucose absorption from gastrointestinal tract is accompanied by diminished hepatic glucose Production.

Aim of the Study: To assess effect of thyroid dysfunction on control of diabetes mellitus.

Patient and Method: This is a cross sectional study enrolled 60 patients with diabetes mellitus and thyroid disorder; 16 male (26.7%) and 44 female (73.3%) with a mean age of 47.2 ± 13.6. The patients were collected from center of diabetes and endocrine disease in Al-Najaf and Al-Manathera center during the period from April (2018) to December (2018). The effect of thyroid dysfunction on glycemic control has been evaluated using HbA1c as marker of control.

Results: There was a significant relationship between HbA1c and thyroid status in both hyperthyroid and hypothyroid patients. No significant difference was observed in the distribution of thyroid disorder between the two types of DM and among different age groups, but significant difference was reported between female and male diabetic patients.

Conclusion: Thyroid dysfunction in form of hyperthyroidism and hypothyroidism associated with poor glycemic control in diabetic patients.

Keywords: DM – Hypothyroidism – Hyperthyroidism.

Introduction

Diabetes mellitus is a clinical syndrome characterized by hyperglycemia due to absolute or relative insulin deficiency. The chronic hyperglycemia of diabetes is associated with long-term complications of various organs, particularly the eyes, kidneys, nerves, and blood vessels. Several distinct types of DM result from a complex interaction of genetics and environmental factors(1).

Diabetes can be classified into the following general categories(2):

1. Type 1 diabetes (due to absolute insulin deficiency)
2. Type 2 diabetes (due to a progressive β-cell secretory defect on the background of insulin resistance)
3. Gestational diabetes mellitus (GDM)
4. Specific types of diabetes like, such as neonatal diabetes and maturity-onset diabetes of the young (MODY).

The latest estimates show a global prevalence of 382 million people with diabetes in 2013, and expected to rise to 592 million by 2035. Type 2 diabetes accounting for the majority (>85%) of total diabetes prevalence(3).
Hypothyroidism is one of the common endocrine diseases caused by deficiency of thyroid hormone. It usually results from primary thyroid disorder with inadequate thyroid hormone production. Subclinical hypothyroidism occurs in the clinical setting of high serum TSH level and normal serum FT4 concentration. With the exception of iodine deficit areas, Hashimoto’s thyroiditis is the most common cause of hypothyroidism. The prevalence of hypothyroidism in the developed world is about 4-5%. The prevalence of subclinical hypothyroidism in the developed world is about 4-15%. Clinical features of hypothyroidism range from asymptomatic patient to life-threatening condition. The most common symptoms are decrease alertness, fatigue, cold intolerance, obesity, menorrhagia, and hoarseness of voice, but clinical presentation varies with age and sex.

The term thyrotoxicosis and hyperthyroidism are used interchangeably and refer to state of excess thyroid hormone activity. Hyperthyroidism has a prevalence of 1% to 2% in women and 0.1% to 0.2% in men. Graves’ disease is the most common cause of thyrotoxicosis, followed by toxic multinodular goiter (TMNG) and toxic adenoma (TA). Other causes are thyroiditis, and gestational hyperthyroidism. Drug-induced thyrotoxicosis has been associated with amiodarone and iodinated contrast. Graves’ disease is an autoimmune disease characterized by formation of antibodies that stimulate TSH receptors to cause excess secretion of thyroid hormones. This results in hyperplasia of thyroid follicular cells, and goiter. The cause of Graves’ disease is not known, but genetic and environmental factors may play role, such as smoking, stress, and dietary iodine.

The prevalence of thyroid disease in diabetic patients was reported to be 13.4% with higher prevalence (31.4%) in female. Type 2 diabetic patients as compared to (6.9%) in male patients. The prevalence of thyroid disorder in T2DM patients was reported to be 16% in Saudi Arabia. Diabetes mellitus and Thyroid disorders are the two most common endocrine diseases reported in clinical practice. Diabetes and thyroid diseases have been shown to influence each other.

Thyroid stimulating hormone (TSH) level is inversely related to the insulin resistance and function of β cell, this relation can be explained by counter-regulatory effect of thyroid hormones on insulin action. These observations reveal that glucose intolerance is tightly associated with thyroid dysfunction.

This study aims to assess the effects of the thyroid dysfunction on glycemic control in diabetic patients.

**Patients and Method**

This is a cross-sectional study enrolled 60 patients with diabetes mellitus and thyroid disorder; 16 male (26.7%) and 44 female (73.3%) with a mean age of 47.2 ± 13.6.

The patients were collected from the center of diabetes and endocrine disease in Al-Najaf and Al-Manathera center of diabetes during the period from April to December (2018).

**Inclusion Criteria:**

1. T1DM or T2DM
2. Previous or current diagnosis of thyroid disorder

**Exclusion Criteria**

1. History of thyroid surgery
2. Pregnancy.

The patients were exposed to the questionnaire about the onset of diabetes mellitus, duration of the diabetes mellitus, type of treatment, the history of the thyroid disorder and type of treatment. Patients were informed about the study and verbal consent was obtained.

All patients were evaluated for glycemic control by HbA1c and for thyroid status by TSH. Venous blood samples were drawn from all patients enrolled in the study. HbA1c assay, was tested using NycoCard® READER II instruction manual, (NycoCard® HbA1c). The TSH assay, was tested using a mini VIDAS assay, company name is (BIOMETRIEUX).

**Statistical Analysis**

SPSS® Software (version 23.0 for Linux®) was used to perform statistical analysis. Qualitative data are presented as numbers and percentages, while continuous numerical data are presented as mean ± standard deviation. Comparison of study groups was carried out using chi-square test for categorical data, and using Student’s t-test for continuous data. Correlations were assessed using Pearson’s product-moment correlation coefficient. P value of < 0.05 was considered statistically significant.
Results

The demographic data of the study population are illustrated in table 1.

There was no significant difference in the prevalence of thyroid disorder between type 1 and type 2 DM as shown in table 2.

There was significant effect of thyroid dysfunction on glycemic control. Hyperthyroid patients had the worst control among the enrolled patients in this study. Table 3 and figure 1.

Discussion

The present study revealed that poor control diabetes mellitus is more common among patients with thyroid dysfunction than in age matched patients with diabetes mellitus and euthyroid. These results highlighted the need for further investigations for thyroid dysfunction among patients with poor diabetic control.

A cross sectional study done by Maxon et al (2011) in the USA revealed increased hyperglycemia in patients with Hyperthyroidism\(^{(15)}\).

Hyperthyroidism has long been associated with hyperglycemia, and different mechanisms are suggested including, reduced half-life of insulin due to increased insulin clearance rate, an enhanced release of biologically inactive insulin precursors, and increase glucose absorption from the gut\(^{(16)}\). Moreover hyperglycemia, in hyperthyroidism, is aggravated by elevated hepatic glucose production and increased glycogenolysis\(^{(17)}\). These effects are responsible for worsening of subclinical DM and exaggeration of hyperglycemia in T2DM\(^{(18)}\).

Evidence supporting glucose impairment in patients with hypothyroidism. Jiang et al. (2011) who studied a total of 1534 Chines adult, and found a higher TSH level in patients with metabolic syndrome compared to those in the non-metabolic syndrome group, and concluded that subclinical hypothyroidism may be a potential risk factor for metabolic syndrome\(^{(19)}\).

Bhattacharjee R et al (2017) in India, found baseline HbA1c levels were significantly higher in hypothyroid patients compared to control individuals despite similar glucose levels\(^{(20)}\).

In hypothyroidism, reduced glucose absorption from gastrointestinal tract accompanied by diminished hepatic glucose production; in addition to reduced renal clearance of insulin, leads to diminished insulin requirements\(^{(21)}\).

Lastly recurrent hypoglycemic episodes are reported in patients with hypothyroidism and T1DM, and replacement with thyroid hormones reduced the fluctuations in blood glucose levels\(^{(22)}\).

Conclusion

Thyroid dysfunction in form of hyperthyroidism and hypothyroidism associated with poor glycemic control in diabetic patients.

Conflicts of Interest: None of the authors have any conflicts of interest relevant to this research subject.

Ethical Clearance: The study was conducted in accordance with ethical principles that have their origin in the Declaration of Helsinki. The study protocol, care of animals and subject information were reviewed and approved by a local Ethics Committee.

Study the Effect of Cladosporium Spp. on Some Internal Organs of Experimental Animals

Zainab R. Zghair
Zoonosis Unit, College of Veterinary Medicine, University of Baghdad, Baghdad, Iraq

ABSTRACT

This study was designed as Twenty four Balb C mice were used 6 weeks in age and both sexes weight from 25 grams were randomly divided into three groups each one contain 8 animals and suspension (2x10^6) cfu/ intraperitoneal 0.3 cc were obtained first group as F1 group infected with *cladosporium* for two weeks, second group as F2 group infected for three weeks and third group as control group injected with PBS 0.3 cc. Results of liver function were ALT, and Bilirubin F2 group had significantly increase (P<0.01) for tests ALT and bilirubin (83.55 ± 6.49), (5.75 ± 0.59) respectively when compared with control group; while F1 group had non-significantly increase (P<0.01). Histopathological showed lesions in group (F2) more severe than (F1) group specially in liver which appeared necrosis of hepatocytes and karyohexis of nucleus and granulomatous aggregation of inflammatory cells like macrophage and lymphocytes around bile ducts with aggregation of inflammatory cells as clusters between necrotic tissue, kidney revealed degeneration of some epithelial cells of renal tubules, lung showed infiltration of inflammatory cells like macrophage and vacuolation the cytoplasm of alveolar endothelial cells, and showed necrosis and infiltration of inflammatory cells like macrophage in large numbers in spleen.

**Keywords:** *Cladosporium* spp., histopathology, and liver functions.

Introduction

Fungi of the genus *Cladosporium* are common in many areas of the world, they are cosmopolitan organisms. Their spores can be found in air, soil and water. Also, they are commonly isolated from accommodation and public use areas and from food products¹. *Cladosporium* species are ubiquitous, saprobic, dematiaceous fungi, only infrequently associated with human and animal opportunistic infections². Some species are pathogens of various plants, causing economically important plant diseases and others have only endemic importance. Commonly they occuras saprotrophs¹. Allergic reactions in humans can caused by *Cladosporium* spp., that sometimes leads to asthma mainly in people with compromised immune systems such as patients with AIDS or hematological diseases ³.

Materials and Method

**Preparation of cladosporium:** Cladosporium was obtained from Zoonosis Unit/College of Veterinary Medicine/University of Baghdad.

**Experimental Study:** Twenty four Balb C mice were used in this study 6 weeks in age and both sexes weight from 25 grams were randomly divided into three groups each one contain 8 animals and suspension (2x10^6) cfu/ intraperitoneal 0.3 cc was prepared as the method in⁴ as the following:

a. First group as F1 group infected with *cladosporium* for two weeks.

b. Second group as F2 group infected with *cladosporium* for three weeks.

c. Third group as control group injected with PBS 0.3 cc

**Measurement of Liver Function:** After scarified of all groups and obtained blood from animals, serum separation and ALT, Bilirubin were measured.

**Histopathology:** All animals killed after the end of experiment and the internal organs were taken for histopathological examination using 10% formalin as a fixative, and then processed routinely as⁵.
Statistical Analysis: The Statistical Analysis System program was used to detect the effect of difference groups in study parameters. Least Significant Difference-LSD in this study.

Results

1. Measurement of Liver Function: Groups that infected with *Cladosporium* revealed when measured of liver function like ALT, and Bilirubin of F2 group had significantly increase (P<0.01) for tests ALT and bilirubin (83.55 ± 6.49), (5.75 ± 0.59) respectively when compared with control group; while F1 group had non-significantly increase (P>0.01) when compared with control group, just mild increase as in (table 1).

2. **Histopathology:** Histopathological lesions of infected animal with *cladosporium* for two weeks (F1) showed degeneration of epithelial cells of renal tubules in kidney(Fig1), Fig:2 showed infiltration of inflammatory cells in liver around and inside the blood vessels with necrosis of hepatocytes, lung in other sections revealed hyperplasia of alveolar septa and infiltration of macrophage; while in spleen showed necrosis and infiltration of some inflammatory cells.

The pathological changes of group (F2) that animals infected with *cladosporium* for three weeks showed more sever lesions specially in liver which appeared in some sections necrosis of hepatocytes and karyohexis of nucleus, and granulomatous aggregation of inflammatory cells like macrophage and lymphocytes around bile ducts(Fig3), while in other sections showed infiltration and aggregation of inflammatory cells as clusters between necrotic tissue, kidney revealed degeneration of some epithelial cells of renal tubules as in(Fig4), lung showed infiltration of inflammatory cells like macrophage and vacuolation the cytoplasm of alveolar endothelial cells (Fig5), and finally spleen showed necrosis and infiltration of inflammatory cells like macrophage in large numbers.

![Fig. 2: Histopathological changes in liver of infected animal with *cladosporium* for two weeks(F1) shows infiltration of inflammatory cells around and inside the blood vessels (red raw) and necrosis of hepatocytes (blue raw) (H&E stain, X400)](image)

![Fig. 3: Histopathological changes in liver of infected animal with *cladosporium* for three weeks (F2) shows granulomatous aggregation of inflammatory cells like macrophage and lymphocytes around bile ducts (blue raw) (H&E stain, X400)](image)
Fig. 4: Histopathological changes in kidney of infected animal with Cladosporium for three weeks (F2) shows degeneration of some epithelial cells of renal tubules (blue raw) (H&E stain, X400)

Fig. 5: Histopathological changes in lung of infected animal with Cladosporium for three weeks (F2) shows infiltration of inflammatory cells like macrophage (red raw) and vaculization the cytoplasm of alveolar endothelial cells (blue raw) (H&E stain, X400)

Discussion

Groups that infected with Cladosporium revealed when measured of liver function like ALT, and Bilirubin F2 group had significantly increase (P<0.01) for tests ALT and bilirubin (83.55 ± 6.49), (5.75 ± 0.59) respectively when compared with control group; while F1 group had non-significantly increase (P<0.01) when compared with control group, just mild increase as in (table 1). Infection with the mold Cladosporium effected on liver function due to duration of infection were increased and the mold need three weeks for growth 7. Molds can easily be cultured and their spores can be obtained very rapidly in high purity. More importantly, mold spores are complex particles composed of numerous proteins4.

Histopathological (F1) group showed degeneration of epithelial cells of renal tubules in kidney, infiltration of inflammatory cells in liver around and inside the blood vessels with necrosis of hepatocytes, lung revealed hyperplasia of alveolar septa and infiltration of macrophage and the spleen showed necrosis and infiltration of some inflammatory cells. The changes were observed in a dog with Cladosporium infection in the kidney, liver, cerebellum, and spleen 8.

The pathological changes of group (F2) revealed more severe lesions specially in liver which appeared necrosis of hepatocytes and karyohexis of nucleus and granulomatous aggregation of inflammatory cells like macrophage and lymphocytes around bile ducts, while infiltration and aggregation of inflammatory cells as clusters between necrotic tissue. The occurrence of granuloma in the chronic infections of bacterial and fungal diseases, and F2 group after three weeks of Cladosporium infection showed that, so the macrophages with the pool of lymphocytes. Degeneration of some epithelial cells of renal tubules as in kidney, lung showed infiltration of inflammatory cells like macrophage and vaculization the cytoplasm of alveolar endothelial cells and showed necrosis and infiltration of inflammatory cells like macrophage in large numbers in spleen. So the pathogenicity of Cladosporium were not involve the liver, but other important organs like lung,kidney and spleen, Exposure of mice intraperitoneal (ip) to Cladosporium spores developed allergic lung inflammation and hyper-reactivity. The hyperreactivity appeared within 3 weeks and continued 9. This mold need to comprehensive study due to the lack of sources about the experimental infections of this fungus.

Conclusion

Study revealed that infection with Cladosporium that the damage of internal organs especially liver increased in three weeks of infection more than two weeks, also F2 group (three weeks infection with Cladosporium) had significantly increase (P<0.01) for tests ALT and bilirubin.

The Effect of Addition of White Portland Cement on the Physical Properties of MTA Fillapex

Rehab Ali Farag¹, Maged M. Negm², Magdy M. Ali³, Lamia I. Ahmed⁴
¹Assistant lecturer, Faculty of Oral and Dental Medicine, MUST University; ²Professor of Endodontics, Faculty of Oral and Dental Medicine, Cairo University; ³Professor and head of department of Endodontics, Faculty of Dentistry, Minia University; ⁴Associate professor of Endodontics, Faculty of Dentistry, Fayoum University

ABSTRACT

Aim: To evaluate the effect of adding white Portland cement, in the ratio of 25% by weight, on the physical properties of MTA Fillapex.

Methodology: White Portland cement (WPC) powder was incorporated into the paste of mixed MTA Fillapex in the ratio of 25% by weight. Different properties including powder-paste ratio, strength properties, setting time, film thickness, water solubility, and push out bond strength were studied in comparison to MTA Fillapex.

Results: The experimental material showed higher setting time, higher film thickness, higher solubility, higher diametral tensile strength, and higher compressive strength, though the last one was not statistically significant. On the other hand, the push out bond strength of the experimental material was significantly lower.

Conclusions: Addition of Portland cement to MTA Fillapex increases its setting time, film thickness, solubility, diametral tensile strength and compressive strength. However, its push-out bond strength decreased.

Keywords: MTA Fillapex, Strength properties, Portland cement, Push-out bond strength.

Introduction

An ideal endodontic sealer should flow along the entire canal all surfaces, fill all voids and gaps between the core root filling material and dentin and adhere to both dentin and gutta-percha. Mineral trioxide aggregate (MTA) was introduced by Torabinejad in 1993. MTA is a derivative of Portland cement. It consists of 50-75% by weight calcium oxide and 15-25 silicone oxide. These two components together comprise 70-90% of the cement. When they blended together they produce tricalcium silicate, dicalcium silicate, trialuminate and tetracalcium aluminoferrite.

A new calcium silicate –based sealer (MTA Fillapex) has been recently proposed as an endodontic filling material. The MTA Fillapex is a sealer that is composed of MTA, salicylate resin, natural resin, bismuth oxide and silica. Any trial to interfere with the composition of MTA Fillapex in order to improve some of its properties, if possible, would be a logical step.

Materials and Method

Setting Time Test: The time from the onset of mixing to the sealer setting was taken as the setting time. Five measurements were made for each sealer.

Flow Evaluation: The minimum and maximum diameters of the sealer disc were measured by a digital caliper.

Film Thickness: The thickness of the two glass plates and the sealer was measured with a digital caliper.

The Solubility Test: The percentage of weight loss of each sample was considered the solubility of the sealer.

Compressive Strength: Six specimens were made by split Teflon molds. their dimensions were confirmed using a digital caliper.

Diametral Tensile Strength: Five samples were prepared by the split metallic molds.
**Push Out Test:** Twenty single-rooted human teeth. Each root was horizontally sectioned by using a low-speed saw with a diamond disk under continuous water irrigation. The root filling of each sample was loaded with plunger. Loading was performed on the universal testing machine.

**Discussion**

The endodontic sealer properties include good sealing, visible radiopacity, easy handling, good resistance, dimensional stability, and low solubility (1). MTA has established properties and indications for use in several endodontic procedures (2). In the present study the push-out test method was used to test the dentine bond strengths of the sealers. This method has been shown to be effective (3). Also it allows root canal sealers to be evaluated even when bond strengths are low (4). We have prepared 1-mm-thick sections from each root has been found reliable in push-out bond strength measurements (5). Despite the flow ability shown by MTA Fillapex, this sealer does not seem to display bond strength to root dentin (6). The reason could be the low adhesion capacity of these tag-like structures corroborated by the study made by Sagsen et al (7). However, acceptable push-out bond strength values for MTA Fillapex, similar samples filled with AH Plus sealer (8).

Samples filled with MTA Fillapex and Portland cement showed lower push out strength, these values are related to the degree of residual moisture on dentin surface for both materials (9). The Portland product powder consists of fine hydrophilic particles that set in the presence of water (10), with moisture from the surrounding tissues purportedly assisting the setting reaction (11). The setting process is said to be responsible for the development of material strength (12).

The setting time is the period of time measured between the start of mixing until it is no longer possible to handle the sealer without promoting adverse effects on its properties (13). This time is directly linked with the setting time. Both times are dependent on the constituent components, their particle size, the ambient temperature, and relative humidity (14). The setting reactions are complex, and even though the sealer surface becomes hard, the inner mass may remain soft for an extended period (15). Because of the extended setting time is advantageous to the root canal sealers, different studies showed the possibility to modify the composition of MTA-based materials in order to delay the setting time (16). The initial setting time of MTA Fillapex with Portland cement obtained in this study was in agreement with previous studies (17).

The solubility of a specific material is the loss of mass during a period of immersion in water (18). The solubility testing in the current study was devised according to the methodologies reported previously (19). This methodology is based on the measurement of the mass loss of the specimen before and after immersing the sample in distilled water for 7 days. Which are significant for Portland or MTA Fillapex as these materials have high water uptake ability (20), which can play a significant role in the results (21).

Materials with higher solubility may release irritants and increase the risk of leakage and bacterial colonization (22). These results are in agreement with Borges et al (23), who attributed the high solubility of this experimented material to the complex setting reaction of this material, resulting in a fragile matrix (24). Also, MTA Fillapex has MTA in the composition, which is less soluble than Portland cement (25) and bismuth trioxide that could had exert a negative effect as other studies affirmed that it can lower the molecular stability of MTA-based materials (26). MTA Fillapex should be resistant to solubility and disintegration in an aqueous environment (27). MTA Fillapex was less soluble than the experimental material, which is consistent with previous findings (28). This difference between experimental MTA Fillapex with Portland cement and other cements may be related to its chemical composition, which shows different structures after setting (29).

In the development of Portland-derived cements, it should be considered that the differences in particle uniformity and reduction of gypsum content cause a delayed reduction of cement solubility, and also lengthening of setting and structure weakening (30).

Film thickness and dimensional stability are affected by flow which determines the ability of sealers for filling the irregularities, while the viscosity determines the flow characteristics (31). A root canal sealer should have a flow rate of not less than 20 mm (32). MTA Fillapex had flowability higher than 20 mm and a film thickness
lower than 50 µm. MTA Fillapex was significantly more flowable than MTA Fillapex with Portland cement. Other investigators stated similar flow, film thickness and inferior compressive strength of MTA Fillapex when compared to AH Plus sealers. Flow of MTA Fillapex was higher than MTA Fillapex with Portland cement. Film thickness of MTA Fillapex with Portland cement is higher than MTA Fillapex with significant difference. The flowability test results revealed that the addition of Portland cement provides a reduction in flowability of the MTAF. This can be explained by an increase in the powder/liquid ratio also promoted, in accordance with that observed in a previous study.

Endodontic sealers typically exhibit pseudo-plastic properties. However, Portland cement, and hence MTA Fillapex cement in general, typically exhibit shear thickening behaviour unless substantial admixtures are present. MTA Fillapex cement without such additives will not reliably flow into these limited access areas when increased pressure is applied. So addition of MTA Fillapex to Portland cement will decrease flow rate, and hence so it will increase film thickness.

MTA Fillapex had the lowest mechanical resistance in all periods of analysis and it can be related to the composition of this material which is not only composed of MTA. This may be explained by the lack of hydration of Portland compound in the MTA Fillapex as a resinous vehicle was used to mix this sealer instead of water. There for there was no significant difference between the compressive strength in both sealers MTA Fillapex and MTA Fillapex mixed with Portland cement.

Diametral tensile strength (DTS) is a mechanical property that must be assessed because several cements are extremely friable and have a susceptibility to mechanical failure. This test is widely used due to its relative simplicity and reproducible results. Calcium silicate diminishes the plastic deformation of MTA Fillapex causing an increase in the final resistance since this filler can fill any pores in the matrix. The presence of calcium silicate was also proven interesting because it provides radiopacity without affecting biocompatibility.

In the present study, the MTA-based sealer” MTA Fillapex” had the lowest bond strength to root dentin. Sarkar et al in 2005 suggested that the release of calcium and hydroxyl ions from the set sealer will result in the formation of apatite as the material comes into contact with phosphate-containing fluids. The reason for the low bond strength of MTA Fillapex in the present study could be the low adhesion capacity of these tag-like structures, corroborated by the study made by Sagsen et al. Although previous studies have already shown that MTA Fillapex had weak bond strength with the dentin wall, this fact is not normally expected from MTA alone, but in the presence of the other ingredients this may happen. MTA Fillapex with Portland cement properties showed good adhesion to dentin walls, adequate seal and resistance to dislodgement.

MTA Fillapex with Portland cement showed higher bond strength when compared with MTA Fillapex, in all sections tested. The higher bond strength obtained with the experimental sealer may be explained by its ability to react with exposed amino groups in collagen. These cements had low bond strength to the dentin, which may have been caused by the low tensile cohesive strength.

Effectiveness of Generative Learning Strategy for Those with Cognitive Style (Risk/Caution) in the Cognitive Achievement and Motor Compatibility and Learning the Reception Skill (Pass) of The Student in Volleyball

Hatem Flayyh Hafedh¹, Amer Hussein Ali², Zaman Torki Hashim³

¹The College of Physical Education and Sports Science, University of KUFA, Iraq, Najaf; ²The College of Physical Education and Sports Sciences, University of Kerbala, Iraq, Karbala; ³The College of Education Girls, University of KUFA, Najaf, Iraq

ABSTRACT

Generative learning strategy of those with cognitive risk style vs. caution has contributed to develop the cognitive achievement lesser than the followed strategy.

The generative strategy and the followed one are deemed effective strategies in developing the research variations. Cooperative learning strategy of those with cognitive risk style vs. caution plays more great and effective role than the followed strategy in developing the compatibility and learning the skill of volleyball reception.

People with cognitive risk style who has learned under the generative learning strategy are more capable of learning skills subject to the study than the persons with caution style. There is a convergence of skill performance level between those with cognitive risk style and cognitive caution style that have acquired such skills according to the followed strategy. The best results of research groups were achieved by the experimental group which has adopted the cooperative learning strategy.

Keywords: Generative Learning, Cognition, Motor Compatibility, Healthy Practicing

Introduction

Motor Learning is one of the important sciences and the base on which educational process is based in the field of physical education. The educational unit is the basic rule of the curriculum of physical education. It helps the learner to acquire skills of sports games, develop his/her motor performance and provide him/her with educational experiences to practice various sports activities. Learning is one of the most important processes through which knowledge and information are conveyed to the player, which helps to motivate him/her and increase his/her desire to search for full knowledge. The field of learning has witnessed a great development, especially in terms of creating educational situations in a way that motivates the player’s motivation and reach the goal of the educational process [1].

Problem of the Research: Preparation of educational curriculum using the Generative Learning Strategy in the development of cognitive achievement and cognitive compatibility and Learning the Reception Skill (pass) of the Student in Volleyball. Identification of the impact of the educational curriculum using the Generative Learning Strategy of the cognitive method (risk Vs. caution) in cognitive achievement and motor compatibility and Learning the Reception Skill (pass) of the Student in Volleyball.

Methodology of the Research

The researchers used the experimental approach with a(2×2) factorial design. The field procedures of the research are summarized as follows:
Nomination of Tests: Cognitive Style Measurement (risk vs. caution) \(^2\) - cognitive achievement test

- Compatibility Test: Serving and receiving balls on the wall \(^3\)
- Skill Tests: the reception skill by arms from the bottom from different places \(^4\).
- Exploratory Experiments: The exploratory experiments were carried out for (risk vs. caution measurement - cognitive achievement measurement - skill tests - educational curriculum)

Sample Identification: It is made by (Risk vs. Caution) style

Statistical means: Statistical package for social sciences (spss).

By conducting a comparison for the results of the range tests of cognitive achievement among those with cognitive control-style (risk - caution) in the experimental and control groups, which were presented in Table (10), which indicates that there was a significant difference between the Cognitive Style (risk - caution) in the experimental and control groups. Since it has been indicated that the significant difference was greatly in favor of the range of risk and caution in the two experimental groups. The researcher attributes the reasons for such differences of the variable subject to the research to the response of all the students to all the learning requirements within the learning units for a cooperative learning method since it is one of the most effective methods to highlight the
abilities, maintain the level and achieve the goals. Furtherly, the student participation in the work and responsibility is highly significant because the preparation, implementation and evaluation of the level give the student a hint to judge beside the organizational duties by which he is assumed. Accordingly, he/she must use the educational responsibilities and bear the responsibility to ensure learning and the teacher must follow the achievement of levels and help the students as well as the responsibilities entrusted must match, in following-up the performance, with other students.

The researchers also attribute the differences in cognitive achievement to the effectiveness of the generative learning strategy, which raises the level of cognitive achievement of students through the ability to develop and think. Moreover, the changing degree in the cognitive achievement depends on the nature of the situation in which the person obtains the information, its source, style and the degree of proficiency. In addition, the educational curriculum prepared by the researchers using the generative learning strategy, which has had a significant impact on making the process of knowledge development more effective and positive by what the strategy contains of steps that help in the development of the knowledge of the skills. This may be attributed to the fact that the researchers were keen to pay attention to the theoretical side, which has a great role in educating the students and guiding them to the most important strengths and weaknesses in learning skills that will make the student familiar with the technical stages of the skill before its application. While others believe that, although the acquisition of skills depends mainly on the method of teaching and on the team available for training on it, but it is connected with the efficiency of what is offered to the learner of information and knowledge and principles related to them[1].

Based on the aforementioned, we have found that the use of the generative learning strategy has led to an increase in the skill level of the players by retrieving the students’ knowledge and information once needed. Further, the participation in the discussion and dialogue has created an interactive learning environment that helps them to understand the concepts associated with the subject of educational unit and staying away of memorization. As a result, it leads to increased awareness and understanding; in addition, the questions asked to them have attracted their attention and focus as well as created a sense of challenge, which motivates them to get the information that helps them to answer the questions[2]. This has been reflected in the level of performance of the reception skill of volleyball. The cognitive domain is the first set of characteristics and attributes that establish and deepen knowledge, which takes the form of multiple skills and ranges that depend on thinking, in order to record, retrieve and process the information by the individual. Since the generative learning strategy depends on the collection of the ideas and calling them from previous knowledge, focusing on new knowledge, organization of what the student has learned and elaboration in the brainstorming as well as the constructive thinking, it leads to the significant differences.

The results of the experimental and control groups, that have been presented and analyzed for the efficiency of tribal and remote skills performance of the three skills subject of the search for those with Cognitive Style (risk vs. caution) in the experimental and control groups, indicated that there were statistically significant differences between the tribal and Range tests and in the favor of the range tests. Thus, the researcher achieved the first part of the second hypothesis of the research. In addition, the researcher has attributed the reasons for such differences to the impact of educational curricula; (the generative learning strategy and the method adopted by the teacher as we find that the impact of these curricula were effective in making progress in learning skills, which leads to the development of the efficiency of the skill performance of the student with Cognitive Style (risk vs. caution) in the experimental and control groups, but with different differences that are greater in the experimental group (risk (control) - caution). Since the use of the generative learning strategy and what is valid by this strategy of the participation of learners in the selection of the system and rules of the work. Moreover, their participation in the identification of their educational goals and the diversity of sources of learning. The most important characteristic of the strategy is to make the learner focus on the educational process, which is suitable with his/her abilities, interests and patterns of learning, and to connect them to new skills. Further, to learn each player according to his/her ability and help the player to understand himself/herself in addition to discovering the strengths and weaknesses, all of which lead to the availability of communication in all directions between the players and the coach. Following correct, systematic, sequential and logical scientific steps in the planning and implementation of the curriculum will inevitably result in the learning development[1]. The researchers also has attributed the reasons for such differences as a result of the practical practice and training on the variables (compatibility and reception) as well as playing within the educational units, which highly contribute in the improvement of the skill level and achieving better results in the range test[2].

By comparing the results of range tests for motor compatibility and reception of the ball among the people with cognitive style (risk - caution) in the experimental and control research groups that have been presented and analyzed in tables (21, 20, 22); it has been indicated that there is variation in the significant differences between those with cognitive risk style and caution style. The significant difference was found to be in favor of the risk and caution range in the two experimental groups and was greater in the risk and caution range in the control groups in the motor compatibility, efficiency and reception of the ball. This was due to the educational approach using the generative learning strategy developed.
by the researchers, which had a clear effect through the results shown in the development of the physical side. Such effect has been in turn reflected positively on the efficiency of the reception of the ball; moreover, the generative learning strategy is a new strategy for the students that create the spirit of struggle, cooperation, excitement, suspense and active participation among the students.

The learner gains more experience from the leader of the group on one hand and from the teacher on the other hand. Furthermore, the learner is supervised and observed by others such as the leader and members of the group in addition to the teacher while the implementation of the exercise. This positive interaction among them motivates the learner to achieve a better skill level in order to achieve the objectives of the group. Additionally, generative learning strategy makes the learner an active participant in the learning process and not just a receiver of the information, unlike traditional learning. Using new strategies, including generative learning strategy plays a significant role in the development of volleyball skills, as well as, the researchers’ keenness on applying them to the sample of the research and paying more attention to its terms and giving them sufficient time for their implementation. So that the student can remember, understand and retrieve them in a better way. Based on the foregoing, the use of the generative learning strategy, which begins with the introductory stage (the calling element), in which the teacher prepares for the learning unit through dialogue and raising questions that require thinking and experimentation tools. Then, the focus or core stage (focus element) where the teacher instructs the students to work in small groups. Therefore, it combines the prior knowledge and the target knowledge in addition to giving the chance for the students to hold a dialogue between the groups. After that, the conflicting or challenging stage (the organizing element) where the teacher leads the discussion with all groups and allows them to be aware of the achievements and perceptions of their colleagues and helping them by the proper educational support. In addition, holding the challenge between what is known by the learner in the introductory stage and what he learns in this stage. Finally, the stage of application (elaboration) in which the learner implements the new experience gained with his creative attempt to find strengthening and applications results in different situations as well as expansion of the application scope of this experience.

Conclusion

Generative learning strategy of those with cognitive risk style vs. caution has contributed to develop the cognitive achievement lesser than the followed strategy. The generative strategy and the followed one are deemed effective strategies in developing the research variations. Cooperative learning strategy of those with cognitive risk style vs. caution plays greater and more effective role than the followed strategy in developing the compatibility and learning the skill of volleyball reception. People with cognitive risk style who has learned under the generative learning strategy are more capable of learning skills subject to the study than the persons with caution style. There is a convergence of skill performance level between those with cognitive risk style and cognitive caution style that have acquired such skills according to the followed strategy. The best results of research groups were achieved by the experimental group which has adopted the cooperative learning strategy.

Recommendations

The necessity of practicing the educational method by following the generative learning strategy in acquiring the skills of volleyball reception. The need to develop the cognitive strategies that owned by the learners upon selecting the educational curricula. The educational methods that are followed by the teacher should be varied, in addition that the teacher should not rely only on the followed strategy. Conducting studies similar to the other cognitive strategies other than those are adopted in the research. Conducting studies similar to the other essential skills otherwise, those are adopted in the research.

Risk Factors of Rotavirus Infection among Children Hospitalised with Acute Diarrhoea in Sabah, Malaysia Borneo

Abraham Chin Zefong1, Mohammad Saffree Jeffree1,2, Syed Sharizman Syed Abdul Rahim1, Firdaus Hayati1, Khamisah Awang Lukman1, Mohd Yusof Ibrahim1, Kamrudin Ahmed2

1Department of Community & Family Medicine, Faculty of Medicine & Health Sciences, Universiti Malaysia Sabah, Kota Kinabalu, Sabah, Malaysia; 2Borneo Medical and Health Research Centre, 3Department of Surgery, Faculty of Medicine and Health Sciences, Universiti Malaysia Sabah, Kota Kinabalu, Sabah, Malaysia

ABSTRACT

Background: Diarrhoeal disease is one of the leading causes of morbidity in children under five years of age but the disease burden particularly of rotavirus and its epidemiology is currently unknown due to under reporting. Around 700–1,000 children were admitted every year due to acute diarrhoea. These admissions can be prevented if proper vaccination is done. This study aimed to determine risk factors of rotavirus infection among young children hospitalised with acute diarrhoea in Sabah.

Method: A comparative cross-sectional study was conducted in Sabah’s Women and Children Hospital from April to June 2018 and investigated 66 children less than five years of age admitted with acute diarrhoea using universal sampling method. Stool samples were collected and tested for rotavirus using Enzyme Immunoassay. Positive samples for rotavirus were then analysed using PCR method. A validated questionnaire was administered to determine risk factors associated with rotavirus infection and to determine the knowledge, attitude and practice of parents or caretakers on prevention of diarrhoeal disease among young children in Sabah.

Results: The response rate was 100% which give an overall proportion of rotavirus infection of 28.8%. The significant risk factors were male sex OR 4.3(95% CI 1.1–16.8), poor environmental sanitation OR 5.0 (95% CI 1.6–15.6), and poor diarrhoeal prevention practice OR 4.0 (95% CI 1.0–15.4). Rotavirus strains circulating in Sabah are comprised of G1 P(8), G4 P(8), G9, and other unknown genotypes.

Conclusion: The identification of risk factors for rotavirus infection and the circulating genotype in Sabah is beneficial for a more strategic preventive effort.

Keywords: rotavirus infection, acute diarrhoea, risk factors, rotavirus genotype

Introduction

Globally 450,000–550,000 children succumb to rotavirus infection every year, most of them in the developing countries of Asia and Africa1. Rotavirus infection is the single greatest cause of diarrhoea-related deaths among children. Multiple factors such as social, breastfeeding, nutritional status, age of first infection and contact with household pets have been associated with rotavirus infection2. Variation of rotavirus strains which is critically important for the effectiveness of rotavirus vaccine, cannot be understood totally unless we look at the problem critically. According to Sabah’s acute
gastroenteritis surveillance, 46,000–63,000 cases are attended by at health facilities across Sabah every year from 2012–2016 but only rectal swab for vibrio cholera test was performed due to the surveillance being a proxy for cholera cases. With the data obtained through this study, perhaps rotavirus vaccination can be introduced in the routine immunization schedule as an effort to reduce morbidity and mortality from acute gastroenteritis in young children. The study objectives are to determine the risk factors associated with rotavirus infection, the level of knowledge, attitude and practice of caretaker on prevention of diarrhoeal disease and to identify the rotavirus genotype distribution in Sabah Borneo Malaysia.

Material and Method

A comparative cross-sectional study was conducted in Sabah’s Women and Children Hospital from April to June 2018 and investigated 66 children less than five years of age admitted with acute diarrhoea using universal sampling method. Prior to the commencement of this study, about two to three children under five years of age were admitted into this paediatric ward daily due to acute gastroenteritis. Sabah’s Women and Children Hospital ward admission has more than 7,000 children under 5 years of age annually. Stool samples were collected and tested for rotavirus using Enzyme Immunoassay. Positive samples for rotavirus were then analysed using the PCR method to identify the genotype. A validated questionnaire was administered to determine risk factors associated with rotavirus infection and to determine the knowledge, attitude and practice of parents or caretakers on prevention of diarrheal disease among young children in Sabah. This study had compared two different groups of children less than five years of age attending the study site. The first group was the group who presented with acute gastroenteritis symptoms and required admission into the paediatric ward with positive rotavirus result. The second group was the group who presented with acute gastroenteritis symptoms and required admission into the paediatric ward with negative rotavirus result. Exclusion criteria were children with drug history of immunosuppressive or documented significant background disease such as immune-deficient syndromes, bloody diarrhoea, previously vaccinated against rotavirus, hospital stays more than 48 hours and duration of diarrhoea of more than 7 days.

“Sample youki” stool collector (Fujirebio Co. Ltd., Japan) for this study was supplied to the nurse-in-charge. A training session was held with the nurse prior to commencement of study to familiarize usage of the stool collection kit. Enough stool sample was collected in a wide mouth sterile screw container from each suspected subject during the acute illness, which was on the day of presentation and admission to study site. Stool samples were collected as soon after the onset of symptoms as possible from each patient. The stool specimen was properly labelled with information that includes a subject ID and date of collection and was immediately stored in a cold box with an ice pack. The samples collected from the ward had been transported with the cold box and transferred on the same day for storage at −70°C at the Universiti Malaysia Sabah laboratory for prolonged storage prior to testing by batches. Rotavirus was detected by enzyme immunoassay by using a commercial kit, Premier Rotaclone. The enzyme immunoassay (EIA) is a simple, highly sensitive method for the detection of rotavirus antigen, and is well suited for the analysis of large numbers of samples. The stool samples stored at −70°C were put at room temperature for thawing process then vortexed at 1800 rpm for 30 seconds each. 1 ml of Sample Diluent was added to properly marked tube, using a precision pipette. Then, the sample was resuspended in 1 ml of Sample Diluent in a 2 ml vial and stored at −70°C for RNA extraction in another day. The G and P genotypes were determined by reverse transcription polymerase chain reaction (RT-PCR) and confirmed by the nucleotide sequence of VP7 and VP8* portion of the VP4 genes. The whole genome sequence was done by amplifying all the segments separately then full genome sequence was read by using primer walking. Positive results by Spectrophotometric Determination: specimens with absorbance units (A450) greater than 0.150 were considered positive. Specimens with absorbance equal to or less than 0.150 were considered negative.

For data collection through questionnaire, “Good Sanitation”, a maximum score of five was given for each fulfilment of safe water supply, safe drinking water, scheduled waste disposal, owning a toilet and perfect form of a latrine. Subjects with a score of less than five will be labelled “Poor Sanitation”. “Good Diarrhoea Prevention Habits”, of which a maximum score of nine is given for combination of hand washing habit with use of soap and water, more frequent hand washing with sound reason for hand washing, breastfeeding status, cessation of breastfeeding after 2 years of age, and cleaning of milk bottle using soap, water and boiling technique. Subjects with a score of less than seven were labelled as “Bad Diarrhoea Preventive Habits”. As
for knowledge about diarrhoea, “Good Knowledge” was awarded to subjects who managed to get all three answers correctly namely definition of diarrhoea, main diarrhoeal symptoms, and the way to prevent diarrhoea. Subjects with less than three correct answers were labelled as “Poor Knowledge”. For “Good Attitude and Practice”, 17 marks are given for each answer of “Agree” or “Disagree”. Subjects with a score of less than 17 were labelled with “Poor Attitude and Practice”.

Statistical analysis was performed using SPSS software version 17.0 (SPSS, Chicago, IL, USA). The ethical clearance for this study was obtained from the National Medical Research Registry (NMRR) 18-266-39756 (IIR) and UMS ethical committee (1/18 – 14). Information regarding the study was explained to the parents or caretaker of the participating children before the collection of samples. Oral and written consent for participation in the study was obtained.

**Findings**

Response rate for the study was 100% \((n = 66)\). The median age of respondents was 15 months, interquartile range (8–24 months). The majority were from the age group of 7–12 months (28.8%). Most were boys which corresponded to 63.6%. The highest proportion of nature of the job of parents or caretakers were Professional with 31.8% \((n = 21)\), followed by Unemployed 28.8% \((n = 19)\). The mean monthly family income of children hospitalised with acute diarrhoea was RM 3,412 (SD RM 2330), with approx. USD1000=RM4000. Majority of the parents and caretakers of subjects has good knowledge of diarrhoea and prevention of diarrhoea \((n = 60)\) which corresponds to 90.9%. Majority of the parents and caretakers of subjects has Poor Attitude towards prevention of diarrhoea \((n = 41)\) which corresponds to 62.1%. Majority of the parents and caretakers of subjects has Poor Practice towards prevention of diarrhoea \((n = 43)\) which corresponds to 65.2% (Table 1). A total of 24 out of 66 children had fever upon admission but the majority was low-grade fever of less than 38.5°C. A total of 47 (71.2%) children had a short period of diarrhoea of three days or less, with 40 (60.6%) children had five to 10 times of watery stool per day, and three children had more than 10 episodes of watery stool per day. Majority of the children (65.2%) did not have vomiting and almost all children (97.0%) had moderate dehydration. Meanwhile, 19 (28.8%) respondents have positive rotavirus.

</table>
The significant risk factors were male sex OR 4.3 (95% CI 1.1–16.8), poor environmental sanitation OR 5.0 (95% CI 1.6–15.6), and poor diarrhoeal prevention practice OR 4.0 (95% CI 1.1–15.4). Majority of typeable strains of rotavirus from children positive for rotavirus infection showed G4 P(8) type (six out of 19), followed by two G9, two unknown genotype P(8), one G1 P(8) and one G3. There were 7 un-typeable strains in the specimens. All parents and caretakers were willing to get rotavirus vaccine if it meant that their child’s diarrhoea can be prevented.

**Discussion and Conclusions**
