There was a statistically significant association between male sex and rotavirus infection among young children hospitalised with acute diarrhoea with male children having a 4 times higher chance of getting rotavirus infection compared to being female children. Although there was almost double the number of admission of boys compared to girls due to acute gastroenteritis, we found that the proportion of boys with rotavirus infection is greater than the proportion of girls with rotavirus infection. Many studies have shown similar findings, but no specific reasons were given on this occurrence. The studies conducted in Nigeria and Vietnam showed a higher prevalence of rotavirus infection in male children.

The majority number of children admitted was from mean age of 19 months and below. This could explain the lack of association for younger age with rotavirus infection. Most literature states that rotavirus affects mostly children aged two years and below. It was documented as well that the number of rotavirus positive and diarrhoeal cases showed variations throughout the year in different countries. The highest incident of rotavirus has been associated with young children aged 6–24 months, particularly those who are placed at day care centres, while the greatest risk for developing severe rotavirus infection are those under 12 months of age.

Incidence of acute gastroenteritis of all causes were known to be related to environmental sanitation. Poor environmental sanitation which was found in this study includes unsanitary household garbage disposal and unimproved sanitation facility. The fact that most admissions to government hospitals were from low-income family could suggest that their living conditions are also poor. However, further analysis and research to correlate the living conditions with income level need to be conducted to prove this association. A review of current rotavirus management in Ghana has added that improved sanitation alone does not decrease the prevalence of rotavirus disease. It suggested that vaccination together with other preventive methods like breastfeeding, oral rehydration therapy, zinc treatment, environmental and water sanitation can reduce the effects of rotavirus infection.

The diarrhoeal prevention habits such as hand washing, and breastfeeding among others in combination are very effective and a proven way to reduce the incidences of acute gastroenteritis. The knowledge of parents or caretakers correlates with the recommended guidelines of prevention of diarrhoea. However, when it comes to their practice, much is left to be desired. Health promotion programs should be emphasized to empower the community to make informed choices on the maintenance of good health and prevention of diseases, especially with children at growing up stage, a life without diseases can mean that they are able to grow up to their maximum potential. Although this study was unable to prove the association of poor caretaker’s
knowledge and attitude with rotavirus infection, we were exposed to the fact that many parents and caretakers had sufficient knowledge on diarrhoeal disease, but are very much lacking in their attitude and practice when it comes to prevention of diarrhoea.

Malaysian Dietary Guidelines 2010 has outlined 14 Key Dietary Messages for the maintenance of good health. This includes exclusive breastfeeding from birth to six months of age, or when the infant is supplemented with other forms of feeding whilst breastfeeding is to be continued for up to the age of 2 years9. Although we could not prove the association between cessation of breastfeeding before age of two and rotavirus infection, we managed to point out that more than half of the children involved in this study had stopped breastfeeding before the age of two. Several barriers towards breastfeeding includes the inadequate training and education of clinicians and particularly community nurses who lack in personal breastfeeding experiences to educate as well as assisting mothers who are breastfeeding10. Mothers should be empowered to make the best choice for their infant by giving them breastfeeding which has proven to be beneficial for both mothers and children.

The genotype of rotavirus in Sabah was almost like that circulating worldwide such as G1 P(8), and G4 P(8). However, there were a total of 7 untypeable strains. The possibility for this to occur might be due to the different rotavirus strains circulating in Sabah which was not detected with existing primers. Hence, further analysis is needed with the extension of primers to detect other strains which are not commonly found circulating in the world.

In conclusion, this study provides the baseline data for the public health personnel and policymakers to evaluate the existing programs of rotavirus control and acute gastroenteritis surveillance among young children hospitalised with acute diarrhoea. There are pressing needs to identify the effective strategies and future programs for health promotion on prevention of diarrhoea. The introduction of rotavirus vaccination to not only reduce the incidence of rotavirus disease in Sabah but also to reduce the economic burden of rotavirus disease on our healthcare system.

Acknowledgement

We would like to thank Universiti Malaysia Sabah, specifically the Faculty of Medicine and Health Sciences for the opportunity to conduct this study. We would also like to thank the Director General of Health Malaysia for his permission to publish this article. The authors would also like to express our gratitude to the Sabah State Health Department as well as the Sabah’s Women and Children Hospital.

ABSTRACT

One of the key for family planning is contraceptive. According to the most recent Indonesian Demography and Health Survey, 2017, women in reproductive age in east java province have relatively high participate in using contraceptive methods compared to west java province and middle java province. This study examines factors that influencing contraceptive use in east java. Logistic regression was used to finding factors that influencing with contraceptive use. Data come from Indonesia Demography and Health Survey (IDHS) 2017, which limited on 5371 married women/living with partner in east java. The findings show that age, number of living children and education attainment are associated with contraceptive use.

Keyword: family planning; contraceptive; married woman.

Introduction

Family planning is a continues and unfinished program and never. It attempts to regulate number of children and determine of pregnancies. It is achieved through use of contraceptive methods and the treatment of infertility(1). Therefore in this study, family planning is called contraceptive.

Figure 1 show that total population in 2010 is 37 million people and still develop. It’s make east java province as a number two largest population in Indonesia, which number one is west java(2). Population projection showed that in 2017 total population in east java is 39,292,972 people, and 0.46 percent is under 25 years old(2). Based on cohort study of young people enter the reproductive life span, the growth and size of population in a area/country depend on their reproductive behaviour. Because a considerable number of young adults get married every year(3).

According to the most recent Indonesian Demography and Health Survey, 2017, 70% woman in reproductive age in east java using contraceptive. It’s achievement is number 2 largest in Java(4). On the other hand, IDHS 2017 show that 33 percent of women in east java was discontinue using contraceptive after twelve month after using(4). Some reason for discontinue using contraceptive is side effect/health and desire to become pregnant(4). Discontinuation contraceptive may lead lower prevalence rate of contraception. Because of that, this study wanted to see the factors that influencing a woman in east java to using a contraceptive.

This study adopted from the part of theoretical framework of Precede-Proceed by Lawreens Green(5).
This study uses predisposing, reinforcing, and enabling factors and associated with “contraception”. Predisposing factors are age\(^6\), education level\(^7\), and number of living children\(^8\). Reinforcing factors are ideal number of children. Enabling factors are wealth index\(^8\), employment status\(^8\), and residence\(^8\). Therefore, the purpose of this study is to analyze and find the influencing factors of contraceptive use.

**Method**

This study was cross-sectional and used 2017 Indonesian Demographic and Health Survey (IDHS) data. Unmarried woman and individuals with missing data were excluded from the analysis. This study analysis was limited to those 5371 currently married woman aged 15-49 years at the time of data collection.

Data were analyzed descriptively and using logistic regression for multivariate analysis. Statistical analyses were performed using SPSS version 21.0; p <0.05 indicated statistical significance.

Dependent variable was current contraceptive method. Contraceptive use was measured as to current contraceptive method (0 = Not using; 1 = using any method). The independent variables were grouped as predisposing, reinforcing, and enabling Factors. The predisposing factors were age (years), number of living children, education level (0 = no education; 1 = incomplete primary; 2 = complete primary; 3 = incomplete secondary; 4 = complete secondary; 5 = higher).

The reinforcing factors are ideal number of children. Enabling factors are wealth index (1 = poorest; 2 = poorer; 3 = middle; 4 = richer; 5 = richest), employment status (by respondent work in last 12 months, 0 = no work; 1 = currently working) and residence (1 = urban; 2 = rural). In this study, we attempt to analyze some of these factors as indicated in the method section. Therefore, the purpose of this study is analyze and find the predictors of contraceptive use.

**Results**

One of three woman in east java didn’t yet using any contraceptive. By age, educational attainment, and wealth index, there is inverted U pattern in the percentage of woman who using a contraceptive. Women in 35-39 years old, complete primary, and in middle wealth index are more likely report to use contraceptive than women in other groups.

Table 2 show that 2 model of logistic regression formed using the enter method. Model 1 is crude model dan model 2 is multivariate model. Model 2 show that every addition 1 number of living children, chance of woman using contraceptive will increase 3.264 times. In educational attainment, any attainment have significantly influencing of contraceptive use. Model 2 show that woman who have complete primary in educational attainment 3.497 times having contraceptive use than woman who have no education.

Both model 1 and model 2, age, number of living children, ideal number of children, and educational attainment show consistently influencing on contraceptive use. Model 2 show that employment status, wealth index, and residence is not significantly influencing contraceptive use.

Discussion

Every married woman has decide how many children will be born. Seventy three percent of women said that 1-2 is ideal number’s of child. So, as long as their married and before menopause, they must have at least 2 children. Seventy four percent women who’s using contraceptive have at least 1-2 children. It show when number of living children is appropriate with their ideal number of children, they decide to spacing or stopping for having children. One way is using any contraceptive method, both modern contraceptive or traditional contraceptive. Number of living children is a biggest motivation for woman to using contraceptive. Woman will use a contraception when they felt enough to have a baby or want to spacing pregnancy. Age and family size was significantly influencing on contraceptive use. When woman in pre-menopause age and feel enough to have children, they will be use a contraceptive. the result show that the biggest proportion who use a contraceptive is the woman in 35-39 years old.
In otherwise, even though the woman in pre-menopause but have no children they are not using any method\(^9\).

Educational attainment was significantly influencing on contraceptive use. This result had been reported consistently in several studies\(^8,10\) More higher education, more easier to receive any information, especially information about family planning\(^9\) and reproductive health\(^11\). Education was related to low fertility rate because woman who have high education is tend to delay their marriage and want to increase their socioeconomic status\(^12\).

Employment status was not significantly influencing on contraceptive use. Generally, a woman who have a higher education will work in formal sector. In formal sector they feel difficult to access a public health facility because they have to work in work-hours. One way is using a private health facility to access family planning\(^13\). Private health facility that would be a private midwife, midwife in rural area, clinic, and private hospital.

In Indonesia, the cost of using any modern contraception method covered by National Health Care Insurance. Therefore, any woman from any wealth index can accessing family planning. If family planning services does in public health facility is free, or cheap fee if services does in private health facility. For example : In rural-midwife or private-midwife most contraceptive fee is adjusted by economic capability of woman\(^13\). Like in Nigeria where the contraceptive fee is free, but still fee for services in health facility\(^14\). Maybe that’s one of causes why wealth index not significantly influencing contraceptive use in east java.

Generally woman who live in urban area will have a good/higher education than woman in rural area. Beside that in urban area is easy for accessing family planning than in rural area\(^15\). But, in east java type place of residence is not significantly influencing on contraceptive use. Maybe it can be happen because of rural-midwife and family planning health workers help for promotion and supporting a family planning in a rural area. This result is different with studies in West Nusa Tenggara where place of residence influencing to contraceptive use\(^16\).

### Conclusion

Factors that influence of contraceptive use are age, number of living children, ideal number of children, and educational attainment. Employment status, wealth index, and residence is not significantly associated with contraceptive use. It can be happen because in family planning program is good, not lagging in any residence, and covered by National Health System.

Processes of Change for Weight Control Behavior among Collegians

Ahmed Adil Ali Basha¹, Arkan Bahlol Naji²

¹Specialist Nurse (MSc), Child Welfare Hospital, Medical City Directorate, Baghdad, Iraq; ²Professor, Department of Community Health Nursing, College of Nursing, University of Baghdad

ABSTRACT

A randomized controlled trial was used to guide this study. This study aimed to examine the effect of the Transtheoretical of Change-based intervention (TTM) in bettering collegians’ readiness to adhere to weight control behavior.

The study was conducted at the College of Languages, University of Baghdad. The study included 152 students who were randomly selected and assigned into two groups; study and control groups. Each group included 76 students.

The study instrument consists of the sociodemographic sheet and the Processes for Change for Weight Control Scale. Data were collected by a self-report questionnaire. Data were analyzed using the statistical package for social science (SPSS) for windows, version 24.

The study results demonstrated that there is a statistically significant difference in the Processes of Change for weight control for students in the study group over time with an approximately 73% of variance in the value of the Decisional Balance that could be attributed to the administered TTTM-based intervention. There was a positively significant correlation between students’ BMI and each of Processes of Change over time.

The researcher concluded that the TTM-based intervention enabled students to employ more both the cognitive and behavioral Processes of Change for weight control behavior.

Keywords: Processes of Change; Weight Control Behavior

Introduction

The increase in the prevalence of obesity found in various countries characterizes this situation as an epidemic and a worldwide problem (1). Since the 1980s, the rates of obesity have increased by about three times, in regions such as the Middle East and countries such as China and Australia. Even in countries with a lower prevalence, the rates observed are considered high. It is estimated that, in the coming two decades, the increase in the number of new cases of obesity will be over hundreds of millions (2).

It is possible to observe that in countries where obesity affects a large proportion of the population, such as the United States, investments are made in public and private initiatives with the aim of preventing obesity among the young through Special Nutrition Programs, interventions, programs and actions encouraging healthy eating and the undertaking of physical activity (1).

It is known that genetic and metabolic factors directly influence weight gain; however, other factors, such as physical inactivity, an unhealthy diet and psychosocial stress increase the risk of developing obesity. As a result, interventions geared towards these factors must be undertaken to prevent or reverse the situation of obesity in the individual and population ambit (3).

In spite of obesity and the proposals for its treatment being widely publicized, as far as is known, there have been few intervention studies aiming for the control not
only of body mass, but principally changes in behaviors of risk. In this regard, as part of the therapeutic process, it is important to assess and determine how the individual feels in relation to a possible change in behavior, and how to motivate the person to change his or her lifestyle, as this will be reflected directly in the results desired and in healthier standards (4). Both women and men report dissatisfaction with their overall appearance and specific characteristics like weight and muscle tone (5), and weight-control behaviors are common (5).

As a result, the Stages of Readiness for Behavioral Change (SRBC) model, or trans-theoretical model (TM), is used for assessing behaviors related to the practice of physical activity and eating and to propose necessary intervention strategies. It allows one to classify the individuals in their respective stages of change, making a distinction between those subjects who are genuinely disposed to change their lifestyle, and those who do not have the intention of doing so. In the light of the above, this study’s objective was to ascertain the effectiveness of an intervention program on the anthropometric variables and on the Stage of Readiness for Behavioral Change among women with excess weight.

This study aims to (1) determine the efficacy of the TTM-based intervention in enhancing weight control for students, and (2) identify the association between students’ age, body mass index, family’s socioeconomic status and their weight control.

Method

Design: The research design for this study was an experimental, randomized controlled trial design. Control occurs to decrease the possibility of error and thus increase the probability that the study’s findings are an accurate reflection of reality and the researcher can reduce the influence or confounding effect of extraneous variables on the study variables, also controlling extraneous variables enable the researcher to identify relationships among the study variables accurately and examine the effects of one variable on another (Borglin & Richards, 2010). Quantitative research requires varying degrees of control, ranging from minimal control to highly controlled, depending on the type of study, experimental studies are highly controlled (Borglin & Richards, 2010; Forbes, 2009; Shadish et al., 2002).

Population: The study population included collegians. The target population for this study was drawn from College of Languages, University of Baghdad, male and female students, aged 18 to 24-years who met the inclusion criteria mentioned below.

Sampling: The study applied the randomized sampling method. The researcher distributed (296) copies of the study questionnaire to the accessible students. The returned questionnaires were 223; 71 of them were incomplete. So, they were excluded from the data analyses. The final sample size was 152.

Inclusion/Exclusion Criteria: The inclusion criteria were for collegians, male and female students, those who do not experience any physical disability, and those who were fluent in Arabic. Exclusion criteria addressed students who have physical disability, and non-Arabic speakers.

Instrumentation: In addition to collecting demographic data, the researcher used a survey based on three constructs of the TTM (Stage of change, Decisional balance, and Process of Change) and the handbook of participating in regular exercise for the female adolescents.

The Weight Control Processes of Change Scale (WCPOCS): The Weight Control Processes of Change Scale (Prochaska, 1979; Prochaska & DiClemente, 1982) was used to measure the experiences can affect the exercise habits of some people. This scale is a 5-point Likert type scale that is composed of 48 items self-report measure previously validated for use with adolescents. These items were measured on a 5-point Likert scale. Responses on this scale range from 1 (Never) to 5 (Repeatedly). Total scores range from 48 to 240, with a higher score indicating greater Processes of Change (University of Rhode Island, 2016). This scale has shown satisfactory reliability (Cronbach’s Alpha = 0.81) external validity as well as good to excellent internal validity (Blaney et al., 2012).

Setting: The accessible population included university students (College of Languages) in Bab Al-Muaadham Complex in Baghdad City. Participants were those who met the previously mentioned inclusion criteria and were willing to participate in the study. Data collection took place at these locations.

Data Collection Plan: The subjects were randomly assigned to either the control group and the study group. All measurements were taken by personnel who did not know if the subjects were in the active or the control group.
(the measurement technicians were blinded). The study questionnaire was given to participants to complete (self-reporting). The questionnaires were also used to collect the data in 3 time points (pre-intervention, post-intervention I after one month of intervention, post-intervention II after three month of intervention) in university. The researcher collected data throughout morning time of the day. The estimated time range for each participant to complete the study questionnaire ranged between 15-20 minutes, to be reaffirmed by the pilot study.

Data Analyses: The descriptive statistical measures of frequency, percent, mean, and standard deviation were used to describe participants’ demographics. The repeated measures analysis of variance (RM-ANOVA) was used to measure the difference in the constructs of the TTM over time.

The TTM-based intervention enabled students to employ more both the cognitive and behavioral Processes of Change for weight control behavior.

Students whose families have better socioeconomic status employ both cognitive and behavioral Processes of Change greater than students whose families are of poorer socioeconomic status.

The age mean for participants in the study group is 20.93 ± 1.56; more than a third age 20-years-old (n = 26; 34.2%), followed by those who age 21-years-old (n = 17; 22.4%), those who age 19-years-old (n = 12; 15.8%), and those who age 23-years-old and 24-years-old (n = 8; 10.5%) for each of them, and those who age 22-years-old (n = 5; 6.6%).
For the control group, the age mean is 19.98 ± 1.03; around two-fifth age 18-years-old (n = 30; 39.5%), followed by those who age 19-years-old (n = 25; 32.9%), those who age 20-years-old (n = 15; 19.7%), those who age 21-years-old (n = 5; 6.6%), and one who ages 24-years-old (n = 1; 4.2%).

Concerning gender, most in the study group are females (n = 52; 68.4%) compared to males (n = 24; 31.6%). For the control group, most are females (n = 55; 72.4%) compared to males (n = 21; 27.6%).

Regarding the SES, more than a half in the study group are of the upper middle class (n = 45; 59.2%), followed by those who are of the lower middle class (n = 17; 22.4%), those who are of the upper lower class (n = 11; 14.5%), and those who are of the upper class (n = 3; 3.9%). For the control group, less than a half are of the upper middle class (n = 35; 46.1%), followed by those who are of the lower middle class (n = 25; 32.9%), those who are of the lower middle class (n = 14; 18.4%), and those who are of both the lower class and upper class (n = 1; 1.3%) for each of them.

Regarding the BMI, Regarding the BMI, most of participants in the study group are of normal range (n = 51; 67.1%), followed by those who are overweight (n = 20; 26.3%), those who are underweight (n = 4; 5.3%), and one who has class I obesity (n = 1; 1.3%). For the control group, most are of normal range (n = 50; 65.8%), followed by those who are overweight (n = 19; 25.0%), those who are underweight (n = 5; 6.6%), and those who have class I obesity (n = 2; 2.6%).

**. Correlation is significant at the 0.01 level (2-tailed).

There are positively significant correlations between students’ BMI and each of Processes of Change over time ($r = .463$; $p < 0.01$; $r = .329$; $p < 0.01$; $r = .337$; $p < 0.01$) respectively.

Discussion

This randomized controlled trial was used to enhance collegians’ behaviors for weight control. The values of the POC for weight control for the study group noticeably increase by time. For the control group, such values slightly decrease by time with significant differences in the values of the POC over time for participants both in the study and control groups.

There was a significant difference in the POC for weight control over time for participants in the study group. The omnibus effect (measure of association) for this analysis was .734, which indicates that approximately 73% of the total variance in the POC for weight control values is accounted for by the variance in the administered intervention.

For the control group, there was a significant difference in the POC for weight control over time. The omnibus effect (measure of association) for this analysis was .147, which indicates that approximately 14% of the total variance in the POC for weight control values is accounted for by the chance. This finding reflects the TTM-based intervention enabled the students to employ both behavioral and cognitive processes that help them in changing unhealthy behavior (uncontrolled weight behavior) to a healthy behavior (weight control).

There were positively significant correlations between students’ BMI and each of Processes of Change over time. This finding could be explained as that students with higher body mass index think more about using both the cognitive and behavioral processes of change that could help them in exerting control over their weight control behavior.

Implications for Educations: There is a need to incorporate educational materials that focus on the behavioral change models into the curricula of nursing students in different educational levels.

Implications for Research: There is a need to replicate this study on larger sample size on broader geographical areas across Iraq.

Conflict of Interest: The researchers report no conflict of interest.

Source of Funding: This study did not receive any funding from any agency.

Ethical Clearance: A permission to conduct this study was obtained from the ethical committee in the College of Nursing, University of Baghdad

Estimation of the Width of Un-Erupted Canines and Premolars in Basrah Population: A Cross Sectional Study

Ali S. Thedan¹, Hasanen A. Alnamel², Rafid M. Albadr³

¹M.Sc. Orthodontic Dentistry, ²M.Sc. Prosthetic Dentistry, ³PhD. Dental Material, College of Dentistry, University of Basrah, Basrah, Iraq

ABSTRACT

Exact prophecy of the space gives a significant portion of an orthodontic valuation in the mixed dentition. However, the most frequently used procedures of space analysis are built on data established on Caucasian populations, so the purpose of the present study is to appraise the applicability of the method of Moyers to estimate the mesiodistal widths of permanent canines and premolars in an assemblage of young people from south of Iraq represented by Basrah city individuals and to associate the predicted teeth widths from this formula with those gotten from Moyers' tables and Tanaka and Johnston's equations. From a complete list of schools, 20 were randomly selected and a random sample of 207 school children was identified according to predefined selection criteria. The width of lower incisors unit, maxillary canine and premolar unit and mandibular canine premolar units were measured and used to create a regression model and a prediction equation. There was an apparent agreement between Moyers model and the present study in estimating the width of canine and premolar segments in both maxillary and mandibular arches and in both sexes. However, dimorphism in both sexes was noticed in the lower incisors widths. Moyers model of predicting canine and premolar widths was used as a comparative model for many studies worldwide. Applicability of Moyers model in Basrah seems valid from the results of this study although there is an apparent underestimation of the widths when Moyers model is applied. It is recommended to carefully use Moyers model for Basrah population.

Keywords: Un-erupted canines, Premolars, Basrah population, Maxillary canine

Introduction

Mixed dentition analysis is the prediction of the tooth size of un-erupted permanent canine and premolars, It's plays an important step of orthodontic diagnostic procedures through defining the difference between the available and necessary space in each dental arch. It’s become clear in orthodontic treatment that a noteworthy quantity of cases of dental discrepancies start at the mixed dentition phase, which locate at the time interval from the 6.5th year to the 13th year of life. Doubtless many of these cases may be reduced in severity or eliminated at all by at time management. In the meantime, an inappropriate and invalid mixed dentition space analysis results could lead to withdrawal decisions that prime to detrimental changes of patient’s soft-tissue and facial profile.

Measurement of the un-erupted teeth on radiographs was studied; however, radiographs are suggested by many authors including considerable accuracy, but it is time consuming requires an expensive setup and a well-trained operator which makes this prediction method difficult to be applied to predict the accurate mesiodistal widths of un-erupted canine and premolars. On the other hands, probability tables are more reliable and less sensitive when it’s based on accurate and related racial data.

Supremely, the mesiodistal dimensions of un-erupted canines and premolars have been appraised from widths of the erupted permanent mandibular incisors using the Tanaka and Johnston prediction equations or Moyers probability tables. At each prediction procedures were established using a populace of North European descent or Caucasian populations that brands prediction procedures built on a solo racial sample that may not be considered for other races.
The persistence of this study is to investigate the reliability of prediction tables of Moyers mixed dentition analysis in selected school children of at south of Iraq, Basrah city, and to produce regression equations to be used for space analysis in this specific population. There is no published mixed dentition analysis for the south Iraqi population.

**Methodology**

This is a cross-sectional study accomplished in Basra city. It is based on measuring the width of mandibular and maxillary incisors together with those of the canines, first and second premolars in both jaws using casts of both two arches.

The study population is composed of intermediate and secondary school children aging 13-17 years old. Twenty schools were randomly selected from the list of 198 schools after giving numbers and entered into SPSS version 20 to obtain random sample. From each school 11 pupils were selected and the headmasters obtained verbal consent from their parents to take the measures of their teeth. Because some children were excluded from the study as they do not fulfill the inclusion criteria, the final number that was included in the study is 207 after exclusion of 13 children. The sample was composed of 118 male and 89 female children.

**The Exclusion Criteria Include:** Dental caries, Dental deformity of any cause, missing of any tooth, History of surgical intervention including tooth extraction, Abrasion and bruxism any degree of malocclusion

**Measuring the Width of the Teeth:** The mesiodistal dimensions of the permanent incisors, canines and premolars were measured on all the study models in all four quadrants. Themesiodistal dimension of the teeth measured at the contact area by using a calibrated caliper (Figure 1).

Reliability of measuring the width of teeth was assured through repeating the measurement of every 10th cast and the results were correlated to the original readings. This manoeuvre confirmed a high reliability with a correlation coefficient of 0.81 (confidence interval 0.76-0.86).

The collected information was fed into an SPSS spreadsheet including the sex and the measurement of the teeth. The values gotten from right and left canines premolar sections in each arch were averaged so that there would be one unit value for the mandibular canine-premolar segments (LCPMs) and a corresponding maxillary one (UCPMs) for each mandibular unit of incisors (LIs). The LIs unit is considered as the autonomous variable or the predictor. Therefore, the two dependent variables are the upper and lower units separately.

The rays of analysis are: Predicting LCPM unit, Predicting UCPM unit and comparing the results to Moyers probability tables to the 35th, 50th and 75th percentiles.

Statistical management of data used regression analysis to develop the prediction equation and independent sample t-test/ANOVA to ascertain the significance of the variability. P value of 0.05 is considered as a level of significance for all tests.

The obtained data were compared with Moyer’s probability tables to 35th, 50th and 75th percentiles using paired t-test.

**Results**

The sample is composed of 118 male and 89 female children aging 13-17 years. The mean and standard deviation of the basic units of the teeth are shown in Table 1.

**Discussion**

This study faced the difficulty of obtaining a large sample size. However, the sample size obtained was proved sufficient through sample size estimation calculations with the consideration of statistical methods which are mean, standard deviation, correlation and regression analysis. (11)

Some studies have larger sample size. (12-13) Other studies included a similar average of participants as this study did. (14-15) However, a considerable number of studies had sample sizes lower than the current study. (16-17-18-19)

The choice of sex distribution was determined by the random selection of schools and subsequent use of candidates to include in the study (exclusion criteria in methodology section, as well as sampling procedures). Initial comparison of measurements in both sexes revealed that the predictor unit (LIs) is not statically different contrast to LCPMs and UCPMs and this was also revealed by Vanesa et al. (20) and in agreement certain studies of Chinese and Indian population. (14)

Sex distribution was not intentionally predetermined in the comparative studies as far as the search of the researcher yielded. However, sex distribution was equal in some studies (21-22-23) and disproportionate in other studies. (24-25-26)

Genetic and environmental factors play role in determining the size of the teeth. It is necessary to study indentation in terms of race and gender at generation intervals (30 years) because of changing trend of malocclusion. (27)
It is critically important to correctly estimate the width of unerupted teeth so that an accurate diagnosis is made. The frequently followed approach of estimating the width of unerupted teeth is prediction via regression equations. Researchers identified permanent mandibular incisors as the best predictor.

This study aimed to measure applicability of Moyers model to Basrah population.

Regression model of the LIs and each of LCPMs and UCPMs units was done through correlation and linear regression after validating the data to fit the model. The data were tested for normality and size to ensure proper model building. Tables 2, 3 and 4 present the parameters of regression analysis. Because of the variability among male and female children, the statistical analysis was split accordingly.

In male children, the correlation coefficient is almost fair for both Maxilla and Mandible 0.61 and 0.41 respectively. However, the attributed variability of these values is lower in the mandible than in the maxillary teeth widths. In the female counterpart, the correlation coefficient is slightly lower and the induced variability ($r^2$) is marginal. Overall of the sample revealed higher values for both correlation coefficient and the attributed variability.

Table 5: Regression analysis estimated the values to develop the regression equation. The following equations were developed

</tbody>
</table>

This study estimates that regression equation and prediction tables that are significantly different from Moyers model.

For the male children, the actual and predicted width of LCPMs was correlated significantly at 35th and 50th percentiles with $r$ values of 0.947 and 0.999 respectively (p value < 0.001). However, it was different at 95th percentile with an $r$ of 0.452 (p value = 0.121). Paired t test confirms these results (Table 9 and table 10).

**Conclusions**

Basrah city students represent a cooperative population from which a representative sample can be drawn. Moyers model of predicting canine and premolar widths was used as a comparative model for many studies worldwide. Applicability of Moyers model in Basra seems valid from the results of this study although there is an apparent underestimation of the widths when Moyers model is applied. It is recommended to carefully use Moyers model for Basra population. It is also recommended to have other studies in other governorates like Thiqar and Maysan so that a comparative and unified model for Southern Iraq is developed.

An Analysis of Factors Associated with the Relapse History of Clients with Schizophrenia at an Outpatient Polyclinic

Alifiatul Oza Hamanu, Ah. Yusuf, Rizki Fitryasari Patra

1Community and Mental Health Department, Faculty of Nursing, Universitas Airlangga, Jl. Mulyorejo, Surabaya city, Jawa Timur

ABSTRACT

Introduction: Schizophrenia is a chronic illness with which the sufferer may experience remission, recovery, and, at times, relapse. Relapse per se is affected by varied factors. Relapse in patients with schizophrenia may put themselves and their environment into danger. This research aimed to analyze factors associated with the relapse history of clients with schizophrenia who took outpatient medication.

Method: This research was a descriptive correlational study with a cross-sectional design. This research's population consisted of 75 people, 45 of whom were enrolled as respondents by the consecutive sampling technique. Data were collected using questionnaires. The independent variables in this research included medication adherence, family knowledge, family support, and social stigma, while the dependent variable was schizophrenia relapse history. The data were analyzed using the Spearman’s Rho calculation at a significance level (α) of ≤ 0.05.

Results: The research results show that there was a relationship between medication adherence and schizophrenia relapse history (p = 0.00), that there was no relationship between family knowledge and schizophrenia relapse history (p = 0.255), that there was a relationship between family support and schizophrenia relapse history (p = 0.00), and that there was a relationship between social stigma and schizophrenia relapse history (p = 0.01).

Conclusion: Medication non-adherence was the biggest factor that caused relapse in schizophrenia patients, followed by family support and stigma from society.

Keyword: schizophrenia, medication adherence, family support, social stigma

Introduction

Schizophrenia is a disabling, chronic illness with repeated exacerbation episodes and psychotic relapses. Many factors are responsible for this illness, including genetic factor, biochemical factor, psychosocial factor, socioeconomic status, stress, and drug abuse. In 2016 as many as 268 million people worldwide suffered from depression. The prevalence rate of schizophrenia stood at 0.2%–0.45% with an estimated 21 million people in the world suffering from schizophrenia. Fifty percent of clients with schizophrenia experienced relapse in the first year, 70% in the second, and over 70% in the fifth after withdrawal from hospital.

Schizophrenia sufferers may experience remission, recovery, or relapse. Relapse is a normal thing in the progression of an illness. In clients with schizophrenia, relapse refers to the exacerbation of symptoms or behavior that may put themselves as well as their environment into danger. Relapse rates are measured by calculating the time passed between the last medication and the next and the number of hospitalizations in a given period.

Relapses often occur in schizophrenia. With or without medical treatments, a schizophrenia patient may come into a relapse. International guidelines highlight prevention as a key to therapy for this illness. Symptoms
of schizophrenia relapse include clients feeling scared, losing appetite, having difficulties concentrating, experiencing sleep disorders, having depression, lacking interest, and engaging in self-withdrawal.

Many factors can be attributed to schizophrenia relapse. Such factors include medication adherence, work activity, age, gender, marital status, and family. In many cases, social stigma as well as other unidentified factors are also responsible in schizophrenia relapse.

This research aimed to analyzed factors associated with the relapse history of clients with schizophrenia at an outpatient polyclinic.

Method

Research Design: This research is a quantitative study of descriptive correlational type with a cross-sectional design. This research has obtained ethical approval as evidenced by the ethical clearance number 08/KKEPK.FKG/1/2016 from the Faculty of Dental Medicine, Universitas Airlamga, Surabaya, Indonesia.

Sampling: Out of a population of 75 schizophrenia clients with a relapse history who visited the outpatient polyclinic of RSJD Dr. Soedjarwadi, Central Java, Indonesia, 45 people were enrolled as respondents by the consecutive sampling technique. The independent variables in this research included medication adherence, family knowledge, family support, and social stigma, while the dependent variable was the relapse history of clients with schizophrenia.

Research Instruments: This research used 5 instruments to analyze the factors associated with relapse, namely the MARS (Medication adherence Rating Scale), a modified questionnaire about family knowledge, Friedman’s family support questionnaires, an instrument for measuring social stigma, and an instrument for measuring schizophrenia relapse.

Analysis Technique: The data from every questionnaire were numbered. Afterwards, tabulating and scoring were carried out for every instrument used. The data in this research were analyzed using Spearman’s Rho calculation at p < 0.05.

Results

1. Medication Adherence: The relationship between medication adherence and the relapse history of clients with schizophrenia can be seen in Table 1.

2. Family Knowledge: The relationship between family knowledge and frequency of schizophrenia relapse can be seen in Table 2.
3. Family Support: The relationship between family knowledge and frequency of schizophrenia relapse can be seen in Table 3.

Table 3: Relationship between family support and relapse frequency

Spearman’s test (P) = 0.000
Correlation coefficient (r) = -0.599

From the Spearman’s rho calculation, a p value of 0.00 was obtained. As the p value was lower than the predetermined p value (p < 0.05), H1 was accepted, and H0 was rejected. This means that there was a relationship between family support and schizophrenia relapse history. The correlation coefficient (r) identified was 0.599 in a negative direction. This suggests that there was a fairly strong relationship between family support and schizophrenia relapse history. The stronger the family support, the lower the schizophrenia relapse rate.

4. Social Stigma: The relationship between social stigma and the frequency of schizophrenia relapse can be seen in Table 4.

Table 4: Relationship between social stigma and relapse frequency

<td>24</td>
</tr>
</tbody>
</table>

Spearman’s test (P) = 0.010
Correlation coefficient (r) = 0.557

From the Spearman’s rho calculation, a p value of 0.010 was obtained. As the p value was lower than the predetermined p value (p < 0.05), H1 was accepted, and H0 was rejected. This means that there was a relationship between social stigma and schizophrenia relapse history. The correlation coefficient (r) identified was 0.557 in a positive direction. This suggests that there was a fairly strong relationship between social stigma and schizophrenia relapse history. The higher the social stigma, the higher the schizophrenia relapse rate.

Discussion

Many factors may influence relapse in patients with schizophrenia. Antipsychotics are among schizophrenia medications that are effective in treating positive symptoms in acute episodes (e.g., hallucination, delusion) and preventing relapse20. Adherent consumption of antipsychotic therapy enables clients with schizophrenia to minimize symptoms and relapse21. Thus, medication adherence becomes a relapse factor and will influence the progression of the illness toward chronicity22.

Relapse risk often occurs after discontinuation of antipsychotics consumption, and it is unrelated to the duration of medication23. This research is in line with a previous study which found that medication non-adherence becomes one of factors that influence relapse, accompanied by other symptoms such as lack of social support and high emotional expression24. But although antipsychotics are effective in reducing relapse, 30%–40% schizophrenia patients experienced relapse 1 year after withdrawing from hospital while taking outpatient treatments regularly25.

Schizophrenia is a problem that not only affects the patients, but also affects the family26. Family plays a prominent role in financially supporting clients’ lives as they are fully responsible for the clients and in caring for the clients27,28. Patients with chronic illness may elude relapse if they take medicines regularly and receive social support fully. Social support serves as an intervention that is needed to overcome them29. The outpatient medications family gets patients with mental disorders shows improvement in the patients’ conditions30.

Social stigma is a negative interaction with the environment clients with schizophrenia often come into contact with31. Social stigma has such elements as avoidance, rejection, moral judgment, stigma of association, unwillingness, discrimination, and abuse32. More than a few people confront people with schizophrenia with stigmatization32. This certainly can cause relapse in clients with schizophrenia, either directly or indirectly. Clients with schizophrenia who
have better individual coping with social stigma have better-quality life with better functional proportion toward recovery.\(^{33,34}\)

More factors associated with schizophrenia relapse history remain unknown in this study. Four factors that have an association with relapse history include medication adherence, family knowledge, family support, and social stigma. Further study, thus, is needed to investigate other factors.

**Conclusion**

Many factors can cause relapse in clients with schizophrenia. Medicine non-adherence became one of the most important factors to cause relapse in schizophrenia patients. Family support and social stigma also have an effect on relapse, albeit less dominant.

**Ethical Clearance:** This research has obtained ethical approval as evidenced by the ethical clearance number 08/KKEPK.FKG/I/2016 from the Faculty of Dental Medicine, Universitas Airlangga, Surabaya, Indonesia.

ABSTRACT

Euthanasia (eu means good and thanatos means dead) which literally means death well without suffering. Euthanasia brings many pros and cons from various aspects, both medical, social, cultural and religious.

Design: The first part is formulating the initial theory (draft stage of the moral development of the problem of euthanasia) hereinafter abbreviated as TPM2BS. The second part is designing data collection instruments and product testing (instruments).

Results: The results of this assessment indicate that written theories and assignments that are arranged theoretically are very valid, meaning the written stages and assignments are in accordance with the theory revealed, and the researchers’ mindset to construct that stage is acceptable. This means that the content validity and construct of the theory is sufficient, so that it can be implemented and verified in the field.

Conclusion: 1. Content validity and hypothetical construct theory Phase of Moral Development of Euthanasia Problems already fulfilled and can be verified in the field, 2. Validation test of 4.81 with a very valid category and reliability of 98.13% shows written assignments arranged theoretically are very valid it means they can be implemented and verified in the field.

Keywords: Morality, Euthanasia, Problem, A dilemma, Students

Introduction

Current development produces various thoughts and technology inventions which had an impact on shifting perspectives, social and cultural values. In 1945 Constitution of the Republic Indonesia written that health is one of the fundamental rights of every human being. So many people who suffer from serious illness, undergo long-term treatments and conditions with morbidity and high mortality are at risk for depression and hopeless thought that pain will ended by death. Based on that thought, people finally found a new way of death, in Greek term known as euthanasia (eu means good and thanatos means dead) which literally means death well without suffering. According to Sutarno, euthanasia is the act of killing a patient or letting the patient die naturally, where the patient suffers from an incurable disease according to medical science, with the aim of shortening the patients suffering.

Euthanasia brings many pros and cons from various aspects, both medical, social, cultural and religious. In terms of religion, in Indonesia it has been regulated in the MUI fatwa that euthanasia is murder based on media considerations for people with diseases that are no longer possible to be cured. However, the essence of life is entrusted by the Almighty God so that it must not be ignored. The law of killing in the Qur’an is very clear forbidden, as in surah Al-An’am verse 151 which means “And do not kill a soul that is forbidden by Allah (to kill it) but with a right cause.” Killing in this verse is all forms and types of murder including euthanasia especially active euthanasia, while what is meant by the right cause is for example in the war against infidels. Whereas the prohibition to do passive euthanasia is one of them in surah An-Nisa verse 29 which means “And do not kill yourself, verily Allah is Merciful to you.” Even in the conditions of infectious diseases, euthanasia is avoided as much as possible. For example for sufferers of AIDS, isolation action on sufferers is seen as a better solution than eliminated his life (euthanasia).

The issue of euthanasia when viewed from the aspect of criminal law and human rights in Indonesia
is still caused the endless debate between the provision of human rights and the contradiction of national law, especially the Criminal Code which is applied in Indonesia. Basically, euthanasia is still prohibited in the criminal law system or health law in Indonesia, no matter whatever the reason is and whoever request it individually for their own selves or those who request euthanasia for their families are all still forbidden.12

Every efforts that have been made of course lead to pros and cons, moreover South Kalimantan has been known as “religious regions and have many theologians”. Moreover, it will give an impact to the community especially “students” who have family members who suffer from chronic illness while there is a desire of family members to choose euthanasia as the way out of pain.

According to it has become an axiom in education that education will achieve the most Dewey said that morality is related to moral is things that are related to prohibitions and actions that speak incorrectly or correctly.2,9,14

Martin Hoffman complements of Piaget and Kohlberg’s work by paying the attention to the role of cognitive abilities and reasoning skills in explaining moral behavior. Hoffman argues that empathy for the suffering of others or called emphatic distress. Cognitive abilities determine the types of emphatic distress that a person can experience and as a consequence, empathic abilities develop in a pattern resembling levels.15 Thus all stages of moral development proposed by Piaget and Kohlberg can be predicted, taught and identified in students.10,18,19,21

Based on above description, research studies on moral development have not been carried out in Biology science learning field. Meanwhile, in biology we cannot be separated from things that related to God’s power and good morals towards disease and its treatments.22,23 Biology teaches how to behave towards ourselves and others. Biology instills these values without patronizing, obtained consciously by students through a process, so that it can increase the power to receive/store that information.

This problem has never been examined before, therefore moral dilemma research in the issue of euthanasia is expected to produce a moral representation of students about euthanasia. This also will contribute to biology study in Junior High School level in psychotherapy substance uses, treatment aspect assessments, law and human rights aspects.

The purpose of this study was to produce an overview of the moral development of Junior High School students in the problem of euthanasia through problem solving.

Method

This research is a type of research and development. The aims to develop research instruments about the stages of students’ moral development for each stage through solving the problem of euthanasia.

Design: This study uses a model of ASSURE development which developed by Heinich, Molenda, Russell and Smaldino.3 Broadly speaking this research was carried out in two parts of the series of instrument development activities. The first part is formulating the initial theory (draft stage of the moral development of the problem of euthanasia) hereinafter abbreviated as TPM2BS.

The second part is designing data collection instruments and product testing (instruments), followed by expert validation and readability tests for students.

Developed Instruments: The developing instruments include Defining Issue Test (DIT) which adapted from Rest (1999), this used to measure the stage of student moral development. DIT was modified by using a moral dilemma discourse on the problem of euthanasia. Discourse related to science-biology learning material that has been taught by the teacher is Addictive and Psychotropic Substances.

Research Subjects: The subjects of the study consisted of learning experts and educational practitioners as validators of the research instruments which amounted 5 (five) persons. While the research subjects for readability test came from VIIIth grade students of junior high school. Determination of research subjects came from class 8th junior high school with considerations: a) subjects were at a formal level who were able to think more abstractly, b) moral development of subjects tended to be more rigid in looking at right and wrong than older children, c) material about Various Organ Systems in humans, chemicals in the fields of industry and health, as well as chemicals in foodstuffs have been studied by students on grade 7th in the previous material.
Data Analysis Technique: Analysis of data from DIT validation, written assignments, and interview guidelines was carried out based on Table 2. The results of validation from the validator or expert if the research instrument was declared valid, then the research instrument was feasible to use based on the validator’s suggestion. Readability test, analysis activities carried out by identifying research instruments that are not well understood by students, then make revisions based on the results of the identification.

### Table 1: Assessment criteria

Calculation of the reliability of device assessment instruments uses the following formula:

$$R = \frac{A}{D + A} \times 100\%$$

**Explanation:**

- $R$ = Instrument Reliability (percentage of agreement)
- $A$ = Frequency of match between the two assessors (agree)
- $D$ = Frequency of discrepancy between the two assessors (disagree)

Device assessment instruments are said to be reliable, if the reliability is $\geq 75\%$.

### Results and Discussion

#### a. Results of Hypothetical Theory Validation

**TPM2:** Validation of the draft stage of moral development the problem of euthanasia to experts to find out the validity of the content and the theoretical constructs developed. Content and construct validity is obtained through the assessment of 3 experts. Assessment is given through a validation sheet with a suggestion/comment column. The results obtained and the summary are presented in Figure 2 and Table 3.

![Fig. 2: Graph of Validation Results TPM2E by Experts](image)

The results of the validation carried out by the expert, obtained an average score for the stage assessment aspects as much as 4.50(very valid), for the content aspect getting a score 4.67(very valid), and language assessment aspects getting score 4.67(very valid). The overall average results obtained for TPM2E based on the expert validation test amounted to 4.61 with a very valid category.

Based on the results of the validation carried out by the expert, the average score for the stage assessment aspect was 4.50(very valid), the content aspect got a score of 4.67(very valid), and the language assessment aspect got a score of 4.67(very valid). The overall average results obtained from this TPM2E based on the expert validation test amounted to 4.61 with a very valid category, while for reliability obtained 96.31%.

The results of this assessment indicate that TPM2E and the theories compiled theoretically are very valid, it means that the stages and theories are in accordance with what was revealed, and the researchers’ mindset to construct that stage is acceptable. This is consistent with the opinion of Rest\(^{13}\) that some researchers have tried to develop new methods to identify someone’s moral development. The moral that is held and believed by a person does not run stagnant, but
experiences the stages of moral development found four prominent moral developments in one’s development based on spiritual life factors, moral awareness, moral emotion, and post-conventional morality. Thus the content validity and construct of the theory is sufficiently fulfilling, so it can be implemented and verified in the field.

The results of this assessment indicate that written theories and assignments that are arranged theoretically are very valid, meaning the written stages and assignments are in accordance with the theory revealed, and the researchers’ mindset to construct that stage is acceptable. This means that the content validity and construct of the theory is sufficient, so that it can be implemented and verified in the field.

b. Written Validation Results: Validation of written assignments of discourse moral dilemma to experts to find out whether this moral dilemma discourse is appropriate and feasible to be used as a written task with the problem of euthanasia in junior high school. Assessment is given through a validation sheet and a suggestion/comment column. The results obtained are presented in Figure 3.

The draft written assignment was then validated to two teachers as presented in Table 2 and tested on 3 students in each school. The results of the revision of draft 2 are the final instruments that will be used in the next research. Task validity is known from the results of content and construct validation by lecturers/experts, teachers and students.

Table 2: Results of Validation of Written Tasks by the teacher

<table>

</tr>
</tbody>
</table>

The first written assignments using the discourse of skin disease related to the concept of Negative Impact Use of Psychotropic Substances that are made in the discourse of the first task is authentic problems that often occur among people, thus providing problem solving alternatives for students. The format is quite simple and is expected to help students make solutions according to their stages.

The scores obtained only come from two validators, because there are validators who do not fill in the validation sheet. However, the non-writing validator continued to write the recommendations in writing, ie the assignments were each suitable to be used with repairs and then validated by two teachers.

Based on the results of the validation carried out by the experts, obtained an average score for the aspect assessment which is 5.00(very valid), for the construction assessment gets a score of 4.83(very valid), and the material assessment gets a score of 4.67(very valid), and language assessment 5.00(very valid). The overall results obtained from this written assignment based on the expert validation test is 4.88 with a very valid category.
obtained from this written assignment based on the expert validation test are 4.81 with a very valid category and 98.13% reliability.

The results of this assessment indicate that written assignments arranged theoretically are very valid, meaning that the written assignments are in accordance with the mindset of the researcher to construct written assignments that are acceptable. Thus the content validity and construct of the theory is sufficiently fulfilling, so it can be implemented and verified in the field.

**Conclusion**

a. Content validity and hypothetical construct theory Phase of Moral Development of Euthanasia Problems already fulfilled and can be verified in the field.

b. Validation test of 4.81 with a very valid category and reliability of 98.13% shows written assignments arranged theoretically are very valid it means they can be implemented and verified in the field.

Effect of *ChannaStriata* Extract on the Expression of Tumor Necrosis Factor-α (TNF-α) in Rat Experience Periodontitis

Andi Mardiana Adam¹, Hasanuddin Thahir¹, Harun Achmad²

¹Periodontics Department, ²Department of Pedodontic, Faculty of Dentistry, Hasanuddin University, Makassar, South Sulawesi, Indonesia

**ABSTRACT**

Chronic inflammatory processes in periodontal disease are triggered by a number of bacteria that stimulate the body’s immune response, resulting in the release of inflammatory mediators namely cytokines which reduce the ability of cells to repair damaged tissue. Mechanical or anti-infective periodontal therapy is focused on eliminating the inflammatory process and stopping the development of the disease using certain ingredients. *Channasstriata* extract has a substantial content, such as albumin, Zn, Cu, and Fe which accelerates the healing process of inflammation and tissue regeneration. This study aimed to measure the effect of *Channasstriata* extract on inflammatory healing in Wistar rats induced by periodontitis through immunohistochemical examination on day 3 and 7 to see expression of tumor necrosis factor (TNF-α). This is an experimental study with a post-test and control group design. The sample consisted of 2 treatment groups, namely the *Channasstriata* extract treatment group, and the negative control group. The average TNF-α expression peaked on day 3 in both the control and treatment groups but was lower in the treated group. T-test showed a significant decrease in TNFα expression [p < 0.05] on day 7 the group used albumin as an additional treatment. In conclusion, the application of snakehead fish extract significantly reduced TNF-α expression.

**Keyword**: *ChannaStriata extract, Periodontal pocket, Periodontitis. TNF-α expression.*

**Introduction**

Chronic inflammation in periodontal disease is triggered by a number of bacteria that stimulate the body’s immune response, resulting in the release of inflammatory mediators namely cytokines which reduce the ability of cells to repair damaged tissue. As a result, there will be an inflammatory pathway that stimulates the process of osteoclastogenesis that causes alveolar bone destruction. The inflammatory pathway of periodontitis stimulates the secretion of inflammatory mediators including interleukin-1, interleukin-6, prostaglandin E (PGE), tumor necrosis factor alpha (TNF-α), receptor activator of nuclear factor B ligand (RANKL), and matrix metalloproteinase (MMP-8, MMP-9, and MMP-13) which aggravate chronic inflammatory reactions in the periodontal tissues. Collagen fibers become damaged so that a periodontal pocket is formed between the gingiva and teeth.¹

Mechanical or anti-infective periodontal therapy is focused on eliminating the inflammatory process and stopping the development of the disease. To restore the supporting structure of missing teeth, various regenerative procedures have been proposed, tested and evaluated in the past two decades. Previous research has supported the idea that various sources of albumin are relevant substrates for tissue regeneration applications. Albumin synthesis is stimulated by hormones, such as insulin, cortisol and growth hormone, and is inhibited by pro-inflammatory media, including interleukin-6 and tumor necrosis factor-α.²

The use of *ChannaStriata* and its products, empirically in the community and not as a source of animal protein can also be used as an alternative supplementary therapy in the process of wound healing after surgery, increasing endurance, increasing albumin and hemoglobin levels, eliminating edema, accelerating the healing process. Some previous studies have shown that *ChannaStriata* is a type of fish which has a high enough albumin content.⁴ *ChannaStriata* extract significantly increases albumin levels in hypoaalbuminemia and accelerates the wound healing process in postoperative patients.
Another study on the content of ChannaStriata extract by Santoso, et al. stated that ChannaStriata extract also contains ingredients that are essential for the human body, such as zinc [Zn], copper [Cu], and Iron [Fe], which play a role in wound healing.5

This study aims to measure the healing mechanism in periodontitis using ChannaStriata extract as an additional treatment material in periodontal treatment, by calculating and comparing the number of TNFα expressions.

**Method**

This research is an experimental study with pre-post design and control only. The study was conducted on Wistar rat samples using simple random sampling based on Federer’s formula. This study was approved by the Medical Research Ethics Committee.

Twenty-four male Wistar rats, weighing 200-250 gr, 2-2.5 months of age with 24 healthy conditions performed groin anesthesia, then induced periodontitis using silk ligature and porphyromonasgingivalis. After 14 days periodontitis, rats were divided into 2 groups of treatment, namely negative control and 100% Gabus extract. Rats were given inhalation anesthesia then curettage with gracey curette and application of albumin extract. Decapitation was carried out on days 3 and 7 after extract aplicated. Subsequently immunohistochemical histological preparations were made and examined under a microscope with 400x magnification.

**Result**

The results of statistical analysis using the t-test, showed a significant difference (p <0.05), which can be seen in table 1.

Table 2 shows there was a decrease in TNFα expression in periodontal pockets control group and albumin on day 3 and day 7 but lower in the group using albumin on day 7.

**Discussion**

Periodontal diseases varies by age onset, the bacteria and the host response. The host response has been identified as the primary factor determining periodontal disease progression and is influenced by other factors. The host response to antigens and irritants released by bacteria includes the local release of antibodies, lymphocyte and netroufil activation and their infiltration into the gingival tissues. The activation of lymphocytes and neutrophils is defensive and involves bacterial as well as possible tissue destruction. The cytokines like tumor necrosis factor (TNF) and chemokines produced by leucocytes lead to inflammation which is followed by attachment loss and bone resorption. TNF also reduces fibroblast activity.7,8

Serum albumin, a major plasma protein, is ubiquitous and complex in ways that are still being uncovered. By elucidatinmechanisms of the albumin molecule’s multiple roles as bindingprotein, carrier, scaffold, and active agent, we can harnesss potential for functional healing and tissue remodeling. It acts as a pro-attachment protein for mammalian cells, especially stem cells, while at the same time blocking bacterial colonization.5,9

The results showed that TNFα expression increased significantly in the negative control (SRP without Chanasta triata extract) on the 3rd and 7th days. This indicates that the 7th day in this group was still in an
inflammatory phase due to the release of TNFα as a pro-inflammatory cytokine. The negative control group showed lower TNFα expression and decreased again on day 7 indicating the inflammatory process had subsided and transformed into the proliferation phase.

Research in groups given snakehead fish extract showed lower expression of TNFα than other groups on day 3 and decreased day 7. This proves that cork fish extract has several components, including albumin, iron, zinc, and copper, proven to be able to accelerate wound healing. Research results from Restiana, et al. showed that Haruan extract is one type of fish that is rich in albumin. Albumin is needed by the body every day, especially for the healing process.

It is still largely unknown which bioactive compound(s) of Haruan had involved in the anti-inflammatory mechanism. It had been suggested that high content of docosahexaenoic acid (DHA) in Haruan could have contributed to the anti-inflammatory action. Notably, DHA had been shown to suppress the production of some inflammatory mediators including TNF-α, IL-1β and COX-2. It is also possible that several major fatty acids including palmitic acid, stearic acid and linoleic acid, which are abundant in Haruan, have contributed to the anti-inflammatory effect of Haruan as they had been reported to inhibit both COX-1 and COX-2.10,11

Conclusion

ChannaStriata extract can decrease TNF expression in periodontal pocket so it can be use as a adjunct in periodontal treatment.

Conflict of Interest: There is no conflict of interest in this study.

Effect of Moringa Leaf Extract (Moringa Oleifera) on Increasing the Number of Osteoblasts as a Marker of Bone Remodeling

Arni Irawaty Djais¹, Hasanuddin Thahir¹, Muchammad Hatta², Harun Achmad³, Melyanti Sari⁴
¹Department of Periodontology, Faculty of Dentistry, ²Department of Microbiology, Molecular Biology and Immunology Laboratory, Faculty of Medical, ³Department of Pedodontia, ⁴Professional Program Students, Faculty of Dentistry, Hasanuddin University, Makassar

ABSTRACT

Introduction: The process of bone remodeling will continue to occur when a balance between cell activities such as osteoblasts and osteoclasts also occurs. This process is controlled by hormones such as estrogen. Estrogen is known to increase the process of osteoblast differentiation and bone formation so that estrogen therapy is currently considered an effective therapy in preventing bone damage. The activity of estrogen hormone is similar to phytoestrogen activity. One type of phytoestrogens is quercetin. One of the plants in nature which contains the most quercetin is Moringa oleifera.

Objective: To determine the effect of quercetin obtained from natural ingredients namely Moringa leaf extract to increase the number of osteoblasts as a marker for bone remodeling.

Literature Review: Leaf extract of Moringa oleifera plant contains many flavonoids. One of the most common types of flavonoids found in Moringa plants is quercetin. Quercetin is proven to increase bone formation by suppressing osteoclast formation and activity. Quercetin also has anti-oxidant and anti-inflammatory effects.

Conclusion: Leaf extract of Moringa oleifera plant can increase the number of osteoblasts as a marker of bone remodeling.

Keywords: Moringa leaf extract, quercetin, osteoblasts, osteoclasts, bone remodeling

Introduction

The process of bone remodeling is likened to a “circle” that will continue to occur when a balance between cell activity also occurs. These cells are osteoblasts and osteoclasts. Osteoblasts are cells that can produce bone organic matrices and stimulate the mineralization process. Whereas osteoclasts are one type of exocrine cell that prevents bone mineralization and can chemically damage the extracellular matrix. The process of bone resorption by osteoclasts is systemically controlled by four main hormones, calcitonin, PTH, vitamin D³ (1,25 vitamin D³), and estrogen. The main role of estrogen in the skeletal system is bone-sparing hormone which acts as a receptor produced by osteoblasts and osteoclasts. This hormone is very crucial in regulating the survival of osteoclasts and can cause osteoclast apoptosis.¹ The activity of estrogen hormone is similar to the activity of phytoestrogens (estrogen-like activity), but the effect is still under the hormone estrogen. However, phytoestrogens are known to be safer in long-term use because they come from plants.²

Quercetin is the largest polyphenol compound in nature, which belongs to the flavonoid group. Flavonoids have antioxidant effects and have bioactivity as a drug. These compounds can be found in stems, leaves, flowers, and fruit. Quercetin is also categorized as water-soluble pigments that cannot be produced by humans. Quercetin is also called phytoestrogen. Phytoestrogens are components of non-steroidal plants that can bind to estrogen receptors (ERs) and have estrogen-like action. As is known, estrogen is known to increase the process of osteoblast differentiation and bone formation so that estrogen therapy is currently considered an effective therapy in preventing bone damage.³ One of the plants in nature which contains the most quercetin is Moringa oleifera.
Based on this description, this paper is a literature review about effect of quercetin (phytoestrogens) obtained from natural ingredients namely Moringa leaf extract on increasing the number of osteoblasts as markers of bone remodeling so that it can be used as literature for the development of research for bone remodeling therapy in humans and utilization of herbal ingredients, especially Moringa oleifera.

**Bone Structure and Bone Remodeling Process:**

Bone is a dynamic network that has a complex cellular regeneration system. Bone consists of 4 types of cells namely osteogenic cells (osteoprogenitor), osteocytes, osteoblasts, and osteoclasts.4

**a. Osteogenic cells (osteoprogenitor):** Osteogenic cells are pluripotent stem cells that have not differentiated and originate from mesenchymal connective tissue. These cells are usually found on the surface of the bone in the inner layer of the periosteum, in the endosteum, and in the vascular ducts of the fracture bone. There are two types of osteoprogenitor cells: 1) preosteoblasts that have little endoplasmic reticulum and will produce osteoblasts; and 2) preosteoclasts which contain more free mitochondria and ribosomes, and produce osteoclasts.

**b. Osteocytes:** Osteocytes or bone cells are osteoblasts which are buried in the bone matrix. The amount ranges from 90-95% of the total number of cells. It is the most cell and has the longest life span in bone (up to 25 years). Electron microscopy shows that the osteocytes and branches do not attach directly to the surrounding matrix, but are separated from the walls of the lacuna and canaliculi by thin amorphous regions. This area seems to function as a metabolite exchange medium.

**c. Osteoblast:** Osteoblasts are cuboidal cells along the bone surface. The amount is about 4-6% of the total number of cells in the bone and the cell that has the most role in bone formation. Osteoblasts are derived from mesenchymal stem cells (MSC), but can also be derived from osteogenic cells. Osteoblasts make, secrete, and precipitate organic elements of the new bone matrix called osteoid. Osteoblast contains an alkaline phosphatase enzyme which indicates that these cells are not only related to matrix making, but also to their mineralization. Osteoid is a bone matrix that has not calcified, is newly formed, and does not contain minerals, but shortly after deposition, the osteoid is immediately mineralized and becomes bone.

**d. Osteoclasts:** Osteoclasts are large multinuclear cells located along the bone surface where resorption, remodeling, and bone repair occur. Osteoclasts are often found in a shallow curve in bone that is absorbed or enzymatically eroded called lakuna Howship. Osteoclasts which were originally inside the bone came from monocyte-like precursors. These cells secrete collagenase and other proteolytic enzymes which cause the bone matrix to release part of the calcifying base substance. After the resorption process is complete, the osteoclasts disappear, degenerate or change again into their original cells.

The remodeling process is two stages of cellular activity that occur cyclic, namely the resorption of old bones by osteoclasts and new bone formation by osteoblasts. First of all, osteoclasts will resorb through a proteolytic acidification and digestion process. As soon as osteoclasts leave the resorption area, the osteoblasts invade the area and begin the formation process by secreting osteoid (matrix of collagen and other proteins) which then undergo mineralization. Normally, the speed of resorption and bone formation takes place at the same speed so that bone mass remains constant.

Resorption activity and bone formation are regulated by various complex systemic factors. The balance between osteoclastic and osteoblastic activity is maintained by a constant supply of steroid hormones in bone cells. Disruption in the regulation is evident in aging and estrogen hormone deficiency. In addition to age and menopause, risk factors also known to affect bone mass and density include initial bone density (brought at birth) and calcium availability. Another factor that plays a role in regulation of bone remodeling is vitamin D, where vitamin D supplementation has been shown to increase bone density, even in menopausal women. Parathyroid hormones can increase bone resorption by releasing calcium from the bone matrix into the blood circulation to keep blood calcium levels normal. Other regulators are parathyroid hormones and various cytokines and enzymes which act as coregulators and coreceptors in the differentiation and activity of bone cells.1,4
**Moringa oleifera and Quercetin leaves extract:**

*Moringa oleifera* is one of the herbal plants, belonging to the family Moringaceae and is native to South Asia.5 All parts of this plant such as leaves, roots, stems, fruits and flowers are beneficial for health. Leaves from Moringa plants are the most frequently processed parts for consumption as well as herbal medicines.5

The largest chemical content in Moringa leaf extract is flavonoids. Flavonoids have the benefit of overcoming microbial infections due to the presence of benzo-γ-pyronone bonds in flavonoids. Flavonoids have been shown to have a positive effect on chronic diseases associated with oxidative stress. Most flavonoids are found in the leaves of Moringa plants. One of the most common types of flavonoids found in Moringa plants is quercetin, with a concentration of 1362.6 mg/kg).9 Quercetin is a strong anti-oxidant. This is because quercetin consists of three clusters that help maintain stability and act as antioxidants when reacting with free radicals. The three groups are: O-dihydroxyl group on ring B, 4-oxo group in conjugation with 2,3 alkenes, and 3- and 5-hydroxyl groups. The functional group can donate electrons to the ring which will increase the number of resonances of the benzene structure of quercetin compounds. Another benefit possessed by quercetin is that it can reduce oxidative stress reactions (ROS) in the brain neuron, effective as an antiviral agent (such as HSV-1, parainfluenza type 3, pseudorabies, and cardio viruses), as anti-cancer, as well as anti-inflammatory.8

**Correlation of Quercetin and Bone Remodeling:**

Based on the results, leaves of Moringa plants are very rich in flavonoids. Flavonoids are chemicals in plants which are very important in health. The most common type of flavonoids found in Moringa leaves is quercetin.9,10

Quercetin is the main phytoestrogen found in plants. Phytoestrogens are components in non-steroidal plants that can bind estrogen receptors (ERs) and have estrogen-like activities.11 Estrogens have an important role in bone tissue hemostasis in the form of estrogen levels decreasing during menopause is the main cause of bone damage and osteoporosis. The mechanism of action of estrogen in bone tissue is completely unknown, but several studies have reported that estrogen preserves bone hemostasis by inhibiting osteoblast and osteoclast apoptosis and preventing excessive bone resorption. Estrogen suppresses the formation and activity of osteoclasts as estrogen inhibits osteoclast apoptosis. Estrogen inhibits osteoclast formation by inhibiting the synthesis of osteoclasogenic cytokine RANKL by osteoblasts and osteocytes. In addition, estrogen inhibits osteoclast formation through reducing levels of other osteoclasogenic cytokines such as IL-1, IL-6, IL-11, TNF-α, TNF-β, and M-CSF.12,13

The estrogen activity described above is the same as phytoestrogen activity, the difference lies in the source. Estrogen cannot be produced by plants, while phytoestrogens can only be produced by plants, except algae. Therefore, phytoestrogens began to be developed in skeletal therapy. Interesting phytoestrogens are studied because they have the potential to prevent and treat diseases such as osteoporosis, menopausal symptoms, and so on. Kanno et al. reported that there were effects of phytoestrogens and estrogen on the differentiation of osteoblasts using MC3T3-E1 cells, an osteoblast cell in mice. Phytoestrogens increase alkaline phosphate activity and stimulate bone mineralization in these mouse cells. This shows that there is a possibility that quercetin can improve the process of bone formation locally. The effect of quercetin on the differentiation and proliferation of human adipose tissue-derived stromal cells (hADSC) also began to be investigated.14

Quercetin also has anti-oxidant and anti-inflammatory effects. In a study conducted by Napimoga et.al., quercetin can inhibit bone damage in mice that experience periodontitis. The mechanism of action of quercetin is to reduce the production of inflammatory molecules, inhibit intracellular entry pathways such as mitogen-activated protein kinase (MAPK) and NFKB so that inflammation and oxidative stress decrease, and inhibit cytokine production (IL-1β, TNF-α).15 As it is known, increasing the amount of TNF-α will lead to increased osteoclast activity. In another study it was stated that TNF-α was actually produced by osteoblasts and superimposed by binding to RANK receptors (receptor activator for nuclear factor kB) macrophages which would later lead to differentiation of macrophages into osteoclasts and increase bone resorption. TNF-α production by either macrophages or osteoblasts alone caused by infection can cause an increase in the number of osteoclasts which in turn causes an increase in bone resorption activity and decreases bone density. If the production of TNF-α can be inhibited, then of course osteoclast production can also be inhibited.16
Quercetin is found to increase osteogenic differentiation at certain doses (the dose of flavonoids in the body is around 23 mg, of which 60-75% is quercetin). Quercetin in excessive amounts can also cause toxic effects. A case report states that a 69-year-old man was diagnosed with carcinoma of the heart after consuming quercetin (400 mg/day) and bromelain (100 mg/day). Normally, the supply of quercetin from fruits and vegetables in the body is 15-40 mg/day. However, for therapeutic purposes such as allergic, anti-inflammatory, and other diseases, quercetin can be prescribed. The therapeutic dose of quercetin ranges from 250-500 mg three times a day. Quercetin is available in capsules (250 mg, 300 mg and 500 mg) and tablets (50 mg, 250 mg and 500 mg). Recommended quercetin doses for adults vary depending on the patient’s health condition during treatment.

Conclusion

Based on the literature review that has been done it can be concluded that the leaves of *Moringa oleifera* are rich in flavonoids. The most common type of flavonoids is quercetin. Quercetin is proven to increase bone formation by suppressing osteoclast formation and activity. Quercetin also has anti-oxidant and anti-inflammatory effects. Quercetin can reduce the production of inflammatory molecules, inhibit intracellular entry pathways such as mitogen-activated protein kinase (MAPK) and NFkB so that inflammation and oxidative stress decrease, and inhibit cytokine production (IL-1), TNF-α. As is known, increase the amount of TNF-α will increase osteoclast activity.

ABSTRACT

Oral health of preschool children can be deteriorating by dental caries and periodontal disease. Early childhood caries is highly prevalence dental public health problem that affect the primary tooth in children below the age of 71 months. Salivary soluble cluster of differentiation 14 and salivary toll like receptor 2 are proteins that have the ability to recognize different bacterial component and play role in prevention of infection. This study was conducted to determine the salivary levels of soluble cluster of differentiation 14 and soluble toll like receptor 2 in children with active dental caries and caries-free controls and found the correlation with gingival parameter. Sixty children with an age range between (4-5) years were participated in this study; they categorized into two groups, 30 children with severe stage of early childhood caries as the study group and 30 caries free children as the control group. Oral examination done by recording decay, missing, filled surfaces, measuring dental caries severity, gingival health status was assessed by using gingival index, in addition to plaque index. Saliva samples were collected from both groups. Enzyme-linked immunosorbent assay was carried out to estimate the salivary level of soluble cluster of differentiation 14 and soluble toll like receptor 2. The present study found significant elevation in the mean level of soluble cluster of differentiation among early childhood caries group, moreover there are no differences in mean level of soluble cluster of differentiation between caries severity groups. On the other hand, a positive non-significant correlation was found between the concentration of soluble cluster of differentiation in both groups and each of plaque index and gingival index. Regarding the soluble tool like receptor 2 a higher level in caries active group than caries free group was revealed without significant difference between them. Significant differences in soluble tool like receptor 2 mean levels was found between caries severity group. Furthermore, positive significant correlation was observed between salivary level of soluble tool like receptor 2 and gingival index in both groups, on the other hand, positive non-significant correlation was found between the levels of soluble tool like receptor 2 and plaque index. It can be conclude that the levels of salivary soluble cluster of differentiation 14 and tool like receptor 2 increased as the oral disease progress and they may have a suspected protective role against microbial burden. Salivary soluble cluster of differentiation 14 could be an important biomarker of caries activity.

Keyword: CD14, TLR2, ECC

Introduction

Dental caries and periodontal disease are the most popular and widely spread diseases affecting populations at different ages including children. Over the past 50 years ECC has been argued so widely as a most common clinical disease occur in preschool children seven times more than fever and five times more than asthma (⁰). American Academy of Pediatric Dentistry (AADP, 2016) (⁰) defined ECC as any a sign of presence of one or more decayed (non cavitated or cavitated lesions), missing (due to caries), filled tooth surfaces in any primary tooth in a child under the age of six. The definition of severe ECC (S-ECC) is any sign of smooth-surface caries in a child younger than three years of age, and from ages three through five, one or more cavitated, missing (due to caries), or filled smooth
surfaces in primary maxillary anterior teeth or a decayed, missing, or filled score of greater than or equal to four (age 3), greater than or equal to five (age 4), or greater than or equal to six (age 5). Although the etiology of ECC similar to other types of dental caries, there is no clear recognition of its predisposing factors. However, there is no suspicion that the disease has an infectious origin, and the immunologic response by the host has effective role in its development. Salivary proteins have been revealed to have a role in the development of caries, one of these proteins is cluster of differentiation 14 (CD14). Soluble (sCD14) is a glycoprotein predominantly expressed on the surface of macrophages, monocytes and neutrophils. It plays a critical role in the recognition of multiple microbial products, such as lipopolysaccharides, peptidoglycans and endotoxins, which are main components of cell wall of Gram-negative and Gram-positive bacteria. In addition, toll like receptor (TLRs) family are part of the innate immune system that responds to the microbial associated molecules. TLR-2 is a key mediator in the innate immunity against Gram positive bacteria which is the most common cariogenic bacteria. TLR-2 have the ability to recognize the peptidoglycan of Gram positive and Lipopolysaccharide of the Gram negative bacteria respectively either alone or in organization with the common co-receptor CD14. Cytokines produced by human odontoblast-like cells in response to ligands that interact with TLR-2. These molecules are essential in coordinate the intensity of pulp response to Gram positive bacteria which are infiltrating to dentine during decay formation. Gingival diseases affecting children are various and may continue to jeopardize the periodontium of the adult. Periodontal health can also be a mirror expressing some of the systemic diseases and disorders. Early screening, diagnosis and treatment of the disease could assist rule out the cause in initial stage.

Materials and Method

Sixty children with an age of 4-5 years old were enrolled in this study during the period from December 2018 to February 2019, they were chosen from kindergartens in Tikrit city, Iraq. They were divided into two groups; 30 child with sever type of ECC according to Wyne (1999) category as the study group and 30 free caries child according to World Health Organization (WHO, 2013) criteria as the control group. Exclusion samples were children who were taking antibiotic, or any medication, children who were ate during one hour before sample collection, children who had flu or any systemic disease, any child with ECC but not as sever type. ELISA sCD14 kit (Al-shkairate establishment for medical supply. Amman, Jordan) and ELISA TLR2 kit (Al-shkairate establishment for medical supply. Amman, Jordan) were used to quantify the biomarkers. At 9-11 am at the day of the examination the selected child from the kindergarten was invited to separate room with sufficient room light and comfortable position. The examination start by measuring the dentition status by recording the decay, missing and filled surfaces according to criteria of WHO (2013) using Community periodontal probe (CPI); dental caries severity was measured according the International Caries Detection and Assessment System (ICDAS) plaque Index (PI) was measured according to plaque index criteria of Silness and Löe (1964). Gingival Index (GI) was measured according to criteria of Löe and Silness (1963). After ensuring that child not drink ate or at least 1 hour before the procedure, the method of saliva collection was explained clearly to the children, 3-5 mm of unstimulated saliva was collected by drooling method into sterilized plane tube, then the samples were transported to ice box. The whole collected samples were transferred to the laboratory immediately for centrifuge the sample to inhibit the hydrolysis of proteins. Each sample was centrifuged for 10 minutes at 400 rpm at 2-8°C. The supernatant which is about 1-2 ml was removed to eppendorf tube. The sample was stored at -20°C for further analysis. Level of sCD14 and TLR2 was quantified by sandwich Enzyme-Linked Immune-Sorbent Assay (ELISA) technology. Data description, analysis and presentation were performed using Statistical Package for social Science (SPSS version 21).

Results

Salivary sCD14 level in the study group was significantly higher than the control group (P<0.05) (Table 1). Positive non-significant correlation between sCD14 level and caries experience (ds and dmfs) was reported (Table 2), a non-significant differences in the relation of sCD14 level in study group between two different stages of caries progression (d5, d6) was revealed in Table 3, also positive non-significant correlation was found between sCD14 level and caries severity (Table 4) and a positive non-significant correlation between the concentration of sCD14 in both group with GI and PLI as shown in Table 5.

*Significant correlation

Regarding TLR2 level, it was higher in the study group than the control group, although the difference was not significant (P>0.05) (Table-1). Positive significant correlation between TLR 2 and each of (ds) and (dmfs) (Table-2), also highly significant differences (P<0.001) in TLR 2 concentration between different stages of caries severity (d_{6}, d_{5}) (Table-3). Positive highly significant correlation was found between the TLR2 level and caries
stage of severity (Table-4), also positive significant correlation between salivary level of TLR2 and GI in both group, while positive weak non-significant correlation was found between TLR2 with PLI (Table-5).

**Discussion**

Although ECC and gingival problem are usually not life threatening, it should be remembered that oral health is one of the most important part of the general body health\(^{(12)}\). Early childhood caries is an infectious, chronic disease affecting young children, comprises an important public health problem \(^{(13)}\). The identification of possible biomarkers to oral disease, allowing the intervention in a pre-symptomatic condition. To the best of our knowledge this is the first study in Iraq to investigate the association between ECC and biomarkers of innate immunity (sCD14 and sTLR2).

The present study revealed that the level of sCD14 was significantly higher in ECC group, also positive correlation was found between sCD14 level with (dmfs) scores and caries severity and higher level of sCD14 was found in \(d_5\) severity score than \(d_4\). This finding was in accordance with previous studies \(^{(14-15)}\). The elevation in level of sCD14 could be due to the fact that 3-5 year old children have not yet been developed specific immune responses completely. sCD14 stimulate immune response by recognizing several microbial products, such as endotoxins, LPS and peptidoglycan, which are major ingredient of Gram-ve and Gram+ve bacteria, respectively \(^{(16)}\). On the other hand this finding disagreement with the some studies \(^{(17-18)}\), the discrepancy of results among various studies may be due to sample size, type of sample (saliva or GCF) and selection of the subjects, or could be attributed to the difference in the methodology and socioeconomic status. Interestingly, this finding reinforced the hypothesis that sCD14 is an inflammatory protein that is increased in response to the ECC bacterial stimulus and fill the gap between innate and specific immune responses \(^{(19)}\). Positive weak correlation was shown between the concentration of sCD14 and PLI and GI, which was in accordance to previous study \(^{(20)}\). This findings can explained by the fact that the microbial biofilm, composed from different microbial community, one of them is Gram–ve bacteria which LPS one of the important cell wall component, as sCD14 responsible for recognize LPS and other microbial cell wall component this cleared the elevation of concentration of sCD as the gingival disease develop.

The current data also revealed that TLR2 level was higher in study group than control group but the differences was statically not significant, this contradictory to some studies \(^{(16-21)}\) that revealed there is significant increase in mean concentration of TLR-2 in ECC group. The incompatibility in the results between current study and other studies may attributed to the differences in sample age, size and the way of saliva collection. Positive significant correlation was cleared between TLR 2 level and ds and dmfs. This result was in accordance to other study \(^{(22)}\). In general the increase in sTLR-2 in carries active saliva may represent a host strategy to counter the increased Gram + ve cariogenic bacteria. This study reported a positive highly significant correlation with carries severity, as well there was a high significant differences in TLR2 concentration between \(d_5\) severity stage as compared to \(d_4\). However, there was no previous data to compare the current result with it. Positive correlation was shown between TLR and (GI) and positive non-significant correlation with (PLI). Regarding the correlation of TLR with gingival parameter in preschool children is absent. Research has determined that along with immune cells, periodontal tissues also expressed TLRs \(^{(21)}\). Since the gingiva is always exposed to bacteria present in plaque biofilm and as TLR is responsible for recognize the peptidoglycan of Gram+ve bacteria, TLR signaling play a significant role in the innate response and preservation of periodontal health \(^{(22)}\).

**Conclusion**

Dental caries and periodontal disease are the major component of oral disease. In this report, two soluble proteins, sCD14 and sTLR-2 modified in carries active saliva and in accordance carries severity, in addition a positive correlation with gingival parameter was shown. Therefore sCD14 and sTLR2 are potential biomarker for oral diseases.

Determination of Serum and Seminal Gamma Glutamyl transferase (GGT) on Sperm Parameter in Infertile Patients

Asmehan Adnan Al-LNaqeeb¹, Muhammed Baqir M- R.Fakhrildin²

¹Department of Basic a Science, College of Nursing, University of Baghdad; ²Prof., Jabir ibn Hayyan Medical University, Iraq

ABSTRACT

One of the enzymes created in the bile ducts is known as Gamma-Glutamyl Transpeptidase, abbreviated as GGT. It is a kind of cell surface protein, advantageous for Glutathione extracellular catabolism. The core aim of the research is to research the clinical value of seminal and serum levels of GGT in infertile and normozoospermia men, specifically in men having azoospermic (NOA) and asthenozoospermic (A) It has been noticed that the renal tissue produces maximum GGT but hepatobiliary system creates the enzyme and thus the efficacy of GGT is enhanced in the form of liver disease. The present study included 3 sections of infertile males, the total was 58, from which normozoospermia were 38, asthenozoospermia were 7 and NOA were 13, experimented in High Institute of Infertility Diagnosis and Assisted Reproductive Technologies of Al-Nahrain University, situated in Baghdad, Iraq. The considerable value of (P≤0.05) was obtained in men having Normozoospermia when they were compared with other factors of infertility. A considerable decrement (P≤ .05) was also obtained in men having asthenozoospermia in comparison to other. Assessment of seminal GGT appeared more important than serum GGT and its associated with the safety of accessory genital glands.

Keywords: Gamma-Glutamyltransferase, Asthenozoospermia, non-obstructive azoospermia (NOA).

Introduction

A great group of enzymes is found within the seminal and blood plasma, but in a lot of situations, the gland responsible for their creation hasn't been recognized yet. The seminal stages of enzymes are especially major designed for metabolism and functions of sperms in addition (2).

In the year 1973, Rosalki and Rowe obtained a greater level of GGT action in the human seminal fluid and it is linked with the existence of Semen (11, 9).

Nakanishi et al. (10) have indicated that a link exists among serum GGT and the factors of lifestyle. It was concluded that obesity, cigarette smoking, and drinking alcohol are fully linked with enhanced serum GGT and on the other hand, drinking coffee is inversely linked with serum GGT. A relationship study conducted among semen factors in Arabian horses and seminal plasma enzyme action obtained an insignificant relationship, excluding HOST and PH. Another investigation calculating the enzyme action in bovine semen specified that the enzymes are connected in bovine sperm metabolism and suggested that they can indicate the subtle symbol for the calculation of the semen quality after and before the storage, time-dependent inactivation, the seasonality assessment in the association among conservative semen factors, and enzyme activity. This is the cause to increase the enzyme tool for the purpose of evaluating the quality of semen. It has been noticed that it is not compulsory to demonstrate GGT for productive purpose but GGT has a significant part in cysteine homeostasis in the mouse procreative axis (4, 8).

Materials and Method

The case-control investigation of infertility was conducted in “High Institute of Infertility Diagnosis and Assisted Reproductive Technologies of Al-Nahrain
University in the duration of Mar-Dec 2014. The experiment was conducted in accordance with the rules of WHO (14). The study included 7 asthenozoospermic, 38 normozoospermic, and 13 azoospermic men. The analysis of semen was also conducted in accordance with the rules of the WHO (14).

The sample was gathered after the absence period of 3 to 5 days in a petri dish that was sterilized, disposable, and non-toxic. This was done in a secret room, adjacent to the laboratory to decrease the effect of temperature and to regulate the duration between the analysis and collection. The sample was marked with lab number and the name of the patient and it was then liquefied using an incubator at the temperature of 37 degrees and then the sample was mixed with care by a pipette and in the end, it was investigated deeply using microscopic and macroscopic analysis.

**Seminal Plasma Preparation and Storage:** The centrifugation was applied to the sample for a duration of 15 minutes at around 3000 revolutions per minute. The supernatant of the sample was carefully and quickly obtained and then inserted in the freezer at the temperature of around -20°C for later analysis. The CPK concentrations estimated with the help of enzymatic procedure (5).

**Blood Collection:** The blood of around 5 ml was aspirated from all the men. It was gathered in plain tubes and was permitted to clot and then it was centrifuged at around 2500 revolution per minute for the duration of 10 minutes. The samples were classified in accordance with the analysis into two main groups. The AMH concentrations were calculated using the ELISA method.

**Statistical Analysis:** The obtained data were assessed statistically with the help of SPSS software (SPSS, Chicago). Complete Randomized Design (CRD) was employed to analyze the seminal and serum amylase AMH levels and sample parameters. The Duncan multiple ranges test was then employed for testing the differences (Duncan, 1955).

**Results**

Table 1 presents the parameters of semen for men involved in the investigation. According to the macroscopic investigation, the sample, its volume, liquefaction time, and PH were normal and according to the WHO criteria (14). The microscopic examination also revealed normal results and matched with the WHO criteria. The microscopic examination includes simple grade mobility, concentration, total progressive sperm, sperm agglutination and normal sperm morphology (11).

The table one also presents the results of microscopic investigation of semen factors of asthenozoospermia which includes sperm volume, liquefaction, viscosity and PH and these results also found to be normal and matched with the WHO criteria. Moreover, the progressive sperm motility percentage was found to be minor as compared to the standard values of WHO criteria. The count of round cells was greater as compared to the normal WHO values, while all other microscopic investigation parameters were found to be normal and matched with the WHO criteria.

Moreover, the microscopic investigation of sample parameters for azoospermic men pointed out normal values for sperm liquefaction, PH and volume and they also matched with the WHO (2010) criteria, while the concentration of sperm was almost zero in comparison to the WHO (14) standard criteria. However, the count of round cells was found to be normal.

The serum GGT levels were classified in accordance with the male infertility factors and are represented in figure 1. The men having norozoospermia indicated considerable increment that is P value less than or equal to 0.05 in comparison to the other infertility factors groups and a considerable decrement was found for men having asthenozoospermia.

The seminal GGT levels were classified in accordance with the male infertility factors and are represented in figure 2. The men having normozoospermia indicated a considerable increment that is P value less than or equal to 0.05 in comparison to azoospermia groups. An insignificant difference of (P > .05) was noticed in the seminal GGT fluid level in men having normozoospermia in comparison to asthenozoospermia.

The relationship between seminal plasma and serum GGT were also classified in accordance with the male infertility factors and are represented in figure 3. A considerable decrement of (P ≤ .05) was noticed in the serum GGT level in comparison to the seminal plasma GGT.

![Figure 1: Serum GGT level (IU/L) categorized in accordance with male infertility parameter](image)

- Means dissimilar superscripts in each column are considerably diverse (P ≤ .05).
- Means alike superscripts in each column are insignificantly diverse (P > .05).
Means dissimilar superscripts in each column are considerably diverse (P ≤ .05).

Means alike superscripts in each column are insignificantly diverse (P > .05).

Discussion

It is commonly known that the prostate gland secretes GGT in seminal fluid and it is around 200x greater in comparison to the blood. The contribution of GGT in male infertility is not presented well and the stages of GGT in abnormal and normal seminal fluids are contradicting (1, 12).

The current investigation indicated a considerable decrease in the serum GGT levels in comparison to the seminal GGT levels of all age groups. A recent investigation indicated little GGT changes with age for men, however, serum GGT is linked with parameters such as age, drinking alcohol, smoking cigarette, and BMI and they are definitely related with the levels of serum GGT. The clinical variables comprise diastolic and fasting insulin, fasting plasma glucose, systolic BP, and cholesterol also specified a relationship with a baseline level of GGT (7).

A substantial decrement was found in the serum GGT level when comparing to the seminal GGT level of all infertility period groups. It has been noticed that the strong GGT activity is due to the seminal fluid and not due to the sperms. These results are found to be consistent...
with functional GGT view in which multiple factors are involved such as “blood-brain barrier”, transport at cell membranes, and the safety of the atmosphere in which the sperm is created and kept while considering the oxidation damage (13).

The prostate gland secretes GGT and its estimation in the seminal fluid can be noted for the assessment of the operation of this gland.

A considerable decrement was found in the serum GGT level of all infertility groups in comparison to the seminal plasma GGT level, however, it was noticed that GGT has an impact on the viability and production of sample because it has a great part in the glutathione structure in reducing oxidative stress on spermatozoa (6). The seminal fluid GGT level is a good indication for the recognition of contagion in the genital glands (3). The experiment found that the extensive creation of GGT seminal fluid is linked with the safety of genital glands.

Utilization of Lactobacillus Acidophilus FNCC-0051 Microencapsulation: Potential Benefit of Giving Combination of Sodium Alginate and Gelatin to Attributes and Role of Probiotic Against Staphylococcus Aureus

Arumentin Diana¹, Tutiek Purwanti¹, Isnaeni¹
¹Department of Pharmacy, Faculty of Pharmacy, Universitas Airlangga, Jl. Airlangga No.4 - 6, Airlangga, Gubeng, Surabaya, East Java

ABSTRACT

Background: The use of Lactobacillus acidophilus as an antimicrobial is still not optimal, even though this type of probiotic has benefits for skin health. One of bacteria causesthe turnaround cause effects of the skin is Staphylococcus aureus.

Objective: To evaluate the effect combination of sodium alginate and gelatin matrix 2.25%: 0.75% to the characteristics, viability, and antibacterial activity of probiotic microparticles.

Method: The experimental study used the ratio of sodium alginate and gelatin 2.25%: 0.75% (FI), 3% sodium alginate (FII) and 3% gelatin (FIII). Tests were carried out to assess viability (TPC method), making microparticles by extrusion method and antibacterial activity (agar diffusion method). The data obtained was analyzed by statistical tests.

Results: Particle size distribution was obtained, including 8.85 μm (FI), 9.69 μm (FII) and 5.40 μm (FIII). The viability of probiotics after being made microparticles is still in the range of probiotic minimum requirements despite a decrease. The lowest decrease in viability was 1.32% ± 0.06 (FI) and the highest decrease in viability was 14.77% ± 1.21 (FIII) which was significantly different (p <0.05). The lowest antibacterial activity test 9.27 ± 0.19 mm (FIII) and the highest antibacterial activity 10.83 ± 0.51 mm (FI) which was significantly different from FIII.

Conclusion: The combination of sodium alginate and gelatin 2.25%: 0.75% can increase the role of Lactobacillus acidophilus probiotic as antimicrobial against Staphylococcus aureus and can be an alternative in preventing infection.

Keywords: Lactobacillus acidophilus FNCC-0051, role, attributes, sodium alginate, gelatin

Introduction

Studies of probiotics and their use in various products have developed in recent years.¹ Probiotics provide health benefits if given in sufficient quantities.² Lactobacillus and Bifidobacteria are common microbes used as probiotics.³ Probiotics are widely used in the form of nutrients and orally.⁴ Probiotics can also provide health benefits such as antimicrobial activity, immunomodulators, and anti-diare.⁵ Probiotics is used in the fields of dermatology, cosmetics and preventive or therapeutic benefits, especially Lactobacillus acidophilus as an antimicrobial.⁶
The probiotic suspension has more optimal antimicrobial activity compared to probiotic supernatants. In this study *Lactobacillus acidophilus* was used in the form of probiotic suspensions that being cultured on MRS media. In topical use, it is expected that the active ingredient’s stability must be maintained, that last long enough in the skin, and released gradually by means of encapsulation in the form of microparticles.

The matrix that commonly used in microencapsulation is alginate, carrageenan, Chitosan, and protein. Gelatin is a matrix in the form of proteins that are often used in making microparticles. Gelatin is biocompatible, biodegradable, non toxic, inexpensive, swelling index good and easy to experience cross linking. Sodium alginate is also common, used as a microencapsulation matrix of probiotic bacteria. The advantage of microencapsulation using sodium alginate is easy, safe and cheap. Microencapsulation can be done by several methods, namely, emulsification, coacervation, spray drying, and extrusion.

Sodium alginate evidently has a disadvantage, namely the particles produced were too porous to protect probiotics from environmental factors. So that an alternative is needed through a combination with gelatin. The commonly used gelatin concentration is between 5-15%, the concentration of sodium alginate is 0.5-4% and calcium chloride is 0.05-1.5 M. In this effort a Crosslink is needed. Crosslinking commonly used in gelatin and sodium alginate is calcium chloride. The effectiveness of *Lactobacillus acidophilus* needs to be improved as an effort to prevent skin infections in health services. This study aimed to determine the effect of sodium alginate and gelatin combination with a ratio of 2.25%: 0.75% on particle shape and size, viability, and antibacterial activity of *Lactobacillus acidophilus* microparticles, by extrusion method, and CaCl2 1.5M cross linker.

**Method**

This study was an experimental study. Microbiological examination was carried out at the Health Laboratory Center in Surabaya and *Lactobacillus acidophilus* material came from the Center for Food and Nutrition Studies at Universitas Gajahmada. This study consisted of 3 formulas namely formula I (Probiotics + sodium alginate and gelatin combination with a ratio of 2.25%: 0.75%), formula II (Probiotics + 3% sodium alginate) and formula III (Probiotics + 3% gelatin). Sodium alginate and single gelatin were used as a comparison, compared with a combination of sodium alginate and gelatin.

The procedures in this study were carried out in several stages. The first stage was the examination of the materials, including probiotics, gelatin, sodium alginate and CaCl2. The second stage was carried out for the preparation of probiotic *Lactobacillus acidophilus* starter, optimization of growth at 0, 6, 12, 14, 18, 24 and 48 hours. In this phase the viability test was carried out by the TPC (Total Plate Count) method. Probiotics were mixed into the matrix (sodium alginate - gelatin) then viability tests are carried out using the TPC method. The next step was the formation of formula I (Probiotics + sodium alginate and gelatin combination with a ratio of 2.25%: 0.75%) , formula II (Probiotics + sodium alginate 3%) and formula III (Probiotics + gelatin 3%). Making microparticles with an extrusion method with cross linker CaCl2 1.5 M, pH checked at pH 8.5. Evaluation of the characteristics of the microparticle including the shape examination, viability and particle size distribution using an optical microscope. Activity test for *Staphylococcus aureus* bacteria with the agar well diffusion method set after preparation of *S. aureus* bacteria. Antibacterial activity tests were carried out before and after microencapsulation by measuring the diameter of the inhibition zone (mm) against *Staphylococcus aureus*. Next, to find out the equivalence of probiotic concentrations in microparticles with antibiotics, then comparing probiotic inhibitory zones that have been encapsulated with antibiotic inhibition zones (gentamicin) at various concentrations.

Qualitative examination carried out for the *Lactobacillus acidophilus* bacteria is by gram staining. Qualitative examination was also carried out an in the sodium alginate and calcium chloride matrix including organolectic examination, FTIR and DTA, and also in a gelatin matrix including organolectic examination and FTIR. The data obtained were then analyzed through statistical tests with the One-Way ANOVA variance analysis method, then analyzed by Tukey’s Honesty Significant Difference (HSD) test with a confidence level of 0.95 (α = 0.05).
Results

Identification results of *Lactobacillus acidophilus* FNCC-0051 showed that gram-positive bacteria were formed. Sodium Alginate, Type B Gelatin and Calcium Chloride used in this study have met the requirements as listed in the literature monograph. The results of pH showed in the range $5.22 \pm 0.08$ in 48 hours and $6.49 \pm 0.07$ in early hours. The minimum TPC is $1.14 \times 10^8 \pm 0.36 \times 10^8$ cfu/ml while the maximum is $3.82 \times 10^7 \pm 3.05 \times 10^7$. The highest log TPC of *Lactobacillus acidophilus* is $8.46 \pm 0.17$ log cfu/ml while the lowest is $7.09 \pm 0.13$ log cfu/ml.

Interactions between polymers and Crosslink CaCl2 solutions are characterized by the wave number of $C=O$ either shifted or disappears from alginate and gelatin. Sodium alginate-gelatin combination (2.25%: 0.75%) has the wave number of 3432.0 for the Sodium Alginate hydroxyl group and 1633.6 for $C=O$ Streching in Gelatin. The measurement results of a single raw material were found that IR spectrum (cm-1) of the sodium alginate Hydroxyl group was 3466.38 and gelatin $C=O$ is stretching was 1651.63. The results obtained from an optical microscope of 400x magnification are presented in Figure 1.

![Formula I](image1)
![Formula II](image2)
![Formula III](image3)

**Figure 1:** Microparticles form of probiotic Formula I, II, and III with 400x magnification optical microscope

The mean size of probiotic microparticles in each formula, as follow; formula I (8.85µm), formula II (9.69 µm) and formula III (5.40 µm). Based on the particle size, percentage calculation of microparticles between formulas, FIII (3% gelatin) has the smallest particle size and FII (3% sodium alginate) has the largest particle size, while the combination between the two polymers causes smaller size than just single sodium alginate and larger from gelatin. The particle size obtained from the microparticles of each formula has an unequal distribution, the smallest particle size is 3.06 µm found in formula I, II, III while the largest particle size is 18.38µm at FI, 24.5µm at FII, and 15.31µm on FIII.

The microparticle viability test results were obtained from viability percentage, which compared the TPC and Log TPC values of *Lactobacillus acidophilus* at Formula I, Formula II, and Formula III before microparticles and after microparticles. The smallest TPC value after manufacturing process of dry microparticles found in Formula III, but it still covered the required viability requirements, namely $10^6 - 10^7$ cfu/ml or log results which was 6-7 cfu/ml.

The viability decrease of *Lactobacillus acidophilus* in probiotic microparticles on the manufacturing process of microparticles (extrusion and oven). The highest decrease in viability was obtained in Formula III at 14.77% and the lowest decrease in viability was obtained in Formula I at 1.32%. The entrapment efficiency of *Lactobacillus acidophilus* in probiotic microparticles on the manufacturing process of microparticles (extrusion and oven) was decreasing compared to viability before microparticles manufacturing process. The highest entrapment efficiency obtained in Formula III at 87.94% and the lowest entrapment efficiency was obtained in Formula I at 76.35%. Viability and entrapment efficiency of *Lactobacillus acidophilus* against the microparticles manufacturing process were presented in Table 1.

The results of the One-Way ANOVA test with Tukey test, it can be seen that Formula III has the highest reduction in viability against the manufacturing process of microparticles and has a significant difference with Formula I and Formula II. From the results of the One Way ANOVA test with post hoc Tukey, it can be seen
that Formula I produces the highest inhibitory activity compared to other Formulas and has a significant difference with Formula III. Table 2 presents the Tukey test results of \textit{Lactobacillus acidophilus} viability against the manufacturing process of microparticles (extrusion and oven) and One Way ANOVA test with post hoc Tukey on inhibition zone diameter for each formula against \textit{Staphylococcus aureus}.

### Discussion

This study showed the effect of a sodium alginate and gelatin combination with concentration of 2.25%: 0.75%. The effect that occurs is the size difference of the \textit{Lactobacillus acidophilus} FNCC-0051 microparticles and an increase in the role and effectiveness seen from the increase in viability and antibacterial activity against \textit{Staphylococcus aureus}. This study showed that the effect of the matrix ratio (sodium alginate - gelatin) on the rate of decline percentage in the viability of \textit{Lactobacillus acidophilus} per formula and it can be seen that FIII had the highest reduction in viability which had significant differences with FI and FII. Although there was a decrease in the viability of probiotics during the manufacturing process of microparticles from all three formulas, the number of probiotic TPCs in the three formulas still met the requirements of probiotics as antibacterial. The results of the microparticle entrapment efficiency test were obtained from percentage data on viability, the results of the viability percentage of formulas I, II, and III were 76.35%, 84.20%, and 87.94%. This can be related to the smaller particle size, the entrapment efficiency is greater because of the large surface area of the matrix.

The reason for gelatin was chosen in this study, because it has a good swelling index ability and is useful as a thermally reversible gelling agent for encapsulation. Besides the compact structure between alginate and gelatin will give small particle size and small particle size because of gelatin can fill these pores when cross links occur with CaCl$_2$, besides, gelatin has the ability of self-assembly, so that more compressed particles can be formed when compared to the use of a single alginate matrix that has very porous microparticle properties.

The method used in this study was the extrusion method because it is suitable for sodium alginate and gelatin matrix. The method is simple and inexpensive, does not damage probiotic cells, produces a high probiotic viability, and can be carried out in aerobic or anaerobic conditions. A few factors that affect microparticles formation, including the diameter of the syringe needle and the distance between the syringe needle and the cross-linked solution can affect the shape and size of the microparticles, the stirring speed also affects the microparticles, the faster the stirring speed, the smaller the particles produced.

Qualitative examination of probiotic, namely gram staining on \textit{Lactobacillus acidophilus} FNCC-0051.
was obtained from gram-positive bacteria, according to the morphological characteristics of *Lactobacillus acidophilus*, which were classified as gram-positive and rod-shaped. The results of organoleptic examination of gelatin shows that it was in the form of powder, with pale yellow granules to dark yellow, odorless and tasteless. The results of the infrared spectrum showed the same results with the literature so that it can be concluded that these results meet the characteristics of gelatin. Qualitative analysis on Calcium chloride as a cross linker also carried out, namely organoleptic and thermal analysis using DTA. The organoleptic analysis of calcium chloride showed that it was white, crystalline powder, hard, odorless and hygroscopic, whereas according to literature it was white or almost white crystalline powder, hard, odorless and hygroscopic.

**Conclusion**

Not only there is a difference in the size characteristics of *Lactobacillus acidophilus* FNCC-0051 microparticles with a combination of sodium alginate-gelatin 2.25%: 0.75% but there is an increase in role and efficacy that observed from increased viability and antibacterial activity against *Staphylococcus aureus*.

The Correlation of Sleep Quality Factors in Overweight Adolescents in a Developing Country

Nur Faizah¹, Elida Ulfiana¹, Setho Hadisuyatmana¹

¹Department of Nursing, Faculty of Nursing, Universitas Airlangga, Jl. Airlangga No.4 - 6, Airlangga, Gubeng, Kota SBY, Jawa Timur

ABSTRACT

Introduction: Good sleep quality is a significant health indicator that needed by people, especially overweight adolescence. The case of overweight adolescents in developing countries is quite significant where earlier studies suggested that overweight adolescents who have poor sleep quality will increase the risk of obesity. So an understanding of the correlation between the sleep quality factors in overweight adolescents is needed.

Objective: This study aimed to find out the factors associated with sleep quality in overweight adolescent in a developing country.

Method: The research used descriptive corelative design. Fifty overweight adolescents respondents were involved using total sampling technique. The data were collected with questionnaires and analyzed using Spearman’s Rho test (α<0.05).

Result: The results showed that stress and diet have significant correlation with sleep quality (Pstress =0.020, pdiet = 0.000) However, physical exercise and fatigue, environment, illness, drug and substance and habits before sleep (p>0.05) are not explainable because the respondents didn’t have the habits and conditions that may be correlated with their sleep quality.

Conclusion: This study suggested the factors of sleep quality in overweight adolescents related to stress and diet. The other related factors that examined did not show any association.

Keywords: Sleep quality, adolescence, overweight, obesity

Introduction

The World Health Organization (WHO) defines obesity and overweight as two different things, but both of them mean an accumulation of excessive fat in the body, which is indicated by an increase in the value of the Body Mass Index (BMI) above normal. Adolescents is one group that experiences significant overweight in decades ¹ including the number of cases of obesity in adolescents in developing countries ²³, one of them is in Indonesia. Overweight in adolescents is currently evidenced by the existence of national prevalence based on data from the Baseline Health Research of Indonesia, called Riset Kesehatan Dasar ⁴. The prevalence of adolescents who experience overweight are 7.3% (5.7% overweight and 1.6% obese). This result is far higher than year of 2010, which was only 1.4% of adolescents who were overweight. Based on a previous study in a group of adolescents at SMAN 1 Gresik, Indonesia, showed that 8 out of 10 overweight students had poor sleep quality, so an understanding of factors which related to sleep quality was needed, especially for overweight adolescents.

Overweight and obesity are nutritional problems that can occur in all age groups including adolescents. Adolescents are active individuals with a rapid growth rate (growth spurt), both height and weight. However,
multiple studies have shown that adolescents who are overweight have a greater risk of obesity in their adulthood. Adolescents who are overweight and have poor quality sleep can increase the risk of obesity.

Adolescents who are overweight tend to have poor sleep quality than normal-weight teens both submitted to polysomnography. The samples were matched for age, sex, and apnea-hypopnea index. Body mass index (BMI). Poor sleep quality refers to the insufficient NREM and REM cycle. The NREM cycle lasts for approximately one hour and the person can still listen to the sounds around him. Meanwhile in the REM cycle, it lasts for approximately 20 minutes for 6-8 hours in a night’s sleep. Both these cycles (NREM and REM) occur alternately 4-6 cycles. The impact on poor sleep quality in adolescents will affect the learning process such as experiencing decreased concentration, drowsiness during learning, and being late for school. Poor sleep quality will also have a negative impact on physical conditions, especially in overweight adolescents, namely excessive daytime sleepiness and sleep-disorder breathing. Furthermore, stress, physical exercise and fatigue, environment, illness, drugs and substance, habits before going to bed, and diet are determinants of a person’s sleep quality. Therefore, this study aimed to determine factors related to sleep quality in overweight adolescents in one of developing countries, Indonesia. The study will evaluate factors related to overweight adolescents.

**Method**

This study was conducted at SMAN 1 Gresik, Indonesia. The study used descriptive correlative design. The study used cross sectional approach. In this study used total sampling technique, by taking all members of the target population into a sample so that the final number of respondents involved in this study was 50 overweight student. The overweight category calculated based on the quarelet index (weight in kilograms divided by the square of height in meters (kg/m2)) with BMI based on The International Obesity Task Force, namely: 25-30kg/m2.

Demographic data of respondents consisted of gender, age, class, weight, and height. The instrument of this study was a questionnaire containing closed questions. The data was collected from respondents by asking to answer questions and wrote the answer on the questionnaire sheet. The study used questionnaire instrument in which contained questions consist of three parts, namely: 1. Respondent data consists of gender, age, class, weight, and height. 2. The Pittsburgh Questionnaire Sleep Quality Index (PSQI), The third part is a question related to the variable quality of sleep, namely by using The Pittsburgh Sleep Quality Index (PSQI), to measure sleep quality. 3. Questionnaire factors that affect sleep quality. Variables of factors that influence sleep quality include stress, environment, physical exercise and fatigue, illness, drugs and substance, habits before going to bed, and diet. This questionnaire consisted of 20 questions, while stress factors consist of 14 questions using the DASS questionnaire (Depression Anxiety Stress Scale). The dependent variable in this study was the quality of sleep. The data then gathered and calculated using the Rho spearman statistical test with the level of significance $\alpha = 0.05$.

Conted…

Table 2 showed that the distribution of respondents mostly had poor sleep quality as much as 36 people (72%). A total of 20 respondents (40%) experienced mild stress, and 8 respondents (16%) with moderate levels. Most of the respondents who did not do physical exercise and did not experience fatigue were 34 people (68%). Most respondents felt comfortable with the environment while sleeping as many as 44 people (88%). 27 people (54%) did not have the disease. A total of 47 people (94%) respondents did not consume drugs and substance. Most respondents had a habit before going to bed, which were 34 people (68%). Habit before sleep include watching television and praying. Most of the respondents consumed food and beverages such as eating heavy foods and drinking milk and water before going to bed as many as 40 people (80%).

Sperman rho P=0,752
Spearman Rho statistical analysis showed that there was a relationship between stress levels and sleep quality (p = 0.020) with a correlation coefficient r = 0.329 which indicated that the strength of the relationship was weak and the direction of positive relationships meant that the higher the stress level the worse the quality of sleep. There was a relationship of diet with sleep quality (p = 0.000) with a correlation coefficient r = -0.579 which indicated that the strength of the relationship was moderate and the direction of the negative relationship meant the lower level of food consumption, the better quality of sleep. It indicated a relationship between stress factors and diet with sleep quality. There were 17 respondents (34%) who experienced mild level stress with poor sleep quality while respondents who underwent moderate stress with poor sleep quality were 7 respondents (14%). However, the factors of physical exercise and fatigue, environment, disease, medicine and substance, and habits before going to bed were not related to sleep quality (p> 0.05).

**Discussions**

The study showed stress and diet have a significant relationship with sleep quality in overweight adolescents. The results were supported by previous studies where stress experienced and eating habit or food intake before going to bed can affect difficulty in going to sleep. Most people who are under stress will eat more often because they believe that eating can overcome stress. Sleep quality is very important for the body, one of which is normal metabolic function and hormonal processes. Hormones play an important role in triggering stress and appetite for sleep quality. The cortisol is a hormone that regulates stress. In someone who experiences a high level of stress will experience an increase in cortisol levels so that it will increase the level of one’s appetite. This condition indicates a correlation between stress and weight. However, the relationship between the two factors cannot be explained through research that has
been carried out especially on the scope of sleep quality. Hormones have an important role in regulating one’s appetite due to an imbalance in the hormones leptin and ghrelin. The hormone leptin functions to capture the signal of how much fat is in the body so that it can be regulated in the breakdown of fat metabolism and the hormone ghrelin serves as a regulation of appetite, if the quality of sleep is bad there will be a decrease in leptin and an increase in ghrelin is likely to increase appetite. This indicates that adolescents who have poor quality sleep will cause an imbalance between the hormones leptin and ghrelin, which are hormone absorbers and appetite stimulants which cause metabolic disorders in the body.

The results also showed that physical exercise and fatigue, environment, disease, drugs and substance and habits before going to bed did not have a significant relationship with the quality of sleep in overweight adolescents. This is consistent with previous studies which suggested that physical exercise during the day will help a person sleep soundly at night. But heavy physical exercise can cause fatigue that will disrupt someone’s sleep patterns. However, most respondents did not do physical exercise and experience fatigue, so this study could not prove the relationship between physical exercise and fatigue with sleep quality in overweight adolescents.

Based on the distribution of data shows that as many as 88% of respondents have a comfortable environment with mostly poor quality sleep. The environment in which a person sleeps influences a person’s ability to fall asleep. Sound, level of lighting, room temperature can affect sleep quality. Furthermore, most respondents were comfortable with the room environment, so that this study could not prove the relationship between the environment and sleep quality in overweight adolescents. The disease also does not have a significant relationship to the quality of overweight adolescent sleep considering that 54% of respondents did not have a disease or physical comfort disorder both good and bad sleep quality. Based on the questionnaire filled out by respondents, they did not experience physical problems, but thought of problems before going to bed so that they were difficult to start and wake up in the morning so that good quality sleep was not achieved. There is a problem before going to bed like thinking about personal problems with friends can also interfere with the quality of sleep respondents. Physical pain and discomfort can cause sleep problems. This indicates that physical discomfort during sleep can affect a person’s sleep quality. However, the presence of other factors such as diet and stress that more affect sleep quality in respondents so that the disease factor does not prove to have a relationship with sleep quality in overweight adolescents.

Drugs and substances showed no correlation to sleep quality in overweight adolescents, given that 94% of respondents did not consume drugs and other substances that had good and bad sleep quality. Medications can affect the sleep process. Some types of drugs that affect the sleep process are types of diuretic drugs that cause insomnia, anti-depressants can suppress REM, caffeine can increase sympathetic nerves that cause sleep difficulties, beta blockers can have insomnia, and narcotics can suppress REM so easily drowsy. However, in the absence of facts about the consumption of drugs and other substances in the respondents, this study cannot prove the relationship between drugs and other substances with the quality of sleep in overweight adolescents.

This study also showed that there was no association between eating habits before sleep and sleep quality in overweight adolescents. Based on the distribution of data showed that as many as 68% of respondents have a habit before going to bed that is watching television and most have poor sleep quality. The theory stated earlier that effective bedtime habits can reduce the awakening time of someone between their sleeps. Based on the theory and results of this study states that someone who has a habit before going to bed like watching television late at night will cause the poor sleep quality. However, respondents mostly had the habits before going to bed, but in the presence of other factors that affect sleep quality such as stress and diet so this study could not prove the relationship between habits before going to bed and the quality of sleep in overweight adolescents.

**Conclusion**

The results of this study indicated that the most of respondents have poor sleep quality. Stress and diet have a relationship with sleep quality in overweight adolescents but physical exercise and fatigue, environment, disease, drugs and substance, and bedtime habits have no association with sleep quality in overweight adolescents.
Ethical Consideration: This study has obtained the feasibility of ethical review in the Health Research Ethics Commission of the Faculty of Nursing, Airlangga University, Surabaya, Indonesia with No. 130-KEPK.

Conflict of Interest: The author reports no conflict of interest of this work.

Carbon Emission Disclosure in Manufacturing Companies in Indonesia

Bangun Tri Saputro¹, Basuki¹
¹Department of Accounting, Faculty of Economics and Business, Universitas Airlangga, Jl. Airlangga 4, Surabaya, East Java

ABSTRACT

Background: Industries that are established in Indonesia with the materials of coal, oil, and gas are the largest contributors to environmental pollution. Rapid industrial development in Indonesia has a negative impact on the decline in environmental quality. Companies' participation in preventing environmental pollution creates carbon emission disclosure in contributing to reducing greenhouse gases.

Objective: This study aimed to determine the effect of firm size, media exposure, profitability, and leverage on carbon emission disclosure in companies listed on the Indonesia Stock Exchange with PROPER criteria.

Method: This study was conducted by taking samples of 144 companies from 2011 to 2013. Company samples were selected through a purposive sampling method with PROPER criteria obtained from the Ministry of Environment Publication and have been listed on the Indonesia Stock Exchange from 2011 to 2013. This study used quantitative types of research. Data were then analyzed using regression analysis.

Results: Mean carbon emission disclosure during 2011-2013 was 0.588 which showed that there was no extreme variation in carbon emission disclosure data. Mean total assets of the company in this study was 29.49. Mean profitability with Return On Asset was 0.08. The mean company revealed in the media from 2011-2013 was 0.32 (32.4%). The mean value of leverage was 0.42 (42.4%), and there was no extreme value.

Conclusion: Variables that affected carbon emission disclosure are firm size, media exposure, and leverage that significantly influence partially. However, the profitability variable did not show a significant effect on carbon emission disclosure.

Keywords: Carbon Emission Disclosure, Company, PROPER, Environmental Pollution

Introduction

Human involvement in climate change is currently a concern for some people. The Industrial Revolution that occurred in the 18th century in England caused significant changes to the development of the industry in the world, including in Indonesia. The revolution succeeded in transforming the industry which initially moved slowly into rapidly. However, these changes have a negative impact on the environment. Retention of carbon and greenhouse gases has always increased from year to year. This happens because of industrial activities that cause the transition of forest functions and the use of non-renewable natural resources, such as natural gas and coal. Environmental pollution is one of the causes of global warming until now.

In 1997, a protocol was held in Japan called the Kyoto Protocol which regulated the reduction of greenhouse gas emissions, and also established procedures, targets, mechanisms for reduction, and procedures for structuring and resolving disputes. Kyoto Protocol explained that there are three types of emission reductions that are flexible for industrial countries, namely clean development, joint development, and emission trading. In 2004, Indonesia signed the Kyoto

Protocol as written in Law Number 17 of 2004. This proves that Indonesia’s efforts to participate in protecting the environment are because Indonesia has industry as large as other developed countries.

Participation in protecting the environment must also be considered by every company by reducing greenhouse gases so as to create a Carbon Emission Disclosure. Disclosure of carbon emissions has been carried out in several industrial countries, such as Australia, China, Brazil, the European Union, Mexico, India, and America. Most countries that disclose carbon emissions are developed countries. However, in Indonesia, this is still rarely found because there are still several factors that must be considered in the disclosure of carbon emissions. There are factors that influence the disclosure of carbon emissions, i.e. firm size, leverage, company performance, market to book ratio, Kyoto Protocol, Return On Assets, and Return On Equity.

The independent variables are developing country basis, leverage, profitability, growth, firm size, carbon emission, the legal system, emission trading scheme, and asset newness.

One theory that relates to disclosure of environmental social responsibility is legitimacy theory. The theory can disclose social and environmental information which then becomes a consideration in economic, social, and political factors in the business context. Legitimacy is a fact that the company discloses as a reaction to environmental, economic, social and political factors. The legitimacy will be considered in the economic performance of a company as long as the company produces profits. According to the viewpoint of legitimacy theory, the higher the leverage of a company, the greater the amount of emission disclosure. The positive coefficient has an increase in the leverage ratio of 2.14, thus increasing the level of carbon emission disclosure.

Stakeholder theory indicates that organizations get differences in demand and pressure from stakeholders. Each has different views and expectations regarding the desires of the organization that have an impact on the decision-making process. This theory is used to determine the behavior patterns of other actors other than shareholders who have an interest in each company’s activities and obtain information related to the activities of other companies. Disclosure of carbon emissions is a relatively new reporting concept and includes voluntary disclosure. In PSAK 1 of 2015 paragraph 14, it is stated that there are reports that add to the value of the company relating to the disclosure of carbon emissions.

In this study, there were four independent variables that influence the disclosure of carbon emissions, including firm size, media exposure, profitability, and leverage. The size of the firm or company has a positive influence between firm size and total assets on carbon emission disclosure because companies that have good finance will disclose information that signals that the company can prepare itself for certain times, especially regarding environmental issues to respond more timely and effectively. Submitting news about environmental disclosures involves the role of both electronic and printed media. The media has a positive influence on the disclosure of carbon emissions and is considered as the driver of the emergence of several environmental groups. Another predictor that acts as an independent variable is profitability. Profitability using Return of Asset has a strong influence on disclosure of carbon emission. In a legitimacy perspective, the relationship between leverage and disclosure of carbon emissions has a level that is inconsistent and is considered a constraint factor. Based on the background above, this study aimed to examine the factors that influence the broad disclosure of carbon emissions in companies in Indonesia.

Method

The data sources were from the Indonesia Stock Exchange which consist of the company’s annual report and sustainability report. Sampling was done by selecting the PROPER recipient companies. PROPER is a Corporate Performance Rating Program published by the Indonesian Ministry of Environment and Forestry. The company is divided into five categories which are represented in color, namely gold, green, blue, red, and black. The dependent variable used was the disclosure of carbon emissions which in its measurement used a checklist containing an information request sheet. The checklist sheet has been developed by the Carbon Disclosure Project, a non-profit organization that holds information on climate change in the world.

The category of companies chosen in this study were companies that had gold, green and blue PROPER listed on the Indonesia Stock Exchange during the 2011-
2013 period with the category of manufacturing and mining companies. The gold color indicates that the company has demonstrated environmental excellence in production or service and has ethics and is responsible for the surrounding community. Green indicates that the company has carried out environmental management more than is required through the implementation of an environmental management system and utilizing resources efficiently and carrying out social responsibility well. The blue color indicates that the company has made environmental management efforts. The data that had been collected were then analyzed using SPSS software using multiple linear regression analysis with the equation model as follows:

\[ Y = \alpha + \beta_1 \text{Size} + \beta_2 \text{Med}_\text{Exp} + \beta_3 \text{ROA} + \beta_4 \text{Leverage} + e \]

**Annotation:**
- \( Y \) = Carbon Emission Disclosure
- \( \alpha \) = Constant
- \( \beta_1 - \beta_4 \) = Regression coefficient
- \( \text{Size} \) = Firm size
- \( \text{Med}_\text{Exp} \) = Media Exposure
- \( \text{ROA} \) = Return On Asset
- \( \text{Leverage} \) = Total debt/Total asset
- \( e \) = Error

The number of samples in this study was 38 companies for three periods so that total observations were obtained as many as 114 observational data.

**Results**

In table 1, it can be seen that the disclosure of carbon emissions that have been carried out by the company in the annual report and the sustainable report is at least 0. Of the 114 samples of the company studied, there were several companies that did not report or disclose carbon emissions. Only companies with gold and green PROPER ratings have made ongoing reports. In the annual report, the company had actually provided information related to Corporate Social Responsibility but had not revealed the disclosure of carbon emissions that were outlined by companies that were the object of study. It can be said that the awareness of carbon emissions disclosure was still very low.

In table 2 it can be seen that the average disclosure of carbon emissions during the 2011-2013 period is 0.58. The companies as the samples of this study had made disclosures of \( 7.64 = 7-8 \) of the 18 items disclosed by the Carbon Development Program. Variations in carbon emissions disclosure data had a standard deviation value of 0.32 which indicated that there was no extreme data because the value was below the mean. Table 3 shows that the average is 29.49. The minimum value in table 4 shows a negative value. This is because the company’s ability to generate profits through the assets used had a loss.

Table 5 shows that in 2011 and 2012 the means are the same, which is equal to 0.28 and in 2013 the mean is 0.39. This shows that the company revealed in the media on average from 2011-2013 was 0.32 (32.4%). Analysis with media exposure variables is used to see the value of the role of the media in revealing every event related to carbon emissions disclosed by the company.

<td>0.19</td>
<td>0.09</td>
<td>2.14</td>
<td>0.03</td>
</tr>
</tbody>
</table>

Based on table 7, the regression analysis equation is obtained as follows:

CED = -1.80 + 0.07Size - 0.17ROA - 0.07Med Exp + 0.19Leverage
The carbon emissions disclosure constant was -1.80. This is because there was a considerable difference between the scale on the dependent variable and the independent variables. The constant value of each variable is the intersection between the x and y-axes. The value of C is the intercept value for all existing companies. The intercept value of the variables in the model explains the intercept together on the model, while the intercept value for each sample company explains the intercept for each company. To determine the value of disclosure of carbon emissions of each company, the value of C is reduced by the value of each company intercept.

Disclosure of carbon emissions has been explained by independent variables (12.87%) and other variables (87.13%) which were not mentioned in the research model. Partial panel data regression analysis on the independent variables on the dependent variable with a confidence level of 0.05 ($\alpha = 5\%$) showed that the Return On Asset variable did not significantly influence the disclosure of carbon emissions for three periods. The size of the company, media exposure, and leverage had a significant effect on the disclosure of carbon emissions for three periods.

**Discussion**

Firm size showed a significant positive effect on disclosure of carbon emissions because the larger the size of the firm, the higher the disclosure of carbon emissions. Large scale companies have greater social and political pressure compared to smaller companies. This pressure comes from the spotlight of stakeholders who want more relevant and reliable information, including information on the disclosure of carbon emissions. Large companies will do more disclosures to get high expectations in terms of the environment and the demand from several stakeholders. The size of the firm has a positive and significant effect on disclosure of greenhouses because large companies will be more open and do more disclosures to face any criticism from the public. Large companies are very aware of disclosures other than any environmental disclosures because companies with large sizes tend to be higher in disclosure compared to small companies. Media exposure showed significant and negative influence so that it had a reverse relationship with carbon emission disclosure. The media doesn’t overly expose companies that have published disclosures on carbon emissions. Companies that reveal a little will be highlighted by the media. This is not in line with the legitimacy theory which states that companies exposed to the media will tend to make disclosures as a motivational basis for companies to be better.

Profitability with a Return on Asset proxy showed a non-significant effect on disclosure of carbon emissions disclosure. The condition of the study sample showed that many companies were in a high-profit condition, but there were 6 companies that suffered losses. Return on Asset is not included in the aspect that sufficiently affects the disclosure of carbon emissions so that it is not significant and has a negative effect. The higher Return On Asset, the less disclosure of carbon emissions will be. The significance test value of the t-statistical test with the Random Effect Model estimation model with a probability value of 0.03 was less than the required significance of 0.05 ($\alpha = 5\%$). According to the theory of legitimacy, the higher the leverage ratio, the higher the amount of disclosure disclosed.

**Conclusion**

Firm size showed a significant positive effect on carbon emissions disclosure. Media exposure as an assessment criterion showed a significant negative effect on carbon emissions disclosure. Proxy profitability using Return On Asset showed insignificant results on carbon emissions disclosure. Leverage calculated by using total liabilities divided by firm size showed positive significant results. The implications of this research can be used as consideration in choosing a place to invest in companies that are more concerned about environmental conditions and preserving nature.

The Effectivity of Brain Gym and Memory Games Therapy for Improving Cognitive Function in Elderly People with Dementia

Maulana Arif Murtadho¹, Elida Ulfiana¹, Setho Hadi Suyatmana¹
¹Faculty of Nursing, Universitas Airlangga, Mulyorejo street, Surabaya (60115), Indonesia

ABSTRACT

Background: The aging process impacts cognitive impairment can cause dementia. Elderly with dementia will experience a disruption in daily activities. Dementia leads to spatial disorientation (indoor), resulting in the tendency of wandering and lost. Precautions are needed to impede the negative impact of dementia, such as an activity that can enhance the cognitive ability of elders. Brain Gym and therapeutic memory games can become a way to reduce dementia’s effect because they can stimulate the memory and cognitive ability of elders.

Objective: The purpose of this study was to compare the efficacy of therapy Brain Gym and memory games against cognitive therapy elderly with dementia

Method: This study is comparative study using sample of 16 people. The sampling technique used was total sampling. The independent variables in this study were the Brain Gym and therapeutic intervention of Memory Games. The dependent variable in this study was the cognitive function of the elderly. The instruments for this research used MMSE form and statistical tests Paired-Samples T-Test and Independent Samples T-Test.

Result: The results showed the value of the cognitive function in the intervention group therapy Memory Brain Gym and Games with the result that significant p = 1.000 p > 0.05, which means there was no difference effectiveness of an increase in cognitive function after being trained Brain Gym and therapeutic Memory Games. Both of them can improve the cognitive function of the elderly with dementia.

Conclusion: Brain Gym and therapeutic Memory Games equally improve cognitive function in older adults with dementia

Keywords: Cognitive function of elderly, dementia, Brain Gym, Therapy Memory Games

Introduction

Dementia can have an impact on emotional, physical, and psychological disorders (¹). Elderly with dementia will experience a disruption in daily activities and result in the disorientation of spatial (room), so that there is a tendency to wandering and (²). Dementia occurs due to various things. First, dementia is caused by amyloid mutations. Amyloid plaques come from larger proteins, amyloid precursor proteins or Amyloid Precursor Proteins (APP) and cause brain tissue damage. Secondly, dementia is caused by neurofibril tangling. A neurofibrillary node is a group of twisted nerve cell fibers, called helical filament pairs. Third, acetylcholine and other neurotransmitters are chemicals that are needed to send messages across the nervous system (³). Neurotransmitter deficits cause the breakdown of complex communication processes between cells in the nervous system associated with Behavioral and Psychological Symptoms of Dementia.

In the elderly, memory is one of the cognitive functions that are often to be declined. Long-term memory is rarely changed, while short-term memory can be instantaneously deteriorates in 0-10 minutes. Some studies stated that brain gym and memory games therapy can prevent dementia. Brain gym and memory games can be used to stimulate cognitive function at every stage of the game, and are proven effective in improving cognitive function in the elderly (4).

The benefits of brain gym include reducing emotional stress and clearer mind, improving the relationship between humans and learning atmosphere/work more relaxed and happy, increasing the language and memory skills, causing people become more enthusiastic, more creative and efficient, people will feel healthier because of reduced stress and improving their learning and work performance (2). While Memory Games therapy can activate sensory functions both visual, auditory and touch receptors from the body’s surface and even provide psychomotor stimulation. The various sensory organs become thousands of information that received by the nervous system. Then integrated to determine an immediate body reaction. The memories can be stored in the brain for minutes, weeks or years and they can help determine the body’s reaction in the future (5).

Memory Games therapy is an activity that focuses on tasks or games that lead to cognitive (memory) in which the therapist guides members of therapy to take the prescribed steps (6). Memory capabilities only occur in human learning, which is a crucial process for humans by flowing information captured by the senses, forwarded, reduced, collaborated, rediscovered, and utilized (7). The purpose of this activity is to make closer the relationship between the participants, to stimulate the cognition and communication in every stage of the game, and to foster cohesiveness and sharing, and participants can socialize (8).

This study aimed to find out whether there were significant differences in the effectiveness of brain gym therapy and memory games for elderly people suffering from dementia. Furthermore this study was also purposed to identify cognitive function in the elderly group of dementia before and after therapy using both methods.

**Material and Method of Research**

This study was a comparative study, conducted by comparing the conditions before and after treatment in two groups with characteristics that are more or less the same in one analysis (2). This study intended to assess the cognitive function of the elderly before and after treatment, then the results of two group were analyzed. The design of this study is as follows:

**Table 1: Comparative study design of the influence of brain gym and memory games therapy on improving cognitive function in the elderly**

B₀: first observation (before Brain gym)  
B₁: second observation (after Brain gym)  
M₀: first observation (before Memory games)  
M₁: second observation (after Memory games)  
IB: Brain gym intervention  
IM: Memory games therapy intervention

**Sample and the population of the study:** The target population in this study were 16 elderly people with dementia disorders who were in the nursing home. The inclusion criterion for the elderly were aged 60-70 years, experienced a decline in cognitive function at a sufficient and insufficient score, at least have ever been experienced in elementary education

**Sampling Technique:** This study used a total sampling technique which means that the number of samples is the same as the population (9).

**Variable of the Study:** The independent variable in this study was Brain gym intervention and Memory Games therapy. While the dependent variable in this study was the cognitive function of the elderly.

**Research Instrument:** The instrument in this study, in the intervention variable, was using a comparison between Brain gym which consists of activities stimulating the right and left brain (Lateral Dimension), relaxes the front and rear brain parts (Focusing Dimension), stimulates the system associated with emotional or feeling, namely the brain middle and cerebrum (Centering Dimension) with memory games therapy consists of stages of orientation, intervention, and evaluation (10).
Whereas the dependent variable used the MMSE (Mini-Mental State Examination) form, which consists of an assessment of time and place orientation, registration, attention and calculation, recall, and language skills. Patients were assessed quantitatively on these functions, perfect values are 30 (2).

### Data Analysis

The initial analysis of the data was carried out, by editing, coding, scoring, and data entry. The data was processed and statistical analyzed using the Paired-Sample T-Test with a significance level of \( p < 0.05 \) (SPSS program) with the aim of comparing between the two sample groups. The scale of the data used is ordinal.

### Results

Table 1 shows that there is a cognitive function improvement of the elderly in the treatment group. With the elderly interacting in an activity, cognitive abilities will be formed because of the influence of the environment in which the surrounding environment can facilitate orientation abilities, attention to be able to stimulate a person’s cognitive functions. Besides, social influence or social transmission can support the process of the cognitive ability of the elderly.

Based on the table above, the cognitive function in the group before being the treatment was considered as poor. While the post-treatment results showed an increase in the cognitive function abilities of respondents, however, did not show an increase in cognitive function abilities as expected by researchers. This is possible because respondents experienced dementia which was aggravated by the absence of activities that could improve the memory of the respondents while in the nursing home (1).

P = 0.007 Paired-Samples T, Test (p ≤ 0.05)  
P = 0.001 Paired-Samples T, Test (p ≤ 0.05)  
P = 1.000 (p > 0.05) Independent T Test

The results of statistical analysis using the Independent T-Test showed that the hypothesis was rejected. That means there was no difference in the effectiveness of cognitive function improvement after being treated by Brain Gym and Memory Games therapy. Because both of Brain Gym and Memory Games therapy were improving the cognitive function of the elderly with dementia.

**Discussion**

Based on the results of the study, the data shows that there was no difference in cognitive function improvement effectiveness after being treated by Brain Gym and Memory Games therapy in the elderly with dementia because both Brain Gym and Memory Games therapy improved cognitive function in the elderly. From the results in the Brain Gym treatment group, half of the respondents experienced an increase in cognitive function. While in the Memory Games treatment group, the majority of respondents had their cognitive functions increased. This is caused by severe dementia experienced by respondents, and the lack of cognitive activity in the institution which causes a dull cognitive function of the elderly. According to the results of the study, Brain Gym can improve cognitive function in elderly people with dementia. In addition, brain exercise can significantly improve the cognitive function of the elderly (11). The positive impact of Brain Gym on the elderly, after 2 weeks of implementation there has been an increase in memory (cognitive) function, concentration, attention, and alertness to reduce senility or dementia. The method of Brain Gym can improve brain performance to better cognitive function in the elderly group of dementia before and after Memory Games therapy.

Brain Gym will stimulate brain function which consists of three dimensions which are interconnected as one unit, among others: stimulating (Dimensions of Laterality), alleviating (Dimension Focusing), and relaxing (Dimensions of Certering) (2). Brain Gym itself aims to maintain the optimal balance between the right and the left brain. Brain Gym provides a repair stimulus to the fibers in the corpus callosum that provide many
two-way neural connections between the cortical areas of both brain hemispheres. Including several brain structures including the hippocampus and amygdala. Brain gym movement reactivates the neural connections between the body and brain so as to facilitate the flow of electromagnetic energy throughout the body. These movements support electrical and chemical changes that take place on all mental and physical events (12).

Decreasing cognitive function in the elderly can be inhibited by implementing Brain Gym therapy. In the application of the Brain Gym method, there is a concentration dimension for the limbic (midbrain) and cerebral cortex systems (11). Inside the cerebral cortex, there is a functional area that divides the functions of each right and left hemisphere. The brain of the left hemisphere is largely tasked with regulating the right body which functions to think logically, rationally, analyze, the ability to write and read, speak, time-oriented, and things that are detailed, while the left brain is also the center of mathematics (13).

Memory Games therapy will be able to activate sensory functions both visual, auditory and touch receptors from the body surface and even provide psychomotor stimulation. The various sensory organs become thousands of information received by the nervous system and then integrated to determine an immediate body reaction and memories can be stored in the brain for minutes, weeks or years and they can help determine the body’s reaction in the future come. Information storage is a memory process and is a synapse function (14).

Memory Games therapy allows someone especially the elderly to be able to carry out activities in a group so that it stimulates sensory abilities that will support cognitive function for action. In addition, these activities will be able to motivate the elderly to communicate, socialize and be more creative who will support the next life process. But this is not supported by the employment history of the elderly and activities in his spare time (15).

Conclusion

This research shows that there was no significant difference in effectivity between Brain Gym and therapy of Memory Games. Because both of them also enhance the cognitive function of elders with dementia symptoms.

Ethical Clearance: The study process involved participants in the survey using a questionnaire that is consistent with the ethical research principle is based on the regulation of the research ethics committee. The present study principles were carried out in accordance with the research principles. This basic implementation study of the principle ethics of respect, beneficence, nonmaleficence, and justice.

Conflict of Interest: There is no conflict of interest in this study.

Source of Funding: This research was carried out by a team and funded independently.

Effects of Intensity of Reading Short Stories Activities and Retelling the Story on Elderly Cognitive Impairment

Devi Ayu Kumalasari¹, Hanik Endang Nihayati¹, Elida Ulfiana¹, Rista Fauziningtyas¹
¹Department of Nursing, Faculty of Nursing, Universitas Airlangga, Jl. Airlangga No.4 - 6, Airlangga, Gubeng, Kota SBY, Jawa Timur

ABSTRACT

Introduction: Minimizing the risk of cognitive decline in the elderly can be done by developing the brain activity, one of them is by reading the story and retelling the story again, but little attention has been paid to the intensity of reading short stories and retelling the story against cognitive impairment in the elderly.

Objective: This study aimed to determine the effect of the intensity of reading short story activities and retelling the story on the elderly cognitive impairment

Method: This was a pre-experimental study with one group pre and post-test design. The sample was determined using the purposive sampling technique, with total sample was 14 respondents who met the inclusion and exclusion criteria. The independent variable was a reading short story and retelling the story, the dependent variable was the cognitive function. The data were collected using MMSE questionnaires and analyzed using the Wilcoxon test (α<0,005).

Results: The result indicated a therapeutic effect of reading short story activities and retelling the story on the increase of elderly cognitive function (p=0.001). Most respondent experienced an increase in cognitive function in the aspects of material recall which is equal to +1.15.

Conclusion: Reading short story and retelling the story activities can be used as an intervention to improve the cognitive function of elderly. Future research is needed to confirm this study and qualitatively assessed the benefits of this study.

Keyword: reading, retelling the story, cognitive function, elderly

Introduction

Impaired cognitive function is one of the health problems that can arise in adults where the majority are elderly ¹. Possible cognitive function disorders can be in the form of forgetfulness, which is the mildest form of cognitive impairment. In this phase a person can still function normally even though it is difficult to recall information that has been studied, this kind of impairment not rarely found in the elderly so that it affects the quality of life of the elderly where it can often make the elderly feel scared, embarrassed, and have a low self-esteem ²this qualitative, grounded-theory study investigated the experiences and consequences of becoming forgetful. In-depth interviews with 32 participants were conducted and analyzed. The findings show that forgetfulness became part of daily life through 3 strategies, conceptualized as doing forgetfulness: (1. One of the nursing intervention that can be applied to overcome the problem of decreasing cognitive function is using the memory enhancement techniques that can be done through the cognitive activity, so that the results of better functioning or quality of life of the elderly can be achieved³. In 2015, 47.5 million people worldwide suffered from dementia, 58% of these were residents of developing countries, including Indonesia, and there were

Correspondence Author:

Gubeng, Kota SBY, Jawa Timur 60286
Email: hanikendangnihay@yahoo.com
7.7 million new cases each year \(^5\). Dementia patients certainly experience impaired cognitive function, the condition complained by 39% of the elderly aged 50-59 years, increased to more than 85% at the age of more than 80 years\(^6\). The number of 80-year-old populations will increase to approximately four times to 395 million between 2000 and 2050, and the majority of the elderly population are living in the developing countries\(^7,8\) including Indonesia.

Based on preliminary data obtained by the researchers through an interview with nurses at the UPTD Griya Werdha Surabaya, Indonesia, in April 2016, there were 76 elderly people treated. The most common health problems in the elderly at the institution are dementia and hypertension, 39% or 30 of the elderly who live in the institution experience the impaired cognitive function. Elderly who can read is about 50% of the total number of elderly people that live in the nursing home. The UPTD Griya Werdha has carried out several activities to improve or maintain cognitive levels in the elderly but some of the activities have not shown a significant increase.

Cognitive health promotion in the elderly is affected by age-related changes, namely the brain degeneration, decreased reaction time, negative functional consequences, which are a mild decrease in some cognitive functions, slower reception of information, and several risk factors, namely myths regarding cognitive aging, decreased vision and hearing, side effects of alcohol and drugs, and also disease (dementia, depression)\(^3\). If the decline in cognitive function in the elderly is not immediately addressed, it can lead to an increase in the number of people with dementia. Reading stories by the elderly can improve cognitive functions, such as memory, intellectual function, and attention to the elderly, because reading is one of the cognitive activities that can stimulate the brain to think \(^9\). Storytelling can build resilience \(^10\) and reduce stress \(^11\) in the elderly. Retelling the contents of the story will trigger thinking process, where it is one of the cognitive activities that affect cognitive function. Without effective prevention there will be an increase in the incidence of cognitive function disorders in the elderly that can cause inability to carry out daily activities and dependence on others to take care of themselves. Therefore, this study aimed to determine the effect of the intensity of reading and retelling the story on the elderly at the UPTD Griya Werdha Surabaya, Indonesia.

**Method**

Location for data collection was at UPTD Griya Werdha Surabaya, Indonesia. In this study used a Pre-Experimental design with a One-group pre-post test design. This study used one of the Non Probability Sampling techniques, namely purposive sampling. The populations were elderly in the Griya Werdha UPTD Surabaya, Indonesia with 76 elderly. The inclusion criteria for the study were: (1) Elderly with mini mental interpretation status examination (MMSE) score ≤ 24; (2) Elderly who is able to read. While the research exclusion criteria are: (1) Elderly people who experience impaired vision without assistive devices and hearing senses that have not been corrected; (2) Elderly people who experience verbal communication disorders; (3) Elderly people who experience severe psychological problems when the research is still ongoing so as to disturb the concentration level of the client; and (4) Elderly people involved in other research with the same dependent variable. The samples size after being classified according to the inclusion and exclusion criteria were as many as 14 people.

Data were gathered by demographic questionnaire including age, gender, last education, occupation. The independent variable in this study was the provision of treatment in the form of reading short stories (short stories) and retelling the contents of stories carried out by the elderly. While the dependent variable in this study was cognitive function. The instrument in this study used to measure the dependent variable is the mini mental symptom examination status sheet (MMSE) as a pre-test and post-test. Mini mental status examination (MMSE) there are various questions that are used to measure cognitive function in the elderly. This questionnaire contained 11 questions consisting of 5 material aspects, namely orientation, registration, attention and calculation, recall, and language. Each question in the questionnaire has a quantitative answer in the form of a score that is if the answer is correct, then it will be given a score of 1. The score will be summed with a maximum score of 30 and a minimum score of 0. The scores obtained by respondents are summed and categorized into 4 categories, namely 25-30 not experiencing cognitive or normal function disorders, the number of scores 18-24 had mild cognitive impairment, the number of scores 11-17 had moderate cognitive impairment, and the number of scores 0-10 experienced
severe cognitive impairment. The mini mental status examination (MMSE) was measured by the researcher, then the respondent was asked to answer questions in the order of the list of MMSE questionnaires.

Other instruments needed were short stories with fable themes with 4 different titles, namely Kancil and Crocodile, Ape Becomes King, Arrogant Rabbit and Turtles, Little Frogs and Small Snakes. The theme of folklore with 4 different titles, namely Keong Mas, the Miserable Poor, Lutung Kasarung, Timun Mas. Indonesian fairy-tale theme with 4 different titles namely Bearded Weasel, Princess Melati Wangi, Putri Warna Warni, Moon that Envy Hearts. The theme that consist of advice with 4 different titles is Jack the Slacker, the Sick and the Fire, the Farmer and his Children, a bundle of wood. The theme of legend stories with 4 different titles namely Tangkuban Perahu, Telaga Pasir, Origin of the Bali Strait, Lake Toba. International fairy-tale themes with 4 different titles, Gonbe and 100 Ducks, Star Stories, Princess Rings, Five Potatoes. The tabulated data was then processed using statistical tests by using Wilcoxon test with a significant level of \( p \leq 0.05 \).

Results

Demographic characteristics of respondents

</table>

Based on table 1 it shows the characteristics of 14 respondents in the Griya Werdha UPTD based on the age category, the majority of respondents aged 60-74 years, namely as many as 10 people (71.4%). Based on gender, most of them are female, that is as many as 10 people (71.4%). Based on the last education level most of them have elementary education, that is as many as 5 people (35.7%). Based on previous work, most of them previously worked as entrepreneurs, as many as 6 people (42.9%). Based on free time activities, most of them are prefer to watch TV to spent their free time as many as 6 people (42.9%).

Cognitive functions before and after an intervention was given in the form of reading short story and retell the story.

Table 2: Distribution of respondents based on the level of cognitive function at UPTD Griya Werdha Surabaya, Indonesia

Based on table 2, it can be seen that most cognitive functions before intervention are moderate as many as 8 elderly (57.14%). After being given an intervention to read short stories and retell the contents of the story, most of the respondent’s cognitive functions were improved to the mild category as many as 8 elderly (57.14%). Analysis with the Wilcoxon statistical test shows that \( p = 0.001 \) so that the value of \( p < 0.05 \), this value shows that the intervention given in this study was effective in improving cognitive function in the elderly.

</tbody>
</table>

Based on table 3 shows that most of the respondents experienced an increase in cognitive function, especially in memory recall, which is equal to +1.15.

**Discussion**

Reading short stories and retelling the contents of the story had a significant influence to the improvement of cognitive function in elderly, this is evidenced by an increase in cognitive function after intervention in respondents. The result is in line with previous studies which showed that reading activities had an effect on cognitive function of the elderly.

A high cognitive function score will prevent the elderly from experiencing a decline in cognitive function which if it continues can lead to dementia. Dementia is not a natural thing, but it is a pathological condition caused by the death or damage of brain cells so that intellectual ability decreases. Decreasing cognitive function always involves memory, usually in the form of impairment of working memory (WM), abstract thinking disorder, focusing-execution, poor decision making, and mood disorder. Reading and retelling the story’s contents considered as an activity to train the brain that can improve memory or prevent dementia as well as stimulate the mental to increase brain capacity which can result in reorganization of neuro cognitive tissue, suppress the detrimental effects of stress hormones on the brain. Engaging in cognitive activities can improve brain compensation for pathology condition by increasing brain reserves so as to protect or slow the clinical onset of cognitive disorders and dementia.

Improved cognitive function shows a significant relationship to aspect of material recall, material aspect that included in the cognitive aspects of verbal memory. Memory is a storage of the knowledge that has been obtained and to be recalled. Memory enters the brain through synapse (information flow). The three basic processes of memory are encoding (entering information), storage (storage) and retrieval (generating returns).

Based on the theory of Carol A. Miller that focused on the role of nurses in slowing down the decline or improving cognitive function of the elderly by giving intervention in reading short stories and retelling the
contents of the story to improve the health status of the elderly. Observations at the time of the intervention showed that there were some respondents who showed lack of enthusiasm and were a little inferior to other respondents because the process of reading it was long, unable to tell the story completely. One of the tasks of author as nurses is to encourage the elderly and provide motivation to the elderly to continue to follow interventions with other respondents. The patient’s demographics also affect the scope of significance of reading and retelling the story’s content of the cognitive function of the elderly. The incidence of impaired cognitive function increases with age, every 5 years of age progression the risk will be increased 2 times than normal. Gender is considered to affect one’s memory even though there is no certainty between men and women. Women are thought to be more numerous and tend to be forgetful due to hormonal influences, namely a decrease of estrogen in menopausal women, thus increasing neuro degenerative disease, because estrogen is known to play an important role in maintaining brain function. In addition, the life expectancy of women is higher than the life expectancy of men, so that the population of older women is greater than men. Then, most of the respondents were only educated up to elementary level wherein education is a very important factor in preventing cognitive impairment. Based on the research that has been done, most of the respondents previously worked as entrepreneurs. Work that emphasizes thinking skills like an entrepreneur who has a major influence on the neuropathology of cognitive function disorders. Most of the respondents spend their free time by watching television. Watching television such as entertainment programs can stimulate the audience to think, it can actually slow down the cognitive function impairment than those who watch broadcasted news.

**Conclusion**

Based on the results of the study that conducted at Griya Werdha UPTD Surabaya, Indonesia, it can be concluded that there was an increase in cognitive function assessment scores in the elderly who experienced impaired cognitive function before and after the intervention by reading short stories and retelling the contents of stories. The intensity of the activity had an effect on reducing or slowing down a cognitive function impairment in the elderly and especially in the memory recall aspect.

The Influence of Dhakonan Games to Impede Dementia in Elders

Mita Nur Lathifah\textsuperscript{1}, Joni Haryanto\textsuperscript{1}, Rista Fauziningtyas\textsuperscript{1}

\textsuperscript{1}Faculty of Nursing, Universitas Airlangga, Mulyorejo street, Surabaya (60115), Indonesia

ABSTRACT

\textbf{Background:} Dementia can interfere the elderly in their daily activities. One of therapy that suitable for people with dementia is memory therapy using a traditional game, known as dhakonan.

\textbf{Objective:} The purpose of this study was to explain the influence of traditional dhakonan games on the level of dementia severity in the elderly.

\textbf{Method:} The research uses quasi-experimental design. The total sample was 20 respondents who met the inclusion criteria, namely the elderly with symptoms of dementia. The sampling technique used simple random sampling. The independent variable was a traditional dhakonan game, the dependent variable was cognitive function, depression level, and dementia level. Data were collected using a Mini Mental State Examination (MMSE) design questionnaire, Geriatric Depression Scale (GDS) questionnaire, and Functional Assessment Staging Tool (FAST). Data analysis was carried out using the Wilcoxon Sign Rank Test and Mann Whitney Test with a significance level of $\alpha < 0.05$.

\textbf{Result:} Wilcoxon Sign Rank Test obtained $p$ value $< 0.05$ for cognitive function, depression level, and dementia level in the treatment group (cognitive function, $p = 0.005$; depression level, $p = 0.005$; dementia level, $p = 0.014$). There was the influence of traditional dhakonan games on the level of dementia in the elderly.

\textbf{Conclusion:} Traditional dhakonan games can significantly improve cognitive function, reduce depression, and prevent the progression of dementia.

\textbf{Keywords:} traditional dhakonan games, elderly, cognitive function, depression, dementia

Introduction

Dementia is a neurodegenerative syndrome that arises due to chronic abnormalities and a progressive degradation in intellectual ability which results in a decrease in cognitive function, causing disruption of social functioning, work, and daily activities \cite{1}. There is no disorder of consciousness but there are impaired cognitive functions accompanied by worsening emotional, behavioral and motivational control. Risk factors that can cause dementia include vascular disease in the brain, coronary artery disease and atherosclerosis \cite{2}. The more the number of elderly people, the more likely the incidence rate of dementia, because age is one of the factors causing dementia \cite{3}.

Dementia can be overcome with a variety of therapies, one of them is memory therapy with cognitive stimulation to improve cognitive function in patients \cite{3}. Cognitive stimulation can be in the form of activity therapy, one of which is the dhakonan game. The dhakonan game will stimulate motor, cognitive, and emotion simultaneously, so that it will train one’s intellectual intelligence and emotional intelligence. Problems faced by elderly people with dementia include changes in cognitive function, behavior, decreased physical activity, mental, social function and decreased quality of life \cite{4}.
Decreasing cognitive function in dementia causes the elderly to forget easily and is not even able to maintain the newly received information. Disturbed memory can lead to a decrease in the ability to remember time, recognize people, objects, and places. Not only that, dementia also causes behavioral disorders such as easily suspicious, stubbornness, anger, depression and crying for no apparent reason and also unable to carry out daily activities independently so that the quality of life of the elderly becomes decreased. If this happens then there is no one who meets the needs of the elderly, such as fulfillment of nutrition, personal hygiene, and others. This will have an impact on reducing the health of the elderly. Another impact is caused if dementia is not handled properly, including behavioral changes in the elderly, such as forgetting oneself, opposing people around, and often wandering at night so that it is easily lost.

Dementia can be overcome by pharmacological therapy using anxiolytic agents, antipsychotic drugs, acetylcholinesterase inhibitors such as rivastigmine, donepezil, galantamine, and memantin. However, pharmacological therapy is considered detrimental because the elderly consume a lot of drugs for their physical and psychological illnesses so that other therapies need to be developed, namely nonpharmacological therapy. One of the nonpharmacological therapies is reminiscence therapy. Memory therapy can also improve cognitive function and mood in someone with dementia.

Dhakonan game is one of memory therapy that causes pleasure and trains cognitive brain. The dhakonan game trains the brain to make strategies, improve intelligence, exercise patience and honesty. Based on the statements above, the purpose of this study was to identify the level of dementia that can be indicated by observing at cognitive function and the level of depression in the elderly, before and after being given traditional dhakonan games.

**Method**

This research was a quantitative study with quasi experimental design and using a pre post test to the groups. In this study involved two groups, namely the control group and the treatment group. The treatment group was given an intervention of the dhakonan game, while the control group was not given the dhakonan game intervention, so that it could compare the changes in dementia levels in both groups. In both groups the pretest was given before the intervention, then post-test was given after intervention.

**Population and Sample:** In this study the target population was elderly people with dementia in Wedoro Village, Waru District, Sidoarjo Regency. Respondents in this study were elderly who had dementia and met the inclusion criteria, namely the elderly aged 60-74 years who had premensia, mild dementia, moderate dementia and severe dementia. According to Chen & Lin in their research (2009), ages 60-74 years are classified in the elderly group. Elderly with Clock Test score <4 at screening. Elderly who has played dhakonan in young age, elderly who lives with family, and the elderly who is cooperative and wants to be respondents to the study.

**Sampling Technique:** In this study, a multistage sampling technique was used from the district level to the village level. The next step was to determine the sample using a simple random sampling technique. The number of respondents per group was 10 people. The next stage was added with a drop out criterion sample of 10%. This was used to anticipate if someone as a respondent drop out during research.

**Variable Identification:** In this study, the independent variable was the game of dhakonan. While the dependent variables in this study were cognitive function, depression level and dementia level.

**Research Instrument:** In this study, the instruments used to measure the independent variables were Mini Mental State Examination (MMSE) and Geriatric Depression Scale questionnaire 30 items as pre-test and post-test on respondents, and Functional Assessment Staging Tool (FAST) used by researchers to determine the level of dementia. On the MMSE there are several questions that are used to assess cognitive function and the level of depression in the elderly, before and after being given traditional dhakonan games.
**Data Analysis:** The data collected by the researcher was analyzed to measure the influence between the independent and dependent variables using the Wilcoxon Signed Rank Test statistical test significant level $\alpha \leq 0.05$. This test was used to determine changes in cognitive function, depression levels and dementia levels before and after dhakonan game intervention in the treatment and control groups. Data was analyzed using Mann Whitney Test with a significant level of $\alpha \leq 0.05$.

**Research Ethics:** Researchers was conducting this research through research ethical procedures. Researcher did not include the respondent’s name on the data collection sheet to maintain identity confidentiality, and the researcher treats all respondents fairly and well and gives the become the right of the respondent.

**Table 1:** Characteristics of respondents based on their coffee consumption habits

Wilcoxon Test $p = 0.183$  
Signed Rank Test $\alpha = 0.05$  
Mann Whitney Test $p = 0.005$  
Mann Whitney Test $\alpha = 0.05$

Table 2 shows that the results obtained $p = 0.005$, causing $p < 0.05$. This result shows that there were significant differences between the results of the pre test and post test. In the pre test control group and treatment the Mann Whitney Test results obtained $p = 0.704$, which means there was no difference between the two groups, while in the post test results obtained $p = 0.002$ which means there were significant differences between the control group and the treatment group. It can be concluded that there is an influence of traditional dhakonan games on cognitive function of the elderly.

**Table 3:** Results of the dementia level in the pre test and post test in the control and treatment groups

</tr>
</tbody>
</table>

Table 3 shows that there were significant differences between the results of the pre test and post test. In the pre test control group and treatment the Mann Whitney Test results obtained $p = 0.704$, which means there was no difference between the two groups, while in the post test results obtained $p = 0.002$ which means there were significant differences between the control group and the treatment group. It can be concluded that there is an influence of traditional dhakonan games on dementia level of the elderly.
Table 3 shows that the results in the control group obtained \( p = 0.157 \) which means there was no difference between the results of the pretest and posttest. In the pre-test control group and treatment the Mann Whitney Test results obtained \( p = 0.579 \), which means there were no differences between the two groups, while the post-test results showed \( p = 0.004 \) which means there was a significant difference between the control group and the treatment group. When posttest, the majority of respondents experienced stage 3 dementia or early dementia and 1 person experienced stage 2 or Subjective Cognitive Impairment (SCI).

### Discussion

Based on the results of the Mann Whitney test, there were significant differences in the two groups after being given a treatment of dhakonan game intervention. In the treatment group, it was found that there were significant differences before and after being given traditional dhakonan games. Most respondents who are depressed were respondents who have low cognitive function values \(^{(12)}\). Based on table 2, the data of cognitive function values in the two groups did not show differences. The results showed that the majority of the pre-test results in the control group experienced mild cognitive impairment and a small proportion experienced moderate cognitive impairment. Most of the respondents were unable to repeat words and imitate images correctly at the MMSE test. This includes disorders in the region of the language and visuospatial functions.

From the results of the study, it was obtained that the majority of the control group who had coffee consumption habits. While in the treatment group the respondents who consumed coffee and those who did not consume coffee had the same percentage. Caffeine in coffee can block adenosine receptors so that there is an increase in brain neurotransmitters, namely dopamine and norepinephrine, which will have a fresh effect and increase concentration \(^{(13)}\). Caffeine also functions to inhibit some of the negative effects of cholesterol which can make brain blood vessels break and inhibit the activity of the enzyme acetylcholinesterase which can break down neurotransmitters and acetylcholine \(^{(14)}\).

The lower a person’s education level, the higher the prevalence of dementia. The more often training and using the brain, it can slow cognitive decline. High intelligence will be able to compensate for intellectual deficits \(^{(15)}\). Intellectual stimulation, social involvement or adequate physical activity increases neural synaptogenesis which can reduce the risk of dementia \(^{(3)}\).

Memory therapy will give impulses to memory. Memory therapy also aims to provide opportunities for socialization, transfer, pleasure, communication, reducing depression and social isolation and increasing self-esteem and life satisfaction of the elderly based on self-assessment and achievements \(^{(6)}\). Memories therapy affects cognitive, psychological, social habits and the health level of the elderly \(^{(8)}\). Memories therapy will have a happy effect on a person, reduce the level of depression and improve cognitive abilities \(^{(2)}\).

Cognitive function is the ability to process information, apply knowledge, change tendencies, beliefs obtained from thought processes, and in the form of mental activities such as thinking, remembering, analyzing, understanding, learning, imagining, and speaking \(^{(15)}\). Cognitive function consists of several aspects including attention, memory, visuospatial, language, and executive abilities such as planning, assessing, monitoring, and evaluating \(^{(7)}\). Cognitive function is influenced by age, education level and one’s occupation. Most of the elderly who experience a cognitive increase in their depression rates will decline. Vice versa, the lower the cognitive function of the elderly, the more severe the depression rate will be \(^{(6)}\).
Dhakonan games can improve mood, besides being seen from the social aspect, this game makes the elderly establish interaction with fellow elderly people so that it can create a sense of comfort. If the stimulation of the dhakonan game is done repeatedly it will have an effect on the brain which will automatically deliver impulses through the same synapse so that memory can be easily remembered and will prevent the development of dementia levels and reduce the level of depression (4).

**Conclusion**

Based on the results of this study, the traditional dhakonan game intervention can improve the cognitive function of the elderly through analyzing exercises, thinking strategies, counting, and motoric training. The effects of traditional dhakonan games can maintain dementia levels or prevent the progression of dementia because in traditional dhakonan games, depression can be reduced to normal levels by having social interactions with playing partners and being able to recall a pleasant past.

The Effect of Indomethacin and Ambon Banana Stem Extract (	extit{Musa paradisiaca var. sapientum}) on Ileum Histopathology of Indomethacin-induced Rats (Rattus norvegicus)

Dian Afikasari¹, Kadek Rachmawati¹, Romziah Sidik¹

¹Faculty of Veterinary Medicine, Universitas Airlangga, Mulyorejo Street, Surabaya, East Java, Indonesia

ABSTRACT

Background: Indomethacin belongs to Non-Steroidal Anti-Inflammatory Drug (NSAID), used for fever, rheumatoid arthritis, and post-surgical medicaments. Indomethacin is known to have an inflammatory side-effect on the ileum. The flavonoid in ethanol extract of Ambon banana stem (Musa paradisiaca var. sapientum) had the possibility to be used as a therapy.

Aim: This research was aimed to analyze the effect of combining indomethacin and banana stem extract Ambon in the improvement of histopathological imaging of the white rat ileum.

Method: A dose of 3.15 mg/kg indomethacin was given per oral. This experiment used male rats (Rattus norvegicus) aged 8-12 weeks, weighing 150 grams, that were divided into five experimental groups, those were control-rats, Indomethacin-induced rats, and a group of Ambon banana stem extract with a dose of P1=100 mg/kg, P2=300 mg/kg, P3=400 mg/kg. Each ileum specimen was processed and the histopathological changes were observed. A score of submucosal edema, PMN infiltration, the number of goblet cell, epithelial integrity as qualitative data were analyzed with Kruskal Wallis test continued by Mann Whitney test.

Result: The result of the study showed that ethanol extract of Ambon banana stem could repair the damage of ileum histopathology (p<0.05). The administration of indomethacin at 400mg/kg dose showed the best result of histopathological imaging of ileum improvement.

Conclusion: Ambon banana stem extract can repair damage due to indomethacin side-effect of the ileum. Ileum histopathological repair was marked by improvements in epithelial cells of the ileum.

Keywords: Inflammatory, Indomethacin, ambon banana stem (Musa paradisiaca var.sapientum), histopathology ileum.

Introduction

Non-Steroidal Anti-Inflammatory Drugs (NSAIDs) is an active ingredient that has a pharmacological characteristic to work heterogeneously inhibiting prostaglandin production. This drug family is used for the treatment of acute and chronic pain, which has the ability to reduce pain, fever, and inflammation¹. One kind of NSAIDs drug is indomethacin. The long-term treatment of indomethacin may induce its side-effects on the digestive tract, namely damage and inflammation in the small intestine, including ileum².

Indomethacin belongs to NSAID drug that works by inhibiting Cyclooxygenase-1 (COX-1), an enzyme functioning in prostaglandin synthesis. The decrease of prostaglandin synthesis will reduce the amount of mucus production that protects the mucosa against pathogenic bacteria. This may lead to a weaken ileum immunity thus increasing the risk of inflammation due to the high level of Reactive Oxygen Species (ROS) that may trigger oxidative stress, characterized by the appearance of mucosal damage in ileum histopathology². To maintain the ileum functioning properly, the therapeutic alternatives are needed. Cases of inflammation of
the digestive tract usually treated with drugs derived from chemicals and have a side effect that aggravates inflammatory conditions\(^3\), so that anti-inflammatory therapy that based on natural is needed\(^4\).

Indonesia has many types of plants that have the potential as medicinal plants. Treatment with medicinal plants is one alternative to meet the basic needs of the community in the health sector, one of which is Ambon banana plant. The stem of Ambon banana is known to contain several types of phytochemicals, namely saponins, flavonoids, and tannins that function as antibiotics, rapidly growing new cells, stimulating fibroblast formation, inhibiting bacterial growth, and also antifungal\(^6\). Ambon stem banana extract is believed to be effective in reducing inflammatory pain in post-tooth extraction of the white rat. Against the foregoing background, this study is aiming to analyze the effect of indomethacin and extract of Ambon banana stems administration in improving the white rat ileum histopathological imaging.

**Material and Method**

This study was conducted in the Laboratory of Biochemistry, Veterinary Pathology laboratory, and Department of Veterinary Basic Medicine at the Faculty of Medicine, Universitas Airlangga, Surabaya, Indonesia. The experimental animals in this study were 20 Wistar male rats (Rattus norvegicus), aged 8-12 weeks with an average body weight of 150-200 grams. The therapeutic dose of indomethacin for white rats in this study was 3.15 mg/kg. The specimen taken from the experimental animals is part of the ileum by excision from ± 4 cm before the caecum, up to 2 cm before the caecum (length = 2 cm).

The study was divided into five treatment groups with one negative (-) control and one positive (+) control, namely: The negative control group was given a 2 ml suspension of CMC Na as much as 2ml per oral. The positive control group was given indomethacin at a dose of 3.15 mg/kg as much as 2 ml per oral. The first treatment group was given banana stem extract dose of 100 mg/kg per oral and followed by indomethacin at a dose of 3.15 mg/kg as much as 2 ml each substance. The second treatment group was given banana stem extract with a dose of 300 mg/kg per oral, followed by indomethacin at a dose of 3.15 mg/kg as much as 2 ml each substance. The third treatment group was given banana stem extract with a dose of 400 mg/kg per oral followed by indomethacin at a dose of 3.15 mg/kg per oral as much as 2 ml each substance. The treatments were administered regularly on each experimental animal for 5 days. On the 6th day, the rats were sacrificed by means of neck dislocation and were dissected to isolate the ileum. The organ was put into a pot containing 10% formalin solution, then prepared into histopathological preparations\(^7\).

The degree of ileum damage at this examination determined by scoring the ileum histopathological slides, including submucosal edema, infiltration of PMN in the lamina propria, number of goblet cells, and epithelial integrity\(^8\). The degree of damage from each sample was determined by Barthel methods\(^8\).

The data obtained then analyzed by nonparametric statistical tests, Kruskal-Wallis. If there were significant differences, then proceed with the Mann-Whitney test. The entire analysis process was carried out with the Statistical Product and Service Solution (SPSS) program for Windows.

**Results**

**Submucous edema**

![Figure 1: Differences in ileum mucosal histopathological. (H.E staining; 200x enlargement; Olympus microscope; Opti Lab).](image-url)
Figure 1 shows that edema in the K+ group is the worst, where almost all surface was submucosal edema (arrows). The results of the mean observation and scoring of submucosal edema are presented in Table 1.

The different a; b; c superscript in the same column shows a significant difference between treatments (p <0.05).

Based on the results with the Kruskal-Wallis test showed that there were significant results in each treatment group (p <0.05). The Mann-Whitney test found that K- was not significantly different from P3 (p> 0.05). However, K- is significantly different from K+, P1, P2 (p<0.05).

Discussion

This study showed the negative control group (K-) had mild damage, this was due to uncontrolled external variables, initial intestinal conditions especially the ileum, poor ideal cage conditions, and stress factors during the study. This study revealed a significant difference between the K-group and K+. The daily administration of indomethacin at a dose of 3.15 mg/kg that was given to the K+ group resulted in submucosal edema in the histopathology of the ileum. Indomethacin works by inhibiting Cyclooxygenase-1 (COX-1) which plays a role in the formation of prostaglandins. Inhibition of COX-1 has an impact on decreasing prostaglandin synthesis in the ileum which results in decreased protection of the mucous barrier which facilitates the invasion of pathogenic bacteria.

There was a significant difference between the treatment group K- and P1. The daily dosage of Ambon banana stem extract 100 mg/kg has not been able to minimize edema in the ileum of white rats given indomethacin. In the other treatment, groups showed that
K- with P2 and P3 did not have a significant difference. The daily dose of Ambon banana stem extract 300 mg/kg and 400 mg/kg could minimize submucosal edema in white rat ileum histopathology. This shows that the protection of the ileum is getting better in accordance with increase the dosage of Ambon banana stem extract. The flavonoid content of Ambon banana stem extract functions as an anti-inflammatory and antioxidant.

**PMN Infiltration at Lamina Propria:** The results of statistical tests show that between K- and K+ have significant differences. This shows that indomethacin has side effects in the digestive tract, one of which is the ileum. In the treatment group the results showed that between K- with P1, P2, and P3, there were no significant differences. This shows that a dose of 100 mg/kg body weight/day, 300 mg/kg body weight/day and 400 mg/kg body weight/day can minimize infiltration of inflammatory PMN cells in the ileum lamina propria because the flavanoid effects in the form of quercetin which works by inhibiting T cell activation results in TNF-α inactivation which causes a decrease in the presence of neutrophils\(^{10,11,12}\).

**Number of Goblet Cells:** The results showed that between K- and K+ and P1 showed significant differences. This shows that the treatment group with a dose of 100 mg/kg/day has not been able to maintain the presence of goblet cells in the ileum epithelium. In this study, the optimum dose below 100 mg/kg/day has not been able to overcome inflammation in the ileum which is characterized by a continued reduction in the number of goblet cells in the ileum villous epithelium.

In group P3 the result was not significantly different from the K- group. This shows that in the treatment group at a dose of 400 mg/kg/day can maintain the presence of goblet cells in the ileum villous epithelium. The ileum histopathology in the P3 group showed that in the ileum villi there was no necrosis that led to erosion so that the number of goblet cells could be maintained properly. This happens because the ambon banana stem has an active content of flavonoids which it quercetin. This flavonoids can inhibit the activation of T cells (Th 1).

**Epithel Integrity:** The results showed that between K-, K+, P1, and P2, there were significant differences. The study in the K- group with the treatment groups P1 and P2 showed significant differences even though there had been a slight improvement in the ileum epithelium. This shows that the dose of Ambon banana extract given 100 mg/kg/day and 200 mg/kg/day has not worked optimally in the improvement of ileum epithelial damage, in the white ileum histopathology there were still necrosis and epithelial erosion. In the P3 treatment group, the results were not significantly different from the K-group. These results indicate that the dose of banana stem extract 300 mg/kg/day provides optimal improvement in ileum epithelial damage. This happens because in the extract of Ambon banana stem there are flavonoids which act as antioxidants and anti-inflammatory.

Flavonoid as an antioxidant in Ambon banana stem extract functions as an excess free radical scavenger in the ileum due to indomethacin administration. Free radicals that have been suppressed by flavonoids can also suppress the formation of NF-Kβ. NF-kβ cannot occupy an element response that should be able to trigger transcription and translation of pro-inflammatory cytokines (TNF-α). Pro-inflammatory cytokines that are not formed will reduce the activity of inflammatory cells\(^13\). This causes an improvement in the histopathological picture of the ileum which is characterized by the regeneration of epithelial cells so that the distance of the villi is seen to recur, necrosis and villous erosion decrease. Intestinal mucosal epithelial cells are known to have a rapid rate of regeneration, which is about 3 to 6 days\(^14\). Cells in the mucosa of the ileum include labile cells. Unstable cells are cells that have high regeneration ability, occur continuously and have a short G0 phase (resting phase). Damaged cells are stimuli for cells that in a resting phase to undergo the mitotic phase so that there is an improvement in ileum tissue damage.

**Conclusion**

The administration of indomethacin and Ambon banana stem extract at a dose of 400 mg/kg/day was the optimum dose in providing improvements to the histopathology of the ileum.

**Ethical Clearance:** The research process involves participants in the survey using a questionnaire that was accordant with the ethical research principle based on the regulation of research ethic committee.

Attenuation of *Eimeria tenella* with Immersion Various Concentration of Formaldehyde in Inducing Protective Immunity after Challenge Test by Featuring Macroscopic and Microscopic Caecum

Rizki Rohmah Armiani¹, Muchammad Yunus¹, Chairul Anwar Nidom¹

¹Faculty of Veterinary Medicine, Universitas Airlangga, Mulyorejo Street, Surabaya, Indonesia

ABSTRACT

**Background:** *Eimeria tenella* parasite is one of the most pathogenic coccidia that can infect chickens. The strategy for prevention and control of coccidiosis is done by administering anticoxidia drugs and live oocyst vaccines. However, anticoxidia can cause resistance to coccidiosis. So it is necessary to make vaccines (attenuation) using formalin or formaldehyde.

**Aim:** The purpose of this study was to determine whether the attenuation of the pathogenicity *E. tenella* with immersion various concentrations of formaldehyde can induce protective immunity and the concentration of formaldehyde that is most effective in inducing protective immunity for attenuation of *E. tenella* in featuring cecal macroscopic and microscopic (lesion score).

**Method:** Twenty-five chickens at three weeks old were divided randomly into five groups. Challenge test did after the first infection. The first infection was inoculated *tenella* by divided the first group (P0) is chicken group was inoculated with 0% formaldehyde soaked *E. tenella* at 1 x 10⁴ doses as control, the 2nd, 3rd and 4th groups (P1; P2, P3 and P4) were inoculated 0.15%, 0.3%, 0.6% and 1.2% of formaldehyde soaked *E. tenella* at the same doses, respectively. On challenge test performed two weeks after the first infection by inoculated 15x10³ infective oocysts of *E. tenella*.

**Result:** The results showed that the attenuation of *E. tenella* with immersion various concentrations of formaldehyde can induce protective immunity by featuring cecal macroscopic and microscopic (lesion score).

**Conclusion:** The most effective concentration of formaldehyde in inducing protective immunity of the attenuation pathogenicity *E. tenella* was 1.2%.

**Keywords:** attenuation, *E. tenella*, formaldehyde, protective immunity

Introduction

Poultry coccidiosis is an intestinal disease caused by Genus *Eimeria* parasitic protozoa¹. *Eimeria* multiplies in the digestive tract and causes damage to the intestinal mucous tissue². *Eimeria* causes damage to the intestine thereby reducing the efficiency of feed use, body weight, decreased endurance, and decreased egg production³. Coccidiosis in chickens is located in two places, namely the caecal (cecal coccidiosis) caused by *Eimeria tenella*⁴. *Eimeria tenella* parasites develop in cecum cells, which are two dead end sacs near the back end of the small intestine. *Eimeria tenella* parasite is one of the most pathogenic coccidia to infect chickens. Acute infections often occur in young chickens. Infection can be characterized by blood in the stool and with high morbidity and mortality⁴. In addition, the immune response for *Eimeria* involves many aspects of both the cellular and humoral immune mechanisms⁶⁻⁷.

So far, strategies to prevent and control coccidiosis are carried out by anticoxidia and live oocyst vaccine. However, anticoxidia can cause resistance to coccidiosis. The development of increasing anticoxidia drug resistance has stimulated the search for biological control methods by vaccination. Some vaccines have been tried in the form of whole attenuated oocysts. One potential explored vaccine material is a live vaccine from oocysts that can be developed, produced and applied in the field. The development of live vaccines using low virulence lines from *Eimeria* oocysts can be used as an alternative for more efficient and effective protection compared to other coccidiosis vaccines, such as vaccines containing switched off microorganisms and subunit vaccines. Vaccine making can be done by activating or weakening the organism (attenuation). A simple way of attenuation can expose the organism to active chemicals to the limits of sublethal concentrations such as the use of formaldehyde or formalin.

Giving vaccines can stimulate the body to form antibodies to the *Eimeria* antigen so that the chicken is able to deal with new infections (challenge tests). The use of separated *Eimeria* types in vaccines makes it easy for users to apply vaccines according to the prevention of the desired disease. Based on this, the purpose of this study was to determine whether the attenuation of the pathogenicity *E. tenella* with immersion various concentrations of formaldehyde can induce protective immunity and the concentration of formaldehyde that is most effective in inducing protective immunity for attenuation of *E. tenella* in featuring cecal macroscopic and microscopic (lesion score).

**Materials and Method**

This research was conducted at the Laboratory of Parasitology, Faculty of Veterinary Medicine, Universitas Airlangga, Surabaya, Indonesia, from August to September 2016. The experimental animals used in this study were 25 broiler chickens strain CP 707 produced by Charoen Pokphand. The chickens were two weeks old and breed in a battery cage in Besah Village, Kasiman District, Bojonegoro Regency, Indonesia. *Eimeria tenella* inoculation was performed on 3 weeks old chickens after being adapted for 1 week by ad libitum feeding and drinking. Feed which given, it does not contain koksidiostat.

**Calculation of Dosage:** Calculation of dosages of *E. tenella* oocysts was carried out using micro pipets measuring 1-10 μl and white chips. The suspension of *E. tenella* oocysts was diluted using distilled water then the diluted liquid was vortexed so that both materials are homogeneous. The oocyst calculation was carried out by dripping 1 mL oocyst into a glass object with 5 replications and then calculating the number of oocysts found in all replications with a 100x ratio and looking for an average. From the results of calculations in the average can be 15,000 oocysts/ml.

**Formula:** This research was an experimental laboratory research with the Completely Randomize Design (CRD). The chicken grouping is based on the treatment given, namely:

**Treatment 0:** As a control, oocysts were not soaked in formalin

**Treatment I:** *E. tenella* was soaked in formalin with a concentration of 0.15%

**Treatment II:** *E. tenella* was soaked in formalin with a concentration of 0.3%

**Treatment III:** *E. tenella* was soaked in formalin with a concentration of 0.6%

**Treatment IV:** *E. tenella* was soaked in formalin with a concentration of 1.2%

After *E. tenella* was soaked, then chicken were inoculated as many as 10,000 oocysts orally. After 14 days, a challenging test was carried out by re-inoculating *E. tenella* without immersing 15,000 formaldehyde as a formalin.

**Chicken and *Eimeria tenella* infections:** Twenty-five 21-day old chickens were inoculated with 10,000 *E. tenella* oocysts that were patented using formalin with various levels of concentration (0.15%, 0.3%, 0.6% and 1.2%) for 96 hours. Chickens were inoculated using *E. tenella* orally which had been washed using distilled water and centrifuged at a speed of 1500 rpm for 10 minutes at five times. After two weeks, twenty-five 34-day-old chickens were re-inoculated with 15,000 *E. tenella* oocysts without formaldehyde immersion. Chicken is inoculated with *E. tenella* orally.

**Cecum Lesion Scoring:** Scoring of cecal lesions was carried out on the fifth day after inoculation,
The cecal abnormalities were recorded and the degree of damage to the mucosal surface of the chicken cecum was calculated based on a score of 0-4.

**Histopathology observation:** Histopathology observation was carried out at the Pathology Laboratory of the Faculty of Veterinary Medicine, Universitas Airlangga, Surabaya, Indonesia. Microscopic examination was carried out based on the histopathological changes that occurred in the cecum which had previously been made histopathological preparations, assessed by scoring seen based on the Goodwin method.

**Challenge Test:** The challenge test was carried out 14 days after the first *E. tenella* inoculation, *E. tenella* which was soaked with various formalin concentrations. The challenge test was carried out by re-inoculating *E. tenella* without immerse as much as 15,000 oocysts formally. The indicator that shows the success of protective immunity is the reduced scoring of cecum lesions observed macroscopically and microscopically.

**Data Analysis:** Data to be obtained was macroscopic lesion scoring and microscopic lesion scoring. Data were arranged in table form using Kruskal Wallis analysis, if there are differences data, then proceed with the Mann Whitney test.

### Results

**Macroscopic Scores of Chicken Fecal Lesions**

![Figure 1: Macroscopic score of Chicken Fecal Lesions](image)

The figure above is a comparison of the scores of chicken cecal lesions macroscopically after being challenged with *E. tenella* infective in each group of chickens with a dose of 15 x 10^3* oocyst *E. tenella*. Each shows mean ± SD (N = 5). NS, not significantly different; *, p < 0.05.

**Figure 2: Macroscopic description of chicken cecum**

The figure above is a macroscopic picture of chicken cecum which has been challenged by inoculating *E. tenella* infective in each group of chickens with a dose of 15 x 10^3 oocyst *E. tenella*. The intensity of petechiae is reduced by *E. tenella* infection which is soaked in formalin with higher concentration. A small circle shows bleeding in the cecal mucosa, the arrow shows thickening of the cecum wall.
Microscopic score of Chicken Fecal Lesions

Figure 3: Cecum lesion microscopically in chickens

Figure 3 is a comparison of the scores of chicken cecal lesions macroscopically after being challenged with *E. tenella* infective in each group of chickens with a dose of 15 x 10^3 oocyst *E. tenella*. Each shows mean ± SD (N = 5). NS, not significantly different; *, p <0.05.

Microscopic description of chicken serum

Microscopic description of chicken cecum which have been challenged by inoculating *E. tenella* infective in each group of chickens with a dose of 15 x 10^3 oocyst *E. tenella* with various magnifications (A (100x) and B (400x)). The small circle shows the *Eimeria* distribution in the cecum and the black line shows the cecum mucosa.

Discussion

Macroscopic description of chicken cecum: From the macroscopic observation of the cecum, data were obtained based on histopathological abnormalities assessed based on a score of 0-4. At P0 it shows a normal condition because there is no damage to the caecal lesions macroscopically and there is no thickening of the cecum wall. P1 shows the degree of damage to mild level cecal lesions, characterized by bleeding spots (petechie) that spread onto the surface of the mucosal mucosa with slight changes in the color of the wall or the contents of the digestive tract. P2 shows the degree of damage to moderate cecal lesions, characterized by more bleeding and lesions with a slight thickening of the cecum wall. P3 shows the degree of damage to mild cecal lesions, there are several bleeding spots that spread to the mucosal surface of the cecum with slight changes in the color of the wall or the contents of the digestive tract. P4 shows a normal condition because macroscopically there is no damage to cecum lesions and there is no thickening of the cecum wall. These changes are due to the administration of *E. tenella* infective oocysts when the challenge test has no effect on cecal damage macroscopically, which means that the administration of oocysts that have been soaked in formalin before the challenge test can induce protective immunity seen macroscopically from chicken cecum.

The results of the statistical analysis using the Kruskal Wallis test also did not show significant differences in each treatment. It can be explained that macroscopically, the challenging test by inoculating as many as 15,000 *E. tenella* infective oocysts did not affect the damage to the cecum which had been inoculated with *E. tenella* with soaking various formalin concentrations (0.3%, 0.6%, 0.9 %, 1.2%). So it can be concluded that immersion of *E. tenella* in various concentrations of formaldehyde can induce protective immunity seen from the results of scoring and the results of macroscopic examination statistics after the challenge test which shows the results are not significantly different. The optimal formalin
concentration in patenting *E. tenella* is 1.2% indicating a normal state because macroscopically there is no damage to cecum lesions and there is no thickening of the cecum wall14.

**Microscopic description of chicken cecum:**
Histopathological observations on cecum, data obtained based on histopathological abnormalities contained in the preparations were assessed by scores seen based on summations of A and B, where A represents the distribution of *E. tenella* development stages found throughout the caecum, while B represents the severity of damage caused by *E. tenella*15.

The results of statistical analysis using the Kruskal Wallis test showed no significant differences in microscopic examination. The results obtained by histopathological preparations showed no significant differences in each treatment with the average scale which tended to be the same, namely P0: 3.88, P1: 4.28, P2: 4.22, P3: 4.04 and P4: 3.88. There are three immunity to *E. tenella*, which are totally invulnerable to parasites and do not develop parasites, chicken is immune to a certain degree, where oocysts are able to complete the life cycle but no lesions occur in the intestine, and chickens show no clinical symptoms but lesions occur in intestine16.

The microscopic scoring value in figure P0 did not experience abnormalities in cecum histopathology. Microscopic observations showed normal intestinal cells, the intestinal epithelium looked compact and did not show any rupture in the cecum villi. The first infected chicken, Schizont will develop properly due to immunity to *E. tenella* infection is still in the process of initiation, causing damage to the cecum.

The results of the P1 scoring data indicate histopathological abnormalities with moderate degrees of damage to the mucosal cecum. The cecal epithelium is compact and there are several villous ruptures. When compared with P0, P1 has a higher cecum damage. This is because previously chickens were inoculated with *E. tenella* which was soaked in formaldehyde with low concentration so it was suspected that schizont could still damage the caecum. Tissue damage to the cecum is caused by the outbreak of the schizont stage which has three generations before entering the gamete stage. P2 shows histopathological abnormalities with mild degrees of damage to the mucosal cecum. The cecal epithelium appears compact and only a few villi rupture, when it compared with P0, P2 suffers more damage, it suspected that P2 has a low immune system that is lowered by its parent.

At P3 it showed almost no abnormalities in the histopathology of the cecum, the cecal epithelium appeared to be compact and rarely found in ruptured cecum villi. If vaccines are used to better control disease in an animal population and not individually, the concept of group immunity should be considered. If group immunity is carried out by reducing the likelihood of sensitive animals meeting the infected, there will be no spread of disease13. In P4 there is no abnormality in the histopathology of cecum. Microscopic observations showed normal intestinal cells, the intestinal epithelium appeared to be compact and did not show any rupture in the cecum villi and rarely found in the development of parasites.

**Conclusion**

Attenuation of *Eimeria tenella* through immersion in various concentrations of formalin (0.15%; 0.3%; 0.6%; 1.2%) can induce protective immunity in terms of macroscopic and microscopic images of the cecum. The most potential formalin concentration for patenting *Eimeria tenella* in induces protective immunity serum in terms of macroscopic and microscopic images of cecum is 1.2%. Macroscopically there is no damage to cecal lesions and no cecum wall thickening. Whereas microscopically shows the intestinal epithelium looks compact and there is no rupture in the cecum villi.

**Ethical Clearance:** The research process involves participants in the survey using a questionnaire that was accordant with the ethical research principle based on the regulation of research ethic committee. The present study was carried out in accordance with the research principles. This study implemented the basic principle ethics of respect, beneficence, non-maleficence, and justice.

The Potential of Immune Response Improvement through \textit{Brucella abortus} Outer Membrane Protein and Whole \textit{Brucella abortus} S19 Vaccinations on White Pulp Diameter of \textit{Lepus nigricollis}

Muhammad Ardiansyah\textsuperscript{1}, Chairul Anwar\textsuperscript{1}, Imam Mustofa\textsuperscript{1}

\textsuperscript{1}Faculty of Veterinary, Universitas Airlangga, Jl. Airlangga No.4-6, Airlangga, Gubeng, Kota SBY, Jawa Timur

ABSTRACT

\textbf{Background:} Brucellosis is a disease that is still commonly found in developing and developed countries. The disease can be transmitted from animals to humans through food products made from animals. One of the efforts to control Brucellosis is by \textit{Brucella abortus} S19 vaccine. However, the vaccine may still deliver the same reaction as natural \textit{Brucella} infection. Safer vaccine development is carried out by using Outer Membrane Protein (OMP) from the infecting bacteria.

\textbf{Objective:} The study was established to determine the potential of immune response enhancement after administering OMP \textit{B. abortus} and whole \textit{B. abortus} S19 vaccine that were observed through the white pulp diameter of \textit{Lepus nigricollis}.

\textbf{Method:} An enhancement in the immune response can be determined through measuring the white pulp diameter of \textit{L. nigricollis}. The measurement data of the white pulp diameter would be analyzed by conducting one way ANOVA and Duncan statistical tests.

\textbf{Results:} The results suggested that the measurements of white pulp diameter experienced a significant enhancement (p <0.01) in each treatment. The vaccine treatment by employing OMP \textit{B. abortus} indicated the highest diameter measurement results with an average value of 553.73 μm.

\textbf{Conclusion:} Vaccination by employing OMP \textit{B. abortus} had a good potential to improve the immune response since there was a significant enhancement in the white pulp diameter of \textit{L. nigricollis}.

\textbf{Keywords:} white pulp diameter, OMP \textit{B. abortus}, immune response, vaccine, whole \textit{B. abortus} S19

Introduction

\textit{Brucellosis} is one of the primary zoonotic diseases that can have a negative impact on public health and public economy\textsuperscript{1}. Brucellosis is classified in B list, as the disease transmission affects the socio-economic or public health in a country and influences the trade development, especially in animals or products made from animals\textsuperscript{3}. In the veterinary field, at least 37\% of cows are infected by Brucellosis and causes miscarriages annually. The prevalence varied from 1\% to 40\% in 2002\textsuperscript{3}.

The economic losses caused by Brucellosis include the occurrence of abortion, animal youngs born weak and dead, sterility due to reproductive disorders, drop of milk production, and drop of market access, both nationally and internationally\textsuperscript{4}. Some efforts to reduce these effects can be applied by conducting an early diagnosis by a combination of two methods, i.e., Rose Bengal Test or RBT and Complement Fixation Test or RBT\textsuperscript{5}. Another effort in reducing \textit{Brucella abortus} effects is by administering a vaccine extracted from \textit{B. abortus} S19\textsuperscript{6}. Each type of vaccine has its advantages and disadvantages. The disadvantages of \textit{B. abortus} S19...
vaccine is that it is an active vaccine which contains attenuated B. abortus. Thus, there are still side effects after injection. The injection of B. abortus S19 vaccine often causes a misdiagnosis which may be mistaken from B. abortus infection because there are difficulties to differentiate the immune system formed due to the vaccine injection and that by natural B. abortus infection. In addition, the injected vaccine can deliver broad reactions to the tissue. Based on some of the weaknesses of the B. abortus S19 vaccine, several efforts were established to produce other types of vaccines such as the Outer Membrane Protein (OMP), which is the first barrier exposed to the agent/host, causing the produced immune response tends to attack the outer membrane.

Vaccination is one of the solutions to deal with a specific disease so that specific antibodies or body defense will be formed. The immune response from vaccination will activate the formation of immunity in the body where lymphatic tissue also plays a role. The spleen is the largest lymphatic organ in the body that filters the blood and plays an important role as the immune response site towards antigens in the blood. The spleen consists of red pulp and white pulp. Microscopic lymphatic organs are indicated by the proliferation of lymphocytes and white pulp diameter enhancement in the spleen. Based on these reviews, the study was established to determine the immune response enhancement as indicated by white pulp diameter enhancement of the spleen of Lepus nigricollis after being vaccinated with whole B. abortus S19 and OMP B. abortus.

Materials and Method

The study was an experimental research utilizing a Completely Randomized Design method (CRD), and the data results were statistically tested. The research was carried out at the Laboratory of the Faculty of Medicine, Universitas Airlangga.

Instruments and Materials: The research instruments to use during the trial period included wooden experimental animal cage with wire mesh as the base, animal feeder, and 1ml syringes. The equipment for breeding bacteria consisted of petri dish, inoculating loop, Bunsen burner, and incubator. The equipment utilized for necropsy and producing histopathological preparation consisted of surgical scissors, scalpel, tweezers, object glass, cover glass, hot plate, small pot and lid as organ storage, Bunsen burner, oven, aluminum foil, microtome, staining jar, refrigerator, optical lab, and Olympus® CX-41 microscope.

The materials utilized in this study consisted of 1) the whole bacterium of B. abortus S19, heated at 80°C and then added with CFA; 2) the whole bacterium of B. abortus S19, heated at 80°C then added with IFA; 3) OMP B. abortus added with CFA; and 4) OMP B. abortus local strain added with IFA, which were cultured in Bacteriology and Microbiology Laboratory at the Faculty of Veterinary Medicine, Universitas Airlangga. Additional materials included ketamine, acetylpromazine, 10% formalin, alcohol and cotton, and PBS. The materials utilized to treat the experiment animals consisted of feed given in the form of BR II pellets, drinking water, and preparation staining by using Hematoxylin-Eosin (HE).

Research Procedure: The experimental animals employed in this study were male rabbits (Lepus nigricollis) with body weight of approximately 1-2 kilograms and approximately aged eight weeks. In this study, 18 samples were employed to be divided into three treatment groups. The first group was the control group (P0), administered with NaCl at a dose of 1 ml/rabbit. The second group was the treatment 1 group (P1), vaccinated with B. abortus S19 at a dose of 0.5 ml/rabbit, and a dose of 1.0 x 10^8 CFU, and Complete Freund Adjuvant (CFA). The third group was the treatment 2 group (P2), vaccinated with OMP B. abortus at a dose of 0.5 ml/rabbit and Complete Freund Adjuvant (CFA).

The adaptation process period of L. nigricollis towards the laboratory environment lasted for one week. The first injection was subcutaneously administered by using Complete Freund Adjuvant (CFA) in the second week. Two weeks later, after the first injection, the booster was implemented by using the Incomplete Freund Adjuvant (IFA). The booster was implemented for two times per 2 weeks of injection. Then, they were euthanized and necropsied to take the spleen for histopathological preparations.

The euthanasia and necropsy stages were carried out five weeks after the last booster administration. Premedication by administering acetyl promazine (1 mg/kgbw) was delivered subcutaneously or intramuscularly. Then, euthanasia was carried out by using acetyl promazine 100 mg/kgbw, injected intramuscularly. The necropsy in the spleen organ was carried out through
surgery, and the organ fixation was carried out by using formalin 10%. The histopathological preparations from the animal tissue was conducted by using Hematoxylin-Eosin staining.

The white pulp diameter observation was carried out by using an Olympus microscope and equipped with Optilab support facilities. The measurements were calibrated by using Image Raster software. The microscopic observation was carried out by using 100x magnification. The measurements were carried out by drawing a straight line from the white pulp’s tip to the other end by using Raster Image Application. The measurements were carried out in the entire visible white pulp on the visual field. Then, the values were averaged.

**Data Analysis:** The data obtained from the white pulp diameter in this study were analyzed by F test in ANOVA, then analyzed by using Duncan Alpha test to determine the differences among treatments.

**Result**

Based on the analysis attachment by using the one-way ANOVA method (F test), the test suggested that the group treatment for OMP *B. abortus* vaccination had significantly different results among the treatment groups (p <0.01). The comparison of the white pulp diameter of each treatment group can be observed in **Table 1**.

**Notes:** P0 = control group with physiological NaCl, P1 = treatment 1 with *B. abortus* S19 vaccine, P2 = treatment 2 with OMP *B. abortus*. The letter notation indicated a significant difference (p <0.01) among each treatment. The same-letter notation means that the results were not significantly different. The different-letter notations mean that the results were significantly different.

Based on **Table 1**, the average white pulp diameter had different values in each treatment group. The diameter enhancement in the control group reached 347.25 µm; the treatment 1 group reached 452.16 µm; and the treatment 2 group amounting to 553.73 µm. The treatment 2 group, vaccinated with OMP *B. abortus*, indicated significant different results (p <0.01) from the control group. Meanwhile, treatment 1 group, vaccinated with *B. abortus* S19, indicated relatively insignificant increase from the control group. The spleen histopathology in each treatment is indicated in **Figure 1** as follows.

**Figure 1:** White pulp diameter in *L. nigricollis* spleen in each treatment, 100x magnification. A = control group (P0) administered with physiological NaCl, B = treatment 1 (P1) administered with whole *B. abortus* S19, C = treatment 2 (P2) administered with the Outer Membrane Protein *B. abortus*
Based on Figure 1, it can be observed that the white pulp diameter of *L. nigricollis* spleen in the control group (P0) had the smallest diameter. The white pulp diameter at P0 was approximately 240.9 µm. The white pulp in treatment 1 group (P1) indicated a larger diameter size than that in the control group of approximately 536.7 µm. The white pulp diameter in treatment 2 group (P2) indicated the largest diameter compared to treatment 1 and control groups, reaching approximately 790.6 µm. Based on these results, the OMP *B. abortus* treatment group had better immune enhancement compared to treatment utilizing whole *B. abortus* S19.

**Discussion**

The treatment group injected with OMP *B. abortus* vaccine had a significant different enhancement in the immune response (p < 0.01) compared to the control group. The treatment group injected with whole *B. abortus* S19 did not have much different immune response compared to the control group. There was an enhancement in the treatment groups because an antigen was injected so that it was capable of forming antibodies. Antigens will be recognized earlier by macrophages and presented in the form of fragments that will stimulate B and T lymphocytes to carry out proliferation that produces antibodies. The proliferations of both lymphocytes are mostly found in the white pulp of the spleen, causing mutual pressure on the lymphocytes due to its fission, causing the white pulp diameter became broader.

*B. abortus* bacterial structure is quite unique. It is unlike other negative gram bacteria. The outer surface of this bacterium does not have pili, and is not encapsulated. It has an outer membrane to protect bacterial cells from molecules diffusion, hydrolytic enzymes, and helps the conjugation process in controlling DNA replication. The outer membrane is composed of two components that have been identified as potential virulence factors, i.e., Outer Membrane Protein (OMP) and Lipopolysaccharide (LPS) proteins. These outer membranes are hydrophobic, causing them to be more resistant and potential as virulence factors. OMP in negative gram bacteria is a potential immunogen that can directly induce humoral specific immune responses, namely B lymphocyte cells so that it accelerates the antibodies formation faster. *Brucella* has a lipid component called lipoprotein. Unmodified lipids can enhance *Brucella* pathogenicity. Lipoproteins induce cytokines associated with nonspecific immunological reactions. The cytokines production in the immunological system is closely related to the inflammatory reaction.

Other studies have discovered that purified lipoproteins from OMP *B. abortus* such as L-OMP16 and L-OMP19 can stimulate cytokine production from innate immune response cells. Such stimulation occurs due to the interaction of OMP16, OMP19 or other *B. abortus* lipoproteins and cells, such as macrophages, which causes cytokine production, proliferation and the fusion of other inflammatory cells, resulting in tissue inflammation.

The immune response towards Brucellosis involves the humoral and cellular immune systems. The humoral response system is formed by antibodies produced by B lymphocytes that are located in peripheral lymphoid tissue. Antigens will be bounded by B lymphocyte immunoglobulin, which will stimulate proliferation of B cells into plasma cells and form antibodies to fight *Brucella* infection and neutralize the toxin.

*B. abortus* is an intracellular pathogen that can survive on macrophages in a hostile environment. Previous research has been carried out on mice and monkeys. It results in an important response to this infection, i.e. the presence of IL-2 and IFN-γ secretions, involving APC and Th1 cells. *B. abortus* has the capability of producing antibody response in the forms of independent T helper cells and independent CD4 + T cells. Peptides or proteins can be conjugated to *B. abortus* where the conjugates are used to obtain strong antibody and CTL responses, even without the presence of CD4 + T cells.

The development of Brucellosis vaccine is carried out by looking at IgG levels in vaccine administration of all bacteria *B. abortus* S19 and OMP *B. abortus*. The results of this study suggested significant differences among treatments, in which, OMP *B. abortus* vaccine resulted the highest IgG level. IgG is the antibody result by plasma cells in the blood where plasma cells are the mature forms of lymphocyt B. Before plasma cells are formed in the spleen’s white pulp, proliferation of lymphocytes is stimulated and ripens into plasma cells in the bloodm then producing antibodies. Therefore, it can be correlated with high IgG levels in vaccination of OMP *B. abortus* and lymphocyte cell proliferation in the spleen’s white pulp. The highest average spleen’s pulp white diameter of the OMP *B. abortus* treatment indicated the highest IgG level. The two results of the study suggested that the administration OMP *B. abortus* vaccination is capable of providing good antibody formation.
Conclusion

This study concludes that the diameter measuring experienced different results. The vaccination by using OMP B. abortus has the potential to improve immune response by having an enhancement in the L. nigricollis white pulp diameter. It is suggested for future research that there is a requirement to measure the formed antibody levels resulted from whole B. abortus and OMP B. abortus vaccinations.

Ethical Clearance: The research process was using experimental method that was accordant with the ethical research principle based on the regulation of research ethic committee. The present study was carried out in accordance with the research principles. This study implemented the basic principle ethics of respect, beneficence, non-maleficence, and justice for animal.

Conflict of Interest: The author reports no conflict of interest of this work.

Source of Funding: This study is done with individual funding.

The Effect of Adding Moringa Leave (*Moringa oleifera*) to Male Broiler Feed

Mien Qurrati A’yuni Muis¹, Kadek Rachmawati¹, Mohammad Anam Al Arif⁰

¹Department of Veterinary Education, Faculty of Veterinary, Universitas Airlangga, Jl. Mulyorejo, Surabaya, East Java

ABSTRACT

**Background:** Broiler chickens are popular in the community due to their inexpensive price and thick meat. Nevertheless, its high-fat content worries consumers.

**Objective:** This research aims to investigate the effect of Moringa leave powder added in commercial diets on increasing the protein level and decreasing the fat content in broiler chickens.

**Method:** This research employed 20 male Day-Old Chicks (DOC) of CP 707 strain, aged 21-35 days. This research applied CRD (Complete Randomized Design) with four treatments and five replications. The protein and fat of broiler meat were measured as the parameter in this study. After that, the data were analyzed using Analysis of Variance (ANOVA) and continued by using the Duncan test.

**Result:** Moringa leaves powder as a substituent in commercial diets had a significant effect (p <0.05) on the increase in meat protein. It was identified that P1 gained meat protein by 20.02%; P2 by 19.87%, and last P3 by 19.99% from the P0 group with 19.37% protein increase. There was also a significant influence (p <0.05) on meat fat decrease where P1 decreased fat by 1.23%; P2 by 1.30%, P3 by 1.13% from P0 with 1.50% fat content.

**Conclusion:** Moringa leaves powder supplemented to chicken diets impacts on increasing protein level and decreasing fat content of broiler chickens.

**Keywords:** Broiler, Meat protein, Meat fat, Moringa oleifera

Introduction

Broiler chickens are the type of chicken specifically raised for meat production with rapid growth as its economic characteristic. A fast harvest time, soft fibrous meat, thicker meat, and high nutrient make broiler chickens favorable. In addition, broilers are popular among the community due to their affordable price. However, the high fat contained in broiler chickens causes some people to worry. The high-fat content brings negative impacts on health and positively correlate with metabolic diseases such as atherosclerosis, hypertension, and coronary heart disease. Therefore, meat companies should provide chicken meat with low fat and high protein content to increase consumer interest in chicken meat.

Amino acids are vital substances required in protein synthesis. Amino acids, nonetheless, are not produced by the body. Hence, it must be imported in a completed form. One of the amino acid sources that can be obtained is Moringa leaves. Some active compounds contained in Moringa leaves include saponins, leucine, and methionine which have benefits for the body. Fresh Moringa leaves contain 492 mg of leucine, which is essential for the synthesis of muscle protein and normal cell function. Meanwhile, saponins is a compound which is capable of reducing cholesterol level in broilers due to its essential function in cholesterol metabolism and fat accumulation decrease. In addition, saponins are also capable of lowering lipid and blood cholesterol levels by inhibiting cholesterol absorption.
The supplement of Moringa leaves powder in the chickens’ diet positively affects the yellow color increase of the eggs. Furthermore, green vegetables on chickens’ diet are considered to contain useful substances such as vitamins and minerals that are essential for livestock. Green vegetables serve as vitamins and minerals source and are regarded as more efficient than factory-produced vitamins. Green vegetables are considered better because of their lower price, natural ingredient, and relatively perfect food substances such as protein, fat, and water. These factors can improve the quality of the food consumed. Based on the potential content of Moringa leaves, this research needs to be taken into account to examine the effect of Moringa leave powder addition in commercial diets toward meat protein and fat levels in male broilers.

**Method**

This research was conducted at the Faculty of Veterinary, Universitas Airlangga. The experimental animals employed were 20 male broiler chickens of CP 707 strains and aged between 21 to 35 days old. This research applied four treatments with a minimum of five replications for each treatment.

The treatment groups were arranged as follows:
- P0 (control): 100% commercial diets
- P1: 95% commercial diets + 5% Moringa leave powder
- P2: 90% commercial diets + 10% Moringa leave powder
- P3: 85% commercial diets + 15% Moringa leave powder

The treatments above were carried out for two weeks, preceded by an adaptation period of 7 days.

Powdered moringa leaves were utilized as the ingredient of supplementary diets. In this study, the broiler chickens were fed with commercial diets (PT. Charoen Pokphand, Thailand). Moreover, the cages were disinfected with Lysol. In addition, the chickens were administered an ND (Newcastle Disease) vaccine to prevent Newcastle disease. The ND vaccine consisted of 2 strains, namely Hichner B1 strain and Lasota strain. The drinking water provided to the chickens was mixed with anti-stress vitamins. Cipro antibiotics were also given adequately to unhealthy chickens. After that, the data obtained were analyzed using the ANOVA (Analysis of Variance). In addition, Duncan’s Multiple Distance Test was performed to discover the best treatment.

**Results**

**The Protein Level of the Broiler Chicken Meat:** The addition of Moringa leaves powder in the male broiler chickens’ diets suggested a significant difference (p <0.05) of meat protein increase.

Table 1: Average protein levels of the broiler chicken meat supplemented with Moringa leave powder

<table>
<thead>
<tr>
<th>Treatment</th>
<th>Meat Protein Level (%) (X ± SD)</th>
</tr>
</thead>
<tbody>
<tr>
<td>P0 (100% commercial diet)</td>
<td>19.37132 ± 0.36708</td>
</tr>
<tr>
<td>P1 (95% commercial diet+5% Moringa leave powder)</td>
<td>20.02166 ± 0.51725</td>
</tr>
<tr>
<td>P2 (90% commercial diet+10% Moringa leave powder)</td>
<td>19.87110 ± 0.19768</td>
</tr>
<tr>
<td>P3 (85% commercial diet+15% Moringa leave powder)</td>
<td>19.99622 ± 0.30299</td>
</tr>
</tbody>
</table>

The data analysis result using ANOVA on the meat protein level detected that P0 (control group) was significantly different from P1, P2, and P3 (p<0.05). Meanwhile, P1 was not considerably different from P2 and P3 (p>0.05). The data analysis results illustrated that the addition of Moringa leaves powder affected the protein level increase of the male broiler meat.

**The Fat Level of the Broiler Chicken Meat:** The analysis results of the ANOVA test described that the Moringa leaves powder added in the broiler chickens’ diets had a significant effect (p <0.05) on the fat level of the male broiler chicken meat.

Table 2: Average of the fat level of the broiler chicken added with Moringa leaves powder

<tr>
<td>P3 (85% commercial diet+15% Moringa leave powder)</td>
<td>1.13550 ± 0.14861</td>
</tr>
</tbody>
</table>
The average fat level of P0 (control group) differed significantly (p < 0.05) from P3, but not significantly different (p > 0.05) from P1 and P2. In contrast, P3 illustrated a different result from P1 and P2. The highest fat level was identified in P0 (control), and the lowest level was in P3. The results of this data analysis described that the addition of Moringa leaves powder in the ration could reduce the fat level of the male broiler meat.

**Discussion**

Based on the data analysis results using the ANOVA test which was then followed by Duncan’s multiple distance test, the addition of *Moringa oleifera* leaves powder in the ration significantly influenced (p < 0.05) meat protein level increase. The lowest protein content of meat was produced by in the control group (P0), reaching only 19.37%. The highest protein content of meat was generated from the addition of 5% Moringa leave powder in treatment group 1 (P1), amounting to 20.02%. Meanwhile, the protein content of meat produced with the addition of 10% Moringa leave powder (P2) reached 19.87%. This figure was not significantly distinctive from the addition of 5% Moringa leave powder (P1) reaching 20.02%, and the addition of 15% *Moringa* leaves powder (P3), amounting to 19.99%.

The meat protein level in the treatment group experienced an increase, compared to the control group, despite within the normal range. The energy contained in the feed nutrient composition from P0 to P3 decreased, namely 3,040.06 kcal/kg to 2,962.93 kcal/kg. The decrease in the energy contained in the ration composition caused an increase in ration consumption. It leads to more protein intake from ratio due to high ration consumption. The feed with higher energy is less consumed. On the other hand, the feed with lower energy will be consumed more and more to meet their needs. The ration consumption in large amount will be followed by high protein intake. The consumption of high protein will also affect meat protein intake. Moreover, amino acids intake will be sufficient; hence, cell metabolism in the body occurs normally. It causes the meat protein level to increase.

Moringa contains essential amino acids that are not produced by the body. Hence, it must be supplied into the body in a completed form. This amino acid is highly vital in protein synthesis. Protein is essential for the growth of chickens’ body parts and for replacing damaged body tissue. One of the active compounds contained in fresh Moringa leaves is 492 mg of leucine, which plays a role in muscle protein synthesis and normal cell function. The results of previous studies on the benefits of Moringa leaves as a broiler chicken feed has proven that *Moringa oleifera* leaves could be added up to 5% in feed to substitute fish powder and soybean.

The highest protein content of the broiler chickens fed with Moringa leaves powder added in their diet was found out in P1 with 5% Moringa powder level, resulting in 20.02% protein increase. This result was significantly different from P0, which only reached 19.37% protein increase. The addition of 10% and 15% Moringa powder, P2, and P3 treatment groups, produced lower protein content than P1, i.e., 19.87%, and 19.99% respectively. Nevertheless, it was still higher than P0. Moreover, the protein content in the nutritional composition of feed P1, P2, and P3 was not significantly different. Thus, the mean and standard deviations of the meat protein level were not significantly different as well. The results of this data analysis identified that the addition of Moringa leaves powder on the chicken feed influenced the protein level increase of male broiler meat.

The average fat content of the broiler chickens after being treated with the addition of Moringa leaves powder, from each treatment group was 1.50% fat addition in P0 (control), 1.23% fat addition in P1, 1.30% fat addition in P2, and last 1.13% fat addition in P3. The highest fat content resulted in P0 (control), and the lowest was in P3. The statistical analysis results with ANOVA test, followed by Duncan’s Multiple Distance test identified that the addition of Moringa leaves powder on commercial diets had a significant effect on decreasing the fat content of the male broiler chickens meat. The fat content in P0 (control) was significantly different from P3, which was 1.50% and 1.13% respectively. Meanwhile, P1 and P2 were not considerably different, namely 1.23% and 1.30% respectively.

In order to maintain the quality of the broiler chickens, the ration standard for the finisher phase requires crude fiber content, amounting no more than 6.0%. It is found out that the crude fiber content in the nutrient composition of P3 feed reached 6.94%, and it increased from P0. The high crude fiber content in the ration appeared to reduce the cholesterol and fat level in the chickens’ body. Moreover, the average...
and standard deviation of the meat fat level illustrated that P0 (control) was significantly different from P3. The fat distribution in the body decreased, along with the increase of crude fiber content in the diet, and the presence of probiotic addition in the body 16.

Diet is one of the factors that play a role in various chemical and physiological activities, converting feed nutrients into animal body substances 17. Some active substances in Moringa include saponins, tannins, methionine, flavonoids, and essential oils 18. The active substances such as saponins, vitamin C, flavonoids, and tannins are also capable of reducing fat accumulation 19. This component can be utilized to inhibit the accumulation of fat and cholesterol in the body of livestock to improve carcass quality and reduce carcass cholesterol in the broiler chickens. The addition of alfalfa saponins is capable of lowering cholesterol and fat level in chicken’s breast meat 20.

Based on these reasons, the results of this study are better since the fat content percentage of the broiler chickens was still in a low range. The results of this data analysis identified that the addition of Moringa leaves powder affected the fat content decrease in the male broiler meat.

Conclusion

*Moringa oleifera* leave powder addition on the commercial diet can increase the protein content of male broiler meat up to 15% powder addition and reduce the fat content of the male broiler meat up to 15% powder addition.

The Effect of Vitamin on Wistar Rats’ Testicles Exposed to Lethal Insecticide

Gabriella Ayu Pitaloka¹, Kusnoto¹, Thomas Valentinus Widiyatno¹
¹Department of Veterinary Education, Faculty of Veterinary, Universitas Airlangga, Jl. Mulyorejo, Surabaya, East Java

ABSTRACT

Background: Agricultural products exposed to endosulfan insecticides potentially lead to organ dysfunction in living organisms that can cause morphological changes in the reproductive system such as a decrease in the number of sperm cells, an inhibition on the testosterone production by the Leydig cells, and a decline in the ascorbic acid levels in the testicles.

Purpose: This study aimed to determine the effect of vitamin C on testicle weight and the number of Leydig cells in adult male Wistar rats exposed to endosulfan.

Method: This study used 20 male Wistar rats with an average weight of 25 grams as samples, where the rats were equally divided into four groups, i.e., P-, P+, P1, and P2. The testicles of all Wistar rats were harvested on day 19 and then prepared for a microscopic examination with routine H & E staining. The results analyzed by using ANOVA and the Waller-Duncan T-test.

Results: The testicle weight of the Wistar rats administered with endosulfan suggested a significant difference (p <0.05) and had the lowest value compared to the other treatments. The Wistar rats administered with endosulfan and then followed by vitamin C administration did not indicate a significant difference (p <0.05). Vitamin C administration to Wistar rats caused an increase in testicle weight. Conversely, administering endosulfan to the Wistar rats caused a decrease in testicle weight.

Conclusion: Administering vitamin C to Wistar rats exposed to endosulfan could potentially lead to an increase in the testicle weight and the Leydig cells.

Keywords: endosulfan, vitamin C, Wistar rats, testicle weight, Leydig cells

Introduction

Some chemicals in recent years still need to be evaluated and examined as they potentially lead to toxicity in the reproductive system ¹. One of the widely used chemicals is endosulfan. This insecticide can enter the body through various intermediaries such as food, air, or skin contact can inflict several toxic effects on the body ². The endosulfan contained in agricultural products will enter the body of living organisms and lead to organ dysfunction if ingested. Endosulfan is a type of insecticide classified as highly toxic and potentially cause damages to the reproductive organs, especially the testicles ³. The endosulfan toxicity can lead to morphological and functional changes in the reproductive system such as a decrease in the number of sperm cells and inhibition on the testosterone production by the Leydig cells ⁴. The endosulfan distribution is carried out through agricultural lands and the surrounding aquatic environment ⁵. In mammals, endosulfan disrupts the central nervous system and the metabolic system so that it inhibits the nervous system transmission in the brain ⁶, activates cholinergic, dopaminergic ⁷, and serotonergic systems in the body mechanism ⁸, and causes very high gonad toxicity ⁹. At a more severe level, it also causes lethal and sublethal effects, which result in a high percentage of death and disability effects on animal larvae ¹⁰.
Vitamin C is the main chain-breaking antioxidant that neutralizes hydroxyl, superoxide, and hydrogen peroxide radicals and prevents sperm agglutination. The amount of vitamin C found in infertile men is quite low. At a dose of 200-1,000 mg/day, this vitamin can increase the sperm amount of infertile men in vivo. Administering vitamin C can forestall cell lipid peroxidation, as evidenced by the diminishing occurrence of cell damage. Vitamin C has positive effects on the reproductive organ weight and sperm parameters such as motility, development, feasibility, number, and anomaly. Besides, vitamin C can also increase testosterone levels in the blood.

Based on the background above, this study aimed to determine whether administering endosulfan followed by vitamin C administration affected the testicle weight and the number of Leydig cells of the male Wistar rats. This study hypothesized that vitamin C could improve the testicle morphology and increase the number of Leydig cells of the Wistar rats exposed to endosulfan.

**Method**

This study used Federer’s formula to determine the number of samples for experimental research. The number of sample groups divided into 4 treatment groups. The total number of samples in this study were 20 adult Wistar rats aged 2-3 months with an average weight of 25 grams. Its placed in closed plastic cages with a bed of husk in a ventilated room that is indirectly illuminated to adapt to the research site for seven days and consisted of five Wistar rats. The amount of endosulfan orally administered to the Wistar rats was 3.2 mg/kg BW, while the amount of vitamin C administered was 25 mg/kg BW and 50 mg/kg BW.

There were four treatment groups of the Wistar rats placed in cages for seven days to adapt to the research site, namely:

- **P-**: administered with 0.5 ml aquadest for ten days starting on the 8th day to the 18th day
- **P+**: with 0.5 ml endosulfan at a dose of 3.2 mg/kg for ten days beginning on the 8th to the 18th day
- **P1**: administered with 0.5 ml endosulfan at a dose of 3.2 mg/kg BW for ten days beginning on the 8th day to the 18th day, and then followed by vitamin C administration at a dose of 25 mg/kg for seven days beginning on the 11th to the 18th day
- **P2**: administered with 0.5 ml endosulfan at a dose of 3.2 mg/kg BW for ten days beginning on the 8th day to the 18th day, followed by vitamin C administration at a dose of 50 mg/kg for seven days beginning on the 11th day to the 18th day

The dissection of the Wistar rats was carried out on the 19th day. The Wistar rats were euthanized by using chloroform PA and then dissected by using dissecting kits. After the scrotum was opened, the testicle organs of the Wistar rats were taken and then weighed using a 0.1 analytical scale to determine the testicle weight. After the weighing process, the testicles were washed with a physiological solution and put into a pot containing 10% formalin solution for subsequent histopathological preparation. The changes in the testicle weight and the number of Leydig cells in histopathological preparations were analyzed and examined by using SPSS program using the One-Way ANOVA method then followed with Duncan’s Multiple Distance Test.

**Results**

The right and left testicles of the Wistar rats were weighed with an analytical scale of 0.1 and then examined using the ANOVA test. The average results of testicle weight in the P-, P +, P1, and P2 treatment groups were 0.056 grams, 0.024 grams, 0.064 grams, and 0.098 grams, respectively. The ANOVA test results on the testicle weight indicated a significant difference in the existing treatments (p <0.05).
significantly different (p <0.05) compared to the other treatment groups. It indicated that administering vitamin C at a dose of 50 mg/kg BW to Wistar rats caused testicle weight to increase. The lowest testicle weight occurred in the P+ group and was significantly different compared to the other treatment groups. This finding denoted that the endosulfan administration at a dose of 3.2 mg/kg BW to Wistar rats caused testicle weight to decrease. On the other hand, the testicle weight in the P- and P1 groups did not differ significantly (p <0.05).

The observation of Leydig cells in histopathological preparations of the Wistar rats’ testicles using a microscope with 400x magnification in ten visual fields were between three to four seminiferous tubules.

The results of the 5% Duncan test indicated that the highest number of Leydig cells occurred in the P- group, reaching 296 cells, and differed significantly from the other treatment groups. The lowest number of Leydig cells in the P+ group, which only reached 169 cells and differed significantly (p <0.05) from the other treatment groups. It indicates that administering endosulfan at a dose of 3.2 mg/kg BW in Wistar rats caused the number of Leydig cells to decrease. The number of Leydig cells in P1 and P2 groups that reached the amount of 210 and 269, respectively, were not significantly different (p> 0.05). It proved that vitamin C administration to Wistar rats could improve the number of Leydig cells in each treatment, but the most optimized Leydig cell recovery was at a dose of 50 mg/kg BW.

**Discussion**

Vitamin C as an antioxidant has been proven to improve the testicle morphology and weight, increase the number of Leydig cells, and prevent cell damage of the Wistar rats exposed to endosulfan. Endosulfan acts as a gamma amino butyric antagonist, which is an inhibitory neurotransmitter in the central nervous system. Acute symptoms of the endosulfan effects include motion incoordination, gagging, vomiting, diarrhea, anxiety, convulsion, and loss of consciousness. Moreover, endosulfan also inflicts the kidney, liver, reproductive organ, respiratory organ, and immune system disorders in mammals.

The results of the statistical analysis using ANOVA presented that the testicle weight of the Wistar rats in the P+ treatment group differed significantly from the other treatments. In the P+ treatment, the Wistar rats were given endosulfan at a dose of 3.2 mg/kg BW for ten days. The testicle weight in the P+ treatment had the lowest number compared to the other treatments, which was only 0.024 cells. It indicated that the peroral administration of 0.5 ml endosulfan at a dose of 3.2 mg/kg BW for ten days to the Wistar rats caused the testicle weight to decrease. In P1 treatment, where the Wistar rats were administered with 0.5 ml endosulfan at a dose of 3.2 mg/kg BW for ten days followed by 0.5 ml vitamin C administration at a dose of 25 mg/kg BW for seven days, indicated a value of 0.064. Both treatments did not have a significant difference (p <0.05). It implied that vitamin C administration could not protect spermatogenic cells from free radicals inflicted by endosulfan, disrupting the spermatogenic cell formation in the seminiferous tubules in the testicles.

The heaviest testicle weight among all treatments was in P2 where the Wistar rats were administered with 0.5 ml endosulfan at a dose of 3.2 mg/kg BW for ten days, followed by a 0.5 ml vitamin C administration at a dose of 50 mg/kg BW for seven days, reaching an amount of 0.980. It showed that administering vitamin C could increase the number of spermatogenic cells formed so that there would be an increase in the epithelial thickness of the seminiferous tubules, affecting the testicle weight. The spermatogenic cells formed in the testicles were closely associated with an increase in the epithelial thickness of the seminiferous tubules. The abundance of spermatogenic cells in the seminiferous tubules in the testicles could determine the increase in the testicle weight itself. Administering vitamin C at a dose of 50 mg/kg BW affected the number of spermatogenic cells in Wistar rats exposed to endosulfan, causing the testicle weight to increase. The results of the ANOVA test on the number of Leydig cells implied that the
endosulfan and vitamin C administration in Wistar rats had a significant difference in the number of Leydig cells. The highest number of Leydig cells occurred in the P- treatment group as a control group, reaching an amount of 296 cells and was significantly different from the P+ group with only 169 cells. It indicated that drug solvent administration did not lead to central nervous system disruption to secrete gonadotropin-releasing hormone which stimulates the luteinizing hormone and follicle-stimulating hormone secretion from the anterior pituitary gland.

Luteinizing hormone increased the activity of the desmolase cholesterol enzyme, stimulating the testosterone secretion. On the other hand, follicle-stimulating hormone increased the Leydig cell responses to luteinizing hormone so that the spermatogenesis process ran normally. In the P+ group, the endosulfan administration to the Wistar rats at a dose of 3.2 mg/kg BW for ten days disrupted the hypothalamus by inhibiting the gonadotropin-releasing hormone performance so that the follicle-stimulating hormone and luteinizing hormone formation became inhibited. If the levels of follicle-stimulating hormone and luteinizing hormone were inhibited, the proliferation of Leydig cell development in the testicles decreased. The results in P- group did not differ significantly from P2 with 269 cells indicated that the drug solvent and vitamin C administration at a dose of 50 mg/kg BW had the same function in maintaining the number of Leydig cells. At a dose of 50 mg/kg, vitamin C increased the luteinizing hormone secretion, which led to an increase in the number of Leydig cells produced. Testosterone produced Androgen Binding Protein used in the spermatogenesis cycle to increase the number of spermatozoa.

The P1 and P2 treatment groups did not show a significant difference (p> 0.05). Whereas in P1, the Wistar rats were administered with endosulfan at a dose of 3.2 mg/kg BW, followed by vitamin C administration at a dose of 25 mg/kg BW, and reached a total of 210 cells. In P2 group, the Wistar rats were administered with endosulfan at a dose of 3.2 mg/kg BW, followed by vitamin C administration at a dose of 50 mg/kg, and reached a total of 269 cells. These findings implied that vitamin C administration at a dose of both 25 mg/kg BW and 50 mg/kg could improve and maintain the number of Leydig cells, but the latter dose was proven to be more maximal. Vitamin C provides spontaneous and rapid stimulation to the hypothalamus, arising signals to increase the follicle-stimulating hormone and luteinizing hormone secretion by protecting the brain and brain fluids. Therefore, the chain reaction of free radicals would stop, the central nervous system would be safely protected from damage, and the pituitary gland would typically produce hormones like follicle-stimulating hormone and luteinizing hormone. If the follicle-stimulating hormone and luteinizing hormone levels became normal, the proliferation of Leydig cell development would normally run in the testicles.

**Conclusion**

The administration of specific doses of vitamin C could increase the testicle weight and the number of Leydig cells in Wistar rats exposed to endosulfan.

The Potency of Formalin in Atenuation of Pathogenicity in *Eimeria Tenella* at the Caecum of Broiler Chicken

Enik Setywati¹, Muchammad Yunus², Dadik Rahardjo¹

¹Faculty of Veterinary, Airlangga University, ²Department of Parasitology Veterinary, Faculty of Veterinary, Airlangga University, Kampus C, Mulyorejo, Kec. Mulyorejo, Kota Surabaya, Jawa Timur

ABSTRACT

**Background:** Coccidiosis is a parasitic disease that disrupts digestive tract, especially in caecum. It causes a lot of harm to chicken farms. Formalin, can be a new invention as an alternative for *Eimeria tenella* protozoa attenuation in vaccines.

**Aim:** To determine formalin effect and optimum concentration for formalin attenuation of pathogenicity to cecum lesions inoculated score in boiler chickens.

**Method:** This study was an experimental study using completely randomized design (CRD) with five treatments. Treatment variation is formaldehyde with a concentration of 0%, 0.15%, 0.3%, 0.6%, 1.2%

**Results:** Results of the study showed that formalin with different concentrations resulted in a significant decrease. Decreasing microscopic cecum lesions inoculated score in boiler chickens in each treatment 0%, 0.15%, 0.3%, 0.6% and 1.2% were 10.32; 9.86; 7.00; 5.14; 4.98 respectively. The largest decrease in lesion score was at 1.2%.

**Conclusion:** Formalin with 1.2% concentration could reduce cecum lesions inoculated score in boiler chickens

**Keywords:** Formalin, *E. tenella*, Caecum of boiler chicken, Attenuation

Introduction

Chicken could get diseases caused by protozoa with high morbidity and mortality. Coccidiosis is one parasitic that cause disease especially in caecum of digestive tract, resulting almost 80-90% morbidity and mortality. In addition, this disease could also cause decreasing egg production, body weight and increasing in medical expenses. Economic losses due to coccidiosis in United States between 450 million dollars to 1.5 billion US dollars. Coccidiosis is one among all diseases always occurs in every period of chicken maintenance.

Various ways to control coccidiosis have been carried out, but not yet fully successful. Maintenance with good sanitation can break *Eimeria* development cycle, but this method is still not fully able to prevent occurrence of coccidiosis. It is caused by the small size of the oocyst can contaminate water, feed, and cage equipment. Residue in meat also could endanger consumers. One effective action is using a vaccine that induce immunity. Live vaccine is giving immunity in a certain range of time and protecting against infection with pathogenic agents. In coccidiosis, the best type of vaccine to use is an active vaccine, where vaccine functions got protection in live vaccines form.

Formalin is a 37% formaldehyde gas solution and contains methanol as a stabilizer. Coccidiosis vaccine development needs to be explored to prevent infection through various immersion concentrations of *E. tenella* with formalin as a live vaccine in chickens. Exploration of optimum immersion time to produce attenuation could induce the most effective protective immunity in chickens. This study aim was to determine formalin
effect and its attenuation optimum concentration on pathogenicity against cecum lesion scores inoculated in boiler chickens.

**Method**

This study was located in experimental cages, parasitology laboratories and pathology laboratories at the Faculty of Veterinary, Universitas Airlangga, Surabaya. Method used in this study as follow (i) Animals subject used in this study were 25 broiler strains of CP 707 produced by Chaeron Pokphand and aged 21 days. Two-week-old chickens were kept in a battery-powered coop, fed ad libitum and did not contain coccidiostat. Saturated sugar solution, chlorine, distilled water, formalin with concentrations of 0.15%, 0.3%, 0.6% and 1.2%. (iii) Research tools used were battery-powered chicken coop, feed-drink containers, microscope, object glass, cover glass, lab optics, surgical scissors, tweezers, scalpel, centrifuge tube, centrifuge, tray, pot ointment, paper label, tissue paper, stapler, and pipette, micropipette and white chip

Study was an experimental study using complete randomized design (CRD), consist of four treatments. The treatment given is:

- **Treatment 0**: As a control, oocysts was not soaked in formalin and inoculated with 10,000 oocysts.
- **Treatment 1**: *E. tenella* was soaked in formalin with a concentration of 0.15% for 96 hours, then oral inoculated with 10,000 oocysts.
- **Treatment II**: *E. tenella* was soaked in formalin with a concentration of 0.3% for 96 hours, then oral inoculated with 10,000 oocysts orally.
- **Treatment III**: *E. tenella* was soaked in formalin with a concentration of 0.6% for 96 hours, then oral inoculated with 10,000 oocysts.
- **Treatment IV**: *E. tenella* was soaked in formalin with a concentration of 1.2% for 96 hours, then oral inoculated with 10,000 oocysts.

Macroscopic and microscopic scoring was performed on 5th day after inoculation with scoring done macroscopically, cecal abnormalities were noted and degree of damage to mucosal surface of chicken cecum was calculated based on a score of 0-4:

**Description:** Different letter transcripts show significant differences

Macroscopic and microscopic mean value of boiler chicken cecum lesions score showed a significant difference. In macroscopic scoring, cecum lesion score decreased with increasing formalin concentration. However, treatment concentration of 0.6% and 1.2% did not show a significant result of 0.547. The biggest decrease in the lesion score was in treatment group of 0.6% and 1.2% with value of 0.6.

Microscopic observation scoring showed a significant decreasing in lesion scores between treatments on boiler chicken cecum along with increasing in formalin concentration. Decreasing in lesion scores in treatment concentration of 0%, 0.15%, 0.3%, 0.6% and 1.2% were 10.32; 9.86; 7.00; 5.14; 4.98 respectively. The biggest decrease in lesion score was in the addition treatment concentration of 1.2%

Results of chicken cecum obtained from image observation macroscopically. Picture showed degree damage of each treatment due to *E.tenella* inoculation can be seen in Figure 1.

![Macroscopic image of chicken cecum inoculated with E. tenella soaked using several formalin concentrations](image-url)
Intensity of pteciae was reduced by immersion in formalin with higher concentrations. Circle showed bleeding in the mucosa and arrows for thickening of the mucous cecum. Picture was taken using an iPhone 5s camera.

Histopathological picture showed degree damage of each treatment due to *E. tenella* inoculation can be seen in Figure 2.

**Figure 2: Histopathological description of chicken cecum inoculated with *E. tenella* and soaked using several formalin concentrations [0% (P0); 0.15% (P1); 0.3% (P2); 0.6% (P3); 1.2% (P4)]**

**Description:**  
- Arrow showing ruptured cecum villi, arrow showing bleeding, arrow showing *E. tenella* oocyst; (0.1 - 4.1, 100x magnification; 0.2 - 4.2, 400x magnification).

**Discussion**

Chemicals for *E. tenella* attenuation in vaccines usually using chemicals that can cause antigen changing responsible for stimulating protective immunity. Formalin reacts with amino and amide groups in proteins. Amino bonds are bound to non-water substances with basic ingredients of purine nucleic acids and pyrimidines forming cross-bonds and provide structural rigidity in the organism. Structural rigidity of organism will result in cell death, could reduce virulence of the organism. Organism could lives but not potent enough to cause disease and has large influence to improve antibodies.

Formalin will react chemically with almost all substances in cell thereby suppressing cell function and causing cell death. Formalin is also a source of reactive oxygen compounds (ROS) and oxygen free radicals. Safe threshold of formalin in chicken bodies according to International Program on Chemical Safety (IPCS) in liquid form is 1 mg/l.

*E. tenella* infection phase in the cecum is at sporozoite stage penetrates epithelial cells in cecum villi and crypta. After in cecal epithelium, parasite develops asexually and sexually. This development results in damage to cecal epithelial cells due to schizont ruptured which liberated merozoites. Larger size and increasing amount of *E. tenella* that infects cecum could increase cecal epithelial erosion, and vice versa. In previous study, it was resulting a decrease in number and precocious lines. It caused a decrease in the cecal epithelial erosion score in each treatment group. Formalin could denaturate protein enzymes, and causing enzyme structures changing. It inhibits enzyme activity and unable to catalyze metabolic processes in cells, causing microorganisms weaken and inhibit schizont process. Inhibition of schizont process results in decreased opportunities for reproduction and lesions will decrease. Formalin is able to react with *E. tenella* oocysts because its outer layer wall consists of protein and inner layer consists of fat, related to protein. Formalin could easily binds to protein, able to make organism cell dehydrated and resulting in structural rigidity.

Macroscopic observation of the cecum at P0 showed a moderate damage, characterized by more bleeding and lesions with a slight thickening of cecum wall. This was supported by clinical symptoms as chickens look limp, tangled chicken feathers, decreased appetite. P1 showed moderate level cecal lesions, characterized by more bleeding and lesions with a slight thickening of the cecum.
wall. P2 showed mild cecal lesions, some bleeding that spreads to mucosal surface of cecum with slight changes in wall color or digestive tract content. P3 showed mild cecal lesion, some bleeding that spreads to mucosal surface of cecum with slight changes in wall color or contents of digestive tract. P4 showed mild cecal lesions, some bleeding spreads to mucosal surface of cecum with slight changes in wall color or contents of digestive tract. 12. Conclusion of above discussion shows that optimal formalin concentration for attenuating *E. tenella* in terms of macroscopic aspect was 1.2%. It showed a mild degree damage to cecum mucosa. Inoculation at doses of 1000-3000 Oocysts of *E. tenella* could cause bleeding and other characteristics caused by infection 24. *E. tenella* infection causes lesions in cecum that cause bleeding and diarrhea 25. Inoculation at treatment with 1.2% formalin, there were several bleeding spreads to mucosal surface of cecum with slight discoloration wall or contents of the digestive tract 12.

Histopathological observations in microscope on the cecum, based on P0 image, there was a lot of damage to the cecum mucosa and development of parasites, cecal epithelium was not compact, and many ruptured cecum villi were found. P1 showed histopathological abnormalities with mucosal damage and discovery of clear parasites development in several parts. Cecal epithelium did not appear to be compact, and cecum villi that rupture was found in several parts. P2 values indicate histopathological abnormalities with mild degrees damage to mucosal cecum. Cecal epithelium appeared to be compact, rupture of cecum villi was rarely found and development of parasites also minimum. Value of the microscopic scoring on P3 showed almost no abnormalities in the histopathology of cecum. Cecal epithelium appeared to be compact and ruptured cecum villi was rarely found. P4 shows cecum cell tend to be normal, cecal epithelium appeared patchy and almost did not show any villi rupture 14. Other studies have obtained results on microscopic examination of chicken cecum infected with 5000 oocysts that shows cell necrosis, degeneration, thickening of the muscularis layer, inflammatory cell infiltration, presence of parasites surrounded by inflammatory cells and bleeding 26.

**Conclusion**

Based this result study, we can conclude that formalin can attenuate *E. tenella* in cecum of broiler chicken. There was a difference in the attenuation degree of *E. tenella* in each formalin concentration. The optimal formalin concentration for attenuate *E. tenella* in terms of macroscopic and microscopic features of broiler chickens was 1.2%.

**Ethical Clearance:** This study procedure used test animals were approved with the principles of ethical research based on research ethics committee rules. This study applied the basic principles of replacement, reduction and refinement.

Fasciolosis Prevalence on Several Cattle Breeds

Kurnia Winda Pratiwi¹, Setiawan Koesdarto¹, Nenny Harijani¹
¹Faculty of Veterinary Medicine, Universitas Airlangga, Jl Mulyorejo Kampus C Universitas Airlangga, Surabaya, Indonesia

ABSTRACT

Background: Parasitic fluke infection diseases which affect livestock remain issues for big economic loss in Indonesia and other parts of the world. Fasciola fluke infection is zoonotic. Hence it could infect animals and human. Furthermore, fluke infection is hazardous and could result in big economic loss for farmers.

Purpose: This study aimed at determining the fasciolosis prevalence in cattle at an abattoir.

Method: The study applied a quantitative method with non-experimental design without any preceding treatment. The independent variables included liver organs and cattle breeds, while the dependent variable was fasciolosis prevalence. Cow livers and feces samples each were 100 samples examined in this study through post-mortem and fecal examinations.

Result: From the examination, 17% of liver samples and 12% of feces samples were positively infected with *Fasciola sp*. In aggregate, the total prevalence of *Fasciola sp.* infected cattle amounted to 27%. Viewed from each cattle breeds, Simmental, Limousin, and Ongole cattle were positively infected with *Fasciola sp.* with a prevalence of 12%, 12%, and 3%, respectively.

Conclusion: In this study, the prevalence of *Fasciola sp.* fluke infection was low. There was no correlation between cattle breeds and *Fasciola sp.* prevalence.

Keywords: *Fasciola sp.*, cattle, prevalence, abattoir

Introduction

Cattle produce approximately 50% of the global needs of meat, 95% of milk and 85% of skin needs for industry ¹. Nonetheless, many diseases infect cattle, including fluke infection. Fluke infections on livestock, cause huge global economic loss indirectly. Many of them are zoonotic and have become major community diseases ²⁻⁴. *Fasciola sp.* or liver flukes are among the fluke parasites that infect cattle. It is a trematode from *Fasciola* genus. *F. hepatica* and *F. gigantica* are two species commonly reported to have the greatest impacts ⁵. *Fasciola hepatica* is an endemic parasite in Europe countries, Africa, Asia, the United States, and Oceania.

On the other hand, *Fasciola gigantica* is only found in Africa and Asia and is rarely found in the northern part of Europe. According to a study, *Fasciola hepatica* originated from Europe and used Galba tuncatula as its intermediate host ⁶. Several countries, namely North America, South Africa, Republic of Iran, and West Europe, are majorly affected ⁷. In several provinces in Indonesia, Fasciolosis prevalence by *Fasciola hepatica* reaches between 30-90% ⁸,⁹.

*Fasciola sp.* has a flat shape; similar to a leaf, with the anterior body wider than its posterior. Adult *Fasciola sp.* has a greyish brown color, measuring 30 mm long and 13 mm wide. *Fasciola sp.* infects ruminants as its definitive hosts that then survives and matures in the liver and gall bladder. Several ruminants, namely bulls, cattle, goats, and sheep, are commonly infected after swallowing *F. gigantica* metacercariae ⁸,¹⁰⁻¹².

The cattle livers infected with *Fasciola sp.* are damaged and partly or completely rejected with chronic disease and other comorbidities causing decreased
livestock meat, milk, and skin production. Infected cattle can exhibit decreased body weight and production. Furthermore, even though the cattle are free from the adult flukes, performance disturbance remains present prior to the slaughter process. Other symptoms caused by Fasciola sp. infection include poor nutrition, slow growth, as well as liver and bile inflammation. Moreover, the prolonged mild infection may cause cattle unable to reach optimal body weight, exhibit weak body condition, decrease food appetite, inflammations on a mandibular lymph node, hunger edema, and death. This study aimed at determining fasciolosis prevalence in cattle at the abattoir.

Method

This study applied a quantitative approach with non-experimental research design without any preceding treatment. The field survey was conducted using random sampling. The independent variables included liver organs and cattle breeds. The liver organ variable was defined by the measurement of infection severity and sickness duration of the cattle breeds. The infection indicators included any occurrence of inflammation, blockage of the bile ducts, and hardening tissues as the result of cirrhosis and atrophy. The cattle breeds included Simmental cattle, Limousin cattle, and Ongole cattle. Meanwhile, the dependent variable was fasciolosis prevalence. The data were analyzed with Chi-Square by using SPSS program for Windows (SPSS, Chicago, IL, USA).

Instruments: The instruments in this study included a camera, plastic pots, 10% formalin, scalpel, tweezers, gloves, filters, plastic cups, centrifuge tubes, centrifuge tubes rack, stirring rod, object glass, cover glass, label papers, pipets, optilab, and microscope. 3.6

Feces samples examination: The fecal samples were examined with native and sedimentation method to identify any existence of fluke eggs, along with its genus and species that infected the cattle. The sample was stated positively infected if there are any Fasciola sp. fluke eggs found.

Result

The post-mortem and fecal examination results of liver and feces samples from cattle breeds in the abattoir are presented in Table 1 as follows.

<table>

</tbody>
</table>

Result of post-mortem and fecal examinations in cattle breeds: The samples collected were cow livers and feces, each of the samples amounted to 100 items. The result indicated that there were 17% liver samples collected through post-mortem examination and 12% feces samples collected through fecal examination that were positively infected with Fasciola sp. In aggregate, the total percentage of infection amounted to 27%.

Differences of Prevalence Numbers between Cattle Breeds: The post-mortem and fecal examinations were conducted to identify the prevalence and susceptibility numbers of Fasciola sp. fluke infection among several cattle breeds. The indicator was if one of the examinations indicated the occurrence of fluke or Fasciola sp. eggs, the animal was assumed to be infected with Fasciola sp. flukes.

According to Table 1, twelve samples of Simmental cattle, 12 samples of Limousin cattle, and 3 samples of Ongole cattle were positively infected with Fasciola sp. Meanwhile, 22 samples of Simmental cattle, 43 samples of Limousin cattle, and 8 samples of Ongole cattle were negatively infected.

Discussion

Fasciolosis is a global health issue, causing a huge economic loss for farm animals. Despite the significant importance to economic conditions and veterinarian field, fasciolosis has spread globally and shown its emergency state as zoonotic parasites, which also infect humans. The result of this study indicated lower infection prevalence than previous studies.

Fasciolosis in ruminants refers to the agents’ life cycle which causes the infection. Adult Fasciola sp. flukes are capable of surviving in ruminants’ livers for 1-3 years. The eggs were then discharged from the ruminant body along with feces, and they are capable of surviving for about 2-3 months in a humid environment.

Several aspects that influence Fasciola sp. development include climate and temperature conditions.
Other conditions include land altitude, rainfall, food system management, and parasite distribution, as well as the intermediate host. Those aspects may have different roles in *Fasciola sp.* development. One of the most significant aspects in *fasciolosis* in certain areas is the suitable snail habitat. In addition, the cattle conditions of having poor nutrition are also susceptible to fluke infections.

The standard temperature that *Fasciola sp.* needs for its development in a snail body ranges from 10°C to 16°C. The optimum humidity for the development of snail and larva stage development inside the snail occurs when heavy rainfall takes place which increases the saturation and humidity. Furthermore, studies found that the highest *Fasciola sp.* prevalence occurs as the result of increased rainfall during winter and autumn, along with the higher infection prevalence in snails during the wet season than in other months.

Besides climate and temperature conditions, other contributing factors in *Fasciola sp.* infection include poor housing management, food and nutrition, grazing, sanitation, and farmers’ lack of knowledge about infection control. The increase of *Fasciola sp.* prevalence number is caused by the existence of swamps and well-irrigated grass which are suitable for the intermediate hosts’ reproduction. Since green grass is the habitat for flukes of metacercariae infective stage, farmers should not provide fresh grass to cattle. These external factors result in no difference in *Fasciola sp.* infection among cattle breeds.

In acute disease condition, the life cycle of flukes is not completed, and the eggs are not produced, resulting in the absence of *Fasciola sp.* eggs in the fecal examination. After 16 weeks, young flukes grow mature and live inside the bile ducts. Then, mature flukes produce *Fasciola sp.* eggs. This stage resulted in the absence of *Fasciola sp.* flukes in post-mortem examination because the fluke migration never reached the liver.

If observed through bare eyes, the appearance of the infected liver organ in cattle is visible on the organ enlargement as the result of inflammation in liver parenchyma and gall bladder fibrosis, which contained mature flukes. In acute condition, the liver organ is swollen or enlarged with the dull-formed liver edge, has pale-colored compared to the normal state with several bleeding marks spread at the organ surface with sizes variations from small to big.

There was no correlation between post-mortem and fecal examinations. *Fasciola sp.* flukes cannot be inspected through only one examination. Therefore, two examinations were conducted. Fecal examinations were conducted to detect the *fasciolosis* occurrence in cattle, to prevent further occurrences and avoid economic loss. This is the only examination that can detect safely without having to kill animals. Meanwhile, post-mortem examinations, in addition to detecting fasciolosis, also serves to prove the feasibility of food in terms of veterinary public health.

According to the descriptions above, fasciolosis is a widespread global occurrence and causes huge loss for farmers and consumers in the form of liver failure, low-quality meat, as well as growth and productivity rate decrease. It has been mentioned that the high prevalence number is associated with poor management practices and farmers’ lack of knowledge about infection control. This situation can be prevented by conducting control toward intermediate hosts, therapeutic strategies, and being supported by adequate grazing management to control fasciolosis.

**Conclusion**

The result of this study indicated that the *Fasciola sp.* prevalence in infected cattle breeds was lower compared to previous studies from other areas in Indonesia. There was no correlation between cattle breeds and *Fasciola sp.* infection prevalence. Nonetheless, the fluke infection can be prevented by proper grazing management, intermediate host controlling, and therapeutic strategies.

**Ethical Clearance:** The research process involves participants in the survey using a questionnaire that was accordant with the ethical research principle based on the regulation of research ethic committee. The present study was carried out in accordance with the research principles. This study implemented the basic principle ethics of respect, beneficence, non-maleficence, and justice.

**Conflict of Interest:** The authors report no conflict of interest in this work.

**Source of Funding:** This study is done with individual funding.

BPJS Kesehatan Patients Satisfaction on Pharmaceutical Services in Community Health Center (PUSKESMAS)—South Surabaya Area

Assyifa Ilmi Auliya\textsuperscript{1}, I Nyoman Wijaya\textsuperscript{1}, Catur Dian Setiawan\textsuperscript{1}, Gesnita Nugraheni\textsuperscript{1}

\textsuperscript{1}Pharmacy Department, Faculty of Pharmacy, Airlangga University, Indonesia, Jl. Airlangga No 4-6, Airlangga, Gubeng, Surabaya city, Jawa Timur

ABSTRACT

Background: The implementation of health care efforts in the Puskesmas, as primary health care facility, needs to be supported by proper pharmaceutical services through patient perceptions. The measurement of patient satisfaction is based on five dimensions of service quality, namely reliability, responsiveness, assurance, empathy and tangibles.

Objective: The purpose of this study was to determine satisfactory of the patient using Social Health Security Agency (BPJS Kesehatan) Health Insurance on pharmaceutical services in the Puskesmas

Method: This was a descriptive cross-sectional study which including 120 respondents who had pharmacy services at that time in the puskesmas. Questionnaire with a Likert scale were used in this study, which was previously tested for validity and reliability. Data analysis was done by comparing the patient’s perception of performance and expectations using the servqual and customer window methods.

Results: It shown that there were 18/25 items of negative statements which meant that the patients were not satisfied. The results using the customer window method shown an illustration in 4 quadrants. Quadrant A (indicators that are the top priority to be improved), quadrant B (indicators that need to be maintained), quadrant C (indicators that are in low priority) and quadrant D (indicators that are perceived as excessive by patients).

Conclusion: In general, patients were still not satisfied with the pharmacy services in the Puskesmas. This patient’s perception was influenced by the quality of services as well as the experience they have

Keywords: Satisfaction, expectation, service performance, servqual method, customer window

Introduction

The Social Health Security Agency (BPJS Kesehatan) is a legal entity established to administer national health insurance program in Indonesia\textsuperscript{1}. Health insurance is a health protection in which participants receive proper health care and protection in meeting basic health needs given to everyone who has paid contributions or fees paid by the government\textsuperscript{1}.

The World Health Organization (WHO) also explained that one of health problems are related to health services\textsuperscript{2}. Health services in this case the health center that should provide services include promotion, prevention, curing\textsuperscript{3} and rehabilitation services including medicines and consumable medical materials in accordance with the medical needs. The intended health services include all primary-level health facilities and advanced health facilities, other health facilities determined by the Minister in collaboration with BPJS Health including supporting health facilities consisting of laboratories, hospital pharmacy installations, pharmacies, blood

transfusion units/Red Cross Indonesia, optics, service provider for Consumable Ambulatory Peritonial Dialysis (CAPD) and midwife/nurse practice or equivalent.  

The implementation of health services which are a shared responsibility of the government and the community is mostly carried out in health centers. The responsibility of the government is to provide quality health services in accordance with health service quality standards. Patients/communities assess quality services as services that can meet the expectations and needs, they feel. The quality of health services related to patient satisfaction can affect the degree of health and community well-being, because patients who are satisfied will comply with the treatment and want to come back for treatment.

Satisfaction is the feeling of being happy or disappointed someone who appears after comparing between impressions of the performance or results of a product and its expectations. By knowing satisfaction with the services provided, it can be known the needs, desires, and expectations of patients so that service quality improvement can be carried out in accordance with patient expectations. To find out satisfaction with service quality can use the SERVQUAL (service quality) concept that measures patient expectations and is associated with what should be done to produce high-quality services. The indicators used to measure satisfaction in this study are tangible, reliability, responsiveness, assurance, and empathy. In organizing pharmacy staff pharmacy services use the Service Standards guidelines that cover standard management of drugs and medical consumables material and standard clinical pharmacy services. This study aimed to determine the patient satisfactions who were the user of the BPJS Kesehatan health insurance on pharmaceutical services in the puskesmas.

**Method**

This was a descriptive study, namely research that describes important events. The study was conducted using cross-sectional data retrieval with data sources form of primary data and secondary data. Measurements can be made on subjects that are observed only once but do not have to be at one time.

Data sampling in this study using non-random sampling or accidental sampling method. In accordance with the inclusion and exclusion criteria, the minimum number of respondent taken on each puskesmas was as many as 7 patients. The instrument used in this study is a questionnaire with a Likert scale that has been tested for validity and reliability. Likert scale was used in this study because there were a few aspects such as attitudes, opinions and perceptions of a person or group of people about social phenomena that about to be measured.

The data validity test was carried out in this study by using visual validity, content validity, and construct validity. The visual validity test was done by comparing between two types of instruments that have different paper sizes. In addition to validity testing, this study also carried out a reliability test. The reliability of the questionnaire in this study was tested by the Alpha Cronbach technique.

Data analysis is performed using a customer window derived from the concept of SERVQUAL (service quality) by measuring patient expectation (customer expectation) associated with the performance should be done to produce high-quality services. The SERVQUAL method is used to measure the quality of pharmaceutical services for each indicator, which is satisfied or dissatisfied. In analyzing customer window, the average value of total performance and expectations is used, which are described by two variables, namely X and Y.

**Results**

The results of this first study are in the form of demographic data. Demographic data in this study were not counted as patient satisfaction factors but were only used to find out visitors’ data on the health center at the time the study was conducted.

SERVQUAL Analysis: The calculation results with the SERVQUAL method, 18 items of statements obtained are negative which means the patient is not satisfied and 7 statement items are positive which means the patient is satisfied. The first dimension is tangibles, three statements of patients feel dissatisfied and three more statements are quite satisfied. For the statement ‘Comfort of the waiting room’ the score produced is negative (not satisfied). Then in the statement “There are posters/brochures/health magazines or the like for drug information or counseling efforts” the resulting score is also negative (not satisfied). But in the administration of drugs in good condition and packaging and clear use of letters, patients have been quite satisfied as evidenced by positive results.

Almost all statements in the reliability dimension did not meet the patient expectation. For statements “Pharmacy officers give information directly or in writing about the usage of drugs” the score produced is negative (not satisfied). The biggest dissatisfaction in this dimension is in the statement “Pharmacy officers give explanations if patients forget to take medicine”. Only one statement “The officer gives information directly or in writing about the rules for taking drugs and when taking medication” which is positive (satisfied).

The majority of the patients were not satisfied in the statements on assurance and responsiveness dimensions. The biggest dissatisfaction result lies in the statement “The pharmacy officers asks the patient to repeat the explanation” then the second in the statement “The clerk asks the patient’s medication history” and third in the statement “The pharmacy officers asks the patient’s allergy history” the score is below -0.50.

Performance–Expectation Quadrant (Customer Window): One way to observe the overall service quality is to use the Customer Window. To obtain each coordinate of each indicator is by multiplying the frequency of each score, then calculate the average score for each statement. X value is obtained from the average performance score and Y value obtained from the average score of expectation. Then, to obtain the intersection of X and Y, the average performance score is divided by the number of statements on the questionnaire for intersections on line X and the average expectations score divided by the number of item statements on the questionnaire for intersections on line Y.

The minimum respondent number for each puskesmas is seven patients. However, to avoid the lack of respondents, 8 patients in each health care will be given a questionnaire to get the results of 120 respondents in one area of South Surabaya. More than 50% of respondents were female. The age of the respondents in this study varied from 17 years to 69 years old.

</table>
The greatest value of dissatisfaction is in the drug use monitoring by the health workers indicators, for example via telephone or when the patient comes back (value -1.07) which means that the patient’s expectation on these indicators is very high but the performance of pharmacy service officers is very low. This shows that patients understand the importance medication use monitoring. On the other hand, patients with the smallest dissatisfaction value were found in the using easy-to-understand language indicators (value 0.42) which means that the service performance have met patient expectations. This shows that the patient is satisfied with the performance of pharmacy service officers on the indicator.

Discussion

One of the most important dimensions of quality and the main indicator of health care success is patient satisfaction\textsuperscript{14}. Patients will feel satisfied if the performance of health services have met or exceed their expectations, otherwise patient disappointment will arise if the performance of health services obtained is not in line with their expectations\textsuperscript{6}. Patient satisfaction is a valid indicator of the quality of services\textsuperscript{15}. Service quality and satisfaction are subjective for each patient.

Using the SERVQUAL method we can reveal the difference between patient preferences and experience\textsuperscript{14}. There are 7 positive statements and 18 negative statements. The first dimension is tangible evidence. This dimension is important to grow the image of service providers or in this case, The Puskesmas, for patients\textsuperscript{16}. One of the patient dissatisfaction is the uncomfortable waiting room at the puskesmas. This patient dissatisfaction also occurs because patients do not understand the purpose of giving such media/posters/brochures/magazines.

The second dimension is reliability. This dimension importance is that customer satisfaction will decrease if the service provided is not in accordance with what was promised (on time)\textsuperscript{16}. Based on observations in the field, there are officers who always provide information directly about the medicinal uses. Patient dissatisfaction can occur because the patient has repeatedly obtained the drug and feels that he already knows the information about the drug that been given so that when the officer provides information related to the drug, the patient does not pay too much attention. Officers also often do not explain this to patients because officers shorten the information given to patients at the time of delivering...
medicines so that all patients can be served. But this should be explained, for example, in patients who get antibiotics. This can increase the incidence of resistance due to the wrong method of using antibiotic drugs.

The third dimension is assurance. The importance of this dimension is due to the knowledge and behavior of service providers to build trust and confidence in consumers to use their services. Observations in the field, officers only call the names on the recipe but do not make sure who take the drugs. By identifying the owner properly, swapped drugs between patients who have the same name can be prevented. Patients have realized the importance of this, thus there must be an improvement in delivering prescribed drugs by pharmacy services in the puskesmas.

The fourth dimension is responsiveness. The importance of this dimension is to provide service quickly and responsively. Responsiveness can foster a positive perception of the services. This dimension emphasizes the attention and speed of the officers involved in responding to patients’ requests, questions and complaints. The time needed by the officer to do the service is not too long, but the patient’s dissatisfaction can be due to the psychological state of the patient who feels unwell and wants to return home quickly so that the service is felt relatively long. Another factor that can cause long service time is because the queue piles up at one period of time.

The fifth dimension is concern (empathy). The importance of this dimension is to give attention to customers by placing themselves in the customer’s situation. Overall for this dimension the patient feels dissatisfied. Most patients consider drug use monitoring via telephone is an important thing but it was never been done by pharmacy officers at the puskesmas. This proves that the patient knows that drug use needs to be monitored by pharmacy officers to see the progress of treatment, especially for chronic diseases.

Measurement of the gap between performance and expectations is needed to determine patient satisfaction for each item statement of pharmaceutical services. The purpose of knowing patient satisfaction on each statement is to know the lack of services available in the puskesmas so that it can be used as a recommendation to improve the performance of pharmacy services in the puskesmas.

Conclusion

In general, the patients were not satisfied with pharmacy services in the Puskesmas based on the SERVQUAL method. Patient satisfaction was carried out based on five dimensions of service quality, namely care (empathy), physical evidence (tangibles), responsiveness, assurance, and reliability. Several pharmacy-services indicators have not yet fulfilled patient expectation, therefore its improvement has to be prioritized. Other pharmacy-services indicators that have met patient expectation must be maintained so their satisfaction will generally improve.

Ethical Clearance: The research process involves participants in the survey using a questionnaire that was accordant with the ethical research principle based on the regulation of research ethic committee. The present study was carried out in accordance with the research principles. This study implemented the basic principle ethics of respect, beneficence, nonmaleficence, and justice.

Conflict of Interest: None declared

The Effect of Lower Extremity Massage with Lavender Essential Oil on Decreasing Blood Pressure in Elderly with Hypertension in UPTD Griya Werdha Surabaya

Fatih Haris Maulana1, Joni Haryanto1, Elida Ulfiana1
1Community and Mental Health Department, Faculty of Nursing, Airlangga University, Jl. Mulyorejo, Surabaya City, Jawa Timur

ABSTRACT

Introduction: Hypertension is one of the degenerative diseases that occur in almost all the elderly in the world. The high rate of hypertension may lead to mild or severe strokes even to death. The purpose of this study was to determine the effectiveness of lower extremity massage with lavender essential oil in the elderly with hypertension.

Method: This study used a pre-experimental design with one group research pre-test and post-test design. The sample in this study was 13 elderly who had hypertension who were selected according to the specified inclusion and exclusion criteria. Thirteen respondents in this study were in accordance with inclusion and exclusion criteria. The variables studied were administration of lower extremity massage with lavender essential oil on elderly blood pressure. Furthermore, the data obtained were analyzed by the Shapiro Wilk normality test.

Results: Elderly blood pressure were measured before lower extremity massage with lavender essential oil and reaches a value of 180/100 mmHg. After being given therapy, systolic pressure has a maximum value of 160 mmHg and for diastolic values has a maximum value of 90 mmHg. There was a significant effect of lower extremity massage with lavender essential oil on decreasing blood pressure in hypertensive elderly people (p≤0.05).

Conclusion: The lower extremity massage with lavender essential oil was effective in reducing blood pressure in elderly hypertension. This therapy can be used as one of the complementary treatments in the form of lower extremity massage with lavender essential oil.

Keywords: Hypertension in the elderly, massage, lavender essential oil

Introduction

Along with the progression of age, the physiological changes will occur in the elderly accompanied by various health problems that cause high degenerative diseases. One degenerative disease that causes high mortality rates is hypertension1,2.

Hypertension is a persistent blood pressure with systolic pressure above 140 mmHg and diastolic pressure above 90 mmHg. About 20% of the elderly population has hypertension. In 2008 there were about 40% of people over the age of 25 in the world suffering from hypertension and that number will continue to increase in Amerika terjadi lebih dari 65 juta orang usia dewasa keatas mengalami hipertensi dan berpotensi terjadinya infark miokard, stroke hingga gagal jantung. In Indonesia, this case increases continuously every year and becomes the main cause of outpatient clinics in the 45-64 age group and over 65 years of age. In East Java, the number of elderly people with hypertension in 2011 was 174,041 people. Preliminary study in Griya Werdha...
UPTD in Surabaya, East Java, Indonesia. Elderly people usually feel dizzy and after their blood pressure is checked or their blood pressure increases.

Hypertension that mostly found in the elderly is isolated systolic hypertension. The high rate of systolic pressure can cause the possibility of fatal or mild strokes\textsuperscript{10,11}. In addition to strokes, isolated systolic hypertension can also cause the arteries to become rigid, this is what will cause morbidity and mortality in the elderly\textsuperscript{12,13}.

Massaging with lavender essential oil therapy as one of the non-pharmacologic therapies that not giving side effects. A number of studies have shown that regular massage therapy can reduce systolic and diastolic blood pressure, reduce stress and cortisol levels, reduce anxiety so that blood pressure will decrease and body functions improve\textsuperscript{14}. Intervention using massage to the patients can overcome various symptoms of hypertension such as anxiety, depression, headache, neck pain, vertigo and provide calm and relaxed conditions\textsuperscript{15}. So that this study was conducted which aims to determine the effectiveness of the massage therapy with lavender essential oil in the lower extremities on elderly people with hypertension.

**Method**

This study was a pre-experimental study desing, consisting pre-test and post-test. This study was conducted to determine the effect of lower extremity massage with lavender essential oil on the reduction of blood pressure in elderly people with hypertension at Griya Werda UPT Social Services in Surabaya City. This study only used one group sample, without any control group. This study was conducted by giving the initial test (pre-test) and giving as many as seven treatments, then the final test (post-test) will be carried out\textsuperscript{16}.

**Population, Sample, Sampling:** The general population in this study were all elderly who had hypertension in the whole world. Then the target population of the study was all elderly in Griya Werda who had hypertension with a population that consisting 17 people\textsuperscript{16}. From the entire population, the participant will be selected according to the inclusion and exclusion criteria that had been determined, and as a result, 13 participants were obtained.

**Variables and Instruments:** The independent variable in this study was the treatment of lower extremity massage with lavender essential oil. The dependent variable was blood pressure in the elderly with hypertension after and before the massage. The research instrument used was the SOP (Standard Operating Procedure) that was determined and the observational sheet containing the respondent’s data as well as the results of blood pressure that had been measured with sphygmomanometer and stethoscope.

**The Process of Collecting Data and Statistical Analysis:** The ethical clearance of this study was with ethics certificate number 232/EC/KEPK/FKUA/2016 along with the location permits for the research from various related parties. The respondent was asked to lay in a comfortable position on the bed and given a lower extremity massage with lavender essential oil by a physiotherapist as an intervention provider. The author as observers of the interventions that were carried out 7 times a week, every day for each the respondent and duration of each intervention was 10 minutes. The data were analyzed using the Shapiro Wilk normality test.

**Results**

The number of respondents in this study was 13 people representing the total population of elderly who had hypertension. The characteristics of respondents were presented in full in the table below:

**Table 1: Characteristics of elderly participants with hypertension (n = 13)**

<td>11.26601</td>
<td>70 - 100</td>
<td>77.8074 - 91.4324</td>
</tr>
</tbody>
</table>

Blood pressure examination before being intervention was conducted. The respondents had a minimum value for a systolic pressure of 140 mmHg and for diastolic pressure had a minimum value of 70 mmHg. The results of the interval estimation of the study concluded that 95% were considered to be an average of diastolic blood pressure of the respondents 150.65 - 164.74 mmHg and diastolic pressure 77.8075 - 91.4234 mmHg.

2. The respondent’s blood pressure after the intervention was given

<table>
<thead>
<tr>

<td>80.00</td>
<td>11.26601</td>
<td>70 - 100</td>
<td>77.8074 – 91.4324</td>
</tr>
</tbody>
</table>

Based on table 3, it is known that after being given intervention, the respondent’s blood pressure, that is systolic pressure had a value of at least 110 mmHg and for diastolic pressure had a value of at least 60 mmHg. Systolic pressure after the intervention was given, it had a maximum value of 160 mmHg and for diastolic pressure, it had a maximum value of 90 mmHg. The results of the interval estimation study concluded that 95% considered that the average blood pressure in respondents for diastolic pressure was 123.72 - 142.43 mmHg and for diastolic pressure was 69.8456 - 82.462 mmHg.

3. Differences in blood pressure before and after the lower extremity massage with lavender essential oils were given

<table>
<thead>
<tr>
<th>Variable</th>
<th>Mean value before the intervention</th>
<th>Mean value after the intervention</th>
<th>Difference</th>
<th>P value</th>
</tr>
</thead>
<tbody>

</tr>
<tr>
<td>Diastolic</td>
<td>86.6154</td>
<td>76.1538</td>
<td>8.4616</td>
<td>0.01</td>
</tr>
</tbody>
</table>

Based on the Shapiro Wilk normality test, the significant value of systolic and diastolic blood pressure before and after treatment ≥ 0.05 so that it can be concluded that the data are normally distributed, then the data is analyzed using paired t-test with a confidence level of 95% (α = 0.05). From the results of analysis data
showed that there was an influence of lower extremity massage with lavender essential oil on decreasing blood pressure in elderly people with hypertension.

**Discussion**

The classification of blood pressure chosen is in the range of grade 1 with systolic blood pressure starting from 140 mmHg and up to 200 mmHg. Blood pressure in the respondent, the highest systolic pressure was 180 mmHg and the highest diastolic was 100 mmHg. The lowest systolic blood pressure is 140 mmHg and the lowest diastolic is 70 mmHg.

Prevalence of blood pressure increased by 24.6% in women over 30 years old and increased every year\(^{17}\) nonsynchronized design to investigate the effect on home blood pressure (BP). Women usually have higher blood pressure after menopause\(^{18}\). At the pre-menopause stage, women begin to lose estrogen gradually which has been protecting blood vessels from damage\(^{19,20}\). Menopause is one of the factors in cardiovascular disease, because of changes in the distribution of body fat from a gynoid to android patterns, reduced glucose tolerance, abnormal plasma lipids, increased blood pressure, increased sympathetic tone, endothelial dysfunction and vascular inflammation\(^{20}\). These factors make older women have a greater risk of hypertension.

The anti-hypertensive therapy given to respondents in this study was the Calcium Channel Blocker (amlodipine) group. In this study, the majority of respondents consumed one type of antihypertensive drug, namely the Calcium Channel Blocker. Amlodipine works to inhibit the entry of calcium ions through slow canals in the secular muscle tissue and causes relaxation of deep arterioles. Calcium channel blockers work on all degrees of hypertension\(^{21,22}\).

The elderly's blood pressure after the intervention was given: The frequency distribution of respondents showed that the lowest systolic pressure was 110 mmHg and diastolic pressure with a minimum value of 60 mmHg. The systolic pressure has a maximum value of 160 mmHg and the diastolic pressure has a maximum value of 100 mmHg.

This study showed that the respondents experienced a decrease in systolic blood pressure and a decrease in diastolic blood pressure. This study is in line with the previous one that the aroma massage combination of lavender, marjoram, ylang-ylang and neroli and mixed with almond oil and jojoba oil can reduce blood pressure in women aged 49 to 50 years\(^{17}\) nonsynchronized design to investigate the effect on home blood pressure (BP).

Massage is one of the healing arts in China that can suppress symptoms of hypertension, depression, headaches, and vertigo. This therapy is very effective as a non-pharmacological treatment for essential hypertension (EH)\(^{15}\). Pain is also quite effective to overcome with massage therapy.

The use of massage therapy has been used for a long time to provide comfort in all conditions\(^{14}\). High blood pressure due to anxiety and stress, depression and catecholamines\(^{23}\). Massage therapy works effectively by overcoming anxiety so that blood pressure decreases, besides that massage therapy can also overcome depression during childbirth, pain due to multiple sclerosis, arthritis, fibromyalgia, asthma, some immune disorders such as breast cancer, and aging problems such as Parkinson’s and demential\(^{14,24}\).

Some studies also proved that essential oils as effective therapies reduce cortisol concentration and control blood pressure\(^{25,26}\). So that clients who get lavender aromas feel comfortable so that the blood flow in the heart becomes smooth and hypertension decreases\(^{25}\). Non-pharmacological therapy in the lower extremities massage with lavender oil can be used as an option in hypertensive patients.

**Conclusion**

The lower extremity massage with lavender essential oil gave an effect on decreasing blood pressure in elderly hypertension. This massage therapy can be used as one of the complementary treatments with lavender essential oil. So that given this therapy the elderly not only reduce blood pressure but also get comfort and relaxation.

**Ethical Clearance:** The research process involves participants in the survey using a questionnaire that was accordant with the ethical research principle based on the regulation of research ethic committee. The present study was carried out in accordance with the research principles. This study implemented the basic principle ethics of respect, beneficence, nonmaleficence, and justice.

ABSTRACT

Introduction: Fine motor and cognitive delays are the things that occur in children with autism. The fine motor activity becomes a component which supports emotional, social and cognitive development. Good motor skill development will optimally trigger the maturity of cognitive ability.

Aims: This study analyzes the effect of finger painting on fine motor skill and cognitive changes in children with autism.

Method: This study applies a pre-experimental one-group design. There are six children with autism without comorbidities selected as respondents by using purposive sampling technique. The sample must be able to receive orders while still getting ABA and BIT therapies. The independent variable of the study was finger painting activity while the dependent variable is a fine motor and cognitive status in children with autism. The observation format from Dr. Rudy Sutadi, SpA, MARS was applied for motor and cognitive skill assessment. The research media used was paper and paint which were safe for children and the Wilcoxon sign rank test was used as the result analysis of the study with a significance level p 0.05.

Result: The results of the study indicated that improvement in cognitive skill (p=0.023) and fine motor skill (p=0.024) in children with autism after treated with finger painting intervention.

Conclusion: Finger painting is potential to be an alternative to develop cognitive and fine motor skills in children with autism. It stimulates motoric and cognitive aspects in the process of recalling the color mix which relates to fingers’ fine muscles.

Keywords: finger painting, autism, cognitive, fine motor.

Introduction

Autistic disorder is often interpreted as a developmental disorder such as social communication, as well as limited interest and repetitive behaviour versus behaviors that are on the borderline of being atypical or rarely occur in only one context. For example, while toe walking may be an example of criterion B, it may not be sufficient by itself to assign the criterion if there is a physical explanation for the behavior (and thus not clearly atypical. Fine motor and cognitive delays are common in children with autism. On the other side, good motor skill is considered necessary in physical, social, and psychologic development in children. Physical activity has a positive impact on the process of cognitive and motor development in children.

Fine motor skill and cognitive developments are the results of the nervous system and brain development relation, also adapting experience of the environment. Less optimal function of brain nerve is a factor that affects fine motor and cognitive perspective as well as physical damage detected. One indicator that children can move their smooth muscle and have the ability in developing their logic is using finger painting.

Finger painting is a direct painting technique using fingers and palms. This activity is expected to develop...
children with autism skill to recognize color, classify, follow the direction, also draw a pattern using fingers. Finger painting assessment is not about the creative aspect but the ability to coordinate their finger movement and motor muscle.

Early intervention with appropriate management is required to get the optimal development of children with autism. The application of finger painting training is all about drawing. It is also a global motor movement where it involves the entire body movement and exercises cognitive function. Finger painting is considered as a method to increase focus and attention in children. Finger painting is also capable of improving the skill of social interaction process in children with autism. The previous study indicates that finger painting has a good impact on fine motor development of pre-school children. Therefore, this study aimed to determine the impact of finger painting intervention on fine motor and cognitive changes in children with autism.

**Method**

**Research Sampling:** This study applied a pre-experimental design (one-group pre-post test design) by adjusting Constructivism theory held in Yayasan Anak Autis in Surabaya, Indonesia on May 12 to June 25, 2015, with a population of 18 people. The samples were selected using a purposive sampling method. This technique determines the sample among the age population by specific criteria. Children with autism who had mental retardation, ADHD (Attention Deficit Hyperactivity Disorder) and other comorbidity were discarded from the sample selection. Children with autism involved must be capable of receiving the order and sufficiently independent while still given ABA (Applied Behaviour Analysis) dan BIT (Biomedical Intervention Therapy) therapies for a year or more. The result of the sampling found six children who fit in the criteria as research respondents.

**Research Variables:** Meanwhile, the dependent variables were fine motor and cognitive skills. The assessment of the dependent variables was measured using Dr. Rudy Sutadi, SpA, MARS’s observation format. The observation format was adjusted to finger painting intervention. Children cognitive skills were assessed in their ability to recognize primary and secondary colors, designate the colors they want to use, distinguish simple patterns, and recall the techniques taught in the intervention. In addition, fine motor assessment consisted of the ability to mix and stir paint mixture, imitate patterns, apply creations on paper, and capable of mimicking 1-10 finger painting techniques.

**Data Collection Mechanism:** After filling out the informed consent sheet, the respondents worked on the pre-test before treated with the intervention. The study was conducted nine times within two meetings in one week. Each respondent was observed for ± 10 minutes in one meeting. The first lesson was to introduce primary colors and to teach the basic techniques of 1 spiral finger and point as well as one straight finger technic. Next, the respondents were asked to dip their fingers into the paint that had been provided to color the paper.

At the second meeting, the respondents were taught the basic techniques of 1 finger swivel, two-finger swivel, and three-finger swivel. On the third meeting, the respondents were taught one-finger diagonal painting, two-finger diagonal painting, the one-finger curve at the fourth meeting.

The respondents began to mix, stir, and recognize primary colors into secondary colors (orange, green, purple) in the fifth meeting. They were guided to imitate patterns previously made by the researchers at the fifth and sixth meeting.

The respondents were guided to apply their creativity to the drawing paper provided at the seventh meeting. The paper was not required to be full of color. Furthermore, at the eighth and ninth meeting, they were capable of freely coloring the paper using three primary colors and it must be colorful by applying three basic techniques which had been taught. The post-tests were performed after the intervention was given in full.

**Data Analysis:** Fine motor and cognitive skills assessments in the respondents were categorized as A (achieved) if they could do the given instructions; P (prompt) if they performed the instructions with assistance; and C if they were unable to do instructions. The research analysis applied for SPSS Windows program with Wilcoxon sign rank test with the significance or p level of lower or same as 0.05. This study had passed the ethical test at the Faculty of Nursing Universitas Airlangga number 273-KEPK.
Result

Respondents' Demography: All respondents had taken ABA therapy (Applied Behavior Analysis) for more than a year. More than half of the respondents (66.67%) were diagnosed with early autism at the age of 2-3 years, and others (33.33%) were diagnosed at the age of more than three years. Most of the respondents (66.67%) were born when the gestational age was mature (see Table I).

The Effect of Finger Painting on Fine Motor and Cognitive Skills: The observation results indicated a cognitive skill increase in children with autism by giving finger painting stimulation. Before the intervention, there were no children with decent cognitive skills. Respondents with less cognitive skills category, amounting to 66.67%, and the rests were included to adequate category by 33.33%. The finger painting intervention was capable of increasing the cognitive status of the respondents into a good category (100%) (see Table III). The statistical test found a significant cognitive difference (p = 0.023) in children with autism after being treated with the intervention.

The improvement also occurred in fine motor skills since there were no children with good motor status found at the beginning of the study. Fifty percent of children were categorized into less category, and the other half were categorized into the adequate category. After the finger painting intervention was given, all respondents were categorized into the good category (100%) (see Table III). The statistical test utilizing the Wilcoxon Signed Rank Test indicated p-value of 0.024, meaning that the finger painting intervention caused significant differences in the fine motor skills of the respondents.

Discussion

Stimulation is an essential part of consistently honing children’s skills to produce a memory enhancement\textsuperscript{17}. This study found the effect of finger painting intervention on fine motor and cognitive skill improvement in children with autism. Learning finger painting can also develop emotional expressions of the children\textsuperscript{18}.

The result of cognitive observations of children with autism after nine times of finger painting intervention indicated an increase with the final result of $\geq 80\%$. The respondents were introduced to primary colors (red, yellow and blue). Next, the respondents mixed the primary colors to produce secondary colors. The respondents learned to recognize the colors in this activity\textsuperscript{18}. Most respondents experienced a significant increase ($p = 0.023$) based on the post-test results where they were included in the good cognitive skills category (66.67\%). As previously mentioned all of the respondents (100\%) were categorized in the less cognitive skill category. However, the respondents still required help in recalling the nine finger painting techniques.

One of the improving parameters was knowledge about color mixing. In the first lesson, respondents were still confused when they were asked about color mixing. The respondents began to be capable of mentioning new colors produced after continuous and repeated interventions. This situation can develop cognitive skills and pave the way for the respondents to utilize all their potentials. Such a cognitive development means that the children can hone the skills on perception, attention, memory, thinking, concentration, focus on understanding symbols, problem-solving, and reasoning\textsuperscript{19}.

Through finger painting, children can freely move/rotate their fingertips to make a variety of images according to their imagination. This intervention triggered the respondents to have the courage to develop imagination both from the situations they can reach or those they cannot\textsuperscript{20}. The respondents’ cognitive improvement was significantly supported by ABA therapy lasting for more than a year because it was proven to cause persistent cognitive improvement\textsuperscript{21}.

The environmental factors indeed play a significant role in children’s growth and development as the level of intelligence is determined by the experience and knowledge gained from the environment\textsuperscript{22}. These factors can be affected by parents, peer groups, and social influences. Parents’ educational backgrounds are often also associated with development problems. Education and socio-economic levels of parents are highly influential in providing stimulation for children. The lack of knowledge in delivering positive stimuli can be one of the causes of problems or obstacles in children development since stimulation is necessary to improve the cognitive skills of children with autism. Besides, the role of parents is vital to guide children in practicing cognitive skills in various kinds of stimulation such as visual, verbal, tactile (drawing), and so forth, which will help the children develop. However, the parameter of the environment effect on children growth and development depends on the children’s situation themselves as well as their physical and spiritual conditions.

The pre-test results indicated that all respondents’ fine motor skills (100\%) were in the less developed category where the children had not been able to color paper independently. Fine motor improvement occurred after the finger painting intervention was conducted where 50\% of the respondents developed into the good category and the other half improved to the moderate category. One of the indicators were that the children could rub their hands independently. Motor skills do not develop because of the maturity of the organ but because of the need for the learning process\textsuperscript{23}. Gross and fine motor movements are closely related to the development of motoric center in the brain. Through proper training, gross and smooth movements can be improved in terms of flexibility and precision; thus, a child will become gradually more skilled\textsuperscript{6}.

The Wilcoxon Signed Rank Test results indicated that $p=0.024$ which proved that there were effects of finger painting intervention on the fine motor development in the respondents. The muscles of the hands, fingers, and eyes of the respondents became trained. There was coordination of fine motor muscles when doing finger painting and increasing courage of the children to find new things, especially new drawing media\textsuperscript{20}. When children are free to express themselves, it does not necessarily mean they do not know the rules. Every child is expected to be able to use paper optimally so that they can practice eye and hand functions to paint something proportional.

Through learning finger painting, children can freely move or rotate their fingertips to make variations according to their wishes. Therefore, children can increase
the strength of their fingers. The next phase was how the children mix the colors by using hands to stir the paint. The activity trains physical or touching senses, logical thinking, as well as a broader focus and attention\textsuperscript{13}.

This study has limitations. The number of samples was too little because of the limited number of children with autism included in criteria. Also, the lack of active interaction with the respondents’ parents caused less maximized information collection of information related to the respondents.

**Conclusion**

Finger painting interventions can improve fine motor and cognitive status in children with autism. This is because finger painting learning is one of the cognitive development stimulations to train memory from mixing primary colors and the basic techniques. In addition, fine motor development is triggered by the involvement of the muscles of the hands, fingers, and eyes in the process of finger painting.

**Acknowledgment**

High gratitude to Dr. Rudy Sutadi, SpA, MARS who given permission to the authors to use the observation format. The authors would also thank the head of Yayasan Anak Autis in Surabaya and all of the respondent of this study.

The Effectiveness of Afternoon Sunbath in Improving Elderly Sleep Quality

Zaenal Abidin¹, Harmayetty¹, Deni Yasmara¹

¹Faculty of Nursery, Universitas Airlangga, 60115, Surabaya, Jawa Timur

ABSTRACT

Background: A decrease in sleep quality has been an issue lately which occurs in geriatric patient, including early elderly group. One way to improve sleep quality in elderly is by afternoon sunbath.

Purpose: To explain the effectiveness of afternoon sunbath in improving sleep quality in elderly.

Method: This was a quasi experimental study with pre and post intervention. The respondents were divided into two groups (control & intervention). Data was collected using the PSQI (Pittsburgh Sleep Quality Index) questionnaire and analyzed using the Wilcoxon Sign Rank Test and Mann Whitney test with a significant level of α ≤ 0.05.

Results: The results showed that afternoon sunbath significantly improve sleep quality in elderly where p value = 0.000

Conclusion: The afternoon sunbath treatment increases serotonin and endorphin hormones, which improved the sleep quality in the elderly.

Keywords: Elderly sleep disorders, afternoon sunbath, Pittsburgh Sleep Quality Index

Introduction

Aging is a physiological process that starts from birth. The physiological process cannot be separated from health, social, cultural and economic dimensions. The proportion of people over the age of 60 has drastically risen lately, compared to other groups of age, as a result of longer life expectancies and decreased fertility rates. The impact of the aging process includes a decrease in organ system functions and physical changes. These changes result in variety of problems, including disruption of sleep quality. Elderly only use 58% of their time to sleep from the total time spent in bed, with an average sleep duration around 4-5 hours at night while the sleep needs for elderly is 5-6 hours per day. It will affect their concentration and memory, higher risk of falling, drowsiness during the day, feeling powerless, and mood changes. As many as 54% of elderly who experience sleep disorders consumed sleeping pills in order to overcome their sleep problems.

Risksdas 2013 (Indonesian Basic Health Research 2013) reported that 57% or 13.7 million elderly was experiencing some type of sleep disorders, including difficulty in starting or maintaining sleep (43%), waking up at night (30%), insomnia (29%), napping (25%), difficulty sleeping (19%), waking up too early (19%), and not feeling refreshed after waking up (13%) with an average sleep duration between 4-5 hours per day. This is in line with an epidemiological survey conducted in Japan, reported the insomnia prevalence in elderly was 21.4%. Insomnia was defined as experiencing at least one episode of difficulty in starting sleep (8.3%), difficulty in maintaining sleep (15.0%), or getting up too early (8.0%). Sleep disorders were experienced by 50% of elderly who lived at home and 65% of elderly who were staying in long-term care facilities. This condition has an impact on decreased concentration, physical weakness, lack of enthusiasm, and drowsiness during the day.

Changes in sleep patterns occured in the elderly due to changes in circadian rhythms, where the biological
clock becomes shorter and the sleep phase becomes earlier. Circadian rhythm changes are related to the degeneration of supra chiasmatic nucleus (SCN) cells in the hypothalamus(5). Degenerative changes occur in both central and peripheral nervous system, slowing down nerve transmission and decreasing the rate of cortisol and melatonin secretion by 25% which results in disturbance in stages III and IV of sleep (NREM) which causes frequent wakefulness and reduced REM sleep(8).

Improving sleep quality can be done by doing exercise or gymnastics, relaxation techniques, stimulus control, sleep hygiene, light therapy, dietary supplements, massage therapy and aromatherapy use(5). Research in Russian Vladyslav showed bright light therapy can improve sleep quality in people with depression(9).

The intensity of sunlight received by the retina depends on the presence or absence of barriers or obstacles from both physical and environmental aspects. Sunlight exposure at around 3.30 pm to 4 pm has 2500 lux intensity which can be used as a therapy to improve sleep quality. In addition, the sun has UV rays which can stimulate the formation of endorphins. Endorphin triggers calmness and relaxation so that easy to induce sleep and make sleep more comfortable(10). Therefore, this study aimed to see the effectiveness of afternoon sun in improving sleep quality in elderly, especially those who lived in Indonesia since this is a tropical country that receives sunlight most of the year.

**Method**

This study used a quasi-experimental research design (Quasy-experiment). The population of this study was the elderly who lived in Griya Santo Yosef Surabaya, consisting of 120 men and women, but only 33 elderly met the criteria for this study. The independent variable in this study was an evening sunbath and the dependent variable was sleep quality in elderly. This research was conducted from January 13th to 27th 2016.

**Research Instrument:** The research instrument used were a PSQI (Pittsburgh Sleep Quality Index) and SPMSQ (Short Portable Mental Status Questionnaire) sheets to measure the independent and dependent variable which includes seven components, namely subjective sleep quality, sleep latency (difficulty starting to sleep), nighttime sleep, sleep efficiency, sleep deprivation, using drugs to sleep, and disruption of activity during the day.

**Data Collections:** Elderly who were prospective respondents and willing to be respondents are divided into two groups. The intervention group was treated with an afternoon sunbath for 20 minutes starting from 3.30-3.50 pm on the next day after measuring respondent sleep quality. Sunbathing was conducted once every 2 days in 14 days. There were no intervention given to the control group. After 14 days, the sleep quality was remeasured using PSQI with the help of 10 sitters who accompanied the both groups.

**Data Analysis:** The SPMSQ was used to assess the cognitive aspects of respondents, consist of 10 true or false questions. 0-2 (intact intellectual function), 3-4 errors (intellectual functions with minor damage), 5-7 errors (intellectual functions moderate damage), and 8 or more errors (severe intellectual function).

The PSQI questionnaire sheet with seven parameters measured the sleep quality. The data scale used was ordinal. If the number of scores 0 means the fulfillment of his sleep needs is very good, 1-7 is good, 8-14 is lacking, 15-21 is very lacking.

Pre and post intervention in both groups were analyzed using Wilcoxon signed rank test to find out the difference of sleep quality between the control and the intervention group that had given a evening sunbath therapy. The degree of significance used in this study was $\alpha \leq 0.05$.

**Results**

The characteristics of respondents including gender, age group based on the Ministry of Health classification, length of stay in the nursing home, habits before going to bed, length of nap, and daytime activities. Most of the respondents are female (54.5%), dominated by those in 66-70 group of age (39.4%), with the most frequent length of stay in the nursing home around 7-13 months (51.5%). The activities done before going to bed and during the daytime were mostly watching TV (57.6% and 42.4%, respectively). All of the respondents had length of napping time 60-90 minutes per day.

Table 1 showed the distribution of respondents in pre and post interventions in each groups. The length of night time sleep duration were increased in the intervention group and there were 2 respondents on each group who experienced sleep more than 6 hours. The frequency of waking up at night in the both groups did not change. In the intervention group there were still 2 respondents who were not feeling refreshed after waking up while there were 15 respondents the control group who still had the same experience.

There is the change in sleep quality score. After the intervention, most of respondents’ sleep quality scores were 4, which had sleep quality score improvement compared to their pre intervention score. Meanwhile, there were statistically constant sleep quality score in the control group, based on pre and post intervention questionnaire. In the intervention group, the sleep quality of most respondents had been improved and categorized into good sleep quality criteria. In the control group, there were 2 respondents experienced a decrease in PSQI scores and 2 respondents experienced an increase in PSQI scores.

Based on Table 2, 17 respondents in intervention group showed drastic changes in sleep quality from poor to good quality of sleep. Statistical analysis using the Wilcoxon Sign Rank Test found an increase in sleep quality in the intervention group after sunbathing with p value = 0.000, which means afternoon sunbath effectively improve the sleep quality in elderly.

Mann Whitney statistical test showed p=0.000, which means that there are very significant differences between the intervention group and the control group. It can be concluded that afternoon sunbath is effective in improving sleep quality in elderly.
Discussion

This study showed that afternoon sunbath can improved sleep quality in the elderly. In addition to light, the afternoon sunray also produced UV rays that able to stimulate endorphins and serotonin formation, which take part in sleep quality improvement.

The sleep quality before giving afternoon sunbath treatment

All respondents were experiencing sleep disorders with a poor to very poor sleep quality. Most respondents described the disorders as lack of sleep quality, difficulty in starting and maintaining sleep, recurrent urge in urinating during the night, daytime drowsiness, and not feel refreshed after waking up.

Decreased capacity of the bladder (urinary vesica) and weakened bladder muscles causes many elderly experiencing recurrent wake up at night due to the frequent urgency to urinate(11). 29 out of 33 respondents were having poor sleep quality in the beginning of the study, where 17 of them were female. During the day, almost all elderly in this study spent more time indoor, and were taking a nap with 30-90 minutes duration. A person’s daily routine affects sleep patterns(11).

According to data, 17 respondents who had lived for 7-13 months stated that their sleep quality was poor, while respondents who had lived for more than 13 months had better sleep quality. The risk of sleep disorders often increased in patient during the first night of treatment, in both hospital and long-term care places such as nursing homes(11). The difficulty of sleep in elderly is closely related to the ability to adapt to their new environment.

The sleep quality after being given afternoon sunbath treatment

The elderly sleep quality were positive after being treated with afternoon sunbath for 14 days. In the beginning, the respondents in intervention group were having poor and a very poor sleep quality. By the end of the study, all respondents in the intervention group experienced a good sleep quality after being treated with afternoon sunbath.

The improvement in sleep quality happened in both qualitative and quantitative ways, showed by longer duration of sleep, less difficulty in starting sleep and not waking up too early. Most of them able to maintain their sleep until 5 a.m. and the habit of going to the toilet during night time were reduced. In addition, 5 out of 17 respondents in the intervention group were able to maintain sleep duration for more than 6 hours.

There are many factors that influence sleep quality. For example, respondents 31 and 41 stated that they were not feel refreshed when they woke up even after the intervention. They stated that the nursing home environment were not as comfortable as their previous home. This condition frustrate them and resulting in not feeling refreshed after they woke up in the morning. However, their sleep quality were improved from poor to good sleep quality, based on PSQI score before and after intervention. The situation above oftenly occured during the adaptation stage of environmental changes. Another factor influencing sleep quality was the daily schedule of each individuals. For example, the earlier bath turn they got, the earlier they had to wake up, even though they stay up late the night before.

The PSQI questionnaire components that did not change too much before and after the afternoon sunbath intervention were components 6 and 7, namely the use of drugs and the disruption of daytime activities.

Comparative analysis in sleep quality before and after giving afternoon sunbath treatment

After the afternoon sunbath treatment respondents felt the positive effects of intervention gradually in term of sleep patterns and quality. The difficulty to start sleeping more than 30 minutes decreased to be faster or can immediately start sleeping after being treated, with the length of sleep increased to 5 to 6 hours and even can reach 7 hours, sleep efficiency got better, night sleep disturbances subsided, no medicines used to treat their sleep problems and being able to do daytime activities better.

The main concept was that sunlight is naturally easy to obtain. Light stimulation has an effect in increasing serotonin and endorphins production(12). Light that comes naturally from the sun will be received by the skin and retina. Light stimulation that enter through the retina can produce serotonin, GABA, and norepinephrine(13). The high amount of serotonin during the day will be converted into melatonin at night to induce sleep. Exposure of the afternoon sun played role in intrinsic photosensitive retinal ganglion cells (ipRGC) which are carried forward to a system of SCN oscillation.
in the hypothalamus through a special nerve, the Retinohypothalamic Tract (RHT). The smooth delivery through RHT will release a neurotransmitter in the form of glutamate and Pituitary Adenylate Cyclase Activating Polypeptide (PACAP). The release of glutamate and PACAP stimulates the receptors and is expressed in SCN which then releases humoral factors that cause cell modulation in the pineal gland. The combination of inhibitors and stimulators in the SCN will produce output in the form of multisynaptic control in serotonin synthesis. When darkness comes, the pineal begins to convert serotonin to melatonin\(^\text{(14)}\). Theoretically, this hormone play an important role in the body including acting as a regulator of the metabolic processes occur in the body, suppressing brain wave activity and preparing for sleep, reducing the possibility of blood clots forming which in turn protects us from strokes and heart attacks, as antibodies and antioxidants\(^\text{(15)}\).

UVC lights that reach the stratum corneum will increase the synthesis of POMC propeptide which then processed to produce beta-endorphins and other biologically active peptides. The increase in continuous beta-endorphin in plasma is able to increase signals on opioid receptors on the periphery and or the central nervous system to produce endogenous dependent opioids. Opioid receptor signals can alter midbrain nerve activity to produce high dopamine. Increased beta-endorphins can provide a sense of calm and relaxation, making it easier for someone to fall asleep\(^\text{(16)}\).

**Conclusion**

In conclusion, there is a significant effect on afternoon sunbath in improving elderly sleep quality. This can be used as a modification in nursing intervention to treat sleep disorders in elderly. Afternoon sunbath stimulates the formation of serotonin and endorphins which triggered calmness and relaxation, thus improving sleep quality (sleep latency).

**Ethical Clearance:** The current study was carried out in correspondence with the research principles. It is implemented the basic principle ethics of respect, beneficence, non-maleficence, and justice. The research process entangles participants in the survey using a compatible questionnaire that was in accordance with the ethical research principle based on the research ethics committee’s regulation.

**Conflict of Interest:** The author reports no conflict of interest of this work.

**Source of Funding:** This study is completed with individual funding.

Family Burden and Coping in Family Caregivers of Patients with Schizophrenia

Winda Kusumawardani1, Ah.Yusuf1, Lailatun Ni’mah1
1Faculty of Nursing, Universitas Airlangga, 60115, Surabaya, Jawa Timur

ABSTRACT

Background: Schizophrenia is a mental disorder that is still being a stigma and causes a conflict in the family due to maladaptive behavior. Coping strategies are needed by the family members to dealing burden, so that they can care patients well.

Purpose: This study aimed to determine the relationship between family burden and coping with the family ability of caring for patients with schizophrenia.

Method: This study used a cross sectional approach. The population was a family of patients with schizophrenic in the Wijaya Kusuma room at Menur mental hospital. The number of samples was 21 respondents. The independent variable was family burden and coping. The dependent variable was the family ability of caring. Data were collected by questionnaires of demographic, family ability, family burden, and family coping. Data analysis used Spearman Rho correlation test with a significance level of α = 0.05.

Results: The statistical results showed that family burden has a correlation with family ability (r = 0.656), while family coping has a very strong correlation with family ability (r = 0.868) with family integrity better than psychological status and communication.

Conclusion: Family with a low burden did not necessarily have a good ability in caring for patient, but family with good coping will be able to provide good care for patient. Therefore, nurses are expected to develop methods to improve family coping in family caregivers of patient with schizophrenia.

Keywords: Schizophrenia, family burden, family coping, family ability of caring

Introduction

Schizophrenia is a mental disorder that have stigma in society. The stigma in society is that schizophrenia is about craziness or mental illness that needs to be shunned so that causes fear, misunderstanding, and punishment. Schizophrenia is included in the severe schizophrenia group. In the world, schizophrenia affects 21 million people and 1 of 2 people with schizophrenia do not get a treatment (1).

The arised problems in patients are lossing of ability to be independent and a negative symptoms which will affect work and family financial conditions (3). This can be a family burden that can be grouped into objective and subjective burdens. Objective burdens are limited social relations and work activities, financial difficulties, disrupting the physical health of family members. While the subjective burdens are feeling of loss, sadness, anxiety, shame, stress, family can blame each other and hostility between family members. The burden causes high level of stress in families (4–7).

Effective coping is needed by families with schizophrenia. The inability of families to create effective coping exacerbates the needs of schizophrenic patients at home. Treatment failure that causes recurrence in patients who have just returned from a mental hospital but various studies cannot explain the relationship between family and family difficulties in treating patients with schizophrenia(7,8).

DOI Number: 10.5958/0976-5506.2019.02662.7
Schizophrenia which is not handled well will worsen the patient’s condition, cause an impact in the community and family, and can be a family burden so that family coping become ineffective. This burden will be increased when there is no internal support from family members. This burden easily triggers high emotional expression in caregivers (9).

In this case, the family has an important role in treating patients with schizophrenic. Therefore, the family needs to have effective coping abilities as a right way to overcome the perceived burden. Effective coping ability can be achieved if the family has a sufficient knowledge and information in accordance with Ajzen’s theory. (10,11). This study aimed to determine the relationship between family burden and coping with the family ability of caring for patients with schizophrenia

Method

This research was a descriptive correlation study with a cross sectional approach. This descriptive study aimed to make a general description of a situation objectively. While the cross sectional approach is one type of study that emphasizes the observation time of independent and dependent variable data simultaneously (12). This research was conducted at Menur Mental Hospital Surabaya.

Sample: Determining representativeness is based on the inclusion criteria. The inclusion criteria is a family who takes care of patients with a diagnosis of mental disorders of at least 1 year. Selecting diagnosis criteria was based on PPDGJIII include groups F20-F29 (Schizophrenia, Schizotipal, and wedge disorders).

Sampling: The sampling technique in this study was the nonprobability sampling type of consecutive sampling. The chosen study object is the family of patients with schizophrenic who met the inclusion criteria.

Variable: The independent variable in this study was the family burden and coping in treating patients with schizophrenia mental disorders, while the dependent variable in this study was the family’s ability of caring patients with schizophrenic mental disorders.

Research Instrument: Data was obtained by a demographic questionnaire consists of demographics of patients and families. Second questionnaire was the family ability questionnaire consisting of five aspects and was presented in a closed form. Third questionnaire was family burden questionnaire. Finally, the family coping questionnaire was measured using a modification of the 2001 McCubbin coping questionnaire which developed a self-evaluation instrument in the form of a check list: copying health inventory for parents (CHIP) about specific behaviors in dealing with chronic stress experienced by families (8). Third questionnaire consists of 17 questions about three types of family coping patterns that are (1) six questions about maintaining family integrity, cooperation, looking at everything with positive things (2); six question about maintaining social support, self-esteem and psychological stability (3); and five question about understanding the medical situation, communication and consultation with health workers. The structure of coping health inventory for parents (CHIP) questionnaire is based on the important behavior of the family in responding to stress (14).

Data Analysis: This research analyzed using descriptive and statistical analysis used Spearman Rho correlation test. It is processed and analyzed with Statistical Package for the Social Science (SPSS) software (15).

Results

Respondents were patients with schizophrenia for at least 1 and their family caregivers. Data of respondent were obtained from the medical record of Menur mental hospital in Surabaya. Data collection used questionnaires and structured interview on 21 respondents. Frequency distribution of respondents of schizophrenia patient families based on demographic data in Wijaya Kusuma Hospital, Menur mental hospital in June 2016 shows that the respondents who were siblings with patient with schizophrenia are 13 people (62%), 6 people (29%) aged 20-30 years, 17 people (81%) are from the Javanese. There was no patient’s family who do not go to school, almost half the number of families worked as employees (48%), had income between 500,000-1,000,000 (38%), used JKN-KIS (62%), were not discipline in giving drugs to schizophrenia patients (81%) and were discipline in re-checking schizophrenia patients (67%).

The frequency distribution of schizophrenia patients based on demographic data in Wijaya Kusuma Room, Menur mental hospital in June 2016 shows that 14 schizophrenia patients was treated at Menur mental hospital (67%), 7 people (33%) with educational background of junior high school, 8 people (38%) in the age ranged of 21-30 years, patients with status single was 13 people (38%), 14 people (67%) had experienced mental disorders for 1-10 years, more than half of the patients had been referred to the mental hospital for the first time, 13
people (62%) were not doing treatment routinely, 7 people (33%) had experienced rejection and only 4 people (19%) had families with a history of mental disorders.

The table below is the result of a test of the relationship between family burden and family ability of caring for patient schizophrenia.

Spearman’s Rho p = 0.008

Table 1 shows the results of the Spearman correlation test between family burden and family ability of caring for patients with schizophrenia which shows a significance value of p = 0.008 or H1 was accepted which means that there was a relationship between family burden and family ability to treat schizophrenia patients. Correlation coefficient interval value (r) = 0.561 which means having a moderate relationship.

The table below is the result of a test of the relationship between family coping and family ability to care for schizophrenic patients.

Spearman’s Rho p = 0.000

Table 2 shows the correlation spearman statistical test of relationship between family coping with the family ability of caring for patient with schizophrenia which shows a significant value of p = 0.000 or H1 was accepted which means that there was a relationship between family coping and family ability of caring for patient with schizophrenic. Interval value of the correlation coefficient (r) is 0.868, which means having a very strong relationship.

**Discussion**

This research showed that family who have better coping strategies will take care of patient with schizophrenia well and full of affection. However, family with less burden do not always have the ability of caring for patient with schizophrenia properly.

The results of descriptive data showed that family burden is still relatively low. Subjective burden that most families feel is feeling stressed, confused, anxious and only 2 of 21 respondents felt embarrassed when taking care patients with schizophrenia. The objective burden that most families feel is reduced income, and only 2 of 21 respondents felt a rejection from the community when they are taking care patient with schizophrenia patients.

Families who have a high burden of taking care patient with schizophrenia in this study work as
employees with low income so it is difficult to take medication and visit the doctor regularly. It also makes the families often leave the office earlier and result in getting reduced income. In contrast to families that have health insurance facilities that are very supportive to caregivers’ finances, which will reduce the burden. Most respondents have and use health insurance facilities such as JKN-KIS and ASKES.

Contributing factors to the low family burden are the length of time the patient suffers from mental disorders, history of hospitalizing in mental hospital, and history of persecution. Data showed that most patients had suffered mental disorders for 11-20 years. Most of patients had a hospitalized history in mental hospital once and there was no history of persecution. It caused their family do not need to waste long time to take care for and manage patient who need continuous care, patients were less independent and had many needs that must be fulfilled as family burden get low.

Descriptive data showed that family coping were quite good. The component of family integrity which consists of perceptions of schizophrenia, daily behavior to patients, collaboration with patients, and the ability to think positively of situation occupy the highest proportion in family coping rather than components of psychological stability and communication skills. The most common component of family integrity is the ability to provide care and affection to patients and few respondents are able to provide good medical services to patients. Families with high coping also have a better integrity rather than psychological stability and communication skills.

Taking care a patient with schizophrenia can cause stress for the family. It makes family need coping strategies. Coping is a process for dealing with stressors by assessing how heavy the burden and the impact that might occur from the stressor experienced (16–18). Family education background influences whether family’s coping abilities are good or not. This is proven by the higher family education, the higher their knowledge level and awareness in caring for patient with schizophrenia.

Descriptive data showed that family ability of caring for patient with schizophrenia was quite good. The duty of caring a patient is one of the five components of family duties in care that are best implemented, followed by utilizing the health services, then environmental modification, making decisions for the right actions and the most rarely is the task of recognizing health problems. Family have a role in maintaining health, namely recognizing family problems, making decisions to determining the right actions, caring for sick family members, modifying a healthy family environment, and utilizing health service facilities around the environment (19). Family efforts in carrying out maintenance duties are certainly influenced by several factors.

As already stated above, knowledge has an important role in influencing family’s efforts in caring for schizophrenic patients. Without a supportive environment that can help the treatment process, the treatment process for schizophrenia will be ineffective (20). In addition, for the occupation and social economic factors, family members who do not have occupation certainly have more free time to caring for patient than occupied family member. Socio-economic factors in this study include the level of income of the family, family with high economic level will be more supportive and have a better decision-making in caring for schizophrenia patients. Family with excessively socio-economic will have an adequate level of family support. Family income is one manifestation of the intellectual support that will be used in looking for mental health services in treating family members with a history of schizophrenia (21).

As much 38 % of family with low burden had less ability of caring. While 4.8% of family with low burden had a good ability of caring. The results of this study indicated that families with low burden did not always have a good caring skills. These results are contradicted to the theory which explains that a low family burden should have high family ability of caring.

The cause of low-burden families with low caring ability is the length of time patients suffer from schizophrenia, work activities and family education. Eight respondents with low burden but low ability because they did not have enough time to treat patients with schizophrenia. In the education factor, some of them are elementary school. Education that makes family awareness low will be low

The results showed that 7 respondents with a poor coping also had poor ability to treat patients with schizophrenia even though caregiver activities were full of burdens, caregivers still wanted to care for family members because good coping was realized through constructive behavior that was full of wisdom and good values.
Conclusion

Family burden is not a factor that influences the family ability of caring for patient with schizophrenia due to various factors such as education and family economic social. However, family with good coping can provide good caring for patient with schizophrenia.

Ethical Clearance: The study was approved by ethics committee of Faculty of Nursing, Universitas Airlangga, Indonesia

**ABSTRACT**

**Background:** *Streptomyces* sp. is one of the sources of first choice antibiotic for tuberculosis treatment. *n*-butanol is the best solvent to extract antibacterial compound from fermented *Streptomyces* sp. isolates.

**Aim:** To analyze anti-tuberculosis activity of extract *n*-butanol-methanol (1:1) filtrate of the fermentation results of *Streptomyces sp.* B10 against *Mycobacterium tuberculosis* H37Rv.

**Method:** This was a laboratory experimental study. 3 comparisons of the type of solution were observed once a week for 3 weeks. Antibacterial activity test was analyzed from morphological observations on Ziehl-Neelsen staining, then minimum inhibitory concentration and minimum bactericidal concentration were determined.

**Result:** Bacterial growth began in the second week starting from a concentration of 10,50 ppm to a concentration of 1,31 ppm but a concentration of 43.000 ppm to a concentration of 5.375 ppm didn’t show any bacterial growth. The results of Ziehl-Neelsen staining show a red and rod-shaped *Mycobacterium tuberculosis* H37Rv colonies at a concentration of 2.687,5 ppm to a concentration of 1,31 ppm and at a positive control. A concentration of 2.687,5 ppm was determined as minimum inhibitory concentration and a concentration of 5.375 ppm was determined as minimum bactericidal concentration.

**Conclusion:** Extract *n*-butanol-methanol (1:1) filtrate of the fermentation results of *Streptomyces sp.* B10 at a concentration of 2.687,5 ppm to 5.375 ppm has antibacterial activity against *Mycobacterium tuberculosis* H37Rv. This extract can be used as an antibiotic formula for tuberculosis.

**Keywords:** *Streptomyces* sp, *n*-butanol, tuberculosis, antibacterial activities

**Introduction**

After first-line anti-tuberculosis drugs were released, the number of deaths was greatly reduced. The characteristic of tuberculosis that rapidly resistant to drugs, and the ability of bacteria to survive is a major problem for public health. In Indonesia, the total cases that reported in 2016 were 360,565 cases.

In 2014, the prevalence of 660 per 100,000 population with a case incidence of 403 per 100,000 population. The characteristic of *Mycobacterium tuberculosis* is the ability to make a persistent infection that requires long-term antibiotic therapy to cure tuberculosis patient. Tuberculosis (TB) has become a curable disease due to the antibiotic invention.

One genus of *Actinomycetes* which contributes most of its active metabolites to antibiotics is *Streptomyces*, this genus occupies the first position on several antibiotics. Antibiotic as anti-TB were discovered in 1943, known as Streptomycin.

Various strategies including bioinformatics are currently being tested to identify and improve
vaccines against TB. The researchers are undertaking and discovering new microorganisms which produce secondary metabolites. Domestic production of drug ingredients has not been going well, and still depends on imports ingredients. Five out of 15 isolates have been shown to have antibacterial activity from isolation using agricultural soil in Indonesia that planted with kale, spinach, and corn. One of the isolates known as Streptomyces sp. B10 which identified as Streptomyces violaceusniger. Water fraction and n-butanol fraction from fermented Streptomyces sp. B10 has antibacterial activities but the minimum inhibitory concentration remains unknown. Extract filtrate of the fermentation results of Streptomyces sp. B10 showing antibacterial activity against Escherichia coli. n-butanol is a solvent which has been shown to selectively extract antibiotic compounds from Streptomyces isolates with a large zone of inhibition. Methanol is a polar solvent that is mostly used because of its efficient penetration into the cell wall, so it produces more endocellular secondary metabolites.

This study aimed to analyze the activity of extract n-butanol-methanol (1:1) filtrate of the fermentation results of Streptomyces sp. B10 against Mycobacterium tuberculosis H37Rv.

**Method**

This study was an experimental study conducted in the Microbiology Laboratory Faculty of Pharmacy Universitas Airlangga and Tuberculosis Laboratory Institute of Tropical Disease Universitas Airlangga in 2017. Bacterial samples were Mycobacterium tuberculosis H37Rv and obtained from Tuberculosis laboratory Institute of Tropical Disease Airlangga University Surabaya. Streptomyces sp. B10 isolates were obtained from the Microbiology laboratory collection, Pharmaceutical Chemistry Department, Faculty of Pharmacy Universitas Airlangga. This study was conducted by researchers and expert lecturers.

The solution consists of 3 types: extract n-butanol-methanol (1:1) filtrate of the fermentation results of Streptomyces sp. B10, 1 ppm rifampicin (RIF) solution and DMSO solvent, and positive control (Middlebrook7H10 medium and Mycobacterium tuberculosis H37Rv). Incubation temperature, pH, and incubation duration were controlled in this study. Laboratory testing procedures were carried out by using Streptomyces sp. B10 culture, fermentate the Streptomyces sp. B10, freeze dry the culture, extract the crude dry powder using n-butanol-methanol (1:1), evaporate the extraction, extract n-butanol-methanol (1:1) filtrate of the fermentation results of Streptomyces sp. B10, and dilute. Antibacterial activity test was analyzed from morphological observations (shape, elevation, and color) on Ziehl-Neelsen staining, then minimum inhibitory concentration was determined. The assessment was determined by researchers and expert lecturers.

**Result**

Extraction using n-butanol-methanol (1:1) produced brownish yellow colored extract filtrate that has an oil-like consistency and non-distinctive smell. The summary of results from the first week to the third week can be seen in table 1.

Not inhibit the growth of *Mycobacterium tuberculosis* H37Rv (positive growth)

Inhibit the growth of *Mycobacterium tuberculosis* H37Rv (positive growth)

Not inhibit the growth of *Mycobacterium tuberculosis* H37Rv (positive growth)

**Note:** (-): no growth (+): Positive growth

On the first week, *Mycobacterium tuberculosis* H37Rv still has not shown any growth on Middlebrook 7H10 medium and Middlebrook 7H10 medium that contain solutions at several concentrations: 43.000 ppm, 21.500 ppm, 10.750 ppm, 5.375 ppm, 2.687.5 ppm, 1.343.75 ppm, 671.88 ppm, 335.94 ppm, 167.97 ppm, 83.98 ppm, 41.99 ppm, 21.00 ppm, 10.50 ppm, 5.25 ppm, 2.62 ppm, 1.31 ppm, likewise positive control (media and *Mycobacterium tuberculosis* H37Rv), Rifampicin (RIF) 1.0 ppm solution, and DMSO solvent. The growth of *Mycobacterium tuberculosis* H37Rv on Middlebrook 7H10 medium usually occur at the 1st-2nd week, so that observation continue for three weeks.

Observation at the second week shows that in a mastersolutionata concentration of 43.000 ppm to 21.00 ppm still has not shown the growth of *Mycobacterium tuberculosis* H37Rv. The solution at a concentration of 10.50 ppm to 1.31 ppm shows slight growth. The bacterial growth at a concentration of 10.50 ppm and 5.25 ppm can be seen as nebulous white dots, while at a concentration of 2.62 ppm the bacterial growth spread evenly as several small dots and at a concentration of 1.31 ppm show the most amount of growth compared to other concentrations. Positive control (media and *Mycobacterium tuberculosis* H37Rv) show a lot of growth with a white colored and slightly rough texture, in the Rifampicin (RIF) solution and DMSO still has not shown the bacterial growth. But it is not yet known whether the growth appears from *Mycobacterium tuberculosis* H37Rv or other bacteria.

At the third week, the inhibiting ability of extract n-butanol-methanol (1: 1) were decreasing. In a master solution at a concentration of 43.000 ppm to 5.375 ppm on Middlebrook 7H10 medium still has not shown the bacterial growth, which means at a concentration of 43.000 ppm, 21.500 ppm, 10.750 ppm, and 5.375 ppm has the inhibiting ability. Whereas at a concentration of 2.687.5 ppm to 1.31 ppm show bacterial growth. Since the first week to the third week, Rifampicin solution did not show any bacterial growth, which means Rifampicin as a standard that has the ability to inhibit *Mycobacterium tuberculosis* H37Rv growth. While positive control (Middlebrook 7H10 medium and *Mycobacterium tuberculosis* H37Rv) in the second week to the third week show bacterial growth increment, this shows that *Mycobacterium tuberculosis* H37Rv can grow on selective Middlebrook 7H10 medium. But it was not yet known whether the growth appears from *Mycobacterium tuberculosis* H37Rv or other bacteria. Therefore Ziehl-Neelsen staining was undertaken to determine the bacteria that grow in each concentration.

Microscopic observation on Ziehl-Neelsen staining did not show *Mycobacterium tuberculosis* H37Rv at a concentration of 43.000 ppm; 21.500 ppm; 10.750 ppm; and 5.375 ppm, it was plain blue. Whereas at a concentration of 2.687.5 ppm; 1.343.75 ppm; 671.88 ppm; 335.94 ppm; 167.97 ppm; 83.98 ppm; 41.99 ppm; 21.00 ppm; 10.50 ppm; 5.25 ppm; 2.62 ppm; and 1.31 ppm show red, straight, slim rod shaped *Mycobacterium tuberculosis* H37Rv, with blue background.
To determine the bacterial activity in quantitative approaches, the lowest concentration that can inhibit bacterial growth was observed. At a concentration of 10.750 ppm has not shown the bacterial growth, which means this concentration has the ability to inhibit *Mycobacterium tuberculosis* H37Rv growth. At a concentration of 5,375 ppm also hasn’t shown any bacterial growth, so this concentration still able to inhibit *Mycobacterium tuberculosis* H37Rv growth, but at a concentration of 2.687,5 ppm bacterial growth began to appear.

Microscopic observation on Ziehl-Neelsen staining did not show *Mycobacterium tuberculosis* H37Rv colony at a concentration of 43.000 ppm; 21.500 ppm; 10.750 ppm and 5.375 ppm, it was plain blue. Whereas at a concentration of 2.687,5 ppm; 1.343,75 ppm; 671,88 ppm; 335,94 ppm; 167,97 ppm; 83,98 ppm; 41,99 ppm; 21,00 ppm; 10,50 ppm; 5,25 ppm; 2,62 ppm and 1,31 ppm show red, straight, slim rod-shaped *Mycobacterium tuberculosis* H37Rv, with blue background. So that the Minimum Inhibitory Concentration (MIC) from extract n-butanol-methanol (1:1) filtrate solution of fermentation results of *Streptomyces sp.* B10 against *Mycobacterium tuberculosis* H37Rv is 2.687,7 ppm. While the concentration of 5,375 ppm is the highest concentration that still able to kill the bacteria (MBC).

**Table 2: Observation result of Minimum Inhibitory Concentration (MIC)**

The microscopic observation did not show *Mycobacterium tuberculosis* H37Rv colony at a concentration of 43.000 ppm; 21.500 ppm; 10.750 ppm and 5.375 ppm, it was plain blue. Whereas at a concentration of 2.687,5 ppm; 1.343,75 ppm; 671,88 ppm; 335,94 ppm; 167,97 ppm; 83,98 ppm; 41,99 ppm; 21,00 ppm; 10,50 ppm; 5,25 ppm; 2,62 ppm and 1,31 ppm show red, straight, slim rod-shaped *Mycobacterium tuberculosis* H37Rv, with blue background.
Discussion

Extract n-butanol-methanol (1:1) filtrate solution of the fermentation results of Streptomyces sp. B10 has antibacterial activity against Mycobacterium tuberculosis H37Rv. n-butanol is the selective solvent that can extract antibiotic compounds from Streptomyces sp. with a large zone of inhibition15. Ethanol extract has potent ability to inhibit bacterial growth, both gram-positive and gram-negative bacteria17. Methanol is a polar solvent that mostly used because of its efficient ability to penetrate into the cell wall, so it produces more endocellular secondary metabolites16. Several isozymes show high substrate specificity and various homogeneity from Streptomyces sp. Cell extract for several types of alcohol18.

Dilution using this extract can support the attack against Mycobacterium tuberculosis (TB). Since Mycobacterium tuberculosis has a high acquisition to drug resistance, new drug discovery to put into tuberculosis regimen is required19. Streptomyces potential for expressing foreign proteins indicate that Streptomyces can be a useful vector in designing new TB vaccine. Streptomycin is the first antibiotic that attacks Mycobacterium tuberculosis by moomotherapy, so it leads to generate resistance. The mechanism of action of streptomycin is inhibiting mycobacterial protein synthesis in ribosomes. Resistance arises when mutations appear on rRNA and protein-encoding genes. ATCC27294 strains are sensitive toward the activity of streptomycin, rifampin, ethambutol, and isoniazid and ATCC35820 strains are resistant to streptomycin. Several mutated genes are evidenced to cause drug resistance20,21. The clinical trials of streptomycin show a good outlook to suppress TB. Although patient improved compared to the patient without therapy (considered as the first randomized controlled clinical trial), recurrence occurs in many patients and organisms are found to be resistant to streptomycin22.

The concentration ranges from 2,687.5 ppm to 5,375 ppm effective against Mycobacterium. Antibacterial activity against Mycobacterium tuberculosis H37Rv occurs at a concentration of 2.687,5 ppm, which is determined as Minimum Inhibitory Concentration (MIC). Whilst the concentration of 5.375 ppm is determined as Minimal Bactericidal Concentration (MBC), which is the lowest concentration that able to kill bacteria. This result shows that antibacterial activity increased as the increasing extract n-butanol-methanol (1:1) filtrate solution of the fermentation results of Streptomyces sp. B10 concentration, because the extract in this study has not become an antibacterial pure compound.

There are few things as consideration for further research: further analysis with separation of active compounds from Streptomyces sp. B10 using TLC bioautography method or other separation methods, further identification to find out another pure compound as antibacterial that produced by Streptomyces sp. B10, and limiting concentration range from 5.375 ppm to 2.687,5 ppm for antibacterial activity test and MIC determination.

Conclusion

Extract n-butanol-methanol (1:1) filtrate solution of the fermentation results of Streptomyces sp. B10 has antibacterial activity against Mycobacterium tuberculosis H37Rv. This indicates that this extract can be used as an alternative antibiotic formula to fight tuberculosis.

The Correlation between Goat Maintenance Management to the Incidence of Gastrointestinal Parasite Infections

Zahrotul Hurriyyah1, Nunuk Dyah Retno Lastuti1, Lianny Nangoi1
1Faculty of Veterinary Medicine, Airlangga University, Surabaya 60115

ABSTRACT

Background: Gastrointestinal parasite infection in goats is one of the diseases that lead to a poor productivity of livestock. This infection might be caused by a poor maintenance management.

Aim: This study was to study the correlation between a goat maintenance management and the severity level of gastrointestinal parasite infections.

Method: This study used 42 fresh feces as samples which taken randomly from a large population. Sample examination was done by using simple sedimentation method and modified Fulleborn floating method. The degree of parasite infection was measured using the calculation of fecal worm egg count (FEC), 0-500 gram of feces considered as mild infection. Data from the maintenance management questionnaire and the severity of infection in goats were analyzed using the Classification and Regression Tree (CART) test.

Result: Samples examination was conducted in department of parasitology. It resulted 23 samples were positive with worm eggs from Haemonchus contortus and Strongyloides papillosus species. The prevalence of Helminthiasis was 54.76% with a mild degree of infection. The type of worm eggs found in the examination of faecal samples came from the class of Nematodes, namely Haemonchus contortus species (60.87%) and Strongyloides papillosus (39.13%). Single infection was found in 11 positive samples (47.82%) and 12 positive samples were in mixed infections (52.18%) 

Conclusion: Maintenance Management is a major factor in the degree of gastrointestinal parasite infection.

Keywords: the severity level of parasite infection, goat, maintenance management

Introduction

Parasite infections in goats rarely cause death, but this disease is chronic and have an impact to adult goats in decreasing milk production, meat quality, and work ability, whereas in young goats can results in stunted growth, decreased appetite, anemia, diarrhea, and dehydration1. Environmental conditions outside the host’s body which greatly influence the occurrence of helminthiasis cases, include the suitable temperature, humidity, and the availability of oxygen2.

The appropriate environment will promote worm eggs to come out through goat feces. The worms will hatch and develop into infective larvae which will infect new hosts. This means that the more ideal the environmental conditions, the higher opportunities of infection occurrence because the worms will grow well. The environmental sanitation of the host’s residence is need to be considered. Poor sanitation, especially if feces is not cleaned regularly, it can trigger a severe and sustained re-infection3.

Maintenance management in goats is influenced by the limited knowledge of farmers about raising goats method is one of the factors causing worm infections, especially the problem of sanitation cages, poor environmental conditions, extreme climate, and contaminated feed with worm eggs. Infectious larvae attach to grasses then infect the goats. Furthermore, the larvae will mature in the abomasum of goats4. However,
in the effort to develop livestock production, there were obstacles in the livestock industry, one of which was poor livestock management among farmers.

Some efforts to control parasites that exist in livestock because if the parasite is left untreated, it will become very detrimental to farmers. Good maintenance management of goat swill reduce and eradicate the occurrence of parasites infections. Therefore, this study aimed to determine the relationship between the type of worm eggs in digestive tract, the degree of severity, and maintenance management in goats.

**Method**

The study was conducted in Turi Village, Lamongan Regency, Indonesia. Sample examination was carried out at the Helminthology Laboratory, Airlangga University, Surabaya. The sampling period time was from May to June 2017. The time of the faecal examination at the laboratory was in June to July 2017. Feces samples were taken randomly, limited to 10% of the total population with a total of 42 faecal samples. Feces was taken in moderation (approximately 10 grams) with a 2.5% potassium bicarbonate solution and taken to the laboratory for examination. Sample examination was done by simple sedimentation method and modified Fulleborn floating method.

**Simple Sedimentation Method:** The feces sample was put in a plastic cup and then added water with a ratio of 1:10 then filtered. The filter results were put into the centrifuge tube then centrifuged for 2-5 minutes at a speed of 1500 rpm. Supernatant from the centrifuge was removed and the water was added again as well as the previous stage and then centrifuged for 2-5 minutes at a speed of 1500 rpm. This process was repeated until the supernatant is clear. After clear, the supernatant was removed and left a little, then the sedimentation was stirred with Pasteur pipette and taken a little and then dropped over the glass object and covered with a glass cover after it was examined under a 100x magnification microscope.

**Modified Fulleborn Floating Method:** Modified Fulleborn Floating Method was done by making feces suspension then filtered and put into a centrifuge tube to be centrifuged for 2-5 minutes at a speed of 1500 rpm. The supernatant was discarded, while the sediment with added water will be centrifuged for 2-5 minutes at the same speed. The process was repeated to obtain a clear supernatant. After that the supernatant was discarded and left a little, then add the brown sugar solution to 1 cm from the mouth of the tube and do the refining again in the same way. The centrifuged tube was placed on a tube rack then slowly dripped with a brown sugar solution until the surface of the liquid looks convex on the surface of the tube mouth. The glass cover was placed on the surface of the tube for 5 minutes, then the glass cover was lifted and placed on the glass object to be observed under a microscope with 100x magnification.

**Calculation of Fecal Egg Count (FEC):** In a positive sample infected with gastrointestinal worms, the examination was continued with the calculation of Fecal Egg Count (FEC). Calculations use the Lucient Brumpt method. One gram of faeces is mixed with water and made a suspension with dilution 10 times, then filtered and calculated the number of drops in 1 ml of suspension using a pasteur pipette. Examination is carried out under a microscope with 100x magnification. The results of the FEC calculation are classified into three levels, namely the degree of mild infection if FEC ranges from 0-500. The degree of infection is moderate if FEC ranges from 501-1000. And the degree of infection is severe if FEC is more than 1000.

**Prevalence Calculation:** Prevalence calculation of goat digestive tract worms was based on the percentage of positive samples that found worm eggs, divided by the number of all samples multiplied by 100% (8).

**Statistical Analyze:** Data from the maintenance management questionnaire and the severity of goats were analyzed by statistical tests (Classification and Regression Tree (CART) test).

**Results**

Laboratory results obtained 23 positive faecal samples containing worm eggs. This shows the prevalence and degree of gastrointestinal worm infection in goats as much as 54.76%. From the results of the examination found worm eggs from the Nematode class, namely from the species *Haemoncus contortus* and *Strongyloides papillosus*. Figure 1 shows *Strongyloides papillosus* worm egg measures 55.58 x 25.53 μm. The form of *Strongyloides* sp. eggs are elliptical, thin walled and larva shaped like the letter S or U.
The results of examination of faecal samples that have been done, shows the presence of *Haemonchus contortus* worm eggs with a size of 80.28x47.93 μm, oval-shaped worm eggs, and when coming out with feces already in the morula stage (in eggs containing 16-32 cells). Numerous *Haemonchus contortus* eggs are thin-shelled, oval shape with equal polish, edges mombate and morula is not fully filled the eggs cavity. This following picture in Figure 2 is *Haemonchus contortus* eggs.

*Figure 2: Haemonchus contortus eggs. (Magnification are up to 100X).*

*Haemonchus contortus* eggs have an oval shape and there is a clear area inside. Identification of worm eggs was done by looking at the morphology of the egg shape and size of the worm egg. Measurements of worm eggs were carried out using the Optilab Imageraster program. The following is the mean value of worm eggs that infect goats.

**Table 1: Mean Value of Worm Eggs that Infected Goats and Its Degree of Infection**

<table>

</tbody>
</table>

From 23 positive samples, 13 samples were in mild degrees of infection with an average number of 0-500 egg per gram faces (EPG). The degree of moderate infection with a sample size of six had been obtained with average number of worm eggs about 501-1000 EPG, and the degree of severe infection with a sample number of three and the average worm eggs was more than 1000 EPG.

The types of worms that infect goats was *Haemonchus contortus* worm eggs (60.87%) and *Strongyloides papillosus* worm egg (39.13%). Mixed infection were found in 12 positive samples or equal to 52.18% consisting of two worm species from the Nematode class, *Haemonchus contortus* and *Strongyloides papillosus*. While the incidence of a single infection was found in 11 positive samples or equal to 47, 82%.

Based on the results, management of goat maintenance showed an influence on the degree of worm eggs infection in the digestive tract. Wastes disposed of less than 15 meters from the cage have a mild infection rate of 50% and a severe infection of 50%, while the waste disposed at a distance of more than 15 meters from the cage has a mild infection rate of 66.7% and a severe degree of infection 0%.

Goats who had never been given worm medicine had a greater degree of infection than goats who were given worm medicine. Goats given worm medicine had a mild infection rate of 100% while goats who had never been given worm medicine had a mild degree of infection of 57.1%, moderate of 14.0%, and severe of 28.6%. While goat manure stored in closed sacks has a mild infection rate of 50%, medium 25%, and severe of 10%. Whereas the dirt deposited on the ground has a mild infection rate of 75%, medium 25%, and severe of 0%.

The results of research conducted on feeding methods showed that breeders who provided feed from inside the cage had a higher degree of infection than goats which were released to graze in the rice fields. Breeders who provide feed from inside the cage have a mild degree of infection of 65%, moderate of 25%, and severe 10%. Whereas the goats released in the paddy fields have a mild degree of infection of 33.3%, moderate of 66.7%, and severe of 0%. Beside of that, farmers who clean their cages once a week have a mild and moderate infection rate of 0% and severe of 100%. Whereas farmers who clean their cages every day have a mild degree of infection 60.9%, moderate of 30.4%, and severe of 8.7%.
Discussion

The results showed that two species of worm eggs from the Nematode class (Haemonchus contortus and Strongyloides papillosus). Cattle frequently has mixed parasite infections. From the results, mixed parasitic infections was more common than single infections. Mixed infections were found in 12 positive samples or equal to 52.18%. Whereas the single infection was found in 11 positive samples or equal to 47.82%. This was caused by the characteristic of parasite infection does not cause death to the host, but only causes a decrease in host’s immune system, allowing secondary infection from other types of parasites. Seasonal dynamics and age of hosts are significantly influenced by the prevalence of gastro-intestinal nematode infection. Besides, all these worm parasites spend more their life cycle in the host body. The appropriate environment promotes worm eggs to come out with goat’s feces, then it hatch and develop into infective larvae which will infest new hosts. This means that the more ideal the condition of the environment, the more opportunities for the emergence of cases of worm infections.

The results of the FEC calculation did not show a significant effect on the incidence of gastrointestinal worm infections in goats, so the incidence of gastrointestinal worm infections in goats was classified as a mild degree of infection with a range of 0-500 EPG. Differences in the number of FEC calculations on definitive hosts can be influenced by several factors, namely, type of worm, age of worms, time of egg production, amount of feces produced by definitive hosts, density or consistency of faeces, and spread of eggs in feces.

Feces waste that discharged nearby the cage with a distance of approximately 15 meters sometimes has a greater degree of infection than feces that is discharged at a distance of more than 15 meters from the cage. This is affected because the waste that is thown away closer than the cage will make the chance of worm eggs survive and hatch, so that they can re-contaminate the environment around the cage or feed of the goat. In poor sanitation, especially if feces is not cleaned regularly, can be a source of severe and sustained re-infection.

The location of waste disposal on the provision of worm medicine showed that goats who had never been given worm medicine had a greater degree of infection than goats who were given worm medicine. This is because regular administration of worm medicine to livestock will reduce and cut the life cycle of worms in the body of livestock.

The treatment of parasite medication in feces waste management showed that the management of manure stored in closed sacks has more severe degree of infection than the goat manure that is piled above the ground. This is because the dirt stored in a closed sack will cause the condition to become moist, the moist condition that makes the growth of worms become fast and rapid, making the degree of infection greater. Temperature and moisture are dominant influences on the free-living stages of Haemonchus contortus. The condition of a humid climate is the best condition for the life phase of various digestive tract parasites.

The feeding behavior of the ruminant species is a major factor in the development of parasitism. Goats left to graze themselves are more at risk of being infected with worms than goats in cages. Animal grazed for short period (2-3 weeks) Larval reflect availability. However, in this study goats bred more at risk of being infected with worms. The method of feeding in this study shows that breeders who provide feed from inside the cage had a higher degree of infection than goats that are released to graze in the rice fields. This is because feed goats in paddy fields containing fewer worm larvae than the feed given to goats in cages. Breeder clean their cages once a week and this condition may have a greater degree of worm infections, especially Haemonchus contortus and Strongyloides papillosus worms.

Cleanliness of the cage is a major factor in the degree of gastrointestinal worm infection where cleaning the cage is done every day, feeding in the cage, feces was that been stored in closed sacks, not administering worm medicine, and removing sewage waste less than 15 meters from the cage is an action that lacking in maintaining the cleanliness of the cage, thus showing the high degree of reduced worm infection. Farmers should give worm medicine to goats on a regular basis to reduce the number of gastrointestinal worm infections in goats.

Conclusions

From the results, it can be concluded that maintenance management gave a great influences the degree of parasitic infection in gastrointestinal tract of goats.
Ethical Clearance: The research process involves participants in the survey using a questionnaire that was accordant with the ethical research principle based on the regulation of research ethic committee. The present study was carried out in accordance with the research principles. This study implemented the basic principle ethics of respect, beneficence, non-maleficence, and justice.

Histopathology of Esophagus and Crop of Pigeon (*Columbia livia*) Infected by *Trichomonas gallinae*

Aprilia Eva Widiawati¹, Muchamad Yunus², Thomas V Widijatno²

¹Department of Veterinary Medicine, Faculty of Veterinary, ²Faculty of Veterinary Medicine, Universitas Airlangga, Surabaya

ABSTRACT

**Background:** *Trichomonas gallinae* is a protozoa that causes trichomoniasis which is common found in pigeons and it attacks the digestive tract of pigeons. Proper examination can be done to differentiate from healthy pigeons.

**Purpose:** to observe the changes in histopathological images of the esophagus and the crop of pigeons (*Columba livia*) that infected with *Trichomonas gallinae*.

**Method:** Observations were carried out on 20 pigeons with symptoms of presence *Trichomonas gallinae*. Swab examination in the esophagus with the Natif Test and Giemsa Staining. Esophagus and crop was collected through necropsy in the upper digestive tract. Then histopathological examination was performed with Hematoxylin Eosin (HE) staining. Data was analyzed descriptively.

**Result:** Histopathological features of pigeons (*Columba livia*) infected with *Trichomonas gallinae* were different from healthy pigeons. Pigeons infected with protozoa *Trichomonas gallinae* showed changes of the esophagus in the form of erosion and cell necrosis in stratified non-keratinized epithelium (mucosa) and infiltration of inflammatory cells in the mucosa layer and sub esophageal mucosa. In addition, changes in the crop were cell necrosis in the mucosa layer, infiltration of inflammatory cells in the submucosal layer, and congestion in the sub mucosal cavity.

**Conclusion:** There were histopathological changes in the esophagus and crop of pigeons that infected with *Trichomonas gallinae*.

**Keywords:** Histopathology, Esophagus, Crop, *Trichomonas gallinae*, pigeon.

**Introduction**

Pigeon (*Columba livia*) is one type of fowl with a well known species in the Columbidae family. It is one of the fauna diversity in Indonesia which has a high diversity of phenotypes, both qualitative and quantitative characteristics. Pigeons are also farmed for their meat as a source of animal protein. The problem is poor maintenance management causes pigeons become susceptible to disease. One of parasitic infection that can attack a pigeon is *Trichomonas sp.* *Trichomonas gallinae* is a flagela protozoa that causes trichomoniasis in pigeons. *Trichomonas gallinae* is most commonly found in pigeons and has been reported to infect 67.3% of pigeons species. Trichomoniasis causes high mortality in young pigeons and affect the pigeons mortality with a percentage of 77.5% in one subpopulation. *Trichomonas gallinae* attack the digestive tract of pigeons, mostly found in the oral cavity, pharynx, esophagus, and crop of adult pigeon as carriers of the disease.

*Trichomonas gallinae* infection has a pathognomonic clinical signs. The identification can be done from taking samples of lesion in the mouth both necrotic and fluid lesion. Transmission can occur through milk from parent and child of pigeons, as well as through contaminated food and beverages. This infection can spread between

species such as bird and eagle, then considered risk for human health. Species that infect birds and domestic mammals have been identified in human clinical samples. Several phylogenetic analyzes have identified trichomonas derived from animals as taxa of closed relatives of two species of humans. This confirms that efforts to detect disease in pigeons are an important to improve an animal health while distinguishing infected pigeons from healthy pigeons. To reduce the risk of zoonosis more effectively from industrial food animal production, the application of biosecurity must be in harmony with the interest of public health. Surveillance of diseases, as well as in transmission model for poultry and zoonotic diseases are the main things. In addition, the most important is rapid detection and diagnosis.

Observation of symptom is part of the framework of detection and diagnosis. Pigeons infected with T. gallinae will have clinical symptoms namely weight loss, weakness, depression with lesion in the upper gastrointestinal tract. Infection Trichomonas gallinae causes ulceration in the crop, esophagus and proventriculus. Microscopic examination of pigeons infected with Trichomonas gallinae will show an infiltration of heterophil and eosinophil cells in the mucosal layer and submucosal lamina propria. Parasitic infection Trichomonas gallinae can cause infected birds have clinical symptoms that similar to avian fowl pox, deficiency of vitamin A, poultry (fowl diphtheria), capillariasis, candidiasis and aspergillosis, namely the presence of necrotic lesions or lesions in the esophagus. Trichomonas gallinae infection can be established by identification of the T. gallinae parasite in the esophageal swab examination. The method to determine the presence of Trichomonas gallinae is by examining the esophagus swab. Esophageal swab is conducted by the negative method to detect the movement of the parasitic Trichomonas gallina flagella. Giemsa staining is used for morphological identification of Trichomonas gallinae.

In the course of this disease, the difference from other diseases that have similar clinical symptoms can be used as guidelines for management according to the disease found. The information about certain organs changes in pigeon will open up the opportunities for the virus schemespreading. This study aimed to determine the histopathology of the esophagus and crop in pigeons infected with Trichomonas gallinae.

Method

This study was an an observational study. Laboratory examination were conducted at the Parasitology Laboratory, Department of Veterinary Parasitology, Faculty of Veterinary Medicine, Universitas Airlangga, Surabaya Indonesia for 20 weeks. The preparation of esophageal and crop histopathological preparations was conducted in the Department of Veterinary Pathology, Faculty of Veterinary Medicine, Universitas Airlangga, Surabaya Indonesia. This study used replacement, reduction and refinement. Animals were modified in research procedures in such a way that to reduce pain and stress in experimental animals, and considered to the 5 principles of freedom in animal prosperity.

A total of 20 pigeons (Columba livia), both male and female contributing to the sample with the criteria have clinical symptoms of Trichomonas gallinae infection. The symptoms were depression, weight loss, hair standing like cold and gloomy color, when standing curled up, there were lesions with wet and sticky exudates in the oral cavity, especially in acute diseases and in chronic infections there are hard exudations.

Sample examination was carried out in several stages. The first step was a swab examination in the esophagus through Natif tests and Giemsa staining when the pigeons were still alive. The samples were positive if found Trichomonas parasites, proven by the movement of flagellars from Trichomonas gallinae with a 100-400 times magnification microscope. Pigeons with a lesion in the esophagus were positively infected with Trichomonas gallinae. Esophagus and crop collecting was done through necropsy in the upper digestive tract, then were given formalin 10%. After that making histopathological preparations with Hematoxylin Eosin (HE) staining for microscopic examination. Data of changes in esophagus histopathological histories and crop was analyzed descriptively.

Result

Total of 20 pigeons (Columba livia) with clinical symptoms of Trichomonas gallinae infection were positively infected with Trichomonas gallinae. Histopathological changes in the esophagus and crop will be seen as a decrease in blood flow (congestion), irreversible tissue necrosis, partial loss mucosa (erosion), and cells with a defensive reaction as a
response to injury in the form of a vascular reaction to infection (inflammatory cells). Changes in oral lesions and esophagus swab results that showed infection with Trichomonas gallinae are shown in figure 1.

![Figure 1: Lesions in the oral cavity (A), esophagus infected with Trichomonas gallinae (B).](image)

The result of the esophagus swab examination with the natif method was obtained by the movement of flagella from the parasite Trichomonas gallinae. Protozoan was detected from the motility or movement of flagella and in Giemsa staining will leave a bluish color up to purple. The movement of flagella Trichomonas gallinae was found in all samples of pigeons’ esophagus.

Based on the results of examination and microscopic observations carried out there was a histopathological change in the esophagus of pigeons infected with Trichomonas gallinae. These changes in histopathological features included erosions of cell mucosa necrosis due to Trichomonas gallinae infection. Description of histopathological changes in the esophagus of pigeons (Columba livia) infected with Trichomonas gallinae which has erosion and cell necroses can be seen in figure 2.

![Figure 2: Tropozoite Trichomonas gallinae. A: Independent swab check (400x) without staining. B: Swab checks using Giemsa coloring (1,000x).](image)

Other damage that occurs due to Trichomonas gallinae infection was the infiltration of inflammatory cells in the mucosal and sub mucosal layers of the esophagus of the pigeons which cause thickening of the esophageal mucous layer. Histopathological images of the esophageal layer undergoing inflammatory cell infiltration can be seen in figure 3.

![Figure 3: Hitopathological features fromthe esophagus of naturally infected pigeons Trichomonas gallinae has erosion and necrosis of cells in the mucosa (H.E coloring; 100x magnification (A1 and A2) and 200x magnification (B); Nikon microscope H600L ; camera of DS Fi megapixel). (): Erosion and cell necrosis.](image)
The results of examination and microscopic observation showed there were histopathological feature changes in the crop of pigeons with *Trichomonas gallinae* infection. These changes included cell necrosis in the mucosal layer, infiltration of inflammatory cells in the sub-mucosal layer, and there are tendons in the sub-mucosal layer. Histopathology of cell necrosis in the mucosal lining of the crop of pigeons (*Columba livia*) infected with *Trichomonas gallinae* can be seen in figure 4. Histopathology in the sub-mucosal layer experiencing inflammatory cell infiltration can be seen in figure 5. Congestion in the sub-mucosal layer can be seen in figure 6.

**Figure 4:** Histopathological picture of pigeon esophagus which has inflammatory cell infiltration due to *Trichomonas gallinae* infection (H.E staining; 100x magnification (C1) and 200x magnification (C2); Nikon H600L microscope; Camera DS Fi megapixels).

**Figure 5:** Histopathological features of the crop of pigeons infected with *Trichomonas gallinae*. Visible cell necrosis in the mucosal layer. (H.E coloring; 100x magnification (D1) and 200x magnification (D2); Nikon H600L microscope; camera of DS Fi megapixel).
Discussion

Based on the results of esophagus swab examination of 20 samples of pigeons (Columba livia) suspected of being infected with Trichomonas gallinae by showing clinical symptoms of depression, weight loss, feathers stands like feeling cold and gloomy color, when standing curled up, yellow necrotic lesions were seen in the esophagus and crop, and a greenish liquid in the oral cavity. Histopathological changes were supported by the results of a research report that pigeons infected with Trichomonas gallinae will experience infiltration of inflammatory cells in the mucosal layer and esophagus mucosa. In the crop of pigeons infected with Trichomonas gallinae showed histopathological changes of necrosis in the mucous layer and inflammatory cell infiltration in the sub layer mucosal.

Basically, Trichomonas gallinae infects the upper digestive tract of pigeons. All positive samples of T. gallinae detected by microscopic examination were also detected as positive by the PCR test. Most of the samples
identified negatively by microscopic examination were
detected as positive *T. gallinae* by PCR testing and
confirmed in sequence. Positive samples of *T. gallinae*
collected will provide relevant data for studying the
ecology and genetic structure of the population of
*Trichomonas gallinae* and for disease prevention
and control.\(^1\) The degree of change and virulence of
pathological strains was low to high heterogeneity of
*T. gallinae* causes trichomoniasis.\(^1\) Infiltration
of the trachea and lungs is associated with a severe
inflammatory response to the surrounding tissue.\(^1\)

Cytopathological analysis revealed many pyriform
protozoa, compatible with *Trichomonas gallinae*. Protozoa are not proven histopathologically in lesions
after staining the sample with Hematoxylin and Eosin
staining or Gomori Methenamine Silver (GMS).\(^1\)
Histopathological changes in the esophagus of pigeons
undergoing erosion and necrosis occur in the mucosal
esophagus layer of pigeons. Erosion is the erosion or
partial release of the mucosal epithelium. This occurs
because of a traumatic reaction to *Trichomonas gallinae*
infection.\(^1\) Changing histopathological of crop that
undergoes cell necrosis in the mucosal layer. Changes
in infiltration of inflammatory cells in the sub mucosal
layer of the crop. The severity of lesions that occur as
a result of *Trichomonas gallinae* infection in the upper
digestive tract varies from mild mucosal inflammation to
sub-mucosal inflammation.\(^2\)

However, the virulence of *Trichomonas gallinae*
depends on other factors such as exposure to previous
pathogens (protective immunity) and individual
immunocompetence. Factors such as age, concurrent
disease, genetic heterogeneity, geographical variation,
habitat differences, abundance of means of transmission
and availability of food.\(^3\) In addition, livestock should
pay attention to the management of sanitary cages
and feed to break the chain of distribution. Further
studies regarding the degree of infection in esophageal
histopathological changes and caches infected with
Trichomonas gallinae need to be done as a step towards
better diagnosis.

**Conclusion**

There were histopathological changes in the
esophagus and crop of pigeons with infection of
*Trichomonas gallinae*.

The Effectiveness of Back Exercise for the Reduction of Low Back Pain Prevalence on the Emergency Room Nurses

Dinda Nur Fajri Hidayati Bunga1, Harmayetty1, Candra Panji Asmoro1

1Faculty of Nursing, Universitas Airlangga, Mulyorejo Street, Surabaya, East Java, Indonesia

ABSTRACT

Background: Low back pain is a major problem in the musculoskeletal system which affects nearly 84% of adults. Those working for more than 42 hours in a week, including nurses, are at the highest risk of developing low back pain. This research aimed to figure out the effectiveness of back exercise intervention for low back pain on the emergency room nurses.

Method: This research is quasi-experimental research with a control-group pretest-posttest design. This research was conducted on 12 nurses. The respondents were divided into two groups, treatment group and control group, with 6 respondents each. The intervention was measured using McKenzie’s back exercise SOP, general data questionnaires, and the Ovako Work Posture Analysis System (OWAS). The results of the measurements were analyzed using the Wilcoxon Signed Rank Test, while the results of the post-test were analyzed using the Mann-Whitney Test.

Results: The difference in the nurses’ work postures was significant according to the Wilcoxon Signed Rank Test but insignificant according to the Mann-Whitney Test. In the pain measurement, pain frequency was the only factor that yielded a significant value (p < 0.05) in both tests. The risk factors pain scale and pain duration were significant in the Wilcoxon Signed Rank Test but insignificant in the Mann-Whitney Test.

Conclusion: Back exercise intervention for low back pain in nurses is effective in lowering low back pain prevalence by reducing the risk factor pain frequency, especially prior to patient mobilization.

Keyword: low back pain, back exercise, nurse, pain

Introduction

Low back pain is an important health problem from a socioeconomic perspective and is related to high cost and work disability. Sitting has now become the most common posture in today’s workplace. Idea of using motor control learning approach provides the optimal control and coordination of the spine. The McKenzie evaluation was received using repeated movements and sustained positions. Therefore high quality randomized clinical trial was required to compare the effectiveness of these treatments for work related low back pain. Objectives: To compare the effectiveness of motor control exercises and McKenzie exercises in reducing pain and disability in work related low back pain. Method: The study included 40 subjects with work related low back pain due to prolonged sitting. They were randomly allocated into two groups (Group A and Group B. Some 12% of low back pain prevalence occurs in adults, while 40% does in the elderly until the end of their lives. Every year, the world’s LBP prevalence rate stands between 40%–50%. Nine in 10 adults experience back pain at some point in their lives, and 5 in 10 do annually.

The highest risk of low back pain may be faced by those who work for more than 42 hours a week. Nurses work 7- through 8-hours shifts, and the number of hours may increase during night shifts. Of 250 nurses 61% complained low back pain at medium- to high-scale of pain. The prevalence rate of back pain in Hong Kong

Correspondence Author:

Mulyorejo Street, Surabaya, East Java, Indonesia 60115
Email: harmayetty123@gmail.com
nurses stood at 40.6%. A higher prevalence rate of LBP in nurses was reported in a Turkey-based study to stand between 62% and 88%. In Indonesia, as many as 45.5% of the nurses of a type A hospital in Surabaya complained back pain.

From a preliminary observation at the emergency department of a type B hospital in Surabaya, Indonesia, low back pain was found in 12 of 27 nurses (44.4%). This, according to the Public Satisfaction Survey (SKM), has caused the hospital’s service quality to fall from excellent (A) to good (B). The complaint was experienced by the nurses for two years, yet no mutation took place due to the restriction in the number of nurses.

McKenzie exercises were first introduced by doctor Robin McKenzie in 1981. The technique of these exercises is altering the distorted shape of posterior discs. McKenzie exercises are performed by extension that creates pressure at a certain point in vertebrae, reducing the distance between vertebrae and pressing the disc nucleus or pushing it to its initial position, causing the nucleus to move more easily because the disc shifts forward and eventually removing protrusion in the posterior area and reducing back pain. This research aimed to figure out the effectiveness of back exercise for low back pain in nurses of a hospital in Surabaya, Indonesia.

Method

Design, Sampling, Variables: This research is quasy-experiment research with a control-group pretest-posttest design. The research sample was selected randomly by a non-probability sampling technique named purposive sampling. The sample consisted of 12 emergency nurses of RSU Haji Hospital Surabaya, Indonesia. The respondents were randomly divided into two groups: 1) a group of respondents receiving no back exercise intervention and 2) a group receiving a therapy according to the hospital’s program.

In this research, an observation of 4 dependent variables—work posture, pain frequency, pain duration, and pain scale—was conducted. Measurements were carried out based on McKenzie’s back exercise SOP, general data questionnaires, and Ovako Work Posture Analysis System (OWAS) observation sheet.

Procedure: All procedures in this research were approved by the Health Research Ethics Committee of the Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia with an ethical clearance No. 220-KEPK. In the preparation, letters of permission were sent to a number of institutions, including the type B hospital RSU Haji Surabaya, Indonesia.

All respondent candidates were informed about the benefits, aim, and procedure of the research as well as their rights based on the ethics before the research was conducted. The respondent candidates willing to take part in the research were asked to sign an informed consent. In the first session prior to the research, the respondents were asked to complete low back pain complaint questionnaires then subjected to a matching process aimed to distribute the respondents into two groups equally based on the pre-test results. Together with the emergency department party the researchers made a schedule according to the nurses’ shift hour.

The treatment group performed back exercises twice a week for two weeks for a duration of 30 minutes per session. In every back exercise session, the treatment group was guided by a physiotherapist. Follow-up was undertaken every week to monitor the outcome of the intervention. In the last session, the respondents filled the low back pain complaint questionnaires after given the back exercise procedure. On the same day, the researchers also distributed the questionnaires to the control group who received no intervention in a separate place to prevent data bias between both groups.

Data Analysis: The data were analyzed using the Wilcoxon Signed Rank Test (administered to both treatment and control groups) at a significance level (α) of ≤ 0.05. Hypothesis testing for figuring out the post-test results of the treatment and control groups were undertaken using the Mann-Whitney Test at a significance level (α) of ≤ 0.05.

Results

Based on the interview with the head of the emergency department of RSU Haji Surabaya, it was found that in a 24-hour period, there were approximately 100 visits to the emergency department daily.

Wilcoxon Signed Rank Test p = 0.046 Wilcoxon Signed Rank Test p = 0.157

Description: Wilcoxon Signed Rank Test significant at p < 0.05

The questionnaire responses show that in the working posture pre-test, two of six respondents in the treatment group fell into category 3, namely dangerous and in need of immediate correction. Meanwhile, most respondents in the control group (three people) had no problem with their posture.

In the Wilcoxon Signed Rank Test, the treatment group yielded a p value of 0.046, suggesting that there was a significant difference in the nurses’ work posture between pre-test and post-test. Meanwhile, the control group yielded a p value of 0.157 in the Wilcoxon Signed Rank Test, which suggests that there was a significant difference in the nurses’ work posture between pre-test and post-test. As for the Mann-Whitney analysis results, a p value of 1.000 shows that back exercise was ineffective for the nurses’ work posture correction.

\[ p = 0.025 \quad p = 0.317 \quad p = 0.083 \]

Description: Wilcoxon Signed Rank Test significant at \( p < 0.05 \)

From the Wilcoxon Signed Rank Test on the treatment group, a \( p \) value of 0.025 was obtained in the pain frequency category, meaning that there was a significant difference in the pain frequency between pre-test and post-test. No change in the pain frequency value was found in all control group respondents who received no intervention at all \( (p = 0.157) \). The \( p \) value of 0.014 obtained from the Mann-Whitney analysis shows that back exercise was effective in reducing the frequency of pain felt by the nurses.

The Wilcoxon Signed Rank Test results for the treatment group in the pain period category show a \( p \) value of 0.317, meaning that there was no significant difference in the pain period between pre-test and post-test. Two control group respondents experienced a change in category. As for the control group, the \( p \) value obtained from the Wilcoxon Signed Rank Test was 0.317, which means that there was no significant difference in the pain period between pre-test and post-test. Meanwhile, from the Mann-Whitney analysis, a \( p \) value of 0.523 was obtained, meaning that back pain intervention was ineffective in reducing the period of pain felt by the nurses.

From the Wilcoxon Signed Rank Test on the treatment group, a \( p \) value of 0.083 was yielded in the pain scale category, meaning that there was no significant difference in the pain scale between pre-test and post-test. As for the control group, the \( p \) value from the Wilcoxon Signed Rank Test was 0.317, meaning that there was no significant difference in the pain scale between pre-test and post-test as well. A \( p \) value of 0.269 from the Mann-Whitney analysis suggests that back exercise intervention was ineffective in reducing the scale of pain felt by the nurses.

Discussion

Low back pain occurs as a result of muscular strain or spasm, strain of ligaments, degenerative discs, or herniation of nucleus pulposus from the middle section of intervertebalis discs. Ninety-five percent of disc herniation occurs somewhere between the fourth and fifth lumbar regions \((L4–5)\), while the remaining 5% occurs in cervical and thoracic regions. Continuous muscular strain or spasm will induce the breaking down of glycogens into lactic acids. The accumulated lactic acids can irritate muscular nerve fibers and trigger low back pain.

Pain scale may be effectively controlled by exercise therapy (either land- or water-based). A high level of habit may reduce the scale of pain. Back exercises that are performed properly and correctly within a relatively long period will actively increase the muscular strength, hence the name active stabilization. The increased muscular strength will in turn improve the body’s endurance against changes in motion and static and dynamic loading.

Back exercise intervention was also performed in the treatment group with low back pain due to spondylosis lumbalis, which resulted in an increased range of motion. The increase in the range of motion would affect the postures displayed by the nurses during work. Back exercise is highly effective for musculoskeletal strengthening, thereby reducing pain in patients with chronic back and neck pain. Low back pain management principally aims at eliminating pain, returning activity and movement to their normal condition, and preventing relapse.

Back exercise is highly recommended for health lifestyle, longevity, mental health, and management.
of some chronic diseases such as low back pain\textsuperscript{16,17}. After receiving back exercise, nurses will have higher flexibility and endurance in lifting, pushing, or pulling patients when working. The more the nurses improve their muscular strength and grow used to perform the movements appropriate for spinal mechanics, the better they will endure the pain.

**Conclusion**

The dominant factor that influences low back pain is the posture of the nurses. Back exercise is effective for reducing low back pain prevalence by reducing pain frequency, as is the case in the pain frequency reduction in nurses who work at hospitals. After receiving back exercise intervention, nurses will have higher flexibility and endurance in lifting, pushing, or pulling patients when working.

The Effect of Breeding Management on the Prevalence and Trematode Infection Degree in Calves

Haris Setiawan¹, Kusnoto¹, Mas’ud Hariadi¹
¹Department of Veterinary Education, Faculty of Veterinary, Universitas Airlangga, Jl. Mulyorejo, Surabaya, East Java

ABSTRACT

Background: Poor management in farms can have a negative effect on livestock. The low hygiene of animal feed is one-factor causing various kinds of parasitic agents which can infect livestock.

Objective: Examining the effect of breeding management on the prevalence and degree of Trematode worm infection in calves.

Method: The samples of this study were 49 calves aged less than 205 days which were randomly selected; 5-7 grams of fresh fecal samples were taken directly from the rectum rectally and put in a plastic pot containing 10% formalin. Sample examination was carried out by sedimentation method and buoyancy method.

Results: It was found that 12 samples contained Trematode worms. There are several types of worm eggs, including Fasciola spp., and Paramphistomum spp. Calculation of Worm Eggs per Gram of Stool in 12 positive samples showed a single infection of Fasciola spp. on an average of 0-460 worm eggs per gram of stool, a single infection of Paramphistomum spp. on an average of 0-100 worm eggs per gram of stool, and mixed Fasciola spp. and Paramphistomum spp. infection on an average of 0-700 worm eggs per gram of stool. The livestock breeding system which is widely applied is caging. The prevalence of Trematodes in calves was 24.4%, and the average degree of infection was mild, between 1-499 eggs per gram of stool.

Conclusion: The prevalence and degree of infection of Trematode worms are influenced by breeding management applied by farmers.

Keywords: Breeding management, Trematode, Calves, Prevalence, Infection degree

Introduction

Parasites affect not only the health of livestock but also the productive and reproductive performance. Livestock infected with Trematode worms will experience physical changes; the body becomes very thin, resulting in low market value in the market. Calves aged 3 to 12 months are more susceptible to infection with various types of worms such as Nematodes, Trematodes and Cestoda compared to cows. One type of parasites which often infects calves is Trematode worms. Trematodes in the digestive tract is a problem for livestock managers, especially in dairy cattle. Trematode worms commonly infect livestock with low health and immunity. Infection in livestock with a shepherd breeding system occurs passively because the livestock drinks water or eat feed which has been infected by Trematode Metacercariae.

Diagnosis of the possibility of worm infection can be done by looking at the clinical symptoms identified in livestock, such as anorexia, anemia, diarrhea, dirty and gloomy hair, decreased body weight and stunted livestock growth. When a worm infection is found in livestock, the most common drug given to animals is Anthelmintics. Anthelmintics are a group of drugs used to expel worm parasites in the digestive tract and in other body tissues such as the liver, lungs, skin, and blood.
Livestock management is a factor that influences the prevalence of worm infections \(^9\). The breeding system is also one of the causes of parasitic infections \(^10\). Based on the above explanation, the purpose of this study was to determine the effect of breeding management on the prevalence and degree of Trematode worm infection in calves. The hypothesis of this study is that good livestock management results in the low prevalence and degree of Trematode worm infection in calves.

**Method**

This research was conducted at a dairy farm located in Malang Regency, East Java Province. The samples in this study were 49 calves Holstein breeders who were less than 205 days old \(^11\). The first phase of the research is taken the stools from the samples. The stool is freshly released fresh feces or taken directly from the rectum rectally with the amount 5-7 grams. The stools put in a plastic pot containing 10% formalin solution as a preservative. Each plastic pot was given a label indicating the number, origin, owner, information about the calf, and data management applied. The collected stools were examined at the Helminthology Laboratory of the Faculty of Veterinary Medicine, Universitas Airlangga.

Sample examination was carried out by two methods, sedimentation method and buoyancy method. In the sedimentation method, the stools were inserted into a centrifuge tube, added with distilled water with a ratio of 1:10, then filtered and centrifuged for 2-5 minutes at a speed of 1500 rpm. After being centrifuged, the supernatant at the top was removed and few deposits were left. Distilled water was added to the remaining sediment and centrifuged for 2-5 minutes until the supernatant looked clear. After it was clear, the supernatant was removed and the remaining filtrate was left. The sediment then taken with a Pasteur pipette and dropped on an *object glass* and covered with a glass cover. It was then examined with a microscope with a magnification of 100 times.

Examination of the samples using the floating method is similar to the sedimentation method, except that the buoyant method results in clear deposits of the supernatant being replaced with float substances. In this study, the float substance used was sucrose solution. The floating agent was added to 1 cm from the upper part of the tube. The results of the mixture were stirred and then centrifuged for 3-5 minutes at a speed of 1500 rpm. The floating agent was gradually added to the solution with Pasteur pipette until the surface looked convex. The glass cover was taken and placed on an object glass. It was then examined in a microscope with a magnification of 100 times.

The stools positively infected by Trematode worms were then calculated by the Worm Per Gram Stool Egg using the Lucient Brumpt method to determine the degree of infection. The stools were weighed \(\pm\) 1 gram and mixed with water. Dilution suspension was made 10 times and filtered. One drop of suspension was taken from the result. It was placed on an object glass and examined using a microscope with a magnification of 100 times. The examination result then analyzed using the prevalence formula to determine the prevalence percentage of Trematode. Data obtained from the questionnaire analyzed using the Classification and Regression Tree. Data from the calculation of Worm Per Gram Stool Eggs analyzed using Correspondence test.

**Results**

The results of laboratory tests indicated that 12 samples contained worm eggs, including *Fasciola* spp., and *Paramphistomum* spp. The types of eggs from Trematode class were *Fasciola* spp. and *Paramphistomum* spp. From a single infection in calves, 8 samples contained *Fasciola* spp. and 1 sample contained *Paramphistomum* spp. eggs. For the mixed infection, 3 samples contained *Fasciola* spp. and *Paramphistomum* spp. eggs. The identification of worm eggs was conducted by observing the worm morphology. The measurement of the eggs was done using *Optilab Imageraster* software. Sample examination using the sedimentation method revealed that *Fasciola* spp eggs had a shape of an ovoid with an operculum at one end of the egg. The egg size ranged from 162.76µm x 78.64µm. The number of *Paramphistomum* spp. eggs found in the samples using the sedimentation method was 4, where 1 sample was a single infection and 3 were a mixed infection. The wall was clear and the egg size ranged from 143.76µm x 75.02µm.
From the calculation of the Worm Eggs per Gram Stool of the 12 samples, detailed data of the degree of infection based on worm species were obtained. Single infection of Fasciola spp. was on average 0-460 worm eggs per gram of stool, a single infection of Paramphistomum spp. was on average 0-100 worm eggs per gram of stool and mixed infection of Fasciola spp. and Paramphistomum spp. was on average 0-700 worm eggs per gram of stool.

</table>

Based on the livestock breeding system, the prevalence of Trematodosis was 2% for livestock intensively bred and 22.4% for those semi-intensively bred. In terms of medication against trematodes, calves receiving helminthiasis medication were 2% and those never receiving the medication were 22.4%. Based on the condition of housing, clean housing was 0%, housing in a moderately clean condition was 2%, and dirty housing was 22.4%.

Based on the value (p<0.01), the data are significantly different. Samples infected by trematodes were 75.5%; infected by *Fasciola* spp. were 16.3%; those infected by *Paramphistomum* spp. were 2.0%; and samples infected by both *Fasciola* spp. and *Paramphistomum* spp. were 6.1%. The prevalence of Trematodes infection was affected by the medication given to the calves. The prevalence of *Fasciola* spp. infection in calves which never received anthelmintic medication was 63.6%; the prevalence of *Paramphistomum* spp. infection was 9.1%; and the prevalence of mixed infection of *Fasciola* spp. and *Paramphistomum* spp. was 27.3%. On the other hand, the prevalence of *Fasciola* spp. in calves which had received anthelmintic medication was 2.6%. The types of Trematodes in calves which had received anthelmintic medication are affected by the breeding system. There was no Trematode infection in calves bred intensively or caged, while *Fasciola* spp.infection of 25% was found in calves bred semi-intensively. The results of a correspondence test on the relationship between the type of worm and infection degree indicate light infection due to *Fasciola* spp. *Paramphistomum* spp. infection also resulted in light infection degree, while mixed infection of *Fasciola* spp. and *Paramphistomum* spp. resulted in a moderate infection degree.
Discussion

The results of the laboratory tests show that two species of Trematode class were identified: Fasciola spp. and Paramphistomum spp. Most of the farmers had their own farming for growing grass. Some farmers obtained feed from dry land. If the grasses taken are still wet, the farmers will wither the grasses. This treatment is applied to avoid bloating or tympanic cases in livestock and also reduce the chance of livestock being infected by metacercaria.

The feed from wetlands or rice fields might result in higher Trematode infection due to the influence of the hosts which are likely to appear in runny areas because the hosts need water. The prevalence of Trematode in calves which never receive anthelmintic medicine was 22.4%. Meanwhile, the prevalence of Trematode in calves which have received medicine against helminthiasis was 2%. The cleanliness of housing has an effect on the prevalence of Trematode. The highest prevalence was found in dirty housings, which was 22.4%. In moderately clean housings, the prevalence was 2%. There was a mixed infection in the positive samples. The mixed infection from the whole samples was 6.1%. Based on the data, the prevalence of Trematode worms was 24.4%. The prevalence of Trematode varies in different areas. This is due to geographical conditions affecting the presence of snails as the host in the environment. As farming is at an altitude of ± 1,100 meters above the sea level, the rainfall in the area is relatively high. The geographical condition is not suitable for the host of Trematodes, which is the freshwater gastropods [12]. Most freshwater gastropods live in shallow waters with the slow current so that the risk of Trematode infection will be lower in environments which do not support the life of gastropods [13].

This is related to the habitat of the host which tend to be runny areas as the host needs water for living [14]. Calves that have never received Anthelmintic medication have Fasciola spp. prevalence of 63.6%; Paramphistomum spp. of 9.1%; and mixed infection of Fasciola spp. and Paramphistomum spp. of 27.3%. These numbers are greater compared to the figures obtained from calves that have received anthelmintic medicine. The Fasciola spp infection was 2.6%; the number for Paramphistomum spp. infection, and mixed infection of Fasciola spp. and Paramphistomum was 0%. The administration of Anthelmintic is considered effective for eliminating Trematodes, but its effectiveness is influenced by the accuracy of the dose, the Anthelmintic spectrum, and the method of administration [15]. Calves that are bred semi-intensively and those grazed have Fasciola spp worm infection of 25%. This is different from calves that are bred intensively. There was no Trematode infection found. Calves that received Anthelmintic medication but are bred extensively or semi-intensively could be infected by Trematodes. From the results of the correspondence analysis, the relationship between the types of worms and the degree of infection were obtained. A mild infection is often caused by Fasciola spp., followed by infection due to Paramphistomum spp., which also results in mild infection. Meanwhile, mixed infections of Fasciola spp. and Paramphistomum spp. cause moderate infection. Infection of the Fasciola spp. is closer to mild infection compared to that of the Paramphistomum spp. because the host of Fasciola spp., the Lymnea rubiginosa species, can easily be found in the field.

Conclusions

The prevalence and infection degree of Trematode infecting calves are influenced by the breeding management implemented by farmers, especially the administration of Anthelmintic medication and breeding system. No Trematode infections were found in calves receiving Anthelmintic medication and bred with the intensive breeding system.

The Effectiveness of *Cynodon dactylon* Leaf Extract as Hepatoprotector in Liver Damage of Hyperglycemic *Mus musculus*

Ade Mahendra Putra¹, Retno Sri Wahjuni¹, Rahaju Ernawati¹

¹Faculty of Veterinary Medicine, Universitas Airlangga, Surabaya, Indonesia

**ABSTRACT**

**Background:** The number of people with diabetes rises every day. Its treatment commonly causes significant side effects that can even cause damage to body organs, including liver. Herbal medicine development is currently carried out widely as in the *Cynodon dactylon* plant. *C. dactylon* plant contains antioxidant compounds and hepatoprotective effects.

**Purpose:** The study aims to investigate hepatoprotective effect of *C. dactylon* leaf extract on liver histopathological changes of hyperglycemic *Mus musculus* and to investigate how much the dose of *C. dactylon* extract is most effective in protecting the liver.

**Method:** Experimental animals, *M. musculus*, were set up in hyperglycemic condition by administrating 10% glucose with a dose of 2,000 mg/kg of body weight (bw), and administrating extract of *C. dactylon* leaves with the doses of 250 mg/kg bw; 500 mg/kg bw; 750 mg/kg bw; and 1,000 mg/kg bw. Then, observation on the results of *M. musculus* liver histopathology was conducted by a scoring method. Afterward, a statistical test was performed.

**Result:** The most optimal hepatoprotective effect of *C. dactylon* extract was at the lowest administration dose of 250 mg/kg bw. This finding was evident from lowest scores for degeneration damage at 6.50 ± 0.00; necrosis damage at 6.00 ± 0.57; and inflammation rate at 7.13 ± 0.50.

**Conclusion:** Extract of *C. dactylon* leaves has a hepatoprotective effect on the liver histopathological changes of hyperglycemic *M. musculus*.

**Keywords:** hepatoprotective effect, *C. dactylon* leaf extract, liver, hyperglycemia

**Introduction**

In 2015, 415 million adults had diabetes. This figure was a 4-fold increase from 108 million people suffered from diabetes in 1980. In 2013, one of the biggest burdens of the global health expenditure was diabetes, reaching approximately 612 billion dollars ¹. Sixty percent of diabetics are type 2 diabetics in which insulin is incapable of carrying out its task of reducing blood glucose. This condition is commonly referred to as insulin resistance. The cost spent on diabetes treatment is very expensive. The total health budget spent to deal with diabetes was US$ 147 billion for 25.8 million people affected by diabetes ².

Hyperglycemia can deteriorate all organs, including liver. Liver can bind chemicals that enter the body. Liver cells are the main tissue that becomes target of increasing concentration of free radicals. It occurs because liver is organ where xenobiotic metabolism induces death of liver cells ³. Liver also has a central role in metabolism of toxic substances in the body ⁴. Up to the present, people with diabetes require lifelong therapy with various side effects. The application of herbal medicine as an alternative is currently being encouraged as it has natural compounds with fewer side effects as a good alternative⁵. *C. dactylon* contains 12.4% essential oils of triticin,
glycoside, saponin, tannin, flavonoid, and carbohydrate. The contained saponin, tannin, and flavonoid in other herbal plants, so far, are believed to be able to overcome diabetes cases affordably and naturally.

Based on these facts, this study was conducted to investigate the hepatoprotective effect of *C. dactylon* leaf extract on liver histopathological changes of hyperglycemic *M. musculus*. This study is also expected to be able to determine the optimal dose of *C. dactylon* leaf extract to reduce the impacts of liver tissue damage of hyperglycemic *M. Musculus*.

### Materials and Method

This research was conducted in October 2015 at the Laboratory of the Faculty of Veterinary Medicine, Universitas Airlangga.

**Instruments and Materials:** The instruments in this study included 6-7 wire-covered plastic tubs, rat feed, and drink, microtome, cage, paraffin block casts, tweezers, light microscope, 20 G needles, hot plate, digital scales, rat feeding tubes, Easy Touch® digital glucometer, tuberculin syringes, Soxhlet extractor, syringe, freeze drying extract dryer, surgical scissors, tweezers, blade, and scalpel.

The materials in this study were 2-3 months old BALB-C strain mice (*Mus musculus*), weighing 20-30 grams, mice feed, mice drinking water, Bermuda grass (*Cynodon dactylon*), 10% glucose, 70% alcohol, 96% ethanol, Hematoxylin-eosin (HE) stain, generic metformin from Kimia Farma®, tween 80, aquades, label paper, object glass, glass cover, and formalin buffer.

**Work Procedures:** This study used twenty four *M. Musculus* animals to be treated for 22 days. They were classified into 6 groups, i.e., hyperglycemic control group without therapy; hyperglycemic control group with metformin therapy; treatment groups with *Cynodon dactylon* extract therapy with the doses of 250 mg/kg bw, 500 mg/kg bw, 750 mg/kg bw, and 1,000 mg/kg bw. Environmental adaptation process took the first seven days. Then, from 8th until 22nd day, the treatment process was conducted. Research animals were administered with 10% glucose on the 8th day to the 22nd day at a dose of 2,000 mg/kg to obtain hyperglycemic conditions. P1 to P5 treatment groups were administered with 10% glucose treatment with a dose of 2,000 mg/kg bw from 8th day to 22nd day.

However, on 13th to 22nd day, the glucose infusion was carried out 60 minutes after the present of metformin therapy or *C. dactylon* leaf extract with different doses. The treatment group 1 (P1) used metformin therapy amounting to 65 mg/kg bw. P2 used *C. dactylon* extract therapy at a dose of 250 mg/kg bw. P3 used *C. dactylon* extract therapy at a dose of 500 mg/kg bw. P4 used *C. dactylon* extract therapy at a dose of 750 mg/kg bw. Last, P5 used *C. dactylon* extract therapy at a dose of 1,000 mg/kg bw.

Preparation of *C. dactylon* leaf extract employed a solid-liquid extraction method with decocta water solvent. The extract obtained was then diffraction to separate non-polysaccharide fraction by adding ethanol until the precipitation stopped and then filtered to separate the polysaccharide and non-polysaccharide components. Filtrate that was extracted from the results of filtration was a non-polysaccharide fraction evaporated with a Rotary evaporator to vaporize ethanol and aquades solvents until a thick extract was obtained. Thick extract was dried through a freeze-drying method so that it became powder extract.

Measurements of *M. musculus* sugar levels utilized the Easy Touch® digital glucometer after the animals were put to fasting conditions for 6-8 hours. Measurements were carried out on 7th, 10th, 12th, 19th, and 22nd days. Preparation of hepatic histopathology of *M. musculus* was carried out through euthanasia of cervical dislocation. *M. musculus* livers were placed in a pot containing 10% formalin buffer fixation solution. Histopathology was made by Hematoxylin-Eosin (HE) staining. Histopathological examination was carried out by using a microscope at 400x and 1,000x magnifications.

Scoring of liver histopathology changes that occurred in each visual field was carried out by using the scoring method. The degree of damage of each sample was determined by summing up all determined histopathological lesions. In scoring method assessment, there were three forms of observed lesions, i.e., degeneration and focal necrosis, perportal and bridging necrosis, and last inflammatory cell infiltration (inflammation).

**Data Analysis:** The data obtained from scoring results of hepatic histopathology were analyzed with Kruskal-Wallis test and if there were significant differences among treatment groups (p < 0.05), Mann-Whitney test would be applied.
Result

Hepatic cell histopathology changes of hyperglycemic *M. musculus* occurred in the form of degeneration, necrosis, and inflammation. Scoring results of hepatic histopathology were analyzed with the Kruskal-Wallis test and then analyzed with the Mann-Whitney test. The results of analysis can be observed in Table 1.

Table 1: The mean and standard deviation scores of degeneration, necrosis, and liver inflammation of *M. musculus* for each treatment.

Note: P0 = control, P1 = metformin at a dose of 65 mg/kg bw, P2 = *C. dactylon* extract at a dose of 250 mg/kg bw, P3 = *C. dactylon* extract at a dose of 500 mg/kg bw, P4 = *C. dactylon* extract at a dose of 750 mg/kg bw, P5 = *C. dactylon* extract at a dose of 1,000 mg/kg bw. Letter notations stated significant differences (p < 0.05) among each treatment. Same-letter notation means that the difference was not significantly different. Different letter notations mean that the results were significantly different.

Based on Table 1, test results were significantly different (p <0.05) in all treatments. The lowest score of degeneration damage was in P2, reaching 6.50 ± 0.00. Highest score result was in P0 and P5 amounting to 17.50 ± 0.00 and 17.50 ± 0.00 respectively. Lowest score of necrosis damage was in P2, reaching 6.00 ± 0.5.

Highest scores of inflammation damage were in P0 and P5, reaching 20.50 ± 0.00 and 20.50 ± 0.00 respectively. Lowest score was in P2, reaching 7.13 ± 0.50. Highest score was found in P0 with 21.88 ± 0.50. Thus, administering *C. dactylon* extract at the dose of 250 mg/kg bw resulted in best hepatoprotective effect. Qualitative hepatoprotective effects of *C. dactylon* leave extract can be observed in liver histopathology of *M. musculus* in every treatment.
Based on Figure 1, the liver cells seemed to experience degeneration, necrosis, and inflammatory lesions in P0, which was the most severe inflammatory lesion among the other treatment groups. The histopathological descriptions in the P1 shows liver cells experienced degeneration, necrosis, and inflammation but not as severe as in P0 group.

The P2 treatment group with C. dactylon extract therapy was the treatment with the lowest score in the quantitative test. However, there was still degeneration, necrosis, and inflammation damages in a lower intensity. The P3 treatment group suggested that the damages in the livers of M. musculus were similar to the P1 treatment group. The P4 suggested increased damage compared to P1. The liver histopathology of P5 treatment group suggested severe damage comparable to the liver hyperglycemic of P0 group.

The blood sugar examination levels also suggested an influence on each treatment administered by C. dactylon extract. The sugar content can be observed in Table 2.

Note: P0 = control variable, P1 = metformin at a dose of 65 mg/kg bw, P2 = C. dactylon leaf extract at a dose of 250 mg/kg bw, P3 = C. dactylon extract at a dose of 500 mg/kg bw, P4 = C. Dactylon leaf extract at a dose of 750 mg/kg bw, P5 = C. dactylon extract at a dose of 1000 mg/kg bw.

Based on Table 2, it was suggested that the general M. musculus’s normal blood sugar content on the 7th day was normal at less than 100 mg/dL. On the 10th day after 10%, glucose was administered for three days, all M. musculus’s sugar levels increased at more than 100 mg/dL, meaning that M. musculus had reached hyperglycemia conditions. On the 19th day, after the treatment with metformin therapy or C. dactylon leaf extract was administered, the P2 treatment group suggested a drastically decreasing sugar level. On the last treatment day, the 22nd day, only in P2 treatment did the sugar level decreased to less than 100 mg/dL.
Discussion

The lowest liver histopathological degeneration score was in P2, which was significantly different from the control group (P0) and P5 treatment group with C. dactylon leaf extract administration at the high dose of 1,000 mg/kg bw. Many liver cells that experienced degeneration could not maintain its balance so that the damaged cells were irreversible. The prolonged disturbances could result in the initial reversible injury at first. Then, it reached the point of no return phase, and it became irreversible where the cells could not recover and experienced death, known as necrosis. The dead cell nucleus looks smaller and the chromatin, and reticular fibers multiply, the nucleus becomes denser, and then the cells become eosinophilic (karyolysis) 12.

The P2 treatment group reached the lowest histopathological necrosis score, and its value was insignificantly different from P3 and P4 because the antioxidant composition in C. dactylon was capable of protecting liver cells. One of the hepatoprotectors that improves liver function is the antioxidant activity of C. dactylon was capable against hyperglycemic mice’s liver. The highest hepatoprotective plant compounds, including flavonoids, can protect the liver cells and repair the damaged liver tissue 13. P5 and P0 groups were significantly different from the other treatments because both of them regulated the level of severe damage. P5 group had the highest dose of C. dactylon leaf extract. It could be analogized with the optimal dose of drug consumption. The dosage curve and effect had the sigmoid-shaped, so if the administered dose were more than the maximum limit, it would decrease the drug function 14. This fact was similar to C. dactylon dosage, where if the dosage were more than it should be, it would reduce the hepatoprotective effect.

According to the histopathology score, the lowest degeneration score and necrosis score were experienced by the P2 group. The hepatoprotective plant compounds, including flavonoids, can protect the liver cells and repair the damaged liver tissue 15. Quercetin contained in flavonoid extract of C. dactylon leaves is predicted to be capable of preventing liver damage through its activity in suppressing TNF-α production as a hepatotoxic mediator and increasing the production of IL-10 as a hepatoprotective mediator. Thus, TNF-α activity can reduce the spurring of inflammation or damage to the liver tissue. The increasing production of IL-10 by quercetin can prevent the liver from being damaged due to glucose induction 16.

The lowest liver histopathological inflammatory scores in P2 and P3 groups were not significantly different from the P1 group as the standard drug treatment method for metformin. Phenolic compounds, such as flavonoids, have free radical scavenger antioxidant activity 17. In this study, the highest inflammatory score was experienced in P0 group. This situation caused oxidative stress and increased the levels of Reactive Oxygen Species (ROS), which lead to insulin resistance. The hyperglycemia pathogenic effects were mediated to a significant degree by increasing the production of ROS. Oxidative damage could lead to lipid destruction or even hardening, which is the composer of all cell membranes. The destructing or hardening cells occurs due to lipid peroxidation. It causes cell death or the cells inability to get nutrients or the inability to communicate with other cells properly 18.

Low dosage of C. dactylon leaf extract at a dose of 250 mg/kg bw was capable of obtaining a hepatoprotective effect and was capable of reducing blood sugar levels to its normal values. The blood glucose levels in the mice are classified as hyperglycemic if the mice’s blood glucose levels exceed 125 mg/dL after setting up in fasting conditions for 6-8 hours. In fasting condition, the mice’s normal blood glucose levels range from 50-125 mg/dL 19.

Conclusion

C. dactylon leaf extract has the potential to be a hepatoprotector against hyperglycemic mice’s liver. The effective dosage of C. dactylon as a hepatoprotector is at a dose of 250 mg/kg bw.

Further research is required to investigate the effect of administering C. dactylon leaf extract towards the levels of ROS (Reactive Oxygen Species) and other organs in the hyperglycemic M. musculus.

Ethical Clearance: The research process was using experimental method that was accordant with the ethical research principle based on the regulation of research ethic committee. The present study was carried out in accordance with the research principles. This study implemented the basic principle ethics of respect, beneficence, non-maleficence, and justice for animal.

Conflict of Interest: The author reports no conflict of interest of this work.

The Relationship between the Forms of Social Interactions and the Life Quality of the Elderly

Muthmainnah¹, Elida Ulfiana¹, Setho Hadisuyatmana¹
¹Faculty of Nursing, Universitas Airlangga, Surabaya, Jawa Timur

ABSTRACT

Background: The decreasing social interactions in the elderly can make them feel isolated. Some of them feel lonely and experience social isolation and stress, which can affect the quality of life of the elderly.

Purpose: This research aims to analyze the relationship between social interactions, the quality of life of the elderly, and the forms of the social interactions.

Method: This research is a cross sectional study with the population of elders living in Nursing Home. Fifteen respondents were recruited using total sampling technique. Social interaction is used as an independent variable and quality of life is the dependent variable. Research data were obtained using a questionnaire and analyzed using Spearman Rho with a significance level of p <0.05.

Results: The results indicate that there is no significant relationship between social interaction and quality of life in the elderly (p = 0.760).

Conclusion: Social interactions in nursing homes do not have a correlation with the quality of life in the elderly who live in the nursing homes. Other variables that influence social interactions in nursing homes need to be examined. Nurses must maintain social interactions by improving some activities for better quality of life.

Keywords: Social Interaction, Quality of Life, Elderly

Introduction

In Indonesia, the elderly population grows more rapidly compared to other age groups. The rapid growth has occurred since 2013 at 8.9% and 13.4% in the world (¹). Three provinces have the highest percentage of the elderly population compared to the other provinces, which are DI Yogyakarta (13.81%), Central Java (12.59), and East Java (12.25%) (²). It is estimated that the elderly population in Indonesia will continue to grow by around 450,000 people per year. In 2017, there were around 23.4 million elders in Indonesia, or 8.97% of the total population. Most of the elderly were women with a percentage of 52% (³). Therefore, in 2025, the number of elderly people in Indonesia is estimated to be around 34.22 million (⁴). The increasing number reflects the success of the Government in improving the welfare and life expectancy of the community. The Central Bureau of Statistics (BPS) stated that life expectancy within the period of 1995-2000 was 66.0 years; within the period of 2000-2005 was 67.8 years; within the period of 2005-2010 was 69.1 years; and within the period of 2010-2015 was 70.1 years.

This increasing number of the elderly poses quality of life problem. At the moment, there are many families that decide to leave the elderly in nursing homes. Thus, in the future, the nursing homes play an important role in maintaining and improving the quality of life of the elderly. This is not necessarily acceptable to the elderly and can make them feel abandoned, ignored and lonely (⁵). World Health Organization defines quality of life as an individual’s perception of life in the society in the context of existing culture and value systems related to goals, expectations, standards and concerns (⁶). Some
previous studies have shown how social interactions affect the quality of life of the elderly.

The first study indicated that 10% of the elderly in the community had poor interactions, 76% had moderate interactions and 15% had good interactions (7). The second study showed that the percentage of the elderly with poor social interaction who experienced severe depression was 71.4%, while the percentage of the elderly with moderate social interaction who experienced severe depression was 31.4%, and the percentage of the elderly with good social interactions who experienced major depression was 12.5% (8). This shows that the better the elderly in social interactions, the less likely they experience major depression. Social interaction can also affect the psychological condition of the elderly (9)(10). The better the social interaction, the better the psychological condition of the elderly is, and this affects the quality of life of the elderly.

This study aims to provide insights into how social interactions affect the quality of life of the elderly living in nursing homes. It focuses on examining the forms of social interactions that can affect the quality of life of the elderly in Indonesia.

**Method**

**Design:** This study employed the Cross Sectional approach which emphasizes the moment of measurement or observation of independent and dependent variables at one time. In this research, the independent and dependent variables were assessed simultaneously at one time; so, there was no follow-up data measurement (11). This research was conducted at Anugerah Nursing Home, Surabaya from May to June 2016.

**Sample and Sampling:** The samples of this study were 15 elders who met the criteria. The sampling technique used was total sampling.

**Research Variables:** The independent variable in this study is the forms of social interactions while the dependent variable is the quality of life of the elderly.

**Research Instrument:** This research employed three types of questionnaires. The first type was the demographic questionnaire containing such data as number of respondents, gender, age, religion, ethnicity, recent education, period of living in nursing homes, daily activities to spare time. The second questionnaire focused on the form of social interactions which was adopted from the social interaction questionnaire (12) with a total of 20 questions and 5 questions in each form of social interaction. The last was World Health Organization-Quality of Life-BREF (WHOQOL-BREF) quality of life questionnaire (13).

**Data Analysis:** The data analyzed using the spearman rho test and All statistical tests used a significance level of \( \alpha = 0.05 \) (SPSS 20 windows program).

**Results**

**Demographic Characteristics of the Respondents:** The samples of this research were 15 respondents. The demographic characteristics of the respondents were female aged 60-69 years old (33.3%), 70-79 years old (33.3%) and above 80 years old (33.3%). All respondents were Christians and most of them were Javanese (80%). In terms of education background, almost half of the respondents did not have any education background (46.6%). Based on the period of living in the nursing home, 13 elders (86.6%) have lived in the nursing home for 0-5 years and all of the elderly did not work.

**Forms of Social Interactions:** Social interactions have several forms in social situations. The forms are cooperation, competition, conflict and accommodation (14). Data on the forms of social interactions are presented in the following table.

Table 2 indicates that the highest value is code 4, which is accommodation with a total of 8 respondents or 53.3%.

Quality of Life of the Elderly: The quality of life of the elderly is measured from several aspects: health, psychological condition, social relation, and the environment. The life quality of the elderly in the nursing home is generally moderate (13 respondents or 80%) while the rest of the elderly have good quality of life. The analysis on the correlation between the forms of social interactions and the quality of life of the elderly conducted based on the Spearman’s rho test generated a correlation value of 0.760 and a p-value of 0.86. This indicates that there is no significant relationship between the forms of social interactions and the quality of life of the elderly living in Anugerah nursing home.

Forms of Social Interactions: The most dominant form of social interactions is accommodation. Most of the elderly living in the nursing home are Javanese. Based on the anthropology of Javanese, the Javanese culture is seen as elastic. The elasticity of the culture refers to flexibility in overcoming problems or inputs from the social environment. This suggests that Javanese people and Javanese culture have the ability to continuously adapt to challenges and changes.

Discussion

The results of this study are different from those of previous studies focusing on the relationship between social interactions and the quality of life of the elderly. This study reveals that at the nursing home, social interaction does not have a significant relationship with the quality of life of the elderly. This is related to the low number of activities which can facilitate social interactions between elders living in the nursing home. This might be due to the lack of health workers in the nursing home. Most of the activities in the nursing home are spiritual activities such as praying in the morning and evening. Spiritual activities are considered sufficient to meet the needs of the elderly because the higher the religiosity level of a person, the person will be happier, and might have better mental and physical conditions.

Forms of Social Interactions: The most dominant form of social interactions is accommodation. Most of the elderly living in the nursing home are Javanese. Based on the anthropology of Javanese, the Javanese culture is seen as elastic. The elasticity of the culture refers to flexibility in overcoming problems or inputs from the social environment. This suggests that Javanese people and Javanese culture have the ability to continuously adapt to challenges and changes.

The ability of the elderly to continuously establish social interactions is the key to maintaining their social status based on their ability to interact. Good social interactions allow the elderly to get a feeling of having a group in which they can share stories, interests, and concerns. They also have opportunities to do various activities together. The nursing home will become a place for the development of social interactions, because they will live together with fellow elderly people. Besides that, at the nursing home, they will receive trainings aimed at empowering them to remain productive. Physical and health development of the elderly will be effectively monitored.
In this study, social interactions refer to spiritual needs which provides comfort and peace. Based on the social theory, nurses should be able to facilitate social interactions among the elderly by holding discussions, exchange of ideas, and telling stories related to spirituality. Nurses must be able to provide inner peace in the religion which the elderly follow, especially if the elderly are sick or dying. Providing opportunities for the elderly to gather with fellow elderly people means creating interactions for the elderly. In the implementation, nurses can create social relations among the elderly, as well as between the elderly and the nurses themselves. The nurses should provide opportunities for the elderly to interact.

**Quality of Life of the Elderly:** The quality of life of the elderly in Anugerah Nursing Home is at moderate level. Quality of life is a measure of happiness; it comprises five aspects, which are feeling happy with daily activities, considering life meaningful and accepting life, feeling successful in achieving goals, having a positive self-image, and having an optimistic attitude and a good mood. Quality of life refers to individuals’ emotional, social and physical well-being as well as their ability to function in daily life. The quality of life of the elderly is influenced by several factors, which are the ability to adapt and accept all changes and setbacks, and the appreciation and reasonable treatment from the elderly’s social environment.

The decreasing quality of life is related to physiological diseases among the elderly, such as stroke and diabetes mellitus. Nursing is a holistic science which studies individuals from various aspects of life, including physiological, psychological, social, and spiritual aspects. Understanding the effect of social environment on health is important to help implement appropriate nursing care. Data on the quality of life of the elderly in various social settings can be used as an evaluation material for determining empowerment programs for the elderly, so that the program can effectively improve the quality of life of the elderly.

**The Relationship between the Forms of Social Interactions and the Quality of Life of the Elderly in Anugerah Nursing Home:** The forms of social interactions and the quality of life of the elderly at Anugerah Nursing Home are not significant in this study. The results of this study are in contrast with Lemon’s (2009) theory which states that elders who are socially active are more likely to adjust to aging well. Social interaction is the key to carrying out social activities. If the elderly are active in social activities, they will have high enthusiasm and life satisfaction as well as more positive mental health compared to those who are less active. Theory of activity states that in order for the elderly to succeed, they must remain socially active. The older a person is, the more active he or she should maintain social relations, both physically and emotionally. The life satisfaction of the elderly is very dependent on the continuity of their involvement in various activities (Latrancois 1984). This theory supports the elderly who are still active in various activities. The elderly will get satisfaction if they are still involved in various social activities.

This study shows that the elderly in Anugerah Nursing Home have moderate and good quality of life because they can accept their conditions. They pray do some activities with their abilities. They also feel happy and enjoy their time. In line with the role of nurses in providing excellent service through Teach and Support caregivers, nurses can facilitate social interactions among the elderly by holding discussions, exchanging ideas, and telling stories related to spirituality so that interactions between the elderly occur. This is one of the efforts in carrying out social approach. Nurses must be able to provide inner peace in their relationship with God or in the religion they follow, especially if the elderly are sick or dying. Providing opportunities to gather with fellow elders means creating interactions for the elderly so that they can improve their quality of life and enjoy the atmosphere of the nursing home.

Other studies in line with this study also conclude that there is no meaningful relationship between social interactions and the quality of life of the elderly at Abiyoso Paken Nursing Home. The researchers believe that each individual will have different social interactions that can affect the quality of life of the elderly. The results of this study are limited only to female respondents and the number of samples. Because the research subjects were all women, the results could not be generalized to all of the elderly population.

**Conclusion**

In conclusion, the social interactions that occur in the nursing home do not always have a significant influence on the quality of life of the elderly. However, there are
several aspects which can affect the quality of life of the elderly, such as the psychological aspect of the elderly accepting their current situation. This does not have a significant effect on the quality of life of the elderly in nursing homes. In addition, nursing homes can improve social activities based on the needs of the elderly living in the nursing homes.

**Ethical Clearance:** The current study was carried out in correspondence with the research principles. It is implemented the basic principle ethics of respect, beneficence, non-maleficence, and justice. The research process entangles participants in the survey using a compatible questionnaire that was in accordance with the ethical research principle based on the research ethics committee’s regulation.

**Conflict of Interest:** The author reports no conflict of interest of this work.

**Source of Funding:** This study is completed with individual funding.

Educational Game Methods of Attaching Images to Slide Calendar towards School-Age Children’s Knowledge and Attitudes on Choosing Healthy Snacks

Adzan Fachrurrozi¹, Tiyas Kusumaningrum¹, Praba Diyan Rachmawati¹
¹Faculty of Nursing, Universitas Airlangga, Mulyorejo Street, Surabaya, East Java, Indonesia

ABSTRACT

Introduction: There are several problems of fulfilling nutrition that disrupts health, growth, and development in children. There is no knowledge in children that resulting they consume unhealthy snacks. The purpose of this study was to determine the effect of educational game methods of attaching images to slide calendar towards school-age children’s knowledge and attitudes on choosing healthy snacks.

Method: This study was a quantitative study design with quasi experiment approach. There were 47 respondents selected in the treatment group and the control group, by using the method of educational game tools towards their knowledge and attitudes. The instruments used in this study were educational tools of attaching images to slide calendar and a modified questionnaire about attitudes and knowledge. Data analysis used the Mann Whitney test and the Wilcoxon signed rank test.

Results: The results showed there was a significant difference (p≤ 0.05) in the level of knowledge between the treatment and control groups after treatment. Whereas the attitude between the treatment and control groups after treatment resulted no significant difference (p≥ 0.05).

Conclusion: The educational tools methods of attaching images to slide calendar had an influence on increasing the knowledge of choosing healthy snacks in school-age children. Children did not experience changes in attitude of choosing healthy snacks, but children would increase their knowledge with the method of attaching images to slide calendar.

Keywords: paste the slide image calendar, knowledge, attitude, healthy snacks

Introduction

Children often do not have much knowledge, especially related to healthy foods selection¹. Children’s eating patterns give a strong influence on their health, especially in their growth and intellectual development². There are many cases that children experience allergies to foods, so that it is necessary to choose the right food for children³. The mistake in food selection can cause a variety of health problems such as anemia, obesity, and other nutritional disorders³.

Prevalence of children aged 6 to 11 years who experience a problem of nutrients exceeds in the United States as much as 7% then increased to 13% in the following year². In addition to nutrients exceeds, another problem that found is food poisoning. According to the Indonesian food and drug supervisory agency, known as Badan Pengawas Obat dan Makanan (BPOM) data in 2014, showed that schools are ranked second (28.9%) after residence (59.25%) in the most common places where the food poisoning cases found in Indonesia. Surveillance data on food poisoning in East Java, Indonesia, is still very high from year to year. In 2013, the number of outbreaks reached 60 incidences of food poisoning with 1,106 cases and the number of case fatality rates (CFR) of 0.27%⁴.

The results of preliminary data collection on students’ knowledge and attitudes about a healthy
snacks selection in two elementary schools, namely Sumbersekar I and SDN Mulyoagung II, found that the knowledge and attitudes of fourth grade students were still poor. Schools only overcome the problems by using posters about healthy snacks and providing a canteen with a healthy environment but still unable to increase the student’s awareness. There are still many students who often experience nutritional disorders such as vomiting, stomach ache, or diarrhea.

Children tend to like to consume random and unhealthy snacks, and not often occur dental caries. Children can recognize a variety of snacks that sold in schools by buying snacks. Snacks can contribute to 36% energy intake for school children, 29% protein, and 52% iron. Therefore, snacks have an important role in the growth and learning achievement of school children. According to Food and Agriculture Organization (FAO) in 2008, food or drinks sold by the street vendors are sold without proper preparation and processing. Snacks for children who are less nutritious will disrupt the child’s learning process.

Environment and society will shape children’s behavior and activities. One of places that can be used as a media for promoting health nutrition for children is school. Almost half a day spent by children at school, they also spend their breakfast and lunch time at school. Schools are the right medium for developing children to improve the children’s knowledge and attitudes. This study aimed to determine the effectiveness of educational game methods of attaching images to slide calendar towards knowledge and attitudes about the selection of healthy snacks for school-age children.

Method

This study used a quasy experimental design, which try to reveal a causal relationship by involving a control group in addition to the experimental group. The selection of these two groups did not use random techniques.

Population in this study were all elementary schools in the Dau Malang region which were reachable populations, namely all students in SDN Sumbersekar I and SDN Mulyoagung II. The inclusion and exclusion criteria were determined, so that 47 respondents were obtained for the treatment and control groups.

This study aimed to determine the effect of a educational game tools methods of attaching images to slide calendar on changes in knowledge and attitudes about the healthy snacks selection in school-age children. Some of the research instruments used in this study were the attaching images to slide calendar and modified questionnaire about knowledge and attitudes.

Attaching images to slide calendar game was made from modified images and used calendars. Images are presented by relating to the healthy snacks, which consists of the definition of snacks, types of snacks, characteristics of snacks, the positive or negative effects of snacks, sanitation and safety of snacks, and also the foodborne illnesses. When implementing health education by attaching an image to slide calendar, the researcher used the event program unit. The data obtained were processed and analyzed using the SPSS for Windows 21 software. Statistical analysis used in this study were the Mann Whitney test analysis to compare between the control group and the treatment group, then it was continued with the Wilcoxon signed rank test analysis to determine the difference between before and after treatment.

Results

The results of this research related to the educational game method of attaching images to slide calendar towards the knowledge and attitudes about the healthy snacks selection in school-age children were explained through demographic characteristics. General data describes the demographic characteristics of respondents including (1) age and sex, (2) number of siblings, (3) father’s education, (4) mother’s education, (5) father’s work, (6) mother’s work, (7) parents’ income, (8) breakfast, (9) information about healthy snacks, and (10) sources of information, for more details here is a following table of demographic respondents:

</table>

The results shown in the treatment group and the control group were mostly 9 years old. Most of respondents in both treatment group and control group had a breakfast habits. Most of respondents in the treatment group had received information related to healthy snacks with sources of information from their parents. While the entire respondents in the control group had received information about healthy snacks and the information sources mostly obtained from the school teachers.
The results of the Wilcoxon test analysis in the treatment group showed a p value = 0.000 so that p ≤ 0.05, which means there was a significant difference in the level of knowledge in pre test and post test. While the results of the Mann Whitney test analysis at post test showed a p value = 0.000, so that p ≤ α ≤ 0.05, which means that there was a significant difference in the level of knowledge between the treatment and control groups after the intervention. This proved that health education with educational game tools of attaching images to slide calendar had a significant influence on the level of children’s knowledge in the healthy snacks selection.

</tbody>
</table>

The results of the Wilcoxon test and the Mann Whitney test in the treatment group and the control group obtained p values p ≥ α ≥ 0.05, which means there were no significant differences in attitude levels during pre-test and post-test. This proved that health education with educational game tools of attaching images to slide calendar did not have a significant effect on the level of children’s attitudes in the healthy snacks selection.

Discussion

Before being given a health education with the educational game tools of attaching images to a slide calendar, most of the respondents in the treatment group had a poor knowledge about healthy snacks. After intervention in a period of one day to one week, then post test was performed. Age affects person’s perception and mindset. An increase in age will also develop the ability to capture the information and mindset, so that the knowledge gained is getting better. Based on this theory, changes in knowledge can occur because the respondents in this study were 4th graders who aged 9 to 11 years. Children aged 9-11 years was in the developmental stage that have entered an operational concrete stage where children are able to think logically, make sense, and increasingly socialized. This resulted in an increase in the post test in the treatment group.

The economic status of the respondents’ parents in the treatment group was mostly in a low condition, which as many as 16 respondents. The average income of the respondents’ parents is below the regional minimum wage standard of Malang city. Respondents’ parents who have a low economy often have a difficulty in reaching the healthy food. Many children who have a high BMI due to parent’s inability to provide proper food.

Educational game methods of attaching images to slide calendar was effective enough to improve the children’s knowledge level. Previous studies on an educational program attracted the attention of the children so that children easily apply with the things they learned. Children tend to be interested in a creative learning system that contains elements of education. An activity in the form of a game that contains education will be easy for children to absorb. The creative health education program is also able to control the eating habits of the overweight children.

Educational game tools used in the learning activity provide an optimal function in children’s development, where children can develop physical abilities, language, cognitive abilities, and social adaptation through this game. One educational game tool is attaching images to slide calendar. This game has 3 stages process that can increase children’s knowledge, the first stage is the learning process (entering information obtained into memory), the second stage is the retention process (storing information obtained), and the third stage is
the recall process (recall information obtained). So that someone is expected to be able to improve his/her understanding of information and remember information obtained. Health education with educational game tools of attaching images to slide calendar is used as a method of health promotion to increase a knowledge level about the healthy snacks selection.

This study showed there was no improvement attitudes because respondents did not meet the level of attitudes which included receiving, responding, respecting, and being responsible which took time in the process. This can caused by when the intervention of health education with educational game tools was given, there were some male students who are not paying attention when the researcher gave an explanation, so that disturbed other students to concentrate on receiving the information. According to Gurian (2010) most boys are very active and unable to calm down while studying so they have more difficulty in concentrating than girls.

**Conclusion**

The method of educational tools of attaching images to slide calendar had an effect on increasing the knowledge level in school-age children regarding the healthy snacks selection. Respondents’ attitudes about choosing healthy snacks did not change, but almost all respondents got an increased scores after being given the intervention of educational game tools of attaching images to slide calendar. The method of educational game tools of attaching images to slide calendar can be used as one of the health promotion intervention methods for children in school.

**Ethical Clearance:** This study has obtained the feasibility of ethical review in the Health Research Ethics Commission of the Faculty of Nursing, Airlangga University, Surabaya, Indonesia with No. 168-KEPK.

The Correlation between Dementia Severity and Caregiver Burden Level in Community

Eryin Sulistyani¹, Joni Haryanto², Makhfudli²
¹Faculty of Nursing, Universitas Airlangga; ²Department of Psychiatric Nursing and Community, Universitas Airlangga, Jl. Mulyorejo Kampus C Universitas Airlangga, Surabaya, Indonesia

ABSTRACT

Objective: This research aim is to investigate the correlation between dementia severity and caregiver burden level.

Methodology: This research is a cross-sectional research involving 23 respondents who took care of the elderly with dementia. The questionnaire employed in the data collection was MMSE (Mini-Mental Status Examination) questionnaire to assess the dementia severity level, while the data on the caregiver burden level was collected through the Caregiver Burden questionnaire by Zarit.

Result: Among 23 elderly taken care, 61% of them suffered from severe dementia. Meanwhile, the caregiver burden level of the respondents was measured in mild-moderate level. There were no respondents with severe caregiver burden level. The caregiver burden level suggested a different result in each dementia severity level. Furthermore, the correlation between dementia severity and caregiver burden level indicated p value of 0.001 and r value of 0.694 (significance α < 0.05).

Conclusion: There was a significant relationship between dementia severity level and caregiver burden level. Positive coping played a highly critical role in minimizing the caregiver burden level experienced by elderly caregivers.

Keywords: caregiver burden level, dementia severity, elderly patients

Introduction

Along with the increase in life expectancy, currently, there are 35.6 million people suffering from dementia. This number will double in every two decades where the figure is estimated to reach 65.7 million by 2030. Furthermore, it is estimated that 11.4 million elderly will suffer from dementia in 2050 ¹. Dementia is a primary chronic disease that contributes to disability and care needs in the elderly ². The increase in dementia incidence is one of the health crisis currently observed in the community. It is estimated that 47 million people worldwide in 2017 suffered from dementia and most of them lived together and were taken care of by their families in the community ³. Dementia is the factor of major disability in the world that causes 11.9% of years lived with disability (YLDS). Moreover, dementia leads to the dependence of the elderly life, in either high, medium, or low-income countries. In 2010, the cost to take care of dementia patients was estimated to reach US$ 604 billion globally ⁴. It is generally known that taking care of dementia in elderly patients extremely burdens the caregivers ⁵.

From the previous research, it is discovered that taking care of the elderly with dementia might lead to caregiver burden ¹,²,⁵–⁸. The caregiver burden includes emotional, social and financial hardship, as well as routine activity constraints that can threaten the caregivers in helping the elderly patients to fulfill their daily life ⁶,⁹. Moreover, several studies also state that
taking care of the elderly with dementia can be stressful for the caregivers due to the behavior issue, time spent to take care and psychological well-being provision. In addition, the family taking care of the elderly with dementia incurs financial burden. As a matter of fact, 95% of the elderly live with their family and depend on their family to provide health care and other aids. Family members who are in charge of being the caregivers include the spouse, the adult children, and other close relatives.

The assistance provided by a caregiver is not only limited to housework. Instead, it is divided into four categories: 1) physical care, including feeding, putting on clothes, cutting nails, cleaning rooms, etc.; 2) social care, including visiting entertainment venues, acting as an informant from all over the world outside of the home care; 3) emotional care, including showing concern, love, and affection for the elderly, not only with words but also through the tasks done; and last 4) quality care, covering monitoring the level of care, standard of treatment, and attention to problems that arise due to illness. Another assistance provided by the caregiver include spiritual assistance.

Caregiving to the elderly with dementia requires a lot of time and physical assistance. A survey in 2003 in the United States described that a quarter of caregivers spent 40 hours per week to take care of elderly dementia patients.

Taking care of elderly patients might put on burden or strain to caregivers which affect the family life quality. Caregiver burden is a multi-dimension response toward physical, psychological, social, and financial stressors associated with the caregivers’ experience in treating their clients. The burden in taking care of the elderly are, among others, related to physical problems, such as fatigue, sleep disorder, and chronic condition. Meanwhile, the psychological problems consist of the feelings of anxiety, worry, pessimism, shame, guilt, self-esteem disorders, and depression. The social issues include limitations in building relationships with other people, conducting social activities, and having free time. in addition, financial problems may arise, namely cost and financial limitation since the caregivers cannot work as they take care of their sick family member. This research aims to identify the correlation between dementia severity level and caregiver burden of the family taking care of the elderly with dementia in the community.

Methodology

This research applied cross-sectional approach with quantitative method. The research was carried out in Ponorogo, Indonesia. The sample amount was 23 caregivers for the elderly and was selected based on purposive sampling technique with the following inclusion criteria: i) the elderly taken care aged more than 65 years; ii) family member’s age who took care for dementia patients was more than 21 years; iii) the family member took care for the elderly for more than 6 months.

The independent variable in this research was the dementia severity level of patients treated by their family members. The variable was measured by MMSE questionnaire covering orientation parameter, motorist registration, attention, and calculation, as well as re-introduction of language. On the other hand, the dependent variable in this research was the caregiver burden level of the family members treating the elderly. The variable was assessed by caregiver burden questionnaire of Zarit covering physical load, psychology, social and economy parameter.

The data was analyzed using the correlation test of Spearman Rank Correlation with significance level α < 0.05. Furthermore, the data was tested using SPSS for Windows software.

Results

Demography Data: Based on the research result, the data obtained from 23 respondents indicated that approximately 20 respondents (87%) were female. Meanwhile, nine respondents (39%) were aged around 36-45 years old. A total of 11 respondents (50%) were the biological children of the elderly with dementia. Meanwhile, a total of 8 respondents (35%) had treated the elderly with dementia for approximately 4 to 5 months. in addition, 11 respondents (48%) graduated from elementary schools. Last, 13 respondents (57%) worked as farmers.

This research aims to identify the correlation between dementia severity level and caregiver burden of the family taking care of the elderly with dementia in the community.

Note: * p < 0.005  
Correlation test with Spearman Rank Correlation α < 0.05

Correlation between the severity of dementia and the caregiver burden: Table 2 indicates that out of 23 respondents, three respondents (13%) taking care of the elderly suffered from light caregiver burden; six respondents (26%) suffered mild-moderate caregiver burden; five respondents (22%) suffered from mild-moderate caregiver burden. Meanwhile, eight respondents (35%) out of 14 caregiver respondents who took care of the elderly with severe dementia suffered from moderate-severe caregiver burden.
Discussion

Some issues complained by the caregivers were neuropsychiatric syndrome (NPS), functional disorders, memory disorders, and cognitive impairments. Some caregivers even detected that NPS was a functional disorder that mostly lead to strain and depression. In addition, coping toward behavioral problems of the elderly with dementia was also a heavy burden for the caregivers.

Based on the research results, it was identified that there was a correlation between the severity of dementia and the caregiver burden level. The correlation occurred since the behavioral change shown by the elderly dementia patients became the stressor for the family members taking care of them. These changes comprised of weakening physicality and inability to complete daily activities independently. Consequently, the elderly needed more help from the caregivers to perform their daily activities.

The elderly who were at the level of mild dementia were still capable of carrying out daily activities independently, and most of them could still be oriented to time and place. Nevertheless, the elderly sometimes forgot small things with a low value in the language domain. This finding was congruent with previous studies arguing that the elderly with mild dementia had begun to neglect house chores and were hard to have two-way communication. However they could still recognize people, home addresses and the streets around them. Respondents taking care of the elderly with mild dementia experience a caregiver burden at the level of none-mild and mild-moderate, which might result from the minimum assistance required by the elderly. In addition, the low score in the language domain based on the MMSE evaluation might be caused by the lack of knowledge, hence, the elderly sometimes found difficulties in understanding the assessor’s instruction.

Most of the respondents treating the elderly patients with moderate dementia level were in mild-moderate caregiver burden level. This might result from the respondents’ occasional assistance in fulfilling basic needs such as feeding and bathing. Usually, the elderly only required help in preparing their clothes because they often forgot where they put them. Respondents also stated that they should remind the patients to eat, take a bath and pray for the elderly with moderate dementia.

Moreover, if the elderly met their relatives, they would find it difficult to remember their names. Thus, the respondents should remind them. The elderly with moderate dementia encountered problems in completing a sequenced instruction. It implies that their language aspect was weak. Even, some elderly found it hard to mention time and place.

The respondents taking care of the elderly with severe dementia were at the caregiver burden level of mild-moderate and moderate-severe. It was because the elderly with severe dementia suffered from a decline in doing their activities independently. They occasionally did not recognize their caregivers, often talked digressively, and required maximum assistance in fulfilling ADL. The elderly with severe dementia were in the worst decline condition. They could not maintain their personal health (hygiene), had changed in thinking behavior and could not remember new information. The elderly with severe dementia were not supposed to be left alone since they could harm themselves and other people. Consequently, the family members of the elderly with severe dementia should supervise them strictly.

This study had several limitations, among others; the data collection in this study was based on self-report with questionnaires so that the perception of caregivers was highly personal. The assessment of caregiver burden was in a range. It was probable that the respondents encountered difficulty in selecting the available answers, i.e. “never, rarely, sometimes, often, and always.” Furthermore, the accuracy in completing the questionnaire was highly affected by the respondents’ honesty and understanding. This research detected a significant correlation between dementia severity and caregiver burden level. Nonetheless, further studies should be taken into account by involving larger samples in order to obtain better research objectivity.

Conclusion

This research discovered the significant relationship between dementia severity and caregiver burden level. The elderly with mild and moderate dementia did not require much help from their caregivers since they were still capable of performing their activities of daily living independently. In contrast, the elderly with severe dementia relied more on the caregivers’ help in fulfilling their activities in everyday life. Therefore, the caregivers should bear a heavier burden. It is expected that the caregivers could improve positive coping to decrease the burden they felt.
Ethical Clearance: The research was reviewed and approved by the Health Research Ethics Commission of Universitas Airlangga Number 06-KEPK. The research process involves participants in the survey using a questionnaire that was accordant with the ethical research principle based on the regulation of research ethic committee. The present study was carried out in accordance with the research principles. This study implemented the basic principle ethics of respect, beneficence, non-maleficence, and justice.

Conflict of Interest: The author reports no conflict of interest of this work.

Source of Funding: This study is done with individual funding.

An Exploratory Study in the Indonesian Archipelago: Are There Influenza B Virus (B-Victoria Sub-Type) in the Bat’s Respiratory Organs?

Muhammad Anas Wildanu Rahman1, Chairul Anwar Nidom1, Setya Budhi1
1Faculty of Veterinary, Universitas Airlangga, Surabaya, Indonesia

ABSTRACT

Bats act as hosts in carrying Influenza B disease and can act as a natural reservoir of various types of viruses, including Nipah virus, Hendra virus, and Ebola virus in mammals. This research aimed to study the presence of Influenza B virus (B-Victoria sub-type) in the respiration organs of bats (Chynoptera sp.) in Indonesian Archipelago. A total of 99 bats from several regions representing the islands in Indonesia were taken in Snowball sampling technique. Samples that had been isolated and passed the incubation period were tested using the Hemagglutination (HA) test and Hemagglutination Inhibition (HI) test. The data obtained were processed descriptively. The result showed that there were 13 samples positively in the Hemagglutination (HA) test (13.13%), but after going through the Hemagglutination Inhibition Test (HI) with B-Victoria antisera, no positive samples were found. We conclude that there was no virus type B influenza virus (B-Victoria sub-type) in the bat respiration organ.

Keywords: Influenza B virus, Respiratory Organ, Bats, B-Victoria sub-type

Introduction

Influenza viruses circulate and cause disease in humans every year. Influenza type B is considered a mild disease and lack of attention compared to influenza A, even though it has caused 20 to 50% of the total incidence of influenza in several regions of the world 1. The genus of Influenza B virus is generally considered a human virus. A chain of events that allows influenza viruses to be successfully transmitted in alternative host populations needs to be known 2. Animals can function as an intermediary spread of disease. Cats, like pigs, can act for the emergence of a new virus that has the potential for a pandemic 3. In recent years, bats (Chiroptera order) are known to act as important reservoirs of several viral diseases which allow infection in humans and other mammals 4. Bats play an important role in the emergence of severe acute respiratory syndrome (SARS). Interestingly, bats infected with various viruses rarely show clinical symptoms of the disease. The pathogenesis and potential threat of most viruses transmitted by bats to public health is still unknown. Besides, this host-virus interaction may result in a large diversity of zoonotic viruses in bats.5

Bats are important to be noticed because they consist of nearly 1,200 species in the world 6. The diversity of hosts raises questions about transmission of viruses between individuals of species that same and between species. In the case of multispecific roots, bats show high seroprevalence levels observed and related to ecology 7. Type B influenza is one of the important components of all major influenza diseases that attack humans, both B-Yamagata and B-Victoria. Normally, this Influenza B virus is only found in humans and pigs 8. However, the process of transmitting this virus needs to be known since bats are an important medium in transmitting other infectious viruses. Transmission of influenza viruses may occur directly from the dynamic interactions between animals, environmental factors and the human immune system even though barriers can occur between species and the virus itself 9. Short-term decisions on patient care, for example, in the case of vaccines and...
early onset of epidemiological examination, including WHO’s decision on vaccine composition are important 9.

Infectious diseases are a major threat to the welfare of animals and humans globally through threats from old and new pathogens that continue to emerge. Along with global climate change, agricultural practices and demographic presentations make conditions very favorable for the spread of diseases. Interaction between animals and humans can pose significant additional threats to human health, including influenza viruses10. The spread of viruses/zoonotic infections can occur through direct and indirect contact even though the spread of current diseases depends on strong assumptions about the contribution of indirect contact to the spread of infection 11.

If the Influenza B virus (B-Victoria sub-type) is found in the bat’s respiratory organs, it will easily be carried out further research for prevention of cross infection and treatment on veterinary medicine. Therefore this study aimed to identify the Influenza B virus (B-Victoria sub-type) in the respiratory organs of bats in the regions representing all islands in Indonesia.

Method

This descriptive study was conducted at the BSL-2 Avian Influenza Research Center (AIRC) Laboratory, Surabaya for 12 weeks in 2017. Sampling of 99 bats was carried out through the Snowball sampling method. Samples in the form of Cynoptera sp. bats were captured using bat trapped nets on trees and attics installed for 72 hours.

The research was carried out through several stages. The respiration organs of the bat which included the trachea and lung were taken through the freezing process (thawing). Next, the storage was carried out in 15 ml conical tube with a solution of 1:10 Phosphate Buffer Saline (PBS) at a speed of 3000 rpm for 10 minutes at 10°C. The samples were then placed in eppendorf, mashed, centrifuged, candling then isolated in ECE (embryonated chicken eggs) which have SAN (Specific Antibody Negative) characteristic. Isolation was carried out for 9-11 days to multiply the virus. ECE was then stored in an incubator at 37°C for three days by checking it every day. Embryos which were dead before the third day were removed and stored in the 4°C refrigerator for one night.

After going through the inoculation and isolation stages, the Hemagglutination Test (HA) of the Microtechnics was carried out using a 24-unit 4HA antigen. The Retraction Test was also performed to test the accuracy of the dilution of the antigen used. Positive samples on the Hemagglutination Test were then examined using Microtechnic Hemagglutination Inhibition (HI) Test with B-Victoria subtype Influenza type B antisera with HAU titers/0.025 mL. RBC used in this test came from chickens with a concentration of 0.5%. Data obtained from the results of virus isolation, Hemagglutination test and Hemagglutination inhibition test (HI) are presented in descriptive form.

Result

A total of 99 bats with the type of Cynoptera sp. represented all bats in the Indonesian archipelago. In the several regions, the largest number of samples were taken from the Sumatra Island region, 32 of which were Bintan, but the samples with the most positive Hemagglutination Test (HA) were found on the Borneo island, Pontianak. Therefore, 13 positive samples were obtained by forming hemagglutination at the bottom of the “V” microplate hole and presented in Table 1.

A total of 13 samples were known to get Hemagglutination Test results with HA titers of more than 22, followed by HI test using B-Victoria antisera. The results of the HI test were positive at the highest dilution which could still inhibit complete clotting of erythrocytes. However, it was found that no sample received a positive Hemagglutination Inhibition Test. So that it can be seen that from all samples, no hepatitis B virus (sub-type B-Victoria) was found in bat respiration organs. The Hemagglutination Inhibition Test (HI) results are described in Table 2.

### Discussion

This study found that in bat respiration organs there was no Influenza B virus (B-Victoria Sub-type) found. So far, there has been no risk of transmission of type B (sub-type B-Victoria) through bat respiration organs. The negative results in 86 of these samples may be caused by a virus that cannot be detected in this way. The causes include virus titers that are still low while this study was being conducted, the presence of viral deaths caused by tissue autolysis, viral predilection is more common in other organs, and less diverse sampling locations.

Reagents or diagnostic tests are indeed available for all viruses, but to detect previously unknown viruses, new reagents and approaches must be developed through PCR exploration. Classic methods, including test of hemagglutination inhibition, need to be widely developed.

Viruses originating from bats are the most famous zoonoses that spread from wildlife to domestic animals and human. Transmission of the virus from bat to human requires a hierarchy of conditions that allow the relationship between the host reservoir, viral infection in the host, and exposure and susceptibility of the recipient host. Human cells do not support the growth of bat flu viruses in the test tube. This shows that bat flu viruses may not grow or replicate in humans. However, bat virus genome examination showed that the bat’s internal genes were compatible with human flu viruses. Scientists cannot rule out the possibility of this virus eventually becoming able to infect humans. Although bats are not in close contact with humans, the spread of viruses from bat to intermediate host animals, such as horses, pigs, ferrets, or nonhuman primates, is considered the most likely mode of infection in humans. Humans can also be infected with viruses through aerosols by entering bat caves or through direct contact with bats, such as catching bats or being bitten by bats.

B-Victoria’s subtype of Influenza B virus was previously found in street cats through 26 blood serum samples in the nasopharynx which contained Victoria B-type subtype Influenza B antibodies. In addition, the pathogenesis of type B influenza virus was found in ferrets. B/Brisbane/60/2008 virus and B/Yamagata strains cause the most severe clinical disease in the middle to lower respiratory tract with a high viral load. This type forms the lower respiratory tract that becomes persistent and begins the process of developing the virus in the airways. Although this infection does not induce the initial epithelium, the lesion causes severe damage to the small airways resembling the pathology of Influenza A. The virus then spreads to the lower respiratory tract. The response of specific influenza antibodies is also measured by the haemagglutination inhibition (HI) test. In the hemagglutination inhibition (HI) test, a positive result will show the presence of point erythrocytes deposited in the middle of the microplate well because the antiserum is used homologously with antigens so that the virus is able to agglutinate erythrocytes. In addition to bats which are thought to be related to influenza type B, certain pigs become agents of the B virus, i.e., guinea pig. As in the case of influenza A viruses, transmission of influenza B virus is increased at colder temperatures, providing an explanation for seasonal influenza epidemics in temperate regions.
Influenza B virus B-Victoria subtype is less dominant compared to Influenza B subtype B-Yamagata. Currently, viruses with B/Victoria/2/87 strains are genically and antigenically more closely related to strains B/Brisbane/60/2008. Virus was recommended to be used as a vaccine in the seasonal Influenza region of the northern world in 2015. Research on B-Yamagata Influenza B subtypes on bats showed similar results, i.e. no positive results were found in bats. Although bats are a strong reservoir of human bacterial pathogens in some cases, a large number of pathogenic viruses colonize bats, the bacterial flora of bats and its zoonotic threats remain unclear. Influenza viruses can occur and spread through commercial farms.

Bats are a natural reservoir of a number of high-impact viral zoonoses. Bats host special zoonotic viruses compared to mice, the role of other important hosts. Bats do have more viral zoonoses per species than mice but the total number of zoonotic viruses identified in bats is lower than mice. As a result, there are about twice of rat species number as bat species. Bats are also increasingly known as a host reservoir for viruses that can across species boundaries to infect humans and other wild and domestic mammals, although bats have the function of helping to control insects, replanting logged forests, and pollinating plants that provide food for humans and other species, and their guano is used as fertilizer and for making soap, gasohol, and antibiotics.

Further research needs to be done to check the sample which may react positively to other viral antisera that have hemagglutinin proteins. The strategy used by viruses targets innate and adaptive responses to the immune response phase. With regard to bats, there is evidence that “healthy bats” can be asymptomatic as in the rabies virus. The infected bat which survive are known to have no virus in the brain or saliva.

Conclusion

This study recommend that apart from bats as other viral agents, there is no risk of exposure and transmission of influenza B virus (B-Victoria sub-type) in bats. Further research needs to be done on the pattern of viral development on other virus dan other organs of bat. Vigilance must be increased because bats are still at risk as an important part of the spread of other viruses.

Factors Influencing Publishing Scientific Papers among Iraqi Medical Academic

Yossra K Hanoon¹, Riyadh K Lafta²

¹ MD, Ph.D., Department of Family and Community Medicine, College of Medicine, Mustansiriya University, Iraq; ² MD, Ph.D., Department of Family and Community Medicine, College of Medicine, Mustansiriya University, Affiliated Prof., Global Health Department, University of Washington, Seattle, USA.

ABSTRACT

Background: Assessing research productivity in academic institutions is an important measure of the magnitude of their contribution to knowledge.

Objective: to assess research productivity among a sample of Iraqi medical academic, and to shed light on the barriers that may influence this practice.

Method: This cross-sectional study was conducted during the period from March through June 2018 in Ten medical schools. A questionnaire form was distributed to 200 academic and inquired about the number of articles published during the last five years, types of journals and the obstacles that may influence the rate of productivity.

Results: Most of the respondents reported publishing their articles in local and regional journals, 44% didn’t get a chance to publish in any International journal, 61% reported no previous experience in publishing in “Scopus” journals or journals with an impact factor (38%), and 66% haven’t published any research article after getting their professorship. Career promotion was the main motive for conducting researches (69.7%), followed by job requirements (64.6%). The main reasons behind low research productivity were workload pressure (74.3%), and lack of funds (61.7%).

Conclusion: there are many obstacles that make research productivity and article publishing among Iraqi academic still way beyond ambition.

Keywords: Iraqi, Academic, Publishing, Medical, Papers

Introduction

Assessment of research productivity in academic institutions is an important measure of the magnitude of contribution to the advancement of new knowledge. Research productivity is considered one of the most important markers of ranking universities quantitatively and qualitatively.¹

Medical faculties are subjected to an increasing pressure to raise their research productivity.² The number of publications is frequently used as an index for the scientific output, while the impact is appraised by using data regarding the number of times these publications are cited in subsequent years.³

Globally, the number of scientific papers increased between 2008 and 2014 by 23%, higher in upper middle-income countries (95%) than low-income countries (68%).⁴ A study done on 6874 medical and health science publications from 18,883 different authors revealed that the countries with the highest relative publication productivity were Canada (37.1), Netherland (28.3), New Zealand (27), UK (23), and U.S.A (17.1).⁵
A study conducted among faculty members of Iraqi medical schools in 2001 revealed that 25% have published an article in a peer-reviewed journal in that year. A similar study in Saudi Arabia showed that the research productivity was 38%.

Factors that thought to influence the rate of research publications include gender and race as individual factors, academic discipline, work values and preferences as career factors, and institutional mission, resources, rewards of promotion, salary and challenges of family responsibilities as environmental factors.

This study was conducted to find out the current status of the productivity of researches (and related factors) among academic, after years of weakness resulted from the devastation that affected all the aspects of life following the 2003 war.

Method

This cross-sectional study was conducted in Iraq during the period from March through June 2018. Ten medical schools were included in this survey: the five schools of Baghdad; one from the North, one from the South and three from the middle of Iraq. A purposive sampling technique was adopted for choosing the colleges, so as for the academic; ten to twenty percent of the faculty from each college was included with an inclusion criterion of being working in the high education field for at least five years. A questionnaire form was developed by the researchers, revised and validated by an expert committee of professors from the Department of Family and Community Medicine, Mustansiriya School of Medicine, the validity was 0.84. The questionnaire was then distributed to 200 professors, assistant professors and lecturers from all medical departments in the chosen ten medical schools (20 from each) after explaining to them the purpose of the study, giving them the full choice to participate, and assuring them that all the information would not be used for other than research work. The questions inquired about the number of articles published during the last five years, the quality and rank of the journals and the obstacles they think might influence the rate of articles' productivity.

Statistical analysis was done using IBM/SPSS (Statistical Package for Social Sciences) version 24. Chi-square test was used to describe the association between related variables. P value less than 0.05 was considered statistically significant.

Results

Only 175 forms were collected (out of the 200 that were distributed) giving a response rate of 87.5%.

Table (1) describes the socio-demographic characteristics of the faculty members, whose age ranged from 29 to 68 years, distributed into four age groups, 37% of whom was in the age group (35-44) years, 59% of the sample was males, and 88% carry the degree of Ph.D. (or Board), 26% were full professors and 44% were assistant professors.

*There is no degree of “Associate Professor” in the Iraqi education system

Figure (1) details the research productivity; most of the respondents (87.5%) reported publishing articles in local and regional journals, while 44% didn’t get a chance to publish their articles in any International journal, 61% had no previous experience in publishing in “Scopus” journals or in journals with an impact factor (38%), and 66% of the participants haven’t published any article after getting their professorship.
Only 18.9% of the studies were randomized or non-randomized clinical trials while 66.3% were either cross-sectional, case-control, or cohort studies (not tabulated).

The results also revealed that career promotion was the main motive for conducting researches (69.7%), followed by job requirements (64.6%). (Figure 2)

Figure (3) demonstrates that the main reasons behind low research productivity were workload pressure (74.3%), lack of funds (61.7%) and deficient experience in practicing teamwork concept (45.7%).
Table (2) shows the association of age, gender, qualification and academic degree with the flow of research productivity. Age and being a professor were associated with high rates of publishing in International journals, Scopus journals and journals that have an impact factor, while old age, male gender and being a professor were significantly associated with medium to high research publishing (5 or more during the last 5 years) in local and regional journals (p=0.0001).

### Discussion

The findings of this study demonstrate that about half of the sample reported authoring less than five articles that are published in local journals; this is in the same line with a study conducted in Brazil in 2009, while a previous local study in 2001 revealed that 83% of the articles were published in local journals. This change may be attributed to the new policy of the Iraqi universities that encourages the trend of publishing abroad, however, 38% had no articles published in journals with an impact factor, this is higher than what was found in an Egyptian study in 2014 which revealed that 20% had no articles published in journals with an impact factor.

Unexpectedly; many professors recessed their research activity after getting their professorship, might be because some academic exert their greatest efforts when their promotion is imminent, but immediately after been promoted, their activity slopes down. This is an alarming sign as the opposite should happen; reaching the degree of professorship with all the accumulative experience should improve and upgrade the capacity of the academic making them more productive. This finding is inconsistent with the results of a study done in Taiwan which revealed that only 10% did not publish articles after getting their professorship.

The study revealed that more than two-thirds of the academic embark on doing researches for the sake of promotion to the next academic degree. This matches the outcome of a Nigerian study in 2015 which showed that scientific promotion was on the top of the motives’ list to produce research.

The second motive was job requirements; more than half of the academic stated that they publish researches to contribute to knowledge and because they have a real interest in research work.

The faculty members indicated some barriers that represent the main reasons behind their low research productivity; the top rated reason was workload pressure. In accordance with this result, a previous study done in Bahrain in 2017 concluded that workload pressure due to full-time faculty work and engagement in administrative duties was the main barrier as it leaves no time for research activity. In Iraq; the situation is similar with a different scenario since workload pressure resulted from the...
noticeable shortage in the number of faculty members that leads to an extra teaching load. This shortage is attributed to the void of most of the expertise from Iraq after and as a consequence of, successive wars and continuous violence, especially after the 2003 US invasion. 15,16

Faculty members also indicated that low research productivity is directly related to the lack of funds. This goes with the findings of a study in 2011 which concluded that barriers like teaching load, extra administrative duties along with lack of funds, can negatively affect the attitude of the faculty towards research work. 17

The scarcity of funding is an undeniable obstacle for research papers suitable for high impact journals, particularly randomized trials. Many of the regional and international universities support research activity with a large annual budget, 18 a policy that is unfortunately not applied in the Iraqi universities.

Following the 2003 US invasion and the following anarchy, there was massive devastation to the infrastructure of most of the scientific research centers; this led to lack of information resources and research infrastructure that seriously affected the progress of scientific research work in the Iraqi universities. 19,20

Lack of research equipment was an important barrier especially for the clinician; this disagrees with the results of an Indian study which concluded that interpreting results were the main research conduction difficulty. 21

Surprisingly, language difficulties were the least to state as a barrier. Although this goes with a Bahraini study which found that language was in the bottom of the list of difficulties, 14 but we believe that the journals’ editors may have a different opinion.

Age appeared to be significantly associated with publishing in local, regional and international journals, with no decline when the academic gets older. This is expected since knowledge is cumulative with increasing age and experience. 22 This finding matches results from other studies which concluded that age has a positive effect on the publication rate that increases with time. 23

The results also revealed that male gender is highly associated with the publishing rate in local and regional journals. The probable explanation is that female academic are still having more responsibilities and duties regarding managing the house and looking after the needs of their family members, which leaves a limited time for them to look after their research activities. 24 This finding is seconded by a Canadian study in 2011, 25 but Dutch female academic contradicts that for they are more productive than males. 26

**Conclusion**

There are many obstacles that make research productivity and article publishing among Iraqi academic still way beyond ambition. Efforts through joined collaborated work are needed to bring back the Iraqi academic to their normal position among the International medical schools.

ABSTRACT

Objectives: There is a common belief among Muslims, to consume dates in odd number rather than even, based on cultural and religious claims; although nobody knows its effect on blood glucose level or other metabolic effects in the body.

The aim of our study is to illuminate the changes that affect the 2-hrs postprandial serum glucose level after the consumption of an odd number of dates among healthy young persons and even number.

Method: Intervention study was used to compare 2 groups, Fasting glucose levels was measured for all participants; group A (42 participants), who consumed even number of dates all at Tamer-stage, (net weight about 50 grams); and group B, (42 participants), presumed to consume an odd number of dates (net weight about 40 grams). Two-hrs postprandial blood glucose levels were measured altogether. Blood glucose levels were determined and compared as a means. Statistical analyses were performed using SPSS version 22.

Result: The fasting serum glucose of group A and B participants were 91.65 ± 13.61 and 93.69 ± 8.79 mg/dl, respectively, with an insignificant statistical difference between groups. Subsequently, the 2hrs Postprandial Glucose measurements of group A and B were 99.58 ± 19.56 and 100.33 ± 12.204 respectively; indicated an insignificant statistical difference between groups. All the participants were remaining within normal ranges of serum glucose level.

Conclusion: There is no difference between ingestion of the odd and even number of dates fleshes from the glycemic point of view on the glucose level in fasting and postprandial states.

Keywords: dates, odd, even, glucose level, eating.

Introduction

The date is one of the ancient plants, eldest diet with high energy producing value; it is widely cultivated and adopted in various tropical and subtropical countries worldwide. (¹)

Each date flesh consists of about 60-65% carbohydrates, 2.5% fiber, 2% protein, >2% fat, minerals, and about 15-30% water according to the stage of ripeness and the variety of dates. Additionally, date can provide more than 3000 Calories/kg; (²) that’s mean the consumption of 100 g dates daily (six to seven dates) can provide the human body with a wide variety of vitamins, salts, minerals and provided 50% -100% of the recommended daily intake of fiber. (³) These facts make dates as a most nourishing natural food and best food for consumption by all ages of the population all over the world. (², ⁴)

Even though, some researches, found that the glycemic index (GI) of dates is low and its consumption does not cause a significant shot in the post-prandial blood glucose level, with glycemic indices (GIs) range (35.5 - 47.2) putting the dates in the list of the low GI food items. (⁵, ⁶) Deserve to be one of the fruits which are widely consumed worldwide, particularly in the Arab

DOI Number: 10.5958/0976-5506.2019.02674.3

and Islamic regions and it is one of the few numbers of foods that are directly mentioned in the Holly Qur’an. (7)

However, there is a common belief among Muslims, most of them, they advised to consume dates in odd number rather than even, (8) although, nobody knows the effect of date number on blood glucose level or other metabolic effects in the body, as well as there, was no previous scientific research spot the light on this subject. For these reasons, we try in this study to determine the effect of the date number on blood glucose levels.

The aim of our study is to illuminate the changes that affect 2-hrs. Postprandial Serum Glucose (2hs. PPSG) level after the consumption of odd and even numbers of deaths among healthy younger persons with normal Fasting Serum Glucose (FSG) level and their related variables.

Materials and Method

Study Design: Intervention study was used to compare the glucose levels before and after ingestion of odd and even pattern of dates among two matched study groups.

Sample Recruitments: Participants were recruited from the College members, employees, and students of the Chemical Engineering Department/College of Engineering/Baghdad University, who were informed to participate through invitation posters. The data collection extended from the 1st November to the 1st December 2017.

An 84 participants were completely eligible (42males and 42 females) fit for the inclusion criterion and were recruited for simple randomization to divide them into two groups (no blinding was used); group A (42 participants, 21 male and 21 female), who would consume even number of dates (net weight about 50 grams); and group B, (42 participants, 21 male and 21 female), presumed to consume an odd number of dates (net weight about 40 grams).

Study Protocol: All the participants were asked to have overnight fasting and to stay fasting until they attend the college at 7.30 -8.30 AM. A sample of blood was taken from each one for measurement of FSG level, and then everyone asked to eat 4 or 5 fleshes of dates according to their groups. All flesh of dates was of the same type, at Tamer-stage, each flesh had an average weight of 9.25-10.10 grams. Participants ingest the dates followed by a glass of water (100 ml) and to stay on this regimen without additional foods or drinks, till the 2hs.PPSG levels were measured. Upon the end of the trial, the subjects would become free to join their daily activity.

Samples of blood were collected from all participants to be examined later, in the National Diabetes Center (NDC)/Al-Mustansiriyah University laboratory, for the investigation of FSG and 2hs. PPSG levels; KENZA 240TX autoanalyzer was used for this purpose.

The inclusion criteria were non-smokers, healthy persons (no diabetes, no chronic disease, nor other co-morbidities even the metabolic problems), males and females of age ranging between 18-50 years.

The exclusion criteria were the obesity and morbid obesity (BMI > 35 kg/m²) or a history of previous obesity, pre-diabetes (fasting blood sugar ≥ 100 gm/dl), alcoholic persons, pregnant women.

Ethical Approval: Consents for participation in the study were obtained according to the Helsinki II Declaration (10) after a briefing about the project; and approved by the ethics committee and the scientific research committee at the National Diabetes Center and the College of Medicine/Al-Mustansiriyah University. The demographic data, family and past medical history of participants were recorded also; physical examination of pulse rate, blood pressure and anthropometric measurements of weight, height as well as BMI was measured for all participants.

Statistical Analysis: All obtained data and records were managed by SPSS, version: 22, for statistical analysis. The Anderson-Darling test was done to prove normal distribution of the obtained data, student t-test was used for the comparison of two means, and the chi-square test was used to compare nonnumerical discrete data.

Results and Discussion

Age, the gender distribution of group A and B and their BMI values, revealed insignificant statistical differences (P=0.48771, 0.01792, 0.801 respectively). This mostly due to the cautious manner of choosing samples, and randomization in-group recruitment rendered them equivalent and comparable. (Table-1)
Family history of diabetes mellitus among study participants showed a statistically significant difference between groups (P=0.00072). This expected figure may be because diabetes is a common disorder in Iraq and all over the world (11, 12). (Table-1)

The mean of Measurements of the Fasting Serum Glucose (FSG) of group A and B participants’ were 91.65 ± 13.61 and 93.69 ± 8.79 mg/dl, respectively, with the insignificant statistical difference between groups (P=0.42327); indicates no any pre-diabetic was detected among the participants according to the diagnostic criteria. (13) This healthy metabolic state of respondents, often owing to the high commitment to the study protocol during sample selection. (Table-2)

Participants ingested the dates in an odd or even number of fleshes according to their groups. Dates ingested contain about the same amount of glucose used in oral glucose tolerance test, which is a more definitive test that has no serious risks and gives important clues about health; in addition, an Oral Glucose Tolerance Test (OGTT) shows how well your body handles sugar from foods. (14-16) Subsequently, after ingestion of dates, the means of 2 hours PPSG measurements of group A and B were 99.58 ± 19.56 and 100.33 ± 12.20 respectively, with insignificant statistical difference between groups, (P=0.83553), the higher figure of PPSG found in group B (odd group) may be attributed to the (extra one date) given to this group that might cause trifling personal differences. However, these changes did not manifest themselves statistically. Moreover, the Changes of the glucose level for each participant among group A and B before and after ingestion of the dates seem to be insignificantly different (P=0.62089). Furthermore, all the participants were remaining within normal ranges of serum glucose levels, despite 34.5% of them were found to be with positive family history but they showed no glycemic response to date ingestion. This may be because the vast majority of this sample was young and below the risk of development, such health problem. (17)

Obviously, this indicates the negligible and a trivial effect of ingestion of dates in odd or even manner on the glucose metabolic state with no statistical meaning. (Table-2)

Although there is no obvious indication to ingest dates in any manner in Islamic references, still there is a habitual concept designed or formatted on religious bases solidified through multiple eras to become virtually a traditional norm. Because it ignores the size, weight, dryness and serving a form of the dates which seriously affect its chemical components especially the carbohydrate, the glycemic index and glycemic load of any ingested food.
Conclusion

There is no difference between ingestion of odd or even number of date fleshes from the glycemic point of view on the glucose level in fasting and postprandial states.

Management of Slum Settings Through the Private City Program (Kotaku) Towards a City of Health, Makassar Indonesia

Haslinah Ahmad¹, Indar², Sukri Palluturi², Suriah², Ahmad Yani³

¹Postgraduate Doctoral Program Students Hasanuddin University, Makassar, Indonesia, ²Akademik Keperawatan Reformasi Makassar; ³Public Health Faculty, Hasanuddin University, Makassar, Indonesia;

ABSTRACT

Slums are a strategic issue in spatial planning in Indonesia due to a tendency to increase slum areas. To prevent the occurrence of slums in Makassar which is to break the chain of factors causing slums. In terms of public health, one of the determinants of public health status is environmental factors. Therefore, various studies make recommendations in making a model for handling slums. This study will combine the two methods in analyzing the level of slum settlement as well as the most appropriate risk factor control model in reducing the rate of increase in the number of slum areas with a dynamic model approach. This study aims to look at slum settlement management models. In this study concludes most of the concepts and results of previous studies recommend a dynamic model approach to handling slums.

Keywords: Slums, Healthy Cities, Dynamic Models

Introduction

Slums are a problem faced by almost all big cities in Indonesia and even big cities in other developing countries. The study of slum settlements generally covers three aspects, first the physical condition, the second socio-economic and cultural condition of the communities that live in the settlement, and the third impact by both conditions. The physical condition can be seen from the condition of the building which is very tight with low construction quality, the road network is not patterned and not hardened, public sanitation and drainage are not functioning and the waste has not been managed properly.(1)

Slums can be interpreted into two parts, the first is an area whose formation process is due to the limitations of the city in accommodating the development of the city so that competition arises in using urban land. Whereas high density residential areas are embryos of slums. And the second is the area where the geographical distribution location is urged by the development of the city, which was initially good, gradually becoming slums. The cause is stagnant socio-economic mobility.(2)

The condition of slum housing in Indonesia is about 9.12% of the 64.1 million households in Indonesia living in unsuitable housing conditions, there are 38,431 Ha of urban slum areas spread across almost all regions of Indonesia, urban populations in Indonesia increased sharply between 2000-2010, from 7400 people per square kilometer to 9400 people per square kilometer, it is estimated that 68% of Indonesia’s population will live in cities by 2025.(3)

Slums are a strategic issue in spatial planning in Indonesia due to a tendency to increase slum areas. Since 2008, 26% of Indonesia’s population in urban areas have been living in slums. The tendency to increase the rate of population growth in urban areas empirically triggers the potential increase in the number of urban residents who live in slums by 32%. To face the challenges of the Indonesia Slum Free program in 2020 and the global agreement in the New Urban Habitat Agenda 100-0-
100 that set a target of 100% fulfillment of clean water, 0% of slums and 100% of fulfillment of sanitation facilities in 2020 carried out various programs to deal with slums both short, medium, and long term involving cross-stakeholders which is done through sectoral harmonization and hierarchical synchronization.(4)

In urban areas many problems occur due to the many factors that influence it such as the environment, social, economy, and slums. Kota Sehat is a World Health Organization (WHO) project which was officially launched in 1987-1988). Healthy City is a condition of the city that is clean, comfortable, safe and healthy for residents to live in. The implementation is achieved through the application of several arrangements with integrated activities agreed by the community and local government and Joint Minister of Health & Minister of Home Affairs Regulation No 34, 2015. (5)

Some of the causes of slums in various parts of the world are rapid migration of cities, economic stagnation and depression, high unemployment, poverty, informal economy, poor planning, politics, natural disasters and social conflicts. The strategy attempts to reduce and change slums in various countries, with varying degrees of success, including a combination of slum resettlement, slum relocation, upgrading of slums, and urban planning with infrastructure development throughout the city, and this public housing project. (6)

The focus of the problem in this study is to prevent the occurrence of slums in Makassar, which is to break the chain of factors causing slums. In terms of public health, one of the determinants of public health status is environmental factors. The environment has the greatest influence and role followed by behavior, health facilities and heredity. The environment is very varied, generally classified into three categories, namely those related to physical and social aspects. The environment is related to physical aspects, for example garbage, water, air, soil, science, housing, and so on. Whereas the social environment is the result of human interaction such as culture, education, economics, and so on.(5)

The decline in the quality of the urban environment, of course, is followed by an increase in the amount of pollution in the air, soil and rivers. Cities in Indonesia and several cities in the world, generally become customers of various diseases such as cholera, typhus, shortness of breath and others. The air in the City becomes hot and dusty. Water is polluted by a variety of bacteria and chemicals that are detrimental to health. WHO notes that water, sanitation and hygiene problems contribute 3.5% of total deaths in Indonesia.

In 2017 the government made a new breakthrough through the City without Slums (KOTAKU) program. This city program has advantages that include all aspects that can make city settlements become slum starting from buildings, environmental roads, drinking water supply, Drainage provision, Waste water management, fire fighting and green open space, this program runs from 2017 until 2019. However, there is still 35% of slum area that has not been handled by this program, therefore an effective and efficient model is needed to predict determinants of an increase in slum area in Makassar, which will affect the health status in the future.

Dengan demikian diperlukan pendekatan model dinamis dalam menggambarkan kejadian pemukiman kumuh yang merupakan bagian dari sistem kompleks pada dunia nyata ke dalam model sederhana. Hal ini penting megingat tinginya kawasan pemukiman kumuh di Kota Makassar. memodifikasi dan mengendalikan faktor risiko kejadiah kumuh untuk menekan dan mengurangi laju peningkatan kejadian pemukianan kumuh di Kota Makassar.

**Research Methodology**

This paper uses a two-stage methodology for the formation of initial models and conceptualizations. In this study collected several concepts, theories and some relevant research results with risk factors for slums to reduce and reduce the rate of increase in slums.

**Results & Discussion**

The results of this study found that the settlement is part of the environment outside the protected area, it can be an urban and rural area, functioning as a residential/residential environment and a place of activity that supports livelihoods and livelihoods. While the word “slum” according to the large Indonesian dictionary is interpreted as dirty or unclean. So, it is not dense, the meeting is muddy, smelly, rickety, or irregular, but it is dirty that makes something dirty. According to Johan Silas, Slum Settlement can be interpreted into two parts, the first is the area whose formation is due to the limitations of the city in accommodating the development of the city so that competition arises in using urban land. Whereas the high density settlement area is the embryo of slums, and the second is the area where the geographical distribution location is urged by the development of the city which was initially good, gradually becoming slums. The cause is stagnant socio-economic mobility.
One of the goals to achieve the MDG’s targets that have ended in 2015, a world agreement has been agreed on sustainable development goals (SDG’s), where the SDG’s point 11 target on Sustainables Cities and Communities is stated “Building cities and settlements that are inclusive, safe, resilient and sustainable. In 2030 (SDG’s point 11.1) is targeted to guarantee access in this case adequate and safe and affordable housing, access to basic services and handling of slums. (8)

Efforts to prevent and accelerate the improvement of the quality of residential areas in collaboration are carried out with a participatory approach that brings together macro planning (top down) and micro planning (bottom up) by placing the community as the subject of development and final decision makers.(9)

As an implementation of the acceleration of slum management, the Kotaku Program will improve quality, manage and prevent the emergence of new slums, with activities in rural/urban villages, as well as regions and districts/cities. These slum-handling activities include infrastructure development and social and economic assistance for better community livelihood sustainability in slum areas. The stages of implementing the Kotaku Program are data collection. The community institution in the village/kelurahan called the Community Self-Reliance Agency/Institution (BKM/LKM) has conducted a baseline survey of 7 Slum Indicators in each village/kelurahan. The data is integrated between community planning documents and district/city planning documents to determine priority activities to reduce slums and prevent new slums. Which will be implemented later, either by the community or by other parties, who have expertise in infrastructure development in regional and municipal entities.(10)

The Kotaku program has been socialized to local governments on April 27, 2016 in Jakarta. The Community Occupation Agency (BKM) will be a factor that can accelerate the achievement of habitable and sustainable settlements because of their experience in planning and implementing poverty reduction activities. This BKM is “revitalized” from before which was focused on poverty alleviation, now oriented to slum management.

Conclusions

In this study concludes most of the concepts and results of previous studies recommend a dynamic model approach to handling slums.

**Abstract**

Telescopic crowns consist of coping, primarily telescopic permanently which is cemented to an abutment permanently, along with a secondary or outer, congruent detachable telescopic crown and is strictly embedded by a prosthesis of detachable type. There has been ample evidence that telescopic overdentures promote oral hygiene, periodontal health and protection of the abutment through primary coping. Telescopic crowns supported with natural teeth have been used successfully in removable partial overdentures. This article presents a successful alternative approach for rehabilitation of patient with removable partial overdenture prosthesis with telescopic crowns to enhance retention and stability.

**Keywords:** Telescopic crowns, Abutment, Telescopic overdentures, Primary telescopic coping, Secondary telescopic crown.

**Introduction**

High incidence and repercussions of lip and palatal clefts are among the most important congenital craniofacial malformation to be taken into account in general dental practice (Incidence 1:600). [1] The tooth supported telescopic prostheses are formed by a parallel surfaced double crown system. Telescopic crowns achieve retention using friction of parallel-surveyed surfaces. It allows cross-stenting of the dental arch thereby facilitating the tooth stabilization over the long term.¹

**Clinical presentation of case:** A 45 years old female patient reported to the Department of Prosthodontics, A.B. Shetty Memorial Institute of Dental Sciences, Deralakatte, Mangalore, Karnataka, India with the chief complaint of missing teeth in upper and lower jaw. History revealed that she had cleft lip and palate with several missing teeth, which was surgically treated five years ago. Patient revisited the hospital for the closure of an oro-antral fistula. Extra-oral examination revealed that there was a post-operative scar on the upper lip (Figure 1). Intra-oral examination revealed presence of maxillary right central incisor, maxillary right second premolar, maxillary left first premolar, maxillary left second premolar, mandibular left canine, mandibular left lateral incisor, mandibular left second premolar, mandibular left third molar, mandibular right first premolar and mandibular right third molar. Gingival examination showed generalized gingival recession and grade III mobility of mandibular left lateral incisor and mandibular left third molar with severe bone loss (Figure 2). Inter-arch space was 18mm measured from crest of the maxillary and mandibular alveolar ridges at the premolar region. Due to surgical repair, complete obliteration of maxillary labial vestibular area was noticed (Figure 3).
Following treatment options were listed for rehabilitation of present case

1. Extraction and complete denture prosthesis.
2. Cast partial denture prosthesis.
3. Simple over-denture prosthesis.
4. Overdenture prosthesis supported by abutment teeth with telescopic crowns.
5. Osseo-integrated implant supported prosthesis.

Treatment planning: The goal of treatment is to improve the functional efficiency, cosmetic result as well as to improve the psychological wellbeing of the patient. An interdisciplinary approach involving an Oral and Maxillofacial Surgeon, a Periodontist, an Endodontist, and a Prosthodontist was planned.

1. Extraction of mandibular left lateral incisor and mandibular left third molar with grade III mobility and severe bone loss.
2. Oral prophylaxis.
3. Advised intentional pulp space therapy in relation to maxillary right central incisor, maxillary right second premolar, maxillary left first premolar, maxillary left second premolar, mandibular left canine, mandibular left second premolar, mandibular right first premolar and mandibular right third molar.

Rehabilitation with Overdenture prosthesis supported by abutment teeth with telescopic crowns to be used to enhance the retention, stability, support and proprioception.2, 3

Steps in fabrication: After the required investigations and preliminary treatment, the definitive Prosthodontic treatment was started. Appropriate maxillary and mandibular stock trays were selected and primary impressions made with irreversible hydrocolloid (Tropicalgin, Zhermack, Italy). Tooth preparation was done by diamond of torpedo type (C&FG, Diamond Point Densply, United States of America). Impression of single stage done by light and putty viscosity polysiloxane vinyl impression material (3M ESPE, Express, U.S.A.) along with working cast made from dental stone of (TYPE III, Asian camicals, India).

Patterns of wax (Pattern wax, BEGO, Germany) for primary coping were prepared on the working cast and was surveyed (MERATHON-103, Saeyang Company, Korea) to achieved relative parallelisms between the abutment teeth with the help of wax knife surveying tool (Figure 4a). Cementation of primary metal coping on the prepared abutment teeth using Cement of permanent luting type (Glass Ionomer Cement typeI, Global Corporation, Tokyo, Japan) was carried out.

Border moulding and Definitive impression was made with custom acrylic resin tray (DPI-RR, Cold Cure, India) by impression material (3M ESPE, EXPRESS, USA.) of putty and light viscosity vinyl polysiloxane respectively then pouring of master cast was done. Wax up for reverse coping on the master cast in which grooves were made on occlusal surface (one horizontal line and one vertical line bisecting each other at right angle) and retention beads (Rententionen - retention beads no-461-0106, Renfert) were placed on the pattern with the help of adhesive provided and invested (Figure 4b). After casting of reverse coping, it was secured into the intaglio surface of heat cure denture base (Figure 4c). Orientation relation recorded using the Artex face bow (Rotofix-218600, Germany) and was transferred to the non-arcon semi-adjustable articulator (Girrbach-TS Germany,). After determining the vertical dimension and recording of centric relation mandibular cast was secured on the articulator and program the articulator using eccentric records.

Following trial of waxed up tooth supported telescopic overdenture prosthesis and acrylization was carried out. After remounting and correction of occlusal discrepancies fit and insertion of the prosthesis was done (Figure 4d). On periodic check-up enhanced retention, stability of the tooth supported telescopic overdenture prosthesis and improved psychological comfort of the patient was noticed (Figure 5).
Figure 2. Ortho Pantograph Radiograph

Figure 3. Maxillary arch - Occlusal View

Figure 4a. Surveying of Primary Coping; 4b. Reverse Coping- Occlusal View; 4c. Reverse Metal Coping Incorporated With Intaglio Surface Of Heat Cure Denture Base; 4d. Polished Prosthesis
Discussion

The tooth supported telescopic overdenture prosthesis is by the concept that the abutments are the retained teeth which provide adequate stimulation onto the dental alveoli hence prevent loss of bone adjacent to the abutments along with this enhancing retention, stability and support for the prosthesis. Yalisove specified that the sufficient tooth structure can be reduced to improve crown to root ratio by intentional extirpation. The poor crown to root ratio, in this case revealed that more reduction was necessary. So, in cases of poor crown to root ratio which arises by extensive loss of periodontal part is indicated for elective endodontic treatment. Balanced occlusion is the standard protocol for the stability of complete denture prostheses and incorporated the same in the present case. It reduces the lateral forces exerted on the residual ridge thereby helping in its preservation. The use of a tooth supported telescopic overdenture prostheses gives an option which is superior to traditional complete denture prostheses and also avoids expensive treatment option like implant supported prostheses. Moreover, the treatment option is highly predictable, reliable and comfortable for patients.

Conclusion

Nowadays, the Prosthodontics retain along with that they restore most of the natural teeth to serve as prosthetic abutments by modern modalities of preventive dentistry. The tooth supported telescopic prosthesis from numerous reports by cross- sectional and longitudinal studies contemplates that – there is conservation of the alveolar bone, proprioceptive efficiency is increased and the most significant advantages is patient acceptance. Due to these favorable outcomes, in cases of abutments which are periodontally compromised further advocates the implementation of tooth supported telescopic prostheses as an alternative modality.

Achondroplasia in an Eleven-Year-Old Male Child

Satya Ranjan Misra
Professor & Head, Department of Oral Medicine & Radiology, Institute of Dental Sciences, Siksha ‘O’ Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Among the many conditions which manifest as dwarfism, Achondroplasia is one of the most commonly encountered. It is characterized by short stature due to shortening of the limbs which have disproportionate growth in comparison to the rest of the body. Achondroplastic patients often report to the dentist for their dental problems like delayed eruption of teeth or malocclusion, and since they present with pathognomonic cranio-facial features the condition can be first diagnosed by dentist. We present a case of 11-year-old male child with char for documentation with characteristic features.

Keywords: Dwarfism, malocclusion, mid face hypoplasia, rhizomelic shortening of limbs.

Introduction

Achondroplasia is the most commonly occurring skeletal dysplasia, a non-fatal form of chondrodysplasia. [1,2] The limbs are short and the growth of long bones, vertebral column and the skull is affected, resulting in stunted growth and a short stature. It is common and affects about 6% of the population worldwide. It is an autosomal dominant disease, having complete penetrance, but more than 80% cases arise de novo due to genetic mutations. [3] The clinical features of the disease are pathognomonic, with a disproportionately short stature, having frontal bossing, megalencephalic head, hypoplasia of the midface, rhizomelic shortening of the upper and lower extremities with a normal length of the trunk, accentuated lordosis of the lumbar spine, genu varum and a trident shaped hand. [5] The teeth are morphologically normal but may be associated with impeded teeth eruption, retained deciduous teeth and malocclusion, as reported in the present case.

Case Report: An 11-year-old male child reported with a complaint of misaligned teeth. History revealed he has stunted growth and has gait problems. The past medical, personal and family history were non-contributory.

On physical examination, the patient had short stature, hyper-extensibility of upper extremities with increased anterior pelvic tilt, reduced hip extension, increased hip flexion, trident shaped hands and a waddling gait. [Figure 1] There was frontal bossing, hypoplasia of the middle third of the face, anterior cross bite, anterior open bite, retained deciduous molars and a high arched palate. [Figure 2]

Figure 1: Clinical pictures showing short stature, increased anterior pelvic tilt, reduced hip extension, increased hip flexion, trident shaped hands.

e-mail: satyamisra@soa.ac.in
Owing to the short stature, hyper-extensibility of the joints and the cranio-facial features, the patient was diagnosed with Achondroplasia.

He was then advised for conventional radiologic investigations. Postero-anterior (PA) view of skull, lateral skull view, antero-posterior (AP) views of the vertebral column, chest, extremities, panoramic radiographs of the jaws revealed frontal bossing, midface hypoplasia, anterior cross bite, dislocation of left humerus and accentuated lordosis of the lumbar spine. [Figure 3]. Correlating the clinical and radiologic findings a final diagnosis of Achondroplasia was made, the deciduous teeth were extracted and the patient was kept under regular follow-ups.

**Discussion**

Achondroplasia is a common disorder with autosomal dominance having complete penetrance. There is a mutation in the FGFR3 gene, which causes low endochondral ossification, with inhibition of the proliferation of the chondrocytes in the cartilages of the hypophysis of the long bones, hypocellularity and low cartilage matrix production which manifests as a plethora of clinical manifestations and often in complications. The chromosomal mapping of the FGFR3 gene is on band 4p16.3. Generally, Achondroplasia is considered non-fatal as it is heterozygous, with the patients leading a normal life with normal brain function/intellect. But complications like as cervico-medullary compression, stenosis of the spine, obesity or obstructive sleep apnea.

When the affected individuals are born, they look normal but there is growth retardation with time. It has been reported that men grow to about 130 cm in height and women about 123 cm on an average. Though characteristic clinical features may not be evident at birth, as the child grows the limbs appear shorter in comparison to the trunk which is longer and narrower.
The head is disproportionately large with frontal bossing and mid-face hypoplasia. In the proximal segments the limbs appear the shortest which is called rhizomelic shortening and the fingers show a trident appearance. The joints exhibit hyper-extensibility and the movements are slightly restricted. Most joints are hyperextensible, but extension is restricted at the elbow.

The radiologic features include large calvarium with smaller cranial base and facial bones. Lateral spine radiograph shows short vertebral pedicles and a decrease in the inter-perpendicular distance between the lumbar vertebrae, all typical to the disease. Round and short iliac bones having flat acetabular roofs are seen. Short tubular bones with irregular flared metaphyses are often seen. Compared to the tibia, the fibia is very long and shortening of the metacarpals and phalanges. The iliac bones are short and round and the acetabular roofs are flat. The tubular bones are short with mild irregular and flared metaphyses. The fibula is disproportionately long compared with the tibia. Hand radiographs show shortening of the metacarpals and phalanges with trident configuration.

It has been reported that achondroplastic patients have normal structure and morphology of teeth but the eruption pattern may be affected, presenting as delayed tooth eruption. Malocclusion is a common finding, where the patient can have cross bite, open bite, dental class III malocclusion, high arched palate with a small maxilla, oligodontia and macroglossia. Periodontitis, geographic tongue and trigeminal neuralgia have been rarely reported.

When considering a diagnosis of achondroplasia, different disorders affecting the cartilage presenting as short stature may be considered, which includes thanatophoric dysplasia, hypochondroplasia and chondroectodermal dysplasia.

The dental management of patients with achondroplasia is akin to any normal patient needing dental treatment, though psychosomatic issues due to disproportionate stunted growth affecting the psychologic well-being of the patient. Rarely due to cranio-cervical instability, stenosis of the foramen magnum stenosis or limited neck mobility may be present which could lead to respiratory complications during dental procedures.

An Introduction to Preventive Orthodontics

Snigdha Pattanaik¹, Swati Patnaik²

¹Associate Professor, Department of Orthodontics, Institute of Dental Sciences, ²Assistant Professor, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha ‘O’ Anusandhan, (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

The prevention of the malocclusion and the control of dental spaces are problem areas in the scope of preventive Orthodontics. The supervision of caries control, teeth eruption sequence and the treatment of the local factors which may influence the eruption of the permanent tooth are done during this period. With the recent improvement in diagnostic tools, novel potential therapeutic devices and techniques it is now easier for the orthodontist to adopt several techniques in the clinic to prevent the occurrence of malocclusion. However, the most significant barrier to providing the preventive orthodontic care by the practitioners may be related to the lack of self-confidence relating to the effectiveness of their chosen treatment plan. When preventive dentistry is practiced properly it helps in the proper development of functional occlusion and reduces the chance of the development of malocclusion. This article will focus on various aspects of preventive orthodontics.

Keyword: Preventive Orthodontics, Premature Tooth Loss, Deciduous Dentition, Malocclusion.

Introduction

Preventive orthodontics is the part of orthodontic practice which is concerned with patient’s and parents education, supervision of the growth and development of the dentition and the cranio-facial structures & the diagnostic procedures undertaken to predict the appearance of malocclusion and the treatment procedures instituted to prevent the onset of malocclusion.

According to Graber Preventive orthodontics can be defined as “action taken to preserve the integrity of what appears normal for that age” Preventive procedures are undertaken in anticipation of development of a malocclusion. Patient education literature must be used by all means¹.

The following are some of the procedures undertaken in preventive orthodontics:

Education of Parents: Preventive dentistry should begin much before the birth of child. Expecting mother should be educated on proper nursing and care of the child. In case the child is being bottle-fed, the mother is advised to use physiologic nipple. Conventional nipples are non-physiologic and do not permit sucking by movement of the tongue and the lower jaw. They cause sucking action which might cause orthodontic problems like, increased overjet/overbite and open bite. On the contrary, physiologic nipples are broad and wider, designed in such a way so as to permit sucking which resembles normal functional activity as in breast feeding.

As the child grows, parents should be educated about the need for maintaining good oral hygiene and proper brushing technique. Fluoride application and dental checkup should be done every 6 months.¹,²

Care of Deciduous dentition: Preventive orthodontics includes care of the deciduous dentition by way of prevention and timely restoration of carious teeth. Deciduous teeth act as natural space maintainers until the developing permanent teeth are ready to erupt into oral cavity. All efforts are taken to prevent early loss of deciduous teeth. Simple preventive procedures such as proper and timely application of fluoride topically/ pit and fissure sealant application help in preventing caries.

e-mail: dr.snigdhapattanaik@gmail.com
Complex treatment procedures may also be followed to maintain the deciduous teeth which includes various pulp therapy and stainless-steel crown delivery.

Caries Control: Caries control should be done with proper diet and oral hygiene. Maintenance and regular dental checkup. Regular fluoride application, prophylactic odontotomy, application of pit and fissure sealants and immunization should be done to reduce the incidence of caries. Caries involving proximal surface of deciduous teeth if not restored early may lead to loss of arch length into that space. Caries can be detected by clinical and radiographic examination. Bitewing radiograph proves to be of great help in detecting proximal caries. Once detected, proper restoration of affected teeth should be done to prevent loss of arch length. Restoration should restore the mesio-distal dimension of tooth, but should not be over/under extended allowing drift of contiguous teeth or promote food impaction. Contact size and position should also be correct. Re-establishment of proper inclined plane relationship with proper anatomic carving will be esthetic and will result in normal function and stability of occlusion.

Maintenance of quadrant wise tooth shedding

Time table: There should not be more than 3 months difference between the shedding of deciduous teeth and eruption of permanent teeth in one quadrant as compared to other quadrants. Delay in eruption may be due to any one of following reasons: Presence of over retained deciduous teeth/roots, Supernumerary tooth, Cysts, Overhanging restoration in deciduous teeth, Fibrosis of gingival, Ankylosis of primary teeth, and absence of the permanent tooth bud.

Extraction of supernumerary teeth:

Supernumerary & supplemental teeth can interfere with eruption of nearby normal teeth. They may cause deflection and abnormal eruption of the adjacent teeth. They should be identified and extracted before there is any displacement of adjacent teeth.

Eliminating Occlusal Interference:

Occlusal interferences may lead to deviations in mandibular path of closure and may predispose the child to bruxism. Occlusal interferences can be detected by using articulating paper and should be removed by selective grinding.

Management of ankylosed teeth: “Ankylosis is a condition characterized by absence of periodontal membrane in a small area or the whole of the root surface.” They do not resorb naturally and prevent or deflect the eruption of permanent teeth. Diagnosis of such tooth and surgical removal at an appropriate time is required for normal eruption of permanent tooth.

Management of abnormal frenial attachments:

Thick and fleshy maxillary labial frenum leads midline diastema which can be diagnosed by blanch test and should be treated at an early stage for prevention of malocclusion.

Space Control in Deciduous Dentition:

An important part of preventive orthodontics is the correct handling of spaces created by the untimely loss of deciduous teeth. Commonly people think that deciduous teeth are going to be lost in due course and there is no need for repair. Unfortunately, some dentists also give the same suggestion, probably because the children are comparatively more difficult to manage. Conservation of every millimeter of space in each child’s original dental arch should be the direct treatment goal of the dentist guarding the developing dentition. The failure to correct the position of an ectopically erupting 6-year molar or to guard against the lingual tipping of newly erupted lower permanent incisors by muscular forces could cause a loss of valuable space.

The main causes for decrease in arch length during the stage of mixed dentition period are the loss of space due to carries caused by interproximal carious lesion in primary teeth and early loss of primary teeth by extraction or caries. Premature loss of deciduous teeth is best tackled with space maintainers.

Whenever a deciduous tooth is lost prematurely than it would normally be shed, predisposing the patient to malocclusion a space maintainer should be placed. Primary dentition is essential for growth of jaws, for normal function and eventually for normal position and occlusion of permanent teeth and so premature loss of primary tooth is to be avoided. Early loss of primary teeth may affect the masticatory function if posterior teeth are lost. Before speech develops in a child if there is loss of anterior teeth it affects speech development, which might become difficult to overcome. Premature primary tooth loss leads to excessive eruption of opposing tooth. Undoubtedly, the premature loss of an primary teeth alters appearance of child which in some cases may produce undesirable psychological effects. Parents usually accept loss of anterior teeth after 6 years of age, but when lost at an early age, some parents are concerned by appearance of remaining dentition.
Attitudes of parents and child towards dental health and care are largely influenced by attitude of dentist towards preservation of primary dentition. Any suggestion that the primary dentition is important is reflected as a positive awareness and motivation towards dental care in minds of parent and child. Space closure after premature loss of tooth is most important sequelae. Space closure by drifting of adjacent teeth into the edentulous space may prevent eruption of succedaneous tooth or deflect or may force it to take an abnormal eruption path. Asymmetric loss of primary tooth that is loss of tooth only on one side of arch may lead to drifting of teeth into extraction site and shift of dental midline.

‘Space Control’ refers to a careful supervision of the developing dentition, it reflects an understanding of the dynamic nature of occlusal development. Space maintainers is a mechanical device which is intended to maintain space which was previously occupied by tooth/teeth in order to prevent further dentofacial anomalies and malocclusion. 8

**Conclusion**

Preventive orthodontics, as a discipline encompasses all the necessary steps to provide proper transition of primary to permanent dentition without any problems into proper functional, esthetic and occlusal relationships helping in proper growth and development of the jaws and face. Thus, prevention is better than cure’ is applied to the role of preventive orthodontics in dentistry.

Minimal Invasive Surgical Approach for Treatment of Excessive Gingival Display: A Case Report

Gatha Mohanty¹, Abhaya Chandra Das², Anurag Satpathy³, Saurav Panda², Rinkee Mohanty⁴

¹Senior Lecturer, ²Reader, ³Professor, ⁴Professor and Head, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha ‘O’ Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

‘Gummy smile’ often the common term used for excessive gingival display may be a source of embarrassment for patients especially when esthetics is a major concern. To reduce the gingival display, a surgical technique was planned that limits the pull of elevator lip muscles by shallowing the vestibule, thereby reducing the excessive display of gingiva when patient is smiling. The procedure is predictable, safe with minimum risks and side effects. It serves as an alternate modality in esthetic treatment.

Keywords: Excessive gingival display, surgical lip repositioning, facial esthetics, gummy smile.

Introduction

Enrichment of facial beauty is inherent to any dental treatment strategy since the smile impacts an individual’s personality¹, ². Restorative dentistry aims to create a pleasing patient smile. However, patients reporting with skeletal and gingival deformities might require a complex and comprehensive esthetic rehabilitation or a multi-disciplinary approach ³-⁵.

Around 50% of patients exhibit some form of a gingival display. This display between the lower border of upper lip and the gingival margin of the central incisors during a normal smile is 1-2 mm⁶, ⁷. In contrast, a gingival display of 4mm or more is considered unattractive by in general ⁸. There could be several causes of excessive gingival display such as delayed eruption, incompetent upper lips⁹ or maxillary vertical excess ¹⁰. The present report presents a case of management of excessive gingival display through a minimally invasive surgical approach.

Case report: A 20-year-old female patient was referred to our outpatient department with the chief complaint of protruded upper front teeth and gummy smile. The patient was cooperative and had no tissue abuse habits. She was concerned for her compromised esthetics and was seeking a correction of the same. Her family history and medical history was non-contributory. No abnormality was detected on extra-oral examination. Intraoral clinical examination revealed a normal gingiva with stippling and gingival hyperpigmentation. However, the smile line presented by the patient was high revealing with 5-6mm of excessive gingival tissue display which extended from maxillary right first premolar to maxillary left first premolar (Fig1). A diagnosis of severe vertical maxillary excess was made. A treatment plan comprising of orthognathic surgery followed by fixed orthodontic treatment was presented to her as a definitive treatment plan. However, the patient wanted a less invasive procedure that would only reduce the chief complaint of excessive gingival display. Thus, a lip repositioning surgery was decided. Procedure was verbally explained to the patient in the language of her understanding and an informed written consent was obtained.

Procedure: After all haematological investigations and due description of the procedure the patient was administered local anaesthesia with lignocaine hydrochloride and 2% adrenaline at 1:100,000 to anesthetize the upper lips and the area between maxillary premolars. Local infiltration was administered in the...
buccal vestibule and extended to achieve additional hemostasis. Upper lip was retracted and an incision outline was marked with indelible marking pencil after drying the tissues with a sterile gauge (Fig 2). A split thickness incision was made following the mucogingival line using a no 15 Bard Parker blade and handle. A second parallel incision was also made 11-12 mm from first incision. Both these incisions were joined at the mesial line angles of maxillary first premolars on either side creating an elliptical outline (Fig 3). Considering the fact that the amount of tissue excision should be two times of the gingival display to be minimised, 10-12 mm tissue was excised. Epithelium was removed within the incision outlines with exposure of submucosa and released for attached fibres (Fig 4). Bleeding was controlled with finger pressure and use of additional local anaesthesia. Stabilization sutures were placed to approximate the tissues with 5-0 vicryl with proper alignment of the first and second incision lines (Fig 5). Hemostasis was achieved by additional digital pressure.

The patient was cooperative and recovered well. Verbal and written post-operative instructions were given. She was prescribed non-steroidal anti-inflammatory drugs for pain relief. She was advised to apply cold compressions for few hours post-operatively.
and was asked to restrict lip movement for few days. After 48 hrs, she complained of tightness around the upper lip while smiling but it was not associated with any swelling. Healing was uneventful and sutures that became loose were removed over a period of four weeks. The procedure limited the functionality of elevator muscles thus reducing gingival display. Patient was pleased with the esthetic outcome. One month (Fig 6) and three months (Fig 7) follow up also showed stable results with increase in lip competency and decrease in gingival display. Overall results were satisfactory.

Fig 6: One month post-operative comparison at rest

Fig 7: Three months post-operative comparison of smile

Discussion

This case report presents a minimally invasive procedure to minimise the amount of gingival display in patients with vertical maxillary excess. The results showed a stable and satisfactory result up to 1 year. Excessive gingival display can occur due several reasons such as vertical maxillary excess, excessive gingival overgrowth, altered passive eruption, anatomically short upper lip, hypermobile muscles of the upper lip or a combination of any of these factors11, 12.

In cases with vertical maxillary excess, an orthognathic surgery is usually required for the correction. In the current case also, gummy smile was a result of vertical maxillary excess. However, patient was not willing to undergo an orthognathic surgery and opted for lip repositioning procedure, which is a minimally invasive procedure in comparison to orthognathic surgery. Further, orthognathic surgery is requiring hospitalisation and is associated with high morbidity and increased.

Lip repositioning is commonly a plastic surgical procedure. Alloplastic or autogenous separators can also be used to prevent reattachment of smile muscles13. Rhinoplasty along with lip repositioning can be performed where the nasal approach combines both procedures with minimal surgical extension14. The presented procedure is relatively safe and had minimum side effects. Although technique sensitive, it is easy and cost effective. Besides results were immediate. This case was uneventful though few cases have reported mucocele, swelling and discomfort15.

Several case reports9, 10 have documented successful outcome of lip repositioning surgery. In a case series of seven cases16, a mean reduction of excessive gingival display in excess of 6 mm was achieved. Our case deals with vertical maxillary excess which is similar to that reported by Ambrosio et al 17 which reported a stable result till two years. Also, Balasubramaniam et al 18 reported a similar stable result with lip repostion surgery in a patient with vertical maxillary excess up to 1 year.

Conclusion

Surgical lip repositioning is a safe procedure to minimise excessive gingival display by re-positioning upper lips. Although the long-term stability remains questionable, still this procedure remains a viable alternate treatment modality in esthetic rehabilitation.

Unusual Presentation of Dentigerous Cysts Arising from Complex and Compound Odontomas

Shubhangi Pareek¹, Swagatika Panda², Subrat Padhiary³, Sreepreeti Champatyray⁴, Neeta Mohanty⁵

¹Post Graduate Trainee, ²Reader, ³Professor, Department of Oral Surgery, ´Senior Lecturer, ⁵Professor and Head, Department of Oral and Maxillofacial Pathology and Microbiology, Siksha ‘O’ Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

An Odontoma arises from developing extra-odontogenic epithelial components of the dental lamina giving rise to an extensive group of tissues which are usually arranged in an aberrant manner, comprising of sound enamel, dentin, cementum as well as pulp. A composite odontome on the other hand has well organized dental tissues making the lesion resemble and have more tooth-like structures. Dentigerous cyst may also sometimes arise in association with such odontomas having a more aggressive behaviour as well as recurrence, hence requiring an accurate histopathological diagnosis, treatment modalities and restablishment of its prognostic potential. This article highlights two case reports of dentigerous cyst arising from complex and composite odontomes.

Keywords: Odontoma, Hamartoma, Complex compound odontoma, Dentigerous cyst, Odontome.

Introduction

The word odontoma is any tumor of odontogenic origin with fully differentiated epithelial and mesenchymal components leading to the deposition of bizarre enamel and dentin by the ameloblasts and odontoblasts respectively.¹ This is so because the alignment of odontogenic cells does not reach the typical state of morphodifferentiation. It is a hamartomatous malformation rather than a neoplasm designating 67% of all odontogenic tumors.²

Case 1: A 24-year-old woman presented with pain and discomfort in the left posterior mandibular jaw region since 6 months. There was no associated medical history. On inspection, a single, hard, well defined bony mass was present on occlusal surface of 38, extending from occlusal surface to distal surface of tooth with attachment to soft tissue, measuring about 3mm x 5mm in size, with a rough surface and non tender on palpation. Intraoral radiograph revealed an irregularly shaped radio-opacity surrounded by a well-defined radiolucency attached to the occlusal surface of 38, which extended distally to involve the soft tissue (Figure 1). Based upon these findings a provisional diagnosis of odontome was given. Complete surgical excision was performed and tissue was sent for histopathological examination. The calcified mass (Figure 2) and soft tissue (Figure 3) were separated and processed individually.

Figure 1. Intraoral periapical radiograph showing a radio-opaque mass surrounded by a radiolucent rim in association with impacted mandibular 3rd molar.
region of the jaw since 1 year. There was no associated medical history. On inspection, a roughly round shaped swelling extending from 22-25 region, with congenitally missing maxillary left canine along with obliteration of labial vestibule. Panoramic radiograph showed well defined radiolucent area with corticated border and impacted 23 pushed superiorly. An area of focal calcification was present within the radiolucency with deviation of regional teeth (Figure 4). Based upon these findings a provisional diagnosis of adenomatoid odontogenic tumor was given. After proper surgical excision the tissue was sent for histopathological examination. The calcified (Figure 5) and cystic components (Figure 6) were processed individually.

Case 2: A 20-year-old woman presented with slow growing, painless swelling in the left maxillary anterior region of the jaw since 1 year. There was no associated medical history. On inspection, a roughly round shaped swelling extending from 22-25 region, with congenitally missing maxillary left canine along with obliteration of labial vestibule. Panoramic radiograph showed well defined radiolucent area with corticated border and impacted 23 pushed superiorly. An area of focal calcification was present within the radiolucency with deviation of regional teeth (Figure 4). Based upon these findings a provisional diagnosis of adenomatoid odontogenic tumor was given. After proper surgical excision the tissue was sent for histopathological examination. The calcified (Figure 5) and cystic components (Figure 6) were processed individually.

Based upon the histopathological findings, a final diagnosis of ‘dentigerous cyst associated with complex composite odontoma’ was made.

**Figure 2.** Photomicrograph of H&E stained section reveals aberrantly arranged eosinophilic stained material with a dentin-like structure (10x view).

**Figure 3.** Photomicrograph of H&E stained section showing a thin, non-keratinized epithelial lining similar to dentigerous cyst lining (10x view).

**Figure 4.** Panoramic radiograph revealed a well defined radiolucent area with corticated border and impacted 23 pushed superiorly. An area of focal calcification is also present within the radiolucency with deviation of regional teeth.

**Figure 5.** The microscopic picture of decalcified section showed eosinophilic material resembling odontome (4x view).
Based upon these findings, a final diagnosis of 'dentigerous cyst associated with compound odontoma' was made.

Discussion

Dentigerous cyst and complex odontoma are very frequent lesions of the oral cavity but very rarely do they occur concomitantly often leading to improper diagnosis and significant jaw destruction. An odontoma passes through similar stages of tooth development so in the initial stage where there is resorption, it is radiolucent followed by an intermediate stage of incomplete calcification, giving a mixed radiolucent and radiopaque appearance on the radiograph. The most radiopaque stage indicates completion of calcification. Compound odontome contains odontogenic tissues in an orderly fashion with the resulting structure having morphologic similarity to teeth but on the other hand complex odontomes are formed by improper arrangement of tooth components without any resemblance to the normal. Some tumors on the other hand are combination of these two types and are called compound complex odontomes (having not only ample teeth-like structures but also calcified mass of dentin tissues in a bizarre manner) 62% of the compound odontome has a predilection for anterior maxilla, without any gender predominance. 68% of the complex odontomes occur in posterior mandible more so in females.

Classification:

According to World Health Organization (WHO) classification, odontomes are classified as:

- Complex odontome: In this type, calcified tissues are in a disorganized fashion with no resemblance to the normal.
- Compound odontome: The odontogenic tissues are present in a well defined manner, giving rise to various teeth-like structures, bearing no morphologic similarity to normal teeth.
- Ameloblastic fibro-odontome: Different quantities of calcified dental tissue and dental papilla-like tissue present, with the dental papilla resembling an ameloblastic fibroma. It is regarded as an immature forerunner of complex odontoma.

A recent variety known as hybrid odontome is also described by some authors.

Etiology:

The precise etiology of odontome is unknown. Some authors suggest the role of trauma and infection in the formation of these lesions while some authors like Hitchin proposed that they are either inherited or due to mutations, mainly postnatal, during tooth development.

Odontomas are mostly found before the second decade of life. The dentigerous cyst on the other hand originates from the follicle of a tooth germ or unerupted tooth or in rare occasions from an odontome containing the same with in it. It progresses by the cystic degeneration of the epithelial counterpart and eventually by fluid buildup mechanism between the reduced enamel and tooth enamel. Their ability to grow in size and destroy the jaw bones, these cysts cause root resorption of the adjoining teeth with neoplastic transformations like ameloblastoma or carcinoma. Thus they should be completely enucleated and thoroughly examined histopathologically.

Conclusion:

Odontomas are non-aggressive, often remain symptomless and may be accidentally discovered during routine radiography. Dentigerous cyst on rare occasions can arise in relation to an odontome increasing the possibility of the combined lesion to grow large in dimension and display an aggressive behavior. The ability of dentigerous cyst to undergo neoplastic transformation and invasion demands a proper and

Figure 6. The soft tissue section showed thin, non-keratinized epithelial cystic lining resembling reduced enamel epithelium classical of dentigerous cyst (4x view).
total enucleation during surgical procedures and also highlights the significance of a proper histopathological diagnosis

Surgical Clinical Crown Lengthening: A Prerequisite for Crown Placement in Fractured Teeth

Abhaya Chandra Das1, Saurav Panda1, Manoj Kumar1, Saumya Kanta Mohanty2

1Reader, Department of Periodontics and Oral Implantology, 2Reader, Department of Conservative and Endodontic, Institute of Dental Sciences, Siksha ‘O’ Anusandhan, (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Treatment options for a fractured tooth, particularly at the level of gum, are extremely limited. While restoring such fractured tooth, the biologic width must be considered. This can be maintained sometimes by surgical crown lengthening procedure. Here, one patient with fractured 21 and 22 reported. In the case, gingivectomy was carried out to remove gingiva around the neck of the tooth under local anesthesia followed by removal of the circumferential bone in the gingival sulcus. A significantly increased length of clinical crown in all aspect was achieved. Then customized posts with cores were prepared and then teeth were restored and two-unit crowns were placed after 6 weeks post-surgically. The marginal periodontal tissue shows well, healthy conditions during 6 months period of healing. Thus, the fractured teeth were restored by creating biologic width by crown lengthening procedure.

Keywords: Fractured tooth, biological width, endodontic treatment, crown lengthening, gingivectomy, post and core.

Introduction

Periodontal health acts as pivotal role for the success of any dental treatment.1 Prior to initiate any dental procedures such as restorative, esthetic or implant dentistry, active periodontal disease should be managed and controlled to have the long-term success, comfort, good function, treatment prognosis and maintenance care.2 However, in compromised short clinical crown, the retention of crown is difficult. Surgical clinical crown lengthening, extrusion of tooth by orthodontic treatment are the option to increase the clinical crown length.3

Crown-lengthening procedures: Surgical clinical crown-lengthening procedures are carried out to increase retention form, which ultimately allow proper tooth preparation, impression procedures,2 and placement of restorative margins and adjustment of gingival levels for aesthetics.3,4 To preserve the biological width is utmost important while performing the surgical crown lengthening procedure. The biologic width is the summation of the physiologic dimension of the junctional epithelium and connective tissue attachment. This measurement has been found to be relatively constant at approximately 2 mm (±30%).5 It has been suggested that there may be development of gingival inflammation, formation of pocket, and loss of alveolar bone, if violation of biologic width has been done by the placement of restoration within its zone.6,7 Consequently, it is mentioned that there should be a minimum of 3.0 mm distance between the gingival margin of crown and alveolar bone crest.8-11 This permits for adequate biologic width when the restoration is placed 0.5 mm apical to the gingival margin.10,11

Surgical clinical crown lengthening may include either the removal of gingival tissue (gingivectomy or flap technique) or both gingival tissue and alveolar bone (alveolectomy).12 Gingivectomy alone is indicated in case of adequate attached gingiva and presence of more than 3 mm of tissue coronal to the bone crest.12 In case
of inadequate attached gingiva and less than 3 mm of soft tissue; a flap procedure along with bone contouring (alveolectomy / or alveoloplasty) is required. In case of caries or tooth fracture, the surgical clinical crown lengthening should provide a minimum of 4 mm distance from the apical extent of the caries or fracture margin to the alveolar bone crest in order to ensure Ferrule effect and have adequate retention.12

Case report: A 25 years old man reported in the Department of Periodontics, with fractured anterior teeth. On intra oral examination, Ellis class III fracture in 21 and 22 (Figure 1) was found, the distance from the marginal gingiva to alveolar crest was 4 mm and 3 mm in 21 and 22 respectively.

Figure 1. Ellis class III fracture in 21 and 22

Oral prophylaxis and endodontic treatment were carried out. Then, gingivectomy was carried out to remove gingiva around the neck of the teeth (Figure 2) under local anaesthesia (2% lignocaine hydrochloride with 1:80,000 epinephrine) followed by removal of the circumferential alveolar bone (Figure 3) with the help of round diamond bur carefully.

Figure 2 Marking done for gingivectomy

3. Part of alveolar bone removed circumferentially

A significantly increased length of clinical crown in all aspect was achieved (Figure 4). With the help of Gates-Glidden reamer (Mani, INC, Japan) number 4 for 22 and number 5 for 21, post spaces were prepared by removing part of gutta percha in both teeth. At least 4 to 5 mm of the obturating material should be left at the apex in order to have an endodontic seal.13 Then impression was made with rubber base material and model cast was prepared. Then customized posts with cores were prepared in laboratory. Then posts with cores were cemented by using glass ionomer cement inside the teeth. Then teeth were restored (Figure 5) and two-unit crowns were placed after 6 weeks post surgically (Figure 6). Marginal periodontium was observed to be healthy during a 6-month recall period.

Figure 3. Part of alveolar bone removed circumferentially

Figure 4. Increased length of clinical crown

Figure 5. Post and cores placed
Figure 6. Two-unit bridge placed

Conclusion
The constructive interdisciplinary approach with proper diagnosis, comprehensive treatment plan should be carried out to have patient comfort, function, esthetic, longevity, maintenance of the restoration. Surgical clinical crown lengthening, which is one of interdisciplinary approach, may be a prerequisite for crown placement in a fracture tooth. Thus, in this case the fractured teeth were restored by creating biologic width by using surgical crown lengthening procedure.

Immediate Placement of Implants in Fresh Maxillary Anterior Tooth Region: 18 Months Follow Up: A Case Report

Monika Samal1, Sreeprada Dash1, Gunjan Srivastava2, Sitansu Sekhar Das2, Bodhisatta Mukherjee1

1Post-graduate Trainee, 2Professor; Department of Prosthodontics, Institute of Dental Sciences, Siksha ‘O’ Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Implant placement in the anterior maxilla poses highest amount of aesthetic challenges concerning with bone loss after extraction of tooth, that is followed by collapse of the buccal gingiva. This leads to a scenario where implant placement becomes difficult and the aesthetic of the surrounding mucosa is compromised. Through the process of immediate implant placement just after the extraction reduces the treatment time and cost, preserves the aesthetic of the surrounding mucosa and increases the comfort of the patient. here in this case report, we have discussed the results of an immediately placed implant in the region of maxillary left and right lateral incisor region with bone regeneration using a non-resorbable membrane and no other graft materials. in the 18 months follow up, the implant placement showed a stable peri implant condition which was confirmed through clinical and radiographic evaluation.

Keywords: Immediate extraction, dental implant, immediate placement, ridge preservation, aesthetics.

Introduction

Tooth loss in the esthetic zone most often results in the loss of bone volume in the vertical and horizontal directions. In order to prevent crestal bone resorption immediate implant placement in the extraction socket was introduced(1). It was first introduced by Schulte, who placed an implant in to the tooth socket immediately after extraction that helped to maintain the periodontal architecture and maintained the gingival contour (2). The indications for immediate implant placement were determined basing upon the ability of the appropriately sized implant to attain primary stability in an ideal restorative position. The timing of implant placement is mainly decided through certain factors those are soft tissue contour and bone quantity and quality of the surrounding bone, the presence of pathological condition and the condition of contralateral teeth(3). To achieve this, there are 5 factors to be considered that can help to prevent blunders which lead to difficult esthetic situations. The following are (I) the presence of a buccal plate of bone, (II) primary implant stability, (III) design, shape and size of the implant (IV) soft tissue and hard tissue grafting between the buccal plate and the implant and (V) gingival biotype (4). The virtues of immediate implant placement in the upper anterior region includes reduction in the treatment time and preservation of the remaining osseous and gingival morphology. This article presents clinical case of immediate implant placement in freshly extracted socket of a left lateral incisor region and right lateral incisor region.

Clinical Report

A male patient, aged 25 years, reported to the Department of Prosthodontics at Institute of Dental Sciences, Bhubaneswar, with the chief complaint of missing teeth in upper anterior region. A clinical evaluation (Figure 1) revealed missing teeth in relation to 12, 11, 21 and slight discoloration with respect to 22. The patient was explained regarding the present state, other treatment options and the planned treatment protocol which included immediate extraction of 22 and implant placement in that region. The patient was very cognizant about his aesthetic and was very keen for the best possible rehabilitation of his teeth and so he opted for proposed procedure.

e-mail: drgunjans22@gmail.com
An CBCT was advised for appropriate treatment planning. The CBCT revealed fractured 22 tooth with unfavourable diagnosis. Immediate extraction of 22 and placement of two root form implants in the region of 12 and 22 was decided as the treatment plan. Equinox myriad plus implants of size 3.8×13mm was chosen for right maxillary lateral incisor region (12) and 3.8×13mm size implant was chosen for left maxillary lateral incisor region (22). The fractured tooth (22) was atraumatically removed after an injection of 2% lignocaine hydrochloride with 1: 100,000 epinephrine local anaesthetics (Figure 2). The extraction socket was debrided and sequential osteotomy was done in the maxillary left lateral incisor region by pilot drill (2.0mm diameter) followed by 2.3mm drill and 3.8mm drill was done up to the length of 13mm mark. The same osteotomy procedure was followed for the maxillary right lateral incisor region and the osteotomy drill was done up to a diameter of 3.8 mm drill & the length of 13mm mark. Parallelism of the osteotomy sites were checked & after confirming the parallelism, Equinox Myriad Plus implants were placed in the maxillary left and right lateral region (3.8×13mm) with the insertion torque of 20Ncm (Figure 3). Radiographic confirmation was done & cover screws were inserted (Figure 4). 3 months later radiographs were taken to check for the Osseo-integration of implants. Cover screws were then removed following which gingival formers were placed respectively and then sutured (Figure 5). Straight or angulated abutment could not improve the angulation issues so a castable abutment (Figure 6) was preferred for the patient in order to enhance the aesthetics in the anterior zone.

After 15 days impression was made in close tray technique. Jig trial was done for the patient to check the appropriate angulation of the abutments and the correctness of the impression made earlier. Cement retained Zirconia crowns were fabricated along with gingival porcelain to mask the gingival defect. After 1 week, the implants were loaded with cement retained zirconia crowns (Figure 6,7). Patient follow up was done after 7 days, 1 month and 6-month, 1 year, and 18 months (Figure 8) subsequently.
Discussion

Immediate implant placement is mostly indicated in cases where extraction of the tooth occurs due to trauma, root fracture, External root resorption, unfavourable crown-root ratio, and intact bone walls of the socket (5). This is most commonly opted treatment plan in the loss of anterior teeth. The success rate of immediately placed implants in maxilla is 66%-95.5% and in mandible 90%-100.(6)

In such cases, the number of surgical visit and time of treatment is reduced as compared to conventional method of tooth extraction and regeneration followed by implant placement at the second surgical visit i.e. after 4 to 6 months of regenerative therapy. An adequate treatment plan was made that comprised of soft tissue treatment protocol that involved a set of well-defined aesthetic goals which included restoring the gingival defect with appropriately shade matched gingival porcelain. In this case report, primary stability was achieved without the use of any bone augmentation procedure as the implant diameter approximates the socket dimension and we are pleased with the gingival aesthetic. Furthermore, in cases with extreme angulation problems where a prefabricated abutment and angulated abutment cannot be used, a customised castable abutment is preferred in order to accommodate proper coping and crown designs. The long-term success of an implant immediately placed in to the extraction socket of a lateral incisor and achieving finest aesthetic in the anterior maxilla is demonstrated in this report. The main objective of our study was achieved thorough proper gingival & anterior aesthetics and optimum patient satisfaction.(8)

Conclusion

Immediate implant placement following extraction of tooth is a feasible and probable solution in case of tooth loss. Minimally invasive surgical procedure, reduced chairside time and treatment procedure along with minimum post extraction complications, preservation of gingival contour and integrity are a benefit not only to the patient but also to the clinician. However appropriate case selection, proper diagnosis and treatment planning, scrupulous post-operative treatment care preceded by an effective surgical and prosthetic protocol forms the necessity in the long term success of the immediate implants.(9) This case report demonstrates that immediate implantation to fresh extraction socket in the upper anterior region is an alternative, predictable surgical
treatment plan in replacement of missing teeth having better prognosis.

Dental College & Hospital, Cuttack, India, ⁶Professor, Department of Prosthodontics, CDCRI, Rajnandgaon, Chhattisgarh, India

Abstract

Recurrent respiratory papillomatosis (RRP) is a benign lesion found in the respiratory airway due to infection of human papillomavirus (HPV). RRP can affects children to young adults. Most of the pediatric occur at birth which contaminated from birth canals of the mother. In adult patients, the infections transmitted via sexual route. The sores are frequently observed as exophytic knobs, for the most part in the larynx and some of the time at the tracheobronchial trees nasopharynx and lung parenchyma. The disease is frequently random and differ from spontaneous reduction to aggressive importunate or recurrence in nature. Although it is a rare happening, RRP has chance for malignant transformation to squamous cell carcinoma. The diagnosis is confirmed by histopathological examination. Hence, no specific treatment for RRP available till date. Along with several adjuvant therapies, surgery is the eventual treatment option.

Keywords: Recurrent respiratory papillomatosis; Human Papilloma virus; Larynx; Laser, Benign.

Introduction

RRP is a self-constraining disease and benign growth brought about by human papilloma virus (HPV), where the sores found in the aerodigestive tract.¹ Bimodal age dissemination is related with RRP where characteristic kids and youthful adults are frequently influenced.¹ This disease is transmitted by contact with contaminated discharges from birth channel. The histopathological presentations are benign squamous epithelium stratification.² This lesion typically confined to the larynx but sometime observed at the tracheobronchial area, nasopharynx and exceptionally found at the lung’s parenchyma.³ The diagnosis of RRP fluctuate from spontaneous reduction to aggressive importunate or recurrence and transmigrating to lungs. The analysis of RRP depends on clinical presentation medical records and imaging. But the last finding of RRP is constantly relied on histopathological analysis where samples are taken from the sores of the larynx and trachea. It regularly starts at the commissure and anterior piece of the vocal strings and later on includes every one of the pieces of the larynx and even lower aviation route like trachea, bronchi and lung parenchyma in certain patients. The lesions of the laryngeal papillomatosis are usually multiple in numbers and rarely solitary.⁴

Epidemiology: The occurrence of RRP is about 4 per 1lakh in kids and only 2 persons per 1 lakh in adults.⁵ The incidence of RRP varies according to different factors like age and socioeconomic status.⁵ These are higher among low educational and socioeconomic backgrounds.⁶ But again the severity of the diseases cannot be associated with socioeconomic status.⁵ The prevalence of HPV infections is more among females. The prevalence of the disease among female is 26.8% in 14-59 years of age and 45% in 20-24 years of age.⁶ The infantile type found in the patients of having
less than twenty years of age. The juvenile type has aggressive presentations with several papillomatosis lesions and also has found high recurrence rate. After the of 20 years, the adult form of RRP is found and more commonly seen in male. In adult RRP, the papillomatosis lesions are frequently solitary with having high extent of inflammation which do not spread and has less chance of recurrence and less common than juvenile type. HPV infection mostly occur during birth as birth canal acts as source of infection. Sometimes transmission of contamination happens preceding birth by means of the placenta in roughly 12% of cases. Anogenital warts of the mother act as risk factors for juvenile type of RRP. Nearness of maternal anogenital papillomatus sores during pregnancy period or during birth of infant increases the danger of RRP by around 231 multiple times in contrast with the nonappearance of such injuries at the season of birth. In grown-up patients, HPV is transmitted explicitly by means of oral contact with contaminated genitalia. Sexual activity increases the risk for HPV infections in adults.

**Etiopathology:** RRP is caused by a virus called HPV, for the most part by the subtypes 6 and 11 which are likewise found in the genital condylomas. Similarly, the subtypes of HPV 16 and 18 are likewise associated with laryngeal papillomatosis and in uterine cervical carcinoma. HPV is a DNA virus which can parasitizes the upper epithelial cells nuclei. It has inclination for the regions where there is an intersection of squamous and ciliary columnar epithelium. The normal area of the RRP are limen vestibule, mid-zone of the laryngeal surface of the epiglottis, nasopharyngeal surface of the soft palate, lower and upper margins of the laryngeal ventricle, carina, under surface of the vocal cords and bronchial spurs. HPV mostly contaminates the basal epithelial layer of the mucous layer by means of minor abrasion. At that point it stimulates the epidermal development factor receptor pathway and restrains diverse tumor-suppressing proteins, finishing in cell multiplication and epithelial separation. These system lead to cauliflower like exophytic mass sores, regular of RRP. These development frequently found in the transitional regions between the squamous epithelium and the ciliated columnar epithelium. The nodular development of RRP frequently found in the larynx (Figure 1), however, regularly include the ventricles, subglottis, laryngeal surface of the epiglottis and at vocal folds. RRP can also affect any region of the aerodigestive tract and stretch out to the tracheobronchial tree and lung parenchyma. RRP influence distal aviation route in just 2 to 5% of the patients with papilloma of the larynx while the pulmonary parenchyma is influenced in just 1% of cases.

**Clinical Presentations:** Juvenile RRP patients presents with multiple lesions and high chance of recurrence. However, in adult RRP, the papilloma can be aggressive and less prone for recurrence. The common clinical presentations are progressive voice hoarseness, stridor and respiratory distress. Cough, failure to thrive and dysphagia are rare. In kids, the clinical presentations include stridor and breathing difficulty and triad of progressive voice hoarseness. In adult patient, the commonest clinical presentation is voice hoarseness. On examination, patients present with wheezing, tachypnea, stridor and accomplice muscle retraction in respiration. In some severe cases, patients often present with respiratory distress and airway obstruction. Due to several non-specific clinical presentations, RRP may mimic to common laryngeal diseases like laryngitis, bronchial asthma, bronchitis and croup. Peripheral dissemination of the lesions may cause recurrent pneumonia, atelectasis and malignant degeneration with presentations of dyspnea, hemoptysis, fever and cough. RRP is often confused with pulmonary tuberculosis. Sometimes the clinicians classify the RRP into aggressive and non-aggressive based on the severity of the symptoms. Destructive RRP is portrayed by prerequisite of at least ten surgeries with at least three surgical procedure being done inside one-year length or by when the illness spread distally towards the subglottic aviation route. Non-aggressive RRP is described by the necessity of less than ten surgeries with lesser than three surgery procedures are being performed inside the one-year time frame or no distal spread of the ailment coming to the subglottic zone. In comparison to adult RRP, juvenile RRP need more surgical procedures because of recurrences more in juvenile variety and larger area of involvement occur in children. Juvenile RRP has similar involvement in the airway between males and females. The dynamic and extensive development (Figure 2) in the aviation route prompts dyspnea and stridor. In juveniles incessant cough and dysphagia are rare. Kids analyzed as RRP before the age of 3 years are 3.6 times almost certain require 4 medical surgery every year and shows multiple infected anatomical areas.

**Investigations:** There are several investigations modalities available for diagnosis of RRP. The diagnosis of the RRP is less commonly done by imaging like
X-ray. In case of pulmonary, chest X-ray may show solid or cavitated nodules in the lungs. Nodular injuries or pedunculated mass are seen less every now and again in trachea and principle bronchi. Helical CT sweep is the perfect methodology of imaging for appraisal of RRP. It has high level of exactness for distinguishing proof of the injuries in tracheobronchial respiratory sores. The CT output picture are central or diffuse aviation route narrowing because of nodular sores happening at the mucosal surface of the tracheobronchial lumen. CT sweep picture of lungs in RRP are single or numerous multi-lobulated well-depicted strong nodular or polyoidal injuries of various sizes with a centrilobular dispersion, dissipated all through the lungs (Figure 3). Lesions are regularly products seen at the basal and back piece of the lungs. Different discoveries in CT output are atelectasis, combinations, air catching and bronchiectasis. Pleural emanation and lymph hub development are once in a while observed with the exception of if there should be an occurrence of harmful change of RRP. Normal examination ought to be finished with CT sweep to discount threatening change. Virtual bronchoscopy is at some point an elective technique for CT check for surveying the tracheobronchial tree. MRI can demonstrate the aviation route structures like larynx, trachea, bronchi and lungs yet its job in the analysis of RRP is rarely assessed. The sores in the RRP may demonstrate take-up on 18F-fluorodeoxyglucose positron discharge tomography/registered tomography (18F-FDG PET/CT) because of raised cell multiplication. Perceptibly, the laryngeal papillomas seem pedunculated, uneven and nodular with changing in sizes. In histopathological assessment, the papillomas are exceptionally vascularized, frequently keratinized neoplasms made up of connective tissue lined by stratified squamous epithelium and task apparently in finger like fronds.

**Treatment:** The treatment of RRP comprises of resection of papillomas for keeping up aviation route patency, improve voice quality and anticipate complexities. Medical procedure is the treatment of decision in RRP. Cold microsurgery, laser or medical procedure with microdebrider or coblation is utilized which extras sound tissue. The total expulsion the injuries may prompt repeats in numerous patients because of inactive infection. In pediatric patients, roughly five medical procedures a year expected to forestall repeats. Presently, the ongoing careful alternatives in RRP are traditional tweezers, CO₂ laser, coblation and microdebrider. Neodymium-yttrium-aluminum-garnet laser (Nd-YAG) and beat light are at some point utilized in Juvenile RRP. If there should arise an occurrence of broad sickness with a genuine hazard for laryngeal aviation route bargain particularly when a few careful mediations fizzled for getting patent aviation route, tracheostomy is required. Comparing with HPV-6 contamination, HPV-11 disease gives off an impression of being bound to bring about tracheostomy. When tracheostomy is must, decannulation is done when the aviation route is steady and sickness is controlled, as it might prompt fast popular colonization and cause distal spread of the illness. Unfortunately, around half of the patients those experiences tracheal papillomas. Approximately 20% of the patients experiencing RRP require adjuvant medicinal treatment notwithstanding medical procedure for controlling the infection. The present criteria for adjuvant treatment are in excess of four surgeries for every year; repeat of papillomas with traded off aviation route and distal different site spread of the infection. Most of the restorative treatment act in immunomodulation and restraint of HPV replication and expansion of the infection. The drugs utilized are interferon, retinoid, antiviral and inhibitors of the oxygenase-2 cycle. There are diverse adjuvant medications are given if there should arise an occurrence of RRP care. These adjuvant treatments have been recorded in the literary works however none appear to accommodating for the fix of the sickness. The palliative consideration has been given as photodynamic treatment, interferon-alpha, indole-3-carbino, cis-retinoic corrosive, cidofovir, acyclovir, ribavirin, Bevacizumab and tetravalent HPV immunizations. Interferon is one of the adjuvant prescriptions in RRP which give positive outcomes as far as sickness advancement by causing decrease of the sore growth. The impediment of the interferon when given in intravenous course lead to fundamental harmfulness with reversible ascent in serum transaminase level and probability for thrombocytopenia and leucopenia. Common symptoms of interferon are exhaustion, transient fever, queasiness, arthralgia, cerebral pain and spastic diplegia in babies. Directly topical utilization of interferon alpha is attempted however it needs further investigations in patients with RRP. Cidofovir is a cytosine nucleotide simple which specifically restrain viral DNA polymerase during replication of infection. In RRP, it tends to be administrated intravenously or by means of nebulization or by intralesional infusion. Adjuvant intralesional
cidofovir is useful for incomplete or all out relapse of the injuries and decrease the recurrence of careful treatment.²⁹ Intralesional infusion has advantage for keeping up low plasma level so lethality will be limited with no symptoms.³⁰ The quadrivalent immunization is regularly given for counteractive action of cervical and anogenital malignancies and pre-carcinogenetic injuries due to HPV subtypes 6, 11,16 and 18.³¹ Currently, HPV antibodies are not affirmed for the utilization in neonates, so it need further research.⁶ Cidofovir is most generally utilized restorative adjuvant in the treatment of RRP.³² It can be administrated by intravenous course or nebulization or intralesional infusion. Intralesional organization of cidofovir cause inclined toward all out relapse of the sores and abatement the recurrence of surgeries in RRP.³⁰ Intralesional infusion of the cidofovir has practically insignificant symptoms.³³ The long-haul hazards in intralesional infusions isn’t notable while the hypothetical hazard for dangerous change can’t be discounted.³⁰

**Conclusion**

RRP is a benign sore described by papillomatous appearance seen any place in the aero-digestive tract. It causes huge morbidity and in few cases mortality because of repeat and obstructive the aviation route. The disease often restricted to the larynx and sometimes spread to whole airway including bronchioles. The diagnosis is confirmed by histopathology. Clinician must know about the etiology, clinical presentations, laryngoscopic picture and imaging features of the disease for early management of the disease. Unfortunately, there is no restorative cure for RRP available presently & surgery is the ultimate treatment.

Laterally Pedicled Flap and Connective Tissue Graft for Management of Orthodontically Inflicted Gingival Recession – A Case Report

Saurav Panda¹, Sital Panda², Anurag Satpathy³, Abhaya Chandra Das⁴

¹Reader, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), K-8, Kalinga Nagar, Bhubaneswar, Odisha, India; Department of Biomedical, Surgical and Dental Sciences, University of Milan, Milan, Italy, ²MPH Student, Department of Public Health, Regional Medical Research Centre, Bhubaneswar, Odisha, India, ³Professor, ⁴Reader, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), K-8, Kalinga Nagar, Bhubaneswar, Odisha, India

Abstract

Orthodontic therapy induces soft tissue responses thereby resulting in occurrence of localized gingival recession. This case report presents management of orthodontically inflicted Miller’s Class II gingival recession using a laterally pedicled flap as an epithelial cover on connective tissue graft. The positive outcome of the treatment approach is well documented with almost complete root coverage at the end of 1 year follow up. This combined approach could be a promising technique for treating advanced gingival recession cases with significant deep recession defects.

Keywords: Gingival recession, root coverage, pedicle flap, graft.

Introduction

Orthodontic treatment corrects various dental irregularities and contributes to better oral hygiene maintenance at patient level and subsequently delivers improved periodontal status.¹ However, orthodontic appliances often induce localized inflammation in the gingiva. Chronic gingivitis, gingival hypertrophy, irreversible attachment loss, periodontal bone loss and gingival recession could be a result of placement of orthodontic appliances. Most of the reported cases of gingival recession owing to orthodontic treatment have been associated with mandibular anterior teeth.² Gingival recession at the mid-orthodontic treatment stage may be accompanied by dentinal hypersensitivity, plaque deposits and caries. Also, it may result in decreased patient compliance and loss of confidence on the orthodontist.³

Correction of gingival recession can be done by root coverage procedures which may be accomplished by using several techniques, however the most predictable procedure include sub-pedicle connective tissue graft (SCTG) procedure.⁴ SCTG procedures have traditionally been done by sandwiching the harvested connective tissue graft (CTG) between the denuded root surface and the coronally advanced flap (CAF). In addition to CAF, a laterally pedicle flap (LPF) can also serve to provide the epithelial cover. Till date, very few cases have reported combination of LPF + CTG in a SCTG procedure for root coverage.⁵⁻⁷ This combination technique has better predictability and diminishes the chances of gingival recession of the adjacent donor site.⁸ The advantages of the LPF technique are retained, such as flap mobility and accomplishing predictable keratinized gingival width.⁹ The case report presented here describes successful management of orthodontically inflicted gingival recession by using laterally repositioned flap along with connective tissue graft.

**Case Report:** A 20 years old female patient was referred to the Department of Periodontology from the Department of Orthodontia, Institute of Dental Sciences, Bhubaneswar, India for treatment of dentinal hypersensitivity and gingival recession in lower front tooth region. Patient was apparently alright 7 months back when she reported for correction of mal-alignment of teeth (Figure 1a). On intra-oral clinical examination, an isolated Miller class II gingival recession of 5mm at labial surface of the lower left central incisor (#31) was present (Figure 1b). Root coverage procedure for the denuded root of #31 was contemplated for management of gingival recession and dentinal hypersensitivity. A written consent was obtained from her after explaining the treatment plan.

After proper pre-surgical preparation, 2% lignocaine HCL with 1:200,000 adrenaline was administered to anaesthetize the area of operation. Recipient site was prepared by placing an internal bevel incision with surgical blade no. 15 around the denuded root of #31. Donor site was prepared by extending sulcular incisions from the distal surface of #31 till the mesial surface of #33. Following this, two vertical incisions were made; one at the distal line angle of #31 and other at the mesial line angle of #33. Vertical incisions were made continuous with horizontal incisions and were extended apically beyond the muco-gingival junction into alveolar mucosa, to permit adequate mobility of the donor flap. The donor flap was elevated using a sharp dissection. A cut back releasing incision was made to facilitate adequate rotation and to ensure that the flap is free of tension, allowing movement to the recipient site.

Connective tissue graft was harvested from the hard palate with a trap door approach by stripping it off from the underlying bone after separation from overlying palatal epithelium. The graft procured, was processed and trimmed to obtain an even thickness of 1.5-2.0 mm and was immediately placed directly over the exposed root and secured by a sling suture by 4-0 resorbable vicryl suture. Pressure was applied with a wet gauge piece for about 10-15 seconds. The pedicled flap was then repositioned over the grafted recipient site and secured by means of placing a sling suture and interrupted sutures (Figure 2a-d). Periodontal dressing was placed. The patient was instructed regarding post-operative care of the surgical site along with prescription of suitable analgesics and antimicrobials.

The patient was followed up at regular intervals up to a period of 1 year. Post operative findings showed complete root coverage with excellent color matching. The recession depth was reduced to 1 mm suggesting almost complete root coverage obtained with this dual approach (Figure 3a, b).

**Discussion**

In this case report, LPF with SCTG was used to treat a case of localized severe GR defect inflicted by orthodontic treatment. This technique has the advantages of having good vascularity, adequate keratinized gingiva in adjacent tooth, better color match and possibility of creeping effect after surgery.
The involved tooth had inadequate keratinized gingiva, thus limiting our option for a coronal repositioning of the flap to completely cover the connective tissue graft. Connective tissue graft has also been left exposed at the recipient site. However, the consequences of the same would result in an uneven gingival margin post-operatively. Further, having an exposed portion of connective tissue graft on the avascularized root surface may lead to necrosis due to insufficient blood supply. Thus, LPF appeared to be a better option than CAF in this clinical situation. LPF can provide an advantage that the CTG is covered by a gingival flap, which ensures a sufficient blood supply bilaterally to enhance the plasmatic circulation during initial healing.

As mentioned earlier, orthodontic tooth movement leading to gingival recession is not uncommon especially when the alveolar bone housing the roots is thin. Orthodontic brackets are a natural habitat for dental plaque and it is difficult for patients to maintain adequate oral hygiene. Nevertheless, root coverage with FGG has been reported along with orthodontic treatment previously. However, it was done towards the completion of orthodontic treatment. In our case we opted for root coverage in the mid-orthodontic phase to simultaneously treat dentinal hypersensitivity and restore confidence in the ensuing orthodontic treatment for correction of her malocclusion.

While the root coverage procedure was completed, the orthodontic treatment continued for another year which enabled us to have a long term follow-up. Duration of at least 6 months is after root coverage procedure is considered adequate for soft tissue maturity and stability. We achieved almost complete root coverage and our result was comparable with Langer and Langer who reported increase of 2-6 mm in root coverage by subepithelial connective tissue graft technique in which the CTG was placed over exposed root surface underneath the split-thickness coronally positioned flap without any attempt to completely cover the root surface with the advanced flap. Nelson achieved around 88% root coverage by sub-pedicle connective tissue graft in which connective tissue graft was placed over the exposed root surface covered by an overlying full-thickness laterally positioned flap. Raetzke et al. obtained a root coverage of around 80% by envelope technique in which connective tissue graft was positioned directly over the exposed root but its major part was placed in an envelope previously created by an undermining partial-thickness incision in the tissue surrounding the defect.

A combination of full and partial-thickness flap as used in this case for laterally repositioning the flap is suitable as it helps in avoiding recession at donor site increases the predictability of root coverage at recipient site.

Conclusion

This combination approach including LPF with CTG placement in treatment of orthodontically inflicted localized and severe gingival recession cases would provide a promising result among various other root coverage procedures. However, Controlled Clinical Trials are required to assess the clinical performance and effectiveness of the same and further confirm the present findings.

Life Threatening Involvement of Bilateral Total Maxilla by a Large Radicular Cyst: A Rare Case Report

Harsh Mohan Pathak¹, Sobhan Mishra², Neeta Mohanty³, Sanchari Sinha Roy⁴, Satchidananda Meher⁴

¹Reader, Department of Oral and Maxillofacial Surgery, ²Professor and Head, Department of Oral and Maxillofacial Surgery, ³Professor and Head, Department of Oral and Maxillofacial Pathology and Microbiology, ⁴Post Graduate Trainee, Department of Oral and Maxillofacial Surgery, Institute of Dental Sciences, Siksha ‘O’ Anusandhan (Deemed to Be University), Bhubaneswar, Odisha, India

Abstract

The radicular (periapical cyst) is the second most common pulpo-periapical lesion arising from cell rests of malassez. Mainly associated with non-vital teeth with necrotic pulp. A case of large bilateral radicular cyst located in the maxilla of a 35-year-old female patient was reported in the dept. of oral surgery, institute of dental sciences, Bhubaneswar. Patient complained of swelling in upper front tooth region. On radiographic examination a well circumscribed radiolucency was seen. Incisional biopsy was taken previously suggestive of periapical cyst. Bilateral cyst was enucleated under general anesthesia and extraction of all root stumps were done. The enucleated specimen sent of H/P study.

Keywords: Radicular cyst; Periapical cyst; enucleation, total maxilla.

Introduction

The periapical (radicular cyst) is the second most common pulpo-periapical lesion. It represents 6% to 25.9% of all pulpo-periapical lesions. Commonest of all odontogenic cyst. It is described an inflammatory cyst as its inflammatory products initiate the epithelial component. This arises from cell rests of Malassez, which are the remnants of Hertwig’s epithelial root sheath; which is the product of the odontogenic epithelial layers (outer & inner enamel epithelium). [1]

The management of radicular cyst depends on the size & shape of lesion and can be treated with conventional therapy or may require surgical intervention (enucleation & marsupialization).

Case Report: A 35-year-old female patient reported to Department of OMFS, Institute of dental sciences & sum hospital, S ‘O’A (Deemed to be University), Bhubaneswar with complains of swelling in the upper front tooth region in the past 2 months; which gradually increased in size.

Extra-Oral Examination: A single diffused swelling present in middle 1/3rd region of the face, extending from ala of nose from left side to right side superiorly till the inferior border of nasal cavity, obliterating the philtrum and is of size 2*3 cm. there is marked asymmetry of face. Patient had purulent discharge from left nostril and struggled to breath. On palpation, it is firm in consistency & is mild tender.

Figure 1: a. Frontal View; b. Left Lateral View; c. Right lateral view

Intra Oral Examination: Diffuse swelling present of size 5*4 cm in the gingivobuccal sulcus wrt. 11, 12, 13, 14, 21, 22, 23 covering the anterior palate extending to the mid of posterior palate and junction of hard & soft palate. Nasal floor is breached along with absence of palatal bone. On palpation areas of bony depression present palatally i.e., firm in consistency, slightly compressible with non-reducible & mild tender with areas of fluctuation. Eggshell crackling was present. Root stumps present with respect to maxillary and mandibular arch 11, 15, 16,17,18, 21, 25,26,27,28, 34, 35, 36, 37, 44, 45, 46, 47, 48.
Radiological Examination: CT reveals a well-defined radioluency extending from root apex of 11-17 of size 5*4cm, with a homogeneous radio-opacity margin which obliterates the nasal floor, maxillary sinus & crosses the midline. Another radiolucency is present on left side extending from 24-27 region of size 3*2.5 cm also obliterates the left maxillary sinus. The buccal and palatal bone were eroded and there was thinning of palatal bone. There was no evidence of root resorption of involved teeth & the radiographic findings were suggestive of radicular cyst.

Histopathological Findings: Incisional biopsy was done on right side. H/P study reveals the cystic cavities is lined by non-keratinized stratified squamous cell epithelium arranged in arcing pattern with intense inflammatory cells, infiltration consisting mainly of lymphocyte, plasma cells, cholesterol clefts, russel bodies and hyaline cells were also noted. H/P findings confirm diagnosis of radicular cyst. Generally, the lumen is filled with straw color fluid occasionally blood tinged\textsuperscript{[16]}.

Treatment: Surgical enucleation of two cystic cavities was done under general anesthesia after obtaining an informed consent from the patient and her relatives. The operating site was injected with 2% lignocaine containing 1:100000 adrenalin. Vertical releasing and crevicular incision were given bilaterally from 23-28 region on left side & from 11-17 region on right side: then trapezoidal flap was raised; the thin overlying bone was removed using bone rongeur & round bur under saline irrigation to expose the cystic mass. Extraction of all maxillary root stumps were done.
During procedure we found that left side was infected with pus discharge and purulent smell. Both the cyst was enucleated, and thorough curettage was done. The sharp edges were smoothened with valcunite bur and bone file. Gauze pack with white head varnish was given on both sides of cystic cavity. Flap closure was done using 3-0 vicryl suture. Enucleated specimen was sent for H/P study.

**Discussion**

Radicular cyst are the inflammatory cysts of the jaw that appear at root apices of non-vital infected teeth with necrotic pulp. Most periapical cyst originate in pre-existing periapical granuloma where inflammatory reaction start to proliferate & there is increase in size of epithelial nests, degeneration of central cells & it liquefies due to compression of capillaries in tissue around the developing cyst.\(^1\) Gradually there is formation of liquid filled cavity which is lined by epithelium & it continues to grow in size because of like cytokines like interleukin 1 & interleukin 6 synthesized by epithelial cells, which are known to cause inflammatory & osteolytic activity.\(^2\) The internal pressure of the growing cyst in alveolar bone causes osteoclastic activity and bone resorption surrounding the cyst.\(^1\) According to Lalonde if the periapical radiolucency diameter is more than 1.6cm, it is more likely to be radicular cyst.\(^7\)

Most radicular cyst involves the permanent tooth apices, 58% lateral incisors \(^3\) sometimes in deciduous teeth mostly in molars.\(^4\) The untreated cysts may slowly grow in size and enlarge the cortical bones, so that a dome shaped swelling is observed on the alveolar bone at periapical region of associated teeth. It develops on buccal and lingual region of alveolar process which covers the mucosa (appearing normal). Initially when palpated it is hard but gradually crepitus is present as the cortical bone becomes thinned. The swelling may be rubbery or fluctuant due to cystic fluid. Almost 20% of root resorption seen in radicular cyst.\(^8\)

Among all cysts of jaw radicular cyst is most common having male predilection more (1.6:1) \(^5\) and anterior maxilla more than that of mandible due to trauma, caries and poor oral hygiene.\(^6\) A small periapical radiolucency diagnosed with granuloma or cyst can be treated with non-surgical endodontic therapy with follow up for 1-3 months and radiological & clinical examination to ensure the lesion is not enlarging. Studies show the success rate are high on this approach (80-84.4%).\(^9\)\(^10\) In case of large cysts where it destroys more amount of bone various type of approaches is done\(^1\):

1. Enucleation by surgical method.
2. Surgical enucleation & placement of graft (autogenous bone graft).
3. Marsupialization.
4. Decompression.
5. Decompression with delayed enucleation and creating a common chamber with nasal cavity or maxillary sinus (in large maxillary cyst).
Liposky-et-al\cite{11} described a method of decortication and have replacement for large cyst to eliminate dead space. Non-surgical therapy failure can be treated with apicocectomy and biopsy.

Sequential post-surgical radiographs are necessary for status of defect. The avg. healing time for cyst of diameter >10mm is approx. two and half years. In case of incomplete removal of lining of cyst can cause residual cyst or more aggressive pathology.

**Conclusion**

It is common jaw cyst encountered during dental practice\cite{12}. Sometimes squamous cell carcinoma\cite{13},\cite{14} occasionally arises from metaplastic changes in the epithelial lining of the radicular cysts. Long standing cases of radicular cysts have shown histopathological evidence of transition from a cystic lining to epithelial dysplasia and further progressing as infiltrating squamous cell carcinoma. Since there are chances of neoplastic transformation within epithelial lining of a radicular cyst, proper treatment and a long term follow up are recommended\cite{12}.

Medical Tourism: Prospects and Challenges

Shakti Rath1, Naushaba Akhtar2, Sangram Panda3

1Assistant Professor (Research), Central Research Laboratory, Institute of Dental Sciences, Siksha ‘O’ Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India, 2Post Graduate Student, Asian Institute of Public Health, Pahala, Bhubaneswar-Cuttack NH-5, Bhubaneswar, Odisha, India, 3Reader, Department of Prosthodontics, Institute of Dental Sciences, Siksha ‘O’ Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

The main purpose of this article is to present a review on medical tourism and identifying its interrelationships and existing risk on health and biosafety. This article focuses on identifying the extent of biosafety risk that encourages an individual to purchase cross-border health services and products. Also, it highlights the causes of growth of medical tourism in India along with the major challenges faced by patients and authorities.

Keywords: Medical Tourism; Biosafety; Biosecurity; Health services; Challenges; Prospects.

Introduction

Medical tourism can be defined as migration of people to different countries for treatment of diseases. Earlier, it was referred to those who moved from poor or underdeveloped nations to advanced hospitals in developed countries for treatment. High-end medical procedures such as dental surgery, gender reassignment procedure, stem-cell therapy, joint-resurfacing, organ transplantation, in vitro fertilization, plastic surgery and other services have been identified as a rapidly growing sector of the medical tourism industry.1 Globalization and the incidence of infectious diseases have also escalated the demand of health services worldwide. People are moving to different countries to obtain valuable medical treatments which are either not present in their native countries or may be restricted by the law and society in their nations. Medical tourism apart from treatment and travelling also emphasizes on vacationing and experiencing the attractions of different countries.2,3 Health and wellness tourism also have a great historical value. For example, in ancient times, Middle Eastern and Asian countries had been a major contributor for the development of health and wellness in terms of yoga, meditation, massage and herbal medicines.2,3

In India, medical system and health industry has taken a massive leap in last two decades due to advancement in technologies and education. India is becoming a popular medical tourist destination due to high quality patient services, world class medical infrastructure, cost effectiveness, experienced staffs and exotic locations.4 India’s clinical outcomes is at par with world’s most recognized and highly qualified specialists with competitive costs which are around 1/5th of that in the West. Government of India spends 16.5 of its GDP in health sector. India has taken various initiatives like National Health Policy (2002) for creation of a department of Ayush (which comprises Ayurveda, yoga, unani, sidha and herbal medicine) for the complementary and alternative medicines and treatments.5 They have also initiated promotion of medical tourism, through marketing development schemes for travelling agents, public–private partnership and medical visa (M-Visa) which can be extended further up to one year. Medical tourism in India has now changed the structure of healthcare system in India.4,5

Medical Tourism is divided into different sectors based upon the types of services it provides. Wellness tourism excludes medical treatment and is generally considered to have a more holistic focus on the physical, emotional and spiritual wellbeing of the individual which
includes alternative system, spa, therapies and natural resorts. Alternative system of medicine provides tourists and travelers physical, emotional restoration which is mostly in the form of traditional healing methods derived from nature and viability of holistic treatments like Ayurveda, Yoga etc. The absence of advanced and life changing health services which include treatment for infertility, implantation, cardiac support technology, etc. has also encouraged migration of people for health services.

**Major Problems Which Leads to Medical Tourism:** Socio-economic status, life threatening complications due to absence of treatment, affordability, expenses of treatment which is much cheaper than that of own their own land is the major cause of medical tourism. However, savings amount will vary depending upon the destination country and type of health service the person needs to attain, quality treatment and care. Manpower, physician’s access to advancement of healthcare technologies and world class facilities in most countries have also flocked migrants for treatment purpose.

Customer care services are provided by the tourism industry also play a major role in assisting a person who intends to go for treatment to other countries. Patients who are unaware about precise therapeutic services overseas are coordinating about their treatment through medical travel agencies, customer care services which provide excellent support such as physician options, guiding throughout communication, and further retention of the patients which is provided online or over call which may not be easily available in their native land. Indian health services provide an opportunity to the medical tourists who visits on medical visas to visit some of the most exotic and historical places by providing them a tourist trip.

**Major Challenges with Medical Tourism:** Despite of being a developing nation, India provides excellent medical services and care with the aid of latest technologies. Indian medical tourism has also raised demand of additional resources in terms of manpower, money, and equipment. However, there is still shortage of trained healthcare and pharmaceutical marketing staffs and sales executives, medical representatives, managers, quality check officers for hospital services; service professionals for biomedical equipment, diagnostics laboratories, pharmacy, and R&D professionals. The major challenge faced since ancient times by nations like Africa, Asia, China, etc. about biosecurity risks as humans are acting as active vectors for disease transmission during their migration to receive healthcare service across country. Medical tourists are highly exposed to different pathogens present in the health care center and so are the people in the healthcare center. Sometimes such patients also act as index cases. India has large number of hospitals with specialization in certain health areas and such hospitals are run by corporate entities that attract only a small crowd those are capable to pay. These private or corporate sectors does not revert revenues to the public sector once earned by them. There can be serious consequences of equity as unequal treatments based upon charges which vary from general citizens of the nations to that of tourists which are generally hiked are problematic for the society and could give rise to further consequences. Other challenges include lack of transportation facilities for patients, power supply issues, lack of drinking water supply, long waiting list, poor hygiene awareness among health care personals, and unavailability of correct guiding principles.

**Biosafety and Biosecurity Issues:** Biosecurity or biosafety means to provide protection of the mankind against genetically modified life threatening and harmful organism. The microbial world is the most complex, dynamic as they readily spread across one person to another. This results in emergence or re-emergence of infectious diseases in the region. This type of technique of spreading infections had also been used during war e.g. *Anthrax vivax* which was used as biological weapon during wars for increasing the mortality rates. The epidemic spread of SARS in southeast Asia and Ebola virus in Africa were prime threat to medical tourism as patients from those area was acting as carrier of the diseases. The World Health Organization (WHO) is continuously monitoring changes in the epidemics and in the context of the outbreak still now to guarantee that support is provided in response to the evolving adverse situations. They travel to nearby countries during periods of heightened insecurity which leads to compound the risks. SARS, HIV, Ebola is prone to spread through human-to-human transmission via direct contacts such as through the blood or body fluids of a sick person or has recently died from Ebola. Bio-risk reduction requires combined expertise and proper advice on high-consequences of pathogens with proper guidance and training on safe handling and on control of disease agents that poses several significant health risks for
the concerned population. These events acknowledged at the time, an infectious disease outbreak happening anywhere is a threat everywhere. It has been observed that over the past years a much greater awareness has been evolved regarding the importance of biosafety and biosecurity regarding pathogens, especially like anthrax, which has already been used to spread bioterrorism previously as a weapon.\textsuperscript{15, 16}

**Current Trends:** Change in demography, especially among ageing population requires medical services with increased epidemiological change, the rising incidences of chronic conditions have also increased demand for more and better health services which are catalyzed by poor medical facilities. This has led to the globalization of health care services which is illustrated by increase persons opting for medical tourism.\textsuperscript{17} Due to various positive impacts of healthcare tourism, many developing nations today are emerging as hot healthcare tourism destinations. Indian health services include innovative along with some critical health care services like organ transplants, cancer treatment, cardiac surgery, and many more. Also, other aspects like leisure, adventures and relaxation, healthcare traveling/wellness-tourism can be enjoyed on such medical tours.\textsuperscript{18} Many national and international agencies, private healthcare providers and medical practitioners see it as a great means of economic development for the country. The related benefits and risks that are attached to medical tourism both for individual and together public health are the areas of interest for future research.\textsuperscript{19}

**Health tourism in India:** India has been the major healthcare center for countries like Afghanistan, Bangladesh, Bhutan, Nepal, Maldives, Pakistan and Middle East. The expansion of medical tourism in India was due to the combination of various factors like well-trained doctors and specialists, abundance of ground level medical staffs, good exposure to contemporary and alternative systems of medicines, availability of centers with super specialty, use of modified technology and advanced diagnostic equipment, and more importantly, premium services availability at an effective but competitive cost.\textsuperscript{4, 5}

**Figure 1. Number of medical and medical attendant visas granted by India in 2013-15**

The above figure (Figure 1) shows that the number of tourists on medical visa and medical attendant visa is highest from Bangladesh. Besides Bangladesh, Afghanistan also shares a major part along with Nigeria, Maldives, Oman, Yamen and Tanzania. In terms of income and employment India’s Healthcare sector is one of the largest sectors which are expanding rapidly. During the 1990s, the Indian health care sector had a massive growth which has compounded to annual rate of 16%. A major share of this progress has been due
to the growth in the medical tourism business in India, because of which India is estimated to be one of the rapidly growing markets owing to improving healthcare infrastructure and system, increasing investment and overseas promotion. Financial assistance is provided as per the provisions of Marketing Development Assistance (MDA) scheme. The Incredible India brand is one of the most recognized brands internationally the logo of which is symbol in wellness and medical tourism events and promotional activities with the permission of Ministry of Tourism which has been decided according to the Indian government. The most important factor behind popularizing medical tourism in India is financial aspects. In India people have been getting “First World Treatment at Third World Prices”. It is quite evident if we compare the price of various medical interventions in India with Western countries, some of them are listed below. According to some industrial estimates the medical tourism market in India has valued over $310 million in 2005-06 with about 1 million foreign medical tourists visiting the country each year.\textsuperscript{20-22}

**Conclusion**

India being one of the fastest growing medical destinations around the world is predicted to drive higher with time. Medical tourism industry has become a multi-billion-dollar industry which is promoted by government, hospitals and tourism industries. Global competition is emerging in the health care industry. Patients with good economic status from developing nations have long traveled to developed countries for high quality medical care and the economic investment of the country has a great influence on the Healthcare services. At the same time occupational health, Biosafety and biosecurity are implemented and enforced in all active bioscience research and clinical laboratories. The weakened public health system, procedure, equipment/infrastructure, increasing population, civil disturbance, human behavior and displacement of the country that arises from misconception and perceptions about the serious and risk, use of anti-infective drugs intake of the people, which basically seen in poverty condition less resourced nations of the country because of which they cross border to get healthcare service and by the time they are incubating unknowingly. Though the level of international trade and travel between African urban have been expanding, national governments and international community have attempted to improve recognition capacity and response capabilities for future outbreaks, there are still much to be done.

The concept of medical tourism provides innovative solutions to healthcare problems rising because of lower GDP investment by the Indian Government. This also improves international standards of healthcare system, but at the same time gives rise to inequity in terms of providing healthcare service, quality, increased in treatment charges for general public, growth in the numbers of unethical practices and unlawfulness. The concept of medical tourism serves the population that can pay their rates charged by the corporate or high end private medical sectors which finally promotes growth of private sectors. The Government of India should take initiatives to provide better services to medical tourist while maintaining international relation and improve retention. A specific infection control system or measure is needed for India, as healthcare services abroad is associated with diverse financial, legal, ethical, disease based and health related problems. So, a better and broad system is needed to ensure high quality healthcare and surveillance when there are complications.

Multiple Major Aphthous Ulcers: An Uncommon Presentation

Satya Ranjan Misra

Professor & Head, Department of Oral Medicine & Radiology, Institute of Dental Sciences, Siksha ‘O’ Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Aphthous ulcers or Recurrent aphthous stomatitis (RAS) are the most common ulcers encountered in the oral cavity and also the most painful ones. They characteristically recur at frequent intervals hence referred to as RAS. The aetiology of RAS is unknown however a number of predisposing factors including genetic predisposition, stress, nutritional deficiencies, diet, trauma, hormonal disturbances and immunological disorders have been proposed. As the cause remains uncertain, a definitive cure for the disease has not been found and all treatments are aimed at ameliorating the disease symptoms. They are of 3 sub-types: Minor, Major and Herpetiform. Major aphthous ulcers occur less commonly and are usually more than 10mm in size, fewer in number, healing with scarring. We present a case of multiple major aphthous ulcers in an immune-competent patient successfully treated with topical glucocorticoids and amlexanox with systemically administered Levamisole.

Keywords: Aphthous ulcer, immune competent, immunomodulators, unknown etiology.

Introduction

Recurrent aphthous ulcerations (RAU) are frequently encountered in the oral cavity and about ten to twenty percent of the population is affected by the disease. Major aphthous ulcers are the less common type of RAU and cause severe discomfort to the patient due to their large size and associated symptoms of pain and burning sensation. They take long time to heal and cause scarring of the mucosa. The selection of therapeutic agent depends on the severity of the disorder, which is evaluated by the frequency, number, location and duration of the ulcers as well the intensity of associated pain. Patients with major RAU generally have severe pain, malaise, fever, and odynophagia associated with recurrent disease generally need systemic therapy. The case of a 26-year-old man with multiple (about 9 in number) major aphthous ulcers, none occurring in the common site i.e. the soft palate, without any associated systemic disease, treated successfully in the dental hospital is presented for documentation.

Case Report: A 26-year-old male came to the dental hospital with multiple painful ulcers in his mouth since 3 days. This was the first time he had oral ulcers and the ulceration was preceded by burning sensation in the oral cavity. The pain increased on chewing or talking. The medical history was non-contributory.
Figure 1a: Two irregular ulcers present on the lower left labial mucosa about 1cm in size, with yellowish-white floor and erythematous irregular borders. 

1b: An irregular ulcer seen on the right buccal mucosa in relation maxillary molars, about 1cm in size, with yellowish-white floor and erythematous irregular borders.

1c: An irregular ulcer present on the ventral surface of the tongue, with yellowish white floor, erythematous borders.

1d: Two irregular ulcers present on the right ventro-lateral surface of the tongue, with yellowish white floor, erythematous irregular borders.

1e: Three irregular ulcers present on the left ventro-lateral surface of the tongue, with yellowish white floor, erythematous irregular borders.

On clinical examination multiple oral ulcers were seen. Well circumscribed irregular ulcers measuring more than 1cm in size, yellowish white in colour with erythematous, raised irregular borders were seen in the left lower labial mucosa, right buccal mucosa, ventral surface and lateral borders of the tongue. The ulcers were soft in consistency, tender and there was no discharge on palpation. Based on the clinical appearance a provisional diagnosis of multiple major aphthous ulcers was made.

Figure 2a: Healing of ulcers on the lower left labial mucosa. 

2b: Healing ulcer seen on the right buccal mucosa. 

2c: Healing ulcer on the ventral surface of the tongue. 

2d: Healing ulcers on the right ventro-lateral surface of the tongue. 

2e: Healing ulcers on the left ventro-lateral surface of the tongue.
A complete blood cell count, serum ferritin, folate and vitamin B12 estimation, test for anti-endomysial antibodies and colonoscopy were performed and the results were normal. The patient was treated local application of Triamcinolone acetonide 0.1% oral paste with Amlexanox 5% oral paste applied thrice daily. 0.15% Benzydamine mouthrinse to be gargled and Benzocaine 20% topical gel to be applied thrice daily for symptomatic relief. Levamisole hydrochloride 150mg tablet was to be taken after dinner thrice a week. The patient was followed up after 2 weeks and the ulcers were healing with reduction in symptoms. [Figures 2a-e] The same treatment was continued for 2 months and the patient was examined after 2 months showed healing of ulcers with scarring. [Figures 3a-e] All topical medications were discontinued. Levamisole was continued for six months then stopped. The patient was followed up for a year without any recurrence.

Discussion

“Aphthous” is derived from “aphtha” a Greek word which means ulcer. Recurrent aphthous ulcers (RAU) are most frequent painful oral mucosal lesions and appear first in childhood or adolescence as multiple, recurrent, ovoid ulcers with yellowish floor and well circumscribed erythematous borders.2 Stanley in 1972 had classified Aphthous ulcers into 3 clinical variants: Minor, Major and Herpetiform.3

1. Minor aphthous ulcers (MiAU) (Miculiz’s aphthae) are the most common variant, constituting 80% of RAS. They are less than 1cm in size and commonly involve the non-keratinized oral mucosa like the labial mucosa, buccal mucosa and the floor of the mouth. These are painful but self-limiting, healing occurs within 10-14 days without scarring.

2. Major aphthous ulcers (MAU) (Sutton’s disease or periadenitis mucosa necrotica recurrens or Sutton’s disease) occurs only in 10-15% of patients. They are more than 1cm in size, about 2-3 in number and can occur in any oral mucosal site, but the most common site is the soft palate, persist for about 4-6 weeks and heal with scar.

3. Herpetiform ulcers (HU) are rare, about 2-3mm in size and occur in large numbers. Like in herpes simplex infection these ulcers coalesce to form larger irregular ulcers but are not preceded by vesicles. HU are seen in an elderly age group.

The aetio-pathogenesis of RAU is yet to be proven but there are some contributing factors have been considered. Family history of RAU with a genetic predisposition, chronic micro-trauma, psychological stress, drugs like Captopril, Nicorandil, gold salts, Phenobarbital, Phenindione, deficiency of cyanocobalamine and folic acid, inflammatory bowel disease, gluten sensitive enteropathy, hypersensitivity to detergent in dentrifices-
sodium lauryl sulphate, hormonal changes in women, micro-organisms like Helicobacter pylori, pro-inflammatory cytokines like TNF-α have been proposed. Smoking has been identified as a negative risk factor and smokers who stop the habit develop RAU, probably the hyper-keratotic mucosal changes due to chronic irritation protect the mucosa from RAU.4 A number of systemic disorders also manifest with RAU in the oral cavity and therefore they need to be excluded before diagnosis. Bechet’s syndrome, PFAFA syndrome, MAGIC syndrome, Sweet’s syndrome, agranulocytosis, cyclic neutropaenia and HIV/AIDS are associated with Aphthous like ulcers besides other systemic manifestations.2,3 The condition is totally detected based on the patient’s history and examination. Complete blood picture, assays for haematinic deficiency, investigations for gastro-intestinal disorders and causes of micro-trauma to be excluded prior to diagnosis.

The treatment is mostly symptomatic and is aimed towards amelioration of symptoms. Topical analgesic-anaesthetic gels and topical glucocorticoids to be applied with antihistaminic mouth rinses to be used as needed.5 5% topical amlexanox gel and 0.1% topical triamcinolone acetonide gels are used to decrease the time period of the ulceration, prevent recurrences and lessen the pain.6 In severe cases immunomodulators like Levamisole, Pentoxifylline, Colchicine, Dapsone and in recalcitrant cases Thalidomide may be used.7 Systemic steroids like Prednisolone may also be used in refractory cases.

Antiplaque Efficacy of a Dentifrice Containing Low Concentration of Chlorhexidine: A Randomized Controlled Clinical Trial

Adrita Purkayastha¹, Rinkee Mohanty², Anurag Satpathy³, Rashmita Nayak³, Rajdeep Beura¹, Utkalika Das⁴

¹Post Graduate Trainee, ²Professor and Head, ³Professor, ⁴Lecturer, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha ‘O’ Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Aim: To assess the anti-plaque efficacy of a dentifrice containing low concentration (0.004%) chlorhexidine.

Methodology: Plaque score was assessed in 28 participants in a randomized, double-blind prospective cross-over study. The study participants either used 0.004% chlorhexidine containing dentifrice (test group) or a commercially available fluoridated dentifrice (control group). Clinical parameters were recorded at the baseline and again after 4 days.

Results: Plaque scores were found to be significantly lesser in the test group (p = 0.02). Also, significantly greater additional plaque (16.06%) was formed in the control group in comparison to the test group (p = 0.01). No statistically significant difference was detected between the test and the control groups at baseline with regard to plaque score. Conclusion: The reduction of plaque scores with a dentifrice containing low 0.004% chlorhexidine was significantly greater as compare to control.

Keywords: Chlorhexidine containing dentifrice, anti-plaque, toothpaste, chlorhexidine, dentifrice, plaque re-growth.

Introduction

Effective daily mechanical plaque control is the mainstay of maintenance of periodontal health and prevention of caries.¹² Dental plaque begins to form shortly after brushing and re-establishes itself in 24-48 hours.³ Dental plaque exists as a tenacious bacterial biofilm with an organized carbohydrate matrix, making it resistant to antibacterial agents.⁴ Since there is no substitution to mechanical cleansing of dental plaque biofilm, much of research has been focused on improving the dentifrices.⁵⁶ A dentifrice can be a carrier medium for antiplaque and antimicrobial chemical agents to offer a potential adjunctive advantage in plaque control.⁷⁸ Currently, a number of dentifrices are available with various active ingredients in it such as fluoride, triclosan, etc.⁹ Among all the antiplaque agents currently used, chlorhexidine gluconate (CHX) stands out in terms of its efficacy. Due to its antibacterial action at low and high concentration and superior substantivity it is considered as the gold standard in antiplaque agents, but a major drawback lies in the taste alteration and stain-producing problems.¹⁰

CHX containing dentifrices were not formulated because of its possible interaction with other components of the dentifrices such as, anionic detergents sodium lauryl sulfate (SLS), abrasives, calcium ions and sodium monofluorophosphate and thereby reducing the availability of CHX.¹¹ Previously reported studies on CHX containing dentifrices and gels mostly have been in the concentration range of 0.2 – 2% with report of mixed results on its efficacy.

Plaque inhibitory effect of CHX is now known to be due to its adsorption on the tooth surface rather than being slowly released from a reservoir in the oral cavity. Therefore, small doses of CHX applied directly to the teeth inhibit plaque similar to that by large doses in mouthwashes. Hardly any investigation has been carried out to assess the anti-plaque efficacy of low CHX concentration-based dentifrices. Therefore, the aim of this study was to assess the anti-plaque efficacy of a dentifrice containing low concentration (0.004%) of chlorhexidine.

Materials and methods

Experimental design and study population: A double-blind, randomized controlled, cross-over study comparing a placebo control-dentifrice to a dentifrice formulation containing a low concentration (0.004%) of chlorhexidine was conducted. All participants were aged between 18 to 25 years of age and were systemically healthy. They had at least twenty erupted teeth without any detectable evidence of unattended dental caries and inflammatory periodontal disease, without any dental prosthesis or orthodontic appliances. A detailed systemic history was explored to exclude participants currently on medications or with medical conditions bearing any influence on the outcome of the study. The study protocol was discussed and approved by the Institutional Review Board. A prior written informed consent was procured from all study participants.

Materials: The test dentifrice used in the study was a commercially available dentifrice containing 0.004% chlorhexidine (Elgydium®, Win-Medicare, New Delhi, India). The placebo control dentifrice was commercially available fluoridated dentifrice.

Randomization, Concealment and Blinding: The concealed allocation of test and placebo control products was randomized by a simple coin toss method to one of the two groups by an independent examiner who was unaware about the details of the study. Test Group (N=15): 0.004% Chlorhexidine containing dentifrice. Placebo-Control Group (N=15): Commercially available fluoride dentifrice containing. All clinical recordings were done by a solitary examiner (AP), blinded to the allocation of groups. In order to validate reproducibility of the outcome measure (plaque scores), an intra-examiner reliability assessment (Kappa Statistics) yielded good agreements (>0.8).

Procedure: Scaling and polishing for removal of all visible dental plaque was done. Plaque was disclosed using plaque disclosing agent (PLAKSEE MD, ICPA, Ankleswar, India) for all participants. Following the oral prophylaxis, prior to the start of the study, all the participants were recommended to use a regular fluoridated dentifrice for one week. At baseline, plaque scores were recorded for all participants on day zero using a plaque index. Participants were randomly allocated with measured quantity [20gm (dentifrice) / 80ml (distilled water)] dentifrice slurry which was to be used by them for four days. All dentifrices were supplied to the participants in a coded and amber colored bottle. All participants were asked to use only the allocated dentifrice slurry twice daily for 30 seconds and refrain from any other forms of oral hygiene practices for four days. Plaque scores were recorded again on day four. A wash over period of one week was given before the same procedure was repeated after switching the group with one another.

Statistical analysis: Obtained data was analyzed using Statistical Package for Social Statistics Version 20.0 (SPSS Inc, Chicago Illinois, USA). Clinical outcomes were tested for significant differences within the baseline and post-treatment groups and between the two groups with the Student’s paired and unpaired t-tests respectively. A value of P ≤ 0.05 was considered statistically significant for all analyses.

Results

A priori analysis of 5% significance level, power value of 0.8 and effect size of 0.8 estimated the total sample size to be 52. Since there were two groups and it was a crossover study 13 participants were required in each group. We enrolled 15 participants in each group in our study taking in account the possible drop outs during follow up. A total of 28 (males =11; females 17) participants aged 22.39±1.64 years completed the study successfully. 1 participant dropped out in each group owing to non-compliance (Figure 1). None of the participants reported any adverse effects or any minor side effects during the study period.

There was no statistically significant difference (p= 0.25) in the plaque scores, between the groups at baseline. However, plaque scores were significantly lesser in the test group (p = 0.02). Also, significantly greater additional plaque (16.06%) was formed in the placebo control group in comparison to the test group (p = 0.01). Further, plaque scores significantly increased at day 4 in comparison to day 0 in both the placebo control (p < 0.001) and the test (p < 0.001) groups.

Discussion

The study was carried out to determine the plaque inhibiting efficacy a dentifrice containing low concentration (0.004%) of chlorhexidine in comparison to regular fluoridated dentifrices. To the best of our knowledge, this is the first study evaluating the antiplaque efficacy of a dentifrice containing such a low concentration of chlorhexidine. The outcomes of the present study which is based on 4-day plaque re-growth model revealed a statistically significant reduction in the plaque score in the CHX containing dentifrice group as compared to placebo control group. As any antimicrobial containing dentifrice product would prove to be efficacious when it is used with a toothbrush, mechanical cleansing by use of tooth brushes was not allowed and a dentifrice slurry was used for the plaque re-growth study. Further, it was also beneficial in lowering the Hawthorne effect which often influences such studies.

Our study revealed significant reduction in dental plaque score in the test group which is in accordance with CHX based dentifrice study by Sanz et al (0.4% CHX), Gjermo et al (0.6% CHX) and Saxton et al (0.8% CHX) but in contrast to that of Johanssen et al (1% CHX) and Jenkins et al (1% CHX).

In a study where the participants were asked to use CHX based dentifrice at home for six months, it was observed that CHX and CHX added with fluoride were more efficacious than the placebo-control dentifrice in reducing dental plaque. It has been believed that the co-formulation of CHX along with other ingredients of a dentifrice would lead to its inactivation. However, a systematic review by Kolahi et al underlines that non-compatibility is mostly known to occur in aqueous solutions and it would not be true to conclude its generalization. Subsequently, it was demonstrated that dentifrice containing CHX reduced anaerobic bacterial counts in supragingival plaque.

Interestingly, Smith et al assessed the antiplaque efficacy of 0.12 % CHX and 0.2 % CHX and observed minimal plaque accumulation as compared to the control, but among them, levels were essentially similar in their effect. Also, Addy et al compared 0.12 % and 0.1 % CHX mouthrinse with regard to their effect on plaque re-growth they observed that the mean plaque scores were mostly lower with 0.12% rinse and the levels were after two weeks, during the 4-week study period. Antiplaque and antimicrobial efficacy was also reported by Escribano et al who carried out a study with 0.05% CHX containing mouthrinse. CHX is a dicationic (at pH levels above 3.5) membrane active substance and acts on the inner cytoplasmic membrane of microorganisms. It is rapidly adsorbed by bacterial cells causing changes in cellular permeability and loss of cytoplasmic components such as pentoses, even at low concentrations.

CHX formulations are the most commonly used oral hygiene products and have been proven to be effective in their antiplaque activity, nevertheless their use in daily practice is marred owing to several side effects. Tooth staining is one of the major concerns in long term use of CHX based oral formulations. However, less staining has been reported in the study by Sanz et al which may be due either inactivation of CHX by the ingredients of the dentifrice or abrasive action of the dentifrice.

Although there was a statistically significant reduction in the plaque scores in the test group, the difference was small and may need further studies to comment on clinical significance and its endorsement over commercially available dentifrices. Therefore, while considering the limitations of the study, we may draw a conclusion that dentifrice containing low concentration of CHX (0.004%) had a better efficacy as compared with the placebo dentifrice. Further studies with a longitudinal study design with varied conditions are needed for conclusive information, in particular with other active substance.

Temporomandibular Joint Disorders: Etiological Factors, Diagnosis and Treatment

K.L. Sushmita

Post Graduate Trainee, Department of Oral Medicine and Radiology, Institute of Dental Sciences, Siksha ‘O’ Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract
Temporomandibular joint is pivotal for normal functioning of jaws and any disarray in the joint may cause discomfort in chewing, speaking, opening and closing of the jaws. Temporomandibular disorders have vast etiologies including the psychological factors, hereditary factors, trauma being the common cause and no definite treatment protocol has still been researched. This article gives recapitulation of various articles describing the key etiology, research diagnosis criteria and effective treatment protocol.

Keywords: Ginglymoarthrodial, Whiplash Injury, Depression, Bio-Behavioural Therapy.

Introduction
Temporomandibular joint where both translatory and circumvolution movements are feasible and the two edges of the bone articulate at the same level, this makes the joint so unique. Since it has a sliding movement additionally to the hinge movement analogues to the diarthrodial joint it is also known as ginglymoarthrodial type of joint1. Temporomandibular joint disorders is not a term attributed to any single dysfunction and cause, it is a colossal term which includes a number of clinical disorders in the temporomandibular joint region, muscles of mastication, clicking or popping sounds, deviation of mouth opening, locking of jaws. temporomandibular disorders have a statistical distribution in general population. There is no gender predilection. This article presents an outline of the aetiology, diagnosis and management of temporomandibular joint disorders.

Etiology: Temporomandibular disorders have multifactorial etiology. The number of studies that were conducted showed poor correlation between single factor being responsible for the signs and symptoms2. An elaborated understanding of the anatomy, physiology, vascular, neurological unit of the temporomandibular joint and masticatory complex is required for the lucid treatment plan of the temporomandibular disorders.

Occlusion: For many years the relation between occlusion being one of the factors contributing to temporomandibular disorders was debatable. For example, asymmetric muscular function3 occurs due to reverse articulation however the connection between this and temporomandibular disorders is not established till now45. Mediotrusion can also be a predisposing factor according to some authors67. Since the topic is widely debatable and still under research it will cause hindrance in standardizing any treatment protocol for the patient. Recently as more and more research are focusing on the multifactorial aetiology of temporomandibular disorders the emphasis on occlusion to be one of the factors is reduced.

Trauma: Trauma can be micro-trauma or macro-trauma. The micro-trauma seen in bruxism and macro-trauma when there is straight hit to the temporal region that affect the temporalis and masseter muscle by the uninhibited movement of the mandible8. Bruxism can be an initiating factor for temporomandibular disorders. Previous study indicates that around 87% of patients having both myofascial pain and disk displacement and around 69% of MFP patients clench their teeth9. This bring about the conjecture that bruxism may
contribute as a possibility for tenderness of myofascial pain, pain in the masticatory muscles and pain from the temporomandibular joint\textsuperscript{10,11,12,13,14}. A study was conducted to assess the consequence of bruxism. It included the effects of clenching, grinding and clenching combined with grinding. The authors came to the conclusion that there was an association between chronic MFP and clenching-grinding, not with just grinding\textsuperscript{15}. The amalgamation between bruxism and temporomandibular disorders signs reinforces the theory that repeated disadvantageous loading of the masticatory system may cause functional disturbances\textsuperscript{16}. Whiplash injury was previously suggested to be an etiology of temporomandibular disorders but later studies were conducted that assessed temporomandibular disorders-related pain in acute whiplash patients in contrast with a matched control group. Temporomandibular disorders affliction following whiplash injury is uncommon, suggesting that whiplash injury solely is insignificant risk factor for accentuation of temporomandibular disorders problems\textsuperscript{16...20}. Endotracheal intubation has also been suggested as a risk factor for temporomandibular joint disorder in a finite number of published case reports and systematic studies.

**Posture:** A relation between head and neck posture to that of temporomandibular disorders is quite inconclusive. Very few studies have been conducted and all of them have insignificant results. A study was conducted to check any relation connecting the head and cervical posture of the patient with temporomandibular disorders, the evidence in that particular systematic review is still unclear and controversial\textsuperscript{21}. Also, there is no relation between the cranio-cervical dysfunction and disk displacement as concluded by other studies conducted which includes the cranio-cervical angles and disc displacement\textsuperscript{22}.

**Psychological Factors:** Psychological studies exhibited that temporomandibular disorders have indistinguishable psychological profiles and dysfunctions as other chronic musculoskeletal disorders. Tension, apprehension and other psychological components instigate muscle hyperactivity and muscle fatigue with the appearance of muscle spasms and the subsequent repercussion: contracture, occlusal disharmony, internal disturbances and degenerative arthritis. These characteristics can change the occlusal scheme of the masticatory system, so that these changes are a result of temporomandibular disorders and not a precipitating factor. On contrary there are studies that have established a deep connection between the myofascial pain and advanced stages of depression\textsuperscript{23} and somatization than those diagnosed with disc displacement.

**Diagnosis:** There is a research diagnostic criteria for temporomandibular disorder which eases the work of diagnosis for the dentist. Since the AD’s president’s conference on temporomandibular disorders in 1983, every major forum on this topic has spotlighted the need for a dependable and plausible diagnostic classification system to recognise temporomandibular disorders cases, including certain subtypes. The study was classified into various axis which helps in differentiating the temporomandibular disorders from orofacial pain thereby helping the dentist providing differential diagnosis. In this article, we have attached the tabulated form which includes all the three groups conforming to the customary factors among conditions.

**Research diagnostic criteria for temporomandibular disorders as given by DWORm IN 1992 is summarised as following:**

**I. Muscle Disorders**

a. **Myofascial pain**-patient will give symptoms like pain in masseter, temporalis, lateral pterygoid and medial pterygoid. There is pain on palpation in at least three regions, one of them on the ipsilateral side of the actual pain experienced.

b. **Myofascial pain with restricted mouth opening:** painless unaccompanied opening less than 40 mm and static stretch more than or equal to 5mm.

**II. Disk derangements**

1. **Disc derangement with reduction:**

   a. Asymptomatic Temporomandibular joint clicking.

   b. Repeated clicking sound on function with either opening or closing of mouth.

   c. Clicking sound while opening mouth occurs when the inter-incisal distance is more than or equal to 5mm rather than on closing the mouth. While the patient protrusive opening the clicking sound disappears.

2. **Disc derangement without reduction with restricted opening:**

   a. Patient gives a history of locking of jaws that would interfere in performing normal functions.
b. Asymptomatic TMJ clicking sounds

c. Independent opening of mouth even painful less than or equal to 35mm and static stretch on more than or equal to 4mm mouth opening.

d. Contralateral excursion less than 7mm or incorrect same side deviation on opening.

3. Disc derangement without reduction without restricted opening:

a. Patient gives a history of locking of jaws that would interfere in performing normal functions.

b. Temporomandibular joint clicking sounds without DDR clicking.

c. Independent painful or painless opening when patient opens his/her more than 35mm and static stretch of more than 4mm.

d. Opposite side excursion more than or equal to 7mm.

e. Additional imaging just to confirm the differential diagnosis.

III. Additional joint diseases.

1. Arthralgia

a. Palpation either laterally or intra-aурicular will lead to pain on temporomandibular joint.

b. Joint pain with or without jaw movement.

c. No crepitus and clicking sound.

2. Osteoarthritis

a. Pain similar to arthralgia

b. Crepitus can be seen on any motion or roentgenographic proof of TMJ changes.

3. Osteoarthrosis

a. Crepitus can be seen on any motion or roentgenographic proof of TMJ changes.

b. No evidence of joint pain nor pain on any motion.

In daily clinical practice, attentive history and clinical exam with imaging, ionising play restricted role in diagnosis of temporomandibular disorders. Electronic devices such as jaw tracking, vibrato-
radiating to the joint. In these cases, a comprehensive dental examination and treatment is needed.

When should a dentist refer the patient to physical therapist

<table>
<thead>
<tr>
<th>Mechanism</th>
<th>Situation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cervical</td>
<td>Neck pain including pain in TEMPOROMANDIBULAR JOINT region. Cervicogenic headache and these headaches are reproduced when neck is palpated</td>
</tr>
<tr>
<td>Postural</td>
<td>TEMPOROMANDIBULAR DISORDERS symptoms aggravate when patient changes his/ her posture.</td>
</tr>
<tr>
<td>Outcome oriented</td>
<td>Initial therapies excluding physical therapy. Patient who would undergo TEMPOROMANDIBULAR JOINT surgery is advised to go to a physical therapy preceding to surgery in order that they may learn about post-surgical exercises.</td>
</tr>
</tbody>
</table>

Different therapies can be given to the patient who show different time on onset of pain. Even though these treatments are not routinely followed by dentists as there is no significant evidence within the literature to support it.

For a patient who wakes up with temporomandibular disorders symptoms

1. Medicative- NSAIDs and/or steroids.
2. Passive approach-Performing physical therapy modalities, and advising jaw-stretching exercises.
3. Active approach- advising head and neck posture improvement exercises.
4. Indirect approach- conducting cervical therapies.

For a patient who wakes up without any symptoms which will develop later in the day-

1. Relaxation/stress management.
2. Orthotic appliance
3. Medicative-prescribing a tricyclic antidepressant.

For patients who awakes with symptoms and continue to have the symptom whole day can follow both the above-mentioned treatment.

It is always advocated that only non-invasive procedure should be applied in the beginning and if this rectify the issue then no other treatment is needed. In addition, always look for non-temporomandibular disorders that may overshadow the deep cause such as neck pain, rheumatic disorder, sinus pain, improper sleep and depression. Inability to correctly treat the non-temporomandibular disorders will lead to unsatisfactory temporomandibular disorders symptom improvement.

Seldom surgery is required for TEMPOROMANDIBULAR DISORDERS patients. Other than for salient features like carcinoma, fractures, infections. There are principally three TEMPOROMANDIBULAR DISORDERS for which a patient should be advised to visit a surgeon:

1. Temporomandibular joint inflammation
2. Acute temporomandibular joint disc displacement without reduction
3. Temporomandibular joint ankylosis.

**Conclusion**

Temporomandibular disorder is of varied clinical features that have to been distinguished precisely from non-temporomandibular disorders, multifactorial etiology and treatment should always be non-invasive. Temporomandibular disorders are analogues to musculoskeletal dysfunction in any different part of body, and identical treatment procedures can be followed. Temporomandibular disorders are heterogenous condition of yet unknown focalisation. It is relevant to investigate the etiological patterns, and precise diagnosis in order to provide a better management of patients. Hence, it is decisive to adopt an integrative approach for the well-being of temporomandibular disorders patients.

Potentially Malignant Oral Lesions: A Clinical Perspective

Suryasnata Nayak¹, Shashirekha Govind², Amit Jena³

¹Post Graduate Trainee, ²Professor and Head, ³Professor, Department of Conservative Dentistry and Endodontics, Institute of Dental Sciences, Siksha ‘O’ Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

In India, the occurrence of precancerous oral disorders is increasing through decades. These conditions should be diagnosed by the dentists at an early stage during regular clinical practice for which, brief knowledge regarding the clinical features and management is necessary. This article will give knowledge about the commonly occurring precancerous oral lesions/ conditions which will be helpful during regular clinical practice.

Keywords: Epithelial dysplasia, erythroplakia, leukoplakia, oral premalignant lesions, oral submucous fibrosis, potentially malignant disorders.

Introduction

During regular dental check-up or operative procedure, dentists encounter various premalignant lesions of oral cavity; however due to lack of sufficient knowledge regarding the clinical features and management aspect, they often remain undiagnosed and untreated. In this article a brief knowledge regarding the commonly seen precancerous oral lesions/ conditions is given which will help the dental professionals for chair side diagnosis and management of such lesions/ conditions.

WHO defined premalignant lesion in 1978 as, “a morphologically altered tissue in which cancer is more likely to occur than in its apparently normal counterpart”. In 2005, WHO recommended the use of the term “Potentially malignant disorder” instead of precancerous or premalignant lesion. In 2005, ‘potentially malignant disorder’ was defined by WHO as, “the risk of malignancy being present in a lesion or condition either at time of initial diagnosis or at a future date”. No such classification exists for precancerous oral lesions/conditions.

The potentially malignant disorders are ¹

A. Premalignant lesions:
   1. Erythroplakia
   2. Proliferative verrucous leukoplakia
   3. Viadent leukoplakia
   4. Candida leukoplakia
   5. Reverse smokings’ palate
   6. Dyskeratosis congenita
   7. Actinic cheilosis

B. Premalignant conditions:
   1. Lichen planus
   2. Oral submucous fibrosis
   3. Discoid lupus erythematosus
   4. Epidermolysis bullosa
   5. Verruciform xanthoma
   6. Graft versus host disease
   7. Cheilitis glandularis
   8. Xeroderma pigmentosum
   9. Third stage syphilis
   10. Plummer Vinson syndrome

Epithelial Dysplasia: The term “dysplasia” was given by Reagon in 1958 which means atypical, abnormal proliferation. “Epithelial dysplasia is an architectural
disturbance accompanied by cytological atypia (variations in the size and shape of the keratinocytes)”

Dysplastic changes are the signs of premalignant lesions which can be observed in histopathologic view especially in epithelium. “The severity of epithelial dysplasia is not related to the risk of malignant transformation, which suggests that the current grading system is not useful in predicting patient outcomes or to determine management strategies. The diagnosis and grading are based on a combination of cytological and architectural changes (Table 1).”

Oral Leukoplakia: Schwimmer used the term “Leukoplakia” in 1877, to describe a white plaque on the tongue. Leukoplakia has been defined by WHO in 1978 as, “a predominantly white patch or plaque that cannot be characterized clinically or histopathologically as any other definable lesion”. Leukoplakia is a clinical terminology which is reported as epithelial dysplasia histopathologically. The etiology is multifactorial, but tobacco and smoking are considered to be important causative factors for oral leukoplakia.

Clinical Features: (Figure 1, 2)

- Homogeneous leukoplakia: uniform, thin white area altering or not with normal mucosa
- Speckled type: white and red lesion with predominant white surface
- Verrucous leukoplakia: surface is elevated, proliferative or corrugated
- Nodular type: small polypoid outgrowth, predominantly white

Figure 1: Oral Leukoplakia
Figure 2: Oral Leukoplakia

Management: 5

- Cessation of habit
- Medications [local and systemic chemo-preventive agents (vitamin A and retinoids), systemic β-carotene, lycopene (α-carotenoid), ketorolac (mouthwash), local bleomycin]
- Surgical excision/ laser ablation/ electro cauterization/ cryosurgery
- Follow up

Erythroplakia: It is defined as “a red patch that cannot be clinically and pathologically diagnosed as any other lesion” 3. Erythroplakia is “A fiery red patch that cannot be characterized clinically or pathologically as any other definable disease” 1. Exact etiology and pathogenesis are unknown; however, use of tobacco and alcohol are involved in most cases 6. Only the true, velvety, red homogeneous OE has been clearly defined while the terminology for mixed red and white lesions is complex, ill-defined and confusing. A recent case control study of OE from India reported a prevalence of 0.2%. A range of prevalences between 0.02% and 0.83% from different geographical areas has been documented. OE is predominantly seen in the middle aged and elderly. One study from India showed a female:male ratio of 1:1.04. The soft palate, the floor of the mouth and the buccal mucosa is commonly affected. A specific type of OE occurs in chutta smokers in India. Lesions of OE are typically less than 1.5 cm in diameter. The etiology of OE reveals a strong association with tobacco consumption and the use of alcohol. Histopathologically, it has been documented that in OE of the homogenous type, 51% showed invasive carcinoma, 40% carcinoma in situ and 9% mild or moderate dysplasia. Recently, genomic aberrations with DNA aneuploidy has been demonstrated. p53 mutations with different degrees of dysplasia may play a role in some cases of OE. Transformation rates are considered to be the highest among all precancerous oral lesions and conditions. Surgical excision is the treatment of choice. Data on laser excision are not available. Recurrence rates seem to be high, reliable data are, however, missing. More studies on OE are strongly needed to evaluate a number of so far unanswered questions. The natural history of OE is unknown. Do OEs develop de novo or are they developing from oral leukoplakia through several intermediate stages of white/red lesions? The possible role of fungal infection (Candida micro-organisms).

Clinical features: 6 (Figure 3)

- Flat or depressed red lesion.
- Sometimes occurs with leukoplakia (erythroleukopakia).
- Some are smooth and others are nodular or granular.

Management:

- Surgical excision and regular follow up

Figure 3: Erythroplakia

Oral Submucous Fibrosis: Oral submucous fibrosis was first described by Schwartz in 1952. Pindborg defined OSMF in 1966 as, “an insidious, chronic disease affecting any part of the oral cavity and sometimes the pharynx”. It is associated with juxta-epithelial inflammatory reaction, followed by fibro elastic change of lamina propria and epithelial atrophy which leads to reduced opening of mouth. The prevalence is increasing in South Asia due to frequent chewing of betel nut. It is considered as a disease in India that has the highest
malignant transformation rate among all the potentially malignant disorders. It is also known as, “diffuse oral submucous fibrosis”, “idiopathic scleroderma of mouth”, “idiopathic palatal fibrosis”, “sclerosing stomatitis” or “juxtaepithelial fibrosis”. Etiological factors include arecanut chewing. Oral submucous fibrosis can be categorized into four stages with some specific characteristic features (Table 2).

### Clinical Features:
- Burning sensation in the mouth
- Pain and ulceration
- Depapillation and reduced movement of tongue
- Blanching of oral mucosa with leathery texture
- Loss of oral pigmentation
- Reduced mouth opening (Figure 4)
- Fibrosis of nasopharynx leads to nasal twang and stenosis of Eustachian tube may cause hearing defect in advanced stage
- Vesicle formation may be present
- Juxta-epithelial inflammatory reaction, followed by fibroelastic change of lamina propria and epithelial atrophy which leads to reduced opening of mouth

### Management:
- Cessation of the habit
- Nutritional support
- Hyaluronidase
- Placental extract
- Steroids
- Anti-inflammatory
- Oxygen radical scavenging
- Antifibrotic
- Chymotrypsin
- Interferon-gamma
- Immuno modulatory drugs
- Oral physiotherapy
- Combined therapy
- Diathermy
- Ultrasound
- Surgical treatment
- Cryotherapy

**Oral Lichen Planus:** Lichen planus is “a chronic inflammatory disease that affects the skin and the mucous membrane”. It is an immunologically mediated mucocutaneous disease. Lichen planus (LP) is a “chronic inflammatory condition that may affect the skin,
scalp, nails, mucous membrane (especially mouth) and the genitalia” ¹¹. It is “a chronic mucocutaneous disorder of the stratified squamous epithelium that affects oral and genital mucous membranes, skin, nails and scalp” ¹², ¹³. The word comes from Greek word “leichen” which means tree moss and Latin word “planus” which means flat. Lichen planus (LP) is “a chronic, inflammatory, mucocutaneous disease that belongs to the group of autoimmune diseases mediated by T cells” ¹⁴. The oral mucosa of patients with OLP exhibits significant cytomorphic changes; however, malignancy is absent ¹⁵. It is common in middle age that affects females more than males, in a ratio of 3:1 ¹⁶, ¹⁷. An overall age-standardised global prevalence of OLP is 1.27% (0.96% in men, 1.57% in women) among general population ¹⁸. It is commonly seen between 5th to 6th decades of life and is twice as common in females than in males ¹⁹, ²⁰, ²¹. Lichen planus occurrence is 76% of conditions in India. The sex ratio in India (male: female) is 3:2. It affects 0.1% to 4.0% of the population ¹⁰, ²². 0.4% to 1.5% malignant transformation to squamous cell carcinoma is associated with lichen planus ¹⁰.

**Clinical Features:** (Figure 5)

- Pinkish- purple polygonal papules which are flat, pearly, pruritic, present with fine white lace like pattern (reticular) in the periphery, known as “Wickham’s Straiae”.

**Figure 5: Oral Lichen Planus**

Modified World Health Organisation diagnostic clinical criteria for Oral Lichen Planus: ¹¹

- Bilateral symmetrical lesions
- Reticular pattern: lace like network of white/ grey lines which are slightly raised
- Subtypes in presence of reticular lesions are: erosive, atrophic, bullous and plaque type
- The term “clinically compatible with” is used for the lesions those resemble oral lichen planus but do not fulfil the above criteria

**Management** ⁹

- Corticosteroids
- Other immunosuppressants: “Calcineurin inhibitors, cyclosporine, tacrolimus, pimecrolimus, retinoids, Dapsone, mycophenolates, low-dose low molecular weight heparin (enoxaparin), efalizumab”
- Other modalities: PUVA therapy, photodynamic therapy, laser therapy

“Apart from, the above-mentioned malignant disorders, clinical features and management of other potentially malignant disorders are summarized in Table 3,”

</table>

**Conclusion**

Potentially malignant disorders are frequently undiagnosed due to lack of awareness and knowledge among dental professionals. It is important to know the details regarding the various potentially malignant disorders for its early and correct diagnosis during any other dental procedures. Prognosis depends on the grade and stage during initial diagnosis. In country like India, premalignant lesions are common due to frequent use of tobacco and/or alcohol; however, people have less knowledge regarding this and people do not want to be treated until the disorder becomes symptomatic. It is the duty of dental professionals to make the people aware about such disorders. Brief knowledge regarding the management of such disorders will be helpful in regular clinical practice.

Prosthetic Rehabilitation of Ocular Defect: A Case Report

M. Krishna1, Abhijita Mohapatra2, Gopal Krishna Choudhury3

1Postgraduate Trainee, Department of Prosthodontics, Crown Bridge and Implantology, Institute of Dental Sciences, Siksha ‘O’ Anusandhan (Deemed to be University), 2Professor, Department of Prosthodontics, Siksha ‘O’ Anusandhan (Deemed to be University), Crown Bridge and Implantology, Institute of Dental Sciences, 3Professor & Head, Department of Prosthodontics, Crown Bridge and Implantology, Institute of Dental Sciences, Siksha ‘O’ Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India.

Abstract

The kind of disfigurement caused due to loss of eye results in significant physical, psychological and social distress for which they require immediate management and functional rehabilitation. The aim of such rehabilitation is to re-establish back the patient’s dignity and self-confidence. The disfigurement can be concealed to an extent to give an acceptable aesthetic appearance. This clinical case report represents the rehabilitation of an ocular defect of a 58 year old patient caused due to a traumatic injury; fabrication of customized prosthesis was done by polymethylmethacrylate ocular intraorbital prosthesis.

Keywords: Prosthetic rehabilitation; Ocular defect; Polymethylmethacrylate ocular intraorbital prosthesis.

Introduction

Ocular defects can be congenital or acquired. Based on the severity of the involvement, the surgical management may comprise one of the approaches: evisceration, enucleation or exenteration.1-3 Enucleation is the surgical removal of the entire globe and a portion of the optic nerve from the orbit. Physiological distress associated with the loss of eye can be considerably enhanced by an ocular prosthesis. The usage of methyl methacrylate resin is considered superior for ocular prosthetic materials in terms of tissue compatibility, light weight, better fracture resistant, translucency, easy fabrication, easy adjustability, and its capability for intrinsic and extrinsic coloring. In this case PMMA material was used for the fabrication. The custom fabricated prosthesis promotes a better fit, & is more contended to use providing better aesthetic results than the stock prosthesis.1

Casereport: A 58-year-old patient reported with a complaint of missing right eye. Examination revealed enucleated right eye socket with no signs of infection. (Figure 1) Patient gives a history of surgical removal of the right eye ball after a traumatic injury experienced 3 months back. After enucleation, the patient was providing with a conformer which had been placed for 4-6 weeks for the reduction of the edema and subsequently maintenance of the socket contours.4 The treatment plan involves replacement of the conformer for the rehabilitation with a custom-made ocular prosthesis. When surgical site ensures adequate healing the fabrication of an ocular prosthesis may be undertaken. Thus, loss of orbital volume and facial asymmetry in an anophthalmic socket can be prevented through early management.4

Figure 1. Preoperative image of anophthalmic defect
The fabrication procedure involves the following:

Impression Making: A custom made impression tray was made from light cure activated polymerizing resin material on the primary cast obtained from putty impression made upon the non-defect eye. (Figure 2a) Perforations were made for the mechanical retention of impression material and a syringe cap was cut appropriately and fixed to the tray. (Figure 2b) Necessary polishing and finishing of custom tray was done to avoid impingement to the soft tissues. Using this custom-made tray impression was made by instructing the patient to tilt the head backward. Vaseline was applied on the eye lashes and light body polyvinyl siloxane impression material (Coltene Affinis A-Silicone impression material) was injected into the right eye socket. The head was moved back to the vertical position and the functional eye movements were made by the patient by moving his eyes up and down. (Figure 2c). This facilitated the proper flow of the impression material to all aspects of the eye socket. The patient was instructed to look and maintain his gaze in a forward direction. The seal was broken by massaging the surrounding tissues, when the material sets.

While retrieving the impression the patient was instructed to gaze upward, the cheek was pulled down and the inferior portion of the impression was removed out of the socket by rotation. The Impression obtained was verified for accuracy, & was invested in type III dental stone (BN STONE Alpha gypsum plaster) in a small medicine cup. (Figure 3a) The space left in the mold was applied with separating media (Coltene separating media) & molten baseplate wax was poured into it to fabricate a scleral wax pattern and the orientation was marked on the cast obtained. (Figure 3b) Finishing and polishing was done in a conventional manner. The wax pattern was placed into the socket and evaluated for proper fit. To achieve satisfactory contours of the eyelids both in open and closed positions, the wax can be added or trimmed from the basic scleral pattern.

Positioning of the Iris: The contra-lateral iris position from the facial midline guides to mark the
expected position of iris on a sclera wax pattern. Prefabricated eye shell matching the patient’s natural left iris in color and size was selected. Iris portion of the shell along with some of the scleral portion was trimmed away with the help of a bur. The iris disc was positioned on the marked area by scooping out wax, followed by blending with the rest of the scleral wax pattern.

**Trial:** After the positioning of iris disc, the wax trail was done in the eye socket followed by polishing of the pattern. The superior border of the pattern was adjusted by removing some wax to engage into the undercut while securing the same eye opening as that of contra-lateral eye and to correct the sagging of upper eyelid (Figure 4a, b). Proper position, gaze and aesthetics of the iris were evaluated by comparing with the contra-lateral natural eye.

**Processing:** Flasking of the iris disc fitted into the wax pattern was done within the stone mold to create a split mold. The iris disc position was secured with the help of a syringe cap fixed with glue. Dewaxing was done and the mold was packed with tooth moulding heat cured acrylic (tooth moulding powder, DPI) of appropriate shade. Short curing cycle was carried out for processing. The split mold was preserved while retrieving the prosthesis from it. About 1mm of the scleral portion was trimmed from the surface, to create space for the incorporation of the nylon fibrils that has been separated from the denture acrylic resin polymer to imitate the veins and effect of sclera vessels (Figure 5a, b). The heat cured clear acrylic resin was used to cover the fibrils on the sclera and was processed in the same mold which had been preserved. This characterization helps to give a life like appearance of the prosthesis. After the prosthesis was recovered, it was finished, polished, disinfected and stored in water for twenty-four hours before insertion into the socket.

**Insertion:** The prosthesis was evaluated for any requisite adjustments during insertion and removal into the socket. Esthetics and comfort of the patient were examined. Patient had been educated regarding the use of the prosthesis. Ophthalmic lubricant was also advised for lubrication of the ocular prosthesis. Patient was instructed to remove the prosthesis while sleeping to relax the muscles and was advised for follow up in every three months.

**Discussion**

Although the effects of enucleation on facial symmetry and orbital volume are still debated. Rehabilitating with a custom-made ocular prosthesis...
can help in building confidence while making them feel more acceptable. Although the ocular prosthesis cannot be able to restore the vision but it has been helpful in reducing the psychological trauma caused due to loss of an eye. This clinical report represents a technique that demonstrates the fabrication of a semi-customized ocular prosthesis with stock iris and a custom-made sclera which is less time consuming and provides functionally and aesthetically acceptable results.  

**Conclusion**

The accomplishment of the custom-made ocular prosthesis relies on the defined laboratory techniques and artistic skill of the operator. It is obvious that an ocular prosthesis is much more necessarily needed to provide utmost comfort while restoring the physiologic function of the eye. Moreover, Fabrication of a custom-made prosthesis allows infinite variations during construction and ensures better fit and patient’s contentment.

Accelerated Orthodontics: A Boost to Orthodontic Treatment

Ananya Panda

Post Graduate Trainee, Department of Orthodontics and Dentofacial Orthopedics, Institute of Dental Sciences, Siksha ‘O’ Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

The molecular mechanisms controlling the behavior of the cells in the alveolar bone and periodontal ligament underlie the remodeling of tissues around the roots which mainly determines the rate of the orthodontic tooth movement under mechanical forces. Hastening of “orthodontic tooth movement” can greatly reduce the treatment period and occurrence of undesirable effects. Also, reduced treatment time results in increased positive and acceptable attitude universally towards the orthodontic treatment. This review synopsizes the contemporary methods to accelerate tooth movement which can be categorized into biological, physical and surgical methods.

Keywords: Orthodontics; Acceleration; Treatment; Orthodontic Tooth Movement.

Introduction

Orthodontic tooth movement is based on the fact that prolonged light forces applied on the tooth results in tooth movement by selective resorption and apposition of bone around the root. Thus, the tooth movement occurs along with its attachment apparatus, as the socket of the tooth migrates. Tooth movement is a PDL phenomenon as the bony response occurs through the periodontal ligament. Acceleration of the movement of the teeth during the orthodontic treatment has its prospects in reducing the duration of the treatment and decreased unwanted effects related to oral hygiene and better post treatment stability.1-3

Methods of Acceleration of tooth movement

The response of the teeth to the sustained force is related to the magnitude of force. heavy forces result in rapid development of pain, cellular necrosis within PDL and the alveolar bone surrounding the affected tooth undergoes undermining resorption. In contrast, Lighter forces are compatible with the tissues in the PDL and remodeling of the bone occurs with relatively painless frontal resorption of the tooth socket. For a tooth movement to occur, osteoclasts are formed at the site of pressure and osteoblasts are formed at the site of tension and thus bone remodeling occurs. Various methods used to accelerate tooth movement can be summarized into:

- Biological
- Physical
- Surgical

Biological Methods: Several Experiments have been done using certain exogenous molecules to hasten the tooth movement both in animal experiments and in humans. These molecules are “Prostaglandin E, Cytokines, Receptor activator of nuclear factor Kappa B ligand (RANKL), Macrophage colony stimulating factor (MCSF)”.

Prostaglandins: In the body, Arachidonic acid that are formed from phospholipids, synthesis Prostaglandins. Prostaglandins causes increase in the number of osteoclasts and thus leads to bone resorption. Several animal experiments have shown that the rate of orthodontic tooth movement is increased by local application of “PGE$_1$, PGE$_2$, or analogs of PGE$_1$, PGE$_2$, or thromboxane A2”. Local Prostaglandin injections at the submucosal region have shown to increase the tooth movements by 1.6 folds.3 However, there are certain drugs that inhibits the PG activity like corticosteroids, NSAIDs and other agents that have mixed agonist and antagonist effects on various PGs such as Tricyclic antidepressants, antimalarial drugs, antiarrhythmic agents and methylxanthines. The drugs taken for control of pain such as the NSAIDs during orthodontic therapy by certain patients may cause interferences with the tooth movement. It is a possibility that there would be decreased response to the treatment in patients on any of the medications, as mentioned above. However certain medications which affect neurotransmitters can show increased response.
Cytokines: High concentration of cytokines like IL-1, IL-2, IL-3, IL-6, IL-8, and tumor necrosis factor alpha (TNF) were found to play a major role in bone remodeling. Also, interleukin-1 (IL-1) stimulates osteoclast function through its receptor on osteoclasts. There was increased production of prostaglandins and IL-1 beta in the PDL due to the mechanical stress caused by the orthodontic treatment. Experiments on animals have shown that the intensity of PGE and IL-1 beta was found to be highest on the tension site when certain amount of force was applied for days on a particular tooth. The bone remodeling process is a balance between RANKL-RANK system and OPG compound. RANKL, a membrane bound protein on osteoblasts, bind to RANK on the osteoclasts and causes osteoclastogenesis and Osteoprotegerin (OPG) competes with RANKL in binding to osteoclast to inhibit osteoclastogenesis.3

Vitamin D: 1,25-dihydroxycholecalciferol [1,25(OH)2D3], an active metabolite of vitamin D, along with parathyroid hormone and calcitonin maintains the calcium homeostasis by regulating the phosphorus and calcium balance in the body. Activation of cells, independent of the cyclic nucleotide cascade, occur due to the activity of 1,25- dihydroxycholecalciferol directly on the nucleus of the circulating monocytes and osteocytes progenitor cells. An extensive increase in tooth movement was seen after a 21-day experimental study following a weekly intraligamentous injection of a 1,25-dihydroxycholecalciferol.4

Parathyroid Hormone (PTH): Earlier studies state that, administration of PTH in a slow and continuous manner in a localized region showed a faster rate of bone resorption than the usual.5 Approximately, 1.6-fold increase in the rate of the tooth movement was seen with 1µg of PTH injected locally in a methylcellulose gel medium. With no systemic bone loss or undesirable side effects, local administration of PTH along with the mechanical orthodontic force seems to be useful in accelerating the tooth movement.

Relaxin: Relaxin hormone is produced by a pregnant female and helps during parturition by relaxing the pubic symphysis and widening the birth canal. Relaxin seems to have the potential to remodel the sutural, gingival and PDL connective tissues resulting in post orthodontic treatment stability, space closure and reduced scar tissue formation following frenectomies.3 The effect of Relaxin on the orthodontic tooth movement is still controversial, as in few studies cites the positive effect on the tooth movement while few cites no significant effect on the tooth movement. According to a study, relaxin reduces the mechanical strength of the tissues around the tooth and increase the tooth mobility. However, few randomized clinical trials conducted on humans showed no major changes in orthodontic tooth movement due to relaxin.

Physical Methods: This approach involves the physical means or the device assisted therapy for hastening the orthodontic treatment. This includes “direct electric currents, pulsed electromagnetic field, static magnetic field, resonance vibration and low level laser therapy”.

Direct electric current: When the mechanical pressure is applied on the tooth, there is some sort of “piezoelectric phenomenon” that occurs in the tissues around the tooth. Many studies have cited that this above mentioned phenomena acts as a signal for the activation of cells and in turn helps in the process of remodeling.6 In an experimental study by ‘Z Davidovitch’, it was shown that local application of electric current to the tissues that is by placing the anode nearer to compression area and cathode nearer to the tension region during orthodontic treatment hastened the tissue remodeling and thus resulted in increase in the tooth movement.

Resonance Vibration: Low magnitude and high frequency vibrations stimulate bone metabolism by enhancing differentiation and maturation of the cells leading in a faster bone remodeling necessary for tooth movement. Few researchers have reported an average rate of 1.16 mm movement of tooth per month with AcceleDent device and 0.79 mm of movement per month without it. Studies have also suggested that, loading a tooth with vibrations for around 1.5 hours in a day for 3 weeks resulted in around 1.3 to 1.4 times higher rate of tooth movement than with a static force. To avoid physical and psychological stress, it is always advised to use this method for a brief period in a clinical set up. The anabolic effect on bone produced by vibratory loading reflects the increased rates of bone resorption and formation, thus raising concern that tooth cementum could be subject to higher level of resorption when exposed to concomitant stresses from orthodontic forces and vibrations. However, root resorption occurs due to the tissue hyalinization caused by the obstruction in blood flow at the region of compression when mechanical force is applied and this might be prevented by the resonance vibration.7
Low level laser therapy: Low level laser therapy (LLLT) plays bio-stimulatory role in healing of wounds, repair, remodeling and regeneration of bone following surgery due to the stimulation of osteoblasts, osteoclasts, fibroblasts via “RANK/RANKL and macrophage colony stimulating factor” expression. The main reason behind the cellular proliferation is the synthesis of DNA following laser light exposure. Kawasaki and Shimizu, in 2000, in their study cited an increase in tooth movement of about 1.3 fold after irradiation with laser and considerably higher bone formation in the tension site and resorption in the compression site. According to few studies on lasers, it can be stated that, the effect of lasers on the tooth movement could be dose dependent and also could depend on certain other factors like the age of the patient and the amount of force applied. The therapy has its own disadvantages in terms of its high cost, long chair time and it also requires efficient and skilled human resources. The effect of laser therapy in boosting the orthodontic treatment is still a controversial issue. Despite its positive effects in various animal and human trials, few studies have also cited its zero or negative effects in orthodontic treatment.

Surgical methods: Hullihan, an American oral surgeon experimented with the moving teeth after making cuts in alveolar bone in the late 19th century and following which many experiments were done till the early 20th century. Due to concerns over infections and bone loss, the approach was not adopted widely earlier. The remodeling of alveolar bone and its turn-over rate is seen to increase after osteotomy, fractures and bone grafting procedures.

Corticotomy: In the mid 20th century, Kole, a German surgeon revived the idea that cuts between teeth led to faster tooth movement. In this procedure, the medullary bone remained intact, while the cuts were made on the cortical bone, thus reducing the resistance offered by the dense cortical bone. The recent surgical technique is further revived and reconsidered by Wilko, as a regional acceleration of the remodeling process of the bone that leads to faster movement of the tooth and not due to the movement of the blocks of bone and a much lighter force is utilized for the movement of teeth and the surgical approach is broadened into “accelerated osteogenic orthodontics (AOO)” by including the decortication of the facial surfaces of alveolar bone. The benefit of AOO lies in the reduction of time for the treatment without any extractions and also there has been reports of post treatment stability as well as retention. The risks attached to this procedure includes the reduction in the height of the alveolar bone if the corticotomy is performed without any replacement with bone grafts. There are chances of bruising and/or any undesirable changes in the gingiva.

Piezocision or Modified Corticotomy: In 2009, Dibart, a periodontist, introduced this technique which he named as “Piezocision”. This technique involves incision on the facial aspects of the gingiva in the incisor region and the cuts on bone is done only in that area using a “vibrating piezoelectric knife”. The Tunnels created beneath the gingiva allows placement of a slurry bone graft. Reports suggest, this technique has increased post treatment esthetic results and it can also be performed in cases with Invisalign.

Micro-osteoperforation: Developed by a commercial company (Propel, Alveologic LLC, Briaciff Manor, NY), this method has an advantage of being performed by an Orthodontist and does not require any periodontal surgery. Special screws supplied by the company are inserted into the gingiva in the area of interproximal alveolar bone, which generates a regional acceleration of bone remodeling leading to faster tooth movement. A recent study by “Tracy Cheung” concluded that Mini Implants help in micro-osteoperforations and hasten tooth movement by 1.86 folds.

Distraction Osteogenesis: Also known as “Inter-septal alveolar surgery” is a method that is divided into “distraction of PDL” where the inter-septal bone lying on the distal aspect of the tooth is undermined by a minor surgery during extraction of premolars with the help of a round bur, and “distraction of alveolar bone”, which includes vestibular dissections and osteotomies along with the above mentioned procedure. This procedure reduces the resistance of bone for the tooth movement and hence there would a faster movement of the tooth.

Conclusion

Although, few techniques have certain downsides, their positive results in creating an environment for boosting the orthodontic treatment should be taken into consideration and eventually used according to the suitable situations. Certain new approaches evolved, have reduced the chances of relapse along with the reduction in the treatment period. Further studies and methods should be encouraged for hastening the orthodontic tooth movement so that new techniques with least side effects and maximum positive effects evolve.

Diagnostic Features of Oral Ulcers: An Overview

Suvranita Jena¹, Rupsa Das¹

¹Post Graduate Trainee, Department of Oral Medicine and Radiology, Institute of Dental Sciences, Siksha ‘O’ Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract
Diagnosis and management of oral ulcers are often challenging due to their similarity in clinical presentation. While many ulcers are result of chronic trauma or irritation from a particular source or due to underlying systemic conditions may be – immunological, malignancies and some are due to acute or chronic infections. Treatment and management of these ulcers requires deep understanding of the pathogenesis of the ulcers. This overview will address how to diagnose and distinguish varying type of oral ulcers for further successful treatment.

Keywords: Oral Ulcers, Acute, Chronic, Recurrent, Solitary, Multiple.

Introduction
Defects in the covering epithelium and underlying connective tissue or both are characteristic of an ulcer. Ulcers are broadly defined as “any break in the continuity of the epithelium brought about by molecular necrosis”. Due to huge diversity of the contributing aspects and clinical presenting features, diagnosis of numerous oral ulcerations has become quite interesting and challenging for the physician. According to the duration of ulcer. A classification has been formulated. If the ulcerative lesions last for 2 weeks or more, it is classified under “chronic”, otherwise if less than 2 weeks, it is considered as “acute”. If any ulceration presents with a history of analogous occurrences with intermittent healing, this type of ulcerative lesion comes under “recurrent” variant. According to the number of ulcers occurring in the oral cavity, a classification has been devised. The word “solitary” implies occurrence of single ulceration in the oral cavity whereas occurrence of several ulceration is termed as “multiple”. Overall, the oral ulcerative lesions are categorized on the basis of number and duration, into three major groups namely acute, chronic and recurrent ulcerative lesions which are further sub divided into sub groups namely solitary acute, multiple acute, solitary chronic, multiple chronic and lastly solitary/multiple recurrent ulcers.¹-³

Acute Solitary Ulcers: Traumatic ulcers- Commonest of all ulcers in oral cavity, commonly occurs on the lateral borders of the tongue, lips and buccal mucosa. These are caused by accidental biting during mastication, injury from piercing objects, thermal and chemical injury or unusual habitual biting of buccal mucosa mostly in stress. These persist for few weeks, generally single ulceration occurs and on the tongue the ulcers become recurrent if the etiologic factors have not been eradicated such as- sharp cusps of any tooth, fractured crown or restorative materials. Clinically the borders of the ulcer are usually raised slightly, can be well circumscribed, floor is covered with whitish yellow necrotic pseudomembranous slough having erythematous in appearance, scrapable and non-tender when palpated. Treatment includes removal of the etiologic factors. The healing will take place within 7 – 10 days. Prescription of any anesthetic gel can be recommended for symptomatic relief to the patient.¹,²

Necrotizing Sialometaplasia – First described by “Abrams and Melrose in 1973”. This is defined as “a benign, non-neoplastic inflammatory disease of the minor salivary gland mainly the mucouserous gland of the hard palate”. With a gender predilection towards middle aged men. Most common site for the involvement is palate followed by lower lips, sublingual region, retromolar area and tongue region. The etiology for the disease is still unclear, but trauma from ill-fitting denture, provoked vomiting (bulimia), upper respiratory tract infection, prolonged use of non-steroidal anti-inflammator drugs can be considered as few predisposing factors. These are diagnosed by a crater like lesion which are initially not ulcerated swelling mostly accompanied with pain having an indurated and well delineated border. This a self-limiting disease and does not require surgery but histopathological confirmation is a necessity as it can resemble many diseases particularly malignant neoplasms.

Acute Multiple Ulcer: Primary Herpetic Gingivostomatitis: Presents as oral manifestation of the symptomatic herpes simplex virus (HSV). HSV-1 presentation occurs above the waist and HSV-2 affects the lower body below the waist. Peak incidence is around 3 years with a range from 6 months to 5 years. Disease presents as numerous pin point vesicles on palate, attached gingiva and tongue that ruptures readily upon trauma or frequent irritation. These becomes painful after rupturing and the floor is covered with yellowish sluggish pseudo membrane and the most distinguishing characteristic features of this lesion is the coalescing scalloped borders where small ulcers merge to form larger one frequently circumscribed by thin erythematus halo. Attached gingiva of maxillary and mandibular arch appears fiery red colour. These heal spontaneously after 5-7 days with no scarring. Anesthetic ointments and mouthwashes can be advised for reducing pain while eating and swallowing.

Herpes Zoster Infection (shingles)- Usually affects in second decade of life and is less common viral infection. Begin with mild fever, malaise, development of “pruritic maculopapular rash and dew drop like vesicles”. Severe tender state, occurrence of multiple clustered ulceration on hard palate and gingiva in a unique unilateral design. These are self-healing lesions within 10-14 day. Management of patient can be done by pain control, supportive care and sufficient hydration.

Herpangina- Occurrence of irregular numerous vesicular erythematos ulcers on the oro pharynx, soft palate and tonsillar pillar with peak incidence usually under 10 years of age. It requires no specific treatment.

Erythema Multiforme – First described by “von hebra in 1866”. Defined as “an inflammatory mucocutaneous disorder that affects skin, mucous membrane or both”. This has been categorized and classified as “Erythema minor, major, Steven Johnson syndrome and Toxic epidermal necrolysis (TEN)”. Former is the mildest of all followed by later is the severe one. Contrary drug reaction and HSV infection can be the triggering factors for the ailment. Single mucosal ulceration and typical target lesions on skin are considered as characteristic to E. minor. Blood encrusted lesions are reported on lips. Management depends on the extent of severity of the clinical symptoms of the patient. In milder forms, resolution of the lesions takes place in 10-20 days.
Necrotizing Ulcerative Gingivitis - Acute infectious disease affecting the gingiva, with “punched out ulcerations and necrosis of the papillary and marginal gingiva” is often encountered. Machine-driven calculus elimination with local or systemic delivery of antibiotics can be preferred as treatment. Plasma cell stomatitis-In late 1960s was described as “hypersensitivity reaction” and likely a contact stomatitis to any allergic component of the product. Numerous irregular ulcerations with epithelial sloughing seen in the gingiva commonly with associated angular cheilitis in some patients. As these ulcers heal by itself, only anti-inflammatory is recommended for pain control. Chemotherapy induced ulcers- “Kolbinson et al. demonstrated that early changes in the oral mucosa such as erythema and ulceration appear between 5 and 7 days after onset of chemotherapy”. Post chemo sessions, these multiple ulcerations resolve on its own, however anti-inflammatory drugs may be prescribed to the patient. Chronic Solitary Ulcers: Eosinophilic Ulcer - also called “traumatic ulcerative granuloma with stromal eosinophilia (TUGSE)” [1]. Presents as chronic isolated ulcer of the oral mucosa and is most frequently seen in patient between 40-60 years of age. This manifests as “slow healing ulcer with rolled or elevated borders mimicking squamous cell carcinoma”. Healing period may vary from one week to one year. Surgical excision is considered as mainstay treatment for this followed by rare recurrence rate. Ulcerative Squamous Cell Carcinoma-accounts about 95% of all oral malignancies. Major distinguishing features is elaborated as “crater like lesion having rolled, indurated margins and presence of velvety base”. “According to Wood and Goaz, a lesion is most likely a SCC if the patient is male, older than 40 years, smokes or drinks heavily, no evidence of trauma or systemic disease exists, serologic findings are negative, and the lesion is not located on the posterolateral region of the hard palate”. Treatment comprises combination of surgery, radiotherapy and chemotherapy. Cytomegalovirus associated ulcers- rarely presents with any clinical symptoms. Characterized by “isolated, painful, large and necrotic ulcerations with minimally rolled borders which affects both keratinized and non-keratinized mucosa”. Superficial anesthetic ointment may be helpful for symptomatic discomfort reduction. Tuberculous ulcer rarely affects oral mucosa, “roughly 1.4% of all the TB cases with man: woman ratio of 4:1 according to WHO”. Presents as solitary ulcer usually an “undermined edges on the tongue most commonly followed by gingiva, floor of the mouth, palate, lip and buccal mucosa” with ragged and indurated margins associated with pale floor. Syphilitic ulcer as a consequence of “oro-genital and oro-anal contact” with an infectious lesion, primary syphilitic ulceration grows. A chancre appears on the upper lip of males and lower lips of female in greatest frequency. Typically seen as red purple or brown base having ragged borders, often cervical lymphadenopathy is associated with this. Tertiary syphilitic ulceration is “punched out lesion” usually on tongue which often undergo necrosis parting behind a deep painless crater. Deep fungal ulceration (histoplasmosis / blastomycosis/mucormycosis)- histoplasmosis related oral lesion is often secondary to pulmonary engrossment where erythematous area alters to granulomatous one. The blastomycosis lesion is nonspecific type verrucous ulcer. In mucormycosis deep palatal ulceration has been reported resulting from necrosis because of palatal invasion. Multiple Chronic Ulcers: Vesiculobullous disease- In pemphigus vulgaris, bulla disrupts to form shallow ulcers. “A thin layer of epithelium peels away leaving a denuded base referred as Nikolsky’s sign named after Pyotr Nikolsky (1858– 1940), a Russian physician”. These lesions are irregular multiple occurring along the line of occlusion in buccal mucosa, palate and gingiva.
In mucous membrane pemphigoid, gingiva appears edematous associated with mild inflammation and desquamation along with multiple vesicles formation. These are less painful than pemphigus ulceration.

Linear IgA Disease defined as “autoimmune subepithelial mucocutaneous disease”. In oral cavity, disease presents as vesicles, painful ulcerative erosions along with cheilitis. Usually use of topical steroids is advised but for severe cases, dapsone therapy is suggested.14, 15

Recurrent ulcers(solitary/multiple): Recurrent aphthous stomatitis- most frequently occurring “recurrent inflammatory disease” with prevalence of 0.5%-75% with female predominance. Commonly occurs on non-keratinized mucosa. These occurs as symmetrically round fibrin covered mucosal defects surrounded with erythematous border. Three clinical types have been categorized into “minor type, major type and herpetiform ulcers”. Minor variety is smaller than 1 cm in diameter and these are self-healing and often not accompanied with scarring. Major variety also called as “Sutton ulcer” usually 1-3 cm in size and herpetiform ulcer seems as minute multiple extremely tender. RAS is self-limiting but in extreme cases topical corticosteroids are advised.16

Lichen Planus- described as “chronic, autoimmune, mucocutaneous disease”. Buccal mucosa is most commonly affected followed by tongue, gingiva and vermilion border. “Reticular, popular and plaque like lesions” are usually asymptomatic where as “bullous, erosive and ulcerative forms” are associated with pain. Topical corticosteroids are prescribed in management of oral lichen planus.

Cyclic neutropenia- defined as “immunodeficiency syndrome considered by regular periodic fluctuations in the circulating neutrophil count from normal to neutropenic levels every 21 days and lasting for 3-6 days”. Incidence of regular episodes of less neutrophils often manifested. Aphthous like ulcerations are encountered with no specific treatment modalities.

Bechet’s Disease- relatively rare disease. the syndrome is comprised of “presence of recurrent oral aphthous-like ulcers (minor, major, or herpetiform ulcers, which recur at least three times within a period of 12 months) along with two of the following: genital ulcers, ocular lesions (anterior uveitis, posterior uveitis, vitreous cellularity, or retinal vasculitis), and skin lesions (erythema nodosum, pseudo folliculitis or papulopustular lesions, or acniform papulae in post adolescent patients.”[1] Infliximab treatment resolves the recurrent oral ulcers completely.

Ulcers in Other Systemic Diseases: Uremic stomatitis- Elevated levels of ammonia complexes and stomatitis appear when “blood urea levels are higher than 300 mg/ml”. Common sites of involvement are tongue and floor of the mouth. Major four types of ulceration are reported namely- “ulcerative, haemorrhagic, non-ulcerative pseudomembranous and hyperkeratotic forms” [1]. Uriniferous breath is normally accounted in such patients. After dialysis, such ulceration resolves on its own and recovery of taste sensation occurs following the treatment.

Crohn’s disease along with ulcerative colitis, Crohn’s disease is considered major entities of “inflammatory bowel disease (IBD)”. Oral findings are reported first than intestinal manifestations of the disease. Patients reports with persistent long-standing lip swelling along with “cobble stone appearance of oral mucous membrane, deep linear or serpiginous ulceration surrounded by epithelial hyperplasia and tissue tags or polyps”. Perioral dermatitis is not frequently accounted.

Diabetes mellitus- patients diagnosed with type 2 diabetes mellitus shows prevalence of both traumatic and aphthous ulcerations, multiple periodontal abscess with mild symptoms of glossodynia, stomatopyrosis and dysgeusia are seen.17

Conclusion

Ulcers are common to oral cavity, so its prime responsibility of dentist to diagnose and render treatment accordingly for patient wellbeing. Proper history taking and thorough clinical examination of the patient will be helpful in proper diagnosis.

Conventional Over Denture-A Successful Clinical Protocol to Treat Edentulous State: A Case Report

Sangram Panda¹, Gopal Krishna Choudhury², Sumita Mishra³

¹Reader, Department of Prosthodontics, Institute of Dental Sciences, ²Professor, Department of Prosthodontics, Institute of Dental Sciences, ³Reader, Department of Orthodontics, Institute of Dental Sciences, Siksha ‘O’ Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

The following case report describes an easy technique of restoring a lower resorbed edentulous mandible, where implants has been ruled out as a Prosthetic option because of financial reasons. Retention of the tissue supported prosthesis in a resorbed mandible is a difficult proposition owing to the reduced surface area. Patient’s refusal to go for an implant-oriented treatment further complicates the treatment protocol. Thereby going for a conventional overdenture by employing the primary & secondary coping technique helps in solving the retention issues while at the same time providing patient with a financially acceptable treatment protocol.

Keywords: Primary copings, Secondary copings.

Introduction

In the age of implants, where implant-oriented treatments have become a norm, conventional treatment protocols are slowly being forgotten¹,². Conventional treatment protocols like conventional tooth supported overdentures are becoming second option of treatment. It is also not disputed that clinical predictability of implant-oriented treatment has been excellent and results phenomenal, but this does not undermine the importance of conventional treatment order. Conventional treatment is still capable of delivering the goods without the burden of increased finances or undergoing trauma of implant surgery. This treatment protocol also holds in good stead for the patients who are afraid of undergoing any surgery. This article describes a treatment protocol of rehabilitation of a patient with primary and secondary coping technique and conventional overdentures in order to restore partially edentulous lower ridge.⁴-⁶

Figure 1: Preoperative picture of the patient

Clinical report: A 66-year-old female (fig 1) reported to the prosthodontic clinic with a complaint of inability to chew food. On clinical examination it was found that patient was partially edentulous with missing 15,17 and 24,25,26 in the upper arch and 33,34 and 37 present in the lower arch. Implant assisted overdentures were suggested to the patient as treatment of choice. However, patient refused any surgical intervention because of financial problems and fear of surgery. Also, patient was not interested in rehabilitation of the upper arch and therefore it was decided that conventional tooth
supported overdenture will be given in the lower arch not including the last abutments after assessment of sufficient VDR and VDO (7.5mm & 7.0mm respectively.

Single sitting root canal treatment of the 2 canines were therefore initiated with rotary system (xsmart, dentsply). Working length was established at 23mm for both the canines. After preparing the canal to the size of f-3(protaper dentsply rotary file system), obturation was done with f-3 size gutta percha cones (Dentsply protaper G.P cones). After access cavity was filled with composite filling material (LUXACORE-Z Dual core composite) reduction of the concerned teeth that is 33 & 43 was done to dome shape with chamfer finish line (Figure 2) for the primary copings.

Figure 2. Root canal treated 33 and 43 with preparation done for primary copings

Upper impression was taken with alginate (3M ESPE) while Lower impression was taken with elastomeric impression material (Aquasil, Dentsply) using dual impression technique (Figure 3a, 3b) for the purpose of fabricating primary coping. Primary copings were then cemented onto prepared teeth that is 33 & 43 with GIC cement (Fugi 2, 3M ESPE). Alginate impression was taken in the lower arch for the purpose of fabricating a special tray.

Figure 3a. Upper and lower impression taken for preparing special tray for the lower ridge; 3b. Master impression taken on the special tray

Figure 4a. Primary copings cemented in patients' mouth; 4b. Secondary copings tried over the primary copings to check the fitting

After fabrication of the special tray border moulding was done in the lower arch. Master impression (Figure 4a) was then taken with light body elastomeric impression material (Aquasil, Dentsply). Secondary copings which would be inserted into the denture were then fabricated on the master cast & tried on to the primary copings to check the fitting (Figure 4b). Pick-up impression (Figure 5a) was then taken with the heavy body elastomeric impression material (Aquasil, Dentsply) with secondary copings in place.

Figure 5a. Pickup impression taken with secondary copings in place; 5b. Jaw relation done in the patients' mouth; 5c. Jaw relation transferred to the articulator and teeth setting done; 5d. Conventional over denture placed in the patients mouth

Figure 6. Final intra oral view of the prosthesis in place
Jaw relation was then carried out for the patient (Figure 5b). Teeth setting was then carried out on 3-point mean value articulator (Figure 5c). Wax trial was then done (Figure 5d) and the denture was subsequently acrylized and delivered to the patient (Figure 6).

**Discussion**

Patient satisfaction is of paramount importance when treating a edentulous patient. Different methods including the use of primary and secondary copings as has been discussed in the case report have been used to gain the additional retention & stability for complete denture in order to achieve patient satisfaction1-5. Dental implants have been used for retention and stability to the overdentures especially in compromised ridges6-8. High success rate of implant has prompted the dentists to recommend implant-supported fixed or removable treatment 9-11 plan to the patient which are costly & require surgical intervention12-15. There are only few studies that have compared the implant-supported overdentures to the conventional overdentures16-17 in which also it is unsubstantiated that one is better than the other. The patient in consideration refused to undergo implant-oriented treatment because of added cost & fear of surgery. Therefore, given the clinical situation and economic & psychological factors involved it was decided that a conventional overdenture will be given to the patient. After extraction of the hopeless teeth root canal treatment of the upper &lower premolar was carried out. Primary copings were given to protect the root canal treated teeth while secondary copings were incorporated to provide increased retention & stability to the overdenture. The final delivery of the denture to the patient & patient satisfaction thereof is evidence enough that conventional overdenture is still an efficient & economical protocol to treat edentulousness.13-17

**Conclusion**

This case report primarily discusses one of the alternatives of treating edentulous patient in detail successfully, were considerations other then implants can be applied to achieve optimum results.

Modified Coronally Advanced Flap Procedure Using Orthodontic Buttons: A Case Report

Saurav Panda1, Sital Panda2, Abhaya Chandra Das1, Rinkee Mohanty3

1Associate Professor, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha ‘O’ Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India, 2MPH Student, Department of Public Health, Regional Medical Research Centre, Chandrasekhar, Bhubaneswar, India, 3Professor and Head, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha ‘O’ Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

The management of multiple adjacent gingival recessions often requires use of surgical procedures for covering the exposed root surfaces. The main requisite of such procedures requires the benefit of ease, avoiding second surgical site, and reduced post-operative complications. Coronally advanced flap is the treatment of choice to achieve complete root coverage in multiple adjacent recession type defects. This procedure takes in to account all patient related considerations and allows correction of all recession defects simultaneously with the soft tissues available adjacent to such defects. This case report describes a modified approach of flap advancement using orthodontic buttons as anchorage for suspending sutures to facilitate coronal placement of gingival margin above the level of cemento-enamel junction during the early healing period for better outcome and root coverage.

Keywords: Coronally advanced flap; Gingival recession; Orthodontic buttons; Root coverage.

Introduction

The root surface exposure due to apical displacement of the marginal gingiva (MG) below the cement-enamel junction, exposing the tooth to oral environment, is termed as Gingival recession. The treatment for the same aims at diminishing root hypersensitivity and improvement of gingival aesthetics.1,2 One of the most reliable and accepted techniques that results in the best long-term clinical outcome is the coronally advanced flap (CAF) procedure,3-5 provided there is adequate attached gingiva and multiple adjacent recession-type defects (MARTD). This procedure may be solely used and also been advocated in combination with connective tissue graft (CTG), barrier membrane, acellular dermal matrices and platelet concentrates in various proposed literatures. Nowadays, some periodontal plastic surgical techniques such as modified CAF technique,6 modified CAF in adjunct with an subepithelial connective tissue graft (CAF + SCTG), CAF in adjunct with CTG, or the tunnel SCTG, or CAF with enamel matrix derivative (CAF + EMD) [7] and CAF with or without releasing incisions, have been proposed for the surgical treatment of MARTD8, 9.

There exist various differences in the management of MARTD when compared with treatment of single tooth recessions. Literature suggests that the treatment choice for MARTD with involvement of two or more adjacent teeth is based on multiple factors, such as anatomic structures (recession defect size, width of keratinized tissue (WKT), amount of donor site connective tissue, vestibular depth and gingival phenotype), number of involved teeth, post-operative discomfort during healing, cost benefit ratio, donor site morbidity and need for multiple surgical procedures to manage and cover the multiple recession site.10
MARTD involves multiple adjacent involved teeth, making the area of surgical operation lengthy involving the entire sextant, hence, demanding a surgical procedure which is to be carried out at ease and does not require any second surgical site for donor tissue. The surgical procedure should allow simultaneous correction of multiple recession sites with adjacent available attached gingiva. Keeping this in mind, it is requisite to follow a modified approach of surgical technique which reduces intra-oral second surgical sites and number of surgeries, together with the need to benefit in satisfying patient’s esthetic demand and alleviating post-operative discomfort. Coronally advanced flaps (CAF) are best suited surgical root coverage procedures in successful management of MARTD.5

The main outcome assessment of root coverage procedures is in achieving complete root coverage (CRC). The CRC is always a predictable outcome and is dependant on flap thickness, tension of flap prior to placement of sutures and most importantly, the displaced placement of gingival margin post-surgically. A study concluded that the post-surgical placement of marginal gingiva affected the probability of CRC, stating if the location of gingival margin was kept at 2mm above the cement-enamel junction, the probability of achieving CRC was almost 100% in coronally advanced flap techniques.11 In a recent study, it was reported that a new technique, employing composite stops for sutures at the inter-dental contacts of the teeth, evidence CRC in MARTD, by not allowing the suspended sutures to collapse.7

As the placement the gingival margin coronal to cemento-enamel junction during early wound healing phase is an important and difficult criterion in achieving CRC in CAFs, orthodontic buttons were bonded to the teeth in this case report to improve the stabilization of the postoperative flap location during healing. However, in a clinical trial on use of CAF with orthodontic buttons for treating maxillary multiple recession defects and found the procedure to be better than CAF alone.12 In this case report, CAF with orthodontic button application was used in a clinical case with mandibular multiple recession defect.

**Case Description:** A patient aged 32 year, reported to Department of Periodontics, Faculty of Dental Sciences, Bhubaneswar, Odisha, complaining of receded gums and sensitivity on taking extremely hot and cold food in his lower front tooth region of the jaw from past 4 months. On clinical examination, multiple Miller class I gingival recessions were present in relation to 34-44 with just adequate keratinized gingiva (Figure 1). Patient presented with thick biotype of gingiva in the area of recession. Thorough oral prophylaxis procedure was carried out one week before the surgery. CAF with bilateral vertical releasing incision and orthodontic buttons was planned in relation to 33-43 for gingival augmentation coronal to the recession defect.
aspect with recession defect for both left and right side (Figure 2c). Vertical incisions were placed on both sides distal to 34 and 44 respectively. The split-full-split approach was employed in the coronal–apical direction, in order to elevate the flap. The full-thickness flap was elevated till 2–3mm of intact bone was exposed apical to the dehiscence. A split thickness flap was raised in the apical portion of the elevated flap and was periosteally scored, in order to facilitate coronal advancement. A partial-thickness dissection was carried out into the vestibular mucosa using a blunt instrument; this incision was made to sever the muscular attachments, in order to relieve flap tension. The flap mobilization allowed the margin of the elevated flap to be passively placed at a coronal position, preferably coronal to cemento-enamel junction and the surgically created papillae overlapped the corresponding anatomic inter-dental papillae, during coronal advancement (Figure 2d).

The advanced flap was secured using 4–0 resorbable vicryl sutures and the sutures were allowed to anchor the central portion of the surgical created papillae on the orthodontic buttons (Figure 3). Post-operatively, the flap margins were assured to be placed preferably at 2–3mm coronal to the CEJ. Careful periodontal dressing with aluminum foil was placed in order to prevent the site from any undue physical or mechanical injuries.

![Figure 3. Sutures suspended on to orthodontic buttons for anchorage](image)

Post-operative instructions with proper oral hygiene instructions were given and the patients were advised not to brush and floss in the surgical site during the first week of surgery. Amoxicillin 500mg TID and Ketorolac 20mg BD for 1 week were prescribed. 0.2% chlorhexidine mouthwash was prescribed 4 times daily for the first 15 days. The sutures along with the buttons were removed after 2 weeks. Healing was satisfactory without any infection or inflammation. The follow-up was carried out till 6 months. Width of keratinized gingiva and clinical attachment gain was observed in relation to 34-44 at the end of follow up of 6 months (Figure 4).

![Figure 4. Post-operative photograph showing root coverage](image)

**Discussion**

CAF with orthodontic buttons technique is proposed to ensure the proper anchorage of the displaced flap in the most coronal position during the initial healing period. The suspended sutures provided coronally positioning of the displaced flap to maximum along with flap stabilization in the post-operative displaced coronal position during the first 2 weeks of wound healing. The literature suggests the positive correlation between post-operative gingival margin placement and achieving CRC. Coronal positioning of the flap margin is directly proportional to the CRC. In our study, the coronal placement and stabilization of the displaced flap margin with the use of suspended sutures on orthodontic buttons, would have been the success criteria for achieving complete root coverage. This result is in accordance with one of the previous studies, which reported that the greater postoperative coronal displacement of the gingival margin may cause greater root coverage. Orthodontic buttons are used by the orthodontists routinely as an anchor component which remains inactive, to provide attachment of elastics. The similar buttons were used in our study to stabilize the flap margin by suspending the sutures onto them.

The partial thickness split approach to elevate the flap from base of surgically created papillae, ensures improved anchorage and maintenance of vascular supply in the inter-proximal region. The full thickness portion of the flap ensured increased gingival thickness, and subsequent formation of new attached gingival with adequate gingival thickness, due to its stability...
in adaptation over the previously denuded avascular root surface without any displacement. Therefore, the treated area achieved optimum root coverage results, with good color blending in respect to adjacent mucosa and gingival suggesting restoration of the original (presurgical) soft tissue marginal morphology.

Fixation of orthodontic buttons on the labial portion of the teeth is not at all technique sensitive, relatively easy, inexpensive with high patient acceptability. The elongation in the chair-side time to fix the buttons, in addition to the surgery, may have displeased the patient perception to the entire treatment. However, the benefit of button placement overcome such issue of lengthy chair time procedure.

**Conclusion**

The amalgamation of using the orthodontic buttons along with CAF was found to be an effective method in treating MARTDs. The ease of post-operative placement of the marginal gingiva coronal to the CEJ with this technique, looks promising, thereby making itself a reliable method for achieving complete root coverage in case of MARTDs.

Pindborg Tumor: A Report of Two Cases

Basanta Kumar Choudhury1, Shayari Niyogi2, Pinali Das2

1Assistant Professor, 2Post Graduate Trainee, Department of Oral Medicine and Radiology, Institute of Dental Sciences, Siksha ‘O’ Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract
Calcifying epithelial odontogenic tumor (CEOT) being an odontogenic tumor of epithelial origin developed in the jaws especially in the mandible than maxilla originating from odontogenic tissues such as hertwig epithelial root sheath, dental lamina and enamel organ. It is characterized as a rare, aggressive, slow growing tumor and asymptomatic in nature often associated with an impacted tooth. CEOT also known as Pindborg’s tumor represents only 1% of all the odontogenic tumors. Here we report 2 cases of Pindborg’s tumor located in the posterior aspect of mandible and both the cases were seen in female of young adult age group. Partial mandibulectomy was performed in both the cases and was on regular follow-up. Both the cases were without any recurrence of the disease; one at 3 months and another one at 12 months of follow-up.

Keywords: Calcifying epithelial; odontogenic tumor; mandible; partial mandibulectomy.

Introduction
Calcifying epithelial odontogenic tumor (CEOT), is a benign neoplasm of odontogenic origin, which is a rare tumor accounting for less than 1% of all odontogenic tumors. Although benign, it is occasionally locally invasive, but slow growing neoplasm. The tumor is associated with impacted teeth in approximately 52% of the cases and is twice more prevalent in the mandible than in the maxilla. Here we present two cases of CEOT occurring in the mandibular posterior teeth region in female patient reported in our department with complaint of a painless swelling.

Case Report: A 24 years old female patient reported to the Department of Oral Medicine and Radiology, Institute of Dental Sciences, Bhubaneswar with chief complaint of swelling in the left side of face for 7 months. The swelling on the left side gradually increased in size to attain its present size and was not associated with pain or discharges from the swelling.

On Clinical Examination: A diffuse swelling was present on the lower third region of the face, extending from mid symphysis region anteriorly to posteriorly till 3cm below the ala tragus line on left side and commissure of lip on left side superiorly to 3cm beyond the inferior border of mandible inferiorly and, measuring 5 6cm in size in greatest diameter of normal skin color with no secondary changes evident. On palpation, swelling was hard in consistency, non-tender, non-compressible, non-reducible, on-fluctuant, with skin over the swelling is loose and pinchable. Mouth opening was restricted with interincisal distance being 35mm. Intraorally, a diffuse swelling was present in respect to 34 35 36, obliterating the gingivobuccal sulcus with buccal cortical expansion in respect to 34 35 and lingual cortical expansion in respect to 36 with elevation present in the floor of mouth. There was missing tooth in respect to 36 with supra-erupted 26 present. On palpation swelling was hard in consistency, non-reducible, non-compressible, non-fluctuant and non-tender. Owing to the nature of swelling, on clinical examination and palpation a provisional clinical diagnosis of benign bony odontogenic neoplasm was made. Ameloblastoma, CEOT and ossifying fibroma were considered in clinical differential diagnosis (Figure 1-3).

Figure 1. (a) pre-operative clinical presentation of the patient with extraoral swelling in the left side lower jaw. (b) intraoral view of the left partially edentulous mandibular arch in 35 36 37 region, with missing 36.

Figure 2. Pre-operative radiographic evaluation of the patient. (a) intraoral periapical radiograph in 34 35 36 showing mixed radiopaque radiolucent lesions involving the periapical regions in 35. (b) Mandibular occlusal radiograph of the left side depicting a localized mixed radiolucency and radiopacity in 34 35 36 region, with buccal and lingual cortical expansion; (c) pre-operative radiographic evaluation of the patient. Panoramic radiographic reveals localised mixed radiolucency and radiopacity surrounded by corticated border in left side body of the mandible in relation to 34 35 36 37 showing Driven-snow appearance.

Figure 3. H & E stain shows sheets of polyhedral epitheloid cells in background of scanty collagenous CT stroma. Few epitheloid cells show pleomorphism and hyperchromatism. Areas of dystrophic calcification and leisegang rings are present.
Radiological Features: IOPAR in respect to 34 35 36 showed mixed radiopaque radiolucent lesions involving the periapical regions in respect to 34 35 and loss of lamina dura and altered bony trabeculae.

Case 2: A 24 years old female patient reported to the department of oral medicine and radiology with chief complaint of swelling in the left lower jaw for 4-5 months. The swelling gradually increased in size and was not associated with pain or any discharges.

Clinical examination: On clinical examination, extra orally, a diffused ovoid swelling was present on right side extending mediolaterally from the line joining the inner canthus of the eye till the outer canthus, and superior-inferiorly from ala-tragus line till 1cm below the lower border of mandible, measuring 4×4 cm in size, on palpation, the swelling was hard in consistency and non-tender on palpation.

Intraorally, diffused swelling present extending from 43 till 46 regions, ovoid in shape and involving the alveolobuccal sulcus measuring 2×1 cm in size, with no secondary changes present. On palpation, the swelling was hard in consistency, non-compressible, non-reducible, and non-tender. Expansion of the buccal cortical plates was felt, the lingual plates being intact. There was retained deciduous teeth in respect to 85 and 45 was missing. Owing to these features, a provisional diagnosis of cystic lesion was given. The differential diagnosis was dentigerous cyst, odontogenic keratocyst.

Radiographic features: Intraoral Periapical Radiograph reveals well-defined mixed radiopaque-radiolucent lesion involving the periapical region in relation to 43 44 85 46, measuring .5×.5 cm in size, having well-defined radiopaque corticated borders, and streaks of radiopacity present within the radiolucency with root resorption in 85 46.

“OPG revealed a well-circumscribed mixed radiopaque-radiolucent lesion involving the right mandibular ramus in relation to 44 85 46, measuring 3×4 cm in size, having well-defined radiopaque corticated borders, with presence of radiopaque mass in the centre of the lesion, with radiopaque streaks from the periphery, suggestive of Driven-snow appearance. There is apical displacement of teeth in relation to 45 with involvement of inferior border of mandible and root resorption in 85 46. Mandibular occlusal radiograph reveals expansion of the buccal cortical plates in relation to 43 44 85 46, with mild lingual plate expansion in relation to 46 seen.”

“CT image revealed oval expansile lytic lesion involving the right mandibular ramus having internal course clumped calcifications and isoattenuating soft tissue compartment measuring 3×2.7cm. Outer scalloped well-corticated rim maintained except a small defect anteriorly (4mm), suggestive of a lytic expansile mandibular lesion with smooth corticated border. Both the patients had undergone partial hemimandibulectomy after incisional biopsy confirmed the tumor to be CEOT, and they were under regular follow-up with no recurrence reported (Figure 4-6).”

Figure 4 (a) pre-operative clinical presentation of the patient with extraoral swelling in the right-side lower jaw. (b) intraoral view of the left partially edentulous mandibular arch int 45 46 47 region.
Discussion

In India with the rampant abuse of tobacco and areca nut, jaw tumors are most commonly seen. It is not surprising to consider a patient presenting with a jaw lesion as malignancy as oral cancers accounts for 30% of cancer burden in India.\(^5\)-\(^7\) CEOT or Pindborg tumour is considered as a rare and benign tumour having odontogenic epithelial origin. It accounts for less than 1% of odontogenic tumours and was first described by Pindborg in 1955.\(^1\)

“As suggested by various authors that the epithelial cells of the Pindborg tumor are found to be reminiscent of the sequestered cells from the stratum intermedium layer of the enamel organ.\(^3\) This idea has been achieved as per the morphological similarity of the tumor cells to the normal cells of stratum intermedium and also there is a high activity of alkaline phosphatase and adenosine triphosphate observed.\(^6\) Due to immunologic response to this stratum intermedium, there is amyloid deposition within the cells in CEOT.” Others insist that it arises
from remnants of the primitive dental lamina found in the initial stage of odontogenesis, and these epithelial rests are the more likely true progenitor cell.6

“However, the exact etiology is unknown. It is classified as intraosseous and extraosseous, 94% of the lesions are central and intraosseous and 6% are extraosseous. Intraosseous CEOT has twice occurrence in the mandible as compared to maxilla and is mainly located in the premolar/molar region and half of the cases have shown association with an impacted tooth. In other studies, fifty-two percent cases have been associated with unerupted or embedded tooth, which is reported in both of our cases. Clinically, CEOT may lead to tooth tipping, rotation, migration, and/or mobility secondary to root resorption. This lesion is often symptomless due to painless swelling and discovered on routine radiography. Alternatively, it may present symptomatically as a slow-growing, painless, expansile, bony swelling with cortical bone resorption and finally perforation.” Our present case has shown cortical bone resorption without perforation of bone.6, 8-10. The radiographic appearance of CEOT may vary depending on the stage of development of the lesion. The stages may be a well-defined radiolucency, mixed radiolucent radiopaque or completely radiopaque mass. In the initial stage, it may appear as dentigerous cyst because of its relationship with impacted tooth and is completely radiolucent.” In the second phase, small intratumoral calcification starts appearing, which is characteristic of CEOT but not diagnostic.10

The lesion often presents as mixed radiolucent radiopaque having many small irregular trabeculae passing through the radiolucent area. There may be presence of flecks of calcification within the radiolucency giving CEOT its characteristic “driven-snow” appearance.4 The margins are usually well defined or sclerotic as is present in our present cases.1 Similar appearing lesions are odontomas, which have an amorphus appearance with multiple discrete foci of calcification, ossifying fibromas, which have more calcification, while fibrous dysplasias are mainly homogenous and expanded lesions.5.

When large polyhedral cells predominate, they give squamoid appearance with amyloid-like stroma, and calcification like keratin arousing suspicion of squamous carcinoma (Case 2). When basal cells predominate, the differential diagnosis includes minor salivary gland tumor. When CEOT is predominantly composed of stellate cells and basal cells, the differentials include ameloblastoma and minor salivary gland tumor.5 “Small, intrabony mandibular lesions with well-defined borders are treated by simple enucleation or curettage followed by judicious removal of a thin layer of bone adjacent to the tumor.2,6 Large tumors require aggressive approach by segmental resection, hemimandibulectomy and hemimaxillectomy, which causes bone discontinuity requiring reconstruction procedures such as grafting or distraction osteogenesis.”10

“The lesions treated with enucleation and curettage procedures show a high recurrence rate ranging from 15% to 30% after just 2-4 years.4 Therefore, CEOT is best treated with a resection using 1.0cm-1.5cm margins in bone. In the current case resection was performed with 1.5cm tumour free margins. Malignant transformation of CEOT is extremely rare and very few cases have been reported.1 The highly vascular nature of the lesion as evidenced by USG prompted the use of sclerotherapy in the current case prior to resection. Sclerotherapy is a conventional method well accepted in the treatment of vascular lesions.” In our 2 cases, both the females have tumor in mandibular posterior teeth region, which was locally aggressive and asymptomatic, and associated with impacted teeth. The radiographic findings in both the cases showed classical “driven-snow” appearance on panoramic radiograph. There was also presence of “leisegang ring” reported in histopathological section of one case and presence of amyloid materials in another, confirming both the cases to be CEOT.

Conclusion

Presently, two cases of CEOT have been discussed with emphasis on radiological appearances in both the cases. However, studies need to be carried out regarding the histopathological features and variants of CEOT. This is to emphasize the need to correlate radiographic, clinical and histopathological findings to arrive at the correct diagnosis and treatment planning.

Hypohidrotic Ectodermal Dysplasia in a Young Male Patient

Satya Ranjan Misra

Professor & Head, Department of Oral Medicine & Radiology, Institute of Dental Sciences, Siksha ‘O’ Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Ectodermal dysplasia represents a heterogeneous group of disorders in which ectodermal derivatives are affected. It is an X-linked recessive condition hence females are commonly affected by this condition. There is aberrant morphogenesis of skin and embryonic ectodermal structures of the oral cavity. Generally, it is manifested by a triad of hypodontia, hypohydrosis and hypotrichosis. These patients have lustrous, thin and dry skin, fine and scanty kinky hair. Intra-orally partial anodontia, with an underdeveloped alveolar process is seen. We present a rare case of ectodermal dysplasia in a 17-year-old male patient with only a single tooth for documentation.

Keywords: Ectodermal dysplasia; X-linked recessive condition; aberrant morphogenesis; hypodontia; Intra-orally partial anodontia.

Introduction

Ectodermal dysplasia is also known as Christ-Siemens-Touraine Syndrome. It presents with a multitude of clinical manifestations and affects 1 in every 100,000 live births. It may occur as a hereditary disease and more than hundred types of this disorder has been reported with various types of inheritance. However, two principal forms of this group of disorders have been identified, on the basis of the affliction of the sweat glands. They are X-linked hyperhidrotic/anhidrotic disease with reduced or absence of sweat glands and autosomal dominant hidrotic type where sweat glands are unaffected[1].

There are few syndromes associated with this condition, like Strandberg-Ronchese’s Syndrome, Rapp-Hodgkin Syndrome and Rosseli-Gulienetti Syndrome[2]. The anhidrotic or hypohidrotic type is common in females but they do not exhibit features of this disorder and on the contrary the males though rarely affected show all the features like scanty hair, missing teeth and reduced sweating as seen in the present case.

Case Report: A 17-year-old male patient reported with missing teeth since childhood. History revealed that he had only 2 deciduous teeth and afterwards only a single permanent tooth erupted in the anterior maxilla. He also had reduced sweating and could not tolerate heat, had reduced salivation and scanty body hair. The medical history was non-contributory but he reported that his parents had a consanguineous marriage.

On physical examination, sparse hair on the head, reduced density of eyebrows and eyelashes were seen. [Figure 1] There was midface hypoplasia with protuberant lips. The lips appeared dry and cracked. [Figure 2] Intraoral examination revealed the presence of a single conical tooth in the anterior maxilla with hypoplastic maxillary and mandibular alveolar ridges. [Figure 3] There was hyposalivation and due to dryness of mouth the mouth mirror sticks to the tongue and buccal mucosa.

Figure 2: Dry, scaly protuberant lips.

Figure 3: Intra-oral picture showing a single conical tooth in the anterior maxilla with hypoplastic maxillary and mandibular alveolar ridges.

In view of the missing teeth, hyposalivation, decreased sweating, heat intolerance and sparse body and scalp hair from childhood, hence a provisional diagnosis of Ectodermal Dysplasia was made. A dental panoramic radiograph was taken, which hypoplastic maxillary and mandibular alveolar ridges, with the presence of a single tooth in the anterior maxilla, possibly 21 which had irregular conical shape. [Figure 4]. The patient then underwent extraction of the single tooth followed by the fabrication of a complete denture prosthesis.

Figure 4: Dental panoramic radiograph showing hypoplastic maxillary and mandibular alveolar ridges, with the presence of a single conical tooth in the anterior maxilla.

Discussion

The first documented case of ectodermal dysplasia was reported in 1848 by Thurnam but the term was coined much later by Weech in 1929. Ectodermal dysplasia belongs to a group of hereditary disorders manifesting with developmental anomalies having abnormal structures emerging from the embryonic ectoderm like the sweat glands, nails, hair and teeth.[3] Broadly it can be divided into two types: hydrotic and anhidrotic or hypohidrotic types.

Clinically, the disease is characterized by scanty hair (hypotrichosis), multiple missing teeth (oligodontia), teeth present may have abnormal conical morphology
as seen in the present case and decreased sweating (hypohidrosis).[4] The tooth present may be the anterior ones, with the incisors or canines appearing pointed incisally with a bulbous conical base at the cervical region, bearing no resemblance to the normal complement of teeth. [5] As the patients do not sweat normally, they have a tendency to have a raised temperature in warm weather and even hyperthermia can develop on physical exertion. Babies may be frequently febrile. The hair on the scalp may be typically sparse, eyelashes and eyebrows may be missing and scanty body hair with pigmentation. Nail abnormalities, scaly wrinkled skin with eczema and loss of vertical dimension due to missing teeth can lead to everted protuberant lips, pseudoraphides and frontal bossing, saddle like nose as well as mucous secretions from the nose and respiratory tract infections have been reported. [6, 7]

The dental management of the condition involves replacement of the missing teeth using different types of prostheses ranging from conventional complete denture to implant supported prosthesis.[8] However, patients having the anhidrotic type of disease, tend to have heat intolerance and need to be careful in warm weather and wear adequate cool apparel.

Management of Mandibular Resorbed Ridges by Combining Two Impression Techniques: A Literature Review and Case Report

Sreeprada Dash¹, Gunjan Srivastava², Gopal Krishna Choudhury³, Debashish Sahoo¹, Monika Samal¹

¹Post-graduate Trainee, ²Professor, ³Professor and Head, Department of Prosthodontics, Institute of Dental Sciences, Siksha ‘O’ Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Most common problem faced by a prosthodontist in cases of severely resorbed ridge is the loose dentures which occurs due to the lack of stability and retention of the denture prosthesis. The atrophied ridges are more commonly found in the mandibular arches. Major problem is faced while recording the denture bearing mucosa and using it for obtaining the stability and support. Though various other factors play role in obtaining a well-balanced and stable complete denture prosthesis in such patients but the impression employed is of utmost importance. And to record the atrophied residual alveolar ridges, an adequate impression technique should be followed. This article describes using of two such techniques, combining which we obtain both functional and anatomic impression of the ridge over which a stable denture prosthesis can be fabricated.

Keywords: Resorbed ridges, functional impression, impression technique, retention, stability.

Introduction

Residual ridge resorption is a complex process which starts just after tooth extraction in the residual alveolar ridges. The resorption rate is accelerated during the first initial years after tooth removal, thereafter the rate slows down gradually. Extreme resorption of ridges is generally seen in the mandibular arch than the maxillary arch¹, ² There are different reasons contributing to the ridge resorption process¹, ³–⁸. They are:

1. Anatomic factors
   • Amount of bone loss in a broad round ridge is less than that of a small flat ridge vertically
   • in dense bone the resorption rate is slow as compared to the cancellous bone.

2. Metabolic factors – bone metabolism is reliant on cell metabolism (especially, osteoblasts and osteoclasts formation and resorption)
   • imbalance in PTH
   • osteoporosis occurring in post-menopausal women
   • Production of local prostaglandins continuously
   • Hypervitaminosis A and D
   • Hypovitaminosis C

3. Mechanical factors: this comprises of the
   a. Functional factors
      • amount and direction of force applied on to the bone
      • Bruxism
   b. Prosthetic factors
      • Type and fit of final denture prosthesis
      • Time interval while the prosthodontic treatment occurs for the patient
      • Maximum amount of time the is patient wearing prosthesis everyday
      • Occlusal imbalance or premature contacts
      • Disuse atrophy

The prime importance in patients with atrophied mandibular ridges is to gain maximum stability
and retention in the prosthesis delivered. (9) So, the impression technique used plays a substantial role in the treatment of these patients where there is scarce tissues and ridge area to fulfill the criteria of retention, stability and support.(10)

An accurate impression governs the efficiency of the definitive prosthesis which not only controls the retention and stability of the denture but also the comfort of the patient. The scenario becomes more challenging in such cases due to the availability of minimal bone height, unfavourable morphology of residual ridge, and/or muscle attachments makes impression making and the retention of the prosthesis difficult. (11) Over the years, tremendous progress has been made to develop impression procedures has been developed in order to manage the cases with residual ridge resorption such as:

**Flange Technique by Lott and Levin** (12): To increase retention, function, comfort and appearance of final denture prosthesis, Frank Lott and Bernard Levin proposed an anatomic and physiologic impression technique. According to this technique, attention should be given to impression making in order to obtain competent bases for dentures as well as on complete denture occlusion. The buccal, lingual and palatal surfaces of dentures, however, have been completely ignored. Generally, these surfaces are carved into an ‘ideal’ form without considering the presence of cheeks, tongue and lip’s position and function.

**Roberto Von Krammede et al** (12): Modelling Compound is used for impression making to record the extended surface without interfering the normal function of mastication and deglutition. The tongue movement are also recorded while helps to stabilize the denture.

**Modified Fournet Tuller Technique** (13): Here the maximal peripheral seal, retention and stability if the denture is achieved through the minimal pressure impression technique, where minimum amount of pressure is applied on to crest of the ridge. In this technique, low fusing compound was used to make the secondary impression by extending its overall in the peripheral areas to record it in functional form.

**Winkler Technique** (14): He described Closed Mouth Functional Impression Technique where the tissue conditioners are used to record the intaglio surface of the denture in their functional form and final wash impression is made with a light body elastomeric impression material. Miller modified the technique by using mouth temperature waxes instead of tissue conditioners to make the functional impression.

**McCord & Tyson technique** (19): He described the admixed technique of impression making for flat mandibular ridges using impression compound and low fusing compound in the ratio 3:7 by weight which is manipulated in to a homogeneous mass by placing in to a hot water bath (60°C). Then this material is loaded on to the custom tray and impression is made.

**Neutral Zone Concept** (22): This concept describes that in each patient there is presence of a specific region where the function of the muscles will not displace the denture and the forces produced by the tongue are neutralised by the forces from the lips and cheek. When the residual ridges resorb over the time, then in order to prevent the shift of the denture prosthesis, the denture teeth should be placed in correct position and proper contour should be maintained where the dislodging forces are minimal.

**Shanahan Technique** (15): He said that training the patient to achieve an ideal tongue position helps to attain an effective lingual border seal. He used alginate for making preliminary impression. Resin tray was fabricated and static final impression was done. Patient was asked to wear the trial denture bases and return in 2 days.

**Klein** (16): He proposed the use of mouldable tray material such as putty consistency silicone elastomeric impression material, reinforced by a metallic core internally. The material was spread all over the residual ridge and border moulding was achieved through various functional movements and speech exercise. Then a light body consistency impression material is placed on the impression surface of the tray obtained, that gave us a functional preliminary impression. According to him, the stock tray should not be used because it causes distortion of the surrounding tissues and also impression recorded is always over extended.

This article describes the management of resorbed residual mandibular ridge by combining two different impression techniques i.e. the admixed technique and the functional impression technique. Then, obtaining the patient’s perception on the retention, stability of the denture fabricated through combining both the techniques.
Clinical Report

A female patient aged 65 years (Figure 1) presented to the Department of Prosthodontics, Institute of Dental Sciences, Bhubaneshwar with a chief complaint of loose denture prosthesis with respect to the lower arch and difficulty in chewing. The patient presented in good health with no significant medical history. For 5 years the patient was wearing denture but she was not satisfied with the prosthesis due to poor stability not only during mastication but also during speech. When intraoral examination was done, a highly resorbed mandibular ridge was detected (Figure 2a and 2b). The patient presented with no hypermobile tissue on palpation. After evaluating patient’s chief complaint and dental history, orthopantomogram report and existing clinical conditions of the ridge, the various treatment options were discussed with the patient that included pre-prosthetic surgeries such as vestibulopathy / ridge augmentation procedure followed by conventional complete denture prosthesis, implant supported overdenture / fixed hybrid prosthesis, conventional complete denture prosthesis. However, the patient denied to undergo any surgical procedures and wanted rehabilitation of her arch through the conventional complete denture prosthesis. So, finally it was decided to fabricate a conventional complete denture using two different techniques of impression making i.e. the admixed technique and the functional impression technique.

Impression compound was used to make preliminary impression of the edentulous maxillary and mandibular arch. On the preliminary cast obtained, a full spacer was adapted and additional spacer was given on the incisive papilla and the mid palatine raphe area over which the maxillary custom tray was fabricated. Mandibular custom tray was fabricated to provide a space of 4 mm using two wax spacers wax with full spacer design for the admix impression material.

For the maxillary and mandibular arch, secondary impression was made using an admix impression technique by mixing impression compound and low fusing compound in to a homogenous mass in the ratio of 3:7 by weight in a water bath of 60 degree Celsius temperature and after removing the wax spacer, custom tray was loaded and impression was made (Figure 4).

On the cast obtained, denture base was fabricated using self-cure acrylic resin and over its occlusal rims were fabricated for both upper and lower arch. The maxillomandibular relations were made. Once the jaw relations were done, then the functional impression was made for the upper and lower arch using the temporary soft-liner material/ tissue conditioners. They exhibit a delayed setting over a longer period of time thereby recording all the possible movements of the mandibular
muscle attachments. On to the intaglio surface of mandibular and maxillary denture base, the tissue conditioning material was added, after the patient was instructed to close the mouth in the previously established vertical dimension (Figure 5c) and do various functional movements such as puffing, blowing the air, whistling, and smiling continuously. The functional impression material stays within the oral cavity for a period of 45-60 min (Figure 5a, b). All oral activities of the patient are encouraged. Once the material has achieved a final set, the tray is removed and the impression is poured. The cast obtained is used as a master cast for fabrication of prosthesis which is then articulated and the teeth arrangement is done. Final try-in procedures were completed (Figure 6a, b, c). The final denture is fabricated using the conventional method of flasking, dewaxing and packing using heat polymerising acrylic resin and delivered to the patient (Figure 7 & 8). Patient was recalled after 24 hours, 15 days, 30 days. The patient was relatively content with the new complete denture prosthesis and her major complaint of loose denture with respect to lower arch was no more.

Discussion

In an atrophied mandible, the major concern is the inability of the ridge and the overlying tissues to bear the masticatory loads. This occurs due to the muscle attachments which gradually becomes closer to the ridge due the resorption process. these muscles apply a dislodging force on to the denture prosthesis upon mastication which can reduced by recording the tissues in functional as well as in rest position through a good impression. For this various impression techniques for resorbed mandibular ridge has been proposed in the literature by different authors, and every technique has its own advantage and disadvantage. In these resorbed ridges, functional impression technique is most commonly used according to the results in a study conducted by Bhupender Yadav et al (2014) concluded that mandibular denture fabricated using this technique showed the highest mean value of retention (17). In the year 2003, Drago (18) conducted a study according to which, the denture bases fabricated from the closed mouth impression technique were more retentive than the open mouth impression techniques for the mandibular arch.

The closed mouth Functional impression technique proposed by Winkler (14) is advantageous as it saves time, it eliminates the interference of the tray handling process thereby removing the chances of over and under extension of the impression. As here the various functional movements are made by the patient and so the pressure applied during the impression process is same as that applied during occlusion. However, this technique also poses certain disadvantages such as the dentist has no control over the movements performed by the patient and also tongue movement is restricted to
move only anteriorly which can alter the anatomy of the lingual border of the impression. McCord and Tyson’s admixed impression technique (19) records the functional position of the muscles and also requires less chair side time.

So, on combining these two-impression techniques in order to obtain a complete denture prosthesis that uniformly covers the residual ridge and thereby increasing the surface area of the denture that comes in contact with the residual ridge preventing displacement of denture base in both rest position as well as on application of masticatory load. Thus, the stability and retention of the mandibular complete denture prosthesis is improved and also this patient satisfaction is high.

According to different survey studies impression compound and zinc oxide eugenol impression paste is the most commonly used impression material in fabrication of complete denture prosthesis due to their capability of reproducing finer details in impression, quick setting property, easier handling and having no noteworthy dimensional changes upon setting. (20,21) Although impression compound serves as an ideal impression material but due to its short manipulation time, quick setting property and its inability to stay in a plastic stage till the functional movements of the vestibular and alveololingual sulcular tissues are completed produces certain limitation for its use in impression making for resorbed mandibular ridges. (22, 23)

**Conclusion**

Rehabilitation of a patient with atrophied residual ridge is a challenging task. Certain modification in treatment plan is required in order to achieve the desired functional and aesthetic goals. The ideal requirement in a maxillary and mandibular impression is that it should cover and transfer all the intricate details of the denture bearing mucosa and soft tissues available to the impression in both functional as well as rest position. It is the role of prosthodontist to select a suitable impression technique for the particular ridge form and also fabricate a successful complete denture prosthesis. This article provides an alternative approach in managing a highly resorbed mandibular ridge. The objective was to maximize the supportive aspect of the available denture bearing area in their functional and anatomic form through the combination of the functional impression technique and the admixed technique.

17. Bhupinder Yadav et al. Comparison of Different Final Impression Techniques for

Evolution of the Begg’s Appliance

Snigdha Pattanaik

Associate Professor, Department of Orthodontics, Institute of Dental Sciences, Siksha ‘O’ Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Dr. Begg formed hypotheses which were backed to some extent by his own researches. This article describes about the steps that were taken by Dr. Begg to finally come up with Begg’s appliance and also the concepts behind them. Further, the materials required for making this appliance is discussed. The advantages are many and are listed in this article along with limitations of this appliance. When the concept is used correctly with skill and implemented, this appliance is capable of producing universal tooth movement with light optimum forces causing minimum discomfort to patients, loosening of teeth and injury to tooth investing tissues which requires understanding of principles by the clinician.

Keywords: Orthodontic appliance, Tooth movement, Extraction, Malocclusion.

Introduction

Dr. Begg After graduating from the Melbourne University in 1923, he went to study with Dr. Angle in California. In 1924 Dr. Angle was developing the edgewise mechanism when Dr. Begg arrived in California. Dr. Angle took ribbon archwire which was normally inserted vertically from the incisal and turned it on its edge- “edgewise” to insert it horizontally. In November 1925 Dr. Begg returned back to Australia and started practicing orthodontics in Adelaide in 1926 with edgewise mechanism and non-extraction principle. Dr. Begg sincerely followed Dr. Angle’s teaching of retaining the full complement of teeth for 2 years. However in many of his patients, he was not satisfied with post treatment facial profile and faced with serious relapses of the treatment results. In February 1928 he started to routinely remove teeth and reduce the mesiodistal width by proximal stripping. He knew from experience that the attrition plays an important role in the development of man’s dentition. He thought that reduction was often necessary to permit the proper repositioning of the teeth to enhance proper occlusion.

Function, Stability and Esthetics: Dr. Begg realized that edgewise mechanism was not designed for rapid closure of the extraction spaces and for quick reduction of the deep overbite. To facilitate such changes, he started using .020 inch round platinized gold rather than rectangular archwire in 1929. In 1931/32 he started using .018inch round stainless steel wire bending the vertical loops, intermaxillary circles right into the archwire. However he soon realized that if round archwires were engaged in edgewise brackets, indiscriminate and often undesired root moving forces could be created. This prolonged the anterior bite opening and taxed loss of anchorage. In 1933, about 2 years after switching over to round wire, he began treating some cases with ribbon arch bracket. He realized that these are relatively narrow brackets with vertically facing slots that allowed the teeth to move under very light forces. Dr. Begg described a treatment approach based on the following hypotheses which were backed to some extent by his own researches.

They were: Theory of attritional occlusion, Theory of differential forces, The employment of a modified form of ribbon arch bracket and light gauge round archwire.

The Theory of Attritional Occlusion: Dr. Begg founded the concept of correct occlusion based on his
own studies on the skulls of Australian aboriginals. He found that the dentitions displayed a considerable amount of attrition, both occlusally and interproximally. The dento-alveolar height was maintained by continuous eruption and proximal contact by mesial tooth migration, facilitated by cuspal wear. The incisor relationship became edge to edge thereby reducing the chance of lower incisor imbrication through overbite obstruction. The total reduction in arch length resulting from attrition amounted around one bicuspid width either side of both dental arches by the time an aboriginal was of 20 years old. These findings accord with the studies of Miss Corisande Smyth with her study of Anglo-Saxon skulls. According to Sir Arthur Keith, in bronze-age Britain, skulls showing edge-to-edge incisor relationship was common. But in the present age, due to the refined and pre-cooked food, less dental attrition was observed. The absence of attrition along with the presence of mesial tooth migration does not relieve the dental overcrowding, particularly in the lower incisor region where the modern overbite prevents their escape into edge-to-edge relationship with the upper anteriors. Dr. Begg used the findings from his study of Australian aboriginal occlusions as a justification to extraction. He believes that if in this present era tooth material is not lost through attrition, it would be reasonable to cause an artificial reduction through extraction. However, care should be taken to restrict the employment of extraction within logical limits. Thus the extraction approach in orthodontic treatment came into existence. Surely, there will be exceptions to the extraction approach just as there were to the non-extraction approach.

Theory of Differential Forces: The theory of differential forces in its original form was described by Dr. Begg in an article. His observation was based to a large extent on the work of Storey and Smith. The range of light pressures which would cause the teeth to move at an optimum rate with minimal disturbance of the supporting tissues. Pressures below this range would produce a slow rate of response while those above incurred a reaction within the bone support, referred as “undermining resorption”. Applying these principles to the Begg technique, the force of the intermaxillary elastics used in stage I of treatment, was kept light so that the upper labial segment was retracted while the lower anchor molars has negligible mesial movement. Later, if it was required that the residual extraction spaces should be closed largely by the mesial movement of the posterior teeth, the elastic forces are increased so that the anterior segment with their relatively small root area received an excess of force sufficient to delay their movement, while the posteriors moved forward. A force of less than 150 grams causes no distal bodily movement of canine. A force of 150 - 200 grams is optimum to move canine distally. A force of 300-500 grams causes the molars to move easily. This high force is resisted by the tissues investing the canine root, thus affording anchorage for mesial movement of molars.

Concept Of Undermining Resorption: According to the concept of undermining resorption, excessive orthodontic forces, when exerted on teeth cause the periodontal membrane and tooth-investing bone to be compressed. This causes the occlusion of blood vessels and the blood supply is cut off in these areas. This inadequate blood supply causes necrosis of the compressed parts of the periodontal membrane and bone. This leads to no tooth movement until phagocytic action removes the necrosed tissues and until new living tissues form this excessive force also causes pain and loosens teeth. The effect of this process is that teeth do not move continually but intermittently and much slower than when lighter orthodontic force is used. On the other hand, if lighter and appropriate orthodontic force is applied, the periodontal blood vessels are not occluded so that the bone on the side of pressure is continually and rapidly resorbed and new bone is simultaneously formed on the side of negative pressure without any discomfort and loosening of teeth. Heavy force causes intermittent movement whereas light force causes continual flow of uninterrupted tooth movement.

The Meaning of Differential Orthodontic Force: In physics and mechanics, differential is defined as the difference of two or more motions or pressures. The orthodontic force values used in this technique cause:

1. Minimum discomfort
3. Minimum damage to tooth investing tissues.
4. Rapid tooth movement
5. Easily controllable forces.

The Meaning of Optimum Orthodontic Force

“The optimum orthodontic force means that force which moves the teeth most rapidly with least discomfort to the patient and with least damage to the teeth and other investing tissues.”
The forces that are most favorable for tooth movement on the standpoint of rapidity and tissue tolerance are according to Storey and Smith much lower than that exerted by edgewise archwire. According to Halderson, Johns and Moyers, the force exerted by edgewise archwire is of very high value of over 900 grams which causes a pathogenic tissue response. Hence, they advocated the use of light round wires as it takes as much advantage of tipping movements as is possible. It utilizes forces much lighter than are possible with a standard edgewise wire.6

Materials, Appliances Necessary for the Begg Technique: The spring quality of the first made steel was a great improvement compared to the rectangular gold platinum wire. However, it was either too soft or too brittle. In 1940’s Dr. Begg met Arthur. J. Wilcock who was directing metallurgical research in the University of Melbourne. After many years of research, Mr. Wilcock finally produced a cold drawn heat-treated wire that combined the balance between resilience and hardness with the unique property of zero stress relaxation that Dr. Begg was seeking. This unusual wire permitted Dr. Begg to open anterior deep bite, while controlling arch form and providing stability to the molar. However, Dr. Begg had the same problem controlling the mesiodistal inclination of teeth with ribbon arch brackets that was experienced 30 years back. Dr. Begg attempted to modify the ribbon-arch bracket by soldering horizontal band spurs to the labial and buccal surfaces of the bands. When the tooth required mesiodistal tipping, the archwire was permitted to contact the horizontal band spur. The arch wire was then deflected towards the bracket with a lockpin or steel ligature. The resultant flexing of the archwire provided a degree of mesiodistal axial control or movement7,8.

Advantages of Begg Technique

1. Light continuous force to move teeth over long distance without excessive strain on the anchorage
2. Greater interbracket distance — lighter force generated
3. Both extraction and non-extraction treatment plan applied effectively
4. Highly resilient wires — gentle force over a long period of time
5. Root torqueing and root uprighting is separated from the main arch wire by the use of auxiliaries
6. Less taxing on anchorage
7. Through the application of differential force it is easy to close the space at any location in the arch
8. Can be used in lingual orthodontics
9. Cost effective

Disadvantages of Conventional Begg

1. Unable to give precise control
2. Posterior torque difficult
3. Rotational control was poor with use of under size wires in first & second stages of treatment
4. During bite opening, true intrusion of upper incisors was nil or minimal
5. Overuse of class-ii elastics:
   • Lack of incisor intrusion
   • Undesirable proclination of lower incisors
   • Unfavorable tipping of mandibular & occlusal planes

Conclusion

The development of Dr. Begg’s different way of orthodontic therapy was not the result of a single discovery but rather, the product of a long tedious, well-organized trial and error process. When correctly applied, his light archwire technique can produce universal tooth movement with light optimum forces, least discomfort to patients, minimum loosening of teeth and least injury to tooth investing tissues. Dr. Begg’s theory does not depend upon cephalometrics to establish angulations nor does it require complicated engineering formulae for moving teeth. Because the Begg technique requires shorter time, it does not mean that it is a “snap” method requiring less orthodontic skill or ingenuity. In spite of the fact that Dr. Begg was born to an industrial executive, and that he could have very well made a fortune in business, he chose to bring smiles in people’s lives around the world. The successful use of a given appliance will be based on an understanding of the underlying principles. These can be taught; but the exact practical application requires a measure of the art of the craftsman, or craft of the artist which are qualities of the individual and cannot be taught.

Glycolic Acid Peel for Gingival De-Pigmentation: A Case Report

Rashmita Nayak1, Sheetal Acharya2, Anurag Satpathy1, Rohina Shamim3, Pratiti Datta3, Bikash Kar4

1Professor, 2Senior Lecturer, 3Post Graduate Trainee, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, 4Professor, Department of Dermatology, Institute of Medical Sciences & SUM Hospital, Siksha ‘O’ Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India.

Abstract

Gingival hyper-pigmentation or black gums is an unesthetic condition requiring correction for a better smile. Hyper-pigmentation of gingiva occurs as a result of excessive deposition of melanin pigment. Several techniques are employed in gingival de-pigmentation procedure with variable results. In this case report, a new non-surgical technique of gingival de-pigmentation by glycolic acid is presented.

Keywords: Gingival pigmentation; black gums; de-pigmentation; acid peel; chemo-exfoliation.

Introduction

Gingival exposure during smiling is one of the important component of an esthetic smile window1, 2. However, visible dark pigmentation of gingiva during smiling and speaking often presents an esthetic challenge3. Gingival pigmentation occurs from the deposition of melanin, a brown pigment deposited by melanocyte below the basal and the suprabasal cell layers of epithelium4. Active melanocytes convert tyrosine to melanin and are stored in the melanosomes or premelanosome from where it is transferred to the keratinocytes 5. Hyperpigmentation of gingiva occur as a result of excessive deposition of melanin. The gingival pigmentation may be physiologic or pathological6. Physiologic pigmentation depends on the race and is genetically determined. Pathologic pigmentation occurs in some systemic diseases such as Addison’s syndrome, Peutz-jegher’s syndrome, von Recklinghausen’s disease and malignant melanomas. Some other factors like smoking, antimalarial therapy and tricyclic antidepressants are also responsible for hyperpigmentation of gingiva7, 7.

Melanin pigmentation of gingiva is not a medical problem and is only of esthetic concern in patients complaining of ‘black gums’8, 9 which can be treated by gingival depigmentation. Gingival depigmentation is a periodontal plastic procedure in which hyperpigmented gingiva is removed or reduced. Historically, several techniques have been used for gingival depigmentation, including surgical scalpel technique10, bur abrasion 11, cryosurgery8, electrosurgery 12, laser therapy 13, free gingival graft14, acellular dermal matrix allograft15, autologus platelet concentrates16, etc. However, each of these techniques have their share of advantages and drawbacks.

Scalpel technique was one of the earliest used method of depigmentation. This method involves simple de-epithelisation by scalpel and is economical however, haemorrhage and exposed wound surface on the gingiva during or after surgery makes it unappealing to the patient in addition to discomfort 17. Also, this is highly technique sensitive procedure and needs a higher level of surgical skill. Gingival abrasion on the other hand is easy to perform and requires no sophisticated instrument. However, this technique is not widely practiced since unwanted abrasion or pitting of the tissue may occur due to lack of control on the speed and pressure 11. Electrosurgery and cryosurgery techniques
are well acceptance due to minimal bleeding and lesser postoperative pain and discomfort although they require special equipments limiting its use though patient\textsuperscript{18, 19}. Laser too is a popular technique for because of good haemostasis, less discomfort and rapid healing. However, re-epithelialization takes longer time with laser. The expensive and sophisticated equipment needed for this procedure limits its use in general dental practices.

In this case report, a new non-surgical technique of gingival depigmentation by Gycolic acid is presented. Glycolic acid (GA) is an alpha-hydroxy acid and is a popular exfoliating agent which is used by the plastic surgeons and dermatologists in the treatment of variety of skin conditions like acne, superficial scarring, photodamage, melasma and skin lightening for esthetic improvement\textsuperscript{20, 21}. They are derived from sugars found in fruit carboxylic acids like sugarcane or sugar-beet hence, also called as fruit peel\textsuperscript{22}. It is not mutagenic or carcinogenic, thus safe to use\textsuperscript{23}.

**Case Report:** A 24-year-old male patient visited to the Department of Periodontics & Oral Implantology, Institute Of Dental Sciences, Bhubaneswar with the chief complain of dark gums. He was concerned about his esthetics and wanted to get treatment for his hyper-pigmented gingiva. He was systemically healthy with no smoking habit. He revealed that his gingival hyperpigmentation was present since childhood depicting physiologic type of pigmentation. Intra oral examination revealed a generalised, diffuse pigmentation of gingiva. The treatment procedure was explained to the patient and a signed consent was obtained. Oral prophylaxis was carried out prior to the depigmentation procedure.

Gingival depigmentation was carried out in the maxillary arch extending from upper right second premolar to upper left second premolar. The pigmented gingiva was first air dried and a topical lignocaine spray was used to anesthetise the area to be de-epithelise. Glycolic acid solution (ASDM Beverley Hill) was applied over the pigmented keratinised gingiva area with the help of a small rounded brush. If during the application patient experienced a tingling, itching or burning sensation, it was minimized by blowing cool air onto the gingiva. After application, it was left there for about 3-5 minutes and subsequently wiped with sterile cotton. Immediately following the peel, the gingiva may appear reddish brown in colour. All the remnants of melanin pigment were carefully removed and then washed with copious water to stop the over-acidification in the applied area. No periodontal pack was placed. Patient experienced no pain during the procedure or postoperatively.

Post-operatively, patient was advised to use 0.12% chlorhexidine mouthwash (Clohex plus, Dr Reddy’s Lab) for 2 weeks. The patient was recalled after one week. Complete epithelisation occurred in about 3-4 weeks. Healing was uneventful without any complication and the gingiva appeared pink and healthy. Patient was re-evaluated at 1 month, 6 months and 1 year. No significant re-pigmentation was observed even after a period of 1 year. (Fig 1-4)

![Fig 2: Immediate Post-operative](image2)

![Fig 3: Post-operative after 1-month](image3)
Discussion

‘Dark gums’ or hyperpigmented gingiva is an esthetic dilemma in many individuals especially if the hyperpigmentation is on the facial or labial aspects of the gingiva along with a high smile line. It is this aesthetic provocation that compels the patient to pay a visit to the dental office. This is the first instance of report of cases of effective use of Glycolic acid as a peeling agent for gingival depigmentation in the management of hyperpigmented gingiva.

Chemical peeling is a procedure where a chemical exfoliating agent is applied to the keratinized epithelium to remove portions of epidermis and/or dermis with subsequent regeneration and rejuvenation of the tissues. Chemical peels are classified as superficial, medium and deep peel according to their depth of action. Superficial peel extends up to the epidermis, medium peel involves epidermis and papillary dermis and deep peel extends to the mid-reticular dermis 24. Various agents such as phenols, salicylic acid, glycolic acid, trichloracetic acid and lactic acid are available for chemical peeling. Glycolic acid peel is most commonly used. It is an alpha-hydroxy acid peel having the smallest molecular weight so they can penetrate easily25. Glycolic acid peels have anti-inflammatory, keratolytic, and antioxidant effects. It reduces sulfate and phosphate groups from the surface of corneocytes, decreasing corneocyte cohesion and hence inducing exfoliation of the epidermis. It also suppresses melanin formation in melanocytes by directly inhibiting tyrosinase activity and can also disperse the basal layer melanin26. They are available in various concentrations ranging from 20-70%. They are not very deep peel and are usually superficial to medium depth peel. The intensity of Glycolic acid peel is determined by the concentration of the acid and the time of application. It has been classified as very superficial peel when its 20-30% concentration is applied for 1-2 minutes, superficial peel in which 50-70% concentration of glycolic acid is applied for 2-5 minutes and medium peel where concentration of glycolic acid is 70% and is applied for 3-15 minutes27. The action of Glycolic acid peel has to be properly neutralized in order to stop acidification of the skin28. Water act as a neutralizer and to further stop the acidification sodium bicarbonate solution can also be used.

Hirschfeld 29 earlier used 90% phenol and 95% alcohol for gingival depigmentation. However, the depth of action was difficult to control and phenol may also induce cardiac arrhythmia as it is rapidly absorbed into the circulation. So it was no longer used for gingival depigmentation. In the present case report Glycolic acid peel was found to be an efficient treatment modality for gingival depigmentation. It is a simple procedure and is superior to other depigmentation techniques. It exhibits good haemostasis, uneventful healing, and no pain during or after the procedure and is also economical. It has good patient compliance. Also, there is no need of anaesthesia and periodontal dressing.

Conclusion

Chemexfoliation by use of Glycolic acid is an efficient technique for gingival depigmentation. It is simple, easy and inexpensive procedure with minimal discomfort to the patient with satisfactory outcome. Further studies are needed to assess the long term effectiveness of this method of depigmentation. More data is required on comparative techniques to ensure the long-term predictability and success.

Laser Assisted Frenotomy with Coronally Positioned Flap for The Treatment of Isolated Mandibular Gingival Recession

Abhaya Chandra Das¹, Saurav Panda¹, Saumya Kanta Mohanty², Nitai Debnath³

¹Reader, Department of Periodontics and Oral Implantology, ²Reader, Department of Conservative and Endodontic, Institute of Dental Sciences, Siksha ‘O’ Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India, ³Reader, Department of Prosthetic Dentistry, RIMS, Imphal, India

Abstract

Root coverage has turned into an essential part to periodontal plastic surgery. It becomes more challenging when there is no attached gingiva with presence of high frenal pull. This article presents a case report of gingival recession in 44 with high buccal frenal pull with complete absence of attached gingiva, which has been treated with frenotomy and coronally positioned flap with LASER. The main advantage of this technique is that it does not need a separate frenotomy procedure and also no second surgical site. The treated case established root coverage with adequate width of attached gingiva.

Keywords: Gingival Recession, LASER, Muco-gingival surgery, Root coverage.

Introduction

Gingival recession is the denuded of root surface with the apical shift in the position of gingiva.¹ It is commonly found in the general population. It is found that its prevalence increases with age.² The gingival recession can be classified as localised and generalised, which results loss of attachment and root exposure.³ There are various etiological factors, including dental plaque, labially placed tooth, faulty tooth brushing, high frenal attachment, uncontrolled orthodontic tooth movement, defective restorations, viral induced periodontal disease.⁴⁻⁸ It has frequently been observed gingival recession simultaneously with high frenal attachment and shallow vestibule.

Apart from root surface hypersensitivity, there may also be resulted in several clinical problems like cervical abrasions, difficulty in plaque control, root caries, and decreased aesthetic gingival line.⁹ Therefore, it should not be considered as merely a soft tissue defect, but rather as the destruction of both soft and hard tissues.³ Hence, root coverage procedure is indicated in such cases, which is a vital aspect of regenerative periodontal therapy.

Among various root coverage procedure, pedicle soft tissue grafts give more predictable results in such indicated cases. This article outlines a case report of recession coverage with frenectomy and coronally positioned flap with LASER in isolated mandibular class II recession defect. It may be considered a new modified technique of semilunar flap for root coverage was done in mandibular premolar region with LASER. The technique gave predictable formation of adequate of attached gingiva which is essential for a healthy gingiva.

Case History: A male subject aged 28 years reported in Department of Periodontology and oral implantology, Institute of Dental Science, Bhubaneswar, India; with a chief complain of receded gum in lower right posterior tooth region. Clinical examination revealed the presence of high buccal frenal pull with no attached gingiva in relation to #44. There was a Class II recession defect in relation to #44.¹⁰ The recession depth was noted to be 3mm (Figure 1). On radiographic examination in relation to #44, there was adequate bone support in interdental areas. Clinical parameters such as Probing Pocket Depth, Gingival Recession, width of attached
gingiva, and Clinical Attachment Level were recorded at baseline, and post-surgically at 6 months and 9 months. After explaining the surgical procedure in details, the informed consent form was signed. The subject was medically sound and fit, so a surgical procedure was designed for root coverage in #44. Scaling and root planning were performed prior to surgery to reduce inflammation.

Surgical technique: After administration of local anaesthesia (2% lignocaine hydrochloride with 1:80,000 epinephrine), the surgical procedure followed the semilunar coronally displaced flap technique as introduced by Tarnow et al. to cover denuded root surface in maxilla. However, there were some modifications done in this case such as straight-line incision instead of semilunar incision, carried out on oral mucosa instead of attached gingiva and the above said procedure was carried out in isolated mandibular recession defect instead of maxilla (Figure 2). Moreover, the straight-line incision was carried out using soft tissue diode laser to achieve haemostasis.

A straight-line incision was placed in the vestibule at approximately 8 (2 X GR + 2) mm from the gingival margin to incise frenum. A straight-line incision was placed deep into the periosteum and the underlying bone was exposed so that scar formation could occur. A sharp dissection was carried out to perform a split thickness flap in the apico-coronal direction, connecting it from the sulcular incision till the first straight incision (Figure 3). The flap was elevated and repositioned coronally to cover the denuded surface. No vertical incisions were made. Thereafter, root planting was performed to remove all irritant and necrotic Cementum. Root conditioning was done with tetracycline HCl. The repositioned flap was then pressed for 3 minutes to avoid hematoma and independent sling sutures were placed (Figure 4). Periodontal pack was given (Figure 5). The donor region was left open to granulate and healed by secondary intention. Written and verbal post-operative instructions were provided to the subjects and antibiotics were prescribed Amoxicillin 250 mg every 8 hours for 5 days and analgesic (a combination of ibuprofen 400 mg and paracetamol 500 mg twice daily for 3 days). Antibiotics and analgesics were given to control any post-operative infections, pain and swelling. 0.2% chlorhexidine mouth wash was advised to rinse twice daily after 30 minutes of brushing up to 1 month after surgery for controlling the plaque.
Sutures were removed after 10 days postoperatively and subjects were instructed to maintain meticulous oral hygiene. The surgical region was observed for any uneventful healing. The subject was recalled and recorded for post-operative measurement at 6 and 9 months follow up visit. There was complete root coverage achieved with 3mm attached gingiva and 1mm probing pocket depth after 15 days and followed up to 9 months (Figure 6).

Discussion

Gingival recession leads to impairment of dental aesthetics. Various techniques are carried out to obtain root coverage. Adequate amount of attached gingiva width plays vital role before deciding any root coverage procedures. Among all, some provide positive outcomes and some fail to achieve the result. These may be due to various factors such as the gingival contour, tooth anatomy, the relationship of underlying bone to the cement-enamel junction, and subject’s post-surgical oral hygiene maintenance.

The amount of attached gingiva needs to be measured as a part of the assessment in this case report. It has been observed that there should be at least 2 – 3 mm of attached gingiva to maintain healthy periodontium. The technique used in this case, includes two surgical techniques such as frenectomy and the flap covers an exposed root surface, which is supplied by plasmatic circulation from the adjacent portion of gingival capillaries. The plasmatic circulation allows the survival of the graft. The idea of straight-line incision was carried out for frenectomy, and it was carried out in mandible as randomly select the case since it has been not carried out till now. LASER was been chosen to decrease bleeding during surgical procedure. A healthy, functional and aesthetic with resistant to recurrence is obtained by this procedure. As per the literature search, this is the first case report where LASER assisted coronally positioned flap was used for root coverage in isolated recession. The flap covers the denuded root surface and is supplied by plasmatic circulation from capillaries in adjacent gingiva, allowing it to survive. In this case, adequate attached gingiva with complete root coverage as defined by Miller in 1987 was achieved.

Conclusion

To get a successful treatment of gingival recession depends on the selection of periodontal plastic surgery technique. Soft tissue maintenance is the primary line of defence in protecting the tissue from bacterial infection. In this report, LASER assisted modified semilunar coronally positioned flap used for root coverage in isolated recession, was found to have satisfactory results. However, careful preoperative diagnosis, case selection plays important role to determine the prognosis of the surgery. Etiological factors should be identified before the treatment and these factors should be eliminated. In this case, LASER assisted frenectomy with coronally positioned flap may be used for successful management of single tooth gingival recession.

Endoscopic Treatment of Sinonasal Ossifying Fibroma: A Case Report

Santosh Kumar Swain¹, Priyanka Debta², Smrutipragnya Samal¹, Jatindra Nath Mohanty⁴, Fakir Mohan Debta⁵, Anurag Dani⁶

¹Professor, Department of Otorhinolaryngology, IMS and SUM Hospital, ²Associate Professor, Department of Oral Pathology and Microbiology, Institute of Dental Sciences, ³PhD Scholar, ⁴Research Associate, Medical Research Laboratory, IMS and SUM Hospital, Siksha ‘O’ Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India, ⁵Associate Professor, Department of Oral Medicine and Radiology, S.C.B. Dental College & Hospital, Cuttack, India, ⁶Professor, Department of Prosthodontia, C.D.C.R.I. Rajnandgaon, Chhattisgarh, India

Abstract

Ossifying fibroma is a highly uncommon tumor with fibro-osseous nature which originates within the cranio-facial bones. It is a benign lesion consisting of fibrous tissue, bone or osseous tissue and cementum. It is rarely seen in sinonasal tract. It is often symptomless and sometimes achieve a large size. Complete ENT block excision is needed to relieve from clinical manifestations and prevent recurrence. In this case, endoscopic complete excision of ossifying fibroma was done from nasal cavity, ethmoidal sinus and maxillary sinus. Owing to aggressive nature of this lesion and high chance of recurrence, prompt diagnosis and wide surgical excision of this tumor is essential. Here, we are reporting a case of ossifying fibroma at sinonasal area which is an extremely rare location for this lesion.

Keywords: Ossifying fibroma, sinonasal area, head and neck region, endoscopic sinus surgery.

Introduction

Ossifying fibroma is an extremely uncommon benign lesion consists of fibrous tissue and bone. It is usually seen in mandible whereas it rarely seen in nasal cavity and paranasal sinus. The first case of ossifying fibroma was documented by Menzel in 1872 and subsequently named as ossifying fibroma by Montgomery in year 1927. [¹, ²] It is often seen among female during third to fourth decades of life. [³] It is a non-capsulated tumor but relatively well-demarcated border from surrounding tissue. Ossifying fibroma is an aggressive tumor and invades to surrounding structures and causes various clinical manifestations. It can spread to orbit, skull base and cranium due to its aggressive nature. [⁴] It is often asymptomatic in nature and attends large size and exhibit aggressive behavior. [⁵] The treatment purpose of this tumor is complete resection. There are several open approaches used for removal of this tumor. After use of nasal endoscopy and endoscopic sinus surgery, it was accepted as treatment of choice for ossifying fibroma of the sinonasal area which avoided cosmetic problem due to open approach. Here, we report a case of sinonasal ossifying fibroma treated with endoscopic approach.

Case Report: A 38-year-old lady attended outpatient department of Otorhinolaryngology with complaints of right nasal obstruction and mild facial swelling in the right side for 6 months. Anterior rhinoscopy revealed a polypoidal mass in the right nostril. She had no history of nasal bleeding or no history of trauma to face in the past. She had no headache and visual problem. There was no bulging in the palate and alveolar process during intraoral examination. There were no palpable neck nodes and with normal chest radiograph. Diagnostic nasal endoscopy showed a smooth mucosa covered polypoidal mass with hard in consistency on probing. Computed tomography (CT) scan showed a hyperdense mass at the right-side nasal cavity and same side maxillary sinus (Figure 1). Initially endoscopic surgery was done...
for biopsy and multiple tissues from nasal mass were taken (Figure 2). The tissues were hard in consistency and difficult to cut by scissors. Endoscopically the lesion from the right nasal cavity was completely removed and showed fibro-osseous lesion (Figure 3). This tumor from the maxillary sinus was completely excised with help of microdebrider (Hummer II, Stryker, USA) after a hole made in the anterior wall of the maxillary antrum at canine fossa and inferior meatus. During surgery, the tumor mass was separated with help of the Freer elevator. Histopathological report revealed proliferation of spindle cells, presence with globular cementum and fragments of woven bone. She was discharged from hospital uneventfully without any complications. When she was reviewed after 6 months of the surgery, found to have without any clinical symptoms.

**Discussion**

Ossifying fibroma is a benign tumor found in the bony structures at the head and neck area. It is an uncommon clinical entity, grow slowly and locally aggressive in nature. It is often seen the mandibular bone, accounts around 70% of the patients followed by maxillary sinus and rare in the other paranasal sinuses and nasal cavity. [6] Ossifying fibroma is classified into 3 types and these are Ossifying fibroma, cement-ossifying fibroma (COF), aggressive psammomatoid ossifying fibroma (APOF). [7] These different types have different biological behavior. Histologically these lesions consist of two main components such as fibrous stroma and bone elements. APOF type of ossifying fibroma consists of irregular bony spicules within a cellular fibrous stroma. Typically, it mimics cementum or calcified psammomatoid bodies. COF type of ossifying fibroma has similar histological presentation with cementum like material seen throughout the lesion. Ossifying fibroma is locally destructive benign lesion, most commonly seen in facial bone affecting mandible in 75% cases. [7] Other than mandible, ossifying fibroma affects ethmoid and maxillary sinus. APOF type most commonly ethmoid sinus followed by maxillary sinus, orbit and frontal sinus. OF commonly affect maxillary sinus and ethmoid sinus but rarely affect frontal and sphenoid sinus. [7]

Patients of ossifying fibroma are usually asymptomatic. They are usually incidentally identified during imaging for other indications. Due to mass effects, patients often present with facial swelling, nasal obstruction, headache, proptosis, loss of vision and diplopia. [8] Clinical presentations of sinus infections like rhinorrhea, nasal block, epistaxis, hyposmia can be observed when the lesion invades the nearby nerves, vision problem. [9] Diagnostic endoscopy shows smooth mucosa covered masses in the nasal cavity. The differential diagnoses of the ossifying fibroma are fibrous dysplasia, psammomatous meningioma and osteosarcoma. [10] Fibrous dysplasia is more monotonous and polyostotic than ossifying fibroma. Psammomatous meningioma presents with polypoidal mass and osteosarcoma is more aggressive in comparison to ossifying fibroma. [10]

The diagnosis of ossifying fibroma is usually done by imaging which shows a well-defined lesion. In early stages the tumor is radiolucent and progress to radiopaque and covered by radiolucent/sclerotic mass. Imaging like CT scan of paranasal sinuses and the nose presents with non-homogenous matrix with opacity of ground glass appearance which shows diffuse calcified and fibrous components. There may be remodeling and thickening in the walls of the affected paranasal sinuses. The magnetic resonance imaging (MRI) picture are similar to fibrous dysplasia on T1 weighted image shows with low to intermediate signal whereas in T2 weighted image shows variable intensity. Endoscopic biopsy and histopathological examination is done to establish the diagnosis. MRI is required to rule out orbital or cranial extensions. [11] Biopsy also helps to rule out malignant pathology such as sarcoma. Microscopically this tumor is of without capsule with invasion of surrounding bony parts and new bone formation in periphery. The tumor possesses fibrous tissue with cellular osteoid with absence of osteoblastic rimming along with slender trabeculae of pre-mature bone having coarse lacunae with several osteocytes and lined by osteoblasts. [12]

The treatment of choice for sinonasal ossifying fibroma is complete excision of the lesion. A more conservative approach may be accepted where there is no or little symptom. [13] This tumor is excised by different surgical modalities. Presently endoscopic approach is recommended for this tumor which holds advantages like direct visualization of the lesion, no external scar and deformity. Other surgical approaches like craniofacial resection e.g. trans-oral, trans-facial and craniotomy can be applied for resection of this tumor. Radiation therapy is not useful in ossifying fibroma although it is helpful in another bony tumor. [14] Radiation treatment should not suggest as it can induce malignant transformation. [9] Ossifying fibroma has a good prognosis but the chance of recurrence should be kept in mind when complete excision is difficult to do or not possible or not done.
due to some causes like cosmetic reason. Endoscopic approach for surgical removal of the ossifying fibroma arising from nasal cavity or ethmoid sinus leads to effective outcome. Endoscopic approach using nasal endoscope is a safe, effective and convenient technique than the conventional open method. Use of endoscope can reduce morbidity, hospital stay and provide cosmetically satisfaction to the patients. In extensive disease, it may require a combined approach including craniofacial resection. Ossifying fibroma must be reminded among clinician as a differential diagnosis of sinonasal mass and treated early for preventing invasion to surrounding vital structures.

**Figure 1.** Endoscopic picture of the nasal mass presenting as fibro-osseous lesion.

**Figure 2.** Multiple piece of nasal mass were taken for histopathological examination.

**Figure 3.** Scan showing hyperdense mass at the right maxillary sinus and right side nasal cavity.

**Conclusion**

Ossifying fibroma is an uncommon and fibro-osseous lesion found in the head and neck area. The clinical manifestations of the patient presented here highlights the rare site of this tumor in the nasal cavity and paranasal sinus. Clinicians should keep in mind about clinical features, imaging pictures and histopathological findings of ossifying fibroma in this uncommon site of the head & neck area for early and effective treatment. Endoscopic removal of this tumor is more convenient, effective and safe method than open approach which is cosmetically satisfactory.

Management of Medical Emergencies in Dental Office

Ananya Oujwoswini

Intern (B.D.S.), Institute of Dental Sciences, Siksha ‘O’ Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

A dentist may encounter an emergency in the dental office during the dental procedures. Therefore, every dental professional should have the knowledge to diagnose and manage the serious condition in dental office. It is important to recognize the patient at risk, so that the treatment plan can be modified and the appropriate measures can be taken. Although the chance of medical emergencies occurring in dental office is rare, the dental office should be well equipped to manage such situation. The essential sequence in managing an emergency is the maintenance of proper position, Airway, Breathing, Circulation and Definitive treatment. The purpose of this article is to provide a vision to the dental professionals about the commonly occurring medical emergencies and complication in dental practice and their management.

Keywords: Anaphylaxis, Dental Office, Medical emergency, Syncope.

Introduction

A medical emergency is an acute illness that creates an immediate risk to a person’s life or long-term health. This condition demands urgent attention and treatment. Dentist must be prepared to manage medical emergencies which may arise in practice. Between 1980 and 1984 a study was conducted in Japan by the committee for prevention of systematic complications during dental treatment by Japanese Dental Society of Anesthesiology. This study stated that about 19% to 44% of dentists had encountered a patient with medical emergency in one year.¹

Medical emergencies cost commonly occurred during and after the delivery of local anaesthesia, primarily during tooth extraction and endodontic. Previous studies have shown that Syncope is the most common medical emergency encountered by the dentists. Other emergencies reported to have occurred in a dental office includes allergic reactions, angina pectoris, cardiac arrest, postural hypotension, seizures, bronchospasm and diabetic emergency.²

During the treatment of the medical emergencies, the dentist requires the knowledge of preparation, prevention and then management as necessary. Prevention can be accomplished by recording a thorough medical history with appropriate alternation to dental treatment required. Nearly all medical emergencies in the dental office can be prevented by providing sufficient oxygenation to brain and heart. Therefore, during the management of all the medical emergencies, it should be ensured that, oxygenated blood is being delivered to the critical organs. The oxygenation should be consistent with basic cardio pulmonary resuscitation with which the dentist must be competent. This provides the skills to manage most medical emergencies, which began with assessment, and if necessary, the treatment of airway, breathing and circulation (the ABCs of CPR). Usually only after the ABCs are addressed properly, the dentist should consider the use of emergency drugs. American society of Anesthesiology (ASA) system of grading the physical status of patient into ASA 1,2,3,4 is a good risk indicator for developing complications, As A grade 3 and 4 patients are at more risk of developing complications. Therefore, a medical review or consultation with treating physician may be required before treating these patients.³

Basic Medical Emergencies and Their Management

Syncope: A transient loss of consciousness due to cerebral ischemia caused by a reduction in blood supply to the brain is known as vasovagal syncope. It is the most commonly encountered medical emergency in dental practice. Vasodilation causes slowing of heart, which causes a dramatic fall in blood pressure. Causes of sudden loss of consciousness and collapse
include hypotension, adrenal crisis, anaphylaxis, cardiac arrest, diabetic collapse etc. The early manifestations include nausea, warmth, light headedness, slow pulse, hypotension, tachycardia. Most of the syncope attacks can be prevented by ensuring that the patient has had their meal before treatment in case of systemic disease like diabetes.4

During the management the patient should be in supine position with legs raised and a cool towel placed on his/her forehead. Recovery is almost instantaneous if the patient has simply fainted. Then airway should be maintained properly, pulse should be checked and CPR should be started immediately. If the pulse is palpable and the patient has not completely lost consciousness, then four sugar lumps may be given orally or intravenous 20ml of 20-50% sterile glucose. A hypoglycemic patient will improve with this regimen. But if there is still no improvement medical assistance should be summoned meantime, hydrocortisone sodium succinate 200mg IV should be given.5

**Hyperventilation:** Some patients because of extreme anxiety and fear may start to breathe rapidly and deeply. This conscious overdrive of ventilation is known as hyperventilation. This can lead to excessive washout of carbon dioxide causing decreased partial pressure of arterial carbon dioxide (below 35mmHg). Hypocapnia cause constriction of cerebral blood vessels can lead to respiratory ankylosis with rise of blood Ph to 7.55. The abnormal feeling coupled with anxiety makes the patient to hyperventilate more, thus making vicious cycle.6

Management: consist of breaking this vicious cycle. The patient should be reassured and asked to breathe slowly and normally. Hyperventilation is the only emergency situation, when oxygen therapy is uncalled for in treatment pain. The most effective method of raising pac02 is to breathe through cupped hands in front of nose and mouth or breathe through detached oxygen mask which has holes for release of excessive carbon dioxide. In most case this will terminate the vicious cycle. In certain refractory cause sedation with diazepam or midazolam may be required.

**Anaphylaxis/Allergic Reaction:** Anaphylactic reactions are a prototype example of a type-1 hypersensitivity immunological reaction which is IgE mediated. The most common allergen that can cause hypersensitivity reaction in the dental setup is latex. Patients become extremely apprehensive, intensive itching occurs and asthmatic breath develops. Urticaria may develop rapidly. Death may occur within a few minutes or several hours later.

Management: Immediate application of a tourniquet above the site of injection. Epinephrine is the drug of choice because of its vasopressor, bronchodilator and antihistamine action. Dose for the adult is 0.3 – 1mg subcutaneously or intramuscularly. If possible, an IV route of drug administration can be started. Oxygen under pressure should be given with assisted respiration. Antihistamines suchas diphenhydramine 50mg are given IV or IM. Corticosteroids such as hydrocortisone 100mg IV or IM are given for peripheral vascular effects.7

**Local Anesthetic Toxicity:** Local anaesthetics and the most commonly used drugs in dentistry. Toxicity is usually either due to the local anaesthetic itself or the vasoconstrictor which can be due to rapid infusion or failure to aspirate before injection. Generally, the reactions are self limiting. Toxicity present with talkativeness, slurred speech, anxiety, confusion, seizure and cardiac arrhythmias in extreme case.

Management: Sessate the administration of injection and monitor vital signs. Administer oxygen and in adverse cases administration of diazepam 5mg slowly is advised.8

**Asthma/Bronchospasm:** Asthma is characterized by increased contractile response of smooth muscles of small airways. In a dental setting, an asthmatic attack may occur in response anxiety, aerosolized particulate matter or certain drugs such as aspirin and NSAIDS. Patient experience coughing, dyspnea and hunger for air.

Management: The patient should be seated upright and oxygen should be administered via mask or nasal cannula. The patient is asked to take puffs from his own inhaler or salbutamol inhaler from emergency kit. Puffs from inhaler are repeated every minute for 5minute or until symptoms improve.In certain cases (status asthmaticus) inhaler medication may not be effective, then one may consider administration of IV salbutamol 100mg IV hydrocortisone may be effective in preventing relapse, 0.3mg of IM epinephrine can be used as last resort or when IV access is not available.

**Angina/Myocardial Infarction:** Angina is feeling of chest pain due to inadequate blood supply to heart. It is because of narrowing or spasm of a coronary
artery. Episode of pain is brief and usually settles within 5 minutes with no permanent damage to heart. Acute myocardial infarction is due to development of clot in one of coronary arteries. There is lack of blood supply to heart muscles with permanent damage. In both cases, the patient complaint of chest pain, heaviness, shortness of breath, the pain may radiate to shoulders, arm, neck, jaw and upper abdomen.

Management: The goals of management of chest pain are to decrease oxygen requirement of heart or increase oxygen supply to heart. This can be done by supplemental oxygen via mask or nasal cannula. Nitroglycerine is single most effective vasodilator to relax smooth vascular wall in case of angina pectoris, can be given sublingually or spray 0.4mg sublingually every 5 minutes with not more than 3 tablet. In case of myocardial infarction, it is recommended that out of hospital, the patient should receive anti-fibrinolytic aspirin in dose of 150-325mg. Therefore, the patient may be asked to chew four tablets of 75mg aspirin and swallow. The patient should be shifted under the care of the cardiologist as early as possible.

Seizure: Patient who convulse in dental office generally have a seizure history and are often characterized as having epilepsy.

Management: If the patient experiencing seizure is unconscious. They should primarily be placed in the supine position and the head tilt chin lift manoeuvre is performed. Dental specialist should remove all the instruments from patient’s mouth and protect the patient. Clear airway, loosen clothing and help patient breath adequately. If seizure continues for long, then the condition is known as status epilepticus. This is a life-threatening emergency and is best managed with IV diazepam 5mg IV/IM or by maintaining BLS till patient is shifted to emergency medical care.

Hypoglycemia/Hyperglycemia: Diabetes mellitus is quite prevalent and these patients are prone to hypoglycaemic and hyperglycaemic events. In dental settings, hypoglycaemic events are more common than hyperglycaemic events. Hypoglycaemic can be sudden and more dangerous, it occurs due to lack of supply of glucose to brain result in confusion. Hyperglycaemic event takes days or weeks to develop clinician should be able to differentiate between the hyperglycaemic events and hypoglycaemic events. Skin of hyperglycaemic patient looks flushed and dry whereas hypoglycemic patients’ skin is cold and wet as the blood pressure is low. Monitoring of blood glucose with glucometer in the dental clinic can also confirm the diagnosis.

Management: If hypoglycaemic is evident, it can be readily corrected by giving glucose or sugar in conscious patient but in an unconscious patient 25-50ml of 50% dextrose should be administered IV. Alternately 1mg of glucagon can be administered IM. Protocol of vital sign monitoring and BLS should be followed as in case of any unconscious patient. Emergency management of hyperglycaemic patient in a dental clinic is supportive in nature and Patient should be shifted to nearby hospital for definitive management.

Hypotension: Low blood pressure (systolic pressure below 90mmHg) can lead to inadequate cerebral perfusion and loss of consciousness. Most common cause in dental setting for hypotensive patient is syncope, it is associated with bradycardia, usually pulse below 50 beats per minute.

Management: Hypotension with bradycardia, atropine is a useful drug dose 0.5mg IM or IV and can be repeated every 5 minutes up to a maximum of 3mg depending on heartbeat or blood pressure. Rapid infusion of normal saline may be warranted to increase the blood pressure. Ephedrine3 can be given 25mg via IM or sublingual injection. When the patient is hypotensive along with tachycardia, phenyl nephrine can be given as 10mg/ml single dose ampoule and should be diluted to make it 0.1mg/ml 0.1-0.2mg increments are given IV slowly.

Hypertension: Hypertension can be encountered with patients in extreme pain or restlessness during lengthy procedure. If the episode is accompanied with symptoms like chest pain, headache or visual disturbances then drug intervention to reduce blood pressure may be required. It is important to note that when stroke is being suspected (aphasia, paresthesia and paralysis are suggestive of stroke) then no attempt should be made to lower the blood pressure.

Management: Esmolol, a selective beta 1 blocker can be used to manage an acute hypertensive event. It is given as 10mg/ml in multi dose vial. Its dose is 0.5mg/kg over 1 minute and can be titrated with 20mg increments (1-2ml) every 1-2 minute.

Recent Advances in Management of Emergencies: The most recent advancement is the revised CPR
guidelines by the American Heart Association (AHA) in 2010. Instead of ABC, now compressions come first only then do the airway and the breathing. Initially, it was believed that the chest compression should be at least 1-1.5 inches deep but now at least 2 inches deep compressions are recommended in adults and in infants its about 1.5 inches but in children it is 2 inches same as adults, and a compression rate of at least 100/min, allowing for complete chest recoil after each compression. Minimising interruption in chest compression. 5-7

**Conclusion**

Emergencies cannot be totally prevented but can be managed appropriately with through knowledge of signs, symptoms and accurate treatment of emergencies. Accomplishing this depends on the combined effort of dental specialist, staff and immediate availability of the critical drugs and equipments for the procedure. However, no drug can replace an efficiently trained health care professional in managing an emergency but an emergency drug kit and equipment does play an integral role in the course and outcome of management of emergencies and complications in interdisciplinary dental practice.

A Rare Case Report of Recurrent Basal Cell Adenoma Involving Minor Salivary Gland of Hard Palate

Harsh Mohan Pathak1, Santosh Kumar Subudhi2, Satya Patnaik1, Swagatika Panda3, Kalyan Sundar Pal4

1Reader, Department of Oral and Maxillofacial Surgery, 2Professor, Department of Oral and Maxillofacial Surgery, 3Reader, Department of Oral Pathology and Microbiology, 4Post Graduate Trainee, Department of Oral and Maxillofacial Surgery, Institute of Dental Sciences, Siksha ‘O’ Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract
Basal cell adenoma is a very rare monomorphic tumor of salivary gland that mainly involves the major salivary glands. Minor salivary gland involvement is a rare entity. A case of basal cell adenoma of heard palate of a 52-year-old woman was reported in Dept. of OMFS, Institute of Dental Sciences, Siksha ‘O’ Anusandhan (Deemed to be University), Bhubaneswar. The patient complains of swelling and discomfort during taking food and draining of pus from that swelling. On radiographic examination (on contrast enhanced computed tomography). Lesion was excised under local anesthesia and the excised tissue sent for histopathological study which reveals keratinized epithelium lined cystic space surrounded by fibrous capsule.

Keywords: Maxilla, Hard palate; Basal cell adenoma; Salivary Gland; radiographic examination.

Introduction
Basal cell adenoma is benign neoplasm of major and minor salivary gland composed of basaloid cells, a prominent basal cell layer and prominent basement membrane-like material and devoid of myxochondroid stromal component which is seen in pleomorphic adenomas. [1] This type of neoplasm commonly involves the parotid gland than the oral mucosa. And in oral mucosa upper lip is the most common site. They rarely involve palatal mucosa in comparison to pleomorphic adenoma that is common in heard palate but rarely involve the lip. Basal cell adenoma appears as small, slow growing, and painless, well circumscribed swelling. There is slight male predilection. This case is presented for its rarity.

Case Report: A lady who is in her 5th decade of life reported to the Oral and Maxillofacial surgery department of our college complaining asymptomatic swelling of the left upper back teeth region since last 2 year and there is no history of pain in that region. The swelling is gradually increasing in size since last 2 years and there is presence of draining sinus since last 2 months. There was history of swelling on the same region 5years back which was excised.

On extra oral examination: Nothing significant.

On intraoral examination: A well circumscribed swelling, which present on left side of the hard palate in relation to edentulous space of 26 and 27. The swelling measuring about 2 cm in diameter and having smooth erythematous surface. The swelling is hard on palpation and during palpation there was discharge of purulent fluid from the sinus opening. A single draining sinus present on the surface of the swelling (Figure 1).
On radiological examination: CT reveals well circumscribed swelling involving left side of the hard palate without involvement of palatal bone. On the basis of this clinical diagnosis of benign salivary gland tumor was made (pleomorphic adenoma) with a differential diagnosis of monomorphic adenoma and canalicul

adenoma (Figure 2 and 3). The tumor was excised under local anesthesia along with 1 cm of safety margin and palatal periosteum (Figure 4) and resected tissue (Figure 5) sent for histopathological study.

On histopathological study: Histopathological study reveals the tumor mass is encapsulated by fibro collagenous capsule. The tumor mass composed of multiple islands of uniform looking triangular hyperchromatic cells resembling basal cell and occasional squamous cell. Distinct basement membrane like substance is also intermingled with tumor cells. Occasional area show cord and strands of tumor epithelial cells separated by collagenous connective tissue stroma. Areas of cystic degeneration are also found (Figure 6 a, b).
Discussion

Above discussed variety of neoplasm, which is very uncommon, have proliferation of basal cells with devoid of myxochondroid stroma, which is plenty in pleomorphic adenoma (11,12). Previously, BCA was considered as monomorphic form of adenoma, but later the word monomorphic is excluded by WHO in 1991 and renamed as basal cell adenoma (13). According to histopathology there are 4 types: 1. Solid 2. Tubuler 3. Trabecular and 4. Membranous. Among them solid variant is the commonest one. But in most of the cases combination of above said histological types are found. The tumor is frequent in middle aged adults (4th -6th decade of life) with slight female predilection. But it can appear at any age. Malignant transformation of the tumor is rare but few case of malignant transformation is also reported in previous studies (15). The membranous type of basal cell adenoma has higher recurrence rate (nearly 25 - 37%) (1) Involvement surrounding normal tissue during surgical excision is necessary for the prevention of its recurrence.

Conclusion

Even of its rarity basal cell adenoma should be considered in differential diagnosis of palatal swelling.

The Relationship between Nutrition and Oral Health: A Review

Sourav Chandra Bidyasagar Bal¹, Sukhvinder Singh Oberoi², Radha Prasanna Dalai¹, Avneet Oberoi³

¹Senior Lecturer, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to University), Bhubaneswar, Odisha, India, ²Reader, Department of Public Health Dentistry, Sudha College of Dental Sciences and Research, Pt. BD Sharma University, Haryana, India, ³Private Practitioner General Dentistry, Oberoi Dental Clinic and Orthodontic Centre, Tagore Garden, New Delhi, India

Abstract
This review is addressing the aspects of nutrition and diet as related to the oral health. Oral health is related to diet and nutrition in many ways, for example through dietary influences on craniofacial development and oral infectious diseases. In the modern diet, soft refined foods tend to cling tenaciously to the teeth and are not removed because of the general lack of roughage. Nutritional status and dietary habits can affect and be affected by all oral conditions. Nutrition interventions may be throughput of in terms of primary prevention, secondary prevention and tertiary precaution. Oral health cannot be exclusively maintained through one approach.

Keywords: Nutrition, Oral Health, Macronutrient, Micronutrients, Deficiency diseases.

Introduction
"Diet as defined by Newbrun refers to the customary allowance of food and drink taken by any person from day to day."¹ Nutrition is defined as the science of how the body utilizes food to meet requirements for development, growth, repair, and maintenance.² Oral health is directly related to diet and nutrition through dietary influences on cranio–facial development and oral infectious diseases.¹ In the modern diet, soft refined foods tend to cling tenaciously to the teeth and are not removed because of the less roughage. Augmenting this collection of debris on the teeth is the reduction of mastication due to the softness of the diet. The detrimental effect of this decreased function on the periodontal apparatus should be obvious.³ The role of fermentable substrate in plaque development, caries and periodontal disease. Nutritional status influence tissue health, immune system function and systemically influences teeth during the pre-eruptive stage including prenatal, perinatal and postnatal periods.⁴ Deficiency of protein energy and vitamins has been associated with enamel hypoplasia and related increases dental caries. Diet more specifically describes foods and foodstuff and the pattern of consumption over a given period of time.⁵ The present review is addressing the aspects of nutrition and diet as related to the oral health.”

Nutrients and their Role in Oral Health
Carbohydrates: “The formation of structural components of the body such as cartilage, nervous tissue and bone is dependent upon carbohydrate.² Carbohydrates are most commonly classified as Simple (Sugars) or Complex (Starches, Fibers). Processed foods, cooked starchy foods, especially when combined with refined sugars can contribute to dental caries and plaque formation, thereby contributing to the development of periodontal diseases. Studies like, Vipeholm Caries study, Hopewood House study, Studies on World War II (among Norwegian children and Takeuchi in Japan) have been conducted to establish the relationship between the diet and dental caries.⁶ ⁷ Vipeholm concluded that the consumption of sugar can increase caries activity. The risk of sugar increasing caries activity is greatest if the
sugar is consumed between meals and in a form in which the tendency to be retained on the surfaces of the teeth is pronounced with a transiently high concentration of sugar on these surfaces. Turku Sugar studies showed almost total substitution of sucrose by xylitol resulted in a substantial reduction in caries incidence.\textsuperscript{8,9} Boyd reported that glucose and other carbohydrates are also used to produce extracellular polysaccharides and, therefore, such diets can increase the plaque mass and facilitate the retention and colonization of the plaque biofilm periodontal infections.”\textsuperscript{10}

**Lipids:** “Dietary lipids can be mainly classified into oils and fats. Lipids or fats contributes to obesity, heart disease and other chronic diseases such as cancer; however, a certain amount of fat is important to maintain adequate health. Lipids oil rich in linoleic acid like safflower, cottonseed and groundnut are good in suppressing the formation of scales on the walls of blood vessels.\textsuperscript{5} Fats are important to oral health from the standpoint that phospholipids are a structural component of cell membranes, tooth enamel and dentin. Fats are involved in the initiation of calcification and mineralization of teeth and bones. In addition, high–fat foods tend to be inhibitory towards dental caries.” Small quantities of nuts and cheeses can be good between meal snack foods or even as ‘dessert’ substitutes for patients concerned with dental caries.\textsuperscript{5} The mechanisms by which fats act to reduce dental caries are probably as follows:\textsuperscript{11}

1. Coating of the tooth food surfaces with an oily substance would mean that food particles will not be so readily retained.

2. A fatty protective layer over plaque would prevent fermentable sugar substrate from being reduced to acids.

3. High concentration of fatty acids may interfere with the growth of cariogenic bacteria.

Chronic swelling of the parotid glands can be the result of the disturbed lipid metabolism that accompanies alcoholism.\textsuperscript{6}

**Proteins:** Protein deficiency during early months of life leads to intellectual dwarfism and it remains lifelong.\textsuperscript{12} Deficiency of protein energy has been associated with enamel hypoplasia and related increases in dental caries.\textsuperscript{5} The caries may be caused either by a quality defect in the matrix of the tooth enamel or equally important by alteration in the salivary gland.\textsuperscript{13} In humans, there is no direct evidence of a correlation between dental caries experience and dietary protein deficiency.\textsuperscript{14} The epithelium of the gingival crevice or pocket adheres to the tooth surface by physiochemical forces mediated by the proteins and glycoproteins in the gingival fluid. The mucoproteins are essential for the maintenance of a regular distribution of water and electrolytes in the tissues. They also have the ability, by cross-linking, to bind collagen fibrils into fibers.\textsuperscript{15} Dietary protein is an important factor in maintaining tooth health – supporting structures. In experimental animals, it has been shown that a dietary protein deficiency negatively affects the activity of fibroblasts, osteoblasts and cementoblasts. The mineralized tissues, bone and cementum, also show similar evidence of breakdown because of size cancellous bone spaces are increased and these are retardation of cementum deposits.\textsuperscript{15}

**Role of Vitamins:** Vitamins are a group of essential nutrients required in trace amounts to regulate chemical reactions within the body. The Vitamins are either water-soluble and fat-soluble vitamins. Water soluble vitamins include Vitamin C and B and Fat soluble include vitamins, A, D, E and K.\textsuperscript{15} Vitamin A is found in the form of retinal and carotene.\textsuperscript{16} Vitamin A is essential for normal development of periodontium, teeth, lip, palate, oral mucous membrane and salivary glands. Vitamin A deficiency produces hyperkeratosis and hyperplasia of gingival tissue. There is a tendency to periodontal pocket formation as a result of proliferation of basal sells of the gingival epithelium and a decreased cellular infiltrate of the lamina propria. When trauma or irritation is superimposed on this conditioned deficiency, severe pocket formation will occur as a result of decreased repairs activity.\textsuperscript{17}

“A deficiency can deaccelerate or stop the growth of the incisor teeth. Accompanying this growth retardation is a disturbance in differentiation and function of ameloblasts; therefore, enamel formation is interfered with. This interference produces hypoplastic and chalky white incisors plus a loss of the usual orange pigment. Also disorders of the labial and lingual odontoblasts occur, producing a thick, regular labial dentin with interglobular spaces and a thin, atubular lingual dentin. There is no absolute correlation between vitamin A deficiency and dental caries or enamel hypoplasia in humans.\textsuperscript{16,17} The atrophy of salivary glands resulting from vitamin A deficiency reduces salivary flow and increases possibility of caries. Vitamin A deficiency is associated with epithelial metaplasia and hyperketerization.” During early development, both deficiency and high
doses of vitamin A have been reported to induce cleft lip and cleft palate. Lack of vitamin D, the enamel calcifies poorly and may in some areas fail to form. The appearance of a calcitroatramatic line in the dentin is the earliest sign of an acute deficiency of vitamin D.16

The relationship between adequate intake of vitamin D and reduced caries incidence has not been clearly proved. Even though a decreased number of enamel cells occur in isolated areas of the enamel surface from vitamin D deficiency, from a chemical standpoint, the enamel is not weakened or more susceptible to caries. However, the physical roughness of the enamel surface from the characteristic pitting of teeth in rickets might dispose to the entrapment and adherence of dental plaque and sugar thus initiate the caries process. Vitamin E is essential for maintaining the integrity of the enamel in incisor teeth as found in the rodents. Iron concentration in incisor enamel was decreased decidedly but no variations in calcium, phosphorous and magnesium concentrations were observed in enamel and dentin that formed during the deficiency.19

Deficiency of vitamin K is rare because of the intestinal synthesis. Vitamin K compounds have been found to be required for the growth of Bacteroides Melaninogenicus, an organism closely associated with periodontal disease.20 It is speculated that a suitable antimetabolite of vitamin K might interfere with the growth of this organism and consequently, prevent the occurrence of periodontal disease.

Vitamin C is an essential nutrient as there is lack of body’s capacity to synthesize. It is also called ascorbic acid because it has antiscorbutic properties. Deficiency of vitamin C results in a disease called Scurvy. The deficiency of ascorbic acid leads to the defective formation of intercellular cement substances. The symptoms of scurvy include hemorrhagic spots on skin, swelling, and infection, bleeding of gums, tenderness and anemia. The characteristic oral signs of scurvy are enlargement of the marginal gingivae that envelopes and almost completely conceals the teeth. The gingivae are bluish red, are soft and hemorrhage spontaneously. The inflamed gums can become secondarily infected by organisms that will result in an acute necrotizing ulcerative gingivitis.6

Thiamine is a water-soluble vitamin which is essential for the utilization of carbohydrates. Severe thiamine deficiency is called beri beri. It affects principally the cardio–vascular, muscular and nervous systems. Beri beri can be separated into three forms 1) Wet, 2) Dry, and 3) Infantile. Deficiency of vitamin B1 increases sensitivity of the oral mucosa, burning tongue, and loss or diminution of taste.6 Riboflavin has a fundamental role in cellular oxidation. It is a co-factor in a number of enzymes involved with energy metabolism. Most common oral lesion associated with riboflavin deficiency is angular stomatitis, which frequently occurs in malnourished children. Other clinical signs include glossitis, cheilosis, inflammation of the conjunctivae, dermatitis.22 Riboflavin deficiency in human beings results in angular stomatitis / cheilosis and glossitis.23

Deficiency of niacin can cause soreness and inflammation of the tongue (glossitis), mouth (stomatitis) and fissured condition of the lips. The tongue is sore, swollen, scarlet in colour and smooth. Acute necrotizing ulcerative gingivitis is common due to secondary infection with fungi or bacteria (eg. fusiform bacilli and spirochetes).13 Eating and swallowing are so painful that food is often refused, which may contribute to worsening of the disease.23

Vitamin B6 deficiency may lead to cheilosis, glossitis and stomatitis. The deficiency has been related to inflammation of the skin and the tongue, loss of appetite and sleep, nausea, muscular pain, increased skin sensitivity and. burning and prickling sensations. The deficiency of biotin causes glossitis.23

Folic acid deficiency results in Megaloblastic anemia, glossitis, cheilosis and gastrointestinal disturbances such as diarrhea, distension and flatulence. The main oral symptoms due to folic acid deficiency are burning sensation in the tongue and oral mucosa. The tongue becomes red, sore and swollen. Angular cheilosis and gingivitis are also present.6

Cyanocobalamin is found as a co-ordination complex with cobalt and cyanide ion. The characteristic symptoms of deficiency include anorexia, dyspnoea, prolonged bleeding time, loss of weight, neurologic disturbances etc. Vitamin B12 deficiency results in atrophic glossitis, which shows bright red, smooth, sore and burning tongue.23

Role of Minerals: Minerals help in growth, repair and regulation of vital body functions. Studies reported that demineralization of the alveolar bone in humans was reversed by daily dietary calcium supplements given for a year.24 These researchers suggested that
periodontal bone loss was a direct result of a calcium-deficient diet leading to secondary hyperparathyroidism and that reversal of this condition by dietary calcium supplements was due to calcitonin production. Others have also suggested that periodontal disease is the result of alveolar bone loss caused by deficiency of calcium and phosphorus.6

Magnesium is present in both enamel and dentin, but its concentration in dentin is about twice that in enamel. If a dietary deficiency in magnesium is induced in rats, the enamel and dentin of the incisor teeth will be hypoplastic because a deficiency produces degenerative changes in ameloblasts and odonto-blasts.25 The oral manifestations of iron deficiency anemia are and fissures at the corners of the mouth. The oral mucous membranes may be atrophied and ashen gray.6 It is believed that oral tissues thus affected are more susceptible to carcinoma. The combination of dysphagia, koilonychias, angular stomatitis, and atrophic glossitis (inflamed smooth surface of the tongue because of reduced size and loss of number of papillae) is called the Plummer-Vinson syndrome. Some study suggests that zinc sulfate supplements will decrease wound-healing time significantly. When zinc peroxide powder was used topically on acute gingival lesions in acute necrotizing gingivitis, the soreness disappeared sooner than expected, and the mouth was quickly restored to normal health.26

Copper concentrations in excess of the normal amounts found in human saliva appear to inhibit acid production. There have been conflicting reports on the ability of dietary supplements of copper to reduce dental caries.27 One of the commonest problems occurring in persons who ingest foods grown in soils that are rich in selenium is a higher than usual dental caries experience. It is speculated that incorporation of selenium during formation of teeth changes the protein components of the enamel and makes it more prone to caries. However, the threshold value of intake below which selenium does not increase caries is not known.27 High molybdenum content of water was responsible for the lower caries incidence among children. Hadjimarkos reviewed the data on this study and commented that the conclusions were questionable because data were incomplete. There have been conflicting reports of the relative caries-inhibiting property of molybdenum when used as a dietary supplement in animal-feeding experiments.21,27 Vanadium resembles phosphorus in chemical behavior. Studies suggests there is an inverse correlation between the vanadium content of water supplies and dental caries.27

**Conclusion**

A basic prerequisite for accomplishing dietary change is the advice that the patient and not the counselor bear the responsibility for making the change. Diet counseling involves giving advice on food selection based on the individual’s likings. Counseling requires obtaining information as to why, where, when, and what specific foods are eaten, how frequently, and what feelings are experienced.28 Nutritional status and dietary habits can affect and be affected by all oral conditions. Nutrition interventions may be throughout of in terms of primary prevention, secondary prevention and tertiary precaution.

Reproductive Health for Adolescents with Intellectual Disabilities: The Implementation of a Psychoeducation Module for Special Education Teachers in Bandung City, Indonesia

Sela Fasya¹, Evi Martha², Hadi Pratomo², Frieda Mangunsong³

¹Graduate Student, Faculty of Public Health, ²Department of Health Education and Behavioral Science, Faculty of Public Health, ³Faculty of Psychology, Universitas Indonesia, Indonesia

Abstract

Adolescents with intellectual disabilities experience the same physical changes as all teenagers. However, the difference for adolescents with intellectual disabilities is that they require greater guidance and attention. Unfortunately, many teachers lack sufficient knowledge and skill for facing these physical changes in their students. This study used a quantitative analysis method with a quasi-experimental one-group pretest–posttest design and qualitative study to discover teacher attitudes and evaluate the provided training. This study demonstrates that there was an improvement in teacher knowledge and a change in teacher attitude from before and after a training intervention.

Keywords: Psychoeducation, Intellectual Disability, Teachers, Knowledge.

Introduction

People with disabilities are often considered sexually inactive. In fact, they have the same physical and hormonal changes as their peers.¹ Many teenagers with disabilities do not receive even basic information regarding how their body is changing and developing.²³ Individuals with physical, cognitive, or emotional barriers have a right to education on sexuality and reproductive health, and they have the same emotional and physical needs and desires as any other individual. As young children, they need touch and physical contact. As they grow older, they are interested in love and relationships. However, individuals with disabilities are often considered as having no need for sex. This situation makes sexuality education for adolescents with intellectual disabilities even more important both for their companions (supervisors) and for the adolescents themselves.⁴

Dewinter revealed that most boys with intellectual disabilities have tried to masturbate, had orgasms, and watched pornographic films over the internet. This should be a concern for both teachers and parents as it shows the importance of sexuality education, including education that pays attention to social factors, communication, personal needs and desires, and safe sex. Individuals with intellectual disabilities are often assumed to be incompetent and unable to manage conflict, particularly in the area of sexuality. Therefore, they need to develop skills to improve their basic communication and generalization strategies.⁵

Psychoeducation programs can shape a teacher’s empathy.⁶ The provision of knowledge on psychoeducation needs to be integrated into the teaching curriculum.⁷ A teacher’s knowledge of psychoeducation for adolescents with intellectual disabilities can also have a positive impact on teacher interventions in the classroom. In addition, after implementing psychoeducation, teachers are better able to identify student behavioural problems, needs, and select and design appropriate classroom intervention techniques for problems in class.⁸ Thus, the purpose of this study is to improve the knowledge, attitude, and practice of teachers at eight schools for special needs children in Bandung City through the use of psychoeducation.
for teaching reproductive health to adolescents with intellectual disabilities.

**Methods**

The research used quantitative analysis method with Quasi-Experimental One Group Pretest-Posttest design where in this design there was not included control group (comparison). In this draft subjects conducted pretest measurement after it was subjected to treatment in the form of intervention of adolescent reproductive health intellectual disability, then done the final measurement (posttest). Then the results are analyzed for differences or changes.

**Measures: Psychoeducation module for the reproductive health of adolescents with intellectual disabilities.** The respondents received training with a psychoeducation module on the reproductive health of adolescents with intellectual disabilities compiled by the Community Service Team of the Faculty of Public Health and the Faculty of Psychology, Universitas Indonesia.

**Instrument:** The instrument used as a tool for this study was a questionnaire designed by the Community Service Team of the Faculty of Public Health and the Faculty of Psychology, Universitas Indonesia with modifications made by the researchers. The instrument was tested first with 15 respondents from special education school X and 5 respondents from special education school Y for a total of 20 respondents. Out of the 30 questions, there was one question that had a lower value than the $r$ table ($r = 0.444$), which was question number 20. However, since question number 20 was considered as important, it was still included in the question instrument. To test the reliability of instrument test result, it was found that the instrument questions were thus considered as reliable. For the training module on the reproductive health of adolescents with intellectual disabilities for teachers, it was subjected to module testing by the drafting team.

**Participants:** The population of this study was comprised of teachers of special education in Bandung City. The number of subjects was 52 teachers who meet the inclusion criteria. For both parts of the study, the sample was chosen purposively.

**Statistical Analytic:** Data analysis in this study uses frequency distribution to describe the characteristics of the respondents, then uses the dependent t test to see the increase’s teacher knowledge before and after the intervention, and using multiple linear regression analysis to see the relationship of the characteristics of respondents to the increase in knowledge that occurs.

**Result**

**Responden:** Characteristics of respondents in this study is where the average age of respondents is 45 years with a variation of age 12 years. The youngest age is 20 years old and the oldest is 60 years old. Then the average length of work is 18 years with a variation of 10 years. The minimum length of work is 1 year and maximum length of work is 36 years. The number of female respondents is higher (81.3%) than for males (16.8%). In addition from the table can also be seen that respondents with majors PLB higher (91.7%) than Non PLB (8.3%). Furthermore, respondents with higher education S1 (81.3%) than S2 education (12.5%) and education D3 (6.3%).

**Overview of Knowledge Up Before and After Training:** The average knowledge before the test was done was 18.94 and after the test was done it increased to 25.23. The difference between before and after training is given is 6.29 with p value <0.05 (0.0001), meaning there is difference of knowledge before and after training is given.

**Improvement of Teacher Knowledge After Being Controlled by Other Variables:** The results of this study after the intervention show that the older the age of the teacher, the lower the teacher knowledge, but this was not significant. Female teachers had lower knowledge improvement than male teachers. In addition, the higher the education level of teacher, the greater the improvement in teacher knowledge, and the more the years of service, the greater the improvement in teacher knowledge.

Discussion

Knowledge Upgrades Before and After Interventions are Given: The results of this study indicate that there is significant difference of knowledge between before and after given intervention proved by p value <0.05 (0.0001). This is in line with research conducted by Hoseinpour which states that there is an increase in knowledge on teachers with an average difference of 6.23.10 In addition, the study also showed that there were significant differences in teacher knowledge before and after training intervention was proved by p value <0.05. Improvement of knowledge before and after intervention by using module in this research is also in line with research conducted by Olfah stating that there is influence of training by using module to increase knowledge.11

The use of pretest and post test in this study serves to see the improvement of teacher’s knowledge before and after the intervention given as in Thailand in 35 teachers who received training where the researcher found that after the training the teacher got a deeper knowledge and understanding about reproductive health and HIV / AIDS, strengthening the ability of teachers to become a facilitator, improve communication skills, and have better relationships with students. In addition teachers also become more willing to participate and commit to provide education on reproductive health and HIV / AIDS.12

It also happens in this study that after being trained in reproduction health psychotherapy, most teachers are motivated to educate students by trying to insert the content of reproduction health into the curriculum that has been formed one of which is self-building program. In addition, the principal as a key policy holder in the school also showed a positive response to his willingness to support activities related to reproductive health education of adolescent girls.

The main objective of providing teacher training on reproductive health and HIV / AIDS is to improve students’ knowledge, attitudes and behavior on reproductive health and HIV / AIDS. But in fact the first thing that results from an effective training is the self-impact of the teacher where it can help teachers to identify teachers’ attitudes about sexuality and behaviors about HIV prevention, understand the content they will teach, learn the skills to teach, and improve confidence in teachers to discuss sensitive and controversial topics such as sexual matters.13

Improvement in Knowledge Before and After Conducting the Intervention Controlled by Other Variables: This study has statistically proven that there was an increase in teacher knowledge before and after participating in an intervention for the psychoeducation of reproductive health for adolescents with intellectual disabilities. This improvement in knowledge was then controlled by other variables, including age, sex, years of service, level of education, and educational background. The aim of studying these variables was to see whether an improvement in teacher knowledge before and after training would be affected by them.

Based on this study, it could be stated that the older the age of the teacher, the lower the teacher knowledge after the intervention, but this was not significant. Notoatmodjo revealed that age was one of the factors that influence knowledge, showing that the older the people, the more developed their mind and memory have become, and this has a positive impact for better knowledge.14 However, as one moves toward old age, a person’s ability to accept or remember something will decrease.15 According to Kooij et al. (as cited in Pati), most factors related to age can have a negative impact on the motivation for working, in that the older worker has lower motivation. This was also the case for the teachers in this study, in which the older teachers had a lower improvement in knowledge because of a lower motivation for the training.16
Furthermore, this study also statistically showed that male teachers had a greater improvement in knowledge than female teachers. Based on one theory, the size of the male brain is 10% greater than the female brain but the female brain has a larger corpus callosum. As a result, this size difference in the brain makes men and women different whereby men tend to focus more on visible objects than women. This is related to the methods used for delivering the materials presented in this study. Although the training was not only focused on a lecture and used a variety of teaching aids, it still turned out that the methods used made it easier for male teachers to capture information than for female teachers.

In addition, this study also statistically demonstrated that the more years of teacher service, the greater the improvement in teacher knowledge after attending the intervention. As stated by Rachman and Tjalla special education school teachers who have more than six years of work experience are more skilled in managing the class because their experience helps them.

This study also showed that the higher the level of teacher education, the greater the improvement in teacher knowledge after completing the intervention. As Rachman and Tjalla showed in their research, teachers with a high level of education have broader insights, facilitating their teaching and learning activities. Notoatmodjo revealed that one of the internal factors that also influence knowledge is education. This demonstrates that the higher the level of education, the easier it is for people to understand new information because they have the analytical skills and ability to receive information.

Furthermore, this study also showed that a teacher’s educational background did not affect the improvement in teacher knowledge. According to Undang-Undang Number 14 Year 2005 of the Republic of Indonesia concerning teachers and lecturers, it is required for the educator certification programs provided by universities to be accredited by the government as to provide structure and equity. As a result, everyone who has obtained an educator certificate has the same opportunity to be appointed as a teacher in their specifically certified field of education. Thus, even though this study found that there were some special education school teachers who were not from a special education background, they had followed the certification procedure as mandated by this law.

Issues such as sexual education need to be understood by all teachers because teachers are the main “transmitters” of knowledge, attitudes, skills, ideas, and competencies for students. They must understand what the best approach is for teaching content on reproductive health education. Nchia has stated that reproductive health education influences knowledge and competency in regard to this subject. This is consistent with this study in that the results show a contribution to the improvement of teacher knowledge.

**Conclusion**

This study shows that the training used psychoeducation module has improving the knowledge of teachers in reproductive health in adolescents with intellectual disability.

**Conflict of Interest:** The authors stated there is no conflict of interest of this study

**Source of Funding:** This research was funded by Universitas Indonesia through the PITTA Grant Program (Indexed International Publication Grant for the Final Project of a Universitas Indonesia Student).

**Ethical Clearance:** Ethical review was conducted in accordance with the procedures at the Faculty of Public Health of the Universitas Indonesia and was approved by the Health Research Ethics Committee of the Faculty of Public Health of the Universitas Indonesia. The number of ethical clearance letter is 51/UN2.F10/PPM.00.02/2018.

**Acknowledgement:** The researchers would like to thank all of the teachers and principals of the eight special education schools in Bandung City and the Education Agency of West Java Province who participated in this study.

Cost Effectiveness of Interventions Using the TB Dots Strategy in Public Healthcare and Private Hospitals in Depok, West Java, Indonesia

Fikrotul Ulya1, Hasbullah Thabrany1, Mardiati Nadjib1, Purnawan Junadi1

1Department of Health Policy and Administration, Faculty of Public Health, Universitas Indonesia, Depok, Indonesia

Abstract

In 2016, the global Tuberculosis (TB) case notification rate was 77%, and 46.5% in Southeast Asia. During the last five years in Indonesia specifically, the rate has been 32–33%; however, in Depok City, it reached 58%. In Depok City, the private sector contributed 18.7% of the notified TB cases in 2016, though only 40% of its private hospitals were involved. However, the costs incurred by the private sector were higher. The aim of this study was to determine the cost effectiveness of implementing the DOTS (Directly Observed Treatment Shortcourse) strategy in private hospitals. A comparative study was carried out for six months, along with a retrospective cohort study between Public Health Centers (PHCs), DOTS hospitals, and non-DOTS hospitals, using 36 samples per group. The calculations of societal perspectives mentioned in Indonesian Rupiah (IDR) using micro-costing. The output was the success rate, which at the PHC hospital was 86.1%, at the DOTS hospital was 77.78%, and at the non-DOTS hospital was 63.89%. The addition of cost providers, especially human resources, at the PHCs and DOTS hospital increased their success rates. The societal cost of TB treatment in the PHCs was 42% that of the private hospital. The average cost-effectiveness ratio (ACER) showed that hospitals that carry out the DOTS strategy are more cost-effective than those that do not. To increase the TB treatment success rate by 1%, IDR 10,084,572 is needed in order to conduct a DOTS program intervention in a private hospital. An independent t-test showed that the cost effectiveness of societal perspectives on TB treatment was significantly different between the PHCs, the DOTS hospital, and the non-DOTS hospital.

Keywords: Cost-effectiveness analysis, DOTS, Private hospital, Success rate.

Introduction

Case detection rate (CDR) is an indicator of a tuberculosis program’s achievement. The 2016 Global Tuberculosis Report showed 77% and 46.5% in Southeast Asia. Indonesia reached a stagnant point in the last five years in the range of 32–33% (1), as did Depok City specifically, which was at 50–58%. In addition, yearly increases in cases of TB recurrence were observed, from 23 in 2014 to 177 in 2016 (an approximately 600% increase). The District Health Office needs to be vigilant because 12% of the MDR TB cases originated from TB relapses. WHO’s global strategy for discovering TB cases involves a non-government health service called Public-Private Mix (PPM), which has diagnosed 36% of the TB cases diagnosed outside PHC (1). PPM has been shown to increase the rate of diagnosing TB cases by up to 20% (2–4) which evolved from ‘Public-Private Mix (PPM)’. Reviono et al. (2017) mentioned that the CDR in central Java increased from 13% to 61.72% after 11 years of PPM implementation. A PPM strategy that involves private health service facilities in TB programs in Depok was activated in 2014 by conducting private health provider training in 10 hospitals and 18 private clinics. Although only four hospitals actively managed DOTS, these hospitals captured 18.7% of the smear-positive patients.
in Depok. Thus, the involvement of private parties in diagnosing TB should be encouraged. The aim of this study was to determine the cost effectiveness of implementing the DOTS (Directly Observed Treatment Shortcourse) strategy in private hospitals.

**Methods**

A comparative study was carried out for six months, between October 2017 and April 2018 along with a retrospective cohort study between Public Health Centers (PHCs), DOTS hospitals, and non-DOTS hospitals, using 36 samples per group. The calculations of societal perspectives mentioned in Indonesian Rupiah (IDR) using micro-costing. The output was the complete treatment rate (success rate) for an intermediate outcome. The inclusion criteria of this study were adult TB patients under Category 1 Anti-TB Drugs (ATD) treatment or a TB treatment plan for six months with no complications or other diseases. The exclusion criteria were patients who, at the time of observation, were found to have other diseases.

This study used primary data sourced from interviews with the respondents. Interviews were conducted three times with each patient; when they were first diagnosed with TB until declared cured, while secondary data were obtained from patient statuses and data reports of TB’s PHC program.

Patient costs consisted of direct costs and indirect costs. Direct costs were divided into the direct medical costs incurred by the patient to obtain health services (consultation fees, investigation fees such as sputum or X photo thorax examinations, and drug costs of both ATD and drug support) and non-medical direct costs, including transportation costs, meals, and other expenses. Indirect costs were the losses to a patient’s income due to their visit to the health provider.

The provider cost was calculated in 2017. Direct costs included fixed and variable costs. Fixed costs were calculated from the investment cost calculation and the DOTS clinic staff, and the room calculated the usage ratio with AIC (Annual Investment Cost), the inflation rate of 2017 by 4%, and the TCM tool grant price. Variable costs consisted of laboratory consumable grants. Indirect costs were the costs of the program, including the start-up costs (if any), honorariums, training, incentives, health promotion, coordination, and monitoring and evaluation.

## Cost Description | PHCs | Dots Hospital | Non-Dots Hospital
--- | --- | --- | ---
**Non-Medical Direct Costs**
a. Transportation Costs:
Registration | - | | 31.7 ± 22.2 (0–98)
Drug Taking | - | - | 34.3 ± 26.4 (0–98)
Medical Services | 59.6 ± 36.6 (0–190) | 109.7 ± 103.5 (29.2–440) | 76.7 ± 58.3 (34.4–296)
Transportation Costs Subtotal | 59.6 ± 36.6 (0–190) | 131.5 ± 97 (51.4–440) | 142.8 ± 87.3 (41.3–408)
b. Meal Costs, etc. | 47.3 ± 76.5 (0–323) | 24.3 ± 45.3 (0–195) | 71.4 ± 74.6 (0–210)
Non-Medical Direct Costs Subtotal | | | 155.8 ± 105.4 (57.7–551)
Indirect Costs | | | 214.3 ± 105.4 (84.1–568)
Total Cost of Patient | 1,238.9 ± 524.6 (484.3–2,928) | 2,946.6 ± 115.9 (1,518–5,031) | 3,434.2 ± 775.3 (2,033–7,892)

### Provider Costs

| Direct Costs: Fixed Costs |  |  | |
| Direct Costs: Variable Costs | 343.5 ± 58.8 (242.7–455) | 122.9 ± 18.7 (96.5–177) | 0 |
| Direct Costs of Provider | 409.1 ± 58.8 (308.3–520.7) | 150.2 ± 18.7 (123.8–204.2) | 1.9 ± 0 |
| Indirect Costs of Provider | 29.7 ± 0 | 6.3 ± 0 | 7.8 ± 0 |
| Total Costs of Provider | 438.8 ± 58.8 (338–550.3) | 156.5 ± 18.7 (130.1–210.5) | 9.7 ± 0 |

**SOCIETAL COSTS**

| 1,677.7 ± 529.8 (822.2–3,478.5) | 3,103.1 ± 550.4 (1,648–5,241) | 3,443.9 ± 775.3 (2,033–7,893) |

N.B: Cost in thousand rupiahs (IDR)

Direct medical costs were largely determined by the examiners. Significant differences are found in the ATD, other investigation costs, and the costs of drugs other than ATD. Most of the costs (80%) were inspection fees; thus, if the examination costs could be reduced, the medical costs would decrease. Application of the DOTS guidelines comprised only 28% of the direct costs of the patients, while the healthcare providers who had not implemented the DOTS strategy had 46% direct medical costs. This is in line with research in India and South Africa\(^7\)\(^8\) in which patient costs were higher when guidelines were not followed.

</tbody>
</table>
The average cost for the TB patients who recovered in PHC was 42% lower than those treated at the DOTS hospital. The non-DOTS hospital had 16.5% higher costs than the hospitals that applied the DOTS program. Table 2 also shows that more than 75% direct medical costs incurred to recover. There was no significant difference in the non-medical direct costs between the PHCs and the hospitals, which were about 5–7% of the total cost. At the PHCs, 50% of the costs were attributed to indirect costs or productivity losses.

</tr>
<tr>
<td>ACER</td>
<td>1,677,667/86.10 = 1,948,284</td>
<td>3,103,092/77.78 = 3,989,576</td>
<td>3,443,877/63.89 = 5,390,323</td>
</tr>
</tbody>
</table>

The lowest societal cost is PHC. Meanwhile, when the interhospitals were compared, the value of the ACER DOTS hospital was 35% lower than that of the non-DOTS hospital. Thus, it can be said that for hospitals that cooperate with the government by implementing the DOTS program, it costs IDR 3,989,576 per 1% increase in the success rate. However, in PHCs, which are the responsible programs in communities, each 1% increase in the success rate only costs IDR 1,948,284.

The results of the statistical (Levene’s) test showed that the data had a 0.703 variance ($p > 0.05$); thus, the normal distributed data under t-test analysis obtained a $p$ value $<0.05$ in terms of patient perspective ($p = 0.016$), perspective provider ($p = 0.002$), and societal perspective ($p = 0.001$). This means that there were significant differences in the cost effectiveness of the TB treatment at the health centers, the hospitals that use DOTS, and the non-DOTS hospitals in Depok City from 2017–2018 from the perspective of patients, providers, and society. This is in line with the research of Mahendradhata et al. (2010), who obtained a $p$ value of 0.01 but only analyzed the perspective of the patient.

### Discussion

When DOTS is applied comprehensively, a patient gains the confidence to follow up with their treatment at certain healthcare service facilities. They are getting enough information and treatment support (9,10). The advantages of private hospitals compared to public healthcare service facilities such as PHCs are their faster responses, greater time flexibility, and more complete service (11). Almost all research has suggested that the success rate for healthcare service facilities that run DOTS is higher than healthcare service facilities without DOTS (7,8,12). This proves that the management of DOTS in private healthcare service facilities can improve the success rate of TB treatment, and this is in line with Ramaiah and Gawde’s (2015) research in India. Even the success rate of healthcare service facilities with the DOTS program in India increased from 70% to 78% in 12 months (6). The success rate of non-DOTS hospitals in the current study was 63.89%, which is lower than a study in India that had a 68% result (6); however, it is higher than the cost effectiveness study for PPM programs in Vietnam and India, which both showed a 51% result (7). This is in line with the increase of Indonesia’s success rate in 2017 by 85%, though the DOTS method has not been run optimally.

The difference in the allocation of provider fees affects the improvement of the success rate. Around 24.39% of the societal cost at the PHCs is provider fees, while at the DOTS hospital, provider fees comprised 6.2% of the societal cost, and at the non-DOTS hospital, only 0.29% of the societal cost was provider fees. Most of the provider cost is used for the addition of human resources, and apparently, the addition of this cost becomes leverage for the increase in the success rate.

The ACER calculation for the non-DOTS hospital compared to the DOTS hospital was 35% higher, while research in Yogyakarta showed three times that difference (Mahendradhata et al., 2010). The results of this calculation are similar to the study conducted by
Floyd et al. (2011) in India, whereas the differences were only 72% and 92% of the study conducted by Ramaiah and Gawde (2015). Thus, the involvement of private healthcare providers in the management of TB programs should focus on using DOTS for the patient’s healing needs.

**Conclusion**

This study was a retrospective cohort study conducted for six months along with cost-effectiveness analysis: three PHCs that use DOTS, one DOTS hospital, and one non-DOTS hospital. A PHC that had implemented a DOTS strategy was used as a comparator. The results from 36 samples per group showed that the success rate of the PHCs was 86.1%, at the DOTS hospital was 77.78%, and at the non-DOTS hospital was 63.89%. The addition of the PHCs and DOTS hospital’s provider fees increased their success rates. The cost of the societal management of TB at the PHCs was 42% of the cost in private hospitals. From the ACER calculation, it was found that the hospitals that implemented the DOTS strategy are more cost-effective, as the ACER value at the PHCs was IDR 1,948,284, at the DOTS hospital was IDR 3,989,576, and at the non-DOTS hospital was IDR 5,390,323. A bivariate analysis revealed that there were significant differences in the cost effectiveness of societal perspectives on TB treatment at PHCs, DOTS hospitals, and non-DOTS hospitals.

Determinants of Nurse Quality Service in Jakarta Private Hospital

Bernadetha Nadeak¹, Sasmoko²,*

¹Lecturer, Educational Administration Department, Faculty of Post Graduate Universitas Kristen Indonesia, Jakarta, Indonesia, ²Professor, Primary Teacher Education Department, Faculty of Humanities, ²Researcher, Research Interest Group in Educational Technology, Bina Nusantara University, Jakarta, Indonesia 11480

Abstract

The quality of hospital services can be seen from the quality of services provided by nurses. This study aims to look at the factors that determine the realization of nurse service quality. The study uses the Neuroresearch method, a mixed method or alternative method used to obtain a truth in the field of social science. Data collection techniques used questionnaire instruments with a Likert Scale ranging from 1-5. Instrument calibration using Orthogonal Iteration with a trial sample of 30 nurses, r-criteria of 0.361. The study population was all nurses in private hospitals in Jakarta with a sampling technique in the form of cluster random sampling, which was chosen by all nurses from UKI, Jakarta, Tebet and Pluit hospitals. The study sample was 300 nurses. The results of the study were nurses who had a very good response to the patients who most determined the Quality of Nurse Service in a private hospital in Jakarta.

Keywords: Nursing, service, quality, neuroresearch.

Introduction

The quality of hospital services to patients is very important because of the nature of the hospital as the service itself. Most governments in developing countries are starting to focus on managing the improvement of the quality of services in health institutions by making infrastructure investments, one of which is given in the human resources section¹. Service itself cannot be separated from everyone in it, in this case a nurse. greatly determined by the quality of services provided by nurses. Because nurses are one of the front liner workers who have a greater chance to interact with patients than other health workers who work in hospitals². Research related to the quality of nurse care has been done because it triggered a question whether there were nurse staff able to provide effective and efficient care and how to measure and monitor this?³.

Before looking further at how nurses are able to provide optimal service quality, a study in Australia emphasizes the importance of understanding nurses’ perceptions of the quality of patient care⁴. On the other hand it is also necessary to have an appropriate understanding of the patient’s perspective about the quality of the nurse’s service as desired⁵.

One of the studies ever conducted in Indonesia to assess the quality of care for nurses is about the Length of Stay (LOS) from patients in the Emergency Department. This study resulted in a time study in identifying and measuring the factors that extend ED LOS. For hospitals in Indonesia there are still 26.9% of cases where nurses need more than the average LOS required.

With the phenomenon and the importance of the role of nurses in the quality of service in hospitals, this study wants to look at the factors that determine the nurse quality service of private hospitals in Jakarta.

Literature Review: Quality is a term that is often considered subjective because it has an intangible nature. The characteristics possessed by this term are difficult to define. So the definition given varies depending on the perspective and context of the term itself. Quality of service in the health sector is even more difficult to
define because it has characteristics that are intangibility, heterogeneity and simultaneity. Therefore the quality of services in the health sector depends on service processes and service providers 6–8.

In this study the dimensions that become a benchmark for the realization of nurse service quality are Tangibility, Reliability, Responsiveness, Assurance, and Empathy 9.

Tangibility is a service that has a physical form. Examples of tangibility are physical facilities, tools or equipment, the appearance of employees, and other customers.

Reliability includes consistency of performance and firmness in work. This factor is one form of appreciation for the customers owned.

Responsiveness is defined as the willingness or readiness of nurses to provide services. One example is timeliness.

Assurance is defined as a guarantee of the right knowledge, politeness and their ability to convey information with confidence.

Empathy is more interpreted by giving care to nurses to patients 9,10.

**Research Methods**

The research method with Neuroresearch as one type of mixed method. Neuroresearch is an alternative method used to obtain a truth in the field of social science11. The procedure in the Neuroresearch method is carried out through three processes: exploratory research (constructing theoretical constructs), explanation research (validity, trend analysis, and hypothesis testing) to find the most dominant indicators that determine the formation of Nursing Quality Services (NursQualServ_Y)12. Data collection techniques with Likert Scale questionnaire range from 1-5. Instrument calibration using Orthogonal Iteration with a trial sample of 30 nurses, r-criteria of 0.361. As a result, all items are valid and reliable at 0.956. The study population was all nurses of private hospitals in Jakarta. The sampling technique with cluster random sampling was selected by all nurses from UKI, Jakarta, Tebet and Pluit hospitals. The study sample was 300 nurses.

**Results and Discussion**

Test requirements analysis carried out by normality test and linearity test. Data normality test for Nursing Quality Services (NursQualServ_Y) variable using the proportion estimation Blom formula approach is Q-Q Plot, because the study sample > 200 nurses in Jakarta. As a result, the distribution of data shows normal because it does not have an outlier. And detrended data also do not form sine and cosine curves.

The linearity test is calculated by deviation from linearity, the line relationship between each exogenous variable, namely Tangibility (Tangibility_X1), Reliability (Reliability_X2), Responsiveness (Respons_X3), Assurance (Assurance_X4), and Empathy (Empathy_X5) with endogenous variables namely Nursing Quality Services (NursQualServ_Y). As a result, all relationships must be linear.

**The results of the first hypothesis:** The researcher determined 5 conclusion categories of conditions for the quality of care for private hospital nurses in Jakarta, namely: (1) very poor quality, (2) not qualified, (3) poor quality, (4) quality, and (5) very high quality. Data analysis was performed with confidence intervals at a significance level of α <0.05. The lower and upper bound result is 117.7511 and 119.8222.

Based on the results of the analysis it can be concluded that nurses in private hospitals in Jakarta tend to be of less quality service at α <0.05.

**The results of the second hypothesis:** The results of the second study analyzed the influence of each exogenous variable together, exogenous variables, namely Tangibility (Tangibility_X1), Reliability (Reliability_X2), Responsiveness (Respons_X3), Assurance (Assurance_X4), and Empathy (Empathy_X5) on endogenous variables namely Nursing Quality Services (NursQualServ_Y). The analysis was carried out with a binary segmentation approach, also called Classification and Regression Trees. In this analysis, researchers determined Depth Prunning of 2, Parent Prunning of 2, and Child Prunning by 1, with a significance level of α < 0.05.

The results of the analysis prove that the nurses who had a very good response to the patients (Respons_X3) predominantly determined the Quality of Nurse Service in a private hospital in Jakarta (NursQualServ_Y). This very positive and very good response (Respons_
X3) increases 62,260 times the quality of Nurse Service Quality in a private hospital in Jakarta (NursQualServ_Y). While this excellent response from nurses in Jakarta will be realized, if done consistently to the patient (Reliability_X2), because it will be able to increase 10,987 nurses’ responses to patients who are working in the hospital provided (Respons_X3).

**Conclusions**

This study provides several results. The first results obtained were that there was a tendency for the lack of nurses’ services in private hospitals in Jakarta. This means that nurses need to improve their physical appearance or skills in the use of facilities and equipment used to serve patients. Nurses also need to be more consistent in their work so that when serving patients it can be seen the nurse’s willingness or readiness to provide services. Nurses need to increase the right knowledge and be more polite in providing information. This certainly has an impact on the empathy of nurses who are not satisfying patients.

This study proves that nurses who have a very good response to the patients most determine the Quality of Nurse Service in a private hospital in Jakarta. Where a very positive and very good response is able to increase 62 times the condition of the Quality of Nurse Service in a private hospital in Jakarta that exists today. While the excellent response from nurses in Jakarta will be realized, if done consistently to patients, because it will be able to increase 10 times the nurse’s response to patients who are being treated at the private hospital.

It is also proven that service quality, especially nurses, can increase patient loyalty. Patient loyalty can be seen from how they recommend hospitals to others. Loyalty can also be seen from the patient’s return to the hospital as the first choice, and referring the hospital to the family.

Analysis of Clinical Pathway Implementation on Pneumonia Case in PMI Bogor Hospital

Musliyah Syahrawani Elsa1, Atik Nurwahyuni1

1Faculty of Public Health, University of Indonesia, Depok, Jawa Barat, Jakarta

Abstract

Background: Pneumonia is the largest infectious disease that contributes to the world child mortality. Around 16% from the death of under five-year-old child is caused by pneumonia. Since the era of universal coverage, the hospital is required to maintain quality control and costs in the form of clinical pathway. Furthermore, Clinical Pathway is one of the requirements that must be met in the hospital’s accreditation standards. The aims of this study were to evaluate the implementation of clinical pathway for pneumonia patients during the inpatient charge that consisted of length of stay, doctor visit, laboratory tests, medication, clinical practice and variation.

Method: Retrospective study was conducted on 73 pneumonia patients. The data and information were obtained from medical records and hospital information systems. In addition, the source of data was from the patient’s recapitulation which obtained from medical record by the medical report unit in hospital that consists of patient’s characteristic, length of stay, consultation, the laboratory test and radiology test.

Result: At first there were 73 pneumonia patients in six months, but there were only 5 patients that met the inclusive criteria. Sample’s characteristics consisted of 3 males (60%) and 2 female (40%) with the age of under five years old and the elderly. The length of stay was shorter with an average of 4.6 days (maximum 11 days and a minimum 1 days), compared with the length of stay of the clinical pathway (around six until seven days). The average of doctor’s visit regarding the clinical practice was about 1.4 times to the patient.

Conclusion: From six pneumonia clinical pathway indicators, there were 2 indicators that produced variances from the hospital practice which consist of laboratory tests and medication. These variances would contribute to the hospital’s expenses.

Keywords: Clinical Pathway, Pneumonia, Variance Analysis.

Introduction

About 16% from all the deaths of children under 5 years old were caused by pneumonia in 20151. Indonesia became one of the 15 countries that were estimated to have the highest number of new pneumonia2. The mortality rate in developed countries is low (<1 per 1000 per year). In developing countries, respiratory tract infections are not only more prevalent but more severe.

Coressponding Author**
Musliyah Syahrawani Elsa
Faculty of Public Health, University of Indonesia, Depok, Jawa Barat, Jakarta
e-mail Address: musliyah.syahrawani@ui.ac.id

Worldwide, lower respiratory tract infections accounted for nearly 800,000 deaths among children ≤19 years of age in 2015 (31.1 per 100,000 population), second only to neonatal/preterm birth complications3. Pneumonia is not only found in children under five years old but also in people aged 65 and over and who have other health problems. In United States, there are 915,900 episodes of pneumonia estimated in adults >65 years of age each year4. Since 2014, Indonesia has enacted Law No. 24 of 2011 concerning the Social Security Administration Agency (BPJS) which demands hospitals to provide quality control and cost control services5. To support this, one of the efforts that can be done by the hospital is to make a clinical pathway. Rotter’s study showed that clinical pathways have contributed to a decrease in the length of stay, a reduced risk of re-admission,
complications, and a reduction in hospital costs. In addition, the study of the Clinical Pathway Implication Effect on the total cost of hospitals in Thyroidectomy and Parathyroidectomy patients showed a decrease in Length of Stay (LOS) in patients that were given services according to the clinical pathways, as well as in average for the costs per case. Furthermore, Clinical Pathway is an important part in realizing Good Clinical Governance in hospitals and is one of the conditions that must be met in the RS Accreditation Standards 2012 KARS version.

The aim of this study is to evaluate the implementation of pneumonia clinical pathway in PMI Bogor Hospital by knowing the description of variations in the output (in compliance with the implementation of clinical pathway).

**Method**

This study used a quantitative method with retrospective analysis from medical records and hospital information systems from October 2016 to March 2017. There were 73 patients diagnosed with pneumonia and then re-selected based on the inclusion criteria of pneumonia with no comorbidities and inpatient patients. The number of cases that met the inclusion criteria was 5 patients. The Clinical Pathway developed at PMI Bogor Hospital was Pneumonia with no comorbidities with ICD-10 code, J18.9.

The source of data was from the patient’s recapitulation which obtained from medical record by the medical report unit in hospital consisted of patient’s characteristic (age, sex, payment method, and inpatient room type), length of stay (duration in days between admission to discharge date), consultation (frequency of doctor specialist’s consultation), the laboratory test and radiology test. Moreover, there was medication data that were collected from the billing unit in the form of drugs name and their frequencies of usage. That medication data was classified into several classes of drugs using ISO (Identifikasi Standar Obat) such as Antibiotic, Analgesics, Antiemetic, Anti-inflammatory, Bronchodilator, Mucolytic, Antihistamines, Anti-hypertension, Antiseptic and Digestive system. All the variance and clinical data were analyzed using Microsoft EXCEL software while statistical analysis was carried out using Clinical Pathway Evaluation Tools version beta 2.6 software. Data were analyzed using descriptive statistics and presented as average utilization then compared with the clinical pathway standard.

**Result**

At first there were 73 pneumonia patients in six months but there were only 5 patients that met the inclusive criteria. Sample’s characteristics consisted of 3 males (60%) and 2 female (40%) with the age of under five years old and the elderly. Three of them had completed the pathway until getting better while two others were dead during hospitalization. All of the samples used the National Health Assurance as the guarantee for hospital care. The patients were cared in class I (20%), class II (20%), class III (20%) and ICU (40%).

Source: Data Analysis

The data shows that the hospital length of stay was shorter with an average of 4.6 days, compared with the length of stay of the clinical pathway (around six until seven days). However, there was one patient who deserved to be taken care of for more than six or seven days. The average of doctor’s visit regarding the clinical practice was about 3 times by the specialist doctor and 0.8 by the doctor to the patient which meant that it had fulfilled the clinical pathway standard. Based on the clinical practice, there were 12 types of laboratory test that had been given to the patient which consist of 5 tests written in clinical pathway document and 7 variance tests.
In addition, medical support and monitoring the patient by the physician and nurse such as monitoring vital sign and nebulizer were utilized in about 0.2 and 0.4 respectively. It means that monitoring was not applied to all patients each day during treatment period. As medical support and monitoring, the radiology usage was only 0.6 which meant that this test was not applied to all five patients. At the end, there was one more variance that was applied to the practice, which was the medication. According to pneumonia clinical pathway, medication consisted of antibiotics, analgesic, antiemetic, anti-inflammatory, bronchodilator, mucolytic and antihistamines. There were three kind of variances and the biggest medication variances was anti-hypertension (utilization = 7.6). The other medication variances were antiseptic and digestive system of about 0.4 and 1.4 times respectively. Furthermore, it was considered that the medicine utilization would also impact the price. Table 3 showed that the price would be decreased around ten thousand rupiahs for every type of medication if the variance can be eliminated.

**Discussion**

Pneumonia clinical pathway in this hospital was designed without considering the payment types such as private, private insurance or universal coverage, and inpatient room classification. Among five patients, there was only one kind of payment, which was universal coverage. That was usual because it had been enforced since 2014 and BPJS users kept increasing over the years. There were six different types of inpatient room, which were class 1, 2, 3, VIP, VVIP and ICU at PMI Bogor Hospital. The distribution of patients according to room care is shown in table 1.

Pneumonia is generally diagnosed based on a history of typical symptoms, abnormal breath sounds that can be heard with a stethoscope, a chest radiograph showing characteristic shadows, and, sometimes, laboratory tests. The Clinical Pathway document manages that characteristic shadows, and, sometimes, laboratory be heard with a stethoscope, a chest radiograph showing of typical symptoms, abnormal breath sounds that can be given a clinical assessment, while the radiology (Ro Thorax) and the laboratory test (complete blood count, Oxygen Saturation (SpO2), ECG, and Sputum Gram Stain) should be tested in the first day of hospitalization. The Ro Thorax had been implemented to most of the pneumonia patients but only a fifth of them that met the clinical pathway standard, which was to be tested in the first day.

In addition, after the patient is diagnosed with pneumonia, the doctor may recommend some laboratory test to ensure about the immune system, bacterial infection, complications and others. The clinical pathways listed seven types of laboratory test which are Blood Test, Pulse Oximetry, Erythrocyte Sedimentation Rate, Arterial Blood Gas, Electrocardiogram, Sputum Test, and Pleural Fluid Culture Pneumonia. Along all the samples, unfortunately, from 8 kind of laboratory tests in pneumonia clinical pathway document, only five that had been tested by the hospital and 3 others were not implemented, especially the ECG which is really important as a part of the clinical assessment and should be tested in the first day of inpatient period. For further details, the CP said that the compulsory laboratory tests of pneumonia are Blood Test, Electrocardiogram, and Sputum Test which should be tested in the first day of inpatient period. In fact, the data described that about eighty per cent of data had met the CP standard but half of them overused the blood test which was tested around two or five times during the period. There was a finding that concluded that the useful diagnosis for pneumonia was by using the erythrocyte sedimentation rate (ESR), leucocyte count, and C-reactive protein (CRP) \(^{10}\)

Treatment of pneumonia depends on its likely cause and how ill the person is. The usual approach is to give effective antibiotics against the most likely bacteria causing the infection. In theory, based on the CP document, there are three kinds of medicine that should be given to the patient which are Empiric Antibiotic, antibiotic related to the bacteria, and symptomatic. However, the data explain that around 22% of the drug types (including three groups of medicine, such as Anti-hypertension, Antiseptic and Digestive system) which were given are not the medicine for pneumonia. In other words, it is not classified in the Pneumonia Clinical Pathway or the variance of care in this hospital. Moreover, about 78 per cent of drugs were known as antibiotic and seven groups were symptomatic.

**Conclusion**

From six pneumonia clinical pathway indicators, there are 2 indicators that produce variances from the hospital practice, which consist of laboratory test and medication. Laboratory and radiology tests are needed for ensuring the diagnostic and supporting medical service. However, there were several unimportant laboratory tests that were given to the pneumonia patients. There was an overuse of complete blood count,
Creatinine, and urea tests in patients with pneumonia. Moreover, the creatinine and urea are not considered as the part of clinical pathway assessment and of course it can impact the hospital’s expenses. In addition, three medication variances, which are anti-hypertension, antiseptic and digestive system, are considered as unnecessary care and would contribute to the hospital’s financial expenses. In fact, the hospital should manage to maintain the expenditure but still keep their quality of care, especially because the INA-CBGs pricing policy for private hospital has been implemented. To prevent the unbalanced cost between the practice and INA-CBGs pricing policy, the evaluation of pneumonia clinical pathway implementation is essential to maintain the quality and cost of hospital services.

Abstract
Servant motivation is a basic thing that must be owned by medical personnel as a profession that prioritizes service. This research wants to see how servant motivation of medical personnel is affected by servant training and leadership style. The study used a correlational survey method with neuroresearch. The results of the study indicate that the role of leaders who have the character of service will increase the effectiveness of training which will ultimately have an impact on servant motivation of medical personnel.

Keywords: Hospital medical personnel, servant motivation, training, servant leadership.

Introduction
Motivation is an important aspect for health care workers who work in hospitals. Motivation becomes a factor that is relevant to the quality of work so it needs to be interpreted fundamentally because there is an increase in demand and challenges in the field of health care 1,2. Various studies have been conducted to carry out an analysis of motivation among medical personnel. One study found that intrinsic work motivation of medical personnel in several public hospitals in the Netherlands was more determined by the elements of work that made the work they did challenging and valuable so that they could improve skills, autonomy, social contacts and opportunities for learning 3,17.

An experiment tried to compare the motivation and impact of training. And to obtain the optimal effect, high interpersonal effectiveness is a determining factor for the success of employees as individuals and as part of the team 4. Training as a learning transfer process has a significant relationship to motivation, where motivation will increase with the implementation of training that is appropriate to the needs 5,6.

For institutions engaged in health services, increasing the motivation of medical personnel and providing appropriate training will be more optimal when there is support from leaders, especially leaders who have a spirit of service. Servant leadership has a picture of a leader who combines their motivation to lead with the need to serve so that a serving leadership is realized.

Therefore this study aims to see the influence of servant leadership and implementation of training on servant motivation of hospital medical personnel in Jakarta.

Literature Review: Motivation theory shows the degree to which one hopes to achieve success so motivation arises as a need to achieve success and avoid failure 7-9. In terms of health services, the success in question is the success of medical personnel in providing quality services to their patients. The key to providing motivation and increasing motivation, including through efforts and the right way in accordance with the needs of medical personnel for example with training 10.

Training as a form of intervention is most often used to develop human resources including medical personnel in a hospital. The effectiveness of training is greatly influenced by trainees and the role of leaders. Trainees

and leaders will help the knowledge transfer process and the ultimate goal of training can be achieved.

Training must begin with an introduction to training needs so that they can be adapted to work requirements and performance appraisal. This can run optimally when the training is also part of the leader's responsibility. Character leaders that are appropriate for the field of medical services are leaders who have a soul of service or commonly called servant leadership.

Servant leadership has several basic characters. The first is the ability to listen. These leaders are valued because they have good communication skills so they are the basis of their decision-making. The second character is empathy. Servant leaders will strive to understand and develop empathy with others. The third character is healing. These leaders have the power to heal themselves and relationships with others who experience emotional wounds. The fourth character is awareness. Awareness of him is an important part of these leaders. This ultimately appears in their awareness in helping others to understand various problems. Another character is that this leader also has a high spirit of persuasion, is able to conceptualize well, foresight, stewardship, commit to the growth of others and has the ability to build community.

Research Methods: The research method with a correlational survey is then equipped with Neuroresearch as one type of mixed method. Data collection techniques for 3 variables used a Likert Scale questionnaire ranging from 1-5. The study population was hospital medical personnel in Jakarta. Sampling technique with simple random sampling.

Results and Discussion: Test requirements analysis carried out by normality test and linearity test. Servant Motivation variable (ServMot_Y) data normality test using the proportion estimation Blom formula approach is Q-Q Plot, because the study sample is > 200 medical personnel. As a result, the distribution of data shows normal because it doesn't have an outlier. And detrended data also do not form sine and cosine curves.

The linearity test is calculated by deviation from linearity of the line relationship between each independent variable, namely servant leadership (X1) and training (X2) to Servant motivation (Y).

Based on results, it can be concluded that the relationship of the lines of each independent variable with the dependent variable are all linear.

The results of the first hypothesis: The researcher determined three categories of conclusions: Servant motivation for medical personnel (Y): (1) very low motivation, (2) low motivation, and (3) high motivation. Data analysis was performed with confidence intervals at a significance level of $\alpha < 0.05$. Lower and upper bound results are 56.5716 and 59.7284.

Based on the results of the analysis it can be concluded that medical personnel tend to have significantly lower motivation servants at $\alpha < 0.05$.

Results of the second hypothesis: The researcher set 3 categories of conclusions on the condition of medical personnel’s assessment of the leadership leadership of the hospital (X1), namely: (1) leadership in the hospital was not as expected, (2) leadership in the hospital was not as expected, and (3) leadership in the hospital it was so strong that it supported the advancement of medical personnel. Data analysis was performed with confidence intervals at a significance level of $\alpha < 0.05$. Lower and upper bound results are 58.1031 and 61.2469.

Based on the results of the analysis it can be concluded that hospital medical staff tend to assess the leadership of the hospital leadership as not as expected significantly at $\alpha < 0.05$.

The results of the third hypothesis: The researcher determined 3 conclusions categories of conditions for the assessment of medical personnel on hospital training (X2), namely: (1) training in the hospital was not as expected, (2) training in the hospital was not as expected, and (3) training in hospitals it is very relevant to support the careers of medical personnel. Data analysis was performed with confidence intervals at a significance level of $\alpha < 0.05$. Lower and upper bound results are 59.2215 and 62.2035.

Based on the results of the analysis, it can be concluded that hospital medical personnel tend to assess the training held by hospitals as not as expected significantly at $\alpha < 0.05$.

The results of the fourth hypothesis: The results of the fourth study are by analyzing the influence together from each independent variable, namely servant leadership (X1) and training (X2) on Servant motivation (Y). The analysis was carried out with a binary segmentation approach, also called Classification and Regression Trees. In this analysis, researchers determined Depth Prunning of 2, Parent Prunning of 2,
and Child Prunning by 1, with a significance level of $\alpha < 0.05$.

The results of the analysis prove that the assessment of medical personnel on training held by hospitals is the most dominant in determining the formation of Servant motivation ($Y$) for medical personnel. A very positive and correct response to hospital training ($X_2$) was able to increase 18,729 times the condition of Servant motivation of hospital medical personnel ($Y$). Whereas a very good response to the training held by the hospital ($X_2$) is very much determined by its assessment of the style of the hospital leadership ($X_1$), because it will be able to increase 12,633 times the response of medical personnel to hospital-organized training ($X_2$).

**Results of the fifth hypothesis:** The results of the fifth study are by analyzing the effect together of the indicators forming the servant leadership variable ($X_1$), namely ($L_1$ up to $L_{15}$) and the forming of Training variables ($X_2$) namely ($T_1$ up to $T_{15}$) on Servant motivation ($Y$). The analysis was carried out with a binary segmentation approach, also called Classification and Regression Trees. In this analysis, researchers determined Depth Prunning of 2, Parent Prunning of 2, and Child Prunning by 1, with a significance level of $\alpha < 0.05$.

The results of the analysis prove that the positive assessment of medical personnel on the opportunity for self-development by the hospital ($T_{13}$) is the most dominant in determining the formation of Servant motivation ($Y$) for the medical personnel. A very positive and correct response to the opportunity for self-development in the hospital ($T_{13}$) was able to increase 22,741 times the condition of Servant motivation for hospital medical personnel ($Y$). While a very positive and correct response to the opportunity for self-development in the hospital ($T_{13}$) is very much determined by the medical staff’s self-assessment of the relationship with the hospital leadership ($T_{15}$), because it will be able to increase 5,033 positive responses to the opportunity to develop themselves medical at the hospital ($T_{13}$).

**Conclusions**

The results of the study show that servant motivation is not something that is easy to be possessed even by medical personnel. This is influenced by their perceptions of leaders and the implementation of programs that do not suit their needs.

Hospital medical personnel who tend to judge the leadership of the hospital leadership are not as expected, being less motivated because they lack the right support for their personal development.

Therefore it is important for hospital management to manage human resources by understanding the motivations and various factors that influence them in depth so that leaders can apply the service values they have through the programs provided.

The Role of Environmental Leadership and Personality on VBN Model

I Made Putrawan¹, Lisa Dwi Ningtyas²

¹Professor at Department of Biological Education, Faculty of Math & Sciences, ²A Master Student in Educational Evaluation and Research, Postgraduate Studies, State University of Jakarta

Abstract

The Value-Belief-Norm (VBN) model found and developed, since 1994, by Stern & Dietz. The objective of this research was to find out whether Instructional Environmental Leadership (IEL) and Environmental Personality (big/five EP) could positively contribute and have the role in affecting Value-Belief-Norm (VBN) model. A causal survey used by selecting randomly 209 senior high schools. There were six valid and reliable instruments developed for measuring IEL, Values Orientation (VO), NEP, EM, and PEB. Data analyzed by path analysis through multiple regression. Research results revealed that IEL only directly affected students’ PEB, but IEL did not have any role in the VBN model. The model itself was not complete since personal norm/moral (EM) did not affect significantly on students’ PEB, compared to VO which directly affect NEP then NEP affects EM, so EM was not good mediated variable. It could be concluded that personality (EP) was the best factor in influencing VBN model indicated by its direct and significant effect on VO, NEP, and PEB, except on EM. If the new model could be built, therefore variables such as environmental personality, values orientation, especially altruistic orientation, the New Environmental Paradigm should be taken into consideration by building new model called PVBN (Personality-VBN). However, the role of leadership could not be neglected since the VBN model was aimed at improving pro-environmental behaviour (PEB) as one of the efforts in saving our planet.

Keywords: Value-Belief-Norm (VBN), Pro-environmental Behavior, Environmental Personality, Environmental Moral, Path Analysis.

Introduction

There are plenty of studies related to environmental issues which focus on environmental behavior. Why behavior? It was argued that whatever the individual level of education, social and economic status, their behavior toward the ecosystem was assumed to be not friendly. Most of the studies associated these phenomena as brought about individual belief, perception toward the environment, their attitudes, their personality intention to act, values, norm, moral, and finally human behavior. It was called a variety of terms such as pro-ecological behavior, responsible environment behavior, environmental protection behavior, citizenship behavior, or only behavior intention (Stern, et.al., 1999, Hines, 1987, Hungerford, 1990, Valentin, 2013, Chang, 2015), especially for Markle (2013) has validated pro-environmental behavior (PEB) found its reliability range 0.62 - 0.74.

Nevertheless, all environmental research conducted in order to look for whether it was right that environmental problems currently brought about by human behavior. Since Stockholm conference (1972) and followed by sustainable development concept (1987/1988) and several meetings to save our planet held around the world, but carbon emission, deforestation, ozone depletion, greenhouse effect, etc. could not be slowdown, indicated by climate change (read Gibson, 2019) That was why, most of the environmental research directed to study about human behavior, one of them called Value-Belief-Norm (VBN).

Needless to say, the problem is, since VBN model has a strong interrelationship among variables and
sociologically/psychologically its subject would be a human being, do leadership, in this case, environmental leadership and personality have an important role at the model?

Garling and Jacobson (2003) have tested the VBN model and found that social altruistic was more than egoistic in term of as a causal effect on pro-environmental behavior. Schultz ((2001) found that there was strong distinction between altruistic, egoistic and biospheric environmental concerns based on theory of environmental attitude derived from Stern, et.al. (1999) Another research conducted by Snelgar (2006) which used SEM found that all closely lead to egoistic such as human or anthropocentrism concern than biospheric concern (as general altruistic).

This VBN model (see fig. 1) has been successfully explained recycling behavior, community contribution in gardening activities, evaluated toward the pharmaceutical company in implementing SD, evaluated also on people land management, etc. Steg (in Stern, 2000) has tested the VBN model which found that all variables involved significantly as a causal chain indicated by its relationship among variables. Currently, this VBN model has been so far studying its interrelatedness among (altruistic, biospheric, dan egoistic), moral (personal norms), (NEP) as behavioral predictors. VBN has been widely studied and validated and its postulate has also been tested which stated that a causal chain which involving all variables relationship was highly significant (p < .001, Stern, et.al.,1999, Stern, 2000).

Research conducted by De Groot & Steg (2007) found out that there was a relationship between value orientation with behavior specific value in those five countries and these values were useful in studying environmental relevant behavior. Their research also showed that all three values (biospheric, egoistic, altruistic) instruments were valid and useful in investigating the relationship between values, belief, and intention related to environmental significant behavior (De Groot & Steg, 2008).

Yu & Yu (2017) proposed big-five personality put as a moderator in his model, actually a modified VBN model, between values sustainability, environmental concerns, the social norm with environmental attitudes/NEP. According to Ogunbode (2013), personality factor should be considered when the NEP scale could be developed. Pro-environmental behavior would be improved, factors such as environmental awareness and pro-ecological view or NEP should be paid attention by program developers (Pavalache & Cazan, 2018). Gifford dan Nilsson (2014) found that environmental behavior affected by around 18 personal and social factors and one of them is personality. Moreover, Kvasova (2015) explained that big-five personality factors such as Agreeableness, Conscientiousness, Extraversion, and Neuroticism, positively correlated with tourism pro-environmental behavior. In predicting environmental concern, agreeableness and openness, from big-five personality have strong contribution and weak relationship found from conscientiousness and neuroticism (Hirsh, 2010).

In sum, meta-analysis results conducted by Bamberg & Moser (2007), showed that Hines et.al. (1986/87) model could be extended by including all other psychosocial such as attitude, behavioral control personal moral.
norm, social norm, and awareness, could be a significant predictor of pro-environmental behavior. Instead, Gifford & Nilsson (2014)\(^8\) found that a combination of personal and social factors undoubtedly as a determinant of environmental outcomes, it could be environmental behavior.

**Research Methodology:** The purpose of this research was to find out whether environmental leadership and personality could be built into VBN model developed by Stern, et.al. (1999)\(^9\) as antecedent factors directly on values orientation and other chain causal variables. A causal survey used in this research by selecting randomly 209 senior high school students. There were six valid and reliable instruments developed to measure Instructional Environmental Leadership (IEL= X1), Environmental Personality (EP=X2), Values Orientation (VO=X3) which consisted of Biospheric (B), Egoistic = E, and Altruistic = A, the New Environmental Paradigm (NEP= X4), Environmental Norm/Moral (EM=X5), and Pro-environmental Behavior (PEB= X6). Its reliability respectively as follows, for IEL was 0.838 (9 items), EP was .715 (19 items, 2 was not valid), VO was 0.823 (24 items, B was 0.694; E was 0.531, and A was 0.606), NEP was 0.810 (21 items), EM was not reliable, and PEB was 0.587 (17 items, 3 items was not valid). Data analyzed by path analysis based on multiple regression and correlation.

**Results and Discussion**

It was not surprising when all of the computation results interpreted, since almost all the research findings supported the VBN model, even it has been modified. There were three critical things which need to be argued found from this research, compared to other findings, first, environmental moral or norm was not proven to be good mediated variable as shown by the model and not significantly affect directly on pro-environmental behavior (PEB).

Bamber & Moser (2007)\(^2\) interpreted that personal norm/moral was good as a mediated factor on behavioral intention before indirectly influenced on PEB. This is one of the reasons why from this finding found moral was not a good mediated factor, so it is suggested to include a behavioral intention for further research. Secondly, instructional environmental leadership (IEL) only has a significant and direct effect on PEB, and fortunately, PEB was significantly affected by environmental personality (EP) as well, so the presence of this IEL at VBN model could be considered. Third, value orientation (VO) was contributed significantly merely by altruistic orientation, the same with what has been found by Aguilar-Luzon, et.al. (2012),\(^1\) not even by biospheric or egoistic (see fig. 2 below).

![Empirical Exploratory VBN Model](image_url)

*Fig. 2. Empirical Exploratory VBN Model X1=Leadership; X2+Personality; X3=Values Orientation; X4= NEP; X5=Moral/Norm:X6=Pro-environmental Behaviour B=Biospheric; E=Egoistic; A=Altruistic (* p < .05; **p < .01)*

When Yu & Yu (2017)\(^23\) put big-five personality as a mediated factor between values orientation (VO) and New Environmental Paradigm (NEP), based on this finding showed that indirect effect of VO on NEP through personality was not significant (0.076). Among those three variables could be built a triangle model which personality directly and significantly affect VO and NEP and VO also directly affect NEP. From this model, it could be stated that personality was not a good mediated factor, it was valued orientation, empirically was good and significant mediated variable (its indirect effect was 0.263) which bridging between personality and students’ NEP. Then, it was also a significant indirect effect of value orientation or concern on environmental moral/norm through NEP (0.104).

Based on this finding, undoubtedly that personality, in this case, environmental personality (big-five personality) indirectly affect also on environmental moral/norm through values and NEP. Moreover, personality also directly and significantly, together with leadership, affect pro-environmental behavior. Therefore, considering these findings, both instructional environmental leadership and also personality strongly support and contribute to the VBN model, even though
environmental moral, empirically, was still weak as a mediated factor on pro-environmental behavior. Nevertheless, since the main objective of the VBN model was to improve environmental behavior to be more positive, both variables, instructional environmental leadership, and environmental big-5 personality could be included in the model. Examine this following figure 2 which show that environmental moral/norm, empirically, did not have a role from this finding.

However, considering the role of leadership and personality, these findings supported by studies carried out by Afsar, et.al. (2016),26 Boiral, et.al. (2014),25 Gils, et.al. (2012),27 Graves, et.al. (2013),28 Gifford & Nilsson (2014),8 Harland, et.al. (2007),29 Hines, et.al. (1986),9 Kvasova (2015),12 etc.

Conclusions

Based on those findings and interpretation, compared to other findings, it could be concluded that the role personality, contributed strongly toward the robust of the VBN model, especially in trying to achieve pro-environmental behaviour to be more positive in order to save the only our one planet. However, the role of personal norm/moral is still questionable from this finding. It implied that the VBN model could be extended to be the PVBN (Personality-VBN) since leadership was not significantly affected values, NEP and norm/moral, it did affect simply on pro-environmental behaviour.

Environment and Commitment, Locus of Control and Intention to Act

Erian Fatria¹, I Made Putrawan²*, Guspri Devi Artanti³

¹Doctoral Student, ²Professor, ³Doctoral, State University of Jakarta, Indonesia

Abstract

This study was aimed at finding out the confirmatory information from the Hungerford and Volk (1990) model regarding the effect of personal investment, personal commitment, locus of control, intention to act, and citizenship behavior toward the environment. A survey method was used by involving 185 generation Z students as sample in this study. There were five instruments in this study for measuring citizenship behavior toward the environment (21 items, reliability .917), personal investment (28 items, reliability .947), personal commitment (30 items, reliability .938), Locus of control (30 items, reliability .923) and intention to act (24 items, reliability .945). Data was analyzed by descriptive statistical analysis, inferential statistics for linearity test and path analysis. The results revealed that citizenship behavior toward the environment significantly affected directly personal investment, personal commitment, locus of control and intention to act. Moreover, it was also found that citizenship behavior toward the environment significantly affected indirectly by personal investment and personal commitment through locus of control and intention to act. Based on those findings, it can be concluded that variations in citizenship behavior toward the environment of generation Z are affected by variations in personal investment, personal commitment, locus of control and intention to act. It means that locus of control and intention to act are suitable mediator variables for personal investment and personal commitment to citizenship behavior toward the environment.

Keywords: Personal investment, personal commitment, locus of control, intention to act, citizenship behavior toward the environment.

Introduction

Environment and humans are an integral and inseparable system in forming a relationship that affects each other. Humans have a dependency on their environment, both physical environment and social environment. The human perspective on the environment, makes humans the main subject in the order of the process of interaction with the environment. The global crisis that has occurred lately, can estimate how the views and patterns of human behavior interact with their environment. During this time the perspective put humans as the center of the universe (anthropocentrism).

The pattern of human behavior that is greedy in utilizing the resources possessed by the natural environment, further worsens environmental conditions to reach the climax of the environmental crisis. This behavior is owned by many people in the current industrial revolution era 4.0, so that the pattern of behavior of generation Z is a generation that is sensitive to environmental issues so that it orientates their pattern of action to wise behavior towards the environment. However, in reality, things are so different we find in generation Z in Indonesia, especially in Jakarta, where their behavior does not reflect wisely towards the environment such as shopping consumptively, reluctant to use recycled products, wasteful in utilizing energy and resources, less interested in action; action of environmental groups, and less concerned with biodiversity. It causes the environment to continue to be degraded both in quality and quantity. Therefore, this study uses the Hungerford and Volk (1990) model to determine the variation of generation Z citizenship behavior from predictor and mediator variables.
Hellen (2012)\(^1\) which provides a definition of the term generation Z known as the digital generation is a young generation that grows and develops with a large dependence on digital technology. Meanwhile Turner (2015)\(^2\) explains that generation Z is also called generation-I, net-gen, and digital natives, referring to community groups born in the mid-1990s to the end of 2010 who are familiar with technological advances in multimedia, such as tablets, smartphones, social media, and flat screen televisions, become accustomed to interacting and communicating in a connected world at all times. Even though the more often they use technology and social media, it will certainly have an impact on increasing consumption of energy sources (especially electricity). This example is one form of Generation Z behavior that is not wise to the environment.

Marin and Pear (1992)\(^3\) define that behavior is everything a person does that is a characteristic inherent in him and in general behavior is equated with activity, action, appearance, response, and reaction. As with the opinion of Santrock (2009)\(^4\), which defines that behavior is everything that humans do, both verbally and non-verbally, and can be directly seen or observed. To develop citizenship behavior toward the environment, Hungerford and Volk (1990)\(^5\) variable identifiers into three categories of variables that contribute to citizenship behavior, namely (1) entry level variables, (2) ownership variables, (3) empowerment variables.

In the behavior model flowchart, it can be seen the predictor variables of citizenship behavior toward the environment, such as personal investment in the resolution of environmental issues which are ownership variables. This means that this variable is essentially owned by someone personally related to his investment in providing resolution to environmental issues or problems. Waymond Rodgers and McFarlin \(^6\) state that, personal investment generally involves all current needs to predict a person’s long-term goals, using personal resources and considering various risks. This investment can be in the form of money, goods and others, the target category of personal investment is divided into three classes, namely maximizing returns, minimizing risk, and personal necessities. Furthermore, Maehr in Tappe (1992)\(^7\) states that personal investment is intended to imply the contribution or investment of individual resources into specific behaviors or actions and is based on subjective meanings of interrelated behaviors, and is a determinant in personal involvement to behave, subjective meanings here consists of categories of thoughts, interrelated perceptions and beliefs that are considered critical so that they reflect reciprocal interactions that occur between factors related to the person with environment and behavior.

Peter and Schmidt (2007)\(^8\) defines that, commitment is a practical reason possessed by someone who does not depend on profit or loss if he is going to take an action, which is manifested in the form of rational recognition and based on a sense of loyalty, fulfillment of duties, and obligations. Firat, Mul, and Wichelen\(^9\) stated that, commitment is often considered to imply a personal identity or position to achieve a goal, often considered a priority that is considered a virtue or quality that any intellectual needs to have. Furthermore Jeffery T. Ulmer (2000)\(^10\) stated that, personal commitment is determined by a variety of choices that encourage internal desire to continue a course of action, in other words, personal commitment refers to individuals who continue the flow of action because they define it as something they want, something they want they do. Furthermore personal commitment flows from three sources: (1) a positive attitude towards the flow of action, (2) a positive attitude towards others with someone who is involved in the course of action, and (3) self-definition in terms of identity mobilized.

Fishbein and Ajzen (2010)\(^11\) explain that one’s desires greatly determine a person’s performance or behavior. The stronger the intention or desire of a person, the more likely that behavior will be carried out. Previously Ajzen (2005)\(^12\) assumed that personal factors that influence the intention to act are: (1) individual attitudes toward behavior, namely positive or negative evaluations of individuals to perform certain behaviors; (2) subjective norms that relate to one’s perceptions of social pressure to do or not take into consideration the behavior; (3) perceived behavioral control such as self-efficacy or the ability to conduct attractive behavior, if people wish to behave when they evaluate it positively, when they experience social pressure to do so, and when they believe they have the means and opportunities to do it. Furthermore Fishbein and Ajzen (2010) explain that intention is the best single predictor for behavior, therefore people are said to do a behavior because they intend to do it, they have the necessary skills and abilities, and lack of environmental constraints to prevent them from doing their wishes.

Methodology: This research was conducted on a number of generation Z students born in 1995 -
There are five instruments used in this study, namely to measure citizenship behavior toward the environment (21 items rel .917), personal investment (28 items rel .947), personal commitment (30 items, rel .938), Locus of control (30 items, rel .923), and intention to act (24 items, rel .945). The technique was using multistage random sampling involved 145 generation Z students as the research sample.

The results of hypothesis testing show that: (1) there is a direct and significant effect of personal investment on citizenship behavior toward the environment; (2) there is a direct and significant effect of personal commitment on citizenship behavior toward the environment; (3) there is a direct and significant effect of locus of control on citizenship behavior toward the environment; (4) there is a direct effect of intention to act on citizenship behavior toward the environment; (5) there is a direct and significant effect of personal investment on locus of control; (6) there is a direct and significant effect of personal commitment on locus of control; (7) there is a
direct and significant effect of personal investment on intention to act; (8) there is a direct and significant effect of personal commitment on intention to act; (9) there is a direct and significant effect of locus of control on intention to act; (10) there are indirect and significant effects of personal investment on citizenship behavior toward the environment through locus of control; (11) there are indirect effects of personal commitment to citizenship behavior toward the environment through significant locus of control; (12) there is an indirect and significant effect of personal investment on citizenship behavior toward the environment through intention to act; (13) there is an indirect and significant effect of personal commitment on citizenship behavior toward the environment through intention to act; (14) there is an indirect and significant effect of locus of control on citizenship behavior toward the environment through intention to act; (15) there are indirect and significant effects of personal investment on intention to act through locus of control; and (16) there are indirect effects and significant effects of personal commitment on intention to act through locus of control. This means that citizenship behavior toward the environment of generation Z students is influenced by variations in personal investment, personal commitment, locus of control, and intention to act.

The results of this study are supported by other studies such as Davis, Green and Reed (2009) which reveal that individuals who have a greater level of commitment to the environment are also investigated to have better pro-environment behavior. Likewise, individuals who have a high level of sense of association with the environment produce better pro-environment behavior. Granzin, Mason and Bahn in personal investment theory assume that personal investment is the decision of people to devote a portion of themselves to a specific action by giving time, energy, and money to an activity because of the image or prospect of getting sustainable profits in the future front. Hwang, Kim, and Jeng (2000) state that internal locus of control can bring a person’s level of positive attitude, but attitudes do not affect intention to act. Ertz, Karakas, and Sarigöllü (2016) find perceived control to have an effect directly or indirectly on behavior, and this study also makes a strong statement that perceived power is a direct antecedent to Pro Environmental Behavior.

Asghar and Nazneen (2016) also explain that there are significant differences in environmental attitudes and conservation of adolescents, attitudes towards energy resources and behavior towards wild life. People with moderate locus of control have a much better attitude towards cleanliness and environmental and behavioral conservation of wild life. Mafabi et al. (2017) revealed that there is a positive and significant relationship between attitudes, subjective norms, perceived behavioral control and desire to behave, this implies that behavioral desires fully process planned behavior predictions. Ilie and Unianu (2012) explained that there is a significant relationship between internal locus of control and environmental attitude, therefore, it is important to grow internality so it is necessary for someone to reduce trust in the strength of others on various occasions.

**Conclusion**

Based on these findings, it can be concluded that if you want to increase the citizenship behavior toward the environment of generation Z, the predictor variables of personal investment, personal commitment, locus of control and intention to act need to be considered. So that environmental education activities can achieve the goal of forming environmentally responsible behavior, these activities should pay attention to strategies for building personal investment, personal commitment. Personal investment and personal commitment formed will then influence locus of control and intention to act as mediator variables and will ultimately develop generation Z citizenship behavior toward the environment.

To develop personal investment and personal commitment, the environmental education activities carried out need to provide opportunities for generation Z students to actively participate, learn various environmental issues through investigative activities, discuss moral aspects of the environment, and facilitate generation Z to conduct activities with the community and build cross-generation partnerships (baby boom, generation X, millennial and generation alpha). The generation Z whose note is the current generation and prospective leaders for future lives certainly has a big contribution in realizing the Sustainable Development Goals (SDGs) so that our environment can be saved and remain sustainable.

Abstract

The objective of the study was to evaluate psychometric properties of a scale which assesses job satisfaction of the administrative staff while working with their Higher Education Institutions (HEI). Data were obtained from 322 administrative personnels from various types of job categories and demographics. The instrumentation utilised the five-point Likert Scale in measuring administrative staff’s job satisfaction to their HEI. The exploratory and confirmatory factor analyses, reliability analysis were executed to investigate the measurement properties of the scales. The results indicated that the psychometric elements were in favour of the factorial structure of the administrative job satisfaction scale.

Keywords: Job satisfaction, administrative staff, higher education.

Introduction

This study of staff’s satisfaction provided imperative feedbacks on how contented administrative staff of the university or HEI felt and acknowledged being part of the university’s members. To scholars, the staff’s satisfaction also influenced and predicted their higher level of creativity and commitment to the university¹. Thus, staff’s satisfaction has been widely employed by previous researchers to indicate staff’s approval to their universities or their HEI. Recently, there are substantial studies conducted which measured academics’ job satisfaction within local context which tried to understand whether local academics obtained their certain level of job satisfaction while working or serving with their HEIs regardless of their public or private-based status. However, little research attention has been directed towards developing the administrative staff’s job satisfaction.

Numerous researchers have proved that university staff, whether academic or administrative, played an important role in realising the university’s mission and vision. Therefore, measuring their satisfaction has received remarkable attention from higher education researchers in ensuring whether their administrative staffs were highly satisfied in ensuring the smooth operation of a university. Nevertheless, most studies on HEI staff’s satisfaction focus on the satisfaction of the academics with fewer studies addressing the perspectives of the administrative staff even though they are also professionals that determine the smooth operation of the university, such as human resources, financial management, facilities and information technology²,³. Further, Smerek and Peterson (2007)² highlighted that most studies related to the administrative posts were mainly concerned with the academicians that hold the administrative roles, such as the department chairs and the academic deans. In fact, previous studies, such as a study by Volkwein and Parmley (2000)⁴ employed samples from the perspectives of, and feedback from, the university’s leadership and administrators and not the whole administrative staff of a public university. In the context of a Korean research university, Jung and Cheolshin (2015)⁵ conducted a study in examining administrative staff’s job satisfaction. Their findings revealed that their demographics, inner motivation, the work environments and the nature of their work -
specifically the clarity of tasks - were predictors of their job satisfaction including interpersonal skills of administrative staff. In addition, through the feedback of 486 administrative staff from three public and three private universities in Kenya, Kipkebut (2010) investigated administrative staff’s job satisfaction and organisational commitment which significantly revealed that employees from private universities were more committed to their universities and satisfied with their jobs than employees from public universities. Statistically, employees’ demographics, their professional commitment, role overload, supervisory support, job security, promotion opportunities, distributive justice and participation in decision making were significant predictors of their job satisfaction among administrative staff in Kenyan universities.

Admittedly, there are limited studies that examine administrative staff’s satisfaction within the context of public universities or HEI in Malaysia. In fact, there are limited studies conducted to develop a scale and evaluation of the psychometrics properties conducted in measuring administrative staff’s job satisfaction within Malaysian context of higher education (colleges and university). Therefore, the purpose of this study is to evaluate the psychometrics properties for administrative staff’s feedbacks towards their job satisfaction.

**Method**

**Participants:** This study randomly selected a sample of 322 administrative staff serving with their HEIs. The distribution of the administrative staff’s demographics is shown in Table 1. Based on Table 1, most of the serving administrative staff are female (Male = 130; 40.2 %; Female = 194; 59.4 %). As for length of working experience, a majority of administrative staff had 5 to 10 years’ experience (N = 85; 26.3%) followed by administrative staff who had less than 5 years of experience (N = 73; 22.6 %) and from 11 to 15 years (N = 61; 18.9 %). 44 administrative staff had 16 to 20 years of experience (N = 44; 13.6 %) with 16 administrative staff had 21 to 25 years of experience working with HEI and another 14 administrative staff had 26 to 30 years of experience and 30 staff had more than 30 years of experience. In terms of their academic qualifications, only two administrative staff had master degrees (N= 2; 6.0 %), 39 administrative staff obtained their bachelor degrees (N= 39; 12.1 %), 86 administrative staff had their Diploma academic qualification (N= 86; 26.6 %), 38 are holders of the pre-university certificates (N = 38; 11.18 %), 137 are the secondary school certificate holders (N = 137; 42.4 %) and 20 administrative staff have others academic qualifications (N = 20; 6.0 %).

N = 322

In terms of administrative staff’s working status, 285 (88.2 %) are permanent staff while 37 (11.5) are contract staff. A total of 109 (33.9) administrative staff are between 31 to 40 years old. While 33.7% are staff ages between 21 to 30 years old. Next, 71 (22.0 %) staff aged between 41 to 50 years old and followed by 42 administrative staff (13 %) are between 51 to 60 years old.

**The instrument:** A closed ended questionnaire with 23 items comprising constructs related to their job satisfaction was used. Attached with the 23 items were six items requesting demographic information such as their gender, working experience, age, academic qualifications and their age. All items are in the positive
expressions. Before proceeding with the questionnaire distribution, detected negative items were gone through the reversing process into the positive expression. All respondents were asked to give their reactions to the 23 items using a five-point Likert scale: 1 – strongly disagree, to 5 – strongly agree. Empirically, the 23 items have three sub-constructs which are: knowledge (2 items), the management process (15 items) and, lastly, escalation elements (6 items).

All items are in the Malay language and demographics indicate respondents are from Malaysian primary, secondary and tertiary education system. Some of the items are adopted from researchers that had studied administrative staff’s job satisfaction such as Jung and Cheolshin (2015) and Volkwein and Zhou (2003) all of whom significantly measured the administrative staff’s job satisfaction from various higher educational systems. All items had undergone a rigorous translation process that involved the forward and backward process of translation by two translators. A Malay language expert and some administrative staff were approached in order to ensure the precision of the Malay language items including the sentence structure, meaning and the measurement of grammatical elements. Items were also translated into English using a backward approach with the help of language experts. Before proceeding with the pilot study, items were checked by a small sample of assigned administrative staff to determine the precision of the meaning, sentence structure and even the relevance of the items to the Malaysian higher educational system.

Before proceeding with the actual data collection, a pilot study was conducted to ten selected administrative staff at a public university. All 10 administrative staff were eliminated from the actual sample for data collection. A vital reason for conducting a pilot study was to obtain the construct validity and reliability of all the items. Through the pilot study, the reliability value was measured at 0.872 based on the Cronbach’s alpha value from the initial pilot study with 10 administrative staff.

Data analysis: Before proceeding with quantitative data analysis, various measurements were taken. First, since some items were negatively worded, the reversing process of data insertion was executed during data analysis. Second, a series of exploratory factor analyses were performed to account for the variance of each dimension and to measure the sampling adequacy. Lastly, the measurement model of the administrative staff’s job satisfaction using the Structural Equation Modelling (SEM) approach was utilised to examine and predict the research university’s staff’s satisfaction.

Results and Discussion

Data normality tests: Based on the 23 items related to administrative staff’s job satisfaction scale, the data normality tests are examined, checked and presented in Table 2 below. Table 2 reports on the normality tests based on three elements of the administrative staff’s job satisfaction from responses provided by administrative staff of the HEI. From the output normality tests, the three studied normality test have skewness between –1 and +1 and there is no extreme value encountered in the checking process.

Correlational matrix: Two major tests were employed in analysing the 23 items that measure the knowledge, management process and escalation of administrative staff’s job satisfaction: the correlational matrix and the exploratory factor analyses. Initially, all the 23 items were assessed through the correlational matrix test which was presented in Table 3. On the basis of the statistical findings, the correlational values were between 0.234 and 0.651, which indicated a strong relationship between the three main constructs of the administrative staff’s job satisfaction. At the same time, the highest value was 0.72 (below 0.9), which indicated the least influence of multi-collinearity based on the three major constructs studied because the correlation values exceeded 0.25 and are below 0.95 values. Results from the correlational matrix (Table 3) indicated that the...
correlational matrix values implied good internal values of the items based on the four related constructs. Hence, all items that measured the administrative staff’s job satisfaction towards their HEI are internally consistent and strongly valid.

</tr>
</tbody>
</table>

In Table 4, all constructs related to administrative staff’s job satisfaction items were checked separately and presented. As for the management process construct, the total variance explained was at 45.044 % with eigen values of 10.360. In addition, the knowledge construct indicates a much lower total variance of 5.605 % and eigen values at 1.289. As for the escalation items, the total variance explained were noted at 10.299% with eigen values at 10.299. After the EFA analysis, an item labelled as KP 13 was deleted due to low value on its

**Exploratory factor analysis:** Subsequently, the exploratory factor analysis (EFA) with the varimax rotation procedure was executed to determine the factorial structure of the items. Through the EFA analysis, results demonstrated items on administrative staff’s job satisfaction had a consistency value higher than 0.30 (cut off value)\(^8,9\). As for the Kaiser-Meyer-Olkin result, the data indicate high values (KMO = 0.925; Approx. \(\chi^2 = 4984\)E3; \(df = 253; \) Sig = 0.00) and the total variance explained for the 23 items overall was 9.48 per cent. As a further measurement and checking on the items’ internal consistency, all items were tested separately.
factor loading (0.200) and communalities value \( (h^2 = 0.71) \). Therefore, only 22 items out of 23 items that have strong validity and consistency in measuring job satisfaction of the HEI administrative staff.

**CFA Measurement model:** In obtaining the structural validity of all items related to job satisfaction of the HEI administrative staff, a measurement model was established using confirmatory factor analysis. The measurement model was constructed using AMOS software. To ensure the internal consistency, the fit statistics indices were referred through the \( \chi^2/df \) Chi-square, the RMSEA (Root Mean Square Error of Approximation), the NFI (Normed Fit Index) and CFI (Comparative Fit Index) values.

In the CFA analysis, the chi-square value was noted at \( \chi^2/df = 4.680 \) with p-value of 0.000 which was significant. In addition, the fit index values were considered accepted with NFI = 0.871, CFI = 0.741. The RMSEA value was determined as 0.100. Figure 2 presents the measurement model based on the confirmatory factor analysis. Therefore, only 22 items were presented in representing the management process, knowledge, escalation for administrative staffs’ job satisfaction in Malaysian HEI.

**Discussion and Conclusion**

This study was an attempt to measure the psychometrics properties of administrative staff’s
job satisfaction which can be used in measuring the Malaysian administrative staff’s job satisfaction. To conduct the study, 322 randomly administrative staff were selected in obtaining their perceptions on their job satisfaction while serving their universities.

Statistically, 22 items that tested with three rigorous tools in determining its’ reliability and validity through the Cronbach’s alpha values, the Exploratory Factor Analysis (EFA) and the Confirmatory Factor Analysis (CFA) in evaluating the internal consistencies of the items of the questionnaire. Through the Cronbach’s alphas analysis, data indicated on high reliability on the 22 items studied. Further, items were analysed through the EFA analysis which two remaining purpose: clustering the items, extracted staff’s job satisfaction and percentage of variance that contributed to the items’ constructs. From the analysis, three factors were extracted which represented the clustering of job satisfaction among HEI administrative in Malaysian tertiary context. The final phase of the analysis involved the development of the measurement model through the CFA analysis. Based on the CFA model, all 22 have been chosen as the suitable revised items and model that represented job satisfaction of the HEI administrative staff with high and satisfactory values on fit statistics.

Admittedly, this study also has its limitation. Firstly, this study relatively used small sample size of 322 administrative staff from Malaysian HEI which can be replicate with much bigger sample size. Secondly, it is appropriate to use only one sample category in assessing these items due to the different preferences on the HEI’ culture and climate even their working condition which assumedly contributed to their job satisfaction. For instance, a study should only use all administrative from a university. To consider, items on the administrative staff’s job satisfaction could be adopted and useful in examining the reliability and construct validity from other positions such as the university and college’s librarians, and other relevance posts. As for future consideration, administrator’s gender and educational background should be considered in examining the job satisfaction while serving with their HEI. In addition, future qualitative research through interviews with administrative staff could be used as sources for triangulation purpose.

Reliability of Sullivan Emotional Intelligence Scale for Children in Malaysian Context Using Rasch Measurement Model

Nor Aizal Akmal Binti Rohaizad1*, Siti Nazilah Binti Mat Ali1, Azlina Binti Mohd Kosnin2, Aqeel Khan2, Norfishah Mat Rabi3, Norwaliza Binti Abdul Wahab3

1 Lecturer, School of Social and Economic Development Studies, University of Malaysia Terengganu (UMT), 2Lecturer, School of Education, Universiti Teknologi Malaysia (UTM), 3Lecturer, Faculty of Human Development, Universiti Pendidikan Sultan Idris, Malaysia (UPSI)

Abstract

Emphasizing only on intellectual intelligence without stressing on feelings and emotions could negatively affect an individual’s emotional development. Development of stable emotion regulation strategies is important for an individual to function appropriately in different contexts. Although there are many scales developed to measure emotional intelligence (EI), there is a dearth of instruments to measure EI in preschool children. One instrument that taps EI in preschool children is The Sullivan Emotional Intelligent Scale for Children (EISC). EISC was developed for use in the United States and there is no such instrument available in Malaysian context (to the best of our knowledge). The aim of the current study was to adapt EISC to measure Malaysian preschool children’s emotional intelligence. EISC was translated into Malay Language and the reliability value of the instrument was then tested using the Rasch Model. There are 50 respondents (preschool children) was random selected from the research area (Johor Bahru) which had same features with the real respondent for this purpose. The results show a high ‘item reliability’ of 0.94 and also a high ‘person reliability’ of 0.93 after distillations (37 out of 59 items retained). The results suggest that The Sullivan Emotional Intelligent Scale for Children (EISC), adapted for Malaysian children, can be used to determine the level of Malaysian preschool children’s EI with psychometric soundness.

Keywords: The Sullivan Emotional Intelligent Scale for Children (EISC), Malaysian preschool children, rasch model.

Introduction

Emotional intelligence has been defined as the ability to control, understand and use emotions to guide the way we think and act. Mayer and Salovey 14 have developed the concept of emotional intelligence to explain the importance of emotions in life. They defined emotional intelligence as the ability to identify one’s own and other people’s emotions as well as the ability to control and regulate one’s emotions 8, 9, 12, 11.

Research in the area of emotional intelligence has found significant findings relating the construct with various positive outcomes such as one’s health and well-being 3,2,16 adaptability to new life situation and better mental health 10 and higher mental abilities and positive personality attributes 6,17,1.

Studies on children have found that proper development of emotions is important for children because it is a regulation skill which promotes social behavior and positive learning 13, 20-22, thus creating a conducive learning environment of a preschool setting. Emotional intelligence enables children to form behaviors that benefit the learning process 19 such as following instructions, paying attention, listening and ability to solve problems with patience 5 thus show better academic achievement.

e-mail: aizal@umt.edu.my
Problem Statement: There are many measurement tools developed to assess the level of individual emotional intelligence. However, the most popularly used measurement tools of emotional intelligence are Bar-On Emotional Quotient Inventory, Schutte Self-Report Inventory, Trait Meta-Mood Scale, Multi-Factor Emotional Intelligence Scale and the latest is Mayer-Salovey-Caruso Emotional Intelligence Test. However, all these EI instruments have been developed with an emphasis on adult and therefore not suitable for children.

There seems to be a lack of measures of emotional intelligence for preschool children. Studies measuring children’s emotional intelligence have often made use of instruments either for adults, youths or older children but with the aid of adults in getting the children to understand the questions. For example Esturgo-Deu and Sala-Roca made use of the Emotional Quotient Inventory: Youth version (EQI-y) to measure the emotional intelligence of 6 to 10 year old children. Adults or older children were also involved to help the younger children in completing the items.

In an unpublished PhD thesis, Sullivan developed a scale of emotional intelligence for children by adapting Mayer and Salovey’s Emotional Intelligence Test (MSCEIT). The Sullivan Emotional Intelligent Scale for Children (EISC) taps the ability to identify, understand, control and use emotions. Its subsets include tests through face expression (20 items) and storytelling (eight items) for the ‘identifying emotion’ dominant also tests through understanding (12 items) and controlling emotion (nine items) and empathy (10 items). There seem to be very limited resources to verify the validity and reliability of the instrument. Nevertheless, a Turkish study translated the EISC into Turkish language and used the scale to measure Turkish children’s emotional intelligence and found the instrument to have strong reliability (alpha ranged between 0.97-0.99).

The present study aims to adapt and test the validity and reliability of Sullivan emotional intelligence scale for children (EISC) for Malaysian preschoolers for possible use in Malaysian context.

Method

The EISC instrument was translated from English language to Malay language using back-translation method. The researchers also changed some of the item statements to coincide with the situations that Malaysian children are more likely to encounter. Some of the stimulus face figures were also replaced with ones resembling Malaysian people. We also changed the response scale from three-option to two-option i.e. ‘yes’, ‘no’ and ‘I Don’t Know’ was changed to ‘yes’ and ‘no’ only because the response categories ‘no’ and ‘I don’t know’ are scored identically. Table 1 shows the examples of changed.

Participants of this study were 50 preschool children from Johor Bahru area of Malaysia. One of the researchers read each item to a participating child and asked questions present in the EISC (Malay version). Based on the Rasch measurement model, this sample size (50) is considered as sufficient to establish 99 percent confidence level for item calibrations stable within ± 1 logit. The children were then shown the response figures one by one and were asked “is this the right feeling?” and the child had to answer in either ‘yes’ or ‘no’ to every question posed.

A total of 59 translated items with dichotomous rating scale of either zero or one were used during the administration of the EISC. Zero represented ‘no’ and one represented ‘yes’. There are four domains in The Sullivan Emotional Intelligent Scale for Children (EISC) which has been adapted in Malaysian preschool children’s context. The first domain is ‘identify emotion’ which has two method of emotion recognizing, i.e. through face expression recognition (20 items) and storytelling (eight items). The second domain is ‘understand the emotion’ (12 items). The third domain is ‘control the emotion’ (nine items) and the last one is of ‘using the emotion’ (ten items).

Rasch Measurement Model was used to test the validity and reliability of the adapted EISC instrument. It is a measurement model that produces person and item separation indices as a result of the consideration that takes into account the ability of the respondents and item difficulty.
Findings: Data were analysed using Winsteps 3.68.2 and results are presented in several sections: Reliability and Separation Index, Item Polarity, Item Fit and Item Misfit, Residual Principal Component Analysis (PCA) and the last one The Result of Distillation.

Rarsch Dichotomous Model is used to measure Malaysian children’s emotional intelligence using the adapted version of Sullivan Emotional Intelligence Scale for Children as the scale for the items were dichomous (‘yes’ or ‘no’).

Reliability and Separation Index: Table 2 and Table 3 shows the statistic generated by Rasch analysis of EISC’s adaptation in order to determine the reliability of EISC’s adaptation test item instrument using Rarsch measurement model and to what extent the adequacy of separation index item instrument of the EISC’s adaptation test. The Rarsch model conforms to item separation index and person separation index and the item reliability and person reliability is shown from the statistic Table 2.

Real RMSE .85 ADJ.SD 1.15 Separation 1.35 Item Reliability .65, Model RMSE .78 ADJ.SD 1.19 Separation 1.53 Item Reliability .70, S.E. of Item Mean = .20

Individual separation index and items can be produces by Rarsch analysis. The number of strata capabilities identified in the sample group is indicates from the individual isolation index. The separation of item difficulty level can see from the item separation index. The value of individual isolation and the item which is more than the value of two is considered as good. The value of separation index > 2.0 is grade measurement system caused by only one or two observation, the value of between 1.5 and 2.0 is not productive for the development of measurement but not demeaning and values between 0.5 and 1.5 and the productivity measurement < 0.5 is less productive for measurement. According to the reliability value of > 0.8 were accepted as high value while the value of reliability between 0.6 and 0.8 and the value which is less than 0.6 is not acceptable for reliability.

Table 3 shows that the separation person measure index for the EISC’s adaptation construct as 1.75 which individual separation index for all construct indicate that the number of strata which measure the ability of individuals are on 2 standard errors. Table 2 shows that separation item measure index for the EISC’s adaptation constructs as 1.35 which mean person measure separation index indicates the number of strata that measured the ability of individuals on 1 standard error. The value of reliability which is more than 0.8 is acceptable and has strong value while value less than 0.8 which is less acceptable. The reliability person measure for the EISC’s adaptation constructs which shown in Table 3 are 0.75 and this constructs have the reliability person measures < 0.8 which is less acceptable. While the reliability item measure for the EISC’s adaptation constructs which shown in the Table 2 are 0.65 which is also there liability item measures < 0.8 and less acceptable.

Real RMSE .69 ADJ.SD 1.21 Separation 1.75 Item Reliability .75, Model RMSE .68 ADJ.SD 1.22 Separation 1.80 Item Reliability .76, S.E. of Item Mean = .22
**Item Polarity:** The validity of a questionnaire can be identified by referring to the analysis of the output program which can check from the polarity item so as to find a correlation coefficient of measurement-point which is known as point-measure correlation coefficient (PTMEA Corr). Rasch measurement model can generate the value of PTMEA Corr in the EISC’s adaptation test instruments.

A high PTMEA Corr means that an item is able to distinguish between the ability of respondents and a negative value or zero indicates that the link for the item response is in conflict with the variable or construct. Have several items which show negative value and zero of PTMEA Corr. The items are 10: A110, 29:B1A, 31:B1C, 37: B3A, 38:B3B, 39:B3C, 40:B3D, 43:C1C, 45:C2B, 55:D6 and 56:D7. Therefore, it can be conclude that has several items cannot be contribute to the measurement of EISC’s adaptation respondents. The items cannot discriminate or differentiate between different types of EISC’s adaptation held by the respondents.

**Residual Principal Component Analysis (PCA):** Table 4 shows a segment of principal contrast analysis of Rasch Principal Component Analysis (PCA) used to identify the uniformity of instrument dimension. The variance explained by measures is noticeably 33.10 percent which is not exceeding the minimum border of 40 percent that Rasch needed. However, the unidimensionality of the survey instrument is confirmed by a more likely to be good unexplained variance in the first contrast (10.1%) which is well controlled and quite far from the ceiling of 15 percent and this evidence further support the structural aspect of construct validity.

<td>0.61</td>
</tr>
</tbody>
</table>

PCA Variance Measured: 56.2% (33.1%), Unexplained 1st Contrast: 11.8% (10.1%)

Based on Table 5, the instrument has been refined to show the reliability characteristics better than before where the changes from 4.54 logic to 7.73 logic for a range of items. While for the person changes from 6.09 logic to 10.49 logic, it is shows an increase longer yardstick and encouraging for the item by 3.19 logic. The PTMEA Corr guideline show that higher increase at 56.2 percent which is over the minimum level of 40 percent needed in Rasch analysis. It is show that the clean instrument (EISC’s adaptive after distillation) has enough ability to measure of what supposed to measure.

**Conclusion**

Based on the result after distillations there are several items that need dropped and leaving 37 items from the 59 items. The clean instrument (after distillations) of Sullivan Emotional Intelligent Scale for Children (EISC) in Malaysian children context was found to be
having a higher value of reliability then the original one. This concluded that the adaptation scale after distillation can be used to measure the level of EI in Malaysian preschool children.

Online Trust: Examining Identity on Health Related Tourism Websites in Southeast Asia

Mohammad Ali Moslehifar¹, Noor Aireen Ibrahim², C. Sandaran³

¹Student, ²Senior Lecturer, ³Senior Lecturer, Language Academy, Faculty of Social Sciences and Humanities, Universiti Teknologi Malaysia, Malaysia

Abstract

Health tourism is the process of leaving one’s home country to travel to a destination country in order to seek medical treatment. In recent years, health tourism has seen a sharp growth, particularly in Southeast Asia. Fuelled with the role of internet to offer information about medical destinations, the trustworthiness of health tourism websites plays a crucial role in the decision-making process of tourist patients. Although trust has been examined in different areas, trust construction of health related tourism websites via the focal theme of identity is still at its infancy. This study examined the construction of trust on three health tourism hospitals in Malaysia, Singapore, and Thailand. The findings of this study revealed how trust is constructed via the central resources of identity. The findings have significant implications for website developers and health tourism researchers as well as providing key insights on trust construction.

Keywords: Health tourism, online trust, identity, health websites.

Introduction

Health tourism is known as the combination of activities which includes hospitality, cultural experience, and medical services when people leave their home country to seek medical treatment¹. High quality healthcare service with lower cost²³ is among the main reasons health tourism industry has seen incredible development with revenue expected to increase to $200 billion by 2020⁴. In Southeast Asia, Malaysia, Thailand and Singapore are known as the top health tourism service providers⁵. Malaysia and Thailand are known for quality healthcare services and qualified medical specialists; and Singapore for the short waiting time and advanced medical technology⁶.

The availability of information via the internet has encouraged tourist patients to seek information about destinations and the offered health services that meet their specific needs⁷. Among the available online resources, hospital websites play a crucial role in providing information about the medical treatment that patients seek⁸. In this sense, access to trustworthy information is key in attracting tourist patients⁹.

Trust is a notable phenomenon that helps tourist patients make decision without feeling fear¹⁰. Numerous studies have been conducted to address the concept of trust in different fields of social sciences such as business¹¹, computing¹², doctor-patient communication¹³, quality of health tourism websites¹⁴, significant effect of trust on medical tourists’ attitudes¹⁵. According to Candlin and Crichton¹⁶, trust is constructed through different focal themes, one of which is credibility. Each focal theme has specific dimensions and in the case of credibility, one of its central dimension is identity. Identity plays a key role in the process of decision making for tourist patients⁹. However, the construction of trust through the central dimension of identity in health websites has yet to be examined. Hence, this paper is interested to investigate trust construction via the central dimension of identity on the top ten health related tourism websites in Southeast Asia.

Online Trust and Health Tourism: In terms of the focal themes of trust, Candlin and Crichton¹⁶ proposed the following: credibility, expertise, identity, characterisation, capacity, recognition, relationship, purpose, agency, membership, risk, and responsibility,
which are twelve interconnected themes to construct trust. The concept of credibility has been identified as synonymous to trust and in other studies may refer to consistency and truth in relation to persuasive sources, message construction, and media perceptions\(^{17}\). Credibility is constructed through the dimensions of identity, which has the following key features: i) background, ii) history, iii) language, and iv) culture of an organisation Candlin and Crichton\(^{16}\). As such, when these four resources are made available, the information will be deemed trustworthy.

Online trust plays a significant role in ensuring better online communication among individuals, groups and organisations\(^{18}\). The lack of trust may lead to ineffectual communication, and unproductive working relationships\(^{19}\). Trust on health related tourism websites is crucial for consumers’ health decision making process\(^{20}\). In this context, Zucker\(^{21}\) believed that the identity of the parties involved can shape trustworthy expectation, which is the main focus of analysis in this paper.

Identity includes resources about locations, dates, names, roles, and relationships\(^{22}\), which in the perspective of Ronzhyn\(^{23}\) are useful components to construct trust. This is aptly pointed out by Perloff\(^{24}\) that the profile of an organisation offers an opportunity to consumers to learn about the identity of the organisation. Establishing the identity of organisations is largely based on the organisational relationship with consumers, supporters, and owners\(^{25,26}\). In addition, according to Wilcox\(^{27}\), providing evidences for institutional achievements are significant for identity construction as it is a testament of the knowledge of the organisations\(^{16}\). With regard to a hospital’s quality improvement, World Health Organisation (WHO)\(^{28}\) reported that accreditations and awards are the major indicators of the hospital’s identity. Similarly, Paliszkiewicz and Klepacki\(^{26}\) pointed out that establishing professional achievements, licenses and awards on websites of organisations; reflect the identity of the organisation.

**Methodology:** Qualitative method of data collection was utilized for this study. Data was collected via documentation by downloading the relevant sections and subsections from the three private hospital websites within the period of one week (2 January 2017 to 9 January 2017). The hospitals selected are ranked top 10 by the world’s best hospitals for medical tourists as reported by the website of Medical Travel Quality Alliance (MTQUA) from 2010 to 2014. The three hospital websites examined in this study are: Prince Court Medical Centre (PCMC), Malaysia; Gleneagles Hospital (GH), Singapore; and Bumrungrad International Hospital (BIH), Thailand. Data for this study were retrieved from the following pages including “Home Page”, “Navigation Bar Sections” and “Sub-Sections” as shown in Table 1.

<table>

</tbody>
</table>

The data for the current study focused on the following sections and sub-sections; the background of hospitals\(^{16,22}\); the hospitals’ relationship with other organisations\(^{25,26}\); and the list of accreditations and awards\(^{26,28}\). Data analysis was conducted on the selected health related tourism websites to identify the central resources of identity on the promoted information.

**Findings and Discussion:** The first central resource of identity were found through the references made to the location of hospitals\(^{24,21,34}\) and the name of owners and supporters\(^{25,26}\) in the “Hospitals’ Foundation” feature. For instance, the hospitals’ location was achieved via the following phrases “located in the heart of Kuala Lumpur, Malaysia” (Extract 1); “Located next to Singapore Botanic Gardens” and “close to the heart of the local shopping district” as underlined in Extract 2;
and “located in the heart of Bangkok” as shown in Extract 3.

(Extract 1): Prince Court Medical Centre is a 277-bed private healthcare facility located in the heart of Kuala Lumpur, Malaysia...

(PCMC-Top Navigation – About Us)

(Extract 2): Located next to Singapore Botanic Gardens and close to the heart of the local shopping district...

(GH-Home Page – Footer – About Us)

(Extract 3): Bumrungrad International is a Joint Commission International accredited, multi-specialty hospital located in the heart of Bangkok, Thailand...

(BIH-Top Navigation – About Us – Corporate Information)

The highlighted phrases address the specific location of hospitals to explicitly locate the hospital in a well-known district or area to show their actual existence. It is interesting to note that the description of the hospital location is always made in reference to a well-known landmark (e.g. Kuala Lumpur, Singapore Botanic, and Bangkok). It is through the identity of these well-known landmarks that the hospitals establish their own identity located in or near an established land-mark that is not only well-known but also accessible.

Under the central resource of “Hospitals’ Foundation”, the names of owners, supporters and affiliates of the institutions and in this case, the hospitals, were highlighted in the health tourism website. The hospitals’ foundation is constructed via claiming evidences (e.g. partners profile, well-known people or organisations) to persuade viewers that the content is trustworthy. For instance, introducing the owner of Prince Court Medical Centre via the phrase “Petronas Malaysia’s national petroleum company” as shown in Extract 4. Introducing supporter was achieved on Gleneagles Hospital via the phrase “Parkway Ambulance Service” as underlined in Extract 5; and highlighting the supporters of Bumrungrad Int. Hospital was achieved via the phrase “CBS’s 60 Minutes, NBC’s Today Show, Time, Newsweek, and other international press” in Extract 6.

(Extract 4): Prince Court Medical Centre is fully owned by Petronas, Malaysia’s national petroleum company. 

(PCMC-Top Navigation – About Us)

(Extract 5): Gleneagles Hospital is supported by Parkway Ambulance Service in the provision of emergency and non-emergency medical transportation...

(GH-Top Navigation – Plan Your Visit – Ambulance and Special Transport)

(Extract 6): ...It has been featured by CBS’s 60 Minutes, NBC’s Today Show, Time, Newsweek, and other international press as a leader in medical tourism...

(BIH-Top Navigation – About Us – Corporate Information)

All the underlined phrases highlight well-known organisations, which are affiliated to the hospitals. Most often, the hospital owners and supporters are trusted or well-known organisations, hence enhancing the trust of the viewers.

As for the third central resource of identity, accreditations and awards, foregrounding professional achievements of a particular organisation enhances the trustworthiness of the organisation. In this study, the central resource of identity is evident in the information available under the “Accreditations and Awards” section. For instance, the name of certificates and awards were highlighted on the website of Gleneagles Hospital “Singapore Service Excellence Medallion Commendation Award” as underlined in Extract 7; and the phrase “Joint Commission International (JCI)” on Bumrungrad Int. Hospital website as shown in Extract 8.

(GH-Home Page – Header – Singapore Service Excellence Medallion)

(Extract 8): Bumrungrad was the first Asian hospital accredited by the Joint Commission International (JCI), the international arm of the organisation that reviews and accredits American hospitals...

(BIH-Top Navigation – About Us – JCI Accreditations and Awards)

According to Wilcox establishing awards on health websites is one of the most important evidences to construct trust and persuade the patients of the organisation’s credible background. In the current study, the data shows that publishing the certificates and awards clearly enhances the credible character of the hospitals.

The analysis of identity as the central dimension of credibility in this study was carried out by analysing information in the central resources of “Hospitals’ Foundation” and “Accreditations and Awards”. Establishing the resources about location and location.
introducing owners and supporters in the central resource of “Hospitals’ Foundation”; and highlighting the certificates and awards in the central resource of “Accreditations and Awards” all contribute to the identity construction of the hospital.

Conclusion

In summary, this paper examined the construction of trust through the focal theme of credibility and its central dimension – identity, across the three health related tourism websites from Malaysia, Singapore and Thailand. The focal theme of identity was found through the two central resources of “Hospitals’ Foundation” on the three selected websites, and “Accreditations and Awards” on the Gleneagles Hospital and Bumrungrad Int. Hospital websites. The analysis show that trust through its focal theme of credibility is constructed through information found on the central resource of “Hospitals’ Foundation” which includes information about the hospitals’ location, and founders and supporters. In addition, identity is also constructed through the central resource of “Accreditations and Awards” which refers to resources about the certificates and awards achieved by the hospitals.

From the findings of this study, it is clear that identity as the central dimension of credibility is important in the construction of online trust. Hence, for website developers or any online platform in which involves the dissemination of crucial information, it is important that the identity of the organisation or institution is readily available for easy access by the public. It is also imperative to include key features of identity such as location, achievement and affiliates to further enhance the trustworthiness of the website. Once the website is deemed trustworthy, important information that needs to disseminated will be readily accepted by member of the public.

Coping Strategies and Challenges among International Married Postgraduate Students in Universiti Teknologi Malaysia

Narjes Rahmani Movahed¹, Mahani Mokhtar², Zainudin Hassan²

¹Student, ²Associate Professor, School of Education, Universiti Teknologi Malaysia, Skudai, Johor

Abstract

There have been numerous researches on international students’ experiences and challenges at Malaysian universities. However, there has been lack of research on the experiences and challenges of married international postgraduate students at Malaysian universities. Therefore, this study explored the experiences and challenges faced by international married postgraduate students during first year of studying in Universiti Teknologi Malaysia. This study investigated their experiences, challenges, effects of the challenges on their academic performance and also their coping strategies. Qualitative research approach and phenomenological design were adopted, and data were collected using semi structured individual interview. The interview data were analysed using thematic analysis. The data showed that international married students and their spouses encountered different types of experiences and faced numerous challenges during their first year of studies. The experiences and challenges were related to children, health care, accommodation, climate and food. As a result, ultimately these challenges affected their academic performance. In addition, the themes on coping strategies were time management, family and social support.

Keywords: International Married Students, Experiences, Challenges, Coping Strategies.

Introduction

Malaysia has become a hub for international students from all over the world. For the purpose of internationalizing higher education, universities are in need to recruit and enrol international students¹. In addition, pursuing higher education abroad and attracting international students for the purpose of academic studies and educational tourism has now become a trend ². The growth of international students’ enrolment in Malaysian universities in postgraduate programs validates the importance of education in this region.

However, homesickness, language barrier, different educational systems and lack of social support are among the challenges faced by international students when they experience new culture³,⁴. Even though universities organise orientation programs for international students, the effects of cross-cultural transition is inevitable.

There are numerous researches on international students studying at Malaysian universities in different settings. However there is lack of research on the issues and challenges of international married postgraduate students. Therefore, this study intended to investigate and identify the experiences and challenges faced by international married postgraduate students during first year of study in Universiti Teknologi Malaysia.

Methodology: This study adopted qualitative research approach since it relies on the opinion and perception of the participants ⁵ and phenomenological design was chosen as it could provide a unified structure of the whole participant’s live experiences⁶. Phenomenological design was used in this research since the design allowed exploration of experiences and challenges faced by international married postgraduate students and their families during first year of study. In addition, issues on how the challenges affected the students’ academic performance and the strategies adopted to overcome those challenges were also being investigated.
Respondents of the study were international postgraduate students who are in their second semester or more and they were accompanied by their families. Therefore purposive sampling method was used in order to provide data for this study. All respondents were interviewed using semi structure interview method. A detailed summary of the respondents’ background is provided in Table 1 below.

The data were analysed using thematic analysis since it allows interpretation of phenomenological data. According to Boyatzis, thematic analysis would assist the researcher to attain an explicit image of the raw data and be more engaged with the collected data.

### Results

Results of the study can be divided into several themes and sub themes. The first theme which emerged from the data of students’ experiences was cultural differences. Most of the respondents highlighted elements of Malaysian multi ethnic culture which influenced their positive living experiences. “I surprised just from one thing. In Malaysia has three different cultures. I see Malays, Chinese and Indians, different culture, different God, different religion but very peaceful” (Aimen, Iraq).

The second theme was about living adjustment and how they settled in new environment. Consequently, at the phase of adjusting, the feeling of homesickness was mentioned by majority of the respondents. For example one respondent highlighted that, “I am totally a home-oriented person. I never lived out of my home before or never got a chance to live in a hostel as such so for me was a shock of moving away from my home and of course, being away from home it was difficult” (Faran, Pakistan).

Furthermore, the data on students’ challenges which was the second research objective of the study revealed a wide range of transitional challenges. Four themes emerged from the findings which are; children, health care, accommodation and climate and food.

The importance of children’s education in a foreign country was the significant challenge. Majority of the respondents who have school aged children put priority on quality of education. Most of them mentioned that the school system in Malaysia is different from their respective countries and therefore it caused challenges to adapt. “Malay public schools are not English, they are not doing in international language and we don’t know Malay language (laughter) and the Chinese schools are good but their study is not too much good like our Pakistanis schools, like their books are much difficult than the Chinese schools, so the study is the major issue for us” (Asima, Pakistan).

Another issue related to education was financial challenge since the high amount of fees charged by international schools became an obstacle for them to send their children to schools which use English as medium of instruction and also with international syllabus. As a result, one respondent had to leave two of his school aged children back home and only brought the infant one. “The system is different here in Malaysia, the international schools are paid monthly but, in my country, it is paid termly which is three times a year and so here is costly. I left the elder ones back home and just brought the small one” (Adu, Nigeria).
Furthermore, some respondents highlighted the challenge in the aspect of lack of day care centre for children. Therefore, for couples whom both are students, it is difficult for them to juggle between studies and childcare. “Like coming here with kids is very challenging. Is not easy at all, because the first issue is when you are going to attend classes is that where do you keep your kids. Like in UTM they don’t have any day care for kids and off-campus day-care centres are expensive and time consuming” (Fatima, Pakistan).

The next theme which emerged pertaining to the challenges faced by students was in relation to health care. “My family don’t have any health coverage. They can have some insurance, but I think is only the payment, no outcome from the insurance because it covers accidental conditions, not a regular. Like if they are feeling cough or they are having fever, ... anything like this the insurance won’t support.” (Ali, Pakistan).

Furthermore, location of health care provider also was mentioned. “Another thing is the hospital. It’s very far from university. I cannot take my children to hospital or clinic. They are just open in the morning and afternoon. But sometimes you need to go to see a doctor at night, like emergency, especially when kids have high fever or cough. So, it’s the most challenge to me, I cannot do anything I just crying because I want to go to doctor” (Amina, Iraq).

In addition, another challenge faced by the respondents was in the aspect of accommodation. Matters concerning process of accommodation application, lack of in-advance platform to apply, conditions of the campus houses and higher cost of off-campus housing were among the feedback of the respondents. For example, “Actually, there was no platform by UTM here for students to get formally accommodation in advance. The system is like you have to get your family here before you get for the accommodation. So, it was very challenging to get accommodation” (Adu, Nigeria).

“The outside houses are a bit expensive and the housing inside the university is very difficult to get because there is a drop process and usually there are very less available flats. For the last two or three times I have tried but it was seven to 10 flats I think was available at a time and the applicants were more than 17. So, it’s not possible and usually is difficult to get home inside university” (Ali, Pakistan).

The next challenge was on climate and food. As an example, one participant claimed that in her home country there are four seasons but there is only one season in Malaysia which is hot throughout the year. This caused difficulty for her in the beginning. She stated that;

“My experience with weather, here is one season and hot and humid but in my country four season. So is difficult because somehow it hurts me. I have Sensitive skin and many mosquitos here were difficult at the beginning (laughter)” (Amina, Iraq). Regarding food issues, Dalia simply replied that “food it takes time because we don’t eat spicy hot food and it was really hard for kids to adopt for the food” (Dalia, Saudi).

The third research objective was on the effects of those challenges on their studies. One theme which emerged from the data was on academic struggles. All the participants reported that those challenges affected their academic performance. One respondent mentioned that juggling between family adaptation issues and time spent on her children’s education had affected her study. “My challenge with having family with me and putting lots of efforts it’s kind of really hard for me and sometimes I struggle my performance won’t be the way I wanted so was really hard for me to teach the kids and at the same time work on my study” (Dalia, Saudi).

Another respondent who is a wife highlighted the struggle her husband had on managing study and family settlement. “Off course while he is attempting to settling our children school and home and a lot of things. He has a lot of pressure, so he is not focusing on his lab work, actually he is a technical student, so he has to be focused on lab”. (Banu, Pakistan).

The last research objective was on the strategies adopted by the respondents to overcome those challenges. The coping strategies they employed were time management, family support and social support.

One respondent highlighted that, “I preferred to study at home at night while my children sleep. My schedule is such that during day I sleep I think time is the only thing that we cope with issues, you need to spend time and to observe things ” (Faran, Pakistan).

Then in relation to family support, majority agreed that emotional and financial support from their family members especially their spouses had reduced the stress which they felt while studying.
One respondent reiterated that, “Their support is of course important so maybe they emotionally charge you in some certain extend that you can always accomplish your academic task well before time... on the other hand I feel that the time I rather spend with my family I could have been spending my on my PhD task but on the other hand I think that if they were not with me I am so emotionally disturb that could not concentrated on my work as such” (Faran, Pakistan).

Other respondent stated that, “My wife is thinking to do activities at home to make some money, just planning. And, she is working hard to home-schooling our children and educate them at home” (Ali, Pakistan).

Lastly, the theme on social support was mentioned, “I try to make friends as much as possible it was only after that I tried to adopt and try to meet with some people even if we couldn’t communicate together. meeting with locals was the most helpful, because by meeting them I was trying to understand few of their language and know how to eat their food, mostly from my neighbours” (Adu, Nigeria).

Discussion

In terms of experiences, Pascoe\textsuperscript{10} indicated that the first reaction an international student has about the new culture is known as culture shock. Indeed, this was the first experience shared by most of the participants. Although being stated as cultural difference in the study, but the meaning is the same. Even though experience of culture shock often accompanied by stress\textsuperscript{11}, only few respondents reported it and for majority the experience of being in a different culture was a pleasant experience.

Issues pertaining to children, health care, accommodation, food and climate were stated by majority of the respondents. In a study by Suárez-Orozco\textsuperscript{12} children’s level of adaptation in a new environment is reflected through their academic and education. In other words, good schools could maintain the need of children, respect their student’s identity and value their culture. However, concern on children’s education, the curriculum and discipline of local educational systems, lack of day-care centre at university and the issue of children’s entertainment were highlighted by all the respondents.

Lack of proper health care services as a general living condition\textsuperscript{13} was pointed out by most of the participants. The insurance coverage for both students and their families were an issue as it only covered for emergency cases. Since most of the respondents were financially tight, for them paying the high health related fees was an obstacle and stressful concern.

The issue of in-campus and off-campus accommodation and its comparison emerged in the data. University accommodations were expressed as their desire accommodation to live as the fees are much affordable and accessible to all the facilities, transportation and academic colleges as compared to off-campus houses. In addition, living inside campus can prevent the feeling of isolation and existence of their homeland fellows would assist them to reduce their acculturation stress and fulfil the sense of their home country\textsuperscript{14}. However, unavailability of advance booking system and limitation in the number of apartments had forced the respondents to choose off-campus housing.

Studying with children is a difficult task for parents, especially when living in a foreign country. Therefore, in that situation, other stressors would affect their concentration on academic work\textsuperscript{15}. Issues with children, more importantly their education condition was among the challenges mentioned in this study. In addition, language barrier also affected their academic performance. Lack of English and Malay proficiency created a challenge in their process of adapting to the new culture and academic work\textsuperscript{16}.

Managing their time wisely was the most common strategy mentioned by the respondents. The theme is similar to other studies by various researchers\textsuperscript{17} who stated that time management is crucial. Another strategy, which emerged from the responses, was family support. For married international students, the existence of their family members is a blessing since it gives motivation for them to persevere and succeed in their studies.

In conclusion, experiences, challenges and strategies adopted by international married postgraduate students are aspects of lifelong learning, which need to be taken into consideration by universities in order to ensure positive learning experience among international students.

Improving Spatial Visualization Skills in Educational Settings

Marlissa Omar¹, Dayana Farzeeha Ali²*, Johari Surif², Mahani Mokhtar², Nurul Farhana Jumaat², Norazrena Abu Samah², Zakiah Mohamad Ashari²

¹Scholar, School of Education, ²Senior Lecturer, Faculty of Social Sciences and Humanities, Universiti Teknologi Malaysia (UTM), Skudai, Johor, Malaysia

Abstract

Spatial visualization skills have been demonstrated to be one of the critical skills to guarantee success in Science, Technology, Engineering and Mathematics (STEM) education and careers. With the fast-paced technological progress nowadays, numerous visualization tools have been designed to address the lack of visualization problems in educational settings. However, there is a lack of studies evaluating the implementation of these visualization tools. To address this gap, this study will provide a systematic review of empirical research involving improving spatial visualization skills in instructional environments. A total of twenty-one articles were examined between 2009 and 2019. Analysis has revealed that the use of visualization training tools significantly enhances learners’ spatial visualization skills, as well as other aspects such as performance, motivation and problem-solving skills.

Keywords: Visualization skills, spatial, education, systematic review, STEM.

Introduction

This paper intends to present a review of the literature that focuses on improving spatial visualization skills in instructional environments. This section will provide the overview of issues regarding visualization skills studies.

Various research in this field is studying the impact of spatial visualization skills towards students’ confidence¹,², performance³,⁴,⁵, motivation⁵ and skills such as cognitive skills⁶ and reasoning skills⁷. Even though these reviews concisely summarize and discuss approaches implemented in improving spatial visualization skills in educational settings, there is an increase in the utilization of technologies as visualization tools, especially in medicine and engineering subject area. This is due to the importance of spatial visualization skill in Science, Technology, Engineering and Mathematics (STEM)⁸. According to Malaysian Blueprint 2013-2025, there are initiatives aimed at fostering STEM learners with the skills to prepare them with the fast-paced advanced technology⁹.

According to Scopus database, there has been an increase in the number of studies regarding spatial visualization skills in education. Researchers have begun to realize the significance of nurturing and training these abilities towards the future of the learners. This skill is also identified as one of the intelligent domains in multiple intelligence theory.¹⁰ Spatial visualization skills are defined as “the mental manipulation of spatial information to determine how a given spatial configuration would appear if portions of that configuration were to be rotated, folded, repositioned, or otherwise transformed”¹¹. Spatial visualization skills have been receiving high interests in various subject areas including Medicine, Computer Science, Engineering, Social Sciences, Mathematics, Health Professions, and Earth and Planetary Sciences¹²,¹³.

Due to the importance of spatial visualization skills, particularly in the STEM field, researchers have

10.5958/0976-5506.2019.02716.5
come out with different approaches to address the spatial visualization skills problems. Some of the issues recognized are the dependence of young people on the machine or technology that has an impact on reducing their perception ability\textsuperscript{14}. Other than that, there are significantly higher differences in individual’s spatial visualization skills, particularly in higher education, because, during the pre-university phase, there is no emphasis on this ability.\textsuperscript{15} Gender differences are also one of the problems in this domain where men’s spatial visualization skills are mostly developed than women\textsuperscript{16}. Several studies also mention a low level of spatial visualization skills among first-year university learners. These are a few of the spatial visualization skills problems that trigger the researcher’s need to create a strategy to minimize learner problems\textsuperscript{17,18}. The issues differ according to the subject area and the complexity of the topics. Thus, this literature review will address the specific literature on the successful implementation of various visualization training tools in various subject areas.

**Research Questions:** A systematically analysis of the empirical research identified in this study is conducted on improving spatial visualization skills in instructional environments. In order to address the issues in the reviewed literature above, these are the research questions that have been constructed for this literature review: (1) Which subject areas commonly studies on approaches to improve visualization skills?; (2) What are the observed advantages of using visualization tools in educational settings?.

**Methodology:** To identify the studies to be included in this literature review, the Scopus database (https://www-scopus-com) is selected. Noted that the searching process for the articles is according to the prepared research string: ((Visualization Skills) OR (Spatial Visualization) AND Tools AND Education).

**Inclusion and Exclusion Criteria:** To ensure all the research questions in the previous sections were addressed, the following criteria are integrated in order to identify the research studies which will be included in the review:

**Inclusion Criteria:**

- Studies must directly address one of the research questions addressed in the previous section (Visualization Skills/Spatial Visualization, Education, Tools)
- Studies should be published between January 2009 and April 2019
- Empirical research studies to ensure that this review will focus on building knowledge surrounding visualization skills in education.

**Exclusion Criteria:**

- Studies which document types are labelled other than “articles” in the databases searched. (i.e., conference papers, conference reviews, book chapter, review, book and undefined)
- Studies which used a language other than English.

**Procedures:** A total of five hundred and ninety-four papers were gathered based on the keywords mentioned in the previous section through the Scopus database. Through the automatic filter function, searches were then filtered automatically by publication years (January 2009 to April 2019), document type (article) and language (English). The database searching for this paper was conducted on June 11, 2019. Manual sorting process was incorporated to ensure that only the most relevant papers that fit the inclusion and exclusion criteria are selected to be reviewed. This is by reading through the title and abstracts of the identified papers intensively. After the manual sorting process, twenty-one articles remained relevant to this study.

**Results**

Based on the reviewed articles, the most cited article (78 times cited) is a paper addressing improving spatial visualization skills in medical subject area. This is followed by a paper in geology (24 times cited) and engineering graphics (15 times cited).

**RQ1- Subject Areas:** Results related to the types of the subject area commonly studied on approaches to improve spatial visualization skills indicates that geography (n=5) is the most commonly studied subject area followed by engineering (n=4), medical (n=4), Science (n=3), and Mathematics (n=1). However, there is other subject areas, such as basic concepts of spatial visualization, apparel design and psychology identified in the reviewed articles.

**RQ2-Advantages of Visualization Tools in Education:** Findings found from the reviewed articles shows that there is an explicit agreement on the use of visualization tools to improve spatial visualization skills in educational settings. Spatial visualization skills are
skills that can be enhanced with appropriate training, mainly intended training design specifically to train spatial visualization skills. In the studies reviewed, varieties of visualization tools were used to enhance the visualization skills of students. However, there are also other aspects found in some of the research apart from improvements in visualization skills.

The first aspects observed in some studies is improved understanding. These studies discovered that apart from enhancing the visualization skills of students, their knowledge also improved considerably. Babu, Suman and Srivinasa Rao drew a comparison between student examination results, showing a drop in the student failure rate of up to 85 percent. The results of the exam are compared between the students’ batch, which utilizes the visualization tools and conventional mode. The results showed an increase in understanding among students learning using visualization tools because understanding spatial representations help to boost the efficiency of learners considerably. Especially among geoscience major, spatial visualization is essential for understanding geological characteristics where there is an essential connection between spatial visualization skills and problem-solving capacity.

Using suitable tools to train spatial visualization skills could improve the training’s efficiency, particularly when the instruments were created solely based on content. As an example, the use of augmented reality to enhance spatial visualization skills has a significant advantage when attempting to make learners understand the rotation and transformation of objects related to each other. Other than that, another aspect is enhanced problem-solving skills. A research that demonstrates students studying geoscience course using visualization tools showed an increase in their geological knowledge-related problem-solving skills. It is also stated that students require visualization skills to solve geological problems, thus contributing to the outcomes provided. Thus, this result may vary depending on the types of courses examined, where it may demonstrate contrasting results for some courses.

Next, the use of visualization tools in educational settings also showed increased motivation among students. A study by Önal, Önal and Büyük found that students showed an increase in motivation when learning using visualization tools in the classroom. It improves their involvement during classes, encouraging learners to learn more interactively. Students were more satisfied with the use of technology as visualization tools as they felt it could boost the quality of education and facilitate learning. Other than increased motivation, they also found that using visualization tools is timesaving. By utilizing visualization tools in the lessons, students can quickly grasp and concretizing the abstract concepts. In addition to students benefiting from the use of these tools, teachers can also save more time to clarify the complex concepts and concentrate more on providing the students with important information.

Discussion

Findings from this literature review demonstrate a prevalent knowledge of implementing visualization tools in instructional environments primarily to improve spatial visualization abilities. There is an increase in the development of visualization tools in various fields in the excluded research papers. These research papers provide an empirical study which statistically proves the effectiveness of the proposed visualization tools. Some of the excluded research papers also proposed a specific framework for developing an effective visualization tool in particular field or subject areas. This shows that there is still a lack of research on the development framework for visualization tools that can work for all fields.

In the literature review sections, it has been addressed that spatial visualization skills are often studied to find out its relationship with performance, motivation and skills. This review has identified some of the relationships in the reviewed studies. Huynh and Sharpe identified that spatial visualization skills positively correlates with problem-solving skills. In this study, it is found that students with higher spatial visualization skills tend to use multiple problem-solving methods while students with low spatial visualization skills tend to use the basic problem-solving method when solving a given task. Other than that, studies also found that spatial visualization skills have an impact on students’ motivation to learn. Findings from this research show a substantial enhancement in the overall spatial visualization skills of learners after integrating visualization tools into the learning environment. The author also receives feedback from learners after learning to use more visualization tools applications as it can assist them to improve the precision of their visualization activity. Based on the review, it is proven that spatial visualization skills are important in Science, Technology, Engineering and Mathematics. In addition, technology has the potential to boost students’ learning as it brought
positive impact in speeding up their learning process. Thus, incorporating technologies as spatial visualization tools is recommended for educators.

**Conclusion**

Visualization is commonly researched in various fields, particularly in science, technology, engineering and mathematics (STEM). Today, a range of technologies are introduced to ease visualization tasks primarily to allow learners to learn effectively, efficiently and interactively. Technologies such as augmented reality, virtual reality, and virtual environment are often used to cater to learners’ visualization problems at school or university level. Increasing numbers of research in this field show that visualization skills are considered necessary for learners, particularly in the STEM field. However, teachers and educators need to find out the most efficient methods to develop and enhance visualization skills based on content characteristics in each respective course. Furthermore, more empirical studies should be conducted to find out whether improvements in spatial visualization skills might affect more aspects in various subject areas. This is to guarantee that efforts are not wasted in creating an appropriate method to improve visualization skills in educational environments.

Enhancing Training for Multicultural Counseling Efficiency According to the School Counselors Perspective Toward Clients Psychological Health

Kamarul Md Shah¹, Aqeel Khan², Rozita Jayus³

¹Senior Lecturer, ³Lecturer, School of Social and Economic Development, Universiti Malaysia Terengganu, Kuala Terengganu, Terengganu, ²Senior Lecturer, Faculty of Social Sciences and Humanities, Universiti Teknologi Malaysia, Johor, Malaysia

Abstract

Malaysian school students are multiracial and multicultural; thus, guidance and counseling services provided should be tailored to the needs of diverse clients. This circumstance requires school counselors to be competent for multicultural client’s psychological health in counseling sessions. The study attempted to obtain feedback from school counselors on the training of multicultural counseling competencies. The findings show, school counselors can demonstrate good training in multicultural counseling efficiencies and enhance the effectiveness of counseling sessions.

Keywords: Training, Multi-cultural Counseling, Psychological Health.

Introduction

Malaysia is a country of diverse cultures and societies. Migrants who come to work and study in Malaysia have added more diversity in society. Recent scenarios show that Malaysians are also faced with various social changes and challenges apart from migrants such as increases in coverage, divorce, family structure changes and illegal immigrant entry. This situation illustrates that the issue of cultural diversity has become important in counseling practices¹,²,³,⁴. Hence, practice on multicultural counseling exercises should be emphasized in counseling studies in preparation for current counselors to deal with cultural diversity issues. A student’s overall experience of school is shaped by many factors including individual characteristics as well as their family and immediate social networks, the societal and cultural context in which they live and learn⁵.

This situation is in line with the focus of the multicultural counseling exercise in America which gives major attention to the training of ethnicity and ethnic majority and minority to the trainees²,⁶,³. Multicultural counseling is a counseling service provided where existing and relevant cultural attributes are incorporated in the context of the counseling process carried out. These cultural attributes include ethnicity, race, gender, sexual identity, socioeconomic status, disability, age, and religious grip. This situation demonstrates the need to have multiple cultural counseling skills developed through a fourth approach in the field of counseling⁷. The same situation occurs in Malaysia where the standards of its counseling programs also emphasize the importance of multicultural competence training⁸.

According to Ministry of Education Malaysia, school counselors are full-time counseling teachers who carry out guidance and counseling activities in primary and secondary schools. They provide full-time service with hours of schooling as well as other subject teachers. Therefore, the full time of work must be fulfilled with guidance and counseling activities for all students in accordance with the prescribed guidelines either in degrees or in other suitable places⁹,²⁸. According to the Code of Ethics of Counselor by The Malaysian Counseling Association to researcher⁸, there are three...
parts to emphasize the importance of the need to improve efficiency and counselors specializing in various aspects of culture. This suggests that the detailed emphasis has been expressed in the code of ethics of counselors in the practice of counseling in Malaysia to meet the needs of counseling services for the diverse Malaysian community and culture.

**Statement of Problem:** At present, there are 5467 counselors in secondary schools with 1907 men and 3560 women who support the vision and mission of guidance and counseling services in the Malaysia’s school system. Meanwhile, in terms of racial proportions, 71.8% are bumiputeras, especially Malays and 28.2% are non-bumiputeras or other races, especially Chinese and Indians. This situation illustrates the diversity of students, leading to cultural diversity among high school students.

According to Ching Mey See and Kok-Mun Ng, at present, there is a lack of clear theoretical framework to be practiced by school counselors in relation to multicultural counseling. Therefore, school counselors only use the existing counseling theories to conduct multicultural counseling sessions, especially in understanding and planning appropriate treatment processes with multicultural clients. For the improvement of its development, school counselors need to incorporate various therapeutic approaches into their practiced techniques such as family counseling approach, psychological approach and multicultural approach. This is because there are features in the school’s diversity that are similar to what is happening in the Malaysian society.

In addition, studies on the effectiveness of multicultural counseling in Malaysia is still lacking as compared to the western context. Meanwhile, this competence is also one of the personal and professional characteristics that need to be addressed to school counselors and to influence their efficacy while carrying out guidance and counseling services to further enhance effectiveness. Therefore, this study aims to identify the various forms of multicultural counseling training among school counselors towards client psychological health.

**Research Methodology**

**Design:** This qualitative study design used the case study method of multicase-multisite by Yin (2003). The purpose of this study is to determining training to improve the efficiency of multicultural counseling. This study not only allows researchers to meet the participants directly but also be able to interact and to observe with empathy as the researcher is the main tool for the study.

**Sample:** The sample of this study consisted of 15 secondary school counselors in Selangor which were randomly selected with regard to demographic factors such as gender, race, education level, professional experience and school location. They also comprise survey respondents who have high levels of multicultural counseling skills based on Multicultural Counseling Competency Questionnaire by Kamarul previously conducted.

**Instrument:** This study was conducted qualitatively in which an interview protocol was developed and reviewed by the expert, and then used as a research instrument to get the information in depth from the sample of the study. The data were then analyzed using Nvivo 8 software to identify the theme to answer the research questions.

**Results**

**Training of multicultural counseling among counseling teachers:** To answer the question of this study, the analysis conducted using Nvivo coding techniques has resulted in three major themes that determine the practice of multicultural counseling skills in guidance and counseling services towards client psychological aspect namely (1) basic training, (2) exposure to multicultural counseling received during study and work, (3) training form during service.

**Basic training:** According to the survey respondents, the basic training they have is through a training course at the university and the training is not enough and requires further training. The knowledge and experience gained are the basis for conducting counseling sessions with multicultural clients. Among the statements of respondents are: “There is no exercise. Learn in the university only” and “Lectures and discussions with multicultural partners”.

The second sub-theme is the basic training received is insufficient for them to obtain or improve the efficiency of multicultural counseling. The following are the statements of respondents: “That’s not enough. Exercises are held like that. Additionally, if we’ve been studying for so long, there are many new things” and “For the knowledge of these competencies be given to
school counselors as much as possible. If there is a case that is too critical we can refer to the school counselor”.

There are also three sub-themes, the first one being the existing training needs to be improved either through university or counseling experience so that school counselors are always ready to carry out multicultural counseling sessions.

**Disclosure of multicultural counseling:** According to the survey respondents, disclosure of multicultural counseling is only through the course that follows their program of study in universities. All study respondents stated that they only received exposure in the form of a cross-cultural counseling course during university studies such as the following statements: “The study time in UPM has a cross-cultural counseling subject”.

We visited three friends in her home to recognize her Malay, Chinese and Indian cultures. We conducted a study using a questionnaire” and “I learned about these cultures through graduate and undergraduate levels”.

The second sub-theme that emerged was a study respondent stated that no exposure on multicultural counseling was received during work and all study respondents stated the same thing except for one study respondent. Here are some of the statements of respondents: “During my work, I have never followed any cultural-related courses or seminars but it feels that this is very important in our service” and “While working, only direct experience is obtained with students of different cultures, especially the Malays and the Chinese.”

**Training form during service:** Training during the service to obtain multidimensional counseling skills is through learning from experience, participating in student activities, learning through electronic media and using internet. For the first sub-theme of learning from experience, study respondents pointed out that they can observe and visit student homes to recognize and understand the student’s culture and way of life. Among the statements of respondents who supported the sub-theme are: “I will if there are other cultures in addition to Chinese and Malay as a foreign culture, I want to know their way of life, including the observation” and “Take a picture and send a report while studying first. A visit to a student’s home can familiarize yourself with the client’s culture. Go down the field and see for yourself”.

The second sub-theme is to participate in student activities, which means school counselors get a lot of benefits if they take advantage of any form of student activity; whether formal or informal. Here are some of the statements of the respondents for this sub-theme: “Join them in doing activities or courses that are considered informal training but this can directly make us aware and understand our students. Not necessarily for us as a committee member only” and “Among students, there is a cross culture that causes misunderstandings. Not only different students, but different teachers and different school cultures. So we’re together with them”.

**Discussion**

The training of multicultural counseling competencies, the study participants stated they only used the training received during their studies at the undergraduate or master’s degree as a guide to conducting multicultural counseling. For them, these exercises are inadequate where with only one cross-cultural course, they use them throughout the service as counseling teachers. They need continues training, so that this knowledge can be recalled and updated. This is in line with the studies that have been conducted on counselors who opted for input in multicultural counseling. This is because the effectiveness of the various cultural counseling services is closely linked to the counselor’s own willingness to deal with multicultural issues. Hence, inputs received at universities are one of the assets to improve the efficiency of school counselors in a multicultural environment. The study by Sue and Sue found that trainee counselors did not receive enough training in various cultures. They have provided feedback that a multicultural or cross cultural course is inadequate in preparation for clients from various cultures. According to Coleman, some experiences can significantly influence the multicultural training in counseling psychology programs. The respondents of this study emphasized more on current courses in the service as a new input and additional inputs for improvement. They see that this effort is important to be realized as school counselors in Malaysia are always faced with various cultural issues due to the diverse Malaysian students and society in particular in terms of race, ethnicity, religion and belief.

Extra knowledge is acquired through lectures, it is still inadequate to identify the needs in multicultural communities. Thus, training through experience requires the individual to engage with a multicultural community that will enhance the intellectual processes. Learning through this experience means a
profound and extensive experience gained by engaging in social, cultural, environmental and other aspects of the community\textsuperscript{20}. Learning through experience is also considered a valuable tool for enhancing the skills and competence of various cultures\textsuperscript{21}. Experiential learning also allows students to learn more effectively, suggesting where it helps them to see the importance of feelings and thoughts in addition to the increase of self-consciousness\textsuperscript{22}. Previous studies show that there are many forms of learning through experience that have been used in multicultural training\textsuperscript{23,24,25}. The benefits gained from learning through this experience can be maximized when an activity reflects the strengths and experiences experienced by the students collectively\textsuperscript{26}.

Furthermore, involvement in cultural activities is one of the ways that school counselors can do for the benefit of multicultural counseling. The study participants noted that through the involvement in cultural activities of the people in terms of festive and religious celebrations, school counselors will easily understand their clients and their cultures. This will help shape mutual respect and create a sense of belonging and similarity to one another. This means, a counselor can plan a treatment program that is appropriate to his client to understand and dive into the perspective of the client from his cultural perspective, life experience and cultural value. The counselor will then be seen as sensitive to his client’s culture and ultimately the counseling process will be enhanced\textsuperscript{27}. A school counsellor who is alert towards his client’s culture will be able to define his client’s problems, build goals and apply consistent treatment methods in the counseling process.

**Conclusion**

In conclusion, school counselors training in multicultural counseling efficiencies and enhance the effectiveness of counseling sessions demonstrate a good services towards clients psychological health. The three main themes that determine the practice of multicultural counseling skills in guidance and counseling services namely (1) basic training, (2) exposure to multicultural counseling received during study and work, (3) training form during service. All of these illustrate that school counselors are conscious of the importance of training multicultural counseling competence that affects the process of counseling and the effectiveness of multicultural counseling sessions. Additionally, school counselors should also be aware that these multicultural counseling efficiencies will increase their confidence in conducting counseling sessions with clients of different cultures and can have a positive impact on clients psychological health such as respect, sense of belonging, self-esteem and sense of equality which in turn will demonstrate the school counselor as an individual who cares for his students.

Abstract

Despite great attention related to organisational citizenship behaviour in the literature, little is known about organisational citizenship behaviour among Malaysia public hospital nurses. Hence, this study aims to investigate the mediating effect of nurses’ psychological empowerment on the relationship between the leader-member exchange and organisational citizenship behaviour. This study was a quantitative study which used questionnaires to gather the data and 539 nurses had participated. The data was analysed using Structural Equation Modelling. The results found that psychological empowerment is a significant mediator between leader-member exchange and organisational citizenship behaviour. This study makes theoretical contributions by providing information concerning the Social Exchange Theory and its application to nursing practitioners.

Keywords: Organizational citizenship behaviour; nurse; psychological empowerment.

Introduction

Nowadays, organisations are confronting unanticipated challenges including changes in technological structure, shocks in economic trends, social changes, and structural transformations\textsuperscript{1}. Meeting all these challenges is indispensable for an organisation’s survival but it has become a tough trade to do \textsuperscript{2,3}. It is believed that positive employees’ behaviour can enable an organisation to cope with these challenges by practising organisational citizenship behaviour (OCB) among employees \textsuperscript{3-5,6}. OCB is an extra-role individual behaviour that is discretionary, not directly or explicitly recognised by the formal reward system, but it promotes the effective functioning of the organisation. Successful organisations need employees who will do more than just their formal job scope and provide performance beyond the expectation\textsuperscript{7,8,9}.

The successive increases in patient admittances to hospitals consequently lead to increases in nurses’ job demands such as workload, working period, pressure, and the need to solve problems in unexpected situations to satisfy patient’s expectations and achieve standard hospital service quality \textsuperscript{10}. The concept of OCB is useful for reducing nurses’ workload by promoting the inclination towards helping others, the feeling of responsibility, sharing information, and sportsmanship within nurses \textsuperscript{10,11}.

Literature Review

Relationship between LMX and Organisational Citizenship Behavior: According to the LMX theory\textsuperscript{12,13}, leaders form relationships of different levels of quality with their subordinates. Subordinates in high-quality LMX relationships receive greater levels of trust, attention, communication, and emotional support from their leader\textsuperscript{12,13}. Employee’s feeling of indebtedness for the good relationship from their leader can be paid back by performing behaviours that are above and beyond formal work requirements \textsuperscript{4,15}. A positive relationship between LMX and OCB is expected because OCB will help fulfil subordinates’ obligations and represent an exchange of
currency. Furthermore, study by Chernyak-Hai and Tziner have found LMX to be significantly associated with the quality of OCB. Meanwhile, those reporting low-quality LMX only perform the more routine tasks of a workgroup. Hence, subordinates with high-quality LMX will actually perform better because of the support, feedback, resources, and opportunities provided to them and it directly leads to OCB.

**Psychological Empowerment as Mediator:** High-quality LMX can increase employees’ psychological empowerment in the workplace. When subordinates feel psychologically empowered by their leader, it will lead to employees’ OCB. Past studies have shown that high-quality LMX is positively and significantly related to psychological empowerment. Furthermore, Schermuly and Meyer have indicated high-quality LMX increase psychological empowerment among employees since they perceive their job is more meaningful, self-determination, impact, and competence.

Furthermore, the past studies indicated that an increased in psychological empowerment will increase employees’ OCB in the workplace. Lin indicated that the smooth operation of an organisation does not simply depend on the employees completing the in-role job requested by the organisation, but also depend heavily on OCB. Besides, being able to participate in decision-making allows the employees to perceive the power of influencing their work and they would be willing to remain in the organisation by making efforts to achieve the organisational performance. Once the employees feel empowered, they are likely to exhibit the extra-role behaviour of their own free will.

### Method

The population involved 59,364 Malaysian public hospital nurses. The researcher distributed randomly 1531 sets of questionnaires and managed to get 539 respondents with the return rate about 35.2%. SEM AMOS 23 was utilized to analyze the data. Majority of the respondents are female nurses with 461 (96.8%), while only 15 male nurses (3.2%) participated in this study. The result also showed that most of the respondents are aged between 25-34 years (62.6%), followed by 114 nurses with the age of 35-44 years (23.9%). Only 36 nurses are below 25 years old (7.6%), while 28 nurses are aged between 45-54 years (5.9).

### Results and Discussion

Table 1 highlighted that high quality perceived contribution can increase the occurrences of meaningfulness which in turn increases the behaviours of altruism, courtesy, and civic virtue among nurses in public hospital of Malaysia. This study supported the previous studies that high quality of perceived contribution can lead to positive effect of meaningfulness feeling among employees and can lead to the behaviours of altruism, courtesy, and civic virtue among employees. High quality of work-based relationship between the leader and nurses benefits them by easing access to data, giving more feedback, and adding support from leader which in turn increase the meaningfulness at the workplace. High experience of meaningfulness causes nurses to feel more likely to perform some positive and extra-role behaviours beyond their formal duties as a return favour to their leader. These extra-role behaviours ultimately lead to performing of altruism, courtesy, and civic virtue among nurses.

Subsequently, meaningfulness was found to be able to fully mediate the relationship of affect with altruism and courtesy, and at the same time partially mediate the relationship between affect and civic virtue. This findings support the Social Exchange Theory stated that people help each other when there is a positive cost-benefit analysis, especially when the benefits outweigh the risks in the relationship. It also refers to human interaction and transaction with the aims of taking advantage of one’s rewards and reducing one’s cost. In this study, when the leader and nurses have a good personal relationship between them, this interaction gives a positive effect on increasing the feeling of meaningfulness among nurses. This, in turn, increases nurses’ behaviour of altruism, courtesy, and civic virtue.

Table 2 shows the results of competence as mediator. The results revealed that mediating effect of competence has the strongest effect on the relationship between affect with civic virtue compared to the other dimensions of OCB among nurses. The plausible reason of this finding is that in the context of nurses, being competent is crucial in explaining the association between affect and civic virtue. Perceiving themselves as competent helps in improving nurse’s civic virtue at the workplace. Furthermore, high-quality affect can increase the experience of competence among nurses, which in turn increases the act of altruism, courtesy, and also civic virtue at the hospital.

The results in Table 3 indicated that self-determination is a significant mediator. A high-quality affect can increase self-determination among nurses, which in turn increases the behaviours of altruism, courtesy, civic virtue, and conscientiousness among them. This study suggested that self-determination is crucial among nurses in explaining the association between affect and civic virtue. The increase in the personal-based relationship between the leader and the subordinate will increase self-determination which in turn lead to the behaviour of OCB.

</table>
The results in Table 4 indicated that high quality perceived contribution can increase impact among nurses which in turn increases their behaviours of altruism, courtesy, and civic virtue. The results also justified the fact that impact has the strongest mediating effect in the relationships of perceived contribution and affect on courtesy compared to altruism and civic virtue. In this study, impact is crucial in explaining the association between perceived contribution and affect on courtesy. The improvement in work and personal relationship between leader and the subordinate will increase perceivability of impact among nurses, which will then lead to the behaviour of preventing interpersonal problems from occurring among nurses. These behaviours include giving earlier notice of any changes in work schedule and leaving workstation in good condition. The higher the quality of work and personal relationship between the leader and the subordinate, the higher the tendency to perceive impact among nurses. When nurses know their action gives an impact to the flow of work and organisation, they will increase their awareness in being more courteous at the workplace. The main idea of courtesy is avoiding actions that unnecessarily make other nurses work harder.

Conclusion

This study contributes to current theoretical development by expanded the original structure of Social Exchange Theory within the context of psychological empowerment. This study also provide valuable information on the importance of OCB among nurses in the workplace. Information gained from this research help hospitals to design better working environment that emphasis on OCB at work.

Social Support, Optimism, Parental Self-efficacy and Wellbeing in Mothers of Children with Autism Spectrum Disorder

Farhan Sarwar1, Siti Aisyah Panatik2, Azizah Rajab3, Norakmar Nordin4

1Student, Azman Hashim International Business School, Universiti Teknologi Malaysia, Johor Bahru, Malaysia
2Associate Professor, Language Academy, 3Associate Professor, School of Human Resource Development and Psychology, 4Lecturer, Universiti Teknologi Malaysia, Johor, Malaysia

Abstract

It was hypothesized that optimism, self-efficacy and social support are positive predictors of life satisfaction and positive affect and negative predictors of perceived stress and negative affect. Data was collected by survey method from 47 mothers of autistic children in Lahore and Faisalabad. Hypotheses were tested on four models of four dependent variables using hierarchical regression analysis. Results depicted that parental self-efficacy was a significant predictor of all four dependent variables, social support was a significant predictor of life satisfaction and perceived stress, while optimism only significantly predicted variance in life satisfaction. The study was first of its type to be done with a sample in Pakistani context and has important implications for clinical psychologist. They can plan interventions to enhance subjective wellbeing and reduce stress directly or indirectly by focusing on antecedents tested in the study.

Keywords: Social support, optimism, self-efficacy, wellbeing, autism spectrum disorder.

Introduction

Mothers of children with ASD are prone to mental health issues and often reports symptoms of stress, depression and lower wellbeing.1-3. Parents of ASD have higher psychological distress as compared to parents of children with other mental disorders such as attention deficit hyperactivity disorder 4, cerebral palsy 5 or down syndrome 6. One of the reason that parents feel greater mental pressure is because apparently autistic child has no signs of disability and any disruptive behavior is subjected to social scrutiny 7. Lower quality of life and greater stress in mothers can have further detrimental effect on child, spouse and families as a whole8. Therefore it is important to explore the factors which influence subjective wellbeing of mothers of ASD children especially in Pakistan where mothers share most burden of parenting without substantial support and structural facilities 9. Subjective wellbeing is an umbrella term which is measured with multiple components such as life satisfaction and stress as cognitive components and positive and negative affect as emotional components 10.

Social support has been identified as a critical resource which can diminish the psychological distress related to upbringing a child with ASD 11. Lu, Yang 12 pointed out that there is a lack of studies on informal social support in Asian context. Research has reported that informal social support can be both emotional and instrumental and is especially important resource when one is coping with stress 2. Literature also indicates that social support especially from spouse is extremely useful in reducing stress and improving wellbeing for families of disable children. Moreover support coming from sources external to family such as friends or certain similar parents support groups also significantly contribute to better mental health, greater life satisfaction and lower stress 11-13.

H1: Informal social support available to mothers is positively related to their (a) life satisfaction and (b) positive affect and negatively related to (c) perceived stress and (d) negative affect.

In addition to social support the current study also endeavored to test trait optimism and parental self-efficacy
as predictors of mother’s wellbeing. It is suggested that focus on positive personality characteristics of individuals along with contextual factors can enhance individual wellbeing. A meta-analytic study on impact of parenting stress in mothers of ASD \(^{14}\) concluded that there is a paucity of research on impact of positive parental characteristics on stress. Optimism is a trait of an individual to expect good outcomes from events occurring in life and leads to positive psychological and physical health\(^ {15}\). A positive relationship between dispositional optimism and effective parenting can be established from earlier researches \(^ {16}\).

**H2**: Trait optimism of mothers is positively related to their (a) life satisfaction and (b) positive affect and negatively related to (c) perceived stress and (d) negative affect.

Self-efficacy is a confidence on ones capabilities to organize and execute specific type of actions in order to achieve goals\(^ {17}\). The parental self-efficacy can be defined as the belief of the parents about their competency to set the environment of their child such that it becomes helpful in their positive development so that they become successful in the walk of life\(^ {18}\). Parents high in parenting self-efficacy are in a better position to response to their children’s needs. Therefore, it is hypothesized that:

**H3**: Parental self-efficacy of mothers is positively related to their (a) life satisfaction and (b) positive affect and negatively related to (c) perceived stress and (d) negative affect.

**Methods**

**Research design and Sample**: A cross sectional survey of mothers of autistic children was conducted in two autism schools in Lahore and two special education schools in Faisalabad city of Pakistan. A total of 94 questionnaires were distributed of which 49 were returned. Two of the questionnaires were rejected leaving sample size to 47. The questionnaire was preceded by informed consent. Filled questionnaires were returned anonymously. All the children whose mother filled that questionnaire were diagnosed as autistic without intellectual disabilities.

**Demographics**: All the mothers were married with mean age of 34.4 years ranged between 25 to 47. The ages of child ranged from two years to 16 years with mean of eight years. 78.7% (37) autistic children were boys. Response on level of autism yielded 16(34.0%) on level 1(require support), 18(38.3%) children had autism of level 2 (require substantial support), and 13(27.7%) children had level 3 autism (require very substantial support). All the children were getting education. In 24 (51.1%) cases only mother (OMC) was the sole care take with minimal external support. Majority of mothers were educated with 6 (13%) intermediate, 7 (14%) having 14 years of education, 18(38%) having 16 years of education and three (6%) had post-graduate (masters/PhD) degrees. Only two mothers reported to be under-matric. Majority of mothers i.e. 40 (85.1%) were not doing job.

**Measurement**: All the measures were adopted from previous studies and administered on a five-point scale. The adopted scales and their reliability values are presented in table 1.

Hierarchical Regression Analysis: SPSS was used to carry out four hierarchical regression analysis. For every regression all eight control variables and three predictors were added simultaneously. The results are depicted in Table 3. From the results it is evident that social support had a significant positive relationship with life satisfaction and negative with perceived stress hence H1a and H1c were accepted. Optimism was only significantly related to life satisfaction therefore only H2a was accepted. However parental self-efficacy had significant and most strongest relationship with all four of the predictors therefore H3a, b, c and d were accepted. From the control variables OMC was significantly related to life satisfaction and level of optimism with perceived stress. The control variables and predictors explained approximately 61% variance in life satisfaction, 30% in positive affect, 52% in negative affect and 60% in perceived stress.

Discussion

The present study focused on the relationships of social supports, optimism and self-efficacy of mothers of autistic children with maternal subjective well-being. To our knowledge, this is the first study to examine these associations among Pakistani parents of children with ASD. Distress and emotional turmoil is obviously very common during parenting in comparison with parenting of normally developing child. To cope with this stress, self-efficacy is established as an overall important factor by this study. Parental self-efficacy not only brings the satisfaction for the family life but has benefits for the children to.
Albeit the higher level of optimism of mother of children with ASD as expressed in the study, there seemed to be no significant reduction in stress and significant corresponding change in positive and negative affect. This insignificance can be attribute to culture. In Pakistani society to express of being positive and optimistic is more a habit rather than cognitive decision. Another explanation is that optimists tend to hope for the best in adverse situations. They have beliefs that can turn into high expectations about a desired outcome. These high expectations lead them to focus obsessively on the outcomes. A child with ASD has pervasive and severe deficits which continuously require the efforts of caretaker and produce the persistent emotional disturbance. In such scenario the high expectations are not fulfilled, and the result is disappointment and distress. Persistent or uncontrollable stressors violated optimists’ positive expectations that they could terminate or control the stressors, leading to distress

The findings on relationship of social support with stress and life satisfaction are in accordance to earlier studies. No empirical support was found for relationship of social support with these components of emotional wellbeing. The social support network in Pakistan is not as extensive and health care facilities are limited. It is mostly limited to the informal social support (spouse, family and friends). As all the members of immediate family also experience the emotional disturbance, so the mother of the autistic child cannot have the adequate emotional benefit from the social support of family members. There is lack of formal support i.e., support from community centers e.g., club for such parents having this same scenario, easily accessible schools for Autistic children, organizations for providing financial aid and healthcare units. It is required that there should be interaction of the families and specifically mothers facing the same situation of having the children with ASD.

Implications and Recommendations: The current research has various implications for clinical and counselling psychologist. They need to understand that various subjective wellbeing measures can also help them identify and treat whole range of mental disorders. For instance both low positive affect and high negative affect reflects presence of depression whereas anxiety is more relevant to negative affect and less related to positive affect. Growing research and awareness of contextual factors and personality characteristics as antecedents of subjective wellbeing and stress suggests that clinical psychological approach can play very influential part. In a study carried out in 2010 on relationship between autism and parents coping behaviour and mental health, it was found that using cognitive reframing techniques was helpful in eliminating their depression and anger thereby improving their wellbeing.

Our findings identified importance of social support in enhancing life satisfaction and diminishing stress. Therapeutic intervention of “social skills training” based on cognitive restructuring can prove to be influential in teaching new behaviours to people enhances individual ability to establish and retain new social relationship thereby positively influencing wellbeing. Moreover antecedents of subjective wellbeing and stress has been found to vary across cultural context. This can help clinical practitioners to device intervention which do not fall into trap of one size and fits all rather be more tailored for the target population which in this case is Pakistani mothers whose child(ren) suffer from ASD. The knowledge of various factors that leads to stress in mothers identified in this study can help practitioners to concentrate on nabbing those issues while providing counselling to the mothers.

Employee Performance of Private Hospital Non-Medical Services

Bernadetha Nadeak¹, Sasmoko²,*

¹Lecturer, Educational Administration Department, Faculty of Post Graduate Universitas Kristen Indonesia, Jakarta, Indonesia, ²Professor, Primary Teacher Education Department, Faculty of Humanities, ³Researcher, Research Interest Group in Educational Technology, Bina Nusantara University, Jakarta, Indonesia

Abstract

The performance of non-medical employees is a very important concept especially for a hospital in measuring the quality of services provided. Therefore a measure is needed that is able to measure how the expected performance and its achievements can provide input to produce optimal performance. This study aims to look at the factors that can be used as benchmarks for performance and how the performance description of non-medical employees in private hospitals. The study was conducted with a correlational survey. The results showed that the performance of non-medical services in private hospitals showed good service supported by the ability of employees to complete a number of service tasks simultaneously and carefully.

Keywords: Employee performance, private hospital non-medical services.

Introduction

Indonesia is currently making efforts to improve in various fields so that it can adjust to the various advances that have taken place. Similarly, industries engaged in services and services, especially hospitals, also experience increased competition, especially in providing quality services provided to their customers. Service quality is one of the performance benchmarks for hospitals which is the output of hospital employee performance, especially for non-medical employees.

Performance is a concept that has been developed and is always interesting to study. Performance is a multi-dimensional concept and is related to many factors. Performance can be related to the process of learning and mastery of tasks, abilities, knowledge and skills in carrying out these tasks. Moreover, performance measures are the most important thing to measure the sustainability of an organization. In addition, performance is important because it can be one of the satisfaction indicators for both employees and the organization itself.

Therefore, considering the importance of performance measures, this study wants to look at factors that can be used as benchmarks for performance and how the performance description of non-medical employees in private hospitals.

Literature Review: Performance is an action that is under the control of an individual or conscious behavior that contributes to the achievement of organizational goals. Performance is divided into task performance and contextual performance, where individual factors play an important role in realizing contextual performance. Performance also has two other dimensions, namely adaptive performance and counterproductive work behavior.

To be able to produce high performance, the employee must be able to fulfill the four components. So that personally each employee must be able to hone themselves to further develop a proactive personality in order to meet the demands of performance as expected.

In terms of task performance, for non-medical employees in private hospitals, performance benchmarks can be seen from how employees are able to fulfill daily...
tasks that can be realized through several indicators, namely employees skilled in doing technical work so they can have the ability to direct work correct, serious in completing tasks, and completing tasks with consistent and efficient use of time. Thus the employee will be able to complete a number of service tasks simultaneously and carefully.

Contextual performance looks more at how someone does things that can support performance. This can be realized through a number of indicators, namely rarely making mistakes, being careful in doing work so as to produce accurate work, working in detail, being able to determine priorities, being able to maintain upward relationships with co-workers, superiors or customers. In addition, employees are also able to show a responsible attitude and are able to account for the work as well as the results because they have full attention to their duties. Therefore contextual performance is usually related to the personality or character possessed by employees.

While adaptive performance can be seen from how employees are able to make decisions, develop alternative solutions and appropriate actions and understand the consequences of the task. In managing change, better ideas are needed from employees and initiatives towards new tasks. Therefore employees can support the organization in making decisions with these new ideas and in different ways.

**Research Methods**

The research method is carried out with correlational surveys. Sampling technique is done by accidental sampling with a sample of 400 employees. Technique of collecting data with self-assessment through a scale questionnaire of 1 to 5.

The instrument was developed through the study of 40 performance indicators for non-medical employees, namely:

1. Technically skilled (X1),
2. Steering ability (X2),
3. Seriously complete the assignment (X3),
4. Complete tasks consistently (X4),
5. Use time efficiently (X5),
6. Rarely make mistakes (X6),
7. Thorough (X7),
8. Accurate (X8),
9. Work with details (X9),
10. Able to determine priority (X10),
11. Maintain relationships (X11),
12. responsible (X12),
13. Able to account for work (X13),
14. Able to complete a number of service tasks simultaneously and carefully (X14),
15. Insured on the results of the assignment (X15),
16. Have full attention (X16),
17. Perform tasks according to the time target (X17),
18. Report to supervisor if there is a problem (X18),
19. Able to make decisions, develop alternative solutions and appropriate actions (X19),
20. Understand the consequences of the task (X20),
21. Discipline (X21),
22. Present on time (X22),
23. Obedient (X23),
24. Obey the leader’s instructions (X24),
25. Complete the task on time (X25),
26. Carry out instructions (X26),
27. Maintain workplaces (X27),
28. Have initiative (X28),
29. Have a better idea (X29),
30. Initiate new assignments (X30),
31. Make decisions with new ideas (X31),
32. Complete tasks in different ways (X32),
33. Work on tasks without being ordered (X33),
34. The willingness of the concerned person to correct the error in carrying out the task with tangka (X34),
35. Give creative ideas (X35),
36. Take advantage of the Bali bait (X36),
37. Have initiatives to deal with institutional problems (X37),
38. Have innovative solutions (X38),
39. Can work independently (X39), and
40. Give support and help from others (X40)
Results And Discussion

Test the normality of variable empirical data on the performance of employees of non-medical services in private hospitals.

First, tested the empirical data distribution normality of the variable performance of non-medical services in private hospitals. Normality test is done by Proportion Estimation through Blom Formula with Q-Q Plot approach. Q-Q approach The plot was taken because the number of research samples was > 200 people (40- non-medical servants).

Based on the results of the Q-Q Plot Normal calculation, the data distribution shows normal, that is, the distribution of the data tends to lead to the normal line, and the distribution of the data does not have an outlier. Likewise if seen from Detrended Normal Q-Q the plot, the distribution of the data does not describe sine or cosine curves. So in conclusion, the variable distribution of empirical data on the performance of non-medical services for private hospitals has a normal distribution.

The results of the first analysis that looked at the trends in the performance conditions of private hospital non-medical services showed that in proving the results of this study, researchers in determining 4 (four) categories of performance of private hospital non-medical service employees were: (a) the service performance was very low, (b) service performance is low, (c) service performance is high, and (d) service performance is very high. Data analysis was carried out with a confidence interval at a significance level of 5%, and a lower and upper bound was produced between 170.7062 to 173.6488. Based on these results, it can be concluded that employees of private hospital non-medical services tend to have high service performance significantly at $\alpha < 0.05$.

The results of the second analysis, carried out with Binary Segmentation called Classification and Regression Trees. In this analysis, the researcher set a Prunning depth of 2, a Prunning Parent of 2, a Child Prunning of 1, and a significance level of $\alpha < 0.05$. The results of this analysis prove that the ability to complete a number of service tasks simultaneously and carefully (X14) is the most decisive shape of the performance of employees of non-medical services in private hospitals. If the task of a number of services carried out simultaneously and meticulously is increased, then its performance as a non-medical service employee will increase 139,380 times from the current condition. To be able to make it happen, non-medical service employees are required to have the ability to make decisions, develop alternative solutions and appropriate actions (X19) as well as jointly with the willingness of the concerned person to correct his / her own mistakes in carrying out the task (X34). If both of these are done well, the capacity of non-media service personnel to complete tasks will increase 33,852 times from current conditions.

The results of the third analysis that looked at demographic influences showed that

From the gender differences both male and female non-medical service employees, the service performance was significantly higher at $\alpha < 0.05$.

In addition, there are differences in terms of service performance of non-medical staff of private hospitals, if differentiated based on their educational background, namely between doctoral (S3) and master’s (S2) education with t-student of 6.394 with a significance value of 0.000 which is very significant at $\alpha < 0.01$. Based on the difference in mean, it was found that non-medical service personnel with doctoral degrees (S3) had a moderate service performance that had a very significant master’s degree (S2) performance at $\alpha < 0.01$.

There are differences in terms of service performance of non-medical private hospital employees, if differentiated based on age with F of 3.191 with significance value 0.013 is significant at $\alpha < 0.05$. Based on the difference in mean, it was found that non-medical service employees of private hospitals aged 50-64 years had high performance, while others, employees who were aged 50 years and over 64 years had low performance.

There are differences in terms of service performance of non-medical private hospital employees, if distinguished by hospital location with F equal to 3.825 with significance value 0.002 is significant at $\alpha < 0.05$.

There are differences in terms of service performance of non-medical private hospital employees, if distinguished based on work experience in private hospitals with F of 3.272 with a significance value of 0.021 is significant at $\alpha < 0.05$.

Conclusions

The results showed that employees of non-medical services in private hospitals had performance that had
good service. This performance is supported by the realization of the ability of employees to complete a number of service tasks simultaneously and carefully. This means that fulfilling task performance is important in producing optimal performance so that employees must clearly understand the job description that must be done\textsuperscript{14-17}.

To be able to complete a number of simultaneous and careful service tasks, non-medical service employees are required to have the ability to make decisions, develop alternative solutions and appropriate actions and also jointly with the willingness of the concerned person to correct mistakes in carrying out tasks with suspicion. Both of these are related to contextual performance and adaptive performance which are important factors in producing performance\textsuperscript{8,18-20}.

16. Lauver KJ, Kristof-Brown A. Distinguishing between Employees’ Perceptions of Person–Job

Perceived Effects of KOACI.COM Health Campaign Targeting Mother-Child with HIV/AIDS in Côte d’Ivoire

Hasmah Zanuddin1, Ousmane Koffi Abdoulaye2

1Associate Professor, 2Student, Department of Media Studies, Faculty of Arts & Social Sciences, University of Malaya, Kuala Lumpur, Malaysia

Abstract

Through a variety of media, many health care practitioners and health sectors have employed mass media to disseminate public health information to the general public and to raise awareness of HIV/AIDS, because media representations are deemed able to impact public perceptions and opinions, advocate behavior change, and influence policy and campaign strategies1. The aims of this study are the access to health information, and able to reach the public through online newspaper services. The analysis of HIV/AIDS awareness campaign through the daily online newspaper, targeting mother-child within the Ivorian people. Koaci.com, a online newspaper created since 2008 and based in Abidjan, which gathers every day on its supports (web, mobile, and application) nearly 100,000 readers per day, it achieved the highest score at the time; all press focal points with a superb trophy. The national AIDS Indicator Survey (AIS) find out that the HIV/AIDS epidemic in Côte d’Ivoire has changed in gender, age, and geographic distribution. Female HIV prevalence declined from 6.4% to 4.6%, still much higher than male HIV prevalence, which remained almost unchanged at 2.7%. Prevalence dropped dramatically among women ages 30-34 (from 14.9% to 6.8%) and women are the HIV-positive partner in about 50% of serodiscordant couples now, down from about 67% in 2005. Geographically, HIV prevalence remains highest in Abidjan and in the Southwest, but other higher-prevalence zones have shifted to the Center-North and the West, where civil and ethnic conflict-displaced populations, disrupted social networks, and increased rates of gender-based violence (GBV).

Keywords: Health information, online newspaper, awareness campaigns, mother-child, HIV/AIDS.

Introduction

This study about HIV/AIDS prevention the Mother-Child with the stated goal of improvement of effective health information and awareness campaigns. The aspiration of women and girls to have a child and become a mother even though many of them lack awareness and information about sexual health expose them to risk. Therefore, to enable women’s access to health care. National control programs against HIV; improved health care of people living with HIV with antiviral therapy; the free testing in some medical centers, along with NGOs and civil society are as well involved in the eradication of this epidemic. In Côte d’Ivoire, sensitization programs were put in place in different areas via the media, including awareness campaigns, advertisements programs1.

The health status of the infant and child mortality rates remain high, at 88 deaths per 1,000 live births. Infectious diseases, primarily malaria, gastrointestinal ailments, respiratory infections, measles and tetanus, account for most of the illness and death among children2. According to the national AIDS Indicator Survey that the HIV/AIDS epidemic in Côte d’Ivoire has changed in gender, age, and geographic distribution. However, HIV prevalence among Female HIV declined from 6.4% to 4.6%, but still much higher than male HIV prevalence, which remained almost unchanged at 2.7%, while, prevalence dropped dramatically among women ages 30-34 (from 14.9% to 6.8%) and increased significantly among older children2.
men (from 5.9% to 7.8% among ages 40-49, reaching 9% among ages 50-59)\textsuperscript{3,4}. Table 1 illustrates the HIV/AIDS as the first most important cause of death in Cote d’Ivoire.

Health Information campaigns: Information, education, and training are important components of Prevention of Mother-to-Child Transmission of HIV (PMTCT) efforts. However, the health workers in the field should receive formal PMTCT training that would allow them to take care of pregnant women\textsuperscript{6,7}. The information and condom distribution campaigns show that the level of awareness about HIV and its transmission modes is rising over time; such approach suffers from a number of limitations. While information campaigns were focused on the urban areas, were of temporary nature and seldom targeted the high-risk groups. The distribution of condom, because of the resistance of religious groups and difficulty to persuade people to use them and, indeed, sexual behaviour does not appear to change easily in response to public information campaigns\textsuperscript{8,9}.

Objective of the Study: The aim of this study is awareness campaigns in relation to child and women health issues, particular, HIV/AIDS, the specific aims as follow:

a. To provide a review of the effectiveness of online media to increase Prevention of Mother to Child Transmission of people living with HIV

b. To determine the effectiveness of social marketing in the view of online media to enhance HIV/AIDS message delivery

Research Questions: The study was guided by the following research questions:

a. What are the health programmes and health awareness campaign covered by the online newspaper?

b. How do social marketing and online newspapers impact community and health awareness campaigns?

c. Could health coverage of HIV preventive and awareness message impact the people?

Literature Review

Health System and HIV Prevention: In early 2012, the government of Côte d’Ivoire shifted toward a program of “targeted free services” for pregnant women, children, and medical emergencies. Given that HIV/AIDS services are fully integrated into the public health system\textsuperscript{10}. To increase the provision and quality of health services at all levels of the health system. The government has adopted the country’s performance-based financing program as a key strategy for reducing maternal and infant mortality among the most vulnerable populations.

Regarding HIV counseling and testing, regularly, women seeking prenatal care at participating health center receive general health education, including information about HIV and major prevention messages. All women obtain specific posttest counseling, which is more time-consuming than was pretest counseling, given the need to effectively shape information for women according to serostatus. Addressing infant feeding choices for mothers is important since one third to one-half of all mother-to-child transmissions occur postnatal through breastfeeding\textsuperscript{11}. In Cote d’Ivoire, the national HIV testing and counseling and antiretroviral treatment programs have continued to grow, with monthly ART enrollment increasing to 2,500 in May 2010 and stabilizing at 2,000 by October 2011\textsuperscript{12}.

Media intervention: Media health campaigns are undertaken to disseminate information about. They can be standalone interventions or be integrated into complex social marketing programmes\textsuperscript{13}. The programs in which mass media is part of a multifaceted intervention approach are more likely to be successful than mass media alone and that one-off or episodic behaviors are more amenable to mass media effects than habitual. In fact, health communication campaigns are almost always implemented in conjunction with other
interventions. However, the successful intervention is one that combines several methods, such as the theory of planned behavior, seeing that HIV/AIDS infection is a perceived social norm.

Although Côte d’Ivoire’s significant progress in mobilizing HIV/AIDS interventions, the level of unmet need for treatment is high and appears to be related to the large number of people who do not know their HIV status and are unable or unwilling to access public services. However, the media can help inform people to act on their healthcare.

Role of Online Newspaper: Media in general provide social movements an opportunity to shape public “collective minds” about specific political or social problems, in this study the role of online newspaper in shaping health information and coverage, such as Koaci.com created in 2008, is an independent pan-African online newspaper based in Abidjan. The following news articles reported by Koaci.com in fighting against parental and child death, as well as coverage of HIV/AIDS, the Ministry of Health and Public Hygiene launched mobile clinics and emergency medical services throughout the national territory. Taking into account the fight against maternal and infant mortality, HIV testing and to assist people in the event of disasters.

To mark, the World AIDS Day, the government announced, “Zero mother-to-child transmission, zero child deaths”, “To increase the mobilization of individuals and communities in order to improve the access of women of childbearing age to HIV prevention services and to satisfy access to prevention and treatment services for all HIV infections.” the world leaders had pledged to eradicate AIDS by 2030. In this perspective, Côte d’Ivoire has adopted a strategic 2016-2020 plan for the fight against AIDS, focused on achieving the objectives 90-90-90, with a rate of disease regression in the country. However, there is a continuing decline in the HIV prevalence rate from 4.7% in 2005 to 3.7% in 2012.

Hypothesis of the study: The hypotheses are formulated based on the reality that health communication campaigns are almost always implemented in conjunction with other interventions. Therefore, the study suggests that:

H1. Online newspaper is positively effective in providing health programmes and health awareness campaigns

H2. Media health coverage has positive effect to reach the people and disseminate the preventive and awareness message, particular the remote area

H3. Social marketing along with mass media intervention will likely affect social norm and improve health promotion and awareness.

Conceptual framework

Social and Behavior Change Communication: To strengthen the effectiveness of HIV prevention, social marketing, and media awareness campaign is essential. Social marketing is commonly used as an approach to reach vulnerable populations with health products and services. Social marketing ranges from tangible products, to services (voluntary counseling and testing for HIV) and practices, to intangible products (such as knowledge of ways HIV is transmitted). The strengths of the social marketing approach is gaining access to these vulnerable sections of the population, which the Agence Ivoirienne de Marketing Social managed with proficiency and great dedication, focusing on promoting the use of condoms for HIV prevention. The programme also offers pills and hormonal injections through health facilities and pharmacies. However, a large market share of social marketing products is a positive sign of their acceptance.

Research Methodology

Data collection and Procedures: The research designed used the content analysis, which is described as: “A technique for gathering and analyzing the content of text, therefore, Ivorian online newspaper’s health awareness and campaigns, which took place from January 2016 to December 2016, a few keywords had been determined that appear in the headlines, such as “HIV/AIDS and “Mother and Child” awareness campaigns.

An initial set of 34 available articles was examined and content analysed. The coding instrument to carry out the quantitative content analysis, which was developed for analysis of 95 items of online newspaper.
**Inter-Coder Reliability:** Inter-coder reliability is deployed as a component of content analysis, a standard method of summarizing the substance of a set of mediated messages. Two independent coders were used to test the coding instrument. The inter-coder reliability testing was calculated by using Holsti Test Format as follow:

$$\frac{2M}{N_1 + N_2} = \frac{2 \times 480}{1140} = 0.84 = 84\%$$

**Data analysis:** Data was analyzed using Statistical Package of Social Sciences (SPSS); and Chi-Square analysis to answer the hypothesis.

**Results and Findings:** The study used 34 articles on health programs coverage and awareness campaigns provided by online newspaper, KOAC1.COM. While the Budd’s attention score frequency and percentage of health coverage in 2016, it appeared that more articles published in November with (21.1%), while in December with (18.2%), August and October with (12.1%).

The results in table 2, 3 and 4 show the range of frequency distribution, health programme and health campaigns, vulnerable of people affected by the health issue and social and behavior change communication campaigns, respectively reported by the online newspaper articles were content analyzed, using (Yes) and (No) agreement between the researcher and two coders.

a. 4 cells (100.0%) have expected count less than 5. The minimum expected count is .33.

**Conclusion**

Côte d’Ivoire’s progress in mobilizing HIV/AIDS interventions, it appears to be related to the large number of people who is not aware about their HIV status. As the women still much higher than male HIV prevalence in the area of Abidjan, capital city of Cote d’Ivoire.

In the analysis of the health programs and awareness campaigns, however, the aggressive public outreach campaigns and education interventions to target people in high-risk, in particular treatment services, are essential at this stage of the epidemic, as online media has the power to change peoples’ attitudes and beliefs, therefore, the online newspaper can be a key part of preventative actions to disseminate health information among the vulnerable group, as an effective messaging
to reach and educate the public health issues, such as prevention and awareness campaigns of mother-to-child transmission.

Do Demographics Matter? A Study on Administrative Staff’s Satisfaction Level Towards their High Education Institutions

Lokman Mohd Tahir1, Narina A. Samah1, Sanitah Mohd Yusof1, Mohd Fadzli Ali2, Noor Azean Atan3, M.Al-Muzammil Yassin1

1Associate Professor, 2Lecturer, 3Senior Lecturer, School of Education, Universiti Teknologi Malaysia, Scudai, Malaysia

Abstract

This study investigates administrative staff’s satisfaction level towards their higher educational institutions (HEI). In this study, we compare administrative staff’s satisfaction differences from their demographic profiles: working experiences, age, and gender. A total of 322 administrative staff provided their feedbacks based on three elements of satisfactions which are: satisfied with their knowledge, satisfied with the management process of their HEI and finally satisfied with the escalation or growth of their HEI. The findings reveal that administrative staff were satisfied with knowledge obtained followed by satisfaction on the management of the university. On the other hand, administrative staff of HEI felt that they are least satisfied with the HEI’s escalation. The findings unveil that female and senior administrative staff have much higher level of satisfaction compared to other related age and working experience groups.

Keywords: Satisfaction, administrative staff, Higher Education Institutions.

Introduction

Recognising the necessities for quality higher education, the role of universities and higher education institutions in Malaysia recently have significant roles in ensuring students’ improvement in terms of their socio-economics as part of the national economic planning strategy 1, 2.

In realising the significant role of HEI, the administrative staff also played their essential roles alongside with the academic staff. With their crucial roles in determining the smooth administration of HEI, their roles are indeed essential within management elements such as human resources, financial management, facilities and information technology 3, 4. While working with their HEI, the administrative staff also experienced similar experiences with the academics in how well they engaged with their own HEI which later leads to their satisfaction as indication for their creativity and commitment 5. Operationally, satisfaction is being defined as an individual’s feeling or reaction towards their job 6, 7 which influenced the feeling of distress, absenteeism and increased job performance 8.

Although the role of administrative staff in HEI is significantly essential, there are limited studies that measure their level of satisfaction compared to the academics. To date, only a few studies that measured the administrative staff’s satisfaction such as a study by Jung and Cheolshin (2015) 9 who served with Korean research university and Kipkebut (2010) 10 with administrative staff of private universities in Kenya. In both studies, a few elements which include the administrative staff’s job specification were analysed as predictors for administrative staff’s satisfaction. Additionally, their demographic variables were assumed to play its role as a predictor of administrative staff’s satisfaction. In Khan, Ullah and Jahan (2015)’s 11 study, administrative staff’s satisfaction that worked at universities in Bangladesh revealed that they were satisfied working with their universities and highly associated with their demographics. Based on findings from both studies, it is assumed that sample demographics have significant implications towards administrative staff’s satisfaction which warrants further investigation.

Corresponding Author**
Lokman Mohd Tahir

e-mail: p-lokman@utm.my
In the context of Malaysian HEI, admittedly, there is a wide gap since not many studies have been carried out that measured their administrative staff’s satisfaction. Notably, previous local studies mostly measured the academics job satisfaction such as studies by Sam et al. (2012) and Sadeghi et al. (2012) from research-based universities in Malaysia. In terms of demographics, it is assumed that demographic variables have strong influence or relationship satisfaction: age, working experience and their gender. Although previous studies elaborated demographics have significant impact on their satisfaction, however the relationship with administrative staff’s satisfaction remains less investigated. Therefore, this exploratory study aimed to identify the administrative staff’s satisfaction towards their HEI’s; secondly, to analyse the differences in administrative staff’s satisfaction based on their demographic profiles of gender, age and working experiences; and finally, to examine whether administrative staff’s demographic profiles have significant influences to their satisfaction towards HEI.

Methodology

Design and sample: Since this study is descriptive in nature, it employed the survey method design, and data were collected from 322 administrative staff from randomly selected HEI. In terms of their working experience, 85 administrative staff had 5 to 10 years’ experience (26.3%) followed by 73 administrative staff who had less than 5 years of experience (22.6 %) and 61 administrative staff who have 11 to 15 years working experience (18.9 %). In addition, 44 administrative staff had 16 to 20 years of experience (13.6 %) with 16 administrative staff had 21 to 25 years of experience working with HEI and another 14 administrative staff had 26 to 30 years of experience and 30 staff had more than 30 years of experience.

Majority of administrative staff that participated in this study aged between 31 to 40 years old (N=109; 33.7%) followed by 101 administrative staff who aged between 21 to 30 years old (31.3%). In addition, another 71 administrative staff who aged between 41 to 50 years old (22 %) and the final age group are 42 administrative staff who aged between 51 to 60 years old (13%). Based on administrative staff’s gender, findings reveal that a total of 130 administrative staff are male staff (40.2%) followed by 192 (59.4%) are female administrative staff.

Instrumentation: This present study employed 23 items which were developed to measure the administrative staff’s satisfaction to their HEI. Overall, the questionnaire consists of two major sections.

In section A, three major items were enquired to administrative staff related to their demographics: age, working experience and their gender. In section B, all 23 items were constructed using the positive expressions and all negative expression items were gone through the reversing process. Items were constructed using a five-point Likert scale: 1 – strongly disagree, to 5 – strongly agree. Empirically, the 23 items within the questionnaire represented with three sub-constructs which are: satisfied with knowledge (2 items), satisfied with the management process (15 items) of HEI and, lastly, satisfied with escalation elements (6 items) of HEI. In constructing the items, previous studies that measured administrative staff’s job satisfaction were denoted such as Cheolshin (2015) and Volkwein and Zhou (2003) studies.

All items were constructed in the Malay language based on the demographics elements of the administrative staff who mostly received their education in the Malay language. In the pilot study, ten selected administrative staff from public university was approached in obtaining their responses on the 23 items. In this study, the measurement of internal consistency was based on the alpha Cronbach values and finding showed that most items internal values were 0.872 which considered as accepted values suggested by Hair et al. (2010).

Results

Measuring administrative staff’s job satisfaction: Results from the survey indicate findings related on the measurement of administrative staff’s satisfaction towards their HEI using descriptive statistics which comprised the mean scores and standard deviations which presented in Table 1 below.

<table>
<thead>
<tr>
<th>Satisfactory Facets</th>
<th>Mean scores</th>
<th>Standard deviations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Knowledge</td>
<td>3.95</td>
<td>0.65</td>
</tr>
<tr>

<td>0.67</td>
</tr>
<tr>
<td>Escalation</td>
<td>3.75</td>
<td>0.61</td>
</tr>
<tr>
<td>Overall</td>
<td>3.83</td>
<td>0.52</td>
</tr>
</tbody>
</table>

In Table 1, the element of satisfaction of having wide knowledge has the highest mean scores (mean = 3.95; SD = 0.65) followed by satisfaction on the management of the university (mean = 3.80; SD = 0.67) and finally the satisfaction of the HEI’s escalation (mean= 3.75; SD= 0.61). The overall mean score indicated the value of 3.83 (SD = 0.52) which pointed out that administrative staff of the HEI have high satisfaction towards their HEI.
Differences based on administrative staff’s demographic profiles: In addressing the differences in relation to administrative staff’s satisfaction towards their HEI, their demographics: gender, age, and their working experience were analysed. In analysing administrative staff’s gender, t-tests were executed and summarised in Table 2 below.

Table 2: T-test results on satisfaction differences based on administrative staff’s gender

</tbody>
</table>

*p < 0.05; N= 322.

Based on the data, it showed that there is no statistically significance difference between male and female administrative staff based in terms of the element of knowledge \( [n = 322( t = 2.048; p = 0.41)] \), management process of their HEI \( [n = 322 \ (t = 1.211; p = 0.26)] \) and lastly the element of escalation of HEI \( [n = 322( t = 1.509; p = 0.19)] \). Comparatively, mean score for female administrative staff are indicated higher than their male counterpart which reflected that female staff has much higher levels of satisfaction towards their HEI compared to male. Therefore, it is concluded that there isn’t any differences based on administrative staff satisfaction based on their gender however, the female administrative staff has higher level of satisfaction towards their HEI compared to the male staff.

Further, we also examine administrative staff’s satisfaction based on their age and working experience with their HEI. For this reason, we employed the one-way ANOVA to compare administrative staff perceptions of their HEI. Based on the findings, there are no significant differences on all three elements on administrative staff’s satisfactions based on their age and working experiences. In terms of administrative staff’s age group, there is no significant differences noted in the element of knowledge \( [N=322(F = .774; \text{ Sig } = .509)] \), management process \( [N=322(F = 2.212; \text{ Sig } = .087)] \), and escalation of HEI \( [N=322(F = .977; \text{ Sig } = .404)] \). Based on the mean scores for age groups, administrative staff aged between 51 to 60 years old has higher mean score compared with other three groups. Thus, it is indicated that the senior administrative staff has higher level of satisfaction towards their HEI. On the contrary, the age group of 41 to 50 years old was revealed as the age group has lower mean score which showed their least satisfaction towards their HEI.

As for administrative staff’s working experiences, all three elements of satisfaction also indicated no significant differences. For instance, for the element of knowledge \( [N=322(F = 1.500; \text{ Sig } = .178)] \), management process \( [N=322(F = 1.434; \text{ Sig } = .201)] \), and escalation of HEI \( [N=322(F = 1.852; \text{ Sig } = .89)] \).

Based on the findings, it is believed that senior administrative staffs have higher level of satisfaction towards their HEI. However, administrative staffs that were at their middle years of service were perceived to have lower satisfaction towards their HEI.

Relationship between administrative staff’s demographic with satisfaction: In identifying the prediction of administrative staff’s demographics towards their satisfaction, regression was performed to analyse how well the demographics predict the staff’s satisfaction.

Table 3: Regression coefficients on HEI administrative staff’s satisfaction

</tr>
</tbody>
</table>

*p < 0.05; N= 322.
In Table 3, the regression results showed that there is least influence of administrative staff’s demographics on their satisfaction based on administrative staff’s demographics. However, the regression indicated that the administrative staff’s gender has effects on the administrative staff’s satisfaction related to knowledge element based on the adjusted $R^2$ value which was indicated at 0.009. This indicates that only 0.9 per cent of the variance in administrative staff’s satisfaction was predicted by administrative staff’s gender within the knowledge element [$F (1, 321) = 2.204; \text{Sig} = 0.028$].

**Discussion**

This study was designed to examine whether administrative staff of HEI have high level of satisfaction towards their HEI based on their demographic variables including gender, working experience and their age. Evidently, administrative staff from HEI indicated that they have high level of satisfaction towards their HEI. Based on the findings, it is revealed that administrative staff of HEI seems to be satisfied while working at their HEI. Thus, it is literally proven that administrative staffs of HEI are satisfied working at their HEI with the element of knowledge obtained scored much higher mean scores among the three elements of satisfaction that was investigated. The differences were measured based on demographic variables of gender, age and working experience. Result obtained from inferential t-test indicates that no significance difference in terms of administrative’ gender based on three elements of satisfaction which are the knowledge, management process and escalation of HEI. Even though, inferential t-test showed no significance difference based on gender, mean score for female administrative staff were indicated higher than their male counterpart who reflects that female administrative staff has higher levels of satisfaction compared to male administrative staff at their HEI. Furthermore, we also analysed the significant differences based on other administrative staff’s demographic variables of age and their working experiences. The findings revealed that all two demographics did not show any significant differences based ANOVA results. However, based on the age and working experiences, it is assumed that senior administrative staff which aged between 51 to 60 and being working almost 30 years has much higher level of satisfaction compared to the other age and working experiences groups.

Finally, we also used regression test to measure the significant linkage between administrative staff’s demographic profile comprised of age, gender and working experience. Results confirmed that all demographic variables were weak predictors of administrative staff’s satisfaction in all three elements of satisfaction. Based on the table, administrative staff’s gender within the knowledge element has little significant implication on their satisfaction.

Benefits of Breast Milk for Health Care: Analysis from the Islamic Perspective

Normadiah Daud1*, Hamizah Ismail2, Siti Roshaidai Mohd Ariffin3, Rahimah Embong1, Nadhirah Nordin1, Ado Abdu Bichi4

1Faculty of Islamic Contemporary Studies, Universiti Sultan Zainal Abidin, Malaysia, 2Kulliyyah of Medicine, 3Kulliyyah of Nursing, International Islamic University Malaysia, 4Faculty of Education, Yusuf Maitama Sale University, Kano Nigeria

Abstract

Breastfeeding truly gives an enormous effect towards the health of a mother and child. Breast milk contains nutrients which are highly beneficial for an infant’s health and growth. Among other benefits for a baby is it helps to develop the baby’s intelligence, it is very clean and it can save a baby from various diseases. There are lots of explanations in Islam with regards to the important position of breast milk in the life of a child however; there is lack of empirical evidences pointing out the importance of breastfeeding for health care from the Islamic perspective. In view of these the present paper aimed at studying the importance of breastfeeding for both child and mother according to the perspectives of Islam. This research is based on literature review method. Data was collected through documents analysis which consists of turath (traditional) and modern books as well as articles related to breastfeeding. The review revealed the importance of breast milk for a baby’s health; apparently the opinions of scientists are in parallel with the opinions of fuqaha. In fact, fuqaha from Shafi‘i and Hambali sects obliged the feeding of al laba’ which is colostrum to newborn babies. Conclusively, Muslims are made by the Islamic injunctions to believe that breast milk is just an effort to prevent a child and a mother from being inflicted with any diseases. This paper provides an important highlight that the breastfeeding is not only significance according to science but also because it fulfils the syarak requirements.

Keywords: Breast milk, Health Care, Islamic Perspective.

Introduction

Breast milk is the best food for babies especially right after birth until about 6 months old. It contains all the nutrients in the right amount. Breast milk also contains colostrum which helps to fight infections from numerous diseases such as diarrhea, cold and pneumonia. Furthermore, it acts as the first immunization for newborn babies1. The benefits of breastfeeding are also in parallel with Allah’s commandment in surah al-Baqarah verse 233 which advocates mothers to breastfeed their children up until the age of two. In fact there are numerous hadiths and opinions of fuqaha’ (experts in Islamic jurisprudence) and sahabiyat (female companions of Prophet SAW) that, discussed the benefits of breast milk.

Therefore the objective of this research is to study the importance of breast milk from the science perspective while at the same time, analyzing it based on the Islamic perspective. Previous researches especially turath books focused primarily on the significance of breastfeeding based on the Islamic perspectives only. For example, literatures produced by 2,3,4 and many others. They only discussed the concept and advantages of breastfeeding from the Islamic perspectives while breastfeeding from the aspect of science was not clearly mentioned.

In Malaysia there are numerous literatures with regards to breastfeeding. Examples include5,6,7,8,9 and others. These literatures present the benefits of breast milk from the aspect of science, and they advocate
breastfeeding. Analysis based on the Islamic perspectives on the science aspects was not carried out. Therefore, the authors saw a loophole in the previous researches hence this paper will discuss both aspects; the benefits of breast milk based on science and the analysis based on the Islamic perspectives.

Benefits of Breast Milk for Health Care: Some of the benefits of breast milk for babies is it can enhance baby’s brain, it is guaranteed clean, it can save lives and avoid obesity problems among babies and many others. Breastfeeding is indeed closely related to children’s mental health. A group of researchers from Adelaide’s Flinders Medical Center, USA conducted an intelligence test on 32 babies. From that test they found that babies who were breastfed were 40% smarter that babies who drink formula milk. This research proves that DHA (kind of fat acid contained in breast milk that increases baby’s mental development) is really beneficial for baby’s brain development\(^{10}\).

Scientific studies also show that brain ability for babies who are given breast milk is better than other babies. A study showed that breast milk given to babies during the first 6 months is highly beneficial for babies’ intelligence, and babies who were breastfed for less than 8 weeks obtain fewer benefits for their IQ developments\(^{11}\). Therefore, babies who are given breast milk obtain the best nutrition for their brain and nerve developments\(^{12}\).

Other than that, breast milk can save babies lives. This is owing to the fact that most diseases can be avoided with breastfeeding. Breast milk is clean and bacteria-free. Besides, it contains anti-infection agent that can fight numerous infectious diseases. One of the agents is the live white blood cells (leucocytes) that kill bacteria. Meanwhile, antibodies (immunoglobulins) can fight against the infection of regular diseases until the baby is capable of forming his or her own antibodies. This is due to an agent called bifidus factor that helps some special bacteria called Lactobasillus bifidus to breed and fight against bacteria that causes diarrhea. Other than diarrhea, breast milk has successfully fought against normal infections such as eczema, asthma and constipation. Babies who were given breast milk also rarely have ear or respiratory problems as compared to babies who were given formula milk. The nutrients in breast milk may also prevent babies from getting allergies. A research done in Finland showed that breastfeeding protects babies from any allergies from small to adulthood\(^{13}\).

In Mexico, 118 underweight babies were given breast milk or formula milk. This experiment showed that babies who were given formula milk were 13 times more prone to have bowel inflammation such as necrotizing enterocolitis and five times more prone to urinary tract diseases. In addition, they are also nine times more exposed to diarrhea\(^{14}\). Besides controlling diseases, breastfeeding may reduce the risk for a baby to be severely obese at a young age\(^{15}\). There are many researches that showed babies who consume formula milk early after birth are more prone to be obese\(^{16}\).

Benefits of Breast Milk from the Islamic Perspectives: The science world knows that the biggest secret contained in breast milk which makes it so beneficial is the existence of colostrum which forms antibody that preserve baby’s health. This view has actually being dominated by early Islamic scholars. For example, in the Shafi’i sect it is stated that a mother is obligated to feed her child with al laba’ or colostrum which is the first milk that comes out after the delivery. This is because a baby normally cannot live without consuming that first milk\(^{17}\). Similarly, the opinions in Hanbali sect\(^{18}\) also obliged the feeding of al laba or colostrum for newborn babies because it is extremely important for the babies’ lives and usually a baby cannot live without it\(^{17}\). This matter is befitting to qawa’id fiqhiyyah: Harm is eliminated\(^{19}\).

The verity on scientific research which stated breast milk is an agent or catalyst for babies’ intelligence has long been proven in Islamic history\(^{20}\). One well-known event in the Islamic history is the story of breastfeeding story of Imam al-Haramayn\(^{21}\). When he (Imam al-Haramayn) was little he was nursed by a stranger because his mother was sick. His father, upon knowing this, straightaway forced the milk out from al-Haramayn’s stomach. Imam al-Haramayn was only allowed to drink milk from his mother who was a pious and obedient servant to Allah SWT. As a result, Imam al-Haramayn grew up to become a faithful servant of Allah who was brilliant in Islamic knowledge. Imam al-Haramayn would mention this story many times to his audience whenever his speech was interrupted. He said:

This is the leftovers of the milk (from a stranger): From what has been uttered by Imam al-Haramayn, it was clear that he acknowledged that all privileges given by Allah SWT to him was the effect of proper breastfeeding from his mother\(^{21}\). As a lesson, if a mother has no milk then she must find breast milk from another
woman with virtuous character and manners. They are not encouraged to straight away resolve to formula milk when obstacles arise to breastfeed because there is no other food better than breast milk.

A Muslim breastfeeding expert from America had written in her article titled *The Importance of Breastfeeding to the Muslim Child* that breastfeeding will produce babies with higher IQ and more stable emotion. This finding is supported by a child specialist in Turkey in his article *Breast-feeding in Islam*. His 10 years research in child study had proven that breast milk nutrients can increase a baby’s IQ. According to him, breast milk contains a very high taurine. Taurine is one of the amino acid which is extremely crucial for brain development. This fact is more interesting to be studied because taurine content in human’s milk is 30 to 40 times higher than cow’s milk.

Mothers should always increase Qur’an recitations and other ibadah when breastfeeding. This will help the child to absorb all virtues done by the mother during the nursing period. If a mother is incapable of breastfeeding, then she must give the child to a pious, noble and smart woman as a wet nurse. She should never give her child to be breastfed by someone with unknown lineage or religion. It is afraid that the feeding may distort brain development and manners of the baby. This statement is enforced by a *mursal* hadith:

> From Ziyad al-Sahmi he said: Rasulullah SAW forbids from asking dumb women to breastfeed children. (Sunan Kubra, The Book of Marriage, Al-murdi’ al-Hamga’ chapter, Hadith no: 4172)

Verily all diseases and disasters come from Allah SWT to test humans’ faith and to cleanse their sins. Nevertheless, as a servant of Allah SWT with a sound mind, one must make an effort to avoid diseases and find a cure when he falls sick from any diseases. One of the treatments recommended in Islam is by performing injunctions in the Quran and hadith nabawiyyah. One of the methods advocated in Islam to avoid diseases is through the habit of eating for babies through breastfeeding until the age of two. This ruling is stated in Surah al-Baqarah verse 233. According to Mohamad ‘Abduh, breastfeeding affect all aspects including in terms of diseases prevention.

Several studies carried out by researchers that recognized the effectiveness of breastfeeding as a family planning method. Nevertheless, breastfeeding is just an effort by human, if Allah wills it, pregnancy will still occur. This is befitting to His commandment in surah Yasin:

> Verily when He intends a thing His command is “Be” and it is. (Yasin: 82)

Al-Qurtubi suggested, when Allah SWT wills for something to happen, it happens without the need for any help or without any difficulties. Similarly, Allah SWT in His commandment stated that:

> We did not idly create the heavens and the earth and all that lies between them. (Al-Dukhan: 38)

Al-Zuhayli in Tafseer al-Munir, translated this verse as everything the Allah created has its own wisdom and purpose. There is not a creation by Allah which is useless. What is more important is a decree or creation serves as an evidence of Allah SWT’s mightiness and oneness.

Therefore one of the creation and instruction of Allah SWT is the instruction to breastfeed. Among the biggest wisdom is it contributes to the mother’s health. However, when mothers avoided breastfeeding their children, numerous harms will inflict on mothers themselves. Numerous diseases due to failure in breastfeeding may inflict upon the mothers whereas Islam forbids its people from getting involved in things that may inflict harm upon themselves. Islam truly forbids such act as stated in *fiqh* method previously.

Breast milk is the best food; it is clean, halal, nutritious and costless. Nevertheless, those are not the only things desired by breastfeeding mothers. What is more important is breastfeeding is an instruction by Allah SWT which is clearly written in the Qur’an. Therefore, surely mothers who breastfeed their children are not only providing the best food the children but also getting multiple rewards from Allah SWT.

**Conclusion**

From the above discussions, it is prevalent that breastfeeding truly gives a huge impact towards the health of a mother and child. Breast milk contains nutrients which are highly beneficial for an infant’s health and growth. Among other benefits for a baby is it helps to develop the baby’s intelligence, it is very clean and it can save a baby from various diseases such as diarrhea, allergies, *otitis media*, obesity and others. Concurrently, Islam advocates breastfeeding because
not only it gives an added advantage towards the children and the mothers’ physical health as studied by scientists; it also contributes to children’s mental health characters.

Looking at the aspect of the importance of breast milk for a baby’s health, apparently the opinions of scientists are in parallel with the opinions of fuqaha. In fact, fuqaha from Shafi’i and Hambali sects obliged the feeding of al laba’ which is colostrum to newborn babies. This is owing to the importance of colostrum for a baby’s growth and development. This superiority has been greatly emphasized by scientists today that most hospitals even ban the use of milk bottles and formula milk early after birth. Conclusively, as Muslims, we must believe that breast milk is just an effort to prevent a child and a mother from being inflicted with any diseases. This is because breast milk is an Allah’s creation which is amazing and perfect.

The Importance of Menu Variety Experience for Public Health Sustainability at Higher Education Institution

Sarimah Ismail1*, Normah Kadir1, Arif Kamisan Pusiran2, Irina Safitri Zen3, Aqeel Khan1

1Senior Lecturer, School of Education, Faculty of Social Sciences and Humanities, Universiti Teknologi Malaysia Johor Bahru, 81310 Skudai, Johor, Malaysia, 2Senior Lecturer, Faculty of Business, Economics and Accountancy, Universiti Malaysia Sabah, 88400 Kota Kinabalu, Sabah, Malaysia, 3Senior Lecturer, Department of Urban and Regional Planning, Kuliyyah Architecture and Environmental Design, International Islamic University Malaysia (IIUM), Kuala Lumpur, Malaysia

Abstract

The importance of menu variety from the perspective of public health has lacked of discussion in the literature in comparison to the profit perspective of a foodservice business. This paper reports finding of a research on the importance of menu variety for the sustainability of public health at higher education institution (HEI) from students perspective. Direct observation towards food displayed on the buffet counter of the cafeterias and interview sessions with students were conducted to identify attributes of menu variety as constructs for a survey research. Complete set of 375 questionnaires were collected among students as customer of 20 food outlets at 11 cafeterias of the HEI. Validity value of the questionnaire was 0.98, that analysed by Rasch Development Model. Survey data was analysed using descriptive statistics. Overall mean value for menu variety attributes was 1.97 and standard deviation, 0.656, which at the moderate level. This study suggested for the cafeteria food providers, customers and the HEI food authority to ensure high level of menu variety is offered to sustain public health of the HEI, customer satisfaction and long tender period of the cafeterias as a food provider.

Keywords: Menu variety attribute, higher education institution cafeteria, direct observation, sustainability, Research University.

Introduction

Among 20 public universities in Malaysia, five of them have recognized as Research University (RU). The Malaysian Ministry of Higher Education is targeting to increase number of international students from 100,000 in year 2019 to 250,000 by year 2025 across the HEIs to enhance international success and recognition of academic research and training1. The increment number of student intake signs the heavier role of cafeterias at the HEIs as a place of selling foods and as a body to taking care of students health. The big challenges are to fulfil diverse need of the students, to meet the requirement of Hazard Analysis and Critical Control Point and to sustain quality menu variety for public health. The mismanagement in food, plates for serving and washing may cause a severe effect on the public health of HEIs.

Food, service, staff, ambience, price and location are among customer satisfaction determinants of food service found from research conducted across the globe. One of the food attributes that bring the customers to patronize a restaurant/ cafeteria is menu variety. The menu variety has been debated in the literature for decades due to its strong contribution in generating revenue for the restaurant/cafeteria2. However, the important role of menu variety to public health received less attention. Since student intakes are increasing by year (both local and international students), and they are worry about their food intake while they are away from home, therefore, a research was conducted to identify menu variety offered at the HEI for the sustainability of public health.

e-mail: p-sarima@utm.my
Methodology: A preliminary study was conducted to identify menu variety attributes for survey research constructs. The study was started with serial direct observations toward food displayed on buffet counter of 20 food outlets at 11 cafeterias of a RU. The observations took place at three main meal times of breakfast (from 7.00am to 10.00am), lunch (from 11.00am to 3.00pm) and dinner (from 5.00 to 9.00pm). Data of the observation were written in the field note. This followed by interview sessions with customers of the cafeterias that selected randomly among students of the RU. Interview questions addressed was assisted by interview protocol. Saturation of data showed sample size of the interview was 20 students while the observation took place for three weeks. Findings of the preliminary study found 12 attributes of menu variety. They were variety in terms of daily menu theme, menu type (buffet and a’la carte), international menu, local menu, trendy menu, main food ingredient, balance nutrition, sensory evaluation (food feature/look, taste/flavour and temperature) and cooking method. Those attributes were later on been used as research construct for item development of survey research instrument of questionnaire.

All research instrument have been verified by two senior university lecturers in the field of Food Service Management. Overall validity value of the questionnaire were 0.98 (for item validity) and 0.90 (for individual validity). Complete set of 375 questionnaires were collected among students as customer cafeterias. Data of the pilot study was analysed by Rasch Development Model and assisted by Winstep version 3.72 computer software. Validity value that more than 0.80 is in the range of high validity and the research instrument is suitable to be used for data collecting³.

Result

Among 12 menu variety attributes, three of them were rated at high level (daily menu themes, various ‘buffet’ service menu and menu consists of various nutrients). Seven attributes rated at moderate level were various menu for a’ la carte, international menu, local menu, menu with various cooking method, menu with various main ingredients, menu with various taste/flavour and menu with various look/feature. Two attributes that rated at low level were menu with various temperature and trendy menu (Table 1).

Discussion

The importance of 12 menu variety attributes toward public health are discussed according to sub-themes as below:

(a) Variety of Menu: Realising students having short period of time during peak meal hours of breakfast and lunch, all cafeterias promote menu variety of cooked foods to provide freedom for students to have choice to choose and adopting buffet service to offer fast service and avoiding long queue.

However, those variety of foods were stereotype and repeatedly everyday as well as similar between one food outlet to another. The a’la carte menu only
available late in the afternoon for tea break and dinner. The study also found only small number of food outlets offer trendy menu. Menu with various theme ranging from traditional local menu according to ethnic and culture, different daily theme, a’la carte menu, international menu, pasta, salad, sandwiches, bread, fresh fruit, stew, dairy products, soup and menu for special need like vegetarian with different group of main ingredients to provide holistic balance nutrients are available only at a few cafeterias with very limited choice.

Menu variety was found as a key factor in attracting and reflecting the need, expectation and satisfaction of customers visiting a cafeteria. It affects performance of food service industry. Through menu variety students are able to have variety of nutrient for the body to function correctly and having choice to choose according to their preference. The fulfilling customers’ preference and expectation will make them happy and having possibility for them to repeat purchase through repeat visit. The repeat purchase promises increment in profit.

The students of today require lots of healthy menu variety that consistent with current market trend to satisfy their taste buds. The new trend of food however, requires skilled chef to incorporate quality attributes of a food to produce healthy and well-balanced meals. This study suggests for the cafeterias to employ qualified chef and kitchen staff that equipped with various food knowledge and skills.

(b) Variety of Main Ingredient: Finding of this study showed that although menu offered are variety like having noodles, snack, rice, dessert, salad and vegetables, but most of them were Malay food orientation that sinoname with rice, flour, red meat, fish, chicken and green leafy as well as rhizome-based vegetables as main ingredients. They were cooked with chillie, soya sauce and coconut milk. These make the foods look red and oily, having hot and spicy taste.

Those food ingredients are rich with high calorie nutrients that take long time to digest. Taking high complex carbohydrate, protein, saturated fat and cholesterol food items for long term will lead to obesity, diabetese as well as silent killer of cardiovascular diseases like heart attack and hypertension. Research claimed people who eat the same food over and over again are likely to be less healthy than those who eat a variety of food. Since 80% of students at the RU of study are local students, those fattening food will contribute to the increment of obesity statistics in Malaysia. A study conducted by also found the similar finding that university cafeterias have prepared ready cook food that served at buffet counter but the food choice focuses on Malay ethnic group.

The best diet should have a little bit of everything of main group of ingredient to provide balance diet. The food variety promotes greater bacterial diversity in the gut to keep body weight. Having variety of food choice is seen as marketing strategy to attract customers attention besides awareness that there is no single food contains all of the essential nutrients in the optimum amount as the body need to keep healthy apart from breastmilk for babies. Knowing this, the cafeteria food providers is suggested to sell variety menu with alternate different item in each major groups of food ingredient: fruit, vegetables, grains, low-fat dairy, lean protein and unsaturated fat to provide variety and sufficient nutrients as the body needs. Number of menu that contains of high complex carbohydrate, protein, saturated fat and cholesterol should be replaced with menu with healthier main ingredients like diary products, fruits and vegetables that consist of high vitamin, minerals and fiber.

(c) Variety of Food Taste/ flavour: Majority of students rated food variety sold at the cafeteria at moderate level. The food taste of spicy, salty, sweet, soury are consistent with Malay food taste. Since Malaysia is a multiracial country that consists of three major races which are Malay, Chinese and Indian besides as a RU that having big number of international students, therefore, the cafeteria food providers is required to aware toward the needs of various food taste of Chinese and Indian students as well as international students with various nationality. Thus, menu variety that fulfill the need of these students with heterogenous background should be offered.

The foods sold were also found mixed with artificial food flavour. This study suggests for the cafeteria food providers to use natural flavor that is free from artificial food elements (like artificial additives, preservatives, food coloring, flavor, and genetically modified organism etc.) that may
harm body health. Natural food that is associated with freshness, organic and local produced food is perceived healthier because it is natural from the perspectives the way the food has been grown, how the food has been produces and processed as well as the properties of the final product\(^7\).

In food business, the sensory characteristic of food (the feature/look, taste/flavour, aroma and texture) influences customers choice and making decision either to buy or not to buy the food\(^8\). The sense of taste drives customers appetite and protect them from poisons and steer them towards the right food groups and away from the wrong ones\(^9\). A study conducted by Department of Statistics Malaysia\(^1\) found the effect on taste toward food demand is very strong and high statistically significant. Therefore, understanding why students purchase some foods but not others is the utmost importance for marketing strategy, advertising, attracting the students to repeat purchase and for planning of new menu variety development.

\(d\) Variety of Food Nutrition: Menus variety offered by the cafeterias are loaded with food items that contains of large amount of complex carbohydrate, protein and fat. Some cafeterias sell fresh fruit and healthier salad as an option. However, they are less varied and flavourful. Besides bad eating habit, the domination of unhealthy food available may contribute to weight gain after one year of studies of the students.

Since 95% of student accommodation at the RU are not allow the students to cook, this means the students have to choose the unhealthy food until end of their study period at the university or until end of business tender of the cafeterias with the university. Thus, the cafeterias should provide menu variety for balanced and healthy diet. A balanced, adequate and variety menu provides nutrients for the body to function correctly; for the body organs and tissues works effectively; avoid disease, infection, fatigue poor performance; and protecting human body against non communicable diseases especially obesity, diabetes, cardiovascular diseases, some types of cancer and skeletal conditions. Poor diet lead to body growth and development problem, poor academic performance and persist them with bad eating habit for the entire lives\(^1\)

\(e\) Food Temperature: Understanding the role of temperature in food manufacturing can help to keep the food safe to be eaten and prolong shelf life of the food. However, this study found low rate for serving food at the right food temperature. This situation happened might be because of four reasons. First, many cafeterias displayed dishes that suitable for lunch early in the morning to fulfill the need of customers who taking heavy meal for breakfast (skip lunch meal). The buffet counter that is not fixed with food warmer system to control dishes temperature above 60\(^\circ\)C and the dishes has been left in the room temperature (32\(^\circ\)C) for more than four hours after been cooked will expose the dishes to bacteria like Staphylococcus aureus, Salmonella enteritis, Escherichia coli, Campylobacter to grow. These bacteria grow rapidly and produce heat resistant toxin in ‘Danger Zone’ (between 4\(^\circ\)C and 60\(^\circ\)C).

Second, low awareness of customers toward the importance of right food temperature and negative impact to body health if disobey this guideline. Third, lacking of knowledge and or bad attitude of kitchen staff and cafeteria food providers about this matter until been portrayed into their bad practices. Fourth, Malaysian food is well known with hot and spicy taste. Eating the food at unsuitable food temperature in hot and humid 32\(^\circ\)C atmosphere is not really matter to the customers.

To improve food temperature and keeping the food safe, food thermometer should be used, buffet counter should be fixed with food warmer to ensure foods displayed are above 60\(^\circ\)C and both kitchen staff and cafeteria food providers should be trained about this matter. Health and safety training play big role in influencing good kitchen staff practices\(^1\)

\(f\) Variety of Cooking Method: Different cooking method gives different impact to food in various way: taste, digestion, introduce variety in meals, presentation, texture, aroma, packaging, nutrient, destroy micro-organism, appetite and increase consumption\(^1\). Finding of this study shows the cafeterias applied unhealthy cooking method particularly frying (both deep and shallow frying cooking methods) to cook majority of food items. The deep frying cooking method that using cooking oil provides additional fat to the food and gives negative impact to body health like obesity and heart diseases. The negative impact become worse if the recycle cooking oil is used in other cookings.
Therefore, it is advised for chef of the cafeterias to apply variety of healthy cooking methods like steaming, boiling, stewing, pressure cooking, simmering, poaching, braising, sauteing, baking, roasting, grilling and broiling for cooking. These cooking methods are not only cost effective but also are seen be able to sustain nutritional value of the food cooked.

Conclusion

Menu variety promotes equity between generating revenue among cafeteria food providers and serving healthy food item for the students. Therefore, reliable paths to detect, identify, quantify and monitor quality of menu variety are of great interest for sustainability of public health and cafeteria food business at the RU as well as high reputation as a RU that are not only excellent in learning and teaching, research and development, publication but also excellent in providing cafeterias that offer high quality of menu variety to students. Suggestions for practical implication to improve moderate level of cafeteria service in term of providing menu variety are as follow:

Cafeteria food providers: Practice high intergrity in selling healthy food with both purposes: profit and public health, educate all kitchen staff through proper training on the importance and impacts of menu variety to public health, customer satisfaction and behavioral intentions of repeat purchase. This followed by daily supervision toward staff practices.

University food au thority: Implement rule and regulation on quality menu variety at all food outlets; provide nutrition information, healthy eating tips tailored to the options on campus; having instrument for quality menu variety supervision; regular monitoring toward quality of menu variety at the cafeterias

Students: Increase awareness about their right and responsibility to get healthy and quality menu variety, having knowledge about food that they eat, right eating habit and maintaining healthy diet no matter where they choose to eat.

Spectrofluorimetric Method for the Determination of Rhodamine B in Syrup

Asmiyenti Djaliasrin Djalil1, Bondan Bagus Wijaksono1, Pri Iswati Utami2

1Vice Dean, 2Student, Department of Pharmacy, Faculty of Pharmacy, Universitas Muhammadiyah Purwokerto, Jl. Raya Dukuhwaluh, PO. Box 202 Purwokerto 53182, Indonesia

Abstract

The rhodamine B has been used as a textile colorant. Its use in food is strictly prohibited because of its ability to form carcinogenic compounds. This study describes a method for determining rhodamine B in syrup by a fluorescence spectrophotometry. The method was validated by determining linearity, range, limit of detection, limit of quantitation, precision, and recovery. Five red syrup samples were collected from markets in Purwokerto city, Indonesia. A fluorescent compound was measured fluorometrically at 570 nm ($\lambda_{ex}$, 550 nm). Linear relationship with good correlation coefficients (0.9975) has been obtained in the range of 0.5-2.5 µg/ml, with a detection limit of 0.1436 µg/ml and a quantitation limit of 0.4787 µg/ml. The precision of the method was satisfactory; the relative standard deviation was 0.29%. The method was successfully applied to the analysis of rhodamine B in syrup with good accuracy; the recovery was 102.8%. The result showed that five syrup samples did not have rhodamine B.

Keywords: Analysis method, rhodamine B, spectrofluorometric, syrup, validation.

Introduction

Synthetic dyes have been widely used in textile, food, pharmaceuticals, and cosmetic. On the other hand, toxicity issues caused by synthetic colorants have initiated an intense research especially in food colorants. The color of a food and beverage play essential criteria in a food’s acceptability.1

Rhodamine B (Fig 1.) is a derivative of the xanthene dyes class. It may cause ovarian toxicity and cervical epithelial cell proliferation in the uterus.2-3 Due to the toxic effects of rhodamine B, FDA and many countries have banned it from using in food samples. In accordance with the Regulation of the Ministry of Health Republic of Indonesia and the National Agency of Drug and Food Control, Indonesia currently prohibits its use as food additive.4-6

The food fraud is the act of deceiving consumers with the aim of increasing company profits. FDA has been reported a number of imported food containing rhodamine B, in 2012. There were approximately 82 food products from 11 developing countries.7 In 2018, Saeeds’s group research has successfully identified the presence of rhodamine B in syrup samples sold in Faisalabad, Punjab, Pakistan. Of 75 samples studied, there were 40% syrup containing rhodamine B.8 Therefore, a continuous monitoring of prohibited colorants in food is needed to ensure food safety.

Many liquid chromatography methods were developed for the determination of rhodamine in food, cosmetic, or wastewater samples.9-11 Tatebe’s group research has developed an HPLC method for the simultaneous determination of rhodamine B, pararosaniline, and auramine in processed foods.9 Furthermore, Chiang’s group research has determined that rhodamine B and rhodamine 6G could be separated by HPLC combined with fluorescence detection.10 Although HPLC method provides good sensitivity for determination of rhodamine B, it has its limitation concerning the high price of the instrument.

Thus far, some spectrophotometric method was reported for the detection of rhodamine B.11-15
though UV-visible spectrophotometer is a simple and low cost apparatus than other instrument, the quantitative detection of rhodamine B in several matrixes needs a sample preparation technique. It step takes a long time and a lot of chemicals or solvents.

Rhodamine B is a fluorescent dye. In this research, based on its native fluorescence, a direct quantitative analysis method of rhodamine B in syrup was developed and investigated using spectrofluorometer. The objective of the present study was to detect the presence of rhodamine B quantitatively in syrup samples collected from local market in Purwokerto City, Central Java, Indonesia by spectrofluorometric method.

Materials and Method

Rhodamine B was obtained from Sigma-Aldrich. Stock solution of rhodamine B (10 µg/ml) was in ethanol (Merck). The stock solution was further diluted with ethanol to give five working standard solution with concentration of 0.5, 1.0, 1.5, 2.0, and 2.5 µg/ml. Samples were chosen on the basis of its color like red and pink. All samples were collected from Purwokerto market, selected syrups manufactured in Indonesia. In total 5 samples were purchased from local shops.

A. Optimization of the Optimum Wavelength and Solvent: The rhodamine B standard solution (1.5 ppm) spectral profiles created using a Shimadzu RF-6000 spectrofluorometer at a wavelength of 500-600 nm. The solution was measured by using a two-dimensional fluorescence. The 3D spectrum menu will display the excitation and emissions wavelength optimal. Furthermore, different solvents were observed for the proper detection. The solvents used were aquadest, methanol (Merck), and ethanol. The solvent that provide the highest fluorescence intensity will be used for further analysis.

B. Method Validation: Method validation is a technique used to check that the analytical method engaged for a particular test is suitable for the intended use. The performance characteristics were assessed by evaluating the limits of detection (LOD), limits of quantitation (LOQ), accuracy, and repeatability of measurements. LOD and LOQ were evaluated by the signal-to-noise S/N > 3 and S/N > 10 ratios of each fluorescence signal in the rhodamine B standard solutions. The recovery test was carried out to evaluate the accuracy of the proposed method. This test was performed by using standard additions method. The method involves adding known quantity of standard to the matrix of a syrup sample that did not contain rhodamine B. The rhodamine B standard solution (1 ml, 1.0 µg/ml) was transferred to 10 ml volumetric flask and syrup (3 ml) subsequently added into the flask. Ethanol was then added to the solution to obtain a 10 ml final solution. Another concentration of standard solutions used for the recovery test were 1.5 and 2.0 µg/ml. Repeatability of the method was assessed by analyzing relative standard deviations of rhodamine B standard solution. Fluorescence spectra and intensity measurements were carried out using a Shimadzu RF-6000 spectrofluorometer (Japan). All the standard and sample solutions were measured with an excitation and emission slit width of 5 nm.

Results and Discussion

Syrup is a concentrated beverage with the main components including sugar, water, and flavours. Syrup may have adulterants such as saccharin (synthetic sweeteners) in addition to prohibited synthetic dyes such as rhodamine B and metanil yellow. In our recent research, we analyzed the presence of rhodamine B in red syrup sold in the local market using a simple and rapid spectrofluorimetric without any previous extraction stages. Rhodamine B is known as a fluorescent dye which has a high quantum yield fluorescence. The fluorescence quantum yields (Φf) of rhodamine B is 0.913.16

Determination of optimum detection wavelength aims to increase a sensitivity and efficiency of measurement. The procedure was performed by using an excitation-emission scan (EEM/excitation-emission matrix), also referred to as a two-dimensional fluorescence. The result shows that the optimum excitation wavelength for rhodamine B is 550 nm, whereas the optimum emission spectrum is 570 nm. Fig. 2 displays a 3D fluorescence spectrum of rhodamine B.
The effect of solvent was studied in order to select the most appropriate solvent to increase the intensity of fluorescence. The emission (fluorescence) spectra including intensity, band position, and shape of a fluorophore show changes in organic solvents. Ethanol was found to be the best solvent for rhodamine B proved by its highest fluorescence intensity compared to other solvents as presented in Table I. Therefore, the experiment was performed using ethanol as solvent.

### Table I: Effect of Solvent on the Fluorescence Intensity of Rhodamine B (1 µg/ml)

The performance of the method was evaluated according to ICH guidelines. Different validation parameters was observed include linearity and range, precision, and accuracy.

A series of solutions containing rhodamine B were analysed and the fluorescence intensity were measured. Linear regression of the data was calculated. The fluorescence intensity-concentration plot was establish to be linear over the range of 0.5–2.5 µg/ml. Calibration curve of rhodamine B was drawn in ethanol. Linearity of calibration was good condition (Table 2). The calibration curve’s given in Fig. 3. Furthermore, Table 2 summarizes the calculated linear regression of the data.

SD = 0.0884, RSD = 0.287%  

The results of intraday precision were stated in the terms of % relative standard deviation (% RSD). Method precision study confirmed excellent precision of the procedure where RSD below 2%.

Accuracy of the proposed procedure was determined by standard addition method at three concentration levels within the concentration range of 0.5-2.5 μg/ml. Three replication of recovery study were performed at each concentration level. The results of recovery studies were described in Table IV.

Heavy Change of Acceptor Contraception Body in Depo Medroxy Progesterone Acetat (DMPA)

Susanti1, Annisa Nurul Chusna2
1Lecturer, 2Diploma student, STIKES Al-Irsyad Al-Islamiyyah Cilacap, Indonesia

Abstract
Depo Medroxyprogesterone Acetate (DMPA) injection contraception is the most widely used contraceptive method. The disadvantages of injectable contraception are increased body weight, amenorrhea, menorrhagia and spotting. The highest side effect of injectable contraception is weight gain. Analysis of differences in body weight before and after using Depo Medroxyprogesterone Acetat (DMPA) injectable contraception. A research design of paired sample tests with a sample size of 55 respondents. The average body weight before using Depo Medroxyprogesterone Acetate (DMPA) injectable contraception was 48.47 kg. After using Depo Medroxyprogesterone Acetat (DMPA) the average body weight was 50.54 kg, with the lowest body weight of 40 kg and the highest body weight of 69 kg. Data analysis using Paired t Test obtained p value = 0.000 < 0.05, meaning that there was a difference in body weight before and during using contraceptive injection of Depo Medroxy Progesterone Acetate (DMPA). Most Depo Medroxy Progesterone Acetate (DMPA) contraceptive sufferers experience weight gain.

Keywords: Injection Contraception, Weight Loss, Family Planning, Depo Medroxy Progesterone Acetate.

Introduction
Many reproductive health issues still need to be studied, not only about reproductive organs but there are several aspects, one of which is contraception. 3-month injection contraception is a popular contraceptive in Indonesia. Injection contraception is a method of contraception through hormone injections and as an effort to prevent pregnancy in women of childbearing age. There are two types of injectable contraception, namely injectable combinations containing injected estrogen and progesterone hormones every 1 month and injections of DMPA (Depo Medroxyproesterone Acetate) containing progestin hormones injected every 3 months1.

Injectable contraception Depo Medroxy Progesterone Acetate (DMPA) is the most widely used contraceptive method. This is because the effective way of working is 30% of pregnancy per 100 women per year. This type of contraception is considered to be easily obtained and used by couples of childbearing age. Injection type contraception is widely used because of its practical, safe, inexpensive, suitable for lactation (breastfeeding) because it does not suppress breast milk production and the rate of failure of injection contraceptive use is less than 1%1.

According to 2 Indonesian Health Profile, the coverage of new family planning participants and active family planning according to the type of contraceptive injection is 49.93% and active acceptors 47.78%. The type of contraception participants of the new Family Planning are the Fertile Age Couples who for the first time use one method or contraceptive after they end their pregnancy. In the 3 Central Java Province Health Profile, the most widely used family planning participants were injection, which was 57.4%. Injectable contraception is one type of contraception that is most widely used by fertile age couples and in the kesugihan area injection contraceptives are the highest choice.

Thus this method has the disadvantage of interrupting menstrual patterns including menorrhagia amenorrhea and spotting, late return of fertility after cessation of use, and weight gain. Weight gain is the
most frequent side effect of injectable contraception. Several studies have suggested that weight gain due to DMPA contraceptive use is associated with increased body fat and an association with appetite regulation. One study found an increase in self-reported appetite by women who used DMPA contraception after 6 months. This can be attributed to the content of Depo Medroxyprogesterone Acetat (DMPA) which is the hormone progesterone, which can stimulate the appetite control center in the hypothalamus, causing an increase in appetite. The results of another study conducted by the University of Texas Medical Branch (UTMB), women who used DMPA contraception on average experienced an increase in body weight as much as 11 pounds or 5.5 kilograms, and experienced an increase in body fat by 3.4% within three years usage.

DMPA injector acceptors in the Kesugihan area are most prevalent in Slarang Village with family planning acceptors of 224 acceptors. Many DMPA injection contraception acceptors said that body weight increased after using DMPA injectable contraceptives. Of the 10 acceptors said they had gained weight after using DMPA injection contraception. Based on this background, the researcher was interested in researching “Analysis of Differences in Body Weight Before and During Using Depo Medroxyprogesterone Acetate Injection Contraception (DMPA)”.

**Method**

Comparative analysis research design, two dependent meanings, is to test the mean difference between 2 data groups. The population in this study were a number of mothers who used Depo Medroxyprogesterone Acetat (DMPA) injectable contraception. Based on data taken by the population of Depo Medroxyprogesterone Acetat (DMPA) injection contraception, 55 respondents. In this study samples were taken using total sampling techniques.

**Results And Discussion**

Based on the results of the study of 55 respondents, the highest age characteristics of Depo Medroxy Progesterone Acetat (DMPA) contraceptive acceptors were at the age of 31-40 years, and the highest duration of use was less than 1 year and the lowest was 3 years.

A. Changes in Body Weight Before and After Using Depo Medroxyprogesterone Acetate Injectable Contraception (DMPA)

The results of the study of body weight in Depo Medroxyprogesterone Acetat (DMPA) injectable contraceptive which is presented in the Fig. 1.

![Fig. 1: Weight Loss of Injectable Contraceptive Acceptors Depo Medroxyprogesterone Acetate (DMPA)](image)

Based on Fig. 1, that of the number of respondents 55 acceptors, 70.90% experienced an increase in body weight. The average body weight at the initial use of DMPA was 48.47 kg, while the average weight after using DMPA was 50.54 kg.

Weight gain has always been a major concern among DMPA acceptors. There is an average weight gain of 0.1 kg at visits 1-3 (first 3 months) and an average weight gain of 1.036 kg at the end of the year. The amount of weight gain is influenced by the percentage increase in body weight after 6 months and the length of use of DMPA injection contraception. Acceptors who experience a 5% increase in body weight in the first 6 months will experience an average increase in body weight of 0.63 kg, 1.48 kg and 2.49 kg after 12, 24, 36 months. While an increase of more than 5% will experience an average increase in body weight of 8.04 kg, 10.86 kg and 11.08 kg. The results of this study illustrate the occurrence of changes in weight, either increasing or decreasing due to consumption of food that is converted into fat and stored under the skin. Nutritional intake also causes weight gain, possibly due to excessive eating patterns that make it easier to gain weight. Or maybe the intake of calories in the body is excessive and does not match the needs that result in weight gain. In addition to hormones and nutritional intake that affect weight gain can also be affected by physical activity. Decreased physical activity can occur due to increasing age which results in less enthusiasm for physical activity. This may occur because of the lack of time and opportunity available. Or maybe an energy intake that exceeds the body’s needs which are usually experienced by people who lack exercise or lack of.
physical activity so that energy entering the body is not burned or used which is then stored in the form of fat which causes weight gain.4.

B. Differences in body weight before and after using Depo Medroxy Progesterone acetate (DMPA) injections (Table 1).

Paired-sample T test: \(df = 54; t = 15.5; p = 0.000\) (0.05)

Based on Table 1 it can be seen that there are differences in maternal body weight before and after the use of DMPA injectable contraception as evidenced by the initial change in DMPA weight is 48.47 kg, while the average after DMPA use is 50.54 kg.

Research results from 6 that there were differences in weight gain in DMPA and Cyclovem injection contraceptive acceptors there was an increase with the results of \(p\) value <0.001. This result was also supported by 7 study that there was a significant increase in body weight after three months \((p <0.01)\) and six months higher in DMPA users than in controls \((p = 0.000 <0.05)\).

Based on research that DMPA injection contraceptive acceptors have more weight than users of combined oral contraceptives and not users of hormonal contraception, DMPA users increase their body weight (+5.1 kg), body fat (+4.1 kg), percent body fat (3.4%), and the ratio of central-peripheral fat (+0.1)4,8. A systematic review found that weight gain with DMPA was not associated with initial weight or BMI in adults but that obese clients or overweight adolescents 4. The acceptors experienced weight gain after using DMPA injectable contraception as much as 57.5%. This is also in accordance with the results of the study of 4 that there is a glucocorticoid-like activity signal, resulting in an increase in appetite after 6 months in the study. In accordance with the results of the study also that there are significant differences in body weight before and after with the results of Paired-sample T test: \(df = 54; t = 15.5; p = 0.000\) (<0.05).

The results of the study9 found evidence of weight gain when using progestin contraception alone. Some significant differences when oral pill methods are compared with no hormonal contraception. This includes studies on oral contraceptives for oral pills, DMPA, levonorgestrel, and implants. Overall, the average weight gain was low for 6 to 12 months, which was less than 2 kg (4.4 lb) in most studies. Weight gain was recorded at two and three years, but the comparison group did not differ much in weight changes. People can gain weight over time regardless of contraceptive use. Appropriate and accurate counseling about typical weight gain can help reduce contraceptive termination because of weight perception.

Side effects of DMPA injection contraception, one of which is weight gain in 12.5% 10 long lasting and reversible agent of fertility control. The objective is to determine the profile of the acceptors, side effects and indication for discontinuation of progestogen-only injectable contraceptives at UCTH, Calabar. This was a retrospective study of the clients who used progestogen-only injectable contraceptives at the family planning unit between 1st January 2008 and 31st December 2014. A total of 1392 clients used the injectable progestogen-only contraceptive out of 5986 total contraceptive users giving the preva-lence rate of 23.3% over the period. Of these, 60.4% of the clients accepted the depot medroxy-progesterone acetate, while 39.6% accepted the norethisterone enanthate. It was mostly utilized by multiparous women, clients with tertiary education and those in their third decade of life. Second- ary amenorrhea was the commonest side effect in 47.7% of the clients. Over the study period, 243 (19.8%). Women who used DMPA experienced an average weight gain of 6.2 kg compared with an average increase of 2.3 kg in the combined oral contraceptives (COCs) group, 2.8 kg with values \((p = 0.02)\) 11. At baseline, the median age was 29 and 30.5 years, and the average BMI was 24.8 and 24.5 kg / m2 in the DMPA group. At 12 months, an increase was observed at the waist and hip circumference in DMPA users and 8/20 of them had a weight gain of 5% (an average of 4.6 kg). And Significant weight gain is caused by hormonal contraception but also because of the age of the acceptor12,13.

**Conclusions**

Depo Medroxy Progesterone Acetate (DMPA) injectable contraceptive acceptors with duration of use between 3 months to 36 months experience weight gain with Paired-sample T test: \(df = 54; t = 15.5; p = 0.000\) (<0.05). Pre-use counseling is very important to
overcome the effects of weight changes that occur in some acceptors of Family Planning so that they become acceptor.

The Overview of Malaysia HIV Counselling Structure

Nur’ain Balqis Haladin¹, Noor Aireen Ibrahim¹, Azizah Rajab¹ and Yasmin Hanafi Zaid⁴

¹ Senior Lecturer, Language Academy, Faculty of Social Sciences and Humanities, Universiti Teknologi Malaysia, Malaysia

Abstract

HIV infection is a chronic disease as there is currently no effective treatment or vaccine which further intensify the psychosocial impacts on HIV patients, their spouse as well as their family. However, HIV transmission is preventable as it is associated with the patients’ behaviour and lifestyle. Therefore, HIV counselling plays a vital role in the prevention and management of HIV transmission. Although studies on the structure of HIV counselling sessions have been done by previous researchers, similar study on the structure of HIV counselling sessions should be done in Malaysia in order to see whether the structure comply with those found in the previous research. Due to the lack of literature on the structure of HIV counselling sessions in the Malaysian context, the need for such research is even more significant in order to contribute to the Malaysian research on HIV. A total of 24 HIV counselling sessions from three government hospitals in Malaysia were recorded, transcribed and analysed. After analysing the data obtained from the audio recorded of HIV counselling sessions, it became apparent that the HIV counselling structure found in this study consisted of different themes which could be distinguished from each other based on the interactional goal each was attempting to achieve in the session and it was evident that the different phases have distinctive interactional structures.

Keywords: HIV counselling, counselling structure, advice giving, information giving.

Introduction

HIV infection is a disease that has hit the world’s population, including the people of Malaysia. To date, there is still no cure or vaccine for this disease. It is, therefore, a challenge in providing services as the demand and the needs of health services will continue to increase¹. As HIV/AIDS is a public health problem, it requires the commitment and cooperation of various agencies from either governments, NGOs, society or individuals. Therefore, the involvement of various sectors in helping people living with HIV are severely needed¹.

The HIV/AIDS committees has approved that the national HIV treatment to be integrated into primary health care level² with the aim to reduce the transmission of infection as well as to improve the health and the productivity of HIV patients. It provides exposure to healthcare professional to HIV patients which could improve their skills in handling cases such as counselling skills, physical examination and reduce the stigma against the HIV patient.

HIV counselling can be defined as a dynamic process of interaction and discussion between a qualified HIV nurse counsellor and a HIV patient who presents with problems associated to HIV with an aim to support the patient to manage these problems effectively and properly². HIV counselling is accomplished to achieve several objectives, which are:

(i) Prevention of infection through promotion of healthy behaviour, lifestyles, and spiritual values.

(ii) Prevention of transmission through modification of risky behaviours and lifestyles.

(iii) Delivery of psychosocial support to HIV patients and their spouse/family to achieve optimum level of quality of life.

e-mail: nurainbalqis@utm.my
(iv) To correct misconceptions pertaining to HIV through health education.

In addition, there are several HIV counselling stages; i) pre-test counselling, ii) post-test counselling, and iii) support/follow-up counselling. Since HIV infection are connected with intense psychosocial impact to patients, their spouse as well as their family, pre-test counselling have to be performed prior to the HIV test. After the confirmation by a supplementary test, the post-test counselling in positive cases should be done without delay. During the post-test counselling, patients should be given the time to comprehend the meaning of test results and to allow ventilation of feelings such as anger, silence, fear, and more. Finally, all cases of positive results should be given follow-up/support HIV counselling. During the follow-up/support counselling, problems can be identified so that further action can be taken.

**Structure of HIV counselling session:** A prominent difference between counselling interactions and medical encounters were that the former were more flexible (Silverman, 1997; Sheon et al., 2010). Past study on therapeutic discourse described the interaction as an artificial structure which is derived from sudden shifts of topics. In HIV pre-test counselling sessions, a flexible structure was also found. It consisted of medical history taking, followed by discussion about sexual matters and then information delivery (Silverman, 1997). Dreaded issues were introduced later on in the session and the session concluded with discussions about the availability of the test result.

On the other hand, other study found that HIV counselling sessions (with men in the USA) consist of several tasks, namely: counselling (client speaks more than the counsellor in one turn), information delivery (risk assessment and health communication), data collection (standard survey regarding risk behaviour required by the particular institution) and sample collection (oral fluid swap and rapid test). These tasks were quantified by mapping when and how often each occurred in the session and it was found that they did not occur in a strict order and when the data collection task was removed from the session, the time the counsellors spent on counselling increased.

It is clear from the research discussed above that order exists in institutional discourses. This is what distinguishes such discourses from everyday talk and informal conversations. This order, however, varies according to the types of encounters as shown in counselling and medical interactions. Such overall descriptions are valuable as they provide an overview and a context for the interactions.

Although studies on the structure of HIV counselling sessions have been done by previous researchers, similar study on the structure of HIV counselling sessions should be done in Malaysia in order to see whether the structure comply with those found in the previous research. Moreover, due to the lack of literature on the structure of HIV counselling sessions in the Malaysian context, the need for such research is even more significant in order to contribute to the Malaysian research on HIV. Hence, it is important for this study to map the structure of HIV counselling sessions which takes place in the Malaysian government hospitals.

**Methodology:** This study takes on a qualitative approach; i) audio recordings of HIV counselling session and the analysis involved examining the pattern of the nature of the HIV counselling sessions. A total of 24 HIV counselling sessions from three government hospitals in Malaysia were recorded, transcribed and analysed. The details of the participants for the audio recordings of HIV counselling sessions is shown in Table 1.

Eight HIV nurse counsellors from the three government hospitals involved in the audio recordings of HIV counselling sessions. These nurses are specialized nurses with more than five years working experience. On the other hand, twenty-four HIV patients involved in both post-test and support/follow-up HIV counselling. With the aim of obtaining an overall mapping of the thematic structure of these sessions, the analysis began by listening to the audio recordings of HIV counselling sessions, reading the transcripts, and transcribing the interactions between the HIV nurse counsellors, the HIV patients and their spouse/family.

**Findings and Discussion:** After analysing the data obtained from the audio recorded of HIV counselling sessions, it became apparent that the HIV counselling structure found in this study consisted of different themes which could be distinguished from each other based on the interactional goal each was attempting to achieve in the session and it was evident that the different phases have distinctive interactional structures. The phases of the HIV counselling sessions audio recorded in this study were mapped along a continuum in which each phase was defined by different colours which refer to different themes/components, developing what is referred to as a “sequence map”.

The analysis carried out on the structure of seven post-test HIV counselling in this study resulted in the emergent of four major themes as shown in Figure 2. These themes were quantified by mapping their occurrence in each post-test HIV counselling session.

![Figure 2. Thematic structure of the post-test HIV counselling](image)

As shown in Figure 2, the thematic sequence found in the post-test HIV counselling structure can be viewed as: i) opening, ii) history-taking, iii) advice and information giving, and iv) closing. Later, the discussion will show that the support/follow-up HIV counselling sessions do not follow the same thematic sequence. For in-depth understanding of the structure of post-test HIV counselling, the researcher identified the percentage of the occurrences of these themes in the post-test HIV counselling sessions as shown in Figure 3.

![Figure 3. The percentage of the occurrences of the themes in the post-test HIV counselling sessions](image)

Similarly, the analysis of support/follow-up HIV counselling also indicates the importance of advice and information giving. Figure 4 provide the findings on the structure of seventeen support/follow-up HIV counselling.
As shown in Figure 5, 72% of the whole support/follow-up HIV counselling sessions was spent on advice and information based on the frequency of the theme during the support/follow-up HIV counselling sessions. The finding is congruent with the analysis of the post-test HIV counselling sessions. This clearly indicates that advice and information giving is not just an important theme in the post-test HIV counselling, but also in the support/follow-up HIV counselling sessions. Therefore, it is worth mentioning that the findings in the current study do not appear to validate the view by past researcher on the need for more HIV-related advice and information for HIV patients as well as their spouse and family.

For an in-depth understanding of the structure of the support/follow-up HIV counselling, the researcher calculated the percentage of occurrences for all the themes found in the support/follow-up HIV counselling sessions as shown in Figure 5.
The structures found in this study further validate previous research\(^4,^5\) that the malleable nature of counselling interactions to a particular structure and varied according to the types of encounters is the prominent difference with the medical encounters. The history-taking in the post-test HIV counselling occurred in the beginning of the HIV counselling sessions which covers the patient’s HIV exposure history which include the date and place of diagnosis, the route of exposure, and how the patient is coping with his/her HIV status. The findings can be supported with a statement\(^6\) that the counsellor should explore and acknowledge the various psychological reactions and concerns of the patient, specifically what the patient plans to do in the short and long term period. In contrast, the history-taking in the support/follow-up HIV counselling occurred toward the end of the counselling session. Since the follow-up patients’ appointments have been arranged, hence, the absence of history-taking at the beginning of the counselling sessions can be justified.

It is worth noting that medication adherence phase occurs right after opening phase in the structure of support/follow-up HIV counselling sessions. Moreover, majority of these patients are on HIV treatment which means that medication adherence is the major concern as past research assert that adherence should be monitored and should be assessed at each clinic follow-up visit as there is an indication that adherence decreases over time\(^9,^{10,11}\). This statement supports the findings of this research whereby HIV nurse counsellors would normally begin their HIV counselling sessions by assessing patients’ medication adherence.

Further analysis of the audio recorded HIV counselling sessions indicated that throughout the post-test HIV counselling sessions, 75% of the whole post-test HIV counselling sessions was spent on advice and information giving, while 72% during the support/follow-up HIV counselling sessions.

**Conclusion**

It is clear from the findings discussed above that order do exists in institutional discourses, particularly in HIV counselling. This is what distinguishes such discourses from everyday talk and informal conversations. The order, however, varies according to the types of encounters as shown in the different order between post-test and support/follow-up HIV counselling. Such overall descriptions are valuable as they provide an overview and a context for the interactions. It is worth mentioning that advice and information giving played key roles in constituting HIV counselling session.
as the percentage of advice and information giving occurrences in HIV counselling are astoundingly high. It is, therefore, believed that it is relevant for further research with the focus on advice and information giving in HIV counselling to be conducted.

A Systematic Review of Learning Application for Students with Dyslexia

Kee Jiar Yeo¹ and Wai Wai Lim²

¹Professor, ²Student, School of Education, Universiti Teknologi Malaysia, UTM Johor Bahru, Johor

Abstract

Dyslexia is a specific learning disability in reading, writing and spelling which are not linked to intelligence. Learning application can be utilized as a gadget to help students with dyslexia (SwD) in alleviating their difficulties. The purpose of this study is to provide a review on learning applications, evaluation of application usability and effect of the application towards dyslexic’s performance. Twenty articles retrieved from electronic databases on learning application for SwD published between 2012 to 2018 were selected and reviewed systematically. There were seventeen learning applications for dyslexia and five were related to English Language. Children were eager to explore the learning application and enjoyed using it. Most of these studies revealed significant improvement in reading, spelling and writing after using the learning application. Evaluation aspect is beneficial to researchers in developing learning application in future.

Keywords: Learning application; dyslexia; learning disability.

Introduction

Dyslexia is a common learning disability and mainly impairs a person’s proficiency in reading, spelling and writing. It is irrespective of intellectual disability¹, health impairments and behavioral disturbances. Students with dyslexia (SwD) often experience difficulties in accurate word recognition², convert specific letters to corresponding sounds or manipulate the sounds together to form a word ³, read with long pauses or frequently lose directionality in text by missing out lines. Because of these deficits, they always being labelled as lazy, slow and idiot kids in school ⁴-⁵. Thus, it makes SwD often feel frustrated and have a low self-esteem compared to their peers.

Research found that conventional teaching methods may not be effective for SwD⁶. SwD need multisensory technique which involves utilisation of visual, auditory and kinaesthetic sensory components to enhance learning process⁷. Multisensory approach makes learning process more effective and students stay focused for long durations⁷-⁸. Mahidin et.al.⁹ claimed that learning applications which allow SwD apply more than one sensory channel to process the instructions is an efficient gadget to teach SwD. Mobile learning application not only give positive effects on the process of literacy acquisition¹⁰ but also assist SwD to practise reading independently. The purpose of this paper is to review literature on learning applications, evaluation of application usability and effect of the application towards dyslexic’s performances. The finding of this literature review contributes in identifying research gaps for future study.

Methodology: Electronic databases, such as Google Scholar, SpringerLink, ScienceDirect, IEEE Xplore Digital Library, Science Publications and ERIC were used to gather previous studies on learning application for SwD. The papers published between year 2012 to 2018 were searched and downloaded under the keywords [Dyslexia AND Mobile Application], [Learning Disability AND Mobile Application] and [Dyslexia AND Learning Application]. There are 20 articles which fulfilled the criteria adopted and categorised into three themes.

Results

Findings from 20 papers which highlighted learning applications, evaluation of application usability and
effect of the application towards dyslexic’s performance. Seventeen papers discussed the development of learning applications, one on the existing learning application in improving participant’s spelling skills and while the other papers focused on doing research field works before the development of learning applications.

**Learning Application:** Thirteen out of seventeen learning applications focused on dyslexia, two of them focused on both dyslexia and dyscalculia and another two focused on dyscalculia. There were five learning applications in English Language\(^4-5,7,11,12\). Android was found to be the prominent platform used as operating system for the mobile application as most of the young people have a mobile device equipped with this operating system.

Mobile application by Borhan et.al \(^4\) focused on English sight words which were incorporated in short stories, rhymes and song verses in mobile application. Tariq and Latif \(^{12}\) termed as Dyslexia, is characterized by difficulties in various aspects of writing skills making the individuals unable to develop age-appropriate and ability-appropriate functional skills. In Pakistan, lack of dyslexia awareness and remedial education training restrains the remediation of dyslexic children at early stages. There also exist noticeable affordance and accessibility issues concerning the remedial help and assistive technology adoption. In this research, we have developed a mobile learning application for android-powered devices that targets developmental progression and usability requirements of dyslexic children with writing difficulties. Our center of interest was to improve introductory writing skills of dyslexic children along with consistent evaluation of their learning performance to highlight the weak areas of learning process. To achieve this objective, we have designed a Writers Learning Algorithm (WLA discussed the mobile application for improvement of SwD’s fundamental handwriting skills in English Language and Mathematics. Dyslexia Aide (2016) \(^5\) was designed to enhance learning of alphabet, spelling of English words and memory skill. Balakrishnan et.al \(^{11}\) highlighted mobile based multimedia tool improves SwD’s writing and reading skills in English language. Mobile application EasyLexia developed by Roxani et.al \(^7\) were aimed to improve reading skills in English Language, Mathematical skills, short term memory and concentration of children.

**Evaluation of Usability Application:** Findings showed that eight studies focused on application usability, five studies focused on effect of the application towards dyslexics and six studies emphasising on both usability and performance settings. SwD enjoy playing the application and will use the application again for more content \(^13-15\). All the students showed their preference in completing the tests on a mobile device rather than on paper \(^7,16\) and majority of them could stay focussed and interested throughout the session when using the application \(^14,17\).

Respondents were happy with the user interface design, colour and picture in Mr.Read V2.0 developed by Borhan et.al\(^9\). Functions and animations in Dyslexia Aide are simple and children enjoyed using the applications while learning. However, level of interactivity in application of Tariq and Latif \(^{12}\) should be improved as learning effectiveness greatly depends on it. In general, evaluators agreed that Dyslexia Baca is well designed in content and multimedia elements\(^18\). However, the user commented that they only have to find one alphabet in level 2 which is too simple and not standardized in the other levels and new version of Dyslexia Baca is required. Study by Madeira et.al\(^3\) and Risqi et.al\(^{14}\) revealed that smooth animation and nice graphic can engage and attract dyslexics’ attention.

**Effect of the Application towards Dyslexic’s Performance:** SwD were able to spell better with mobile learning application\(^4,15,19\). They could sound out words confidently and improved their reading skill significantly after using mobile learning application\(^4,11,15\). The review of Roxani et.al (2013)\(^25\) showed progress in word recognition and phonological decoding. The mobile application facilitates the perception of the visual layout of the letters by rotational movement function \(^20\). All participants achieved top score in the early words, rhymes and sequences of letters in the words but poor performance in syllables structure of words\(^3\). Results revealed that increase in identifying letter shape, letter-sound, pronouncing syllables and self-efficacy belief after using mobile application \(^21\).

The study by Tariq and Latif \(^{12}\) termed as Dyslexia, is characterized by difficulties in various aspects of writing skills making the individuals unable to develop age-appropriate and ability-appropriate functional skills. In Pakistan, lack of dyslexia awareness and remedial education training restrains the remediation of dyslexic children at early stages. There also exist noticeable affordance and accessibility issues concerning the remedial help and assistive technology adoption. In
this research, we have developed a mobile learning application for android-powered devices that targets developmental progression and usability requirements of dyslexic children with writing difficulties. Our center of interest was to improve introductory writing skills of dyslexic children along with consistent evaluation of their learning performance to highlight the weak areas of learning process. To achieve this objective, we have designed a Writers Learning Algorithm (WLA, Rello et.al 2 and Balakrishnan et.al 11 indicated that learning application has an impact in improving writing skills of SwD compared to traditional method. The article by Ariffin et.al 20 indicated that testing shows positive improvement in addition and subtraction operation question (mathematics) after using Calculic Kids application.

**Discussion and Suggestion for Future:** There are seventeen mobile learning applications were developed from 2012 to 2018. Therefore, future researches need to focus more on design and development of mobile application especially in English Language for SwD. Moreover, the meta-analysis results indicated that the mobile learning application is one of the gadgets to improve reading 4, 11,15, writing 2,12, spelling 4,15,19 and mathematics 20. These findings are consistent with the study that proposed applications enhance the SwD with disciplinary literacy 22, writing 23 and reading 24.

However, there are several limitations across the meta-analysis studies. It included the imprecision of data in the studies due to small sample sizes (below 10) 9. The articles searched from electronic databases might not be comprehensive and excluded some articles published in other languages. In future, the articles should be searched in other languages by using translator, period of published articles should be before year 2012 and used large sample size.

**Conclusion**

The articles were reviewed in three main themes, namely learning application developed, evaluation of application usability and effect of the application towards SwD’s performance. This review provided valuable insight on the current trends pertaining to the use of learning application in helping SwD to gain better learning experiences. The review is also beneficial to researchers in developing effective learning application in future based on the evaluation aspects.

Diagnostic Outcomes of Pancytopenia after Bone Marrow Examination in Lady Reading Hospital, Peshawar

Huma Riaz¹, Munawar Ali Shah², Taj Ali Khattak³

¹MBBS, DCP (Diploma Clinical Pathology), FCPS (Haematology), Assistant Professor of Haematology, ²MBBS, FCPS (Haematology), Assistant Professor of Haematology, ³MBBS, M. Phil (Haematology), Professor of Haematology, Department of Pathology, Lady Reading Hospital, Peshawar Pakistan

Abstract

Objective: To determine the causes of pancytopenia after bone marrow examination to identify the correct etiopathology in order to help in implementing timely and appropriate treatment.

Study design: Cross sectional retrospective descriptive study.

Place and duration of the study: Haematology unit, department of pathology of Lady Reading Hospital, MTI.Peshawar, from 01.01.2012 to 31.12.2012. Material & Methods; A retrospective analysis of the data of total 181 patients including all ages and both the gender, who presented with pancytopenia and underwent bone marrow examination was performed. Hemoglobin level below 10gm/dl, white blood cell count of less than 4x10⁹ u/l and platelet count less than 150x10⁹/ul was taken as the criteria for pancytopenia. Cell counting was performed by automated cell counter and platelet count was confirmed by peripheral blood film examination. The findings were recorded in a Performa and results were drawn accordingly.

Results: During this study period, 181 patients fulfilled the criteria for pancytopenia. Age of study subjects ranged from 1 to 80 years (mean age 26 years). 102(56.4%) were male and 79 (43.6%) were females; giving male to female ratio of 1.2: 1. Among 181 cases, the commonest diagnosis for pancytopenia after bone marrow examination was Aplastic anemia; with 64(35.4%) cases. Megaloblastic anemia was the second commonest diagnosis with 52(28.7 %).31.2(17.6 %)were diagnosed with acute leukemia which included 20 (11 %) and 12 (6.6 %) cases of Acute lymphoblastic leukemia (ALL) and Acute myeloid leukemia (AML) respectively. Chronic lymphocytic leukemia was diagnosed with 2 (1.1 %) cases. while 4 (2.2 %) cases were diagnosed with Myelodysplastic syndrome (MDS) and 3 (1.7 %) with Plasma Cell Disorder/Multiple Myeloma (MM). 2(1.1 %) cases were diagnosed with bone marrow metastasis. Mixed deficiency anemia was found in 5 (2.8 %) cases while 9 (5 %) cases were found with peripheral destruction. Storage cell disorder (Gaucher’s disease) was diagnosed in 2 (1.1%) cases. 5 (2.8 %) cases were diagnosed with Visceral Leishmaniasis and 1 (0.6 %) case diagnosed with Plasmodium Vivax Malaria.

Conclusion: Aplastic anemia was the commonest cause of pancytopenia, followed by Megaloblastic anemia after bone marrow examination.

Keywords: Pancytopenia, Bone marrow examination, Megaloblastic anemia, Aplastic anemia.

Introduction

Pancytopenia is a very common observation in routine haematological investigation.¹ It is defined as reduction of all the three formed elements of blood (erythrocytes, leucocytes and platelets) below the normal reference range .the patients are suffering from anemia, leucopenia and thrombocytopenia.¹² There are various
causes of Pancytopenia ranging from a mild nutritional deficiency to a life threatening malignancy infiltrating the bone marrow. The etiology of pancytopenia highly varies according to the geographical and genetic factors. The chief clinical manifestations in patients are secondary to the reduction in blood elements, and are commonly in the form of fever, pallor, fatigue, bleeding, weight loss, organomegaly etc.

Establishment of a correct diagnosis is vital for the management and prognosis of that specific disorder. A prompt diagnosis of various causes of pancytopenia is therefore very crucial and always requires a thorough clinical examination followed by base line investigations like complete blood count, peripheral smear and bone marrow examination.

Diagnosis of the underlying pathology in pancytopenia is the real determinant of the future management and prognosis of such patients. Hence, Bone marrow Examination is a highly informative diagnostic test in evaluating the causes of pancytopenia and thus can possibly prevent grave complications and mortality in these patients by early therapeutic interventions.

Different studies are carried out regarding the etiology of pancytopenia worldwide, but due to high variation in the etiological spectrum of pancytopenia according to the geographical distribution, genetic factors and local environmental conditions, the data of the other countries may not be a true representative of our population. Hence this necessitates local studies in our own local setups. This study therefore was conducted to determine the etiological spectrum of pancytopenia in our setup using bone marrow aspiration as a diagnostic tool.

**Materials and Methods**

This is a cross-sectional retrospective descriptive study conducted at haematology unit, Department of pathology at Lady Reading Hospital, MTI Peshawar over a period of 12 months from January 2012 to December 2012. A retrospective analysis of the data of patients who presented with pancytopenia and underwent bone marrow examination, was performed. The study included 181 patients and diagnoses were made based on criteria defined by De Gruchy.

Pancytopenia was reported by automated cell counter (Sysmex). The criteria for diagnosis are: Hemoglobin <10 gm%, WBC count <4 X 10^3/ul and Platelets < 150 X 10^3/ul

Patients with dry tap and with inadequate bone marrow aspirate sample were excluded from the study.

Diagnostic Data of 181 patients were confirmed after detailed microscopic examination of smears of peripheral blood, reticulocyte count and smears of bone marrow with a detailed morphological study of different cells. Mean was calculated for quantitative variables e.g. age. Frequencies and percentages were calculated for qualitative variables like diagnosis and gender. Data was analysed using SPSS version 16.

**Results**

During the period of our study a total of 512 patients underwent bone marrow examination, Out of which 181 patients were fulfilling the criteria of pancytopenia. Bone marrow aspiration examination and trephine biopsy was performed in all the cases.

Study included patients from all age groups and both genders. Age of study sample ranged from 1 to 80 years. There were 102(56.4%) males, and 79 (43.6%) females (Table; 2), with male to female ratio of 1.2:1. Among these 181 cases 52 (28.7%) cases were diagnosed with Megaloblastic anemia, 64(35.4%) cases were diagnosed with Aplastic anemia , while 32(17.6 %)cases were diagnosed with acute leukemia including 20 (11 %) and 12 (6.6 %) cases Acute Lymphoblastic Leukemia (ALL) and Acute Myeloblastic Leukemia (AML) respectively. Storage cell disorder was diagnosed in 2 (1.1%) cases while Visceral leishmaniasis in 5 (2.8%) cases. Malaria was in 1 (0.6%) cases while bone marrow metastasis was diagnosed in 2 (1.1%) cases. In 5 (2.8%) cases diagnosis of Mixed deficiency anemia was made. Chronic Lymphocytic leukemia CLL was found in 2 (1.1%) cases while Plasma cell disorder (Multiple Myeloma)in 3 (1.7%) cases, Myelodysplastic Syndrome (MDS) was diagnosed in 4 (2.2%) cases and peripheral destruction was diagnosed in 9 (5%) cases.

Discussion

Pancytopenia is a very common haematological finding with a wide spectrum of clinical presentations. Pancytopenia is not a disease entity but a triad of findings in which all three major formed elements of blood (i.e.; red blood cells, white blood cells and platelets) are reduced in number. The severity of pancytopenia and the underlying pathology mainly determine the management as well as the prognosis of the patients. It most often creates a diagnostic challenge to the physician and an appropriate knowledge of accurate etiologies regarding this condition is vital for the management of the patient. Bone marrow examination is of prime importance to establish a diagnoses in the patients presenting with pancytopenia.

The frequencies of the diseases causing pancytopenia highly vary in different studies due to the differences in geographical distribution including nutritional status, genetic differences in population, variety of infections and exposure to bone marrow suppressing drugs.

In our study Aplastic anemia was the commonest cause of pancytopenia (64 (35.4 %) (Table 1). This is in contrast to the previous studies conducted where on the basis of bone marrow examination, the most common cause of pancytopenia was Megaloblastic Anemia , in studies of Khan et al, Isha et al, Varma et al., Kumar et al, Santra et al. Aplastic anemia was reported as the commonest cause of pancytopenia and its frequency ranged from 10% to 52.7% in different studies regarding the outcome of pancytopenia diagnosed on bone marrow aspiration and biopsystudies. In one study done by Singh G and colleagues in 2016, aplastic anemia was seen in 1.1% cases of pancytopenia and was the least common cause of pancytopenia.

The diagnosis of aplastic anemia was made initially after bone marrow aspirate examination which was further confirmed after bone biopsy examination.

The second commonest cause of pancytopenia in our study is Megaloblastic anemia. (Table 1). The incidence of megaloblastic anemia recorded in various studies varies from 0.8% to 32.26% of all pancytopenic patients. In the present study megaloblastic anemia was observed in 52 cases with 28.7 % frequency. Blood films in these cases were showing macrocytosis and hyper-segmented neutrophils while Bone marrow was characteristically showing megaloblastic change in the erythroid lineage. Stainable bone marrow Iron was increased in the bone marrow. These patients were advised strict monitoring of blood counts after therapeutic trials of vitamin B 12 and folic acid. A Study conducted by Memon S and colleagues in 2008 in India showed that megaloblastic anaemia was the commonest cause of pancytopenia followed by aplastic anemia. In another study conducted in 2014 by Prabhala , data of 172 patients presented with pancytopenia who underwent bone marrow examination, was analysed and megaloblastic anemia was found to be the commonest cause of pancytopenia.

Megaloblastic anaemia is found to be common cause of pancytopenia in developing world due to nutritional deficiencies. Usual causes of megaloblastic anemia in our country are chronic inflammatory disorders of the gastrointestinal tract and malabsorption syndromes apart from poor nutrition. Though in our study megaloblastic anemia was still prevalent in a high frequency (i.e.; 28.7%) but aplastic anemia was the leading (i.e; 35.4%) cause of pancytopenia.

Mixed deficiency anemia was observed in 5 (2.8%) cases of pancytopenia in the present study (Table 1). similar findings were observed in a study done by Khan MI et al while in another study done by Singh G and colleagues in 2016 Mixed deficiency anemia secondary to malnutrition was the commonest cause among pancytopenia, and was observed in 27.3% cases.
Similar results were seen in studies by Chandra et al from Delhi and Borelli et al from Brazil. Malnutrition of multiple micronutrients can suppress the normal bone marrow hematopoiesis and thus leads to pancytopenia.

Acute lymphoblastic leukemia (ALL) was found in 20 (11%) cases and Acute myeloid leukemia (AML) was diagnosed in 12 (6.6%) cases (table 1). Together, AML and ALL constitute 17.6% cases of acute leukemia. In a study conducted by Singh G and colleagues in 2016, acute leukemia was found to be the second most common cause of pancytopenia, constituted 18.2% of all the cases of pancytopenia.

Chronic lymphocytic leukemia (CLL) was diagnosed in 2 (1.1%) cases in our study, while 3 (1.7%) cases out of 181 were diagnosed as plasma cell disorder (Multiple Myeloma). Other studies also showed low incidence of multiple myeloma ranging between 0.94% to 4.1%. Bone marrow metastasis was diagnosed in 2 (1.1%) cases in the total 181 cases (table -1).

Myelodysplastic syndrome (MDS) was found in 4 cases at a frequency of 2.2%. MDS as a cause of pancytopenia, reported in few other studies varies in frequency from 0-18%, which is mainly due to variation in environmental factors, genetic and geography.

In our study 9 (5%) cases out of the total 181 were with the diagnoses of Peripheral destruction with normal bone marrow trilineage hematopoiesis (table-1). In a study conducted by ahmad MI et al, 15 (19.7%) patients had peripheral lowering of blood counts. In another study done by Singh G et al in 2016, 9.1% patients had pancytopenia secondary to peripheral destruction. Pancytopenia may be due to splenic sequestration of blood cells or immune destruction of the blood cells.

We had 05 (2.8%) cases diagnosed with visceral leishmaniasis and 01 (0.6%) case with Plasmodium Vivax Malaria among the total 181 cases of pancytopenia. One study showed the same incidence of infective pathology, where plasmodium Vivax Malaria and Visceral Leishmaniasis both were seen in frequency of 1.3% each. Three similar studies done in the past, showed leishmaniasis as cause of infection in 2.8%, 1.2% and 0.67% cases, respectively.

Aplastic anemia, was the commonest etiology of pancytopenia in our setup, followed by megaloblastic anemia and acute leukemia. Education of the general population about nutrition and diet and avoidance of exposure to toxic radiations chemicals, and drugs may help to control and lower the incidence of these diseases and thus reduce morbidity. This study also has shown that through bone marrow examination, a diverse spectrum of diagnoses was made in patients presenting with the single finding of pancytopenia, thus proving the diagnostic significance of bone marrow examination in pancytopenia.

**Conclusion**

Aplastic anemia was found as the commonest diagnosis followed by Megaloblastic anemia in pancytopenic patient in our setup and bone marrow examination is proved to be an important diagnostic tool in evaluating a wide spectrum of diagnoses in patients presenting with pancytopenia. A prompt diagnosis in case of pancytopenia, therefore, can improve the management and prognosis of the underlying disease.

Perceived Causes of Infertility: Accounts of Infertile Individuals in Kwara South, Nigeria

Iwelumor Oluwakemi S1, Shariffah Suraya Syed Jamaludin2, Babatunde Seun K3

1Doctoral Candidate: Anthropology and Sociology Section, 2Senior Lecturer: Anthropology and Sociology Section, School of Social Sciences, Universiti Sains Malaysia, Malaysia, 3Independent Researcher, Staff Quarters, Landmark University, Omu-Aran, Kwara State, Nigeria

Abstract

Infertility is perceived differently across socio-cultural contexts and studies have shown these perceptions affect the overall management of infertility. This study specifically explored the perceived causes of infertility among infertile married persons experiencing primary infertility in Kwara South, Nigeria. The study adopted a qualitative design. Infertile persons were recruited through snowball sampling technique. Data was collected through semi-structured in-depth interviews of 12 infertile married women and 7 infertile men. The data were analyzed using conventional content analysis with the aid of Atlas.ti 7. Findings showed that infertility is defined as barrenness and childlessness. Sociocultural factors rather than biomedical factors were exalted as primary causes of infertility. These include lifestyle choices or habits, rape, spiritual oppression, witchcraft/sorcery, trial and punishment from God. Understanding these perceptions will enhance the development of culture-specific programs targeted at managing infertility in Nigeria.

Keywords: Infertility; Childlessness; Sociocultural perception; Perceived cause; Nigeria.

Introduction

There is no gainsaying the fact that infertility is both a social and medical problem. Infertility literally connotes a condition of childlessness or a failure to achieve desired pregnancy and/or live-birth. Most studies on infertility in developing nations have focused on the prevalence and biomedical cause of infertility with a view to improving service delivery on treatments and assessment for psychological counseling. While a few have examined public perceptions on the meaning of infertility, empirical examples are scarce of how infertile persons perceive the cause of their situation.

This study explored how married women and men experiencing primary infertility in Kwara South, Nigeria perceives the cause of their situation. This is significant because it provides an avenue to better understand the social causes of infertility as perceived by infertile persons rather than have the perceptions of others imposed on them. This would also go a long way to mitigating some of the discriminatory practices against married infertile persons in Nigeria.

Literature Review: Revealing the cause of infertility in developing nations relies on orthodox healthcare and ethnogynecology 1. Several studies in sub-Saharan Africa have shown that sexually transmitted infections and genital tract infections are the primary causes of male and female infertility 2-5. Though many affirm this, sexual promiscuity is believed to be the significant causal factor, rather than those infections since the latter is understood to be prevalent among the morally decadent in the society6-8.

Sequel to promiscuity, abortion is also culturally perceived in Nigeria as a leading cause of infertility among women. This is premised on the belief that promiscuity increases the chance of one having unwanted pregnancies which often lead to unsafe abortions with severe outcomes. Complications from abortions have been linked to procedures and objects some women use to induce abortion which includes solvent, detergent, alcohol, decoctions inserted into the vagina and other traditional herbs9,10.
Similarly, contraceptives are also thought to cause infertility. While some are believed to be outrightly linked to infertility, overuses of others are thought to disrupt natural functions of the body eventually leading to infertility. This is culturally tied to the belief in predestination. Yoruba people believe that everyone comes to the earth with a definite number of offspring which can be expended through abortions and contraceptive use. Such people can become infertile when they eventually resolve to have children.

The belief in supernatural bases of infertility has different dimensions. Firstly, children are believed to be gifts from God and he gives to whomever he wills and at different times. Thus, while many infertile couples live in denial of their conditions with a hope that they will eventually have children, others see infertility as temporary trial or persecution that will be overcome. Secondly, infertility has been attributed to God’s wrath or punishment from ancestors or deities for violation of cultural norms or wicked acts.

Another dimension is the link between witchcraft and infertility. Infertility is sometimes thought to be inflicted by the wicked in the community and that curses can be placed on individuals or couples to be childless through spiritual powers and evil spirits. Some infertile women are also believed to be witches, who have vowed not to have children by not becoming pregnant, ‘devouring’ the fetus in utero or at birth.

Methodology: A qualitative exploratory research design was adopted to explore the perceived socio-cultural cause of infertility among married infertile persons. The study population consisted of twelve (12) women and seven (7) men experiencing primary infertility, at least two years prior to this study from Kwara South Nigeria. Participants were recruited through snowball sampling technique with the assistance of two (2) gatekeepers. The research instrument was a semi-structured in-depth interview, using an open-ended interview question guide. All interviews were recorded with the approval of participants and ranged from 50 to 110 minutes.

Interviews were done at places chosen by research participants and in their preferred languages. The data were transcribed, arranged in codes, and examined for categories and themes using conventional content analyses with the aid of ATLAS.ti (version 7). Qualitative content analysis was done based on the evaluation criteria suggested by Lincoln and Guba. The University of Ilorin Teaching Hospital Ethical Review Committee gave ethical clearance for the study. All selected research participants gave written informed consent.

Results and Findings

Characteristics of study participants: Infertility from this study is broadly defined as a lack of conception and/or inability to bear a child further described as barrenness and childlessness respectively. All the participants in this study were grappling with primary infertility which studies have shown have greater consequences than secondary infertility. They differ remarkably in age, sex, duration of infertility and religion. Their ages ranged between 24 – 52 years, majority of them were women (12 participants), and the duration of infertility was between 3 – 22 years while the bulk of them (17 participants) were Christians.

Also, a good number of the participants were educated as eleven had university degrees or its equivalent, four had postgraduate degrees and the least educated (two participants) had basic Senior Secondary School Certificates. This affirms the findings of some studies that the prevalence of infertility rises with age and primary infertility could be higher among more educated women. Table 4.1 shows the characteristics of the participants.

*Names have been changed to ensure participants’ anonymity.

**Thematic findings:** The findings of this study reflect participants’ perceptions of the cause of their infertility or reasons for their childlessness rather than their general perceptions of infertility. These causes are grouped into two themes and six sub-themes as presented in table 2

<table>

</table>

Source: Researcher’s fieldwork, 2019

**Sociobehavioural causes of infertility:** This theme comprises three subthemes: worldliness, rape, and modernization.

**Worldliness:** Many of the participants believe that infertility mostly results from one’s actions or inactions. Thus, infertility could be self-inflicted or manmade. As inferred from the study, worldliness explains lifestyle choices or habits like waywardness, alcoholism, substance abuse, sexual promiscuity, abortion and the use of contraceptives. These were described by many as the cause of their childlessness.

For example, Lola, who has been married for 10 years, attributed her condition to “worldliness”. He stated that “this delay in childbearing is due to my worldliness. I like to enjoy life and I indulged in heavy smoking, drinking and other toxic substances. It has given me low sperm count...this disorder in my body that I have caused myself”. Similarly, Moses, a bittered 50-year-old man who said he could not divorce his wife ascribed his family’s childlessness to his wife’s worldly actions. He claimed that “My wife that is infertile. I did not know my wife was so loose because we were married in the church... I did not have the chance for worldliness like parties and some other things like her and that has been my nature.”
The study also shows that peer pressure could lure some into actions that could lead to infertility. This perception was reiterated by Seun who is in a polygamous marriage. She stated that “I sometimes blame myself for my past wayward life. To be with friends and be trendy, I have had abortions, used contraceptives and other things that will not allow one to get pregnant. Now I know that shameful pregnancy before marriage is better than infertility later in marriage”.

In the same vein, Shade affirmed that “I am the cause of our childlessness but I cannot bring myself to tell my husband. When I was in secondary school I got pregnant and because I didn’t want my parents to know I mixed so many things … to ensure the pregnancy comes out… I was later told by the doctor that my fallopian tubes are damaged that I may never be able to conceive”.

**Rape:** Unlike reports from previous studies, some of the participants believed that rape can lead to infertility. They claimed that violent rape can destroy the uterus and other vital reproductive organs. Stigmatization of rape victims and the silence that accompanies rape incidents were also held as causal factors. For example, Iyanu related the cause of her infertility to rape. She stated that “when I was in primary school I was raped multiple times by a man who happens to be our neighbor but I was too ashamed to tell anyone….no one suspected anything… I was later diagnosed with pelvic inflammatory disease, which has resulted in the blockage of my fallopian tubes. I always blame myself for not disclosing the incident on time to my parents; maybe I would have been treated and saved my life from this horrible situation”.

**Modernization:** Another peculiar finding is the link between modernization and infertility. Some participants like Tunde believed infertility is associated with the destruction of traditional values and practices and the adoption of Western cultures. He stated that “I blame civilization and Christianity. I just married my wife because she is a Christian. We did not follow the traditional means of ascertaining the type of girl she is or the family she comes from…She might be possessed… I think she could be lying and conniving with the doctor to cover the cause since her father is a nurse”.

**Spiritual causes of infertility:** Spiritual causes of infertility describe participants’ perceptions of infertility as resulting from God or supernatural forces. These are often explained as:

**Trial:** Some participants felt they are victims of infertility, as such, they perceived their conditions as life trials. For instance, Fatima stated “I just believe everything that happens to a man is not without God’s knowledge and permission. The common belief is that promiscuous women might be barren either by destroying their wombs through abortion or killing all the children they are destined to have. I married as a virgin and I cannot tell why God has permitted me to be afflicted this way”.

Aminat also reiterated this belief by saying “I see myself as a victim of infertility. Married a virgin I would never have thought I could be infertile. I kept myself so much and all to experience this”.

Another participant, Tunji, who has infertility for 15 years believed that their condition was God’s will since there’s no medical explanation for it.

**God’s punishment:** A number of the participants believed their situations were justified because of their “wayward or promiscuous past”, hence they are receiving the “right punishment for their deeds”. This perception was clearly illustrated by Wale who asserted that “God could have made me infertile because when I was much younger I had girlfriends and two had abortions for me. I believe God is punishing me for those abortions they had. Medically, nothing is wrong with me and I don’t think my wife has any issues. I know the reasons are spiritual”.

**Spiritual oppression:** It must be noted that sociobehavioural factors often overlap with spiritual factors. Some participants believed infertility could result from “the wicked”. For example, Blessing explained that “the wicked might afflict barrenness on the good ones. According to the gynecologists, they have done everything that is necessary to make sure I get a result but none has succeeded. so, I believe the evil ones are at work. Science has done its part it is now left for God to do his part”.

Faith also believed her situation originates from her mother-in-law. She stated that “in my own case my mother-in-law did not want me to marry my husband. I decided to marry him since he is the one I want to marry not his Mom. At a time I started thinking the delay could be from her because she does not like me still. We have tried the medical, the spiritual and I know that at God’s appointed time, it will happen.” Ola who knew her husband had low sperm count also attributed their
infertility to “the works of the world and the wicked” since she has done intrauterine insemination (IUI) twice without success. She worries that she might be “spiritually oppressed”.

These clearly show that infertility is spiritually perceived to be an ‘attack’ or ‘trial for individuals without sin’. Also, most explanations for unexplained infertility are patterned along supernaturalism. Thus, one can surmise that as demonstrated by several studies 4, 11, 17, 20-22, the sociocultural perceptions of the cause of infertility are exalted above medical causes which the participants believed are aftermaths of the former.

**Conclusion**

In Kwara South, Nigeria, female infertility is defined as the failure of a married woman to achieve a pregnancy that will lead to successful childbirth while male infertility is linked to impotence. Although all the participants acknowledged that infertility could result from sexually transmitted infections (STIs) and other bodily disorders, they altogether believed that these results from lifestyle choices and could be linked to the supernatural. Thus, perceptions of the cause of infertility are rooted in the general Nigerian culture. This study has further established that culture and spirituality play a major role in people’s perceptions and explanations of infertility across nations. There is a need to renegotiate these sociocultural perceptions and integrate them into preventive and curative strategies aimed at improving reproductive healthcare in Nigeria.

The Correlation Between Education and Occupation with the ANC (Antenatal Care) Visit at Nagaswidak Health Care Center Palembang

Resy Asmalia¹, Asmarani Makmun¹

¹Department of Public Health, Medical Faculty of Muhammadiyah Palembang University, South Sumatera, Indonesia

Abstract

ANC (Antenatal Care) is a health service provided for pregnant mothers in order to get healthy pregnancy and baby. Since 2016, in Puskesmas Nagaswidak District, the number of pregnant women was 763. The percentage of K1 is 100% (763 woman), and K4 is 96.2% (734 woman). The aim of this study was to find out whether there is a correlation between mothers’ education and occupation with antenatal care visit at Nagaswidak Health Care Center Palembang. This study applied analytical survey method using Cross Sectional Design. The number of respondents in this study was 76 mothers selected by using accidental sampling method. Data were then analyzed using Chi-square Test. The result of this study showed that from the total of 88 respondents, 51 women (58%) had low education, whereas 66 women (75%) were unemployed, and 63 women (71.6%) regularly had the Antenatal Care Visit. The result of bivariate analysis showed that there was a significant correlation between education (ρ value = 0.019) and occupation (ρ value = 0.010) with the antenatal care visit. Based on the result of this study, the number of regular ANC visits attended by pregnant women was 71.6%, and there was a significant correlation between education and occupation with antenatal care visit.

Keywords: ANC visit, education, occupation.

Introduction

ANC (Antenatal Care) service is a service provided for pregnant women to maintain a healthy pregnancy as well as healthy baby. ANC is an essential factor for pregnant women’s health and is potential to be one of the most effective health interventions to prevent maternal morbidity and mortality¹. In the framework of the Sustainable Development Goals (SDGs), in 2030 the Government targets the maternal mortality rate to be below 70 per 100,000 live births. According to 2012 IDHS report, the number of maternal mortality rate was 359 per 100,000 live births. Whereas, the Government targets that in 2019 maternal mortality rate will be 306 per 100,000 live births by referring the data on maternal mortality rate which is 346 per 100,000 live births² based on 2010 Population Census. Based on the data got from the Directorate General of Public Health, Health Ministry of Republic of Indonesia in 2016, it showed that in general there was an increase in both indicators; K1 and K4 coverage³. This increasing trend indicates an improvement in public access toward health service for pregnant women. Health service coverage for K4 pregnant women in 2015 has met the target of Health Ministry Strategic Plan (Renstra) which was as much as 72%. However, there were still five provinces that had not achieved this target, namely Papua (24.45%), West Papua (30.4%), Maluku (43.88%), East Nusa Tenggara (61.63%), and Central Sulawesi (71.07%)⁴.

Based on District/City Health Office routine reports concerning Maternal and Child Health Program, standardized service coverage for pregnant women had to be given at least four times during pregnancy. In South Sumatra Province, over the past five years,
this also increased by 5%, from 88.6% to 93.21%\(^5\). K1 coverage for Palembang City in 2014 was 99.84%, and K4 was 96.64%. The lowest K1 coverage was in Sako District (98.1%) and the highest was in Gandus Sub-District, Seberang Ulu I, Kertapati, Plaju, Bukit Kecil, Ilir Timur II, and Alang Lebar Alang (100%). The highest K4 coverage, otherwise, was Sako Sub-district (99.79%) and the lowest was in Sematang Borang District (86.33%). In 2015, K1 coverage for Palembang City 2015 was 99.93%, and K4 was 97.41%. The lowest K1 coverage was in SU II Sub-district (99.57%) and the highest was in IB II, Gandus, Kertapati, Bukit Kecil, Ilir Timur II, Kemuning, IT II, Kalidoni and Sematang Borang Districts (100%). Whereas, the highest K4 coverage was in District IT II (99.89%), and the lowest was in Sukarami District (94.93%)\(^6\).

The estimated number of pregnant women in the Nagaswidak Health Care Center working area in 2016 was 763. The percentage of the first visit was 100% (763 pregnant women). Meanwhile, the percentage of the fourth visit was 96.2% (734 pregnant women). The coverage of their visit reflects the health service received by these pregnant women, i.e. by using 10 T principles. The integrated ANC examination standards received by pregnant women consist of weighing, measuring upper arm circumference (LILA), measuring blood pressure, measuring fundal height uteri, calculating fetal heart rate (FHR), determining fetal presentation, giving tetanus toxoid (TT) immunization, administrating blood-added tablets (Fe), doing laboratory test (routine and special), applying case management and effective CIE (Communication, Information and Education)\(^7\).

An understanding of the importance of prenatal care is not influenced by someone’s age, but how she comprehends and understands the given information\(^8\). Improving human resources as well as families’ and communities’ welfare is an effort we can do with the aim of reducing maternal mortality. This can be conducted by improving the quality and providing more equitable access to health services, including developing knowledge and attitudes as well as community healthy lifestyle behaviour. One effort to support this is by providing ANC service which is given properly and as early as possible with the hope that it can prevent maternal and infant mortality as well as improving the quality of maternal resources\(^9\). These findings had triggered the researchers to find out the correlation between education and occupation with the ANC visits at Nagaswidak Health Care Center Palembang.

**Objective:** The objective of this study was to find out the correlation between education and occupation with the ANC visits at Nagaswidak Health Care Center Palembang.

**Methods**

**Literature Search:** The research was conducted at Nagaswidak Health Care Center Palembang on 25 October until 25 December. The study was an observational analytical study applying cross sectional method. The population in this study was all pregnant women who visited Nagaswidak Health Care Center. Additionally, the samples were taken by applying accidental sampling technique using Slovin’s formula, and 88 respondents were taken. The dependent variable in this study was the ANC visits, while the independent variables were the education and occupation.

The inclusion criteria in this study were pregnant women who visited Nagaswidak Health Care Center and were willing to become research respondents. The exclusion criteria for this study were mothers who suffered from chronic diseases. The data of this study were taken from primary and secondary data collected when conducting research on all pregnant women who visited Puskesmas Nagaswidak Palembang during the period of October-December 2017. This research was conducted through a simple interview. If the data obtained were still incomplete, additional data would be taken from medical records and KIA books (Maternal and Child Health) during the period of October-December 2017.

Data processing was conducted through editing, coding and data tabulation. The data analysis used was univariate and bivariate analysis.

**Result and Discussion**

**General Description of Respondents**

<td>15</td>
<td>100</td>
</tr>
<tr>
<td>Total</td>
<td>25</td>
<td>63</td>
<td>88</td>
</tr>
</tbody>
</table>

Based on the table above, respondents with low education level and irregular ANC visits were 19 people (37.3%), while respondents who had low education but having regular ANC visit were 32 people (62.7%). There were 6 respondents (27.3%) who had moderate education level and made irregular ANC visits, while respondents who had moderate education level but did regular ANC visit were 16 people (72.7%). The respondents with higher education level and always did regular visit were 15 people (100%). Chi-square test results showed that \( \rho = 0.019 \) with the value of \( \alpha = 0.05 \), meaning that \( \rho < \alpha \), thus \( H_0 \) was rejected. This meant that there was a significant correlation between education level and ANC visits.

This is in line with the theory mentioning that someone’s level of education is one of the factors that supports maternal compliance in carrying out ANC examination\(^{10}\). This means that the higher the level of education is, the better the mother’s knowledge about the benefits of ANC will be. Therefore, it has an impact on maternal compliance in carrying out ANC visits.

Table 5. Respondent Frequency Distribution based on Occupation and ANC Visit at Nagaswidak Health Care Center Palembang

<table>
<thead>
<tr>
<th>Occupational Status</th>
<th>ANC Visit Regularity</th>

<td>21</td>
<td>95,5</td>
</tr>
<tr>
<td>Total</td>
<td>25</td>
<td>63</td>
<td>88</td>
</tr>
</tbody>
</table>
Based on the table above, respondents who did not work and did not do regular ANC visits were 24 people (36.4%), and respondents who did not work but did regular ANC visit were as many as 42 people (63.6%). Respondent who had a job and did regular ANC visit was 1 person (4.5%), and respondents who worked but made regular ANC visits were 21 people (95.5%). Chi-square test results showed that ρ value = 0.019 with the value of αα = 0.05, meaning that ρ < αα, thus Ho was rejected.

This meant that there was a significant correlation between occupation status and ANC visits. This research is in line with a research conducted by Yolanda Bataha (2016). The results of the Chi-Square test showed that ρ value = 0.03. The value of ρ was smaller than the value of α (0.05). Thus, Ho was rejected which meant that there was a correlation between the education status and regularity of the Antenatal Care (ANC) examination at Ranotana Weru Health Care Center in Wanea Subdistrict, Manado City11. According to Pasaribu (2005), pregnant women who work do not only have a source of income to do an antenatal care, but also are able to interact with other people who understand more about the importance of having a prenatal checkup. Consequently, the mother who works is more aware and willing to have her pregnancy examined12.

This finding is in contrast with Rocha’s (2012) theory which suggests that the busier a pregnant woman is with her work, the less chance the woman gets the antenatal care. Thus, the chances of having her pregnancy checked will decrease. Despite being preoccupied with civil servant work and being private employees, some mothers still do regular antenatal visits13.

Conclusion

Based on the results of the research and data analysis that have been carried out, it can be concluded as follows:

1. There was a significant correlation between education level and ANC visits at Nagaswidak Health Care Center Palembang (ρ value = 0.019).
2. There was a significant correlation between occupation status with ANC visits at Nagaswidak Health Care Center Palembang (ρ value = 0.010).

Sanctioning System in Regulatory Enforcement of Medicine in Malaysia

Nurul Hayati Bohari 1, Abdul Samad Abdul Ghani 2

1Doctoral Student, 2Senior Lecturer, Faculty of Law, University of Malaya, Kuala Lumpur, Malaysia

Abstract

A regulator uses sanction as a regulatory tool to enforce regulations and punish the non-compliant regulatees. Typically, the given sanction by the regulator will be a backfire when the regulatees are not satisfied with the sanction given. This contestation will definitely result in the regulatee’s action against the law and the sanctions will therefore not have any impact on them. However, Responsive Regulation Theory (RRT) has proven that the enforcement pyramid is particularly useful in leading to more compliances, adequate regulatory enforcement and cost-efficiency. The elements of responsiveness in the RRT can lead to the right sanctioning system. Therefore, the aim of this paper is to map the sanctions taken by the Pharmaceutical Enforcement Division (PED) concerning medicine offenses as outlined in the RRT. The method of analysis for this study involved library search of statutory laws or regulation, statistical data, books and annual reports produced by the agencies, and personal communication. This study found that the PED sanctioning system is not in order of the pyramid escalation and a criminal penalty is not reserved as a ‘big gun’ as recommended by RRT. This study also recommends reformation of health policy in Malaysia in regulatory enforcement, enhancement of medicine regulations, expansion of collaboration between the government and businesses and improvement on current awareness programmes to ensure that knowledge given to the regulatees is well comprehended and easily applicable to them. It is suggested that future research should also explore the regulatees response towards enforcement approach.

Keywords: Sanction, enforcement action, regulatory enforcement.

Introduction

Sanctions are an essential part of the regulatory system. People who are sanctioned are always unsatisfied with the given sanction and even members of the Parliament continue to debate and argue for the right sanctioning system to be implemented in the society 1, 2. In promoting norm compliance, a sanction can be defined as a ‘reaction’ triggered due to the infringement of or non-compliance with a norm 3. In the dictionary, sanction is defined as penalty, punishment or fine 4 and the fines will be an ultimate instrument when persuasion and warnings to comply with standards are exhausted Reynaers and Parrado 5. Higher penalties for non-compliance often produce higher levels of compliance 6.

Nevertheless, sanctions can be positive or negative. The success of sanctions should be determined and improved by the agency over time. Responsive Regulation Theory (RRT) relies on the premises that the actions of individual actors are motivated by different factors and interests. A successful regulatory agency is required to have a range of enforcement actions to allow it to deal with doers who are subject to the various motivational factors 7.

A regulator uses sanction as a regulatory tool to enforce regulations and punish the non-compliant regulatees. In European Union (EU), ‘sanctions’ is considered as a restrictive measure and an essential tool. There is a comprehensive range of possible restrictive measures or sanctions that have been imposed by the EU 8, 9. In classical form, sanctions are conceived only as deterrents, and usually in the form of monetary deterrents. Ayres and Braithwaite 7 (1992) have taken a range of sanctions a radical step further.
They argue that regulatory agencies not only require a variety of enforcement mechanisms but also that the enforcement mechanisms must be in order as envisaged in the ‘enforcement pyramid of sanctions’ (Figure 1). Additionally, Macrory also agrees that the system should be less reliant on criminal prosecutions and make greater resolution of other types of sanctions such as administrative penalties or statutory notices.

![Figure 1: The Enforcement Pyramid of Sanctions](image)

According to Ayres and Braithwaite, compliance is most likely to be achieved when a regulatory agency can display an explicit sanction pyramid that contains a diversity of enforcement actions with escalating format as shown in the pyramid in Figure 1 above. The base of the pyramid should include mechanisms that allow the regulator ‘to coax compliance by persuasion’. The following level of the enforcement pyramid may incorporate alternatives such as the issuing of a warning letter. If the warning letter fails to obtain compliance, the following level of the enforcement pyramid may allow for the imposition of a civil monetary or another penalty. The penultimate level of the pyramid may comprise sanctions such as criminal fines and other non-custodial sentences for individuals as well as a temporary plant shutdown or license suspension for bodies corporate. Incarceration for individuals and permanent license cancellation or deregistration for bodies corporate may be at the apex of the pyramid.

The bigger and the more varied the sticks, the bigger the success the regulators will achieve by speaking softly which lessens the sanctions. Through research of articles in the Scopus database, it became apparent that most research on sanctions has been conducted in the EU, Australia, and Brazil. Surprisingly, thus far, no research has been conducted on sanction mapping in Malaysia. Therefore, this paper attempts to firstly map the sanctions and then identify the responsiveness elements in the Pharmaceutical Enforcement Division (PED) through RRT.

**Methodology/Materials:** The qualitative method is employed in this research, focusing on documentary evidence and thematic analysis. This method of research was selected because this study intended to employ a relatively low level of analysis involved narrative materials of regulatory enforcement of medicine. Based on the library search conducted, data were gathered from the statutory laws or regulations related to medicine, statistical books and annual reports produced by agencies through official government websites. In the thematic analysis, the documents were analysed according to identified themes based on sanctions suggested by RRT. Then, the specific sanction was identified in the PED sanctioning system. In this article, the sanctioning system of PED is mapped for the period between 2014 and 2017. Other materials were also used including relevant books and published journals in order to support the analysis and the discussion. Additionally, in this study, personal interviews were also conducted with the relevant officers in charge to obtain further information. All the information was gathered to support and expand the researcher’s knowledge to better and further understand the issue under study with the hope of improving the existing law and sanctioning system.

**Sanction Mapping of Regulatory Enforcement of Medicine in Malaysia:** The framework and systems in regulatory enforcement of medicine are mainly implemented to protect the public interest, particularly for quality, safety, and efficacy of medicines. This medicine prevention governance is integral to health, economic and socio-political sustainability; however, it is well-known that its management is complex and requires coordination across a range of professional bodies and relevant stakeholders’ interests to safeguard the public. In the regulatory arena, laws will be administered by the Courts, independent regulatory commissions or executive agencies. In Malaysia, the agency for regulatory enforcement of medicine is an executive government agency which is Pharmaceutical Regulatory Division (NPRA) and the Pharmaceutical Enforcement Division (PED) which are under the auspices of the principal regulator, namely the Ministry of Health (MOH) Malaysia.
From the regulatory administration above, the regulatory enforcement process is generally taken by PED. Statistical and annual report in 2016 shows that PED is a typical regulatory enforcement agency with Command-and-Control regulation and punitive approach which is merely a policing method. Indeed, the medicine regulatory sanction in Malaysia is more of a legal sanction rather than administrative sanction since the medicine policy leans towards ‘punitive’ regulation. In the inspection activities, the approach of educating, advising and giving verbal warning was also implemented by PED; however, no clear data was collected for this enforcement activity.

In 2017, PED implemented an innovative approach called DiPS. It is an acronym for ‘Didik’, ‘Pantau’ and ‘Serbu’ (or in English ‘Educate’, ‘Monitor’ and ‘Raid’) which is a continuous monitoring plan by PED on selected premises in the hotspot area. This approach is a method to ensure that the non-compliant regulatees comply with the law. The first step in DiPS approach is education and building self-awareness among the seller or owner of the selected premises in the hot spot area. The results of the DiPS approach showed that compliances increased with 63.3% of the premises found to comply with the law.

DiPS approach is a new approach and is starting to be seen as a persuasive method in the regulatory enforcement process. Education in DiPS is an enforcement strategy to create awareness among the stakeholders particularly towards the non-compliance of certain regulatees. The awareness material is distributed to the non-compliant regulatees during inspection or during the operation. However, PED does not implement this persuasive method comprehensively, and there is no escalating process of enforcement as prescribed in the RRT pyramid. DiPS approach is only implemented on selected unlicensed premises in the hot spot area. Other than the DiPS approach on the selected premises, the sanctions are mostly given during inspection or monitoring period where a warning letter or criminal penalty is often the first option. These show that PED does not have any formal application of promoting the persuasive method as envisaged by RRT.

Analysis found that PED applied five among the six sanctions suggested by Ayres and Braithwaite in RRT. In reference to the RRT’s pyramid model, regulatory enforcement of medicine in Malaysia needs to improve on its sanctioning system. The sanctioning system needs to be varied and promote the responsiveness elements. The procedure of the ‘educate and persuade’ method towards non-compliance also needs to be formalised clearly in practice. In relation to non-compliance of licensed sellers, PED issued sanctions in the form of follow-up inspection, warning letter, seizure of the false or illegal products, criminal penalty, license suspension and application of license revocation. Here, the method of persuasion sanction may occur during the ‘follow-up inspection’ period. There is difficulty in deliberating whether a persuasion would be an appropriate regulatory response before considering a warning letter as in the pyramidal type. Thus, it seems that PED has no proper degree of sanction towards the level of infringement as recommended by Ayres and Brathwaite.

With limited sanctions, the considerations on sanctions for non-compliance of the unlicensed seller are far from the RRT’s suggestion. Non-compliance of the unlicensed seller is sanctioned in the form of education, follow-up inspection, seizure of the medicine or pharmaceutical product (during inspection) and criminal penalty application. The illegal product is seized to prevent the crime from happening. Again, criminal penalties (prosecutions) are not reserved as big guns for the worst cases as envisaged by the RRT. Furthermore, PED has no consideration for first-time contravention. From the statistics, the number of products seized during inspection period alleging contravention of provisions is smaller than products seized during the operation period. In 2015, the sanction given through persuasion sanction was 22% compared to 78% of the seized products given criminal penalty sanction.

Additionally, PED sanctioning system is not in order of pyramid escalation, and the criminal penalty is not reserved as a ‘big gun’ as recommended by RRT. According to Responsive Regulation Theory (RRT), the benign big gun strategy is needed to ensure the effectiveness of the enforcement. The element of punitive approach should be at the last process of the regulatory framework. Perhaps the sanctioning system is not in order due to the limited capacity of human and financial resources. The capacity of enforcement officers is not parallel with the number of licensed and unlicensed premises. This situation places a burden on the regulatory work.

Furthermore, PED does not have the power of the civil penalty. In RRT, the application of criminal penalty or prosecution is implemented for the recalcitrant who
refuses to comply even after the civil penalty sanction. In reality, PED’s conduct is based on the power that has been given by law. For the non-compliance of licensed sellers, PED will be sanctioning either through follow-up inspection, warning letter, seizure of the false or illegal products, criminal penalty, license suspension, and license revocation. License revocation is at the apex of the pyramid and can drive the PED as a ‘benign big gun’ (BBG) regulator. In line with RRT, Welsh found that successful regulatory agencies as ‘benign big guns’ are the enforcement agencies with the most infringement cases not in the criminal penalty sanctions at the apex of the RRT enforcement pyramid. Thus, PED needs to strengthen the enforcement tools of the persuasive method.

The deterrent-based strategy is insufficient and needs improvement according to the motivation of the regulatees. Due to the different motivation, behaviour, and attitude, RRT shapes the variety of sanction in a pyramid form. In a pyramid form, several considerations and interventions are involved. Similar to other typical regulatory enforcement, the regulatory only uses one sanction which is criminal penalty. Again, the criminal penalties (prosecutions) are not reserved as big guns for the worst cases.

Malaysia’s medicines regulatory framework is putting in the effort to encourage self-regulation of the regulated parties particularly the interest group (association). According to RRT, the regulatory strategies of enforcement are also in a pyramid form. The strategies need to be in the pyramid form because the individual actors (regulatees) are motivated by different factors and interest. A successful regulatory agency is required to have a range of enforcement alternatives available to allow the agency to administer them to actors who are subject to the different motivational factors. Not all the actors subjected to regulation are driven by the same motivations; this is because while some do so according to the rationality directed to the maximisation of their profits, others are guided by reputation, social responsibility, religious values, adherence to norms, and others.

Conclusion

As a conclusion, improvement in the regulatory enforcement of medicines in Malaysia is needed in administering non-sanctioning compliance tools such as supervising the compliance through inspections, controls, measurement analyses and adopting corresponding matters; calling for a pool of information data; necessitating some of the regulatees for submission of data; providing technical guidelines or directives; and issuing rules and instructions and guiding the regulatees in understanding the law. The government and health policy makers should encourage the regulatees to comply with the law so as to ensure the safety, quality, and efficacy in their practice. The encouragement should not be in the form of just one strategy, but in the form of various strategies. It is hoped that this study would have given some ideas to the authorities on how to develop a better management system in framing the regulatory regime and enforcement specification. This study also recommends the reformation of health policy in Malaysia in terms of regulatory enforcement, enhancement of medicine regulations and improving the relationship between the government and businesses so that these can be easily applied. It is suggested that future study should also explore the regulatees response towards the enforcement approach.

Eating Disorder, Body Fat Percentage, and Physical Activity Among Sarawak Female National Athletes

Patricia Pawa Pitil*1, Wan Juliana Emeih Wahed2

1Lecturer, Faculty of Sports Science & Recreation, 2Lecturer, Faculty of Art & Design, Universiti Teknologi MARA, Cawangan Sarawak, Kampus Samarahan, Jalan Meranek, 94300, Kota Samarahan, Malaysia

Abstract

Purpose: This study aimed to examine the eating disorder and physical activity in relation to type of sports and body fat percentages among national female athletes in Sarawak (N=150).

Methodology: Eating Attitude Test and Global Physical Activity Questionnaire were employed to measure the eating disorders and physical activity. Anthropometric measurement and body composition (body fat percentage) were obtained.

Results: Moderately active athletes explained higher eating disorders in dieting, bulimia nervosa and food preoccupation. The non-weight sports athletes also exhibited higher eating disorders compared to its counterpart. Younger athletes were at higher eating disorder, but age was not significant in the subscales measured; except for food preoccupation where it was prominent in age 16 to 18 years old. Oral control did not associate with all the independent variables. Some relationships observed between body fat percentage and eating disorder and the subscales. Conclusion: This study highlights interesting findings where the less active athletes and the non-weight sports category athletes exhibit higher eating disorders issues.

Keywords: Body Fat Percentage; Eating Disorder; Female Athletes; National Athletes; Physical Activity; Sarawak Athletes.

Introduction

Eating disorders are irrational behaviours that can consume a person’s life to the point of becoming life-threatening1, 2. They are illnesses that are characterized by irregular eating habits and concern too much on body weight or shape3, namely, anorexia nervosa, bulimia and binge eating. These are unhealthy attitudes towards food4 that could endanger life. Self-induced vomiting is one of the characteristics of the episode of bulimic sufferers, where they experience a binge-purge cycle with extreme overeating on non-nutritious high caloric food5.

Heavier body weight among girls makes them tend to restrict their food intake and felt unpleasant with their body image6 due to worrying about body weight. However, individuals who are absent of eating-related disorders had a lower BMI compared to individuals with eating disorders 7. This could suggest that the bodyweight concern has taken the individual with excess body weight to use a shortcut of losing weight by practising eating disorder.

Physical, psychological and social changes occur substantially during adolescence year. To athletes, some of them perceived that being thin is the indicator of fit3. Thus, in the struggle to look fit, these athletes are prone to practice abnormal eating behaviour. As most studies reported that athletes were more likely to have an eating disorder if compare to the non-athletes, however, the factors that associated with the eating disorders among the female adolescents athletes has not yet established.

The rate of this unhealthy behaviour are greater among adolescent and young women if compared to
men. In Malaysia, disordered eating among female adolescents is alarming. Since an eating disorder has shown to be started in adolescence, early identification is a must among the athletes. Thus, this study aimed to measure the relationship between eating disorder and body composition by physical activity, sports categories and age groups among the female athletes of Sukan Malaysia (SUKMA) Sarawak.

**Methodology:** This study employed a cross-sectional design which focusing on national female athletes in Sarawak who competed for SUKMA aged 21 years old and below. The sample size for the study was calculated ($N = 150$) with added number where the total female athletes’ population who competed in SUKMA for Sarawak was 296 (Table 1).

The Global Physical Activity Questionnaire (GPAQ) was utilized to measure the pattern physical activity which has shown a high reliability and validity. The total physical activity was expressed as metabolic equivalent (MET)-minutes/week. For the anthropometry measurements, the participants’ height was measured and the weight and the body fat percentage were obtained by using Karada Scan Body Composition Monitor Model HBF – 375 (OMRON).

The eating disorder presence among the athletes was assessed by using The Eating Attitudes Test (EAT-26) and reported a high internal consistency. It is comprised of 26 scales of three dimensions; dieting, bulimia and food preoccupation, and oral control. A score greater than 20 has a risk of eating disorder.

**Data analysis:** The data were analyzed by using the Statistical Package for Social Science (SPSS) version 22.0. The Pearson correlation test and Chi-square test was conducted to measure the relationship and association between the variables. An independent sample t-test and one-way analysis of variance (ANOVA) were employed to compare the eating disorder between weight and non-weight category sports, age groups and physical activity. The statistical significant was set at .05 ($p < .05$).

**Results**

As overall, the participants were categorized as very active (3034.91 ± 2489.7 METs-min/week). Majority of the participants were moderately active (110 (73.33%)) and only 40 (26.67%) were very active. There was zero percentage of a low physical activity reported.

The distribution of the participants with respect to eating disorder risk categories was significant different for very active and moderate active categories ($\chi^2 = 23.715$, $p < .05$) (Table 2). There was a significant difference of bulimia preoccupation between the physical activity of the participants ($p < .05$).

**Table 1. Demographics of the participants**

*correlation is significant at .05 (p < .05)

The eating behavior and bulimia preoccupation were found significant negative relationship with body fat percentage (p < .05), while oral control was significant positive correlated (Table 5).

Discussion

As overall, the athletes were at low risk of eating disorder. However, in comparing by physical activity and category of sports represented, the moderately active and non-weight sports athletes exhibited a high risk of eating disorder. The weight sports are sports which require athletes to compete for certain weight categories. There was strong evidence that eating disorder was more prominent in weight sports category. However, there is a contrast finding in the present study where the high risk of eating disorder was among the non-weight sports athletes. As being found out that the moderately active and non-weight sports athletes were both displayed a high risk of eating disorder, these two variables could link closely. The young athletes’ misconception that being thinner makes them a better athlete could increase
the risk of developing an eating disorder. The pursuit of sporting excellence could encourage these athletes to eat in wrong ways.

The younger athletes exhibited a great tendency for risk of eating disorder in the present study. Those who were less than 12 years old scored higher than others in the eating disorder. The sports experience was less in the younger athletes, thus the exposure or knowledge on eating correctly were lacking. Specialization in one sport at an early age and sudden increases in training volume could be the reason of developing eating disorder.

Dieting behavior was prominent in the moderately active athletes and non-weight sports athletes as compared with their counterparts. Dieting is the behavior of concerning too much on the food intake quantities by avoiding high calorie food and a pre-occupation of being thinner. This finding alerts us that even though the requirement of the non-weight sports does not emphasize much on some weight categories to compete, the athletes might overthink on eating normally. The present study was contradicted with previous study where they supported the statement that obsess neurotic action on diet is related to the commitment in extreme exercise or physical activity to burn-off the calories.

Interestingly, bulimia preoccupation was greater in moderately active athletes and in the non-weight sports athletes. As many people living with bulimia might have normal appearance, the non-weight sports do not actually need to compete in desire weight, but however they might end up having an unpleasant size. Based on the observation, the non-weight sports athletes were much bigger as compare to the weight sports athletes. Thus, this might develop the bulimic incident. These adolescents were in the process of gaining height and weight due to puberty and it could stress this population to accept it and be in denial at the same time on the changes of their body. The conflict of sports acceptance that athletes must be thin and lean-looking forces them to practise unusual eating behaviour. Again, they might think that fitness is related to thinness or such ‘athletic’ eating will improve performance. Furthermore, it was reported that the adolescents would be more likely low in body weight management knowledge and the idea of ‘athletics’ eating might influence these athletes.

Food preoccupation was significant among all the independent variables measured. The moderately active athletes, non-weight sports athletes and age groups of 16 to 18 years old were assumed to put more significant concern on food. Therefore, the athletes could have possibility of bulimia too. As this group put so much thought on food intake and become more serious in their sports training, the fear of storing excess energy from eating normally might put the athletes at the episodes of binge and purge.

Oral control displayed to be not associated with physical activity level, sports category and age groups. It is the behavior resembles eating control and the perceived pressure from others to gain weight. Scores on food preoccupation were significant on all the independent variables measured, and therefore possibly influence the bulimia nervosa behaviour.

In addition, there were significant relationships between eating disorder and the three subscales (bulimia nervosa, food preoccupation and oral control) with body fat percentage of the athletes. This was contradicted with similar study on Malaysian university students. The relationship of eating disorder and body fat percentage was significantly negative. This indicates that the higher the eating disorder, the lower the body fat percentage and vice versa. This finding contrast with a similar study where they found out that body composition and eating disorder was positively correlated. The athletics make up of these adolescents make them exhibit a different finding. As the body fat percentage is high, the bulimia nervosa and food preoccupation were also greater as shown by the significant negative relationships. As reported, dieting practices were more likely among the heavier adolescents in this very study, the binge and purge and thought of foods were more significant in those with higher body fat percentage. For oral control, there was a contradicted relationship revealed. The oral control was positively correlated with the body fat percentage which indicated that, the athletes did not perceived pressure from others to gain weight and controlling of eating was lower even when their body fat percentage was high.

**Conclusion**

In conclusion, the moderately active athletes and non-weight sports athletes were more likely to have higher eating disorders. The strength of the relationships was small between some of the subscales and body fat percentage. Age groups also not associated with any of these eating disorders. It is recommended that coaches should alert on the less vigorous sports athletes and to
the non-weight sports athletes on their eating behavior. Implementing program to improve knowledge of these athletes on healthy eating and eliminate the ‘athletic’ eating should be conducted so that the normal pattern of eating could be developed in the early age of sporting career.

Improvement of Ankle Brachial Index (ABI) Using Foot Bath Therapy at a Temperature of 40°C in Patients with Diabetes Mellitus

Nur Isnaini¹, Bekti Nurpri Setiyani²
¹Lecturer, ²Bachelor student, Universitas Muhammadiyah Purwokerto, Indonesia

Abstract

Diabetes mellitus has an impact on increasing blood sugar levels and has a risk of complications of decreased vascularity in the feet which can result in complications in the form of foot ulcers. One of the interventions to facilitate circulation is by therapy of foot soak with a temperature of 40 degrees. Purpose this research to determine the effect of temperature of warm water foot bath temperature 40°C on peripheral blood circulation with Ankle Brachial Index in diabetes mellitus patients in health center 1 cilongok. This study uses a Quasi-experimental method with one group pretest-posttest approach. Sampling with random sampling technique and a total of 38 respondents with DM. Data was taken by observing ABI measurements before and after warm water foot soak with a temperature of 40°C. Analysis of the data using the Kruskal-wallis test with the Man-Whitney test. Based on the results of the Kruskal-wallis test p value of 0.001 (p value <0.05) there is a temperature effect of warm water foot soak on the peripheral blood circulation with ABI. Conclusion is warm water foot baths effectively improve peripheral blood circulation in DM patients.

Keywords: Foot bath, ABI, Diabetes Mellitus.

Introduction

Diabetes Mellitus (DM) is a chronic metabolic disease characterized by high blood sugar due to impaired metabolism of carbohydrates, fats, proteins due to lack of insulin and can cause acute or chronic complications1-2. Complications can include damage to blood vessels, nerves, and other structures, one of which is PAD (peripheral artery disease)7-18. Prevalence of DM patients in the Central Java province of Indonesia is ranked second after hypertension, which is 16.5%5-6.

DM management aims to stabilize insulin and prevent vascular complications and neuropathy1.5 pillars of DM, namely education, diet, exercise, medication and examination of sugar levels9. One of the complications of DM is peripheral vascularization and neuropathy. Efforts to prevent complications of PAD are by soaking warm water or often called hydrotherapy.

Hydrotherapy is a therapy using warm water that is useful for relaxing the body, reducing pain and stiffness in muscles, and producing better sleep. The working principle of hydrotherapy is with a temperature of 40 °C within 20 minutes for one time conduction in which heat transfer occurs from warm water to the body which will cause blood vessel dilation10, 12, 13.

Peripheral blood circulation is assessed using the Ankle Brachial Index (ABI) by counting systolic in the legs (dorsalis pedis artery) divided by systolic in the brachial artery14. ABI is a simple method for evaluating peripheral arterial disease and cardiovascular prognosis. ABI has a high sensitivity and specificity for accuracy in determining the diagnosis of peripheral circulation15-16. ABI examination is a non-invasive gold standard for detecting the presence of peripheral arterial disease (PAD) and is recommended as part of an assessment of individuals at risk for this disease because the impact of PAD can lead to amputation15-18.

Method

This research was conducted at a community health center in Cilongk, Central Java, Indonesia, from March to April 2018. The quasi-experimental method used a
one-group approach with a pre-post-test approach. The sampling technique uses random sampling. The number of samples was 38 respondents with DM. Data was taken by observing ABI measurements before and after the foot of warm water soaking in temperatures of 40 °C. Measuring instruments used are Aneroid and Doppler Tensimeter, while for measuring water temperature using a water temperature thermometer. Data analysis using the Kruskal-wallis test. Collecting data in this study using primary data, the researchers measured systolic blood pressure in both extremities in the brachial area and DM ankle patients before and after therapy with warm foot baths.

Blood pressure measurement is done by asking the respondent to lie in a supine position or as comfortable as possible for about 10 minutes, then the researcher measured the respondent’s blood pressure on the right (brachial) arm then on the left arm using a Doppler vascular device and noted the systolic pressure in each arm. Measurements were made at the right ankle and then left using a Doppler vascular device and recorded systolic pressure on each leg, the results can be interpreted with an ABI value> 1.3 Estimated arterial classification, normal 0.91-1.3, 0.8-0, 9 minor disorders, 0.5-0.79 moderate disorders, and <0.50 severe disorders2.

Results and Discussion

The results of this research are presented in Table 1–3.

</tbody>
</table>

Average value of the right ABI and left ABI before being given a warm foot soak with a temperature of 40 °C is the right ABI 0.9395 and the left ABI 0.9308. The standard deviation of the right ABI value is 0.07616 while the left ABI is 0.07663. The minimum and maximum values of the right ABI are a minimum of 0.82 and a maximum of 1.14. While the left ABI is a minimum of 0.83 and a maximum of 1.16. After being given a warm water foot soak there is an increase with the average value of the right ABI is 1.0803 and the average left ABI is 1.0784. The standard deviation of the right ABI value is 0.08049 while the left ABI is 0.07258. The minimum and maximum values in the right ABI are minimum 0.93 and maximum 1.27 while the left ABI is the minimum 0.92 maximum 1.27.

At a temperature of 40 °C it was pointed out that the ABI value of the right and left pre-values were the same, which was 0.93. It could be concluded that the perfusion
status was normal extremity. After being given a foot bath the warm water has increased and while the post value on the right and left ABI shows the difference between the ABI values. In the right ABI of 1.08 and the left ABI of 1.07 it can be concluded that the perfusion status of the right and left extremities is normal. ABI values > 1.3 Estimates of arterial classification, 0.91-1.3 normal, 0.8-0.9 mild disorders, 0.5-0.79 moderate disorders, and <0.50 severe disorders 2.

Characteristics Respondens: Based on table 1, the most respondents were 56-65 years old with 24 people (63.2%). Elderly diabetics have a higher risk of impaired circulation in the legs 13-17. The sex of the majority of respondents is 31 women (81.6%), diabetes mellitus is more susceptible to women than men, the majority of respondent education there are 28 people (73.7%) with basic education, the most work is 28 people (73.7%) as housewives.

ABI Values Before and After Warm Water Foot Bath Temperature of 40°C in Diabetes Mellitus Patients: From table 2 the results of research on foot blood circulation in patients with diabetes mellitus the average value of ABI before soaking the foot with a temperature of 40°C on the right ABI is 0.9395 for the left ABI 0.9308 and after doing the foot soak the right ABI value becomes 1.0803 while the left ABI averaged 1.0784. Based on the average results of Table 2 before foot bath therapy, it was shown that some respondents had mild disturbances in the feet. Peripheral blood circulation in patients with diabetes mellitus has a mild disturbance in the form of tingling and pain when walking, this happens because of impaired blood circulation. Atherosclerosis of large blood vessels in the lower extremities (legs) is the cause of the increased incidence of peripheral arterial occlusion in DM patients which is a major cause of increased incidence of gangrene and amputation. ABI value after warm water soak therapy showed that there was a significant increase in the blood circulation of the respondent’s feet. Warm water stimulates the dilation of blood vessels and circulation in the legs 19-20,22.

The difference in ABI values in the intervention group was 40°C in diabetes mellitus patients: Kruskal-wallis test results in table 3, obtained the value of the right ABI and left ABI p = 0.001. Because the p value <0.05, it can be concluded that “there is an influence of four temperatures in ABI”. To find out which groups have differences, a Post Hoc analysis is performed, for the Kruskal-wallis test is the Man-Whitney test. ABI values can indicate the severity of peripheral arterial disease.

Soaking feet with a temperature of 37-39°C temperature is useful in reducing muscle contraction, causing a feeling of relaxation which can treat symptoms of sleep deprivation and infections and circulation disorders 22-23. Hydrotherapy with a temperature of around 40°C within 20 minutes conduction occurs where heat transfer from warm water to the body will cause the enlargement of superficial blood vessels close to the surface of the skin, when the body is too hot, blood flow to the skin increases and superficial blood vessels dilate 16-23.

Main risk factors for PAD formation are very similar to coronary artery disease and include age > 40 years, hyperlipidemia (low-density lipoprotein / LDL cholesterol or low-density lipoprotein / HDL), hypertension, diabetes, and smoking. The results of this study indicate that there are research subjects who have Peripheral Arterial Disease (PAD) as indicated by the ABI value before the intervention of warm water foot baths with a temperature of 40°C and after the intervention the ABI value has increased 23-24. When body temperature becomes low, arterial blood flow decreases and superficial veins are passed. Meanwhile, when the body becomes too hot, blood flow to the skin increases and superficial blood vessels dilate.

Conclusion

Foot bath therapy is recommended for DM patients because it gives a significant effect on the value of ABI

Acknowledgment: A very deep thank you to the respondents who were very cooperative during the study. Thank you also to the research team who helped implement this research. Especially for my guidance students who can work together in conducting this research.

The Theoretical Model of the Influence of Extraversion Personality and Optimism on Subjective Well-Being by Coping as a Mediator

Nur’aeni1, Asmadi Alsa2, Anizar Rahayu3

1Lecturer Universitas Muhammadiyah Purwokerto, 2Lecturer Universitas Gadjah Mada Yogyakarta, 3Lecturer Universitas Persada Indonesia YAI Jakarta, Indonesia

Abstract
Subjective welfare is one measure of the quality of life of individuals and communities, in addition to economic and social indicators. The hope is that mothers who have children with intellectual disabilities can achieve subjective well-being, so that in accompanying children can optimally meet their needs. But the reality shows that mothers who have children with intellectual disabilities feel disappointed with life in general, the mother feels that the child is a burden on the family. This study aims to examine theoretical model of effect extravertion personality and optimism with coping as mediator to subjective well-being. Subjects in the study were mothers who had children with intellectual disability with the last minimum education junior high school. The data collection instrument consists of subjective well-being scale, coping scale, extroversion personality scale, optimism scale. Structural Equation Model with LISREL program was used as the analysis of research data. The results of the data analysis show that theoretical model of effect extravertion personality, optimism with coping as mediator to subjective well-being is a fit model with the empirical data. The result of hypothesis test shows that there is effect of extroversion personality, optimism with mediation of coping to subjective well-being.

Keywords: Subjective Well-Being, Coping, Extroversion Personality, Optimism.

Introduction
Subjective well-being is a cognitive and affective evaluation of an individual’s life1. According to2 there are two basic components of subjective well-being: life satisfaction as cognitive component and happiness as an affective component. As with mothers with intellectually disabled children, every mother expects to have a healthy and happy child to be able to enjoy life fully without the conditions of disability. The mother who accepts the diagnosis of childhood disability experience difficult emotion3.

The term of intellectual disability in some references is referred as mental retardation, mental deficiency, weak memory, intellectual impairment, subnormal mental, mental disability, mind disability, weak seizure, or idiot. Ref.4 uses terms such as mental retardation, mental deficiency, mental defective, feebleminded. In recent developments to give a more humane appellation, the term intellectual disability is then used.

For parents of children with disabilities, the experience of caring varies based on a number of factors, including the type and severity of disability and whether or not the obstacles are visible to others5. Williams & Wright states that many parents have negative thoughts when they know their children have deficiencies/disabilities, such as guilt and fear of the future. A mother is closest figure to the child, so it is very big responsibility to be a mother with intellectually disabled children3.

The results of interviews with four mothers with intellectually disabled children showed was various problems faced by mothers, ranging from the burden and the responsibility of raising children, feelings of self-blame, anger and anxiety about the future of children, difficulties to control emotions when facing children,
feelings of desperate, being tired of parenting, keeping all deep inside their heart).

The results of interviews indicate that mothers with intellectually disabled children are unhappy, call happiness as subjective well-being that is said to be one measure of the quality of life of individuals and communities, as well as economic and social indicators, but the quality of life is also determined by one’s feelings towards pleasure and displeasure, satisfaction and dissatisfaction. Ref. 9 state that individuals who have high subjective well-being often experience life satisfaction, feel joy, but rarely feel unpleasant emotions.

In order to be prosperous, individuals also need to have a positive attribution to themselves and their lives; therefore the individual needs a way to be able to deal with various events in his life effectively. Some characters of extroversion personality are individual pleasure in establishing relationships with the people around him, being friendly and open and enjoying the relationship. Extroversion personality was found to have a positive relationship with life satisfaction as well as a subjective well-being index.8

Based on the description above, then the problem formulation is “Is the theoretical model of effect extravertion personality and optimism with coping as mediator to subjective well-being a fit model with empirical data?

Method

Research subject: Research subjects in this study are mothers who have intellectual disabled children, biological mother of children who go to SLB (Primary School for Exceptional Children) type C Banyumas and SLB C Purbalingga, Central Java, Indonesia. The number of research subjects was 210 mothers with intellectually disabled children. Research subjects were mothers of students who studied at SLB C Yakut Purwokerto, SLB Kuncup Mas Banyumas, SLB Negeri Purbalingga and SLB Purba Adhi Suta Purbalingga 8.

Research Instruments: There are four instruments used in the research namely; subjective well-being scale, coping scale, extroversion personality scale and optimism scale. The estimation of reliability for coping scale, extroversion personality scale and optimism scale used Alpha Cronbach coefficient while subjective well-being scale used Alpha Stratified coefficient because the scale of subjective well being is multidimensional.8 The coefficient of alpha stratified reliability introduced by Cronbach & McKie is useful for estimating instrument reliability consisting of several subtests.13

The subjective well-being scale is adapted by researchers from SWLS from 14 and SPANE from 15. In this research, a test tool that shows the reliability value was 0.81. Coping is measured using Ways of Coping Scale from 16 that was adapted by researcher. In this research, a test tool that shows the reliability value is 0.863. Extroversion personality was measured using which was adapted by researchers. In this research, a tool test showing reliability value was 0.764. The optimistic scales were compiled by researchers based on the optimism component of 18 which includes indicators of permanence, personalization and pervasiveness. In this research, a test tool that shows the reliability value is 0.697.

Data analysis technique: The data analysis technique used in this research is SEM. The processing is done using Lisrel 8.80 to test the suitability of the measurement model with the available data in the field, whether or not it fits and to test the hypothesis proposed by the researcher. SEM has two main objectives in its analysis, namely to determine whether or not the model fits based on the data held and to test the various pre-built hypotheses.19

Results and Discussion

The result of the model test is obtained by chi square = 48.67, df = 56, p-value = 0.75, RMSEA = 0.00, and CFI = 1.00, NFI = 0.99, NNFI = 1.00, GFI = 0.97, AGFI = 0.94. This means “Theoretical model of effect extravertion personality and optimism with coping as mediator to subjective well-being is a fit model with empirical data. Extroversion personality and optimism play a direct, positive significant coping, also play an indirect, positive and significant effect to subjective well-being through coping. This means that there is a effect of coping as a mediator of extroversion and optimism toward subjective well-being. The theoretical model in this study can be seen in Fig. 1.
The next stage is to test the hypothesis among variables to see the relationship among variables. Hypothesis test results relation among variables both direct and indirect can be seen in Table 1.

The results of this study are in line with the opinion of who states that coping behavior is related to personality, where extraversion personality is positively correlated with coping to face the situation. This means that the more individuals have the tendency of extraversion personality, the easier he/she faces the problem or the easier he/she uses the coping. The findings of Goldberg, Costa & McCrae , states that people with open personality or extraversion easily and quickly reject or accept the pressure faced, therefore they overcome the problem easily.

Coping used by mothers who have intellectually disabled children allows mothers to be able to adjust to the environment so as to facilitate in achieving subjective well-being characterized by the existence of life satisfaction in general that is accepting the child with intellectual disability sincere and having life satisfaction of seeing the child can be independent.

Another very important finding is coping that serves as a mediator of the extraversion personality towards Subjective well-being. The results showed that extraversion personality has both direct and indirect role to Subjective well-being. It means that the relationship between variables is partial mediation, because the direct effect of extraversion personality to subjective well-being of mothers is greater than coping mediation.

The results showed that mothers who have intellectually disabled children mostly have a tendency of extraversion personality characterized by gregarious, open to others and friendly and easy to socialize use better coping, such as seeking social support in the form of information and support from the family when facing problems or solving problems and considering all the events that occur is a gift given by Him, so that mothers can achieve subjective well-being more easily.

The optimism in this research has a direct effect to coping, it means that optimism has a direct, positive and significant effect to coping. The results showed that mothers with intellectually disabled children who have optimism on their children’s ability is characterized
by the belief in the autonomy and the talent possessed by their child, these will affect the coping used by the mothers when facing the problem.

The results are in line with 24, it is suggested that individuals with high optimism can enjoy critical situations and take advantage of a variety of conditions and become stronger to face challenges. In line with Risinger’s et al. findings, 25, he states that optimism is negatively correlated with denial and escaping trial from problems. The research findings are in line with the findings of 26, stated that there is a high positive and significant relationship between optimism and coping stress.

Optimism in research has an effect to subjective well-being, it means that optimism play directly, positively and significantly to subjective well-being. The results of this study indicate that if mothers with intellectually disabled children have optimism characterized by positive response to recent success, they will experience subjective well-being more easily in the future.

A very important finding is coping that serves as a mediator of optimism toward Subjective well-being. The results of this study indicate that there is an effect of optimism towards subjective well-being with coping mediation. This means that optimism can take an effect on subjective well-being indirectly with the mediator of coping. The result of the research shows that optimism have both direct effect and indirect effect to subjective well-being, so it can be stated that the relationship between variables is partial mediation, because the direct effect of optimism toward Subjective well-being of mothers who have children with intellectual disability is greater than if mediated by coping.

The results show that the effect of optimism to subjective well-being is through coping mediator, because individuals who have high optimism will evaluate themselves positively and finally can control the important aspects of life, so they can get along with the social environment well and see the future with positive expectations and hopes. Individuals are able to deal with various conditions, physically and mentally have strong energy. The findings of 27 stated that optimism can be a positive influence in very powerful situations to influence coping in pressing situations and the overall aspect is needed in achieving Subjective well-being.

The results showed that mothers had optimism characterized by the belief of self-reliance, talent possessed by children using social support coping which was characterized by finding sources of support. The optimistic mother also uses positive reappraisal coping which is characterized by creating positive things happening to her by connecting to the belief that everything that is granted to her is a form of God’s trust. Both coping used by mothers who have intellectually disabled children make them easy to achieve Subjective well-being that is characterized by the satisfaction of life in general.

**Conclusions**

1. Model test is accepted, it means that coping as mediator of extroversion personality effect and optimism to subjective well-being of mother fits with empirical data.
2. This study also confirmed that coping becomes a partial mediator in the results of research and that the extroversion personality take an effect directly and indirectly to subjective well-being and optimism play directly and indirectly to subjective well-being.
3. Optimism is the variable that significantly takes the greatest effect and contributes to subjective well-being, it is followed by extroversion personality and the least is coping.

Social Skills for Student Social Anxiety Disorder (SAD) in Elementary School

S. Sriyanto¹*, Tri Na’imah¹, Yudha Febrianta¹, Indri Murniawaty²

¹Lecturer Universitas Muhammadiyah Purwokerto, ²Lecturer Universitas Negeri Semarang, Indonesia

Abstract

This study aims to improve social skills and overcome social anxiety disorders of elementary school students through learning visual thinking strategies. This research uses case study research, with the reason to test the effectiveness of learning strategies for students who experience social anxiety disorder. The study conducted in two schools in Banyumas Regency involving 11 subjects. The results of the study show that visual thinking strategies can improve students’ social skills in terms of working together, interacting, building an optimistic attitude, trying, being realistic, and being able to respect others. In addition, it also reduces the level of child’s anxiety in the form of a graded scale as an indication of subject changes during the process and after learning. The implication of this research is the process of learning in groups and working together will improve students’ social skills.

Keywords: Social skills, social anxiety disorder, visual thinking strategies.

Introduction

Social skills refer to the concept of homo homini socius, which is a group of people who lives to interact with others. Humans are required to be able to overcome all problems that arise as a result of interactions with the social environment and present themselves in accordance with applicable rules and norms. For this reason, each individual is required to master the skills in order to be able to adapt to their environment. At the age of children, the ability to adapt to their environment needs to be developed in order to live normally and healthily in adolescence.

Social skills can be used as a training to reduce the impact of social anxiety on children¹⁴ autism spectrum disorder⁵-⁷, social effectiveness theory⁸ Beidel’s research found that the social effectiveness theory treatment can be an effective treatment, and provide additional benefits to measures of social pressure and social behavior⁹. Psychologically, children’s mental readiness to enter a new environment is a major prerequisite so that their social interactions are not disrupted.

In the era of communication and information technology, social exclusion can occur due to the influence of technology containing a high level of social anxiety⁴. It is proven by a significant increase in social anxiety disorder over the past two decades of a number of students in social studies teaching ¹⁰. Social anxiety disorder (SAD) affects social and academic functions⁸, so this will lead to different responses and interfere with everyday life.

Studies in the United States show that social anxiety disorder are a kind of disorder that is the most suffered by its residents¹¹-¹². Even though it takes place at the top in the type of disorder, efforts to deal with social anxiety disorder are rarely carried out¹¹. From the results of the preliminary study it was reported that there were 25 percent anxiety disorders, while the 13 percent of it were social anxiety disorders¹³. The case of disruption of social interaction in the new environment can give a positive and negative impressions on the child’s psychological development¹⁴. Social anxiety disorder usually appears in children with feelings of anxiety with their social environment, fear of being ridiculed, and afraid of not being accepted by their friends. This anxiety arises when children feel that people will think badly of themselves caused by their inability to work as what is expected or at least equal to others. This disorder can affect one’s confidence and self-esteem as well as disrupt relationships at school¹³,²,³¹.

Children who experience social anxiety tend to think that everything they do seems to judge them\textsuperscript{15-16}. Therefore, they try to avoid scary social situations in order to avoid negative evaluations of others\textsuperscript{16-17}. One anxiety disorder that is often found in elementary school students in Banyumas Regency is social anxiety disorder. These children usually feel anxious about their social environment, afraid of the judgment of others, afraid of being ridiculed, and afraid of not being accepted by their friends. The basis of social anxiety disorder is fear of being observed. This disorder can affect one’s confidence and self-esteem and disrupt relationships at school.

This study developed the social skills of children with social anxiety disorder using visual thinking strategies learning model, namely learning strategies that rely on the thought process of visual image language, shapes, patterns, textures, symbols\textsuperscript{18}.

The indicators of success were first, students are able to cooperate with the members of the group by providing opportunities to get the same rights and obligations with the aim of accustoming group members to respect each other and have a positive view of other members \textsuperscript{30}. Second, learn to do self-control. Third, gain the habit of expressing opinions and being ready to accept the opinions of others although the opinions are different.

Based on the background, the question that arose was were visual thinking strategies able to improve the social skills of students who experience social anxiety disorder? The aim of the study was to improve the social skills of social anxiety disorder students through learning using visual thinking strategies.

**Method**

This research was a case study because it aimed at testing the learning effectiveness on students with social anxiety disorder. In addition, since the samples only covered social anxiety disorder students, so the researchers assumed that it would be freer to explore the research subjects. It was in contrast to experimental research which is only limited by treatment in a predetermined time \textsuperscript{[13]}.

There were three phases to determine the effectiveness of learning, namely during the learning process, the end of learning, and after learning (follow-up). During the learning process of the subjects, observations were carried out. Interviews were also conducted to find out whether the subject involved himself in engaging and interacting in the group, and working with friends. After the learning was done, the things to consider were attitudes and changes in subject behavior about their confidence to communicate with friends.

The subjects in this study were students who met the criteria set in the subject determination from two schools, namely Rempoah Elementary School and Karangtengah Elementary School in Banyumas Regency, consisting of 11 children. The method of collecting self-report data was in the form of interview (group discussion forums). It aimed to obtain etiological data which were in the form of the problems experienced by the subjects. In addition to interviews, the hierarchical scale model used to determine the level of subject anxiety from 0-100 was the Subjective Unit Disturbance. It is commonly used by Martin & Pear\textsuperscript{19}. Also, this scale was used to dig information from other people, namely parents, teachers, and people close to him. For more, the researchers also used observation to ensure changes in attitudes and behaviors of the subjects after participating in learning and the impacts caused by the treatment.

**Results**

Learning with visual thinking strategies has been proven to improve students’ social skills because these strategies met the criteria required in this study, namely children are able to collaborate with their peers, interact, build an optimistic attitude, try, and be realistic, and be able to respect others. The decrease in the level of children’s anxiety in the form of a graded scale was used as an indication to find out the changes that occurred in the subjects during and after learning process.

In general, the learning process of visual thinking strategies can involve students directly, so it is clearly seen that the learning is student-centered. Meanwhile, the social skills of SAD students increased, and marked by the achievement of the indicators:

a. Students work together in groups, respect each other, respect, and have positive views when learning in groups, give friends the opportunity to take turns when asking and answering questions in group discussion and during the presentation of the results of discussions in front of the class.

b. Performing self-control in the form of reminding friends both in the same group and outside the group, providing a conducive learning atmosphere.
The courage of students in expressing opinions and sharing experiences with friends in groups and teachers when learning takes place. Social skills emphasize students’ ability to communicate orally.

Discussion

Social skills are the ability of one’s life to work together, respect the rights of others and be socially sensitive; learn to do self-control and self-direction; share ideas and experiences with others. Failure to develop social skills can make it difficult for individuals to adjust to their environment, behave anti-socially, cause a feeling of inferiority, and can be excluded from association. This situation can lead to achievement and negative self-activity.

Learning using visual thinking strategies could build children’s confidence in social anxiety disorders, so students dared to interact with their peers. Before this learning model was applied, subjects were more likely to work alone, rarely spoke with their friends, passive in learning, even provided no answer to teacher’s questions. The results of the research of Sriyanto, Febrianta, & Yuwono through the experimental approach show the effect of implementing visual thinking strategies learning on students’ social skills. The changes that occur on their subjects were based on observations showing that the students dare to take the initiative to ask questions, help their friends, want to listen during discussion.

Asrori research, that social anxiety disorder in children can be reduced. By doing so, it can even children’s increase self-confidence and social interaction. Efforts to handle social anxiety disorder can be done through several techniques such as the application of behavioral rehearsal the effectiveness of cognitive behavioral theory therapy can also overcome anxiety disorders. These theories assume that anxiety is obtained through the learning process, namely through conditioning and observational learning. According to the cognitive theory children’s behavior during the process of development needs to get help to establish relationships in accordance with their expectations, so social problems that arise in the perception will be overcome.

The results of this study are consistent with the research of Selimović, et.al. to 1639 elementary school students in Bosnia. Their study shows that the learning process can develop students’ social competencies, although the subjects had different characteristics.

This study is also in line with the result of Iniyani and Listiara’s research that the cooperative learning model can reduce the level of anxiety of students when they are about to face an exam. This learning model is made through structured groups by arranging class according to students’ characteristics, and carrying it out through certain teaching techniques.

Bennis and Naus’s view state that learning to cooperate in the learning process integratedly gives benefits. Meanwhile, Cartwright-Hatton, Tscernitz, Gomersall try to distinguish between children aged 10-11 years who have high and low levels of anxiety. They explain that these children cannot be distinguished from their social skill level. However, objectively children who have a low level of anxiety feel themselves nervous in their social interactions. Based on these statements, the learning process in groups and work together will improve students’ social skills.

Efforts to develop social skills for children with social anxiety disorder are needed since building self-confidence requires consistent stages. Through the learning process, it is hoped that the children will be able to build habituation so as to help themselves to have confidence in their social life. This illustration refers to the five principles of powerful learning that should be mastered by teachers, namely, meaningful, integrative, challenging, active, and value based.

Conclusion

Social anxiety disorder can have an impact on the lives of people who suffer from this condition. Individuals who have social anxiety disorder have limited social relationships, feel helpless, lonely, and even alienated. Anxiety and nervousness are related to certain specific social situations; for example, meeting new people, being the center of attention, being observed while doing something, being called in class, taking an exam, speaking during class discussion. The most common symptoms that children experience are limiting activities, avoiding face-to-face situation, staying behind, and refusing to go to school. One effort to overcome this is through visual thinking strategies learning. Besides reducing social anxiety disorder, these strategies can also improve social skills.

Therapeutic Intervention of Respiratory Tract Cases in Children

Umi Solikhah1, Siti Nurjannah1, Supriyadi1

1Lecturer, Universitas Muhammadiyah Purwokerto, Indonesia

Abstract

Therapeutic intervention model for cases in the respiratory tract of children is needed to increase lung capacity in cases of respiratory tract disorders. This study aims to facilitate children’s needs in improving respiratory status and reduce the impact of hospitalization. The research used quantitative method. Researchers conducted a quantitative analysis of therapy with respiratory status. Description of variables were analyzed by numerical and categorical variables. This type of therapeutic intervention is the therapy of developing lung capacity with an inflatable type game. Analysis using paired sample t-test to see changes in respiratory status. The results showed respiratory status after the intervention occurred an increase in respiratory status with criteria for decreased respiratory frequency, increased pulse rate, decreased number of children who showed signs of chest retraction, development of nasal lobes and shortness of breath, and use of oxygen. The impact of hospitalization includes fussy children, feeling bored, afraid of health workers, asking to go home, and afraid of action, on average experienced by 23% of children. There are no tamper-tantrum respondents. Inflatable instrument are recommended for implementation of respiratory tract cases in children.

Keywords: Therapeutic, child, respiratory, inflatable instrument.

Introduction

Respiratory tract cases such as acute respiratory tract infection (ARI), pneumonia, bronchitis, bronchopneumonia, asthma; still a major problem in Indonesia. Respiration is needed to provide oxygen to the tissues and remove carbon dioxide. Normal breathing results in optimal lung development and constriction. In cases of respiratory problems, the child feels shortness of breath. Shortness of breath occurs due to insufficient oxygen to the lungs, so that lung development and deflation is not optimal. Activities are needed that can develop lung capacity to the maximum.

The number of respiratory tract cases in children, in the last three months is quite large compared to other cases. In August 2017 as many as 42% (45 cases out of 105 patients), in September 2017 amounted to 21% (33 cases out of 160 patients), and in October 2017 amounted to 20% (26 cases from 128 patients)1. This requires special attention from health workers. The treated child needs the right therapeutic action innovation to be able to provide nursing care that is appropriate to the patient’s needs2,3. Therapeutic interventions can be carried out in the form of games to reduce the impact of hospitalization and in the case of the respiratory tract to develop lung capacity.

The role of nurses here is very important to prevent the emergence of traumatic mechanisms in children both during treatment and after being treated2. The results of Kim and Cho’s research that patients during hospitalization needed nurses by 87%4. Nurses are in addition to patients for 24 hours, so that nursing care is needed by taking into account the principle of a-traumatic care, besides that it is necessary to involve the family during nursing actions, understand communication techniques that are appropriate for children and families, and creatively apply therapeutic games5-9. Therapeutic games should adjust to the child’s case and condition10-13. The availability of tools that support the nurse’s therapeutic activities in the children’s ward is needed.

The aim of this research is to know the impact of applying the respiratory tract case therapeutic game model on children on the respiratory status of children.

**Method**

Total sample of 80 respondents. Quantitative research methods, researchers conducted a quantitative analysis of therapy with respiratory status and assessed the change in the impact of hospitalization qualitatively. This type of therapeutic intervention is the therapy of developing lung capacity with an inflatable type game. Children need to play, therapy that is done by playing will provide happiness for children\(^{14-15}\).

Bi-variable analysis using paired sample t-test to see changes in respiratory status. The impact of hospitalization before and after the intervention is described qualitatively, through client interviews and observation of children. The intervention method was applied to develop lung capacity in cases of respiratory tract in children, with the medium of an inflatable instrument.

The average age of the respondent’s parents is in the productive age range. In productive age, adults show maturity and creativity in dealing with problems. In this case facing the problem of sick children who are hospitalized. There are still 4 respondents above 50 years old. At that age, parents have sufficient experience in dealing with the problems of sick children, although it does not guarantee they have ever gained sufficient knowledge about the problems faced.

Children at school age are able to receive information, knowledge, and instructions that they can predict\(^5\). In this study is needed because the interventions that are carried out require information in advance according to operational standards, so as to be effective in improving respiratory status.

Parents with higher education, this provides benefits in this study in terms of explanation of information about research procedures. There are more male child respondents. Boys have greater physical endurance to try to blow the tools used to develop lung capacity.

As many as 87.5% of respondents were awaited by their mothers. This shows that maternal attention as a provider of breastfeeding is still the main concern for children’s health, besides father. The mother is the parent who is closest to the child, because the mother is more likely to give the child a direct hug.

Diagnosis of childhood diseases as respondents include asthma, bronchitis, bronchopneumonia, ARI, pulmonary TB. Bronchopneumonia is the biggest case in this study, and ARI is second. At school age, you can start doing more activities outside, consuming unhealthy foods like sauces, cold drinks, and foods with strong spices; making it easier to get respiratory problems. Asthma in children tends to be obtained from family members with similar cases or because of allergens.

**Description of Respiratory Status**

(1) The average RR in the first and second measurements was the same. This shows an increase in respiratory status from RR variables. Normal respiratory is between 20-30 times per minute. If more than 40 times per minute is said to experience breathing difficulties.

After the intervention of the game with an inflatable device, the child experienced a development of lung capacity which was characterized by a decrease in RR up to two times per minute in each measurement.
Two times the measurement of RR decreased from an average of 28 times per minute to 24 times per minute, within 15 minutes of twice the intervention.

(2) The average HR in the first and second measurements is the same as an increase. The first measurement from an average of 89.91 times per minute to 94.07 times per minute, and the second measurement from an average of 89.96 times per minute to 92.90 times per minute. The normal HR in children is between 80 and 90 times per minute.

Increased pulse after intervention, most likely influenced by hospitalization, where children feel worried when intervened by health workers who use uniform\(^\text{15}\). The use of white uniforms can affect child hospitalization\(^\text{16}\). This needs special emphasis, every nursing action in a child needs to be anticipated with the possibility of the child not being cooperative, so that every child who is intervened does happily.

(3) Child patients who use oxygen are 13 children out of 80 children who are sick in their respiratory tract. 67 children do not use breathing equipment despite problems with breathing. There is no difference in the first measurement and there is a difference in the second measurement, which is from 13 children who use oxygen to 3 children who use oxygen.

These results indicate that therapeutic game interventions with inflatable equipment such as balloons can be recommended as interventions for children with respiratory disorders. Oxygen is given to children who show poor respiratory status. Of the 13 children who used oxygen effective after the second measurement. This means that this intervention is not enough just once, it needs to be done at least twice.

(4) *Chest retraction* is one sign of a child who has respiratory problems. Results of chest retraction examination in pediatric patients with respiratory tract disease amounted to 13 children from 80 children who were sick in the respiratory tract. After the intervention in the first measurement, from 13 children to 11 children who still had chest retraction when breathing. While after the intervention in the second measurement, from 11 children to only one child who still had chest retraction when breathing.

Although not many children show symptoms of chest retraction and cannot be generalized, it is sufficient to support that therapeutic game interventions with inflatable equipment such as balloons can be...
recommended as interventions for children with respiratory disorders.

(5) **Nostrils respiration.** Examination of the nasal lobe in pediatric patients with respiratory tract disease is one sign of a disturbance in respiratory status, in the form of nostrils expanding at the time of inspiration, as an effort to maximize the oxygen entering the respiratory tract. Although the number of children who developed their nostrils when breathing only 15 children out of 80 children, the results of the assessment after the intervention in the first and second measurements decreased.

This shows that therapeutic game interventions with inflatable equipment such as balloons can be recommended as interventions for children with respiratory disorders.

(6) **Shortness of breath** is characterized by the use of abdominal muscles during breathing. Shortness of breath occurs due to the body’s efforts to meet oxygen demand in the lungs. Limitations due to narrowing of the respiratory tract, obstruction, there are lenders or secret or foreign objects.

The number of children who experienced shortness of breath after intervention in the first measurement was slightly reduced from 14 children to 13 children. Whereas after the intervention in the second measurement decreased from 13 children to only three children who still experienced shortness of breath. This shows that therapeutic game interventions with inflatable equipment such as balloons can be recommended as an intervention for children with respiratory problems, especially shortness of breath.

The results of the survey on the impact of hospitalization were that the majority of child respondents were calm when hospitalized. The average respondent who experienced the impact of hospitalization was only 23.54%. Calmness of children when treated with an average of 76.46%. This is a positive finding as a result of previous research researchers’ interventions are still applied in the hospital’s children’s room. Management of therapeutic actions and environments supports a reduction in the impact of hospitalization on treated children.

Some things that can reduce the impact of hospitalization include attitudes of health workers, uniforms, environmental comfort, and family support. The impact of hospitalization which previously reached 80% decreased to 23.54%. The tendency of a calm child can be influenced by the calmness of parents accompanying their children who are hospitalized. The attitude of nurses who understand the perspective of child care also has a major influence on the child’s peace.

### Conclusions

Respiratory status after an intervention has increased respiratory status with criteria for decreased RR, increased pulse, decreased number of children showing signs of chest retraction, development of nasal lobes and shortness of breath, and use of oxygen. The impact of
hospitalization includes fussy children, feeling bored, afraid of health workers, asking to go home, and afraid of actions, on average experienced by 23% of children treated from 80 respondents.

Recommendation for this research, every child patient with a respiratory system disorder, applies therapeutic game intervention in the form of an inflatable device to the treated child, so that it is expected to help the healing process of the disease with pleasure. Hospitals, especially children’s wards, provide respiratory tract case therapeutic tool sets for children, so they can improve the quality of care for pediatric patients.

Mortality Rate and Gonotropic Cycle Serotype Denv-2 Transovarial Transmission through Intratoracal

Isna Hikmawati1,2, Hendro Wahjono3, Martini3, Socharyo Hadisaputro3, Edi Darmana3, Kisdjami Retna Mustika Djati3, Sugeng Juwono Mardihusodo4

1Student, University Diponegoro, Semarang, Indonesia, 2Lecturer, Universitas Muhammadiyah Purwokerto, 3Lecturer, University Diponegoro, Semarang, 4Lecturer, University Gajah Mada, Yogyakarta

Abstract

Transovarial transmission is an important role of Aedes aegypti as an intermediate host. This role is one of the factors dengue virus can survive in nature during interepidemic. DENV-2 transovarial transmission is an important problem because there has been evidence of horizontal transmission of DENV-2 serotypes by vertically infected mosquitoes. The study aimed to determine the mortality rate and gonotropic cycle of serotype denv-2 transovarial transmission through intratoracal in Aedes aegypti mosquitoes. The research method used a quasi-experimental design with the intervention of intratoracal DENV-2 serotype virus infection. The population in this study was Aedes aegypti mosquito female laboratory colony. The results showed a mortality rate of 87.2%, there were differences in the number of gonotropic cycle eggs (p <0.0001) with mean different: 13.5. and infection rate of DENV-2 transovarial transmission is 30-40%. An active role for the community is needed in eradicating mosquito breeding places in each gonotropic cycle.

Keywords: Gonotropic Cycle, DENV-2, Transovarial, Intratoracal.

Introduction

DENV-2 transovarial transmission is an important problem because there has been evidence of horizontal transmission of DENV-2 serotypes by vertically infected mosquitoes1. Transovarial is the transmission of dengue virus vertically from female mosquitoes to its eggs2. Dengue as a vector-borne disease is currently still a major disease problem especially in tropical and sub-tropical regions. The results of the research with cartographic approach estimate that there are 390 million / year of infection due to DHF and 96 million indicate clinical or sub-clinical severity. This disease has infected 70-500 million people/year in more than 100 countries around the world3. CDC (Centers for Diseases Control and Prevention) reported that a third of the world’s population is at high risk of developing dengue fever, especially in the tropics and sub-tropics4. Transovarial transmission is an important role of Aedes aegypti as an intermediate host. This role is one of the factors dengue virus can survive in nature during interepidemic. Aedes aegypti is the main vector and the population in nature is more (92.9%) than the co-vector Aedes albopictus (6.8%) with an infection rate of 0.81%5. The proportion of transovarial events in Kenya between 2013-2014 shows the proportion of 8-11%6. Results of research in India on third and fourth instar larvae showed transovarial infection rates of 35%7.

DHF is still a problem in Indonesia due to the presence of all four DENV-1, 2, 3, 4 serotypes and a high incidence rate in some regions8. The results of the research by Hikmawati, I and Pattima, S showed a CFR of 8.699. The results showed that the Transovarial Transmission Index (TTI) ranged from 39.1%-70%10. Transovarial proportion with four types of serotype by 30,3%11. The results of transovarial in Indonesia showed the positive rates of Aedes aegypti higher than Aedes albopictus12. The results of serotype distribution studies in Indonesia found that the overall proportion of DENV-1 was 9.6%, DENV-2 was 55%, DENV-3 was 29% and DENV-4 was 0.4%13. This study aims to determine the mortality rate and gonotropic cycle of serotype denv-2 transovarial transmission through intratoracal in Aedes aegypti mosquitoes.
Method

Research Design: The design of the study used quasi-experimental.

Sampling and Epidemiological Data Collection

Mosquitoes: The population was female Aedes aegypti mosquitoes free of dengue virus from the laboratory colony maintained at the Laboratory of Parasitology, Gajah Mada University. The number of samples were 86 female mosquitoes.

Virus: The dengue-2 virus used in the study was obtained from a parasitology laboratory, Gajah Mada University.

Intratoracal Procedure: Put 86 Aedes aegypti mosquitoes into a test tube, then put it in a beaker glass that has been filled with ice cubes, after fainting, take one at a time, put it under a microscope and a set of mosquito intratoracal devices, then an injection of ± 2 µ supernatant of the DENV-2 virus each tail (Fig. 1).

Maintenance of Mosquitoes after Intratoracal and Detection of Transovarial: Two-three days after the intratoracal, the mosquito was inserted in a 20 cm³ cage (Fig. 2) to feed the healthy human blood by means of membrane feeding. Mosquitoes are left to lay their eggs and are given cotton every day with sugar water and daily deaths are recorded. After being seen laying eggs, take the resulting eggs and count them with a microscope as one gonotropic egg (G1). The mosquitoes are then given blood back in a membrane feeding to lay eggs as gonotropic 2. The eggs produced from the gonotropic cycle are then hatched until they become mosquitoes as farian 1 (F1). Detection of Transovarial Transmission by Immuno Histo Chemistry (IHC) test.

A. Statistical Methods: Bivariate analysis using independent t test with p value <0.05 to see differences in eggs produced in the gonotropic cycle.

B. Ethical Consideration: The study was approved by the Medical and Health Research Ethics Committee (MHREC) Faculty of Medicine Gadjah Mada University and Dr. Sardjito General Hospital by Number: Ref: KE/FK/0176/EC/2018.

Results

Mortality Rate after Intratoracal: 86 mosquitoes are infectious with intratoracal, death occurred in gonotropic cycles one and two 75. The description of the death of Aedes aegypti after the intratoracal supernatant DENV-2 as in Fig. 4.

Gonotropic Cycles: Gonotropic cycles 1 and 2 in the Aedes aegypti mosquito as the following Table 1.

Table 1: Number of eggs and gonotropic cycle length

<sup>a</sup>one sample T test
Transovarial Transmission of Aedes Aegypti Mosquito: The result of transovarial detection of *Aedes aegypti* mosquitoes after intratoracal, the IHC method found an infection rate of 30-40%. As shown in Fig. 5.

![Fig. 5: Transovarial detection with (Immuno Histo Chemistry) Aedes aegypti mosquitoes](image)

**F1 Metamorphosis:** Metamorphosis of egg-larvae (3-19 days), larva-pupa (7-20 days), pupa-mosquito (2-23 days).

**Discussion**

The results showed the mortality rate of 87.2% meant that the intrathoracal infection act only gave a life expectancy of 12.8%. Higher mortality in one gonotrophic cycle than in the second gonotrophic cycle. This is because in the gonotrophic cycle, the content of the supernatant virus is still high, causing a more severe infection which ultimately results in higher mortality. Blood biting/sucking behavior is a parameter underlying the capacity of mosquito vectors in addition to other factors such as population density, extrinsic incubation period and survival. The results of Fouque’s study showed that the survival of female *Aedes aegypti* in French Guiana was on average 0.913. Thus, transmission and endemic patterns of dengue fever are predicted throughout the year. The results of other studies show in urban areas the female mosquito population is lower and this indicates a lower risk of dengue transmission compared to rural areas and slums.

The results of this study indicate that the mean of different gonotrophic cycles is longer (6.7 days) than the normal gonotrophic cycle (3-4 days), this is due to one of the low laboratory temperature factors (20°C-21°C) compared to the optimum average temperature for mosquito development (25°C - 27°C). As it is known that air temperature will affect the metabolic process. At low temperatures the metabolism is slow, affecting egg development. At high temperatures can reduce the size of the larvae so that at the adult level the size of the mosquito becomes small due to high metabolic rate and requires more food intake and more eggs.

Previous research results showed that the duration of the gonotrophic cycle in Wonosobo District averaged 4 days (3 - 5 days) and the average biological cycle length was 10 days (9 - 11 days). The results of previous studies showed that the estimated length of the gonotrophic cycle was different between the rainy and dry seasons, during the rainy season the correlation coefficient was 4 days, at 26.7 ± 1.22 °C, and 3 days in the dry season at 29.8 ± 1, 47 °C. Minimum estimated time to ripen eggs after administration of blood in the 3.5-day rainy season and 3.25 days in the dry season. Research results in Puerto Rico gonotrophic cycles between 3-7 days.

Besides affecting the gonotrophic cycle, temperature can also affect the number of eggs produced. The results of this study show the mean different number of eggs produced by 13.5 fewer than normal production between 100-150 each mosquito without infection. Research conducted by Gloria et al on the effect of temperature on dengue infection shows Extrinsic Incubation Temperature (EIT) and DENV-2 genotype have a direct effect on infection rates and EIT affects infection rates differently in each mosquito population, this shows the effect of environmental interactions on genotypes. These results indicate that the magnitude of the DENV epidemic does not only depend on viruses and mosquito genotypes but also adjustments to interact with local temperatures. The results of Ritadi’s research, et al concluded that the temperature and duration of storage affected the percentage of hatching of *Aedes aegypti* eggs in the laboratory (p = 0.046). The low egg production in this research is likely due to the infection of the DENV-2 virus that enters the mosquito’s body after an intratoracal, so that the mosquito undergoes an inflammation process. An important part to develop and amplify the dengue virus is cells from the salivary and ovarian glands, because for viruses infected by the virus the part shows morphological and histological changes in shape compared to healthy mosquitoes or not exposed to the virus (accentic). Both parts of this mosquito organ look much bigger (swell). The number of eggs produced is influenced by the amount of human blood sucked by female *Aedes aegypti* mosquitoes to ripen their eggs, blood is used for protein intake that is needed to produce eggs. The results of research in Thailand and Puerto Rico estimated that the average Aedes aegypti took 0.76 and 0.63 63 human blood meals per day. The results
of the study concluded that the DENV-2 serotype affects mosquito behavior for motivation to feed (fist feed) compared to avidity (second feed) 23.

The results of this study indicate that vector infectious requires a longer metamorphosis time (12 days) than non-infectious (8 days) from the stage of the egg to adulthood. Siraj’s research, et al. Shows that an increase in temperature can accelerate the epidemic of dengue fever virus, due to the rapid metamorphosis of each generation so that more infections each generation 24.

The proportion of hatched eggs is positively correlated with the immersion temperature. Survival was 30% at 13.2 °C and above 90% at 20 °C, while the development time at low temperatures was 49.4 d at 13.2 °C and 17.7 d at 20 °C 25.

Transovarial transmission in this study showed an infection rate of 30-40% meaning that in 100 Aedes aegypti mosquitoes there were 30-40 infected by DENV-2 through intratoracal. The results of this research clarify the role of Aedes aegypti mosquitoes through transovarials. Research results in Amazon City showed a transovarial infection rate of 46% 26. Population fecundity in mosquitoes infected with DENV-2 was significantly higher than DENV-4, after administering membrane feeding with non-infectious blood for 7 days27. Transovarial phenomena show persistence / maintenance of viral serotypes through intermediate hosts before being transmitted to humans as horizontal transmissions. The results of the study in Colombia showed the presence of dengue virus in larvae in rural areas, all serotypes (DENV-1, DENV-2, DENV-3, DENV 4) were detected in all regions and DENV-1 as the most dominant serotype28. Limitations in this study were not detected in the transovarial transmission of DENV-2 transovarial serotypes via intratoracal, only in the infection rate through IHC test.

Conclusions

The results showed a mortality rate of 87.2%, there was a difference in the number of eggs per gonotrophic cycle (p <0.0001) with mean different: 13.5. The F1 vector infectious metamorphosis takes longer (minimum 12 days) than non-infectious (minimum 8 days) from egg stage to adult and 30-40% infection rate of transovarial transmission of DENV-2 serotype. Vector control through eradication of mosquito breeding sites must be improved considering that the Aedes aegypti mosquito as the main vector of dengue fever has several gonotropic cycles. An active role for the community is needed in eradicating mosquito breeding places in each gonotropic cycle.

Abstract

The aim of this study is to assess the model of problem solving strategies and marital communication styles among married couple in Nigerian. To achieve the purpose a cross-sectional survey design was adopted with a sample of 385 married couple in Kwara state Nigeria. The instruments used are tagged ‘problem solving strategies and marital communication styles Scales’ contained 40 items spread among the 8 sub-constructs, 4 Likert’s type was adopted throughout the scale. The data collected was entered into Microsoft Excel 2016 and SPSS 20 for data cleaning and were filtered to the SmartPLS 3. The data was check for normality using two indicators of as Skewness and Kurtosis. The data analysis was conducted using Partial least square structural equation modeling approaches with SmartPLS 3 software. The measurement models were evaluated by items loading, composite reliability (CR) and average variance extracted (AVE). The results revealed that, the measurement model assessed in this study showed acceptability with validity and reliability tests results presented in the preceding sections. The convergent validity examined through the factor loadings, composite reliability (CR), and average variance extracted (AVE). Thus with the satisfaction of all the measurement requirements, it can be concluded that, the developed problem solving strategies and marital communication styles Scales validated in this study can be used to assess the problem solving strategies and marital communication styles Scales among married teachers in kwara state Nigeria.

Introduction

Domestic violence is pressing issue for divorce. In Nigeria, over 65 per cent of educated women and 55 per cent of low income women are subjected to domestic violence ¹. Domestic abuse and fatal cases of spouse violence are global phenomena. According to the United Nations, 38 percent of murders of women worldwide are committed by their male partners, and partner violence is the most common type of violence against women, affecting 30 percent of women globally ². In parts of the third world generally and in West Africa, in particular, domestic violence is prevalent and reportedly justified and condoned in some cultures. For instance, 56% of Indian women surveyed by an agency justified wife-beating on grounds like; bad cook, disrespectful to in-laws, producing more girls, leaving home without informing spouse, among others ³. It was also shown that 25% of women in Dakar and Kaolack in Senegal are subjected to physical violence from their spouses and that very few admit that they are beaten. The reports also revealed that a law passed in the Senegalese penal code punishing domestic violence with prison sentences and fines is poorly enforced due to religious and cultural resistance. In Ghana, spousal assaults top the list of domestic violence ³.

In Nigeria, reports revealed high level of violence against women ⁴,⁵ while reporting the Immigration and Refugee Board of Canada, stated that around 20 percent of Nigerian women experience physical, sexual...
or psychological violence from a spouse. Spousal abuse is particularly common in polygynous families and polygyny is practiced widely in Nigeria. added that more female had experienced physical violence compared with males in Nigeria. added that large number of cases in the Nigeria customary courts is related to domestic violence against women and a tendency of 60% increase may occur yearly. reported that marriage counsellors have attributed this development to lack of fear of God, intolerance, lack of problem solving and effective communication, incompatibility, increased social and economic pressures on family. It is argued that these changes in family life have weakened family bonds and the quality of relationships within families which in turn threatens societal growth and development.

The Nigeria goal on marriage relationship is to have a stable and functional family system where integrated citizens can be produced for the overall development of the nation. In order to ensure this, in 2012, Nigeria as a nation joined other world nations at the London Summit of Global Family Planning Vision 2020 aimed at giving support to couples’ right to freely make decisions on number of children to have, when to have and whether to have for a better living. The larger society can only plan its affairs to achieve meaningful development when all families are properly planned. However, on a daily basis, many families’ day-in day-out are dissatisfied with their marital life due to lack of problem solving skills as well as communication styles. In today’s world, there are many ways through which couples interacts with each other, they can interact by singing, dancing and playing together without any difficulty. However, dispute, divisions and sometimes violence may arise when they discuss family issues that are deep. This kind of situation is pointing to a defect in human interaction process.

In marriage, however, whether there is effective communication or not, conflict is bound to occur between couple and this may result from varying factors. This necessitates for problem-solving skills between couple. These are special communication skills that could help partners in resolving their areas of differences and satisfy their interest without been cheated or taken advantage of another. According to problem solving strategies and effective communication styles are potent tools in putting conflict at bay.

Methodology: This study is descriptive research with a plan data collection and analysis using cross-sectional survey design to validate the developed Measurement Model of Problem Solving Strategies and Marital Communication Styles. The goal is that, the fully developed and validated scale can be used to assess the Problem solving Strategies and Marital Communication styles among Secondary school teachers in Kwara state Nigeria.

Problem solving strategies and Marital Communication styles: The instrument tagged ‘Problem Solving Strategies and Marital Communication Styles Scales’ were developed by the researchers following the established procedures in the literature. The scale contained 40 items spread among the eight (8) sub-constructs (4 in Negotiation Styles and 4 in Marital Satisfaction). Four points (4) Likert’s type was adopted throughout the scale. i.e SD= Strongly Disagree; D= Disagree; A= Agree; SA= Strongly Agree.

Participants: The participants were the 385 married couple drawn from mostly secondary school teachers as defined in the study’s population in Kwara state Nigeria. The distribution of the participants include male and female

Data Collection: The consent of the respondents was sort by providing them the informed consent form designed. After obtaining the consent of the respondents, the scale was administered to the selected sample by the researchers; the participants’ responses were coded, scored and used as data in this study.

Data Analysis: The questionnaires checked were next entered into a design spreadsheet file using Microsoft Excel 2016 where the responses were filtered for scoring into a single dataset. Finally, the data were transferred to SmartPLS 3 to create dataset appropriate for the software for further analysis. The two indicators of assessing normality namely Skewness and Kurtosis were used to assess the normality of the data set as recommended by. The measurement models were all assessed using some set of indicators. The measurement models were evaluated by items loading, composite reliability (CR) and average variance extracted (AVE)

Results: To identify the level of significance of areas of Problem Solving Strategies and Marital Communication Styles components; measurement models of each of the eight sub-constructs of Negotiation Styles and Marital Satisfaction were developed. These models were presented in the following subsections
Measurement Model of Problem Solving Strategies: The Measurement model of the Problem Solving Strategies construct was evaluated by items loading, composite reliability (CR) and average variance extracted (AVE). Items loading of at least 0.7 showed satisfactory indicator reliability for the measurement model. The item/factor loadings of the 20 items measuring 4 sub-constructs of Problem Solving Strategies were assessed as first order constructs. The initial measurement model is presented in figure.

Figure 1: Initial Measurement Model of Problem Solving Strategies

Based on the analysis results the first order constructs, the 20 items measuring the problem solving strategies through 5 sub-constructs showed loadings 0.7 and above except for item PS4, PS6 AND PS8 which showed loadings index of 0.346, 0.174 and 0.217 respectively (see Figure 1). Consequently, these items with low loadings were dropped to form the valid measurement model used in the construction of pooled measurement model. The model was assessed again and all indicators showed acceptable loading. The loading output after omitting distortion trait from the measurement model is presented in Table 1.

Similarly, all the 4 sub-constructs achieved a satisfactory reliability with the composite reliability (CR) of more than 0.7, an indication that, the CR for the measurement model is above the recommended minimum value of 0.7, as presented in the Table 1. Thus, the outcomes specify that the items represent the constructs with adequate reliability and internal consistency. Convergent validity assessed through investigating average variance extracted (AVE) value; in cases where constructs have an AVE value equal or greater than 0.5, convergent validity is acceptable. Table 1 shows that, all sub-constructs in the problem solving strategies have AVE ranging from 0.5 and above. This exhibits that the proposed measurement model had satisfactory convergent validity.

**Measurement Model of Marital Communication Styles:** The Measurement model of the Marital Communication Styles construct was evaluated by items loading, composite reliability (CR) and average variance extracted (AVE). Items loading of at least 0.7 showed satisfactory indicator reliability for the measurement model. The item/factor loadings of the 20 items measuring 4 sub-constructs of Marital Communication Styles were assessed as first order constructs. The initial measurement model is presented in Figure 2

![Figure 2: Measurement Model of Marital Communication Styles](image)

Based on the analysis results the first order constructs, the 20 items measuring the marital communication styles through 5 sub-constructs showed loadings 0.7 and above except for item MC1, MC4, MC7, MC10 and MC12 which showed loadings index of 0.19, 0.19, 0.17, 0.20 and 0.31 respectively (see Figure 2). Consequently, these items with low loadings were dropped to form the valid measurement model used in the construction of pooled measurement model. The model was assessed again and all indicators showed acceptable loading. The loading output after omitting distortion trait from the measurement model presented in Table 2

Similarly, all the 4 sub-constructs achieved a satisfactory reliability with the composite reliability (CR) of more than 0.7, an indication that, the CR for the measurement model is above the recommended minimum value of 0.7, as presented in the Table 2. Thus, the results specify that the items represent the constructs with adequate reliability and internal consistency. Convergent validity assessed through investigating average variance extracted (AVE) value; in cases where constructs have an AVE value equal or greater than 0.5, convergent validity is acceptable. Table 2 shows that, all sub-constructs in the problem solving strategies have AVE ranging from 0.5 and above. This exhibits that the proposed measurement model had satisfactory convergent validity.

Discussions and Conclusions

The Measurement Model of Problem Solving Strategies and Marital Communication Styles among married couple in Nigerian were assessed for different validity and reliability evidences. Based on the review of the instrument and empirical assessments, a series of statistical analyses were conducted to established validity and reliability evidences of the scale. Generally, the measurement model assessed in this study showed acceptability with validity and reliability tests results presented in the preceding sections. The convergent validity examined through the factor loadings, composite reliability (CR), and average variance extracted (AVE)\(^{12,15}\).

Internal consistency of the constructs was measured using composite reliability (CR)\(^{16}\). For CR, 0.70 is the threshold criterion\(^{17}\) and all the latent variables involved in this study exceeded the threshold criterion. Moreover, the convergent validity of the constructs was assessed by assessing the factor loadings as well as the average variance extracted (AVE). According to\(^{18}\), the factor loadings are acceptable between 0.6-0.7 for social science studies. Likewise, the AVE value above 0.5 suggests an adequate convergent validity\(^ {14,19}\). All the latent variables involved in this study were having factor loadings and AVEs above their recommended levels. All validity and reliability tests confirmed the validity of the model. This indicates that a valid and appropriate model is presented in this study and the estimation of parameters within the structural model to be developed using this measurement model can also be valid. Thus with the satisfaction of all the measurement requirements, it can be concluded that, the developed Problem Solving Strategies and Marital Communication Styles Scales validated in this study can be used to assess the Problem solving strategies and Marital Communication styles among secondary school teachers in Nigeria.

Despite the significance of this study, there are some limitations as well. For instance, this study did not include the content validity process through which the selected dimensions have been included in the study. In addition, since, it was conducted under the context of Nigerian married couple, but it did not examine the differences among the married couple. Thus, to overcome the above study’s limitations, this study recommends describing the process of content validity in details through which the researchers can select specific dimensions of Problem Solving Strategies and Marital Communication Styles. Moreover, this study strongly recommends the future studies to collect data from different types of respondents.

Validation of Anxiety, Life Satisfaction and Social Media Addiction Scales using Rasch Measurement Approach

Ramatu Muhammad Maiwada¹, Aqeel Khan², Adibah Abdul Latif²

¹PhD Student, ²Senior Lecturer, School of Education, Universiti Teknologi Malaysia (UTM), Johor Malaysia.

Abstract

The aim of this study is to assess the validity of Anxiety, Life Satisfaction and Social Media Addiction scales (TELSMAS). To achieve the purpose a cross-sectional survey design was adopted with a sample of 150. Rasch Measurement was adopted to validate the items. The instruments contained 56 items spread among the 3 constructs. The data collected was entered into Microsoft Excel 2016 and Winsteps for the Rasch Analysis. The scale was evaluated through content validity with experts, construct validity with Rasch fit and outfit statistics and Reliability. The results revealed that, the scale has substantial content validity with Kappa value of 0.86, and acceptable reliability values of 0.99 (Anxiety), 0.95 (life Satisfaction) and 0.96 (social media addition). Similarly, the scale satisfied the condition of unidimensional for the Rasch validation. However, 14 items overall failed to satisfied the condition to be certified as valid and therefore completely deleted form the scale (5 in Anxiety and 9 in Social Media Scale). Thus, with the satisfaction of measurement requirements by 42 items, it can be concluded that, the developed TELSMAS validated in this study can be used to assess the level of anxiety, life-satisfaction and social-media addiction among school students and other vulnerable groups.

Keywords: Validation, Anxiety, life Satisfaction, Social Media, Scale.

Introduction

In every human society from time immemorial, individuals develop through stages of life and educational attainment; they encounter problems, challenges and conflict situations. These individuals also need to develop value systems, make decisions, set goals and work towards them¹. The success or failure of the individual especially with regards to educational attainment depends on a number of factors such as anxiety, life satisfaction and relationship with peers and interaction with environment, among others²,³,¹⁹-²¹. Accordingly, the capabilities and attributes of social media have the potential to enhance learning and education, when those tools are used for specific objectives and learning. However, when a general use of social media use that is unrelated to specific academic goals or objectives is considered among students, the results have tended to be negative⁴,⁵,²²-²³.

In contrast to fear, anxiety involves a more general or diffused emotional reaction beyond simple fear that is out of proportion to threats from the environment. Anxiety is defined by⁶ as ‘a complex psychological and behavioural state. Opined that anxiety, an emotional state of a human during life is both life-saving and also causes many problems in the mental life of human beings⁷. Therefore, in terms of the internal struggles, man uses expressions such as anxiety or worry.

Life satisfaction is the subjective, cognitive and conscious judgement of an individual’s overall quality of life based on his or her own standards. It is the rational aspect of subjective well-being and it can behave as an indicator, predictor, mediator and moderator of positive development⁸. Life satisfaction is a crucial indicator of subjective well-being and research implies that measures of life satisfaction can be used to indicate levels of happiness. Previous research suggests the value of life satisfaction in attaining optimal mental health and as a factor in many life outcomes⁹.
Social media is a broad categorical term for technologies that facilitate user sharing, content creation, and information exchange within online communities or networks. Specifically, social media platforms can be defined as technologies, “that allow the creation and exchange of user generated content”\textsuperscript{10}. This definition includes tools that allow users to easily create new content, including blogs (e.g., WordPress), micro-blogs (Twitter, Tumblr, YouTube), and video conferencing (e.g., Google Hangouts, Skype, Facetime)\textsuperscript{11}.

This study considered the importance of these psychological constructs as well as the need to assess them in every individual life. Thus, it is imperative to assess psychometric properties of the develop instrument used in measuring the phenomenon.

**Methodology**

This study is descriptive research with a plan for data collection and analysis using cross-sectional survey design to validate the developed anxiety, Life Satisfaction and Social Media Addiction Scales.

**Participants:** The participants in this study were senior secondary schools’ students in Sokoto state of Nigeria. A sample of one hundred and fifty (150) senior secondary schools’ students participated in the study. The sample size comprises male and female in the five selected schools. Sample size of at least 100 is considered as a reasonable number to participate in a study\textsuperscript{12}.

**Description of the Instrument:** The instrument for this study are constructed and validated is questionnaire and students’ performances as measured by their mock aggregate examination scores in key subjects. The instruments titled ‘Test Anxiety, Life Satisfaction and Social Media Addiction Scale (TELSMAS)’ were divided into four (4) sections; A-D. Section A contain information about the respondents Demographic Information, Section B contained items to measure students’ level of Anxiety Sub-scale, section C contained items to measure students’ level of Life-Satisfaction, section D contained items measure students Social Media Addiction, sect. All the three (3) scale were adapted.

**Test Anxiety Inventory:** This section of the instruments contains items to measure students’ level of anxiety of the respondents. The adapted instrument was modified to suit the current research on a new closed ended with Likert-Type scale. The TAI consists of 20 items rated on a 4 point Likert scale.

**Students’ Life Satisfaction Scale:** This section of the instrument contains items to measure students’ level of life-satisfaction of the respondents. The instrument was developed by\textsuperscript{8} and proposed to be adopted in this study it is a closed ended with Likert-Type scale. It is a seven-item measure of students’ life satisfaction. The SLSS asks students to indicate the extent to which they agree with statements about their life on a 5 point Likert scale ranging from 1 (strongly disagree) to 5 (strongly agree).

**Social Media Addiction Scale:** This section of the instruments contains items to measure students’ level of social media use of the respondents. The instrument was developed by\textsuperscript{13} and is proposed to be adapted in this study. Social Media Addiction Scale is a 5-point Likert type scale which consists 29 items.

**Data Collection:** To achieve the construct validity and the reliability of the questionnaire the scale was administered to the sample of experienced students selected in Nigeria. Prior to the field administration of the instruments for validation purpose a number of processes were followed which include content validation by experts, identification of target population for the pilot study selecting appropriate sample, administration of the draft instruments and reliability analysis as reported.

**Analysis:** To examine the internal consistency reliability of the research instruments in this study, the data collected from the administration were used to conduct test of reliability of the instruments using Rasch Measurement procedure. The data obtained were analysed using WINSTEPS 3.72.3\textsuperscript{14}.

**Results:** To determine the validity and reliability of the Anxiety, Life Satisfaction and Social Media Addiction scale Rasch procedure were used to analyse the data, the results are presented in this section

**Content Validity:** An instrument is said to be valid if it essentially measures what it is intended to measure. The content validity of the TELSMAS was first assessed by two (2) experts at the school of education Universiti Teknologi Malaysia, thereafter, the research submitted to some selected experts in the field of guidance and counselling and measurement and evaluation at the Usmanu Danfodio University, Sokoto in Nigeria. The detail information of the content experts is presented in Table 1.
Table 1: Background information of the content experts

</table>

The experts validated the instruments in terms of clarity of language, ambiguity of the statement, relevance to the topic and appropriateness of the items. After scrutinizing the instruments some constructive suggestions and corrections which were made by the experts were effected before producing the final draft of the instruments for pilot testing. Additionally, the ratings provided by these experts were used to compute the inter-rater reliability using Kappa statistics (see Table 2). The questionnaires have adequate content validity with the modified Kappa of 0.86 for all the three sub-scale.

Table 2: Kappa Statistics

<td>0.86</td>
</tr>
</tbody>
</table>

Reliability (Internal Consistency): The Rasch Measurement approach was used to estimate the reliability of the TELSAQ. The reliability coefficient of the scales in both person and item based on relevant standards has excellent person, item as well as adequate internal consistency reliability. Summary presented on Table 3 showed that, person sample used in the Test is large enough to confirm the item difficulty hierarchy of the test items.

Table 3: Summary Statistics

<table>
<thead>
<tr>
<th>SN.</th>
<th>Reliability</th>
<th>Test Anxiety</th>
<th>Life Satisfaction</th>
<th>Social Media Addiction</th>
</tr>
</thead>
<tbody>
<tr>

<td>2.54</td>
</tr>
<tr>
<td>3.</td>
<td>Cronbach Alpha</td>
<td>0.84</td>
<td>0.73</td>
<td>0.72</td>
</tr>
</tbody>
</table>

The reliability coefficients presented in Table 3 revealed the item reliabilities of 0.99, 0.95 and 0.96, with corresponding Cronbach Alpha of 0.84, 0.73 and 0.72. These parameters were considered satisfactory reliability because according to a Cronbach’s alpha scale greater than 0.70 is acceptable for the internal consistency reliability of the items and can therefore be accepted for research purpose.

Construct Validity

Unidimensionality: In validating the research instrument, the TELSMAS. The alignment of the items to the constructs can be identified using unidimensional characteristics. Two (2) indicators; the raw variance explained by measures (RVEM) and unexplained variance in the first contrast (UVFC) can be used to detect unidimensionality using PCA. The results of Rasch residuals to check unidimensional characteristics of the test items is presented in Table 4.

Table 4: Summary Statistics

<table>
<thead>
<tr>
<th>SN</th>
<th>Sub-Scale</th>
<th>Raw variance explained by measures</th>
<th>UVFC</th>
<th>Expected</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>

<td>57.0%</td>
<td>14.2%</td>
<td>59.8%</td>
</tr>
<tr>
<td>2.</td>
<td>Life Satisfaction</td>
<td>64.3%</td>
<td>11.3%</td>
<td>60.8%</td>
</tr>
<tr>
<td>3.</td>
<td>Social Media Addiction</td>
<td>41.8%</td>
<td>10.8%</td>
<td>41.8%</td>
</tr>
</tbody>
</table>

The result presented in Table 4 showed that the unidimensional nature of the TELSMAS and confirmed further whether the items are measuring Test Anxiety, Life Satisfaction and Social Media Addiction. The raw variance explained by measures are 57.0%, 64.3% and 41.8%. The rule as provided by is that, for an instrument to achieved unidimensionality, it requires the minimum of raw variance explained by measures (RVEM) of 40% and unexplained variance in the first contrast (UVFC) to be less than 15% to fully established that, the TELSMAS is unidimensional and no substantial secondary dimension seem to exist within the data.

Model fitness Statistics: Based on the Rasch model analysis various tests were used to identify error responses labelled as ‘outliers’ or ‘misfit’ as these are commonly referred terms used in psychometrics. As the name suggests ‘misfit’ refers to the estimates that do not fit into the overall model fit. According to the Rasch, model fit is determined by examining the misfit indices revealed by the Outfit Mean Square (MNSQ) measures, the Outfit Z Standard (ZSTD) estimates as well as the Point Measure Correlation indices.
According to the variance is larger for well-targeted observations and smaller for extreme observations. In this study the Outfit MNSQ (+1.05) shows acceptable variances within the responses because the accepted value of this fit statistic is close to 1. Outfit MNSQ measures are more susceptible to extreme responses compared to Infit MNSQ measures. Thus, to maintain any item in a test is should satisfy the following conditions as provided by PTMEA CORR is positive and not 0, INFIT and OUTFIT MNSQ index fall within the acceptable range i.e., 0.7 ≤ MNSQ ≤ 1.3 and the ZSTD values fall within acceptable range of -2.0 ≤ Z ≤ 2.0.

Misfit items in Test Anxiety Scale: Based on the item map (Figure 1), there are 5 items, 4 of the items are higher than the most able student and 1 of the items is easiest even to the least abled respondents. The items are A11, A12, A15, A16 and A1. To decide whether to omit them from the scale or maintain to be use in the next administration, the indicators of fit were investigated i.e., Point Measure Correlation (PTMEA CORR), INFIT Mean Square (INFIT MNSQ) and OUTFIT Mean Square (OUTFIT MNSQ). The result shows that, all these 5 items have very low PTMEA CORR close to zero. Thus items 11, A12, A15, A16 and A1 were deleted from the final instrument.

Misfit items in Life Satisfaction Scale: The investigation on the life satisfaction scale shows that, all the 7 items in the scale have acceptable fitness statistics. Thus all the 7 items are retained in the final draft of the scale.

Misfit items in Social Media Addiction Scale: Based on the item map (Figure 2), there are 12 items higher than the most able respondents out of which 9 items have out of range and unacceptable fitness indices. After careful investigation of the fit statistics in terms of Point Measure Correlation (PTMEA CORR), INFIT Mean Square (INFIT MNSQ) and OUTFIT Mean Square (OUTFIT MNSQ). The result showed that, all these 9 items have poor fitness indices. Thus items SM11, 16, 19, 20, 21, 22, 23, 24, and 26 were completely eliminated from the final instrument.

Conclusion

Several studies showed that, anxiety, life-satisfaction and other life events in the present day such as social-media contributes immensely in learning and many other life events in the present day society especially among youth in schools at different levels. Investigating the level of anxiety, life satisfaction and social media usage as well as their effect to learning is believed to assist in addressing several disturbing trends especially in the academic achievement of students at different level. This study provides the validation report of Test Anxiety, Life Satisfaction and Social Media.
Addiction Scale (TELSMAS). The validated TELSMAS with the revealed validity parameters is can be used as a standardized measure to assess the level of anxiety, life-satisfaction and social-media addiction among school students and other vulnerable groups.

Abstract

The present study aimed to explore the level of psychological happiness and its relationship to the meaning of life among students of the preparatory year at King Khalid University in Abha city in Saudi Arabia. The study followed the cross sectional survey design. The measure of Psychological happiness and meaning of life were used to collect the relevant data. The tools were applied to a sample of 300 students aged between 18 and 20. Findings revealed that, there were no statistically significant differences in the respondent level of the meaning of happiness due to the variable of the academic track, evidenced by the increase in the value of (t) calculated at (0.783, p>0.05), and there were no significant differences in the respondent’s views regarding the level of the meaning of happiness due to the academic track variable as evidenced by the increase in the value of (t) calculated at (0.256, p>0.05). The results also showed a statistically significant correlation between the level of meaning of life and psychological happiness (α<0.05). The study recommended the inclusion of concepts and Strategies to develop happiness and the meaning of life in the curricula of university students, and hold workshops for students and teachers for training them on methods and strategies to achieve happiness and create positive meanings for life among university students.

Keywords: Psychological happiness, meaning of life, university students.

Introduction

The 21st century is the era of positive psychology and subjects such as psychological happiness and the meaning of life are important concepts of positive psychology, because of the many positive effects on the compatibility and psychological health of the individual. I think that the term happiness was included in 1973 when researchers attempted to study many demographic, social and personal characteristics. In order to know the factors that lead to a sense of happiness; where Psychologists focused on happiness through its connection to satisfaction of needs, gradually from the minimum physiological needs to the higher needs of self-realization; because man seeks to achieve his important goals in order to feel happy and achieve a good life when meets the requirements of security and belonging, independence and self-assertion, achieving higher one depends on external factors surrounding, family, society, economic, political, and learning aspects¹.

The Meaning of life has recently become one of the concepts that have acquired since the last century the interest of scientists and researchers in the field of psychology and mental health and in many categories and qualities in society, where he cares about the human and its value, life, satisfaction and self-esteem in the sense of his life, and the role that he can performance in life².

In this sense, the study of the meaning of life is considered a relatively recent study in the field of medicine, public health, psychiatry, psychology and education, and the increasing interest in the sense of life and the desire to reduce the negative effects of disease and disability reflected the maximum aspirations of workers in these fields. The concept of the meaning of life is one of the modern concepts in the Arab world³.

The sense of loss of happiness and the meaning of life on the individual brings more suffering and psychological strikes, where the individual in this situation is a victim of despair, frustration, anxiety and indifference. Its impact is not only limited to psychological or social aspects, but also affects the academic aspects.

The university stage represents a critical stage in human development, as it is the most developed stage characterized by physiological and psychological changes that can generate many pressures and conflicts in the individual. Like other members of the community, university students face many pressures, making them vulnerable to negative emotions and despair because they are unable to satisfy their needs and achieve their goals, especially in light of the pressures and difficulties of modern life. This indicates a state of confusion in their lives.

Hence, the problem of the current study emerged when the researcher noted that many students in the preparatory year dissatisfied with their lives and academic paths and do not enjoy life for the absence of meaning and the will. In the preparatory year at King Khalid University, students suffer from psychological problems, especially the problem of low happiness and the meaning of life which have a great impact on mental health. In the paucity of studies, because presently there is no Saudi study on the relationship between the level of psychological happiness and the meaning of life among students in the preparatory year in Saudi universities.

In the light of the research problem, the following hypotheses were raised and tested in this study, thus:

Hypothesis 1: There is no significant correlation between the meaning of life and psychological happiness among the preparatory year students at King Khalid University.

Hypothesis 2: There is no significant differences in the level of psychological happiness of students with respect to academic track and academic achievement.

Hypothesis 3: There is no significant differences in the meaning of life among students with respect to academic track and academic achievement.

Material and Methods

The current study cross-sectional survey design to examined the relationship of psychological happiness in the meaning of life in for a sample of students in the preparatory year at King Khalid University of Saudi Arabia. The participants were the 300 preparatory year students at King Khalid University in Saudi Arabia in the academic year 2018/2019, aged between 18-20 selected using simple random sampling technique.

The instruments were (1) Psychometric measure of happiness: The Oxford scale, Arabization by which is composed of 29 items. The items were modified to suit the preparatory year students in Saudi society. (2) A measure of the meaning of life, prepared by the researchers consisting of 60 items constructed to suit the sample. Both the scales were on 5 point Likert scale.

The instruments were validated by experts and were pilot tested to confirmed the construct validity and reliability of the scale. Based on the result of the pilot testing and reliability analysis, the two instrument attained adequate validity and reliability evidence with internal consistency reliability of 0.870 and 0.92 for the Psychometric measure of happiness and measure of the meaning of life respectively.

The validated instruments were administered to the sample of 300 preparatory university students of King Khalid University in Saudi Arabia directly by the researchers with the help from research assistance. Prior to the data collection an informed consent form was given to the respondents to obtain their consent. The responses collected were scored entered and used as data in this study.

The data Collected were summarized in an excel 2016 file and prepared it in the SPSS 25 format. The analyses were carried out using Descriptive and inferential statistics. Mean standard deviation were used to summarized the data. Pearson Product Moment Correlation, Independent t-test and ANOVA were used to address the research hypotheses. All the statistical tests were conducted at 0.05 level of significance.

Results and Discussions

The result of this study as explained in the preceding section has been obtained and presented using Descriptive and inferential statistical analyses. The results are presented in table 1 to 8 in the following headings.

Descriptive statistical analysis for data: The descriptive statistics of frequency and percentage showed the distribution of the study respondents. The
distributions showed that, in line with the respondents’ Academic track, 150 (50%) of the students were in Health track and Engineering track respectively. In relation to Academic Achievement, the distribution showed that, 70 (23.3%) were from the low achievement, 144 (4%) were from the medium achievement and 86 (28.7%) were from the high achievement class.

**H01:** There is no significant correlation between the meaning of life and psychological happiness among students at King Khalid University.

The Pearson Product Moment Correlation Coefficient (r) to test the above stated hypothesis is presented in Table 1 at 5% level of significance.

**Table 1: Psychological Happiness and Meaning of Life**

<table>

</tr>
</tbody>
</table>

The results presented on Table 1 showed the relationship in psychological happiness and meaning of life with the r-value of 0.815 and p-value of 0.000, tested at 0.05 level of significance and degree of freedom of 298 is positive and significant (0.484>0.05). Therefore, the null hypothesis is rejected.

**H02:** There is no statistically significant differences in the level of psychological happiness of students with respect to academic track.

The independent sample t-test to test the above stated hypothesis is presented in Table 2 at 5% level of significance.

**Table 2: Difference in psychological happiness (academic track)**

<table>

</table>

The results presented on Table 2 showed the mean difference in psychological happiness scores of Health Track and Engineering Track with the t-value of 0.783 and p-value of 0.434, tested at 0.05 level of significance and degree of freedom of 298 is not significant (0.484>0.05). Therefore, the null hypothesis is accepted.

**H02:** There are statistically significant differences in the level of psychological happiness of students with respect to academic achievement.

The test of ANOVA to test the above stated hypothesis is presented at 5% level of significance. The results showed the F statistics (297) = 6.983 and p value= 0.001, α = 0.05 for psychological happiness. The result of the analysis reveals that the mean psychological happiness scores of respondents based on their Academic Achievement are significantly different (p-value < 0.05). The null hypothesis which says there is no significant difference in terms of Academic Achievement on psychological happiness is rejected. Thus, it is not clear where the difference exists within the three groups. A multiple comparison (Turkey post-hoc-test) presented on Table 3.

A Tukey post hoc test result as presented in Table 6 above revealed that, that there is a statistically significant difference in meaning of life between Average and low achievement (p = 0.000), it also exists between Average and high achievement. However, there were no significant differences in psychological happiness between other group
Conclusions and Recommendations

The findings from this study revealed a very interesting phenomenon at King Khalid University, Saudi Arabia among preparatory year students. First, a positive relationship exists between psychological happiness and meaning of life which is a clear indication that students who know the meaning of life are the happiest among the preparatory year students at the King Khalid university.

Secondly, the findings revealed that, the psychological happiness of students in Health Track and Engineering Track are similarly and therefore in respective of students’ academic track, their level of happiness is homogenous. Similarly, going further another important revelation was that, the psychological happiness of students from different achievement level were similarly, however, there was difference in psychological happiness between Average and High achievement groups.

Thirdly, the findings revealed that, the meaning of life score among students in different academic track are not significantly different. Meaning the students understanding of meaning of life at King Khalid University Saudi Arabia were almost the same for all the groups. Moreover, the meaning of life for preparatory year students at King Khalid University Saudi Arabia was similar among the different class of achieving students. However, difference exists in meaning of life between Average and low achievement.

Overall these findings are consistent with that of 8,9 whose findings established the long standing discussions on the relationship between happiness and meaning of life. Thus the study also led credence to the scholarly, stands and conclusions10.

Based on the findings and discussions above, it is recommended that:

(a) More attention should be paid to develop the aspects of psychological happiness and the meaning of life in preparatory university students as it has revealed to have an important position developing positive psychological health for university students

(b) The curricula be enhanced especially in psychology to relate the content more with happiness and the meaning of life

(c) Workshops and training be organised for university students on psychological happiness and the meaning of life.

(d) More studies should be conducted in the area of positive personality characteristics of University students.

Abstract

Dengue fever was acute fever disease that could cause the death and caused by four distinct virus serotypes and genus Flavivirus. One of method in restraining Aedes was using larvitraps type (used plastic bottles, used bucket, PM Trap) which had been modified. The primary data on 2018 was obtained Dengue fever case which was equal to 154 larvae on larvitraps type on to plastic bucket as much 63,96% larvae. The research aimed to know the Influence of larvitraps modification as the monitoring of Aedes aegypti larvae existence at the area of Rajabasa Indah Health Centre Technical Implementation Unit.

This research used quasi experiment design with non-randomized pretest-posttest control group design. The research subject was Aedes aegypti larvae. Larvitraps was made of used plastic bottles, used bucket, PM Trap and closed with gauze. Larvitrapswas filled out by water on the third type of larvitraps. The research location was Rajabasa Raya, Gedung meneng and Nunyai Sub district. The research sample as many 18 houses decided by using cluster sampling. The data analysis of univariate and bivariate was with Mann-Whitney and Kruskal Wallis method.

The research result showed that Aedes larvae which had been trapping during the research was 154 larvae with 146 larvae spread on larvitraps inside the house and 89 larvae outside the house. The average Aedes larvae which had been trapping on used plastic bottles larvitraps type was 51,18 larvae, 63,96 larvae on plastic bucket and 48,36 larvae on PM Trap, there are differences between the types of larvitrap used plastic bottles and plastic buckets and between plastic buckets and PM Trap (p value <0.001). It was suggested for society to be able to use larvitraps type of plastic bucket as an easy, cheap and productive vector restraint.

Keywords: Aedes, used plastic bottles; plastic; PM Trap (Post Mosquito Trap); larvae existence.

Introduction

Dengue fever is a chronic fever that can cause death and it is caused by four serotype viruses and gunus flavivirus, RNA Virus from Flaviviridae genus. One of the risk factor of Dengue fever is its quick spreading in inner city area, the advancement of public mobilization and transportation, and/or the failing of birth control system that can possibly make this into Extraordinary Condition KLB (extraordinary case)1. Thus, the researcher wanted to inform one of the tools that can be easily and simple to be implemented called ovitrap. The material for this trap is mainly from plastic precisely using a used plastic bottle, bucket and PM Trap (Port Mosquito Trap). By using this tools it is able to reduce the mosquitoes density and reducing the occurrence level of dengue fever2. Ovitrap has been developed worldwide to monitor the spread of Dengue Fever Larvae3. There are also other advantages in using ovitrap than other traps of the same type: it is cheap and easy to use, because of the component that can be made independently by utilizing used items that can be easily found in domestic house, such as used can, a piece of bamboo or wood and water. Besides, of the simplicity, ovitrap is also very easy to maintain and clean the tool. Ovitrap only need to replace the water within the container...
every week and to brush the inner side of the container\(^4\). Research conducted by Hamzah & Basri (2016), suggest that the most successful ovitrap to trap the larvae is the plastic bucket type with over 12 larvae (66.76%), then followed by PM trap (Port mosquito Trap) as much as 10 (55.56%) and the lowest is the used plastic bottle by 3 (16.67%) from each ovitrap installed\(^5\). Every decade, the total cases of DBD in yearly average reported to WHO kept increasing exponentially Meanwhile, Dengue fever in recorded in Technical implementation Unit (UPT) Public health clinic of Rajabasa Indah in 2015 the rate of Dengue fever cases is recorded up to 43 cases, on 2015-2016 the case number of dengue fever increased to 117 cases and on 2017 dengue fever case reach 61 cases. The number of Dengue larvae free number (ABJ) in 2016 reach (85%) and in the year of 2017 the ABJ increase to (86%). Furthermore, the numbers of PE in 2015 reach 59 cases of Dengue Fever, on 2016 the number of PE is increased to 94 cases of Dengue fever and again in 2017 the number of PE reach 62 Dengue fever cases. Because in Technical implementation Unit (UPT) Public health clinic of Rajabasa Indah source of the problem is in the density of population. Thus, the importance of monitoring is to create an indicator of the larvae whereabout.\(^6\) There are varieties of method to monitor the larvae; for example: egg survey, larvae survey and mosquito survey. The monitoring agenda is by surveying the larvae by installing larvitrap, it is considered effective to detect the whereabout of the \textit{Aedes sp} larvae in a region or even in the lower level. From this research it is expected to identify whether there is an effect on modifying the larvitrap as a method to monitor the existence of \textit{Aedes aegypti} larvae in Technical implementation Unit (UPT) Public health clinic of Rajabasa Indah.

**Methods**

The research is conducted in Technical implementation Unit (UPT) Public health clinic of Rajabasa Indah, Bandar Lampung. The time frame of the research started on this June to July 2018, while the installation and positioning of 36 larvitrap was installed for about 14 days and positioned within indoor and outdoor of the house, every day the installed larvitrap will be observed to count the number of the trapped larvae. This research will implement quasi-experiment design with non-randomized pretest-posttest control group design.\(^7\) The subject of this research is \textit{Aedes aegypti} larvae. Larvitrap made from used plastic bottle, plastic bucket, \textit{PM Trap} and closed with gauze. Larvitap then filled with clear water to the larvitraps. The location of this research is in Rajabasa Raya Urban Communities, Meneng and Nunyai Building. The research samples are 18 houses determined by using cluster sampling. The data analysis will be analyzed by univariate and bivariate using Mann-Whitney dan Kruskal-Wallis method. The data collection about the larvae location will be assisted with enumerator that has basic in environment health.

Discussion

Larvitrap type (Used Plastic Bottle, Plastic Bucket and PM Trap): The average from this research, suggest that most of the larvae trapped within the installed larvitrap (plastic bucket) are around 10 larvitraps in Nunyai urban communities 10%. While within the other installed larvitrap (used plastic bottle) the larvae trapped in 14 installed larvitrap in Rajabasa Raya Urban Communities 0,28% and within the (PM Trap) the larvae trapped within 14 installed larvitrap in Rajabasa Raya urban communities 0,14%. The finding is inline with Hamzah & Basri, (2016), that the most ovitrap trapping larvae can be found within bucket plastic which is recorded on having 12 larvae trapped (66,76%), then PM Trap (Port Mosquito Trap) for about 10 larvae trapped (55,56%) and the lowest is used plastic bottlefor about 3 larvae trapped (16,67%) from each ovitrap installed. Plastic bucket can be used for detecting Aedes mosquito and to exterminate its’ larvae. In addition, according to Roeberji, et al (2017), the result of the observation suggest that each larvitrap wcolored black will have a preference for about 79,6%, higher than bright colored larvitrap 70,4%.

Placement Position: The average esult of the conducted research, shows that the average placement position (indoor of the house) is around 146 larvae (1,35%) larger than the outdoor of the house about 89 larvaees (0,82%). The result of the research conducted by Sayono (2011), OI KPN in indoor of the house declined consistently from 60,5% to 36,4% via post intervention. Overall, OI delined to 20,5%. This shows that the placement position (indoor of the house) affecting the larvae positions. Because indoor of the house has 90% more Aedes aegypti mosquitoes residing in the dark area. Research conducted by Lau, et all (2017), ovitrap index (OI) Aedes larvae has highest number within the urban concentrated area (average OI = 90,97%), followed by residential area (69,70%), village (65,45%) dan rural area (52,63%).

Larvae location: In average from the research conducted, shows that the average type of the larvitrap (plastic bottle, plastic bucket and PM Trap) most of the larvaees were trapped in plastic bucket 63,96%, followed by used plastic bottle 51,18% and then PM Trap 48,36%. The result of the analysis using Krusal-Wallis between larvitrap types (used plastic bottle, plastic bucket, and PM Trap) shows that the p value is significant at 0,001 (α < 0,05), based on the analysis Ho is rejected dan Ha is accepted. Thus, there is a difference in average between larvitraps. The result of the research proofs that there is an effect in monitoring the larvae location with used plastic bottle, plastic bucket and PM Trap.

The difference between used plastic bottle in indoor and outdoor of the house: The used plastic bottle in indoor and outdoor of the house has been observed for about 14 days and there is a sign of the location of the
larvae inside the larvitrap with this type. Based on the research there is no distinctive difference between the larvae location between used plastic bottle in indoor or outdoor of the house. Meaning that the data retrieved from calculating the ovitrap indeks is the number of the larvae in the used plastic bottle in indoor and outdoor of the house has similar number and no differences to be found.

The difference between plastic bucket in indoor and outdoor of the house.

The plastic bucket in indoor and outdoor of the house has been observed for about 14 days and there are signs of the larvae location in it. The result of the research shows that there is no distinctive difference between the larvae location between plastic bucket in indoor or outdoor of the house. Meaning that the data retrieved from calculating the ovitrap indeks is the number of the larvae in the plastic bucket in indoor and outdoor of the house has similar number and no differences to be found.

The difference between PM Trap in indoor and outdoor of the house: PM Trap in indoor and outdoor of the house has been observed for about 14 days and there are signs of the larvae location in it. The result of the research shows that there is no distinctive difference between the larvae location between used PM Trap in indoor or outdoor of the house. Meaning that the data retrieved from calculating the ovitrap indeks is the number of the larvae in the PM trap in indoor and outdoor of the house has similar number and no differences to be found.

The difference of the larvae location on larvitrap types (Used plastic bottle, Plastic Bucket and PM Trap): The ovitrap installation in this research has been conducted for 14 days because like any other mosquito around the Aedes sp mosquito gone through perfect metamorphosis phase, which ordered in egg-larvae-pupa-mosquito. The egg, larvae and pupa stage is on water. Usually the egg will hatch itself in ± 2 days after the egg submerged underwater, the larvae stadium runs for about 6-8 days and the cocoon stage last 2-4 days. The result of the research suggest that in Technical implementation Unit (UPT) Public health clinic of Rajabasa Indah most of the larvae trapped in larvitrap plastic bucket type 63,96%, plastic bottle 51,18% and PM Trap 48.36%. It can be concluded that the larvitrap types that trapped the larvae plastic bottle, plastic bucket and PM Trap. While in between group of plastic bottle and PM Trap there has been no distinction of the larvae position. Thus, the most larvae trapped in larvitrap plastic bucket type than plastic bottle and PM Trap.

Conclusion

The effect of modifying the larvitrap, the distinction of used plastic bottle, plastic bucket and PM Trap and there is no effect of placement position as the position monitoring of Aedes aegypti larvae. So, it is recommended to use an effective plastic bucket for larvae traps and reduce the incidence of dengue fever in Technical implementation Unit (UPT) Public health clinic of Rajabasa Indah.

Acknowledgement: Note of gratitude will be appointed to Technical implementation Unit (UPT) Public health clinic of Rajabasa Indah who as supported the researcher in the clearance process, the respondents that give their permission in placing the larvitrap for 14 days in their indoor and outdoor of the house that is critical for the research and also not to mention the enumerator tea who has supported the researcher in the sampling process.

A New Risk Calculation Method for Tuberculosis (TB) based on Decision Tree and Artificial Neural Network

Monisha Ghosh Srabanti1, Eko Supriyanto1,2,3* and Muhammad Nabil Mohd Warid1

1School of Biomedical Engineering and Health Sciences, Faculty of Engineering, 2Advanced Diagnostics and Progressive Human Care Research Group, 3IJN-UTM Cardiovascular Engineering Centre, Universiti Teknologi Malaysia, Johor, Malaysia

Abstract

Tuberculosis is a bacterial infection that affects the respiratory system and may lead to the death of lung cells. In this study, a novel equation based on Decision Tree and Artificial Neural Network application was developed to calculate the risk percentage of tuberculosis. Retrospective data was input in a conventional equation based on the classification of tuberculosis risk factors. Existing methods for disease risk calculation can only predict the odds of contracting the disease, and some are based on population. Therefore, in this study, a new risk prediction method is proposed, where the risk percentage can be calculated as long as the risk factors are known. The risk factors are categorized into three groups, which are Low-, Middle-, and High-energy levels. The calculation is based on a Decision Tree and Artificial Neural Network. Artificial Neural Network was applied for output verification of the novel conventional equation. The limitation of this study is that only common risk factors have been considered. It is recommended that future studies also include other risk factors for better and more precise results. Based on the results of this study, it can be concluded that the proposed method is better than other methods because it takes into account disease risk factors.

Keywords: Tuberculosis, Risk Factors, Decision Tree, Risk Calculation, Artificial Neural Network.

Introduction

Tuberculosis (TB) is an infectious disease caused by tubercle bacillus, also called Mycobacterium tuberculosis. It causes an estimated 2 million deaths per year1. Common signs and symptoms of TB include a bad cough that lasts for 3 weeks or longer, chest pain, weakness or fatigue, coughing up blood or sputum, weight loss, chills, fever, loss of appetite, and night sweats.

There are five stages involved in TB bacterial infection. It begins with inhalation of the bacteria, followed by bacterial multiplication, T-cell activation, tubercle formation, cavitation, and tubercle breakdown2.

In this study, a new method, which includes a novel equation to calculate the risk percentage of tuberculosis, was developed. Artificial Neural Network was applied to verify the output of the equation. The risk percentage was detected by focusing only on the risk factors. The initial weightage value for the calculation was taken from other studies on this disease.

There are other methods that have been developed with a similar objective, but these did not completely focus on risk factor. Some existing methods are unreliable because they use the number of exposed and unexposed people to the disease and do not rely on risk factors. Other methods have been based on risk factors but the results were presented in odd ratios instead of percentages. The new equation developed in this study allows the assessment of the disease in terms of risk percentage. Real-time analysis of the data can also be observed due to the application of a machine learning method.

**Methods**

The dynamic calculation method in this study is based on a Decision Tree and machine learning. The system consists of a database, rule input, and output (Figure 1). The initial database was gathered from 20 subjects. The data included the risk factors that have been classified into three groups i.e. LEL, MEL, and HEL, as described above (Table 1). A conventional Decision Tree was used to develop the new equation, while the ANN algorithm was used to calculate the risk of disease in percentage. A datasheet was created in Microsoft Excel, and the whole system implemented using MATLAB software. The output from previous studies involving risk prediction models was also verified in this study.

**Figure 1. Methodology block**

Figure 2 shows the Decision Tree model developed in this study. It shows the correlation of the risk factors and percentages, which are the risk weightage of a person having TB. This will be used in the calculation directly, according to certain conditions.

**Figure 2. Decision Tree model for TB**
Environment-related risk factors (HEL) have a very huge impact on the disease. In this case, heavy smokers, people with high alcohol consumption, and people who have a high exposure to pollution have greatly increased chances of contracting TB\(^3\)\(^-\)\(^6\).

Lack of immunity is related to malnutrition, which is calculated from the level of albumin and haemoglobin. The level of malnutrition is inversely proportional to the level of albumin and haemoglobin. As people with active TB can infect others, lack of immunity is also considered a factor.

Population in a low geographical status area is usually more likely to be exposed to TB, because of the probability of this area to being exposed to pollution\(^2\)\(^-\)\(^9\). In this study, the geographical factor was not considered as a direct input. On the other hand, pollution was considered as a passive input as part of the geographical factor.

A study showed that males have a higher probability of contracting TB\(^1\)\(^0\)\(^-\)\(^1\(^1\)\(^\)\(^2\). The study also shows that males have a higher rate of exposure to the disease compared to females. A previous study showed that young people had a higher rate of TB exposure. Due to bad health conditions, very old people also have a higher chance of getting TB\(^1\)\(^2\).

Studies have also shown that there is a relationship between age and gender\(^1\)\(^1\)\(^-\)\(^1\(^3\). The studies show that the young and middle-aged people having a higher chance of contracting TB. They also show the influence of gender, where males have a higher rate of getting TB compared to females.

From a study on family history, females at all ages showed a higher incidence of previous contact, ranging from over 30% in those under 15 years down to 17% in those over 40\(^2\)\(^,\)\(^3\)\(^,\)\(^1\(^2\)\(^,\)\(^1\(^3\). It is thought that the wider opportunities of exposure to infection in the female population is due to domestic reasons. Nursing duties might also be an important factor.

Haemoglobin levels have high predictive value of the incidence and mortality rate of TB\(^7\). Increased severity of anaemia is associated with exceptionally high rates of TB, especially during long-term antiretroviral therapy (ART)\(^8\)\(^-\)\(^9\),\(^1\(^4\). In this study, haemoglobin level is considered normal when it is above 11 g/dL.

The risk of TB increased with the number of households in the compound, and with the number of persons in the household who have had TB in the past. The risk of TB was also found to increase with smoking, with a significant dose-response trend according to duration of smoking, as well as with alcohol intake and drug use.

In industrialised countries, TB is classically associated with poor living conditions. There have been a few studies conducted in poor countries to investigate the effect of socio-economic factors on TB. Some of the studies found that the risk of TB was higher in poor living areas.

**Rule/algorithm using conventional equation:**

\[
\text{GENDER [F(1*0.1) or M(3*0.1)]} + \text{ AGE [(20≤Age≤35)*0.2 or (age>49)* 0.2 or (age * 0.1)]} + \text{ FAMILY HISTORY [(NO=0) or YES, If M(1*0.1); F(2*0.1)]} + \text{ MALNUTRITION [Haemoglobin output + Albumin output + polluted area output * 0.2]} + \text{ BEING TOUCH WITH TB PATIENT [Number of months * 0.1]} + \text{ Lack of IMMUNITY [Polluted area + alcohol consumption + smoking * 0.3]} = \text{TB RISK}
\]

Input of risk factors: Albumin < 2.1 g/L (Not healthy), Haemoglobin < 11 level (Not healthy), Smoking = number of cigarettes, Alcohol = mL (1000ml=1L), Polluted area = %, Initial weightage = %.

The number of males that have TB is 3 times higher than females; therefore the input was set to 3 for males and 1 for females, and then multiplied with the weightage. Young people aged between 20 to 35 years old, and older people aged more than 59, are also at risk of having TB more than other ages. The weightage for these two age groups was therefore set higher than the rest. The lack of immunity was represented using the “AND” condition. The inputs were associated with the “AND” condition in the equation. Tobacco smoking, passive smoking, and indoor air pollution from biomass fuels have been implicated as risk factors for tuberculosis (TB) infection, disease, and death\(^6\).

After developing the conventional equation, a datasheet with an initial 20 subjects was created. This is the retrospective data, which was applied with the Artificial Neural Network (ANN) using MATLAB software. The datasheet was then loaded in the workspace as input and output, and the system was trained using the machine learning method. As there are 10 inputs (risk factors for the disease), 10 neurons were chosen for each factor. For each factor, an individual hidden layer was selected. The system was then trained by assigning the
input as input data and output as target data. ANN then produced the final output.

**Results and Discussion**

Table 2 and 3 shows the data input for the 20 subjects using the equation developed in this study. There are 10 inputs and 2 outputs. One of the outputs is the final risk percentage, while the other is the immunity output (a lower value of immunity output is favourable). The input for alcohol consumption was limited to 3 L. Age limit was set to 100 years, while pollution was limited between 0%–100%.

From the result, we can see that there are different ranges of output. Individuals with a risk percentage of more than 50% are advised to consult a medical professional for check-up, while individuals with a very high risk percentage are advised to monitor their health and start treatment immediately after being diagnosed by the doctor. Individuals with a risk percentage below 20% can be considered within the normal range but are advised to maintain a healthy lifestyle and good health.

The ANN produced the output according to the machine learning method. Table 4 shows the results after 20 subjects were input into the system, and the output provided by the ANN.

The results show that most of the output for the conventional method has almost zero errors, while some of the output had errors that were due to the small number of subjects. In this system, the calculation time was set to only 6 seconds. It is assumed that the result will show zero errors if the calculation time were set to 1000 seconds.

Conclusion

This study began with the identification and classification of TB risk factors. A new equation for risk calculation was developed and then verified using ANN and basic analysis performed to verify the method. Machine learning application showed some variance in the output, which is due to the number of factors and the adjusted weightage.

One of the differences between the method in this study and previous studies is that the risk percentage was determined via calculation. The most common risk factors were chosen for input in the calculation so that the result would be easily understood even for non-medical personnel. For future recommendations, after this method has been established, other risk factors should also be considered such as HIV and diabetes\textsuperscript{16}, marital status, and air intake, could be taken into account. This should increase the accuracy of the calculation, which can then be more reliable for public use. Besides the risk percentage of tuberculosis, the risk percentage of other diseases could be calculated as well.

In this study, although the Decision Tree was more accurate than ANN, ANN can be more accurate if the number of training data were increased. The results show that, based on the retrospective data, the newly developed method in this study is better than other existing methods.

Safety Critical Element Methodology in an Oil and Gas Company

Deddy Fernando WH¹, Zulkifli Djunaidi¹, Mila Tejamaya¹*,
¹Department of Occupational Health and safety, Faculty of Public Health, Universitas Indonesia, Depok, Indonesia

Abstract

Barrier systems are used to protect humans and assets from hazards. These barrier systems may be classified as either active or passive barrier systems, and as physical, technical or human/operational barrier systems. Safety Critical Elements (SCE) are part of these barrier systems to protect against major hazardous events such as fire, explosions, collisions, etc. SCEs prevent, control, mitigate and facilitate safe evacuation from the identified major hazards. However, there is no clear methodology to define which systems or equipment are SCE and what to do after SCEs are declared.

This study aimed to develop a specific methodology for implementing SCEs in an oil and gas company. The methodology involved risk assessment, major hazard scenario development, SCE identification, establishing a performance standard, developing maintenance, inspection and testing plans, implementing assurance activities and, finally, issuing a key performance indicator.

The results of this methodology can provide guidance for defining SCE systems and equipment and what to do after these SCE systems are established.

Keywords: Barrier system, Safety Critical element, Major accident.

Introduction

The petroleum industry is facing risk from major accidents, i.e., accidents with major consequences, that can cause multiple fatalities and/or massive oil spills (¹). Many concepts, programs and assessments have been developed to reduce risk to personnel, assets and the environment from these hazards. Safety Critical elements (SCEs) were specifically developed to protect against major hazards. SCEs form barriers to protect personnel, the environment and assets from a major hazardous event. SCEs prevent, control, mitigate and facilitate safe evacuation from the identified hazards. SCEs are defined as those parts of an installation or an operational organization whose failure could cause or contribute substantially to a major accident (²). These

barrier systems may be classified as either active or passive barrier systems and as physical, technical or human/operational barrier systems (³) Because SCEs play an essential role in assurance activities (maintenance, inspection and testing), SCEs must be in place to continuously demonstrate that they remain fit for their purpose during an installation’s entire life.

To implement SCEs for a vast inventory of assets and activities, management efforts should focus on the installation elements that are the most critical to safety, with the objective of minimizing the risk of a major accident hazard (MAH). These critical elements should be designated as SCEs.

Systems and equipment that are designated as SCEs should be treated differently than other systems and equipment. The critical nature of SCEs means that their maintenance must be the highest priority, ranked above that of any other system or equipment. SCEs’ performance must meet required standards, and SCEs should be monitored using dedicated indicators. These processes should be implemented in any company that designates SCEs.

This study focused on SCE methodology. After defining SCEs, a step-by-step implementation process is discussed. There is little research that specifically discusses the methodology of SCEs. Most research has focused on barrier management systems; SCEs are part of these systems, such as the PETROMAKS Innovation project found in SINTEX report A 26845. Gasco company is a leading oil and gas producer in the UAE that has published a methodology for SCE implementation, but this is the only paper that discusses SCE methodology.

**Methods**

The proposed methodology was developed as a guideline to implement SCEs. This research involved a literature review and an observational process. As stated above, there are few sources specifically related to SCEs, as most studies discuss barrier management, of which is SCEs are part.

Gasco company has published an example method in the *Society of Petroleum Engineers* (SPE) journal. In this method, the identification of SCEs is not integrated into the guidelines. The equipment or systems that are defined as SCE have been previously defined⁴. DNV proposed that risk assessment is part of SCE implementation⁵, since this step covers hazard identification, risk analysis and risk evaluation.

The implementation of SCEs should start with identifying hazards that have major consequences. These major hazards are identified and their risks are assessed through risk assessment and major risk register. These steps are mandatory and are a main reason why SCEs are needed.

**Risk Assessment, Major Scenario Development, SCE Identification**

Risk assessment is intended to identify, establish and describe barrier functions and to specify the properties of an individual barrier’s elements⁶. In this paper, risk assessment specifically refers to risks that are generated by flammable, toxic and/or explosive substances. These risks concern personnel, the public, the environment and the integrity of the installation.

Gasco company implements risk assessment to identify major hazards; appropriate measures are developed separately and are not included in the SCE methodology. DNV proposed that identifying SCEs should be done via risk assessment. This step is important, since identified major hazards have serious consequences and specific SCEs against these hazards should be established.

Below is a list of scenarios (Typical) for Major Accident Hazards in offshore and onshore platforms. This list is taken from output studies such as Hazard identification (Hazid), Major Accident Hazard Register, dropped object study, ship collision study, etc.

- Platform Impairment
- Dropped Objects
- Fire & Explosions
- Generic failure: corrosion, vibrations, erosion, mechanical failure, weld defects
- Human Error
- Liquid carryover due to control valve failure
- Overpressure
- Pollution
- Segregation of drain system
- Ship collision
- Vent blockage

**Establishment of performance standards:** A performance standard is a statement that can be expressed in qualitative or quantitative terms, as appropriate, of the performance required of a safety critical element in order to ensure the safety and integrity of the installation⁷.

Once the key safety equipment or systems have been identified as SCEs, it is necessary to define the functions required to perform and confirm whether the actual equipment and systems can consistently and continuously perform these functions. That process is defined in the performance standard.

According to the Health and Safety executive report (safety case, 2005), safety critical elements should be verified through a suitable scheme. This scheme should be dependable and effective when required and perform as intended⁷. DNV strongly proposed that performance standards should be established for safety critical elements⁷.

**SCE Assurance Means:** SCE assurance activities must be designed to continuously demonstrate that SCEs remain fit for their intended purposes during their entire service life. This process will confirm that the SCE requirements are being met and that the results are recorded and assessed. SCE procedures should be continuously improved as part of a Plan-Do-Check-Act (PDCA) process.
SCE Key Performance Indicator: Key Performance Indicators (KPIs) are used to monitor SCEs’ integrity. The measured results should be tracked against a performance indicator target. Tolerability levels for the degree of acceptability performance against those indicators should also be set. An Action Plan is needed in case there are any issues that may affect SCEs’ integrity.

It is recommended that facilities determine which barriers are most critical for managing major incident risk then select suitable leading and lagging KPIs for each critical barrier⁸).

Results

The proposed methodology for SCEs is illustrated below.

Safety Critical Element Methodology: Risk Assessment → Major Scenario Development → SCE Identification → Performance Standard → Maintenance, Inspection & Testing Plan → Assurance Activities → Integrity KPI

Performance Standard Assurance Process, SCE Assurance, SCE Key Performance Indicator: Define SCE Functional Requirement → Define SCE Design Assurance → Define SCE Operational Verification → SCE Measuring Point → Maintenance Plan → Operational Integrity Assurance & Verification → Develop Integrity Reporting → Execute SCE action plans

Discussion

Risk assessment, SCE Identification & Major Hazard scenario Development Process: First, risk assessment is used to identify any risk that is associated with major hazards. A major hazard is defined as any hazard that generates a consequence level of 4 to 5 to people, the environment and assets. The risk is then ranked using a risk matrix. The risk matrix may differ from one company to another. In this case, the risk matrix was a 5x5 table.

Preliminary risk assessment is for conservatively establishing a scenario to be studied in detailed risk analysis. Two methods are commonly used for preliminary risk assessment: simplified method and rigorous method. Detailed risk analysis reconfirms the risk associated with the major scenarios identified in the preliminary risk assessment. The main tasks of this step are to quantify the frequency of events and hazards outcomes, estimate probabilistic damage and present the scenario risk results of the risk matrix.

Risk evaluation is implemented to assist the decision-making process based on the results of risk analysis. This step involves comparing the level of risk with the acceptance criteria. A risk register, or Major risk register (specified for risks related to major hazards), should be created. This register contains a summary of the results of the risk assessment for all identified major risks, as well as a list of all existing risk reduction measures related to major risk.

Performance Standard Establishment and Assurance: Performance standards are key technical requirements to be met by SCEs to ensure they effectively operate on demand, perform as expected and can survive incidents. Performance standards include all the controls that are needed to verify SCEs’ integrity, as well as the minimum performance that should be maintained for each control point through operational and verification activities.

The three criteria of functionality, availability and survivability should cover these main activities:

1. Functionality: To define SCEs’ main functions based on related documents, such as internal documents or any related standards
2. Availability: To ensure the availability of SCEs by maintaining their reliability, which includes managing equipment obsolescence, defining a spare parts’ policy and expediting the procurement process
3. Survivability: To review integrity and design in order to keep SCE’s functions during an emergency

SCE Assurance activities, Maintenance/Inspection & Testing Plan

There are two ways to perform assurance activities: assurance design and assurance operation. Equipment should be checked against the initial design; this can be done through external standards, company standards, codes, etc.

After checking the design, the assurance operation should be done. Operational verification consists of compiling the means of assurance operations for all SCE controls (Functionality, Availability and Survivability). This should be performed during daily normal operations and maintenance/inspection. Operational verification consists of onsite and offsite verification. On-site verification activities include visual checks, function tests, performance tests and preventive maintenance. Off-site verification activities include reviewing related reports (e.g., maintenance reports and inspection reports), work scheduling, stock material availability and data sheets.

SCE Key Performance Indicators: The indicators that can be used to monitor SCEs’ performance include:

- Failure of SCE during tests
- SCE Maintenance Backlog
- SCE Inspection Backlog

Below are the equipment or systems identified as SCEs in the oil and gas industry. They are divided into 4 groups: prevention elements, control elements, mitigation elements and evacuation elements. These main functions are used as barriers against major accident hazards as mentioned in METHODS.

1. Prevention Elements
   - Collision avoidance system: Navigational aids, Fog Horn
   - Structural Integrity: Jacket
   - Process Containment Integrity: Pressure Vessel & Large Storage Tank, Pipework, Exchangers
   - Pipelines and riser integrity: Pipeline & risers
   - Relief systems: Relief valves/PSV
   - HVAC Systems: HVAC systems and fire dampers
   - Ignition Prevention Systems: Flame Arrestors
   - Crane and lifting equipment: Powered Cranes
   - Corrosion Prevention and monitoring: Corrosion monitoring, corrosion inhibitor

2. Control Elements
   - Flammable Gas Detection: Fixed point Gas Detectors, Fixed acoustic leak detectors, Smoke Detectors
   - Fire Detection: Flame Detectors, Fusible loops
   - Fire and gas control system
   - Emergency isolation: ESD system, ESD valves
   - Riser/pipeline ESDV’s
   - Reservoir isolation & containment: Well control facilities, Down hole safety valves
   - Emergency depressurization: Blowdown valves

3. Mitigation Elements
   - Fire pumps
   - Firewater systems: Diesel day tanks, Deluge system, Firewater monitors, Hydrants
   - Portable/trolley mounted extinguishers: Hose Reels, Portable fire extinguishers
4. Evacuation Elements
- Alarm & Public address systems
- Emergency lighting
- Lifeboat
- Liferafts
- Maintained power supplies
- Means of escape to sea
- Personnel protective equipment
- Rescue & recovery facilities: Emergency Response, Rescue Vessel

Conclusions

The present study was aimed at developing a methodology to implement safety critical elements (SCEs), specifically in an oil and gas company. This study involved risk assessment, major development scenario, SCE identification, establishment of performance standards, maintenance, an inspection and testing plan, assurance activities, and a report in the form of a Key performance indicator (KPI).

Applying this method can lead to clear definitions for all equipment/systems defined as SCEs and help ensure these SCEs remain fit during the whole life of an installation.

Linkage Model of Brand Equity and Word of Mouth Toward Purchase Intention in Surgery Speciality Hospital Ropanasuri Padang, Indonesia

Nurmaines Adhyka¹, Ratni Prima Lita² and Rima Semiarty¹

¹Department of Public Health, Medicine Faculty, ²Department of Management, Economics Faculty, Andalas University, Padang, Indonesia

Abstract

Introduction: In order to achieve effective and efficient organization in a hospital, the management team must ensure that the hospital continues to dominate in a highly competitive market. It has been established that brand equity and word of mouth play an important role in influencing patients’ purchase intentions. The aim of this study was to evaluate the association between the dimensions of brand equity and the effect of word of mouth on customer purchase intentions in the health sector.

Method: The survey method was used to collect data from 115 patients without national coverage at the specialist surgery hospital, Ropanasuri Padang, in Indonesia. Convenience sampling was used to choose the patients, and a cross-sectional design was also implemented. Hypothesis testing was performed using structural equation modeling.

Results: This study demonstrates that brand awareness, brand association, perceived quality, and brand loyalty are important dimensions in building brand equity. In addition, brand equity and word of mouth were found to have a significant impact on patients’ purchase intentions in hospitals.

Conclusion: These results provide an insight into the importance of building strong brand equity dimensions in the highly competitive hospital services market.

Keywords: Brand equity; hospital; purchase intention; word of mouth.

Introduction

In today’s world, the paradigms relating to hospital organization are completely different to what they were, and the hospital is no longer simply a service organization. In effect, the evolution of technology has transformed hospitals into profit-oriented business entities¹. In order to achieve dominance in an increasingly competitive market, hospitals need to offer high-quality, competitive services ². One way to win in the market is to maintain the company brand by promising the value that consumers expect for a product (brand equity).

Strengthening brand equity starts from the consumers’ awareness of the brand (brand awareness) and their tendency to remain loyal to brands they know. The next step is consumers’ behavior in associating a brand with a product and differentiating that product from its competitors (brand association)³. The results of this association will establish the consumers’ perceptions of brand quality (perceived quality), and their loyalty will emerge if the perceived quality accords with their perceptions⁴. Marketing communication is formed on the basis of customers’ experiences and willingness to recommend the product; this is also known as word-of-mouth communication⁵. The formation of strong brand equity supported by word-of-mouth communication may influence people’s decisions regarding the purchase of hospital services. In this context, “purchase” relates to buying medical services⁶.

This study was conducted in Ropanasuri Hospital, which specializes in surgery. During the hospital’s development, it used the power of brand equity and word of mouth to increase patients’ purchase intentions during visits. Unlike previous studies, which concentrated solely on the dimensions of brand equity, this study combined the brand equity dimensions and word-of-mouth factors in relation to the purchase intention of patients without national health coverage. Patients who use national health coverage do not have many hospital choices due to zoning systems which require choosing the referral hospital closest to the patient’s home. It is expected that hospital management might see the strength of brand equity and word of mouth from other perspectives.

Methods

The objective of the study was to investigate relationship models in terms of particular brand equity dimensions and word-of-mouth factors in patients without national health coverage who visited the specialist surgery hospital in Padang, Indonesia. The following hypotheses were tested:

**H1.** Brand equity has a positive influence on purchase intentions

**H2.** Word of mouth has a positive influence on purchase intentions

Using the convenience sampling method, samples were collected from 115 patients without national health coverage who were receiving outpatient services at the specialist surgery hospital, Ropanasuri. The data were analyzed using SmartPLS 2.0. In the first step, the data were tested to determine factor loadings and cross loadings. Using Cronbach’s alpha, composite reliabilities and average variances were then extracted. Second, the data were tested using structural models to evaluate the coefficient of determination ($R^2$). Last, we confirmed our hypotheses through partial least square structural equation modeling (PLS-SEM). In essence, SEMs are statistical models of linear relationships among latent (unobserved) and manifest (observed) variables. Their purpose is to estimate the coefficients in a set of structural equations.

Figure 1 presents the conceptual framework tested in this study. We identified four dimensions of brand equity (brand awareness, brand association, perceived quality, and brand loyalty), as well as the effect of word of mouth on purchase intention.

Items for measuring each variable were adopted from existing literature. Table 1 presents the source and details relating to 23 indicators used to measure the variables included in the study. These were measured using a five-point Likert-type scale based on agree-disagree respondent perceptions.

Results

The model used in this study was described in Figure 2.

**Figure 2. Structural Equation Model**

**Measurement of the Outer Model:** The aim of this measurement was to evaluate a validity and reliability instrument. Validity was examined by noting the convergent validity and discriminant validity of a construct. Convergent validity was supported if the outer loading value was more than 0.7. If this was the case, the indicator represented the construct; if not, it was eliminated. In Table 2, we found that some indicators had an outer loading value of below 0.7 (BA2, BA4, and PQ1), and these were therefore eliminated.

Discriminant validity represents the extent to which the construct is empirically distinct from other constructs; in other words, the construct measures what it is intended to measure. Table 3 shows how each indicator has a higher score than the other constructs.

The reliability analysis demonstrated value based on Cronbach’s alpha and composite reliability. Composite reliability is used to examine indicators in internal measurements of consistency. Essentially, it is used to address any deficiencies arising from the Cronbach’s alpha and reliability tests. Composite reliability, which prioritizes indicators based on individual reliability, is in line with the PLS-SEM algorithm calculations; these calculations do not assume all indicator values are the same in the population. All the Cronbach’s alpha and composite reliability values in Table 4 were above 0.6, which indicates that all the constructs used in this study have good reliability. Therefore, we can conclude that the instrument used in the study met the full set of criteria for validity and reliability.

Measurement of the Inner Model: This measurement observed the model’s prediction accuracy, and other external variables were added. The variables measured were brand equity and purchase intention.
Accuracy in relation to brand equity was found in the four dimensions, while purchase intention was built on brand equity and word of mouth. Table 5 shows coefficient of determination value showed that brand equity variable 99.6% were affected by brand awareness, brand association, perceived quality and brand loyalty. Meanwhile, purchase intention variable 54.7% were affected by brand equity and word of mouth.

Discussion

This study showed that brand equity was build from brand awareness, brand association, perceived quality, and brand loyalty. Brand equity has strong influence on purchase intention than word of mouth, although both of variables had significant value on purchase intention to hospital. It also set out to verify the findings of previous studies by Jalivand but this time in a different country and industrial context. Earlier study about healthcare service by Altaf has reported that brand awareness has less impact on loyalty while brand loyalty was the most contributing factors in generating brand equity. Khan, found that Word of Mouth has a positive impact on Consumer Purchase Intention in clothing industry.

Patients without using health national insurance have many choices in choosing hospital. Therefore they will consider many things before it. Hospital should have a characteristic that could be remembered by patients, and then being able to associate it with good things about hospital, able to perceived patients perceptions about service so could foster loyalty and has a willing to inform others about the hospital service.

Strengthening brand equity is strongly recommended to be a priority for managers to increase patient visits. It could be done by differentiating service products and improving personal performance and hospital facilities. The manager must focus on market target in the marketing strategy. In word of mouth marketing strategy, manager has to able to identify loyal patients who could help spreading the information to others. Build strong loyalty bond with customers, help manager to outcompete the competitor. Word of mouth effectiveness reduced the search process in purchasing a product/service and save time and money. Information from trusted sources is believed strengthen someone to purchase intention on hospital.

Conclusions

In four dimension of brand equity; brand awareness, brand association, perceived quality and brand loyalty of surgery specialist hospital Ropanasuri hospital is considered good by patients. There is significant relationship between brand equity and word of mouth to purchase intention to visit in surgery specialist hospital Ropanasuri Hospital in Padang City.

Acknowledgment: The authors would like to acknowledge Surgery Speciality Hospital Ropanasuri’s staff and patient also Departement of Public Health Andalas University for their support in the preparation of this paper.

Conflict of Interest: The authors declare that there is no conflict of interests.

Source of Funding: This study is self-funded.

Ethical Clearance: This study is a literature review so it does not require for ethical clearance.

Abstract

Cortical reorganization post stroke has great impact on upper extremity motor recovery. Purpose: to investigate the effect of low frequency repetitive transcranial magnetic stimulation (LF-rTMS) on cortical excitability and upper limb motor performance post stroke. Forty ischemic stroke patients aged between 50-65 years were randomly assigned into two groups (“A” control & “B” study). Both groups were treated with a selected physical therapy program for the upper limb but only group “B” received contralesional (LF-rTMS) sessions, daily for two consecutive weeks in addition. Cortical excitability, upper limb motor performance and grip strength were measured and compared for both groups before and after intervention using single pulse TMS to measure contra- and ipsilateral active motor threshold (cAMT, iAMT), Fugl-Myer Assessment Upper Extremity scale (FMA-UE), and hand grip dynamometer for grip strength, respectively. There was significant difference in the post treatment findings of all measured variables between both groups in favour of group B (P ≤0.05). The correlation results revealed significant linear correlation between the tested cortical excitability measures (cAMT, iAMT and iAMT/cAMT difference) and the findings of upper limb motor performance (FMA-UE). The study revealed that 10 contralesional LF-rTMS sessions improved the upper limb functional performance via enhancing cortical reorganization post stroke. Cortical excitability measures as (cAMT, iAMT and iAMT/cAMT difference) could act as an accurate predictor regarding the level of upper limb motor recovery in stroke patients.

Keywords: Cortical excitability; Cortical reorganization; Transcranial magnetic stimulation; Single pulse TMS; Upper limb motor performance.

Introduction

Stroke is envisioned as a global health problem and a leading cause of adult disability. Two-thirds of all strokes occur in developing countries1. Upper limb motor dysfunction is a significant disability that affects daily living and increases the burden on the patients and their families2. Cortical modulation interventions could enhance the therapy-induced upper limb recovery in stroke populations3,4.

After a stroke, there is reduced inhibition from the stroke affected area “ipsilesional hemisphere” onto the unaffected “contralesional hemisphere”, resulting in increased excitability of the contralesional hemisphere which ultimately leads to excessive interhemispheric inhibition onto ipsilesional cortex. This excessive imbalanced inhibition impedes the neuroplasticity and limits the gains in motor recovery 5,6.

Repetitive transcranial magnetic stimulation (rTMS) is a non-invasive stimulation that induces electrical currents in the brain tissues aiming to promote cortical reorganization and subsequently enhance the functional
Modulation of cortical excitability via repetitive transcranial magnetic stimulation (rTMS) was discussed in prior studies. However, the effect of contralesional low frequency repetitive transcranial magnetic stimulation (LF-rTMS) on cortical excitability measures of each hemisphere was barely discussed.

Cortical excitability measures using TMS can make a prediction about the level of upper limb motor performance in stroke patients. Other TMS measures used the peak to peak amplitude of the MEP, others measure the functional connectivity between different cortical areas using TMS mapping, cortical silent period (SP), and paired pulse TMS. However, most of these studies require complex application manoeuvres and much time and effort for implementation.

This study was designed to investigate the effect of contralesional low frequency repetitive transcranial magnetic stimulation (LF-rTMS) on cortical excitability and the subsequent changes upon the upper limb functional performance in subacute stroke patients.

**Materials and Methods**

**Area of study and sampling:** The study used a single-blind, randomized controlled design. Intervention procedures for the enrolled patients consisted of ten daily sessions for two consecutive weeks. Each patient in the control group (A) was treated with a selected upper limb physical therapy program, while each patient in the study group (B) was treated with the (LF-rTMS) on the contralesional primary motor “hotspot” in addition to same program as (GB).

Forty first ever hemiparetic subacute ischemic stroke patients from both sexes with age ranged between 50 and 65 were recruited in this study. They were enrolled in the study between January 2018 to November 2018. This study was conducted in the transcranial magnetic lab of the Clinical Neurophysiology Unit and in the Outpatient Physical Therapy clinic, Department 26, Faculty of Medicine, Cairo University.

**A. Cortical excitability examination:** Cortical excitability was assessed before and after the whole treatment protocol for each patient in both groups by measuring the active motor threshold (AMT) of both the unaffected (contralesional-cAMT) and the affected (ipsilesional- iAMT) hemispheres, in addition to calculating the difference in the active motor threshold between both cortices (iAMT/cAMT difference). Single pulse TMS was used to assess (AMT) of each hemisphere with the visible observation of contralateral first dorsal interossous (FDI) muscle contraction (Observational Measurement-Motor Threshold) (OM-MT) (Fig1). Cortical excitability assessed variables for each patient were:

a. Contralesional Active Motor Threshold Examination (cAMT).

b. Ipsilesional Active Motor Threshold Examination (iAMT).

c. The active motor threshold difference between both cortices (iAMT/cAMT difference) = (iAMT) - (cAMT).

**B. LF-rTMS intervention procedures:** The Magstim Rapid2 magnetic stimulator system (Model P/N 3576-23-09, Magstim Company, USA) was used to deliver 1-Hz stimulation at 90% of the Active Motor Threshold (AMT) to the “hot spot” of the primary cerebral cortex (M1) in the contralesional hemisphere via a 70-mm figure-8 coil. Each session lasted 20 minutes.

**C. Correlation between cortical excitability and upper limb motor function:** Correlation between the level of upper limb motor function represented by (FMA-UE) and the cortical excitability represented by (cAMT, iAMT and iAMT/cAMT difference) were assessed for (GA & GB).

**Statistical Analysis**

Descriptive data for patients, characteristics and dependent variables was calculated as mean ± SD. Parametric procedures as paired and unpaired t-tests were conducted to analyze the inter-group and intra-group cortical excitability and upper limb motor function findings before and after treatment. Chi-square ($\chi^2$) and fisher’s exact tests were applied to compare the categorical data of the patients’ main characteristics and clinical features within and between groups. Pearson
correlation coefficient (r) was used to correlate between level of upper limb motor impairment represented by Fugl-Myer upper extremity scale and cortical excitability findings.

**Findings**

**Patients' demographics and clinical characteristics:** There was no significant difference in the distribution of patients between both groups with regards to their main demographics (age & duration of illness) and clinical characteristics (gender & smoking history) (Table 1).

**Cortical excitability Findings:** There was significant improvement in the post treatment cortical excitability findings (increased (cAMT) and decreased (iAMT), (iAMT/cAMT difference)) in favor to (GB). As the post treatment mean values of (cAMT) were (60.5±4.310) and (72.65±4.771), (iAMT) were (81.80±4.797) and (76.35±2.390), while (iAMT / cAMT difference) were (21.30±8.724) and (4.4±5.670) for groups A and B respectively, with (P < 0.05) (Table 2).

**Upper-extremity motor function findings:** There was significant improvement in the post treatment upper limb motor function and grip strength scores in favor to (GB). As the post treatment mean values of FMA-UE scores were (87.85±4.716) and (94.70±4.014), hand grip dynamometer scores were (29.45±6.386) and (33 ±6.122) for groups A and B respectively, with (P <0.05) (Table 3).

**Correlation between cortical excitability and upper limb motor function:** There was a positive linear correlation between (FMA-UE scores) and (cAMT), and negative linear correlations between (FMA-UE scores) and both (iAMT), (iAMT/cAMT difference). Where, the P values were (≤ 0.001) (fig 2).

Figure (1). Cortical excitability measurement using (MagstimRapid2system) with a figure-of-eight coil
a. Measuring the cAMT from the unaffected hemisphere with the coil above the contralesional primary motor ‘hotspot’
b. Measuring the iAMT from the affected hemisphere with the coil above the ipsilesional primary motor ‘hotspot’.
Discussion and Conclusion

This is a preliminary randomized study that correlated upper limb motor performance level in stroke patients with cortical excitability variables using the single pulse TMS-induced observational muscle contraction. Where the previous studies relied on the size of the MEP (amplitude), silent period interval, intracortical inhibition (ICI) or facilitation (ICF)\textsuperscript{11,16}. The use of single pulse TMS-induced observational muscle contraction to predict upper limb motor recovery post stroke could save much more time, effort and expenses exerted by other complicated and more sophisticated procedures.

The study findings revealed that, application of LF-rTMS on the primary motor “hotspot” of the contralesional (unaffected) hemisphere in subacute stroke patients could enhance cortical modulations in both the contralesional and ipsilesional hemispheres compared with the control group. This may be attributed to the ability of contralesional LF-rTMS to apply disinhibition on the surviving neurons in the perilesional areas via diverse molecular, neurotransmitter and synaptic plasticity mechanisms\textsuperscript{17,18}.

Correlation results revealed very high significant positive linear correlation between (FMA-UE) scores and (cAMT) and a very high significant negative linear correlation between (FMA-UE) scores and (iAMT) either pre or post treatment. This suggested that inhibition of the contralesional hemisphere while excitation of the ipsilesional hemisphere would consequently be associated with improved upper limb motor performance. These results emphasize the notion that, normalizing the cortical reorganization is crucial to enhance the functional motor recovery in the hemiparetic upper limb\textsuperscript{19}.

Post treatment changes in the (observational measurement) cortical excitability findings (cAMT),...
(iAMT) and (iAMT/cAMT difference) were associated with improvement in the upper limb function represented by FMA-UE and grip strength in both groups. This support the notion that enhancing cortical reorganization is crucial to augment the functional motor recovery in the hemiparetic upper limb post stroke\textsuperscript{20,21}.

Another point of interest is the (iAMT/cAMT difference) which is the difference in the active motor threshold between both cortices, it refers to the degree of cortical interhemispheric balance. The study findings revealed very a negative linear correlation between (FMA-UE) scores and (iAMT/cAMT difference) either pre or post treatment, which means that as the difference in the active motor threshold between both cortices decrease, the upper limb motor performance would eventually be promoted in subacute stroke patients. Thus (iAMT/cAMT difference) could be used as an accurate predictor regarding the interhemispheric balance between both cortices, where prior studies examine cortical interhemispheric balance using TMS, fMRI, or DTI and many other non-invasive brain stimulation methods\textsuperscript{22,23}.

This study supports the role of contralesional LF-rTMS in re-establishing the cortical interhemispheric balance and upper limb motor recovery post stroke\textsuperscript{24,25}. However, more studies are recommended to figure out whether the changes that occurred on the level of cortical excitability and upper limb motor performance are impacted solely by the application of LF-rTMS regardless the conventional physical therapy program. Also, follow up assessments are recommended to reveal whether these enhancements in cortical excitability and the upper limb motor function are long lasting.

The current study revealed that contralesional Lf-rTMS sessions as an adjuvant to a selected upper limb physical therapy program improved the upper limb functional performance via enhancing cortical reorganization post stroke Also, Cortical excitability measures as (cAMT, iAMT and iAMT/cAMT difference) could act as accurate and more feasible predictors regarding the level of upper limb motor recovery in stroke patients.

**Acknowledgement:** Authors express appreciation to all our study patients. Heartfelt thanks extended to the clinical neurophysiology lab staff.

Correlation Study of Functional Performance between Diabetic and Non-Diabetic Patients with Knee Osteoarthritis

Abla M Hamed1*, Mohamed H. Aboeleinen2, Hala A. Abdelgawad3, Shimaa N. Aboelazm4

1Physical Therapy Department For Cardiopulmonary and Geriatrics, Faculty of Physical Therapy, Misr University for Science and Technology, Egypt, 2Basic Science Department, Faculty of Physical Therapy, Misr University for Science and Technology, Egypt, 3Physical Therapy Department For Gyna and Pediatric and Its Surgery, Faculty of Physical Therapy, Misr University for Science and Technology, Egypt, 4Basic Science Department, Faculty of Physical Therapy, Pharos University of Alexandria, Egypt

Abstract

Osteoarthritis is recently considered a part of metabolic syndrome which shifts the traditional concept that believed on, osteoarthritis is a degenerative joint disease based on continuous mechanical overload to a metabolic pathogenesis. The aim of our study designed to investigate the correlation between type two diabetes and knee osteoarthritis with the impact on functional performance. One hundred women with knee osteoarthritis enrolled in the study with mean age 50.5±3.11 years and mean BMI 26.23±2.48 Kg/m2. All patients were subjected to radiological assessment to detect the degree of knee osteoarthritis, laboratory investigations to measure glycemic control, Western Ontario and Mc Master Universities Index (WOMAC) scale to evaluate functional performance. All patients assigned into two groups, group A (50 women) as a type two diabetic group and group B (50 women) as a non-diabetic group. Results showed a non-significant correlation between glycemic level and limitations in functional performance in mild knee osteoarthritis. However, there were significant differences among diabetic and non-diabetic groups regarding functional performance. Then our conclusion demonstrated non-significant correlation between type two diabetes and functional performance. Meanwhile, there were significant differences among diabetic and non-diabetic patients regarding functional performance.

Keywords: Type two diabetes, knee osteoarthritis and functional disabilities.

Introduction

Osteoarthritis (OA) is the most frequent and disabling joint disease in adults1. A recent hypothesis suggested a new classification for OA as ageing, metabolic syndrome (Met S), post-traumatic and genetic2

This classification was confirmed by Pelletier and Pietrangelo3, who mentioned that, categories of OA are, post traumatic with age less than 45 years which commonly caused by repetitive mechanical stress, joint fracture or meniscectomy. The second type is age related OA, which occurs over 65 years in hip, knee or hand without any previous trauma or metabolic syndrome. The last one is metabolic syndrome associated with OA with age between 45 to 65 years in patients have at least one of the components of metabolic syndrome (diabetes mellitus, hypertension and dyslipidaemia).

The components of Met S including diabetes mellitus (DM), hypertension or dyslipidaemia may together or separately participate in OA pathophysiology 4.

Every metabolic disorder is associated with OA through different mechanism as hypertension causes sub-chondral ischemia. While dyslipidaemia was leading to lipid deposition in chondrocytes. Hyper glycaemia and OA interact through formation of oxidative stress, advanced glycation end-products and low-grade systemic inflammation. Finally, Obesity altered levels...
of adipokines and degradative enzymes, leading to inhibition of cartilage matrix synthesis and sub-chondral bone remodeling.

The OA joint is characterized by osteophytes, synovial inflammation, cartilage degeneration and bone sclerosis. All these findings titled as “systemic metabolic disturbances and low-grade inflammation”. These findings associated with hyperglycemia that causes a decrease in production of collagen II with increase in free fatty acids that cause inflammation and increase in fibroblast like-synovitis. In addition Courties and Sellam found that, elevated fasting glucose concentration has also been associated with bone marrow lesions which predict OA structural damages.

Diabetes causes much musculoskeletal degeneration that lead to different symptoms such as pain, stiffness and swelling in joints; nodules, tightness and thickened skin; trigger finger; carpal tunnel syndrome, frozen shoulders and severely affected foot.

Knee OA might affect the activities of daily living as a result of reduction in strength, power and muscular endurance, providing decrease in proprioceptive and balance. These changes affect physical function and hinder the performance of functional activities.

The Western Ontario and McMaster University Arthritis Index (WOMAC) questionnaire was a self-administered and specific functional performance assessment for hip and/or knee osteoarthritis patients. Currently it is the most frequently used questionnaire and is known to be a valid, reliable and responsive instrument for patients with OA. High score interpret worse of condition and vice versa regarding pain, stiffness, functional disability or limitations.

Subjects, Materials and Methods

Patients: One hundred women with mild osteoarthritis knee enrolled in this study. They were collected from outpatient orthopedic and diabetes mellitus clinics, Misr University Hospital, Giza during the period from April to November (2018). Their age ranged from 45-55 years with mean equal 50.5±3.11 years and BMI ranged from 25±29.9 Kg/m2 with mean equal 26.23±2.48 Kg/m2. The patients were divided according to their glycemic level into two groups, group A (50 women) with glycemic level represent type two diabetes by less than five years and underwent regular conventional treatment in form of oral hypoglycemic drugs and group B (50 women) as a non-diabetic group.

Exclusion criteria: Our study excluded any candidate having history of trauma, previous knee surgery, injection or deformities. Other conditions suffered from local or systemic inflammation, cardiovascular, renal and hepatic or thyroid problems did not share in our study. Also any case underwent hormonal supplements or lowering cholesterol medications excluded.

All patients signed a written informed consent and were subjected to the following evaluation protocols:

Radiological assessment: All patients underwent radiological assessment in form of X-Ray for both knees from standing and bending positions using (Samsung-Collimator-SDR-OGCL 60A apparatus) and the findings were recorded to detect the degree of osteoarthritis. All patients were suffered from knee osteoarthritis by less than two years.

Laboratory investigations: Following twelve hour overnight fasting, 20 ml venous blood samples were collected from an antecubital vein for all patients in sitting position between 8:00 and 9:00, a.m. Serum was separated by centrifugation and samples were stored at (-80 centigrade) until analyzed in the laboratories of Misr University Hospital. Fasting blood glucose level and glycated hemoglobin (HbA1c) were evaluated for detection of glycemic level.

Assessment of functional performance: Functional performance of all patients was assessed by Western Ontario and McMaster Universities osteoarthritis index (WOMAC) as a functional assessment scale. The WOMAC scale is a widely and standardized questionnaire used to evaluate the condition of patients with osteoarthritis of knee and hip. It is also used to assess back pain, rheumatoid arthritis, systemic lupus erythematosus and fibromyalgia. It includes 24 parameters five for pain, two for stiffness and 17 for physical functioning. The WOMAC scale is valid and reliable. Lower scores indicate better subjective functional abilities. The response points were; None 0, Slight 1, Moderate 2, Severe 3 and Extreme 4. The minimal total possible score is 0 while the maximal total score is 96. In the current study only physical function parameters from WOMAC was detected in both groups.

Anthropometric measurements: Weight and height for all patients were recorded by using ZT-160 HEALTH SCALE for calculating of body mass index BMI to exclude any obese candidate. Body mass index was calculated by dividing weight per kilogram on height per meter square KG/m2.
Statistical analysis: Results were expressed as minimum, maximum, mean and standard deviation. Comparison between two groups in all parameters as well as correlation between all parameters done by using (SPSS) computer program (version 24). P value≤0.05 was considered significant.

Results

One hundred women suffered from mild knee osteoarthritis involved in the study. The average age was 50.5±3.11 years and the average BMI was 26.23±2.48 Kg/m2. (Table1).

Table (1) shows minimum, maximum and mean values of age/year and body mass index (BMI)/ Kg/m2 for all patients.

All candidates divided into two groups according to their glycemic level. Group A (50 women) with high glycemic level represented as type two diabetic group and group B (50 women) with normal glycemic level represented as non-diabetic group.

Glycemic levels: Statistical analysis showed, significant difference between both groups in two parameters (Fasting blood glucose level FBS and glycosylated hemoglobin HbA1c), group A recorded a mean of fasting blood glucose level equal 193.7±16.7 mg/dl while group B recorded a mean equal 87.7±8.36 mg/dl with statistical significant difference .Also, Significant difference was observed regarding glycosylated hemoglobin (HbA1c) as group A recorded a mean equal 8.75±.68 % while group B recorded a mean equal 4.9±0.45% (Table 2).

Functional performance: Significant difference was observed between group A and B after using WOMAC scale, group A recorded a mean equal 42.2 ± 2.0 points while group B recorded a mean equal 29.± 3.4 points (Table 3).

Correlation between glycemic parameters and functional performance in diabetic groups: Correlation analysis between functional performance and glycemic variables was detected there was a non-significant correlation between WOMAC scale and fasting blood glucose level as well as HbA1c in diabetic group as shown in (Table 4).

Discussion

Prevalence of osteoarthritis between patients with type 2 diabetes was 29.5±1.2% and type 2 diabetes among patients with osteoarthritis was 14.4±0.1%. These results were confirmed by Rahman et al. 10.

On the other hand, Yoshimura et al., 11 found that, the levels of HbA1c fraction were ≥5.5% that was not completely associated with regression of OA. Which is confirmed our findings.

Visser et al., 12 recorded a unique significant association between DM and hand OA only. The study highlights on the metabolic causes and the systemic nature of hand.

Sellam et al. 13 found that, diabetes itself could be an independent risk factor for osteoarthritis and proposed a diabetes-induced phenotype through chronic, low-grade inflammation. They suggested that, lipid irregularities with inflammatory mediators released from adipose tissue and advanced glycosilated end products can be harmful to cartilage homeostasis.

Schett et al. 14 evaluated the long-standing effect of type 2 diabetes on knee and hip and reported, predicted the necessity for arthroplasty by two fold for these patients as a result of severe osteoarthritis after controlling the analysis for age, BMI and other potential factors.

Results were completely agree with Nielen et al. 15 who demonstrated that, the association between type 2 diabetes and knee osteoarthritis or even knee pain is no longer present after adjusting of body mass index which reflecting the importance of overweight in the relationship. Also, no difference in severity of knee pain in type 2 diabetes patients were detected compared with non-diabetic patients.

In contrast Nicola et al. (16), who analyzed the results of more than one million participants with type 2 diabetes and osteoarthritis and the data showed a clear association between the two variables with elevated risk of osteoarthritis in diabetic patients even with control of body weight.

Thorstensson et al. 17 were investigated the reduction in functional performance in the lower extremity as a predictor of knee osteoarthritis progression. The results were supported that, reduced functional performance in the lower extremity predicted development of radiographic knee osteoarthritis 5 years later among people aged 35–55.

However, Barker et al. 18 examined the correlation between radiographic knee osteoarthritis classification through Kellgren and Lawrence scale and functional performance by using WOMAC index. The parameters of WOMAC scale measured function, pain and power but they found that there are no statistically significant associations between osteoarthritis and WOMAC parameters.

Additionally, Schett et al. 19 assessing the outcomes of knee osteoarthritis symptoms by using Western Ontario and McMaster Universities Arthritis Index (WOMAC) as a functional assessment scale after detection of sonorities and knee effusion by ultrasound in participants with type 2 DM than those without DM. Which confirmed by validity of WOMAC scale in assessing osteoarthritis outcomes.

Conclusion

No significant correlation between functional performance and glycemic variables in diabetic as well as non-diabetic group. However, there was a significant difference between diabetic and non-diabetic group regarding functional performance expressed by WOMAC scale. Our recommendations are to increase the sample involved, selection of moderate or severe degree of osteoarthritis or to test another glycemic variables and finally to increase the time of follow up in form of longitudinal study.

Implementation of Enhanced Recovery after Surgery for Endometrial Carcinoma: A Non-Randomized Controlled Trial

Ahmad Sameer Sanad1, Essam El-Gindi1, Reham R El-Khateeb1, Ahmed M Abdil-Ghany1, AmrNady Abdelrazik2, AhmedBakr Mousa1, AhmedShoukry Hafiz3

1Obstetrics and Gynecology Department, 2Anesthesia Department, Faculty of Medicine, Minia University, Egypt, 3Consultant of Oncology, El-Salam Oncology Center, Cairo, Egypt

Abstract

Study aim: to look at the effect of modified better enhanced recovery after surgery (ERAS) program for endometrial carcinoma, on hospital live length (HLL) and operative outcome.

Patients & methods: the study was done in El-Salam Oncology center; Cairo and Minia Maternity University Hospital, Minia university, Egypt. The study included two groups of patients diagnosed as endometrial carcinoma prepared for operations. First group included patients prepared for laparoscopy (n=27) and was managed with ERAS protocol. The other group of patients were prepared for laparotomy (n=31) and was managed with conventional protocol.

Results: The HLL was abridged in ERAS group when linked with the control group (1.77 ± 1.13 days compared with 6.13 ± 2.25 days; P < 0.0001; CI 3.4013 to 5.3187). Opioid use was reduced in ERAS group compared to the control groups (1.10 ± 0.41mg and 9.83 ± 3.6 mg; P < 0.0001) and postoperative fluid use was also less in the ERAS group compared to the control group (1362.9 ± 234.3 ml compared with 2303.2 ± 512 ml; P < 0.0001; CI 725.4990 to 1155.1010).

Conclusion: Implementation of ERAS protocols in gynecologic surgery for endometrial carcinoma should be tailored according to the situation of each case. But in general, ERAS was connected with substantial reduction in HLL, lessening in the operative time and blood loss, associated with controlled intravenous fluids utilized and comparable pain control to conventional protocols with improvement in complication rates.

Keywords: Enhanced recovery after surgery, hospital live length and endometrial carcinoma.

Introduction

Implementation of ERAS protocol is linked with the decreased HLL, a reduction in rates of postoperative difficulty, reduced illness, and cost funds, while conserving patient approval and life quality1,2.

ERAS programs include preoperative, intraoperative, and postoperative strategies; preadmission counseling, utilization of opioid-sparing multimodal perioperative absence of pain (counting local analgesia), intraoperative goal directed fluid therapy (GDT), and utilization of insignificantly invasive surgical methods with shirking of routine utilization of nasogastric tube, channels and/or catheters. Post-operatively, patients are encouraged for early feeding, early mobilization.

The aim of the present study was to investigate the impact of implementing modified ERAS program for endometrial carcinoma, on HLL and operative results.

Patients and Methods

Setting: The current study was a prospective non randomized clinical study on women who underwent surgery for endometrial carcinoma in Minia maternity
University Hospital (MMUH) and EL-Salam Oncology Center, Cairo. The study was conducted during the period between June 2012 and December 2017.

**Patients:** Eligible subjects were American Society of Anesthesiologists (ASA) physical status I and II females undergoing exploration for endometrial carcinoma.

The study was not randomized. Patients were classified into 2 groups, first group included patients undergoing operative laparoscopic exploration and was done in El-Salam Oncology Center. Patients were managed with enhanced recovery perioperative protocol (active group). Second group included patients undergoing open exploration and were managed with conventional perioperative protocol (control group) in MMUH. Eastern Cooperative Oncology Group (ECOG) Performance Status was used to determine patient’s disease progression and decide suitable treatment and prognosis.

**Sample size calculations:** The study was designed to detect difference with a type I error of .05, a statistical power of 0.80, ratio of sample size (Unexposed / Exposed) = 1, Risk/Prevalence Ratio: 3.3; assuming that length of hospital stay in laparoscopic group=2 day and 4 in abdominal group, this results in sample size of 27 patients in each group and an assumption that up to 10% of patients subsequently would be deemed ineligible and/or have inadequate follow-up. This resulted in a total planned sample size of 30 patients in each group.

**Primary outcome:** Postoperative length of hospital stay.

**Secondary outcomes:** Postoperative morbidities, for example: acute confusion, nausea and vomiting, postoperative fever, secondary hemorrhage, atelectasis, pneumonia, wound infection, embolism and deep vein thrombosis, acute urinary retention, paralytic ileus. Re-admission rate due to bowel dysfunction or wound dehiscence or infection was also reported.

**Methods:**

For first group: (ERAS protocol): First step was to establish of a multi-disciplinary team to implement the protocol of ERAS. The team was consisted of gynecological oncologists, anesthetist, nurse specialist, ward nurse managers, and clinical dieticians. The aim of the ERAS protocol is to reduce HLL without increase in the rate of complication.

**Components of the protocol:**
- Patient counselling and education:
- Patient preparation for surgery:

Preoperative control of chronic disease (cardiac function, pulmonary function, blood pressure, and diabetes) was accomplished. Serum albumin level was maintained greater than 3.5 g/dl. Preoperative prophylaxis against thrombosis, infection and nausea and vomiting was established.

**Perioperative diet:** Fasting at the most for 6 hours preoperatively for solid foods and 2 hours for clear liquids was advised. Preoperative carbohydrate-rich drinks were used to reduce the effect of fasting.

Postoperatively patients were advised to use chewing gums, laxatives and drink clear liquids upon awakening from anesthesia and to eat a general diet when begin walking. Intake of protein and energy-rich nutritional supplements was advised. Management of postoperative nausea and vomiting were guaranteed with the use of multimodal approach by 2 or more anti-emetics in combination.

**Mechanical bowel preparation:** Rectal enemas and mechanical bowel preparations were avoided.

**Minimal access surgery:** Minimal access surgery improves postoperative outcome and enhancing recovery by reducing tissue damage and physical injuries.

**Anesthesia:** Patients of the active group received combined general anesthesia with lumbar epidural analgesia.

**Fluid balance and management:** Perioperative fluid management aimed to maintain perioperative euvolemia. All patients were advised to have plentiful fluid intake before surgery.

Fluid balance was obtained by minimizing crystalloid administration, increasing the use of colloids and the use of vasopressors (epinephrine) in place of crystalloid for treatment of hypotension in a euvolemic patient.

**Pain management:** Our protocol included the use of opioid-free drugs as combining regional anesthetics techniques with multimodal pharmacologic pain management instead of the use of opioids. Multimodal pain management consisted of the use of two pain killers
with different mode of action as NSAIDs, paracetamol or acetaminophen.

**Drains and catheters:** The study protocol discarded the use of drains, tubes, and catheters. Urinary catheters were removed as soon as possible.

**Early Mobilization:** All patients were promoted to start early mobilization and to leave their beds as early as possible. Patients got out of bed a minimum of 2 hours on the day of surgery.

**For second group:** (conventional surgery):
Patients in control group were ordered to fast overnight. All patients received a mechanical bowel preparation. The patients were admitted to the hospital for 2–5 days before the procedures. All patients of control group received general anesthesia. Intraoperative fluid administration was managed by anesthesiologist according to the situation of each case. Postoperative fluids were continued until the intestinal motility was regained. The patients were instructed to start with clear liquid diet on the morning of postoperative day and then continued as afford postoperative pain management depended mainly on the use of opioids and other pain killers.

**Statistics:** Data are presented as numbers and percentages or medians and ranges. Data were analyzed with a two-sided chi-squared test, Fisher’s exact test when appropriate, and continuous variables were analyzed using the Mann–Whitney U-test for two independent groups. A p-value < 0.05 was considered significant. Statistical data were analyzed using the IBM SPSS software package, version 21 for Macintosh (IBM Corp., Armonk, NY, USA).

**Results**
A group of 58 patients was included in the current work, 27 patients were subjected to undergo laparoscopic procedures and managed with ERAS (active group). Thirty-one patients underwent laparotomy for endometrial carcinoma managed with conventional protocol (control group).

*LOS: length of hospital stay or HLL: hospital live length, OR: operative room

There was a statistically significant difference in the HLL which was decreased with ERAS group when related to the control group (1.77 ± 1.13 days compared with 6.13 ± 2.25 days; P < 0.0001; CI 3.4013 to 5.3187).

Similar reductions were seen in median intraoperative fluids used (943.6 ± 213.4 ml compared with 1679.9 ± 270 ml; P < 0.0001; CI = 606.9187 to 865.6813) and postoperative fluid used (1362.9 ± 234.3 ml compared with 2303.2 ± 512 ml; P < 0.0001; CI 725.4990 to 1155.1010).

Visual analogue score (VAS) was less in patients managed with ERAS protocols rather than patients managed with conventional protocols; 3.18 ± 1.15 vs 4.48 ± 1.68 (P = 0.0013 an 95% CI= 0.5311 to 2.0689).

There was a statistical significant reduction in the rate of complication in the laparoscopy group (OR= 0.3116, CI=0.1033 to 0.9394 and P=0.0384) after ERAS protocol implementation.

**Discussion**

This aspirant study is in accordance with the objective to assess efficacy of ERAS approach that is characterized by tailoring the procedures implemented to the needs of organizations and according to the general condition of the patients.

The limitations to the present study is lack of randomization due to unavailability of laparoscopic hysterectomy of endometrial carcinoma in our hospital. Yet, because of the present indication on ERAS protocols, we considered the part done in El-Salam Oncology Center is the active group and we considered it a step to generalize the trial in MMUH. Also, it was not possible to achieve a blind study. One of the most important difficulties we faced during implementation of such a program is the need of joint effort between various wellbeing experts and various strengths. In spite of careful methodology, the study has another limit, lying in the small number of patients.

The strength points of the current study lie in the equity and impartiality. As this study was carried out in general hospitals, generalization of the data become possible and easy to be applied to other similar situations. Another strength point is that our study highlighted HLL, which may be considered as a surrogate outcome for recovery after surgery. Also, all patients underwent the same maneuver (hysterectomy) for the same lesion (endometrial carcinoma).

The success in the current study is attributed mainly to the use of minimally invasive surgery and the strict implantation of ERAS protocol. These finding is in accordance with De Groot’s hypothesis.

Once patients are euvoletic, vasopressors were used to maintain mean arterial pressure. Ideally patients controlled with ERAS protocol must be ingesting, consuming, mobilizing, and napping at the equal day of operation.

The American Society of Anesthesiology recommends a fast of 6 hours preoperatively for solid foods and that clear liquids be consumed for up to 2 hours prior to surgery.
Minimizing the preoperative fasting period increases patient quality of life and satisfaction as prolonged preoperative fasting is annoying for patients and may increase patient anxiety.  

In ERAS program, patients were promoted to start clear fluid upon awakening from anesthesia and to start eating small snack once patient started walking. We advised our patients against use of mechanical bowel preparations. Arnold has supported these advices as bowel preparation is associated dehydration, electrolyte abnormalities, and a prolonged period of fasting. For gynecologic surgery, a recent meta-analysis of 5 RCTs found that there was no benefit of bowel preparation in regard to visualization of the surgical field or decreases in operative time.  

Our policy in postoperative pain control is the use of regional anesthetics techniques with multimodal pharmacologic pain management with decrease use of opioids because use of opioids can deteriorate the patient’s equilibrium affecting patients’ mobilization and depressing the respiratory vitality and this policy is in accordance with many systematic literature review of 60 RCTs.  

Early mobilization is a lineament of ERAS. Many ERAS protocols recommend that patients start walking after a minimum of 2 hours per day of surgery and then 6 hours a day until discharge.  

There are multiple considerations in how to implement ERAS protocols. In our opinion, the most decisive point was to operate a devoted nurse to supervise the procedure from admission till discharge. We have established a follow up visit at outpatient clinic at the day 7 and day 14 postoperative, to detect postoperative complications. This goes in line with many previous studies.  

In the current work, there was a statistical significant lessening in the rate of complication in laparoscopy group reaching the level of statistical significance. These findings were in line with previous data that found a significant reduction in postoperative morbidity in patients undergoing ERAS and a trend towards decreased mortality. A recent meta-analysis included 2,376 colorectal patients from 16 randomized controlled trials that compared ERAS pathways to conventional postoperative care. ERAS pathways were resulted in a significant reduction in overall morbidity (RR = 0.60, 95% CI 0.46-0.76).  

Conclusions

Implementation of ERAS protocols in gynecologic surgery for endometrial carcinoma should be tailored according to the situation of each case. Implementation of ERAS resulted in significant reduction in hospital stay, proper pain management and lessen rate of difficulties deprived of an growth in re-admissions.

Abstract

Background: Acute decompensated heart failure (ADHF) is an important cause of hospital admissions, morbidity and mortality.

Objectives: To evaluate role of plasma cystatin C in prediction of adverse in-hospital clinical outcome in patients with ADHF.

Methods and results: Among 90 patients hospitalized with ADHF, clinical examination and echocardiographic assessment were done. Renal functions including serum urea, creatinine and estimated glomerular filtration rate (eGFR) were followed up daily. Plasma cystatin C was measured on admission and at 24 and 72 hours. The composite in-hospital adverse clinical outcome included the composite of death, need for ultrafiltration for refractory edema and hypotension requiring vasopressors. Mean value of plasma cystatin C on admission was 1822.7±553 mg/l. Independent predictors of the composite adverse in-hospital clinical outcome were left ventricular end-systolic diameter and admission values of plasma cystatin C. Admission plasma cystatin C ≥ 1707.5 mg/l had 80% sensitivity and 72% specificity for the prediction of the composite adverse in-hospital clinical outcome.

Conclusions: Among patients hospitalized with ADHF, measurement of plasma cystatin C on admission can identify patients at increased risk for developing in-hospital adverse clinical outcomes.

Keywords: Acute decompensated heart failure, adverse clinical outcome, plasma cystatin C.

Introduction

Acute decompensated heart failure (ADHF) is an important cause of hospital admissions, morbidity and mortality.

Worsening of renal functions (WRF) is a common complication for the use of diuretics in patients with acute decompensated heart failure (ADHF) with an incidence between 20% and 50%2,3,4 and with increased risk of morbidity and mortality.

Plasma cystatin C6,7 can be considered an ideal marker for WRF as it reflect the glomerular filtration rate (GFR) better than creatinine, and its levels are not affected by age, gender, diet, or muscle mass to the same extent as creatinine.6,7

Accordingly, this study was conducted to describe the changes in plasma Cystatin C as a marker for WRF in hospitalized ADHF patients receiving diuretic therapy and to study the potential relation between these changes and the development of adverse clinical outcomes.

Methods

This was a prospective study that recruited patients with ADHF admitted to the Heart Failure Unit of the Cardiology Department in Kasr Alainy Hospital, Cairo University between June 2016 and January 2017. The
investigation was approved by the ethical committee. All patients provided informed consents.

ADHF was defined based on the presence of rapid onset of, or change in symptoms and/or signs of heart failure.\textsuperscript{1} Enrolment was restricted to patients with New York Heart Association (NYHA) function class III or IV.

Patients were excluded from the study if they were < 18 years or having one of the following: cardiogenic shock, acute myocardial infarction, atrial fibrillation, eGFR < 30 ml/min, stenotic valvular heart disease beyond moderate severity, sepsis, pregnancy.

Study methodology: All eligible patients were subjected to clinical assessment, laboratory work up and echocardiography.

Clinical assessment included full history and physical examination on admission with daily follow up of clinical state, body weight and fluid balance.

Laboratory work up included complete blood picture, liver and renal functions on admission with daily follow up of urea, creatinine, Na, K and follow up of cystatin C at 24 and 72 hours. The samples of cystatin C were collected using EDTA and centrifuged for 15 minutes at 1000 x g at 2-8 degree Celsius then plasma was stored under -20 degrees Celsius. Measurement of plasma cystatin C was done by using human ELISA plasma cystatin C kits.\textsuperscript{8}

Echocardiographic examination was done according to American society of Echocardiography guidelines \textsuperscript{9} on admission to assess left ventricular (LV) dimensions, LV systolic function by Simpson’s method, LV diastolic function by pulsed Doppler assessment of the mitral inflow and tissue Doppler over the lateral and septal mitral annuli. Follow up echocardiography was done after 24 and 72 hours with special emphases on measurements of diastolic function.\textsuperscript{9}

In-hospital management: patients were treated according to the European society of cardiology guidelines for the diagnosis and treatment of acute and chronic heart failure.\textsuperscript{1} All patients received furosemide, the dose of furosemide, the route of administration (IV boluses or infusion) and the uptitration of the dose were left to the treating physician. In case of inadequate response to IV furosemide, another diuretic agent from other class was added (Spironolactone, Metolazone). Regarding the addition, reduction or discontinuation of B-blockers and ACEI, it was left to the treating physician.

In-hospital diuretic response included average net daily fluid loss, ml (defined as UOP minus oral and IV fluid intake) and total net fluid loss, ml.

In-hospital clinical outcome included hospital stay (days), change weight loss (Kg), change NYHA class I-II (%), need for ultrafiltration, need for vasopressors for hypotension and mortality. The composite in-hospital adverse clinical outcome included the composite of death, need for ultrafiltration for refractory edema and hypotension requiring vasopressors.

Statistical Analysis: All statistical analyses were performed using SPSS for Windows (17.0, SPSS Inc.). All continuous variables - except for duration of hospitalization - showed normal distribution when assessed by Kolmogorov–Smirnov test. Continuous variables were presented as mean ± standard deviation while categorical data were summarized as number (percentage). Analysis of Variance (ANOVA) test was used to assess differences in laboratory variables obtained on admission and at 24 and 72 hours. Bivariate correlations were analyzed by Pearson’s test.

Clinically relevant variables were used to identify univariate predictors of WRF and the adverse clinical outcomes using student sample t test for continuous variables and chi-square test for categorical variables; then stepwise multiple logistic regression analysis was performed to assess the independent predictors.

Receiver operating characteristics curves were used to choose cutoffs with best sensitivity and specificity. A p value ≤ 0.05 was considered to indicate statistical significance.

Results: A total of 102 patient were eligible for this study, however 12 patients were excluded 6 patients due to technical difficulties in assessing the intra-renal vessels, 3 patients died before completing the follow up studies and 3 patients withdrew consents). Accordingly, 90 patients constituted the study population.

Baseline Characteristics: Baseline clinical characteristics of the study population are listed in table 1. Of note, about 69% of patients had ischemic cardiomyopathy.
Table 1: Baseline characteristics of the Study Participants

Renal Function (Table 3): Compared to admission values, serum creatinine showed significant elevation at 24, 48 and 72 hours with p-value 0.0001. This was similarly associated with significant decline in eGFR and significant increase in blood urea. Plasma cystatin C showed significant increase at 24 hour and 72 hour follow up with p-value 0.005 and 0.003 respectively. 40% of the patients fulfilled the definition of WRF according to serum creatinine during index hospitalization.

Data are presented as number (%) or mean ± SD

It was proposed that increase in Cystatin C by 0.3 mg/dl can be taken as a measure for WRF in patients with ADHF. In this study we found that there was statistically significant correlation between the WRF assessed by increase in plasma Cystatin C by 0.3 mg/l and WRF assessed by increase serum creatinine by 0.3 mg/l with R 0.439 and P-value 0.001.

Predictors of Adverse Clinical Outcomes: The adverse clinical outcomes occurred in 20 patients (22%): need for vasopressors in 11 patients (12 %); ultrafiltration for refractory edema in 6 patients (7%) and death in 4 patients (4 %). Among 7 variables (Male gender, prior heart failure hospitalization, left ventricular ejection fraction, left ventricular end-systolic diameter, E/e’, admission serum urea and admission plasma cystatin C) that were included in multivariate analysis, 2 variables appeared to independently predict adverse clinical outcomes: increased LV end systolic dimension and admission plasma cystatin C. (Table 5)

For the prediction of adverse clinical outcomes, LV end systolic dimensions ≥ 5.0 cm showed 85% sensitivity and 70% specificity (area under the curve 0.801; p= 0.0001) and admission plasma cystatin C ≥ 1707.5 mg/l was associated with 80% sensitivity and 72% specificity (area under the curve 0.695 and p= 0.01).

Discussion

The main finding of this study is that plasma cystatin C as a marker for WRF have important role in predicting adverse clinical outcomes in patients with ADHF receiving diuretic therapy.

WRF during admissions for acute decompenated heart failure has been directly associated with poor prognosis. It was found in some studies that the rise of serum creatinine ≥0.3 mg/dl is a strong predictor of morbidity and mortality. Unfortunately, serum creatinine has many disadvantages as a marker of WRF as its levels are elevated late after affection of a large proportion of the nephrons and it is affected by multiple factors as age, diet and muscle mass. The lack of early identification of WRF has hampered our ability to prevent and treat it.

Plasma Cystatin C is a better marker of renal function that can reflect the GFR better than creatinine, and its levels of are not affected by age, gender, diet, or muscle mass as creatinine.

Johan and Lassus et al, studied the use of plasma cystatin C in patients with acute heart failure as a marker of early WRF. They found that increase in cystatin C by 0.3 mg/L has a specificity of 90% and a sensitivity of 77% in predicting the development of WRF.

Also Raquel studied the role of plasma cystatin C in predicting early WRF and adverse clinical outcome including re-hospitalization and 60-days mortality in patients with acute heart failure. He found a significant correlation between increase in cystatin C by ≥0.3 mg/L and increase in creatinine by ≥0.3 mg/dl (p=0.001) and he concluded that plasma cystatin C is a better predictor of early WRF compared to creatinine or MDRD GFR and can be considered a more sensitive marker for WRF.

In this study, patients with elevated plasma cystatin C on admission were more prone to develop less change in body weight during hospitalization, and less improvement of NYHA class. Furthermore, admission value of plasma cystatin C was an independent predictor for the development of the composite adverse in-hospital clinical outcomes including death, hypotension requiring vasopressors and need for ultrafiltration for refractory edema. A cutoff value of plasma cystatin C on admission ≥ 1707.5 had 80% sensitivity and 72% specificity in predicting the development of the composite adverse in-hospital clinical outcomes.

This is consistent with the results of many studies including Changlu Gao et al who studied patients diagnosed with systolic heart failure according to clinical presentation or echocardiography for 2 years, they found that higher cystatin C levels is associated with significantly higher adverse outcome rate (P<0.0001).

Also in the study done by Johan and Lassus et al, they found that WRF defined by rise in cystatin C ≥0.3 mg/L within 48 h from admission was associated with longer hospital stay and a three-fold increase in the in-hospital mortality.

In this study, the left ventricular end-systolic diameter (LVESD) was an independent predictor for the development of the composite adverse clinical outcomes. A cutoff value of LVESD ≥ 5.0 cm had 85% sensitivity and 70% specificity in predicting the development of the composite adverse in-hospital clinical outcomes.

The LVESD is one of the parameters that reflect the left ventricular systolic function which is the most important predictor of outcome in patients with heart failure.

This study is predominantly limited by the small number of patients recruited so results should be validated in large multicenter study. Also the study recruited selected population with many exclusion criteria to avoid confounding variables; thus the results cannot be applied to general ADHF population.

Conclusion: Findings in our study suggest that admission plasma cystatin C is an independent parameters that can help identifying ADHF patients at increased risk for developing in-hospital adverse clinical outcomes.

Effect of Dexamethasone on Marbofloxacin Residues in Rabbit Tissues Using HPLC

Gamal A. Shams1, Hosny A. Ibrahim1, Ashraf S. Darwish2, Hend A. Mahmoud3

1Pharmacology Department, Faculty of Veterinary Medicine, Zagazig University, Egypt, 2Biochemistry, Toxicology and Feed Deficiency Department, Pharmacology Unit, Animal Health Research Institute, Dokki, Giza, Egypt, 3Biochemistry, Toxicology and Feed Deficiency Department, Pharmacology Unit, Animal Health Research Institute, Zagazig Branch

Abstract

The present study sought to investigate the residues of marbofloxacin in different tissues of healthy rabbits as well as to detect the effect of dexamethasone on tissue residues of marbofloxacin when co-administrated together after multiple intramuscular administrations. Forty-five rabbits were divided into three equal groups (n=15); the first group, healthy male New Zealand rabbits were untreated and served as control, the second group was injected with marbofloxacin intramuscular at a dose of 2mg/kg b.wt for 5 consecutive days in the thigh muscle, and the third group was co-administrated marbofloxacin and dexamethasone intramuscularly with the same dose and same period. Samples were collected on the 1st, 3rd, 5th, 7th and 9th day from rabbit tissues (Liver, kidneys, breast muscle, thigh muscles, and lung). Samples from each rabbit were extracted and marbofloxacin residues were analyzed using HPLC with ultraviolet detection. The obtained result emphasized a widespread distribution of marbofloxacin in the tested tissues. The highest concentration (0.402±0.007 µg/gm), (0.406±0.010 µg/gm) of marbofloxacin alone or co-administered with dexamethasone was measured in kidney tissue respectively, followed by liver (0.324±0.016 µg/gm), (0.313±0.019 µg/gm), lung (0.204±0.01 µg/gm), (0.205±0.05), breast muscle (0.079±0.003), (0.080±0.006) and thigh muscle (0.0635±0.002), (0.0655±0.007) respectively with no significant changes between two groups. Marbofloxacin remained within detectable limit till the 3rd day in most tested tissues, while in kidneys and liver, it remained till the 5thday following the last intramuscular dose. The obtained results provide a basis for the rational use of dexamethasone with marbofloxacin in rabbit medicine to treat the sensitive bacterial infection with inflammatory conditions.

Introduction

The management of rabbits meat production showed that a very small percentage of the world meat market. This percentage has been increasing continuously throughout another 30 years. Rabbit is considered a minor food species, for that reason no drugs are specifically recorded for ones. This meat is estimated for its nutritional characteristics may be caused by lowering fat, rich in proteins of high biological value and decreasing in cholesterol content.

Due to the extra-label use of veterinary drugs, many greater remains levels may observe in the eaten animal products. Drug remains are a very small quantity of veterinary drugs that stay in animal products.

Moreover, have been suggested a number of potential harmful influences of veterinary drug residues such as allergy, antibiotic resistance, disruption of intestinal flora and chronic toxic effects. To confirm the safety of food of animal origin for consumers, therefore it could be limiting the maximum residue limits (MRL) of veterinary drugs utilized with the food animals.
Quinolone residues may be observed in the food of animal origin if proper checks and balances are not employed. It has been reported that Quinolone residues decrease the effectiveness of quinolones in human treatment due to its emergence of drug-resistant bacteria\(^6\). Marbofloxacin is a fluorinated quinolone derivative with broad spectrum activity that has been developed exclusively for use in veterinary medicine. It has a broad-spectrum and bactericidal activity against many gram-negative bacteria, gram-positive bacteria and mycoplasma SPP \(^7\). Its bactericidal action was achieved by a concentration–dependent mechanism \(^8\). It inhibits the bacterial DNA gyrase enzyme which is responsible for the supercoiling of DNA within the cells \(^9\). In fact, marbofloxacin was shown to be the most effective drug against bacterial strains isolated from rabbits infected with upper respiratory tract diseases compared to doxycycline, enrofloxacin, danofloxacin and tetracycline \(^10\).

Glucocorticoids (GCs) are a class of corticosteroids, which are a category of steroid hormones that connect to the GCs receptor (GR), which is current in nearly every vertebrate animal cell\(^11\). Anti-inflammatory factors such as Corticosteroids are utilized usually in veterinary medicine. Dexamethasone is utilized as an anti-inflammatory and anti-allergic factor for the palliative therapy of a number of conditions, comprehensive itching may be due to by dermatitis or insect bites, inflammation connected with arthritis or ulcerative colitis, and diseases of the adrenal glands \(^12\).

Information about tissue apportionment of an antibiotic may is very worthless to become better therapeutic performance and keep away from the problems connected with residues. Moreover, the objective of this research was to studied marbofloxacin’s tissue residues in rabbits after multiple intramuscular administration and to determine if co-administration with dexamethasone could change residue profile of marbofloxacin or not.

**Material and Methods**

**Animals:** A total of Forty-five healthy male New Zealand rabbits weighing 2–2.5 kg were used in the study. The rabbits were allowed to acclimate for 7 days with free access to water and a drug free pelleted diet. They were housed in batteries in the post-graduate research laboratory at the Faculty of Veterinary Medicine, Zagazig University. No clinically significant abnormalities were noted on rabbits. The study was approved by the Institutional Animal Care and Use Committee (IACUC) of Zagazig University. All animals were humanely handled.

**Chemicals and reagents:** The 10% Marbocyl (a Commercial veterinary formulation whose active ingredient is marbofloxacin) suitable for intramuscular injection was kindly provided by veterinary vetoquinopharmaceuticals (France). Marbofloxacin standard with a chemical purity of (99.82%) was provided by SIGMA ALDRICH (Germany). Methanol, acetonitrile and formic acid of high-performance liquid chromatography (HPLC) grades were purchased from Merck (Germany). The other reagents used in this study were all of analytical grades. Deionized water was purified by using a Milli-Q-system (Millipore, USA).

**Drug administration and sampling:** Rabbits were randomly divided into three groups with fifteen rabbits in each group. Group 1 was used as a control and was treated with the administration medium (physiological solution). Group 2 was weighed and intramuscularly injected on the thigh muscle with Marbofloxacin at the dosage of 2 mg/kg body weight for five consecutive days. Group 3 weighed and intramuscularly co-administered Marbofloxacin and dexamethasone at the dosage of 2 mg/kg body weight for five consecutive days. Three rabbits were slaughtered on 1st, 3rd, 5th, 7th and 9th day after last intramuscular dose respectively. Control rabbits (blanks) were sacrificed 96 h after the end of treatment. Samples of tissues including lung, liver, breast muscles, thigh muscle, and kidney were collected from each animal and stored at -800°C until analysis.

**Analytical procedures**

**Preparation of samples for analysis:** At the time of assay, frozen tissues were partially thawed at room temperature (23°C) for 30 minutes and blended in a food processor for 20-30 seconds at high speed to obtain a uniform paste-like consistency. The extraction was done by using a previously described method (Ding et al, 2013). Briefly, Three grams of tissue were accurately weighed and transported into a polypropylene centrifuge tube. Fifteen ml (15) extraction solution (0.015 mol/L phosphoric acid and 0.015 mol/L perchloric acid in water-methanol (50:50 v/v)) were added and shaken for 1 min. After shaking, Centrifugation was performed (15000 rpm for 8 min) then followed with Hydrolysis for 90 min in 50°C water bath then cooling to room.
temperature. Again, Centrifugation was performed (5000 rpm for 10 min) and An aliquot (50μl) was injected into the HPLC system.

**High-performance liquid chromatographic condition:** The HPLC system (LC Jasco, Italy) consisted of a quaternary gradient system (PU 1200) with an ultraviolet detector set to a wavelength 295 nm. The chromatographic separation assay was performed with the Hypersil gold C18 column (4.6 mm×100 mm×5 μm) (Surveyor, thermo scientific company, Germany) preceded by a security guard column with the same stationary phase. The system was maintained at 25 °C. The mobile phase consisted of 12% acetonitrile, 0.75% formic acid and 0.4% triethylamine at elution flow rate 1 ml/min.

**Statistical analysis:** The data were calculated as mean ± standard deviation (SDs). All statistical analysis was carried out using One way ANOVA. P value higher than 0.05 was considered significant.

**Results**

Marbofloxacin was determined using HPLC method, and no having internal cause interference was reported on chromatograms. The limit of quantization (LOQ) for marbofloxacin was specified have as the foundation for on a single-to-noise rate higher than10, and the LOQ values were 0.01μg/g. Marbofloxacin concentration was linear within the range of 0.025–1.0 μg/g (r> 0.998), standard curve of marbofloxacin were shown in figure (1) The Mean recovery of marbofloxacin ranged from 98.2-102.82 %. Repeatability was measured as within-run and among-run coefficient of differences, worth’s of which were less than 7.52%.

The results for marbofloxacin elimination from rabbit tissues at different times after intramuscular administration (2 mg/kg b.wt once daily for 5 consecutive days) were represented in the table (1). The data represented in this table emphasized a widespread distribution of the drug in the tested tissues (liver, kidney, breast muscles, lung, and thigh muscle). Marbofloxacin remained within detectable limit till the 3rd day in most tested tissues while in kidneys and liver it remained till the 5thday following the last intramuscular dose.

The highest concentration (0.402±0.007 μg/gm), (0.406± 0.010 μg/gm) of marbofloxacin alone or co-administered with dexamethasone was measured in kidney tissues respectively, followed by liver (0.324±0.016 μg/gm), (0.313± 0.019 μg/gm), lung (0.204±0.01 μg/gm), (0.205±0.05), breast muscle (0.079±0.003), (0.080±0.006) and thigh muscle (0.0635±0.002), (0.0655±0.007) respectively. There were no significant changes in marbofloxacin depletion when administered alone or in combination with dexamethasone.

**Table (1): The mean concentrations of marbofloxacin in tissues(µg/gm) of rabbits following the last intramuscular administration (2 mg/kg b.wt once daily for 5 consecutive days) alone or in combination with dexamethasone. Mean ± SD (n=3)**

Discussion

Rabbit meat, although representing a small market percentage in most Middle East countries, has been a valuable meat resource. Drug depletion from the food-manufacturer from components animal, the type should be estimated to limit the time necessary previously the drug cases from the animal tissues and to estimate when the treated animal can be safely consumed. Suitable and sensitive analytical methods are needed to monitor quinolone residues in food and to determine to retreat periods in rabbits after pharmacological therapy. When fluoroquinolones are not adequately administrated to food-producing animals following the legal indications for registered drugs, they can foster drug-resistance phenomena and, if absorbed at certain concentrations, might cause serious pathological changes in the joints of children’s and teenagers.

It is exceedingly known that the co-management of two drugs possibility influence the absorption, apportionment, biotransformation and/or excretion of both factors. The pharmacokinetic interactions between steroidal anti-inflammatory drugs (SAIDs) and antimicrobial drugs have been little studied in veterinary medicine, given their frequent clinical use in combination. SAIDs representative dexamethasone is successfully applied together with bactericidal antibiotics in the treatment of some diseases in different animal species (cows, horses, dogs and cats, and others).

At 24 h after the end of treatment, marbofloxacin concentrations in the tested tissues (Liver, Kidney, and Lung) were higher than the maximal residual limit (MRL) (150µg/kg) recommended by EMEA. However, its concentrations in thigh muscle and breast muscle were below the lowest MRL reported by EMEA. This finding is in agreement with (1) who stated that marbofloxacin in rabbit’s muscle was lower than those measured in the liver and kidney after subcutaneous injection (S/C) at a dose of 2 mg/kg body Wight daily for 5 days. This result strongly supported the safeness of eating the muscle of the rabbit after one day of treatment with marbofloxacin even from the injection site (Thigh muscle).

Marbofloxacin residues have not detected in thigh muscle at the 3rd day, while it was less than the LOD of the analytical method in the Breast muscle and Lung on the 5th day. However, it persisted till the 5th day in the Liver and Kidney following the last intramuscular dose. This is consistent with who reported that the withdrawal time for marbofloxacin in broiler chickens was about 3 days after oral administration at a dose of 2 mg/kg b.wt for 3 days and in agreement with who stated that the withdrawal period was 4 days after oral administration of marbofloxacin to broiler chicken at a dose of 5 mg/kg b.wt for 3 days. Moreover, the withdrawal period in rabbits was 2 days after S/C injection of marbofloxacin at a dose of 2 mg/kg b.wt for 5 days in accordance with previous data mentioned by (1). Indeed, like variations are comparatively popular and usually connected with a lot of agents such as breed, age, body weight, gender, diseases, and heritable traits. Pharmacokinetics is variation possibility to outcome from various edible habits, exercise, and water intake. These suggestions are supported with results published by that demonstrate that the withdrawal period of marbofloxacin for chickens either healthy or infected with E-coli was 3 days after oral treatment at a dose of 2 mg/kg b.wt for 5 days.

The results obtained in the present study confirmed that the absorption and distribution of marbofloxacin injected to rabbits via intramuscular route achieved high levels in a short time in kidney, Liver, Lung, and muscles. It was observed that marbofloxacin residues probably higher in kidneys than other examined tissues and this was in agreement with but was contrast with (1) who found that the concentration was more in Liver than kidney.

Conclusion

In conclusion, co-administration of dexamethasone with marbofloxacin doesn’t alter the high performance liquid chromatographic residual picture of marbofloxacin. Marbofloxacin residues were below the recommended MRL in breast and thigh muscle of rabbits at the 1st-day post-treatment, while in liver and kidney at the 3rd and 5th days post-treatment respectively. Thus, Rabbit’s meat could be eaten safely in the 1st-day post-treatment while in liver and kidney at 5th days post-
treatment without any health hazards on consumers. The obtained results provide a basis for the rational use of dexamethasone with marbofloxacin in rabbit medicine to treat the sensitive bacterial infection with inflammatory conditions.

Call for Papers/Article Submission

The editor invites scholarly articles that contribute to the development and understanding of all aspects of Public Health and all medical specialties. All manuscripts are double blind peer reviewed. If there is a requirement, medical statistician review statistical content. Invitation to submit paper; A general invitation is extended to authors to submit papers for publication in IJPHRD.

The following guidelines should be noted:

• The article must be submitted by e-mail only. Hard copy not needed. Send article an attachment in e-mail.
• The article should be accompanied by a declaration from all authors that it is an original work and has not been sent to any other journal for publication.
• As a policy matter, journal encourages articles regarding new concepts and new information.
• Article should have a Title
• Names of authors
• Your affiliation (designations with college address)
• Abstract
• Keywords
• Introduction or background
• Material and Method
• Findings
• Discussion
• Conclusion
• Interest of conflict
• Source of Funding
• Ethical Clearance
• References in Vancouver style.
• Please quote references in text by superscripting
• Word limit 2500-3000 words, MSWORD Format, single file.

All articles should be sent to: editor.ijphrd@gmail.com

CALL FOR SUBSCRIPTIONS

About the Journal

**Print-ISSN:** 0976-0245  **Electronic-ISSN:** 0976-5506, **Frequency:** Monthly

**Indian Journal of Public Health Research & Development** is a double blind peer reviewed international Journal. The frequency is Monthly. It deals with all aspects of Public Health including Community Medicine, Public Health, Epidemiology, Occupational Health, Environmental Hazards, Clinical Research, Public Health Laws and covers all medical specialties concerned with research and development for the masses. The Journal strongly encourages reports of research carried out within Indian continent and South East Asia.

The journal has been assigned international standards (ISSN) serial number and is indexed with Index Copernicus (Poland). It is also brought to notice that the journal is being covered by many international databases.
